- Allows users to perform authentication through webpages without installing client software.
- Provides ISPs with diversified management choices and extended functions. For example, the ISPs can place advertisements, provide community services, and publish information on the authentication page.

Web authentication system

A typical Web authentication system consists of the following basic components: authentication client, access device, Web server for Web authentication, portal authentication server, and AAA server.

Figure 1 Web authentication system using the local portal server

Authentication client

An authentication client is a Web browser that runs HTTP or HTTPS on the user endpoint.

Access device

An access device has the following functions:

- Redirects all user HTTP or HTTPS requests that do not match authentication-free rules to the Web authentication page before authentication.
- Interacts with the AAA server to complete authentication, authorization, and accounting. For more information about AAA, see "Configuring AAA."

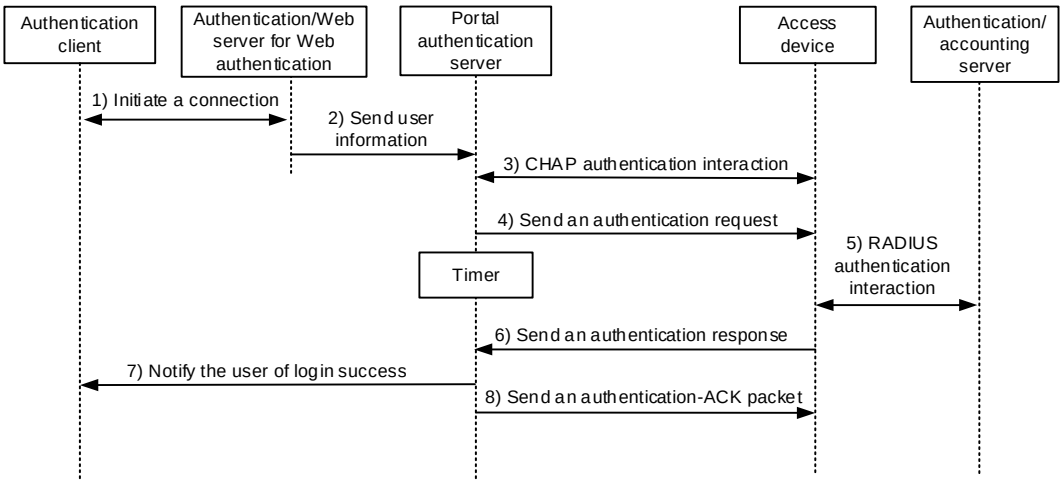
- Allows users that pass authentication to access authorized network resources.

Web server for Web authentication

A Web server pushes the Web authentication page to authentication clients and obtains user authentication information (username and password).

A Web server for Web authentication can be a local Web server or a remote Web server. A local Web server is usually integrated into the access device. A remote Web server is a portal Web server.

Portal authentication server



Web authentication uses a portal authentication server as the authentication server, which exchanges client authentication information with the access device.

AAA server

An AAA server interacts with the access device to implement user authentication, authorization, and accounting. A RADIUS server can perform authentication, authorization, and accounting for Web authentication users. An LDAP server can perform authentication for Web authentication users.

Web authentication process

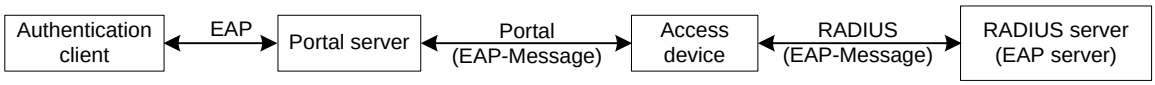
Figure 2 Web authentication process

The Web authentication process is as follows:

1. An unauthenticated user sends an HTTP or HTTPS request. When the access device receives the HTTP or HTTPS request on a Layer 2 Ethernet interface enabled with Web authentication, the request, it redirects the request to the Web authentication page. The user enters the username and password on the Web authentication page.

   If the user requests the Web authentication page or free Web resources, the access device permits the request. No Web authentication is performed.
2. The Web server for Web authentication sends the user information to the portal authentication.
3. The portal authentication server and the access device interact with each other to perform CHAP authentication. This step is skipped if PAP authentication is used. The authentication interaction type is determined by the portal authentication server.
4. The portal authentication sends an authentication request that contains the username and password of the user to the access device and starts a timer to wait for an authentication response.
5. The access device and the AAA server exchange RADIUS packets to authenticate the user.

6. The access device sends an authentication response indicating authentication success or failure to the portal authentication server.
7. The portal authentication server notifies the authentication result to the client.
8. If the user passes RADIUS authentication, the portal authentication server also sends an authentication-ACK packet to the access device.



Web authentication support for EAP

This feature is supported only when Web authentication uses a remote IMC portal authentication server and an iNode portal client.

Compared with username and password based authentication, digital certificate-based authentication ensures higher security.

The Extensible Authentication Protocol (EAP) supports several digital certificate-based authentication methods, for example, EAP-TLS. Working together with EAP, Web authentication can implement digital certificate-based user authentication.

Figure 3 Web authentication support for EAP protocol exchanges

As shown in Figure 3, the authentication client and the portal authentication server exchange EAP authentication packets. The portal authentication server and the access device exchange portal authentication packets that carry the EAP-Message attributes. The access device and the RADIUS server exchange RADIUS packets that carry the EAP-Message attributes. The RADIUS server that supports the EAP server function processes the EAP packets encapsulated in the EAP-Message attributes, and provides the EAP authentication result.

The access device does not process but only transports EAP-Message attributes between the portal authentication server and the RADIUS server. Therefore, the access device requires no additional configuration to support EAP authentication.

Web authentication support for VLAN assignment

Authorization VLAN

Web authentication uses VLANs authorized by the AAA server or the access device to control network resource access of authenticated users. The authorization VLAN information includes VLAN ID and VLAN name.

After a user passes Web authentication, the AAA server or the access device authorizes the user to access a VLAN. If the authorization VLAN does not exist, the access device first creates the VLAN and then assigns the user access interface as an untagged member to the VLAN. If the authorization VLAN already exists, the access device directly assigns the user access interface as an untagged member to the VLAN. Then, the user can access resources in the authorization VLAN.

Table 1 describes the way the access device handles authorization VLANs for Web authenticated users.

Table 1 VLAN manipulation

Port type	VLAN manipulation
• Access port • Trunk port • Hybrid port with MAC-based-VLAN disabled	The device assigns the port to the first authenticated user's authorization VLAN. The authorization VLAN becomes the PVID. All Web authentication users on the port must be assigned the same authorization VLAN. If a different authorization VLAN is assigned to a subsequent user, the user cannot pass Web authentication.

Port type	VLAN manipulation
Hybrid port with MAC-based VLAN enabled	The device maps the MAC address of each user to its own authorization VLAN regardless of whether the port is a tagged member. The PVID of the port does not change.

Auth-Fail VLAN

An Auth-Fail VLAN is a VLAN assigned to users who fail authentication. The Auth-Fail VLAN provides network resources such as the patch server, virus definitions server, client software server, and anti-virus software server to the users. The users can use these resources to upgrade their client software or other programs.

Web authentication supports Auth-Fail VLAN on an interface that performs MAC-based access control. If a user on the interface fails authentication, the access devices creates a MAC VLAN entry based on the MAC address of the user and adds the user to the Auth-Fail VLAN. Then, the user can access the authentication-free IP resources in the Auth-Fail VLAN. All HTTP or HTTPS requests to non-authentication-free IP resources will be redirected to the authentication page. If the user still fails authentication, the interface remains in the Auth-Fail VLAN. If the user passes authentication, the access device removes the interface from the Auth-Fail VLAN and assigns the interface to a VLAN as follows:

- If the authentication server assigns an authorization VLAN to the user, the access device assigns the interface to the authorization VLAN.
- If the authentication server does not assign an authorization VLAN to the user, the access device assigns the interface to the default VLAN.

Web authentication multi-VLAN mode

Web authentication supports single-VLAN or multi-VLAN mode on a port.

In multi-VLAN mode, the port forwards traffic from a user in different VLANs without reauthentication if the user has been authenticated and come online in any VLAN on the port.

In single-VLAN mode, the port reauthenticates an online user when traffic received from that user contains a VLAN tag different from the VLAN in which the user was authenticated. The authentication process differs depending on the MAC move setting in port security and the authorization VLAN assignment status, as follows:

- If no authorization VLAN has been assigned to the online user, the device first logs off the user and then reauthenticates the user in the new VLAN.
- If the online user has been assigned an authorization VLAN, the device handles the user depending on the MAC move setting in port security.
  - If MAC move is disabled in port security, the user cannot pass authentication and come online from the new VLAN until after it goes offline from the port.
  - If MAC move is enabled in port security, the user can pass authentication on the new VLAN and come online without having to first go offline from the port. After the user passes authentication on the new VLAN, the original authentication session of the user is deleted from the port.

  To enable the port security MAC move feature, use the **`port-security mac-move permit`** command.

Web authentication support for authorization ACLs

Web authentication uses ACLs authorized by the AAA server or the access device to control user access to network resources and limit user access rights. When a user passes authentication, the AAA server and the access device assigns an authorization ACL to the access interface of the user. The access device filters traffic from the user on the access interface according to the authorized ACL.

You must configure the authorization ACLs on the access device if you specify authorization ACLs on the authentication server.

To change the access control criteria for the user, you can specify a different authorization ACL on the authentication server or change rules in the authorization ACL on the access device.

The device supports the following types of authorization ACLs:

- Basic ACLs (ACL 2000 to ACL 2999).
- Advanced ACLs (ACL 3000 to ACL 3999).
- Layer 2 ACLs (ACL 4000 to ACL 4999).

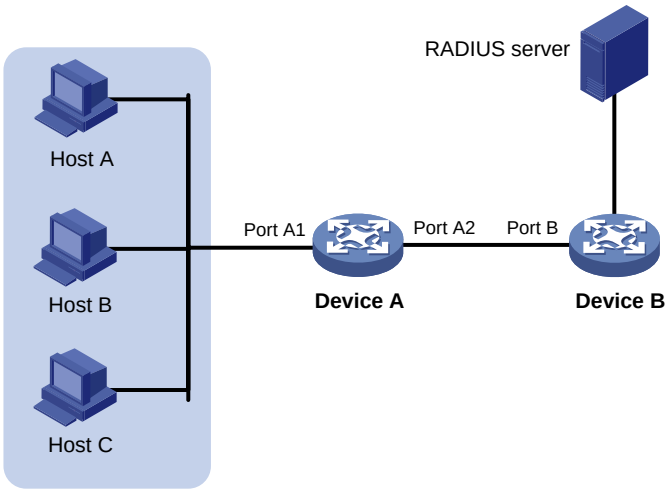
For an authorization ACL to take effect, make sure the ACL exists and has ACL rules excluding rules configured with the **`counting`**, **`established`**, **`fragment`**, **`source-mac`**, or **`logging`** keyword. For more information about ACL rules, see ACL commands in *ACL and QoS Command Reference*.

Restrictions and guidelines: Web authentication configuration

The S5200-EI-G switch series does not support configuring Web authentication on Layer 2 aggregate interfaces.

When you configure Web authentication, follow these restrictions and guidelines:

- Web authentication cannot be configured in conjunction with the guest, Auth-Fail, and critical VLAN settings of 802.1X authentication.
- Web authentication cannot be configured in conjunction with the guest and critical VLAN settings of MAC authentication.
- Auth-Fail VLAN is mutually exclusive with the port security preauthentication domain feature.



To redirect HTTPS requests for unauthenticated users correctly, make sure the packet incoming VLANs have Layer 3 interfaces (VLAN interfaces) configured.

To access the resources in the authorization VLAN or Auth-Fail VLAN, a user must update the IP address of the client after being assigned to the authorization VLAN or Auth-Fail VLAN.

As a best practice, perform Web authentication on users directly connected to the device. As shown in Figure 4, if you enable Web authentication on Port B to authenticate non-directly connected users (the hosts), you must follow these restrictions and guidelines:

- If the RADIUS server assigns an authorization VLAN to the users, make sure the following conditions are met:
  - The link between Device A and Device B is a trunk link.
  - The PVIDs of Port A1 and Port B are the same as the authorization VLAN ID.
- If the RADIUS server does not assign an authorization VLAN to the users, make sure the PVIDs of Port A1 and Port B are the same.

Figure 4 Web authentication for non-directly connected users

Web authentication tasks at a glance

To configure Web authentication, perform the following tasks:

1. Configuring a remote Web authentication service

   Perform this task if a remote Web server is deployed on the network for Web authentication.

   a. Configuring a remote portal authentication server
   b. Configuring a remote Web server for Web authentication
   c. Obtaining user information from ARP or ND entries
2. Configuring a local Web authentication service

   Perform this task if the device is used as the local Web server for Web authentication.

   a. Configuring a local Web server for Web authentication
   b. Configuring a local portal service
3. Enabling Web authentication
4. (Optional.) Specifying a Web authentication domain
5. (Optional.) Setting the redirection wait time
6. (Optional.) Configuring the aging timer for temporary MAC address entries
7. (Optional.) Configuring Web authentication-free subnets or host names
8. (Optional.) Setting the maximum number of Web authentication users
9. (Optional.) Configuring online Web authentication user detection
10. (Optional.) Enabling online detection bypass for Web authentication users
11. (Optional.) Configuring an Auth-Fail VLAN
12. (Optional.) Configuring Web authentication to support Web proxy
13. Applying a portal MAC binding server for Web authentication

    This task is required to perform the MAC-based quick authentication.
14. (Optional.) Enabling Web authentication user logging

Prerequisites for Web authentication

The device supports two methods for Web authentication, which are local authentication and RADIUS authentication.

To use the RADIUS authentication method, you must complete the following tasks:

- Install a RADIUS server and configure the RADIUS server properly.
- Make sure the authentication client, the access device, and the RADIUS server can reach each other.
- Configure user accounts on the RADIUS server and configure the RADIUS client information on the access device.

To use the local authentication method, you must configure local users on the access device.

For more information about RADIUS clients and local users, see "Configuring AAA."

Configuring a remote Web server for Web authentication

About this task

In the view of a remote Web server, you can configure the Web server IP address, redirection URL, and the parameters to be carried in the redirection URL.

By default, the state of the Web server specified by the redirection URL is always **active**. The device cannot obtain the real server state. When primary and secondary Web servers are deployed for continuous authentication service, the device needs to quickly obtain the primary server's state changes to perform primary/secondary switchovers accordingly.

You can associate the Web server with a track entry that is associated with NQA, so the device can periodically detect the reachability of the server through NQA.

- The Track module changes the state of the track entry according to the NQA detection result. The device changes the state of the Web server according to the state of the track entry.
- In this way, if NQA detects that the Web server becomes reachable, the device will set the server state to active. If NQA detects that the Web server becomes unreachable, the device will set the server state to inactive.

For more information about the Track configuration, see *High Availability Configuration Guide*.

Restrictions and guidelines

To deploy both primary and secondary Web servers, you must associate the primary Web server with a track entry to monitor the reachability status of the server. Otherwise, the device cannot sense the reachability state changes of the primary server to perform primary/secondary switchovers.

The NQA detection for server reachability is performed according to the **nqa schedule** configuration, which schedules the NQA operation associated with the track entry. Configure the NQA operation time and other detection parameters as needed.

Procedure

1. Enter system view.

   system-view

2. Create a remote Web server for Web authentication and enter Web authentication remote Web server view.

   web-auth remote server *server-name*

   The local and remote Web servers cannot use the same name.

3. Specify the IP address of the remote Web server for Web authentication.

   IPv4:

   ip *ipv4-address*

IPv6:

ipv6 *ipv6-address*

By default, no IP address is specified for the remote Web server for Web authentication.

The IP address of the remote Web server must be the IP address of the portal Web server used for Web authentication.

You can configure one IPv4 address and one IPv6 address for a remote Web server.

4. Configure the redirection URL of the remote Web server for Web authentication.

   url *url-string* [**track** *track-entry-number*]

   By default, no redirection URL is specified for a Web server for Web authentication.

   To provide Web authentication pages for both IPv4 and IPv6 Web authentication users, configure the redirection URL to carry the domain name of the Web server. For example: **https://example.com**, where **example.com** is the domain name of the Web server.

   A Web server can be associated with only one track entry. If you associate Track with the Web server multiple times, the most recent configuration takes effect.

5. (Optional.) Add parameters to the redirection URL of the remote Web server.

   url-parameter *parameter-name* { **original-url** | **source-address** | **source-mac** | **value** *expression* }

   By default, no parameters are added to the redirection URL of a Web server.

   You must use the URL parameter name supported by the Web browser. Different Web browsers support different URL parameter names.

6. (Optional.) Configure the unescaped special characters in the Web authentication URL redirected to users.

   url-unescape-chars *character-string*

   By default, the device escapes all special characters in the Web authentication URL redirected to users.

7. (Optional.) Configure the Web server to support the Oasis platform.

   server-type oauth

   By default, a Web authentication server does not support the Oasis platform.

   To use an Oasis server as a Web authentication server, execute this command to support the Oasis platform.

Configuring a remote portal authentication server

For information about configuring a remote portal authentication server, see "Configuring portal authentication."

Obtaining user information from ARP or ND entries

About this task

By default, the device obtains user information required by the portal authentication server from MIB entries. However, MIB entries do not contain the Layer 2 user information (such as MAC address and Layer 2 access interface) required for Web authentication. Users will fail the Web authentication as a result.

To resolve this issue, configure the device to obtain user information from ARP or ND entries.

Procedure

1. Enter system view.

   system-view

2. Configure the device to obtain portal user information from ARP or ND entries.

   portal access-info trust { **arp** | **nd** }

   By default, the device obtains user information from FIB entries.

   For more information about the configuration, see "Configuring portal authentication."

Configuring a local Web server for Web authentication

Restrictions and guidelines

Specify the IP address of a Layer 3 interface on the device that is routable to the Web client as the listening IP address of the local Web server for Web authentication. As a best practice, use the IP address of a loopback interface. A loopback interface has the following advantages:

- The status of a loopback interface is stable. There will be no authentication page access failures caused by interface failures.
- A loopback interface does not forward received packets to any networks, avoiding impact on system performances when there are many network access requests.

Procedure

1. Enter system view.

   system-view

2. Create a local Web server for Web authentication and enter Web authentication local Web server view.

   web-auth server *server-name*

   The local and remote Web servers cannot use the same name.

3. Specify the IP address and port number of the local Web server.

   IPv4:

   ip *ipv4-address* **port** *port-number*

   IPv6:

   ipv6 *ipv6-address* **port** *port-number*

   The port number of the local Web server must be the same as the listening port number of the local portal Web service.

   You can configure one IPv4 address and one IPv6 address for a local Web server.

4. Specify the redirection URL for the local Web server.

   url *url-string*

   By default, no redirection URL is specified for a Web server for Web authentication.

   The redirection URL must start with **http://** or **https://**. The IP address and port number in the specified redirection URL must be the same as those of the local Web server for Web authentication.

   To provide Web authentication pages for both IPv4 and IPv6 Web authentication users, configure the redirection URL to carry the domain name of the Web server.

5. (Optional.) Add parameters to the redirection URL of the local Web server.

   url-parameter *parameter-name* { **original-url** | **source-address** | **source-mac** | **value** *expression* }

By default, no parameters are added to the redirection URL of a Web server.

You must use the URL parameter name supported by the Web browser. Different Web browsers support different URL parameter names.

6. (Optional.) Configure the unescaped special characters in the Web authentication URL redirected to users.

   url-unescape-chars *character-string*

   By default, the device escapes all special characters in the Web authentication URL redirected to users.

7. (Optional.) Configure the Web server to support the Oasis platform.

   server-type oauth

   By default, a Web authentication server does not support the Oasis platform.

   To use an Oasis server as a Web authentication server, execute this command to support the Oasis platform.

Configuring a local portal service

For information about the local portal service configuration, see "Configuring portal authentication."

Enabling Web authentication

Restrictions and guidelines

For Web authentication to operate correctly, do not enable port security or configure the port security mode on the Layer 2 interface enabled with Web authentication. For more information about port security, see "Configuring port security."

To deploy both primary and secondary Web servers, follow these restrictions and guidelines:

- Only a remote Web server can be used as the primary Web server. A remote or local Web server can be used as the secondary Web server.
- Associate the primary Web server with a track entry (by using the **url** *url-string* **track** *track-entry-number* command) to monitor the reachability status of the server. Otherwise, the device cannot sense the reachability state changes of the primary server to perform primary/secondary switchovers.

The default HTTPS redirect listening port number on the device is 6654. To change the HTTPS redirect listening port number, see HTTP redirect configuration in *Layer 3—IP Services Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable Web authentication and specify Web servers for Web authentication.

   web-auth enable apply server *primary-server-name* [**secondary-server** *secondary-server-name*]

   By default, Web authentication is disabled.

Specifying a Web authentication domain

About this task

You can specify different authentication domains for Web authentication users on different interfaces. After you specify a Web authentication domain on an interface, the device uses the authentication domain for AAA of all Web authentication users on the interface, ignoring the domain names carried in the usernames.

The device selects the authentication domain for a Web authentication user on an interface in this order:

1. The authentication domain specified for the interface.
2. The authentication domain carried in the username.
3. The system default authentication domain.
4. The ISP domain configured to accommodate users assigned to nonexistent domains.

If the selected domain does not exist on the device, user authentication fails. For information about ISP domains, see "Configuring AAA."

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify an authentication domain for Web authentication users on the interface.
   web-auth domain *domain-name*
   By default, no authentication domain is specified for Web authentication users.

Setting the redirection wait time

About this task

The redirection wait time determines the length of time that the device waits to redirect a user to the specified webpage after the user passes Web authentication.

You need to change the redirection wait time in some scenarios, for example, when a user needs to update the client IP address after passing local Web authentication. To ensure that the specified webpage can be successfully opened, set the redirection wait time to be greater than the time that the user takes to update the IP address of the client.

Procedure

1. Enter system view.
   system-view
2. Enter Web authentication local Web server view.
   web-auth server *server-name*
3. Set the redirection wait time.
   redirect-wait-time *period*
   By default, the redirection wait time for authenticated users is 5 seconds.

Configuring the aging timer for temporary MAC address entries

About this task

If Web authentication is enabled, the device generates a temporary MAC address entry when it detects traffic from a user for the first time. The entry records the MAC address, access interface, and VLAN ID of the user, as well as the aging time of the entry.

The aging timer works as follows:

- If the user does not initiate authentication when the aging timer expires, the device deletes the temporary entry.
- If the user passes authentication before the aging timer expires, the device deletes the aging timer and records online information for the Web authentication user.
- If the user fails authentication before the aging timer expires and an Auth-Fail VLAN is specified for Web authentication, the device binds the MAC address of the user to the Auth-Fail VLAN and reset the aging timer. If the user still fails authentication when the aging timer expires, the device deletes the temporary entry for the user.

Restrictions and guidelines

As a best practice, change the aging timer to a bigger value in the following cases:

- Web authentication users without access rights frequently send traffic in a short time. As a result, the access device continuously initiates the web authentication process, increasing the load on the device.
- When a user fails authentication, the user does not have enough time to obtain resources from the Auth-Fail VLAN, for example, it failed to download the virus patches.

Procedure

1. Enter system view.

   `system-view`
2. Configure the aging timer for temporary MAC address entries.

   `web-auth timer temp-entry-aging` *`aging-time-value`*

   By default, the aging timer for temporary MAC address entries is 60 seconds.

Configuring Web authentication-free subnets or host names

Configuring a Web authentication-free subnet

About this task

You can configure a Web authentication-free subnet so that users can freely access the network resources in the subnet without being authenticated.

Restrictions and guidelines

As a best practice, do not configure the same address value for a Web authentication-free subnet and a 802.1X free IP. Otherwise, when you cancel one of the configuration, the other configuration does not take effect, either.

Procedure

1. Enter system view.
   system-view
2. Configure a Web authentication-free subnet.
   web-auth free-ip *ip-address* { *mask-length* | *mask* }
   By default, no Web authentication-free subnets exist.

Configuring a Web authentication-free host name

About this task

You can configure Web authentication-free host names so that users can freely access the specified host resources without being authenticated.

Restrictions and guidelines

Web authentication-free host names support only precise matching. For example, Web authentication-free host name **abc.com.cn** matches only HTTP/HTTPS request packets that contain the host name of **abc.com.cn**. It does not match packets that contain host name **dfabc.com.cn**.

Prerequisites

Before configuring Web authentication-free destination host names, make sure a DNS server has been deployed on the network, or the host name-to-IPv4 address mappings have been configured by using the **ip host** command. For more information about the **ip host** command, see DNS commands in *Layer 3—IP Services Command Reference*.

Procedure

1. Enter system view.
   system-view
2. Configure a Web authentication-free host name.
   web-auth free-host *host-name*
   By default, no Web authentication-free host names exist.

Setting the maximum number of Web authentication users

Restrictions and guidelines

If the maximum number of online Web authentication users you set is less than that of the current online Web authentication users, the limit can be set successfully and does not impact the online Web authentication users. However, the system does not allow new Web authentication users to log in until the number drops down below the limit.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the maximum number of Web authentication users on the interface.

web-auth max-user [**preauth-domain** | **auth-fail-domain**] *max-number*

By default, the maximum number of Web authentication users is 1024.

Configuring online Web authentication user detection

About this task

This feature enables the device to detect packets of an online user at the specified detection interval. If no packet from the user is received within the interval, the device logs out the user and notifies the RADIUS server to stop accounting for the user.

Restrictions and guidelines

To prevent the device from mistakenly logging out users, set the detection interval to be the same as the aging time of MAC address entries.

On a Layer 2 aggregate interface, the real interval for logging out a user is greater than the specified detection interval. The maximum delay is 300 seconds.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable online Web authentication user detection.

   web-auth offline-detect interval *interval*

   By default, online Web authentication user detection is disabled.

Enabling online detection bypass for Web authentication users

About this task

By default, when all RADIUS servers in the ISP domain are unreachable and online Web authentication user detection is enabled, the device logs out the Web authentication users.

Enable online detection bypass for Web authentication users if you want to use online Web authentication user detection but retain the online users when all RADIUS servers are unreachable.

With online detection bypass enabled for Web authentication users, when all the RADIUS servers are unreachable, the device automatically disables online Web authentication user detection to keep the users online.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable online detection bypass for Web authentication users.

   web-auth auth-server-unavailable escape

By default, online detection bypass for Web authentication users is disabled when no RADIUS servers are reachable.

Configuring an Auth-Fail VLAN

Restrictions and guidelines

To make the Auth-Fail VLAN take effect, you must also enable MAC-based VLAN on the interface, and set the subnet of the Auth-Fail VLAN as the Web authentication-free subnet.

Because MAC-based VLAN takes effect only on Hybrid ports, Auth-Fail VLAN also takes effect only on Hybrid ports.

If a VLAN is specified as the super VLAN, do not configure the VLAN as an Auth-Fail VLAN of an interface. If a VLAN is specified as an Auth-Fail VLAN of an interface, do not configure the VLAN as a super VLAN.

Do not delete the VLAN that has been configured as an Auth-Fail VLAN. To delete this VLAN, first cancel the Auth-Fail VLAN configuration by using **undo web-auth auth-fail vlan** command.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure an Auth-Fail VLAN.
   web-auth auth-fail vlan *authfail-vlan-id*
   By default, no Auth-Fail VLAN is configured on an interface.

Configuring Web authentication multi-VLAN mode

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable the multi-VLAN mode for Web authentication on the port.
   web-auth host-mode multi-vlan
   By default, Web authentication operates in single-VLAN mode on a port.

Configuring Web authentication to support Web proxy

About this task

By default, proxied HTTP or HTTPS requests cannot trigger Web authentication but are silently dropped. To allow such HTTP or HTTPS requests to trigger Web authentication, specify the port numbers of the Web proxy servers on the device.

Restrictions and guidelines

If a user's browser uses the Web Proxy Auto-Discovery (WPAD) protocol to discover Web proxy servers, follow these restrictions and guidelines:

- Add the port numbers of the Web proxy servers on the device.
- Configure a Web authentication-free rule on the device to allow user packets destined for the IP address of the WPAD server to pass without authentication.
- Users must add the IP address of the Web server for Web authentication as a proxy exception in their browsers. Then, HTTP or HTTPS packets that the users send to the Web server for Web authentication will not be sent to Web proxy servers.

Procedure

1. Enter system view.

   system-view

2. Add a Web proxy server port number.

   web-auth proxy [**https**] **port** *port-number*

   By default, no Web proxy server port numbers are configured on the device.

   Do not specify port number 80 or 443 because 80 and 443 are port numbers reserved for Web authentication.

   Do not specify the same Web proxy server port number for HTTP and HTTPS.

Applying a portal MAC binding server for Web authentication

About this task

In Web authentication scenarios where valid users need to frequently access the network, you can configure MAC-based quick authentication to allow the users to pass Web authentication without manually entering the authentication information.

MAC-based quick authentication is also called MAC-trigger authentication or transparent authentication. It requires a portal MAC binding server.

When a user accesses the network, the access device sends the user's MAC address in a query message to the portal MAC binding server. If the portal MAC binding server finds user authentication information bound to the MAC address, it sends the user authentication information to the access device to initiate Web authentication. The user is authenticated without entering the username and password.

Restrictions and guidelines

This feature supports only IPv4 portal MAC binding servers, and the server type must be Oasis platform.

To make the MAC-based quick authentication take effect, complete the following tasks:

- Complete the normal Layer 2 Web authentication configuration.
- Configure the IP address and port number of the portal MAC binding server to be used.
- Apply the portal MAC binding server to a Layer 2 Ethernet interface or Layer 2 aggregate interface.

Prerequisites

Before applying a portal MAC binding server for Web authentication, deploy the portal MAC binding server on the network.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Apply a portal MAC binding server to the interface.
   web-auth apply portal mac-trigger-server *server-name*
   By default, no portal MAC binding server is applied for Web authentication.

Enabling Web authentication user logging

About this task

Web authentication user logs can help troubleshoot and solve issues. This feature enables the device to generate logs about Web authentication users and send the logs to the information center. For the logs to be output correctly, you must also configure the information center on the device. With the information center, you can configure log output destinations and output rules. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Outputting a large number of Web authentication user logs might degrade device performance. As a best practice, enable Web authentication user logging only when necessary.

Procedure

1. Enter system view.
   system-view
2. Enable Web authentication user logging.
   web-auth access-user log enable [**abnormal-logoff** | **failed-login** | **normal-logoff** | **successful-login**] *
   By default, Web authentication user logging is disabled.

Display and maintenance commands for Web authentication

Execute **display** commands in any view and the **reset** command in user view.

The S5200-EI-G switch series does not support M-LAG-related features and parameters.

Task	Command
Display Web authentication configuration information on interfaces.	**display web-auth** [**interface** *interface-type interface-number*]
Display Web authentication-free subnets.	**display web-auth free-ip**
Display information about Web servers for Web authentication.	**display web-auth server** [*server-name*]
Display Web authentication user information.	**display web-auth user** [**m-lag** [**local** | **peer**]] [**interface** *interface-type interface-number* | **slot** *slot-number*]
Log off Web authentication users.	**reset web-auth access-user** [**interface**

Task	Command
	interface-type interface-number | **mac** *mac-address* | **username** *username*]

Web authentication configuration examples

Example: Configuring local Web authentication by using the AAA local authentication method

Network configuration

As shown in Figure 5, the host is directly connected to the device through GigabitEthernet 1/0/1.

Configure local Web authentication on GigabitEthernet 1/0/1, and configure the device to perform local authentication and authorization for the local Web authentication users.

Configure a local Web server on the device that uses the IP address of Loopback 0 and port 80 for Web authentication. Configure the device to use HTTP to transfer the authentication data.

Figure 5 Network diagram

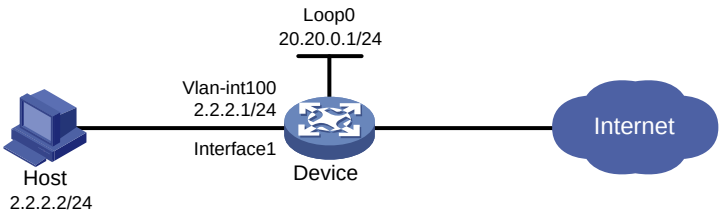


Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Prerequisites

Create VLANs, assign IP addresses to the VLAN interfaces, and assign interfaces to the VLANs.

Procedure

1. Configure a local user:

   # Create a local network access user named **localuser**.

   ```
   <Device>system-view
   [Device] local-user localuser class network
   ```

   # Set the password for user **localuser.**

   ```
   [Device-luser-network-localuser] password simple 123456TESTplat&!
   ```

   # Authorize the user to use LAN access services.

   ```
   [Device-luser-network-localuser] service-type lan-access
   [Device-luser-network-localuser] quit
   ```

2. Configure an ISP domain:

   # Create an ISP domain named **local**.

   ```
   [Device] domain local
   ```

Configure the ISP domain to perform local authentication, authorization, and accounting for LAN access users.

```
[Device-isp-local] authentication lan-access local
[Device-isp-local] authorization lan-access local
[Device-isp-local] accounting lan-access local
[Device-isp-local] quit
```

3. Configure a local portal Web service:

Create an HTTP-based local portal Web service and enter its view.

```
[Device] portal local-web-server http
```

Specify file **defaultfile.zip** as the default authentication page file for the local portal Web service. (Make sure the authentication page file already exists in the root directory of the storage medium on the device.)

```
[Device-portal-local-websvr-http] default-logon-page defaultfile.zip
```

Specify the HTTP listening port number as 80 for the portal Web service.

```
[Device–portal-local-websvr-http] tcp-port 80
[Device-portal-local-websvr-http] quit
```

4. Configure local Web authentication:

Create a local Web server named **user** for Web authentication and enter its view.

```
[Device] web-auth server user
```

Configure the redirection URL for the local Web server as **http://20.20.0.1:80/portal/**.

```
[Device-web-auth-server-user] url http://20.20.0.1:80/portal/
```

Specify the IP address of the local Web server as 20.20.0.1 (the IP address of Loopback 0) and the port number as 80.

```
[Device-web-auth-server-user] ip 20.20.0.1 port 80
[Device-web-auth-server-user] quit
```

Specify ISP domain **local** as the Web authentication domain.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] web-auth domain local
```

Enable Web authentication that uses local Web server **user**.

```
[Device-GigabitEthernet1/0/1] web-auth enable apply server user
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Display online Web authentication user information after user **localuser** passes Web authentication.

```
[Device] display web-auth user
  Total online web-auth users: 1

User Name: localuser
  MAC address: acf1-df6c-f9ad
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 100
  Authorization VLAN: N/A
  Authorization ACL ID: N/A
  Authorization user profile: N/A
  Authorization microsegment ID: N/A
```

Example: Configuring local Web authentication by using the AAA remote authentication method

Network configuration

As shown in Figure 6, the host is directly connected to the device through GigabitEthernet 1/0/1.

Configure local Web authentication on GigabitEthernet 1/0/1, and use a remote RADIUS server to perform authentication, authorization, and accounting for the local Web authentication users.

Configure a local Web server on the device that uses the IP address of Loopback 0 and port 80 for Web authentication. Configure the device to use HTTP to transfer the authentication data.

Figure 6 Network diagram

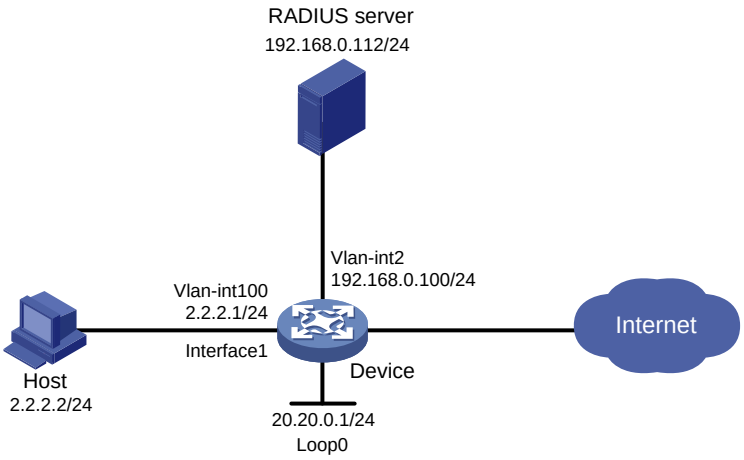

Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Prerequisites

- Configure the RADIUS server properly to provide authentication, authorization, and accounting functions for users. In this example, the username is configured as **user1** on the RADIUS server.
- Create VLANs, assign IP addresses to the VLAN interfaces, and assign interfaces to the VLANs. Make sure the host, the RADIUS server, and the device can reach each other.

Procedure

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1**.

```
<Device> system-view
[Device] radius scheme rs1
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Device-radius-rs1] primary authentication 192.168.0.112
[Device-radius-rs1] primary accounting 192.168.0.112
[Device-radius-rs1] key authentication simple radius
[Device-radius-rs1] key accounting simple radius
```

Exclude the ISP domain name from the username sent to the RADIUS server.

```
[Device-radius-rs1] user-name-format without-domain
[Device-radius-rs1] quit
```

2. Configure an authentication domain:

Create an ISP domain named **dm1**.

```
[Device] domain dm1
```

Configure AAA methods for the ISP domain

```
[Device-isp-dm1] authentication lan-access radius-scheme rs1
[Device-isp-dm1] authorization lan-access radius-scheme rs1
[Device-isp-dm1] accounting lan-access radius-scheme rs1
[Device-isp-dm1] quit
```

3. Configure a local portal Web service:

Create an HTTP-based local portal Web service.

```
[Device] portal local-web-server http
```

Specify the file **defaultfile.zip** as the default authentication page file for the local portal Web service. (Make sure the authentication page file already exists in the root directory of the storage medium on the device.)

```
[Device-portal-local-websvr-http] default-logon-page defaultfile.zip
```

Specify 80 as the port number listened by the local portal Web service.

```
[Device–portal-local-websvr-http] tcp-port 80
[Device-portal-local-websvr-http] quit
```

4. Configure local Web authentication:

Create a local Web server named **user** for Web authentication and enter its view.

```
[Device] web-auth server user
```

Specify **http://20.20.0.1:80/portal/** as the redirection URL for the local Web server.

```
[Device-web-auth-server-user] url http://20.20.0.1:80/portal/
```

Specify the IP address of the local Web server as 20.20.0.1 (the IP address of Loopback 0) and the port number as 80.

```
[Device-web-auth-server-user] ip 20.20.0.1 port 80
[Device-web-auth-server-user] quit
```

Specify domain **dml** as the Web authentication domain.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] web-auth domain dm1
```

Enable Web authentication that uses local Web server **user**.

```
[Device-GigabitEthernet1/0/1] web-auth enable apply server user
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Display Web authentication user information after user **user1** passes Web authentication.

```
[Device] display web-auth user
  Total online web-auth users: 1

User Name: user1
  MAC address: acf1-df6c-f9ad
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 100
  Authorization VLAN: N/A
  Authorization ACL ID: N/A
```

```
Authorization user profile: N/A
Authorization microsegment ID: N/A
```

Example: Configuring remote Web authentication by using the AAA local authentication method

Network configuration

As shown in Figure 7, the host is directly connected to the device through GigabitEthernet 1/0/1.

Configure remote Web authentication on GigabitEthernet 1/0/1, and configure the device to perform local authentication and authorization for the remote Web authentication users.

The remote Web server pushes Web authentication pages to users.

Figure 7 Network diagram

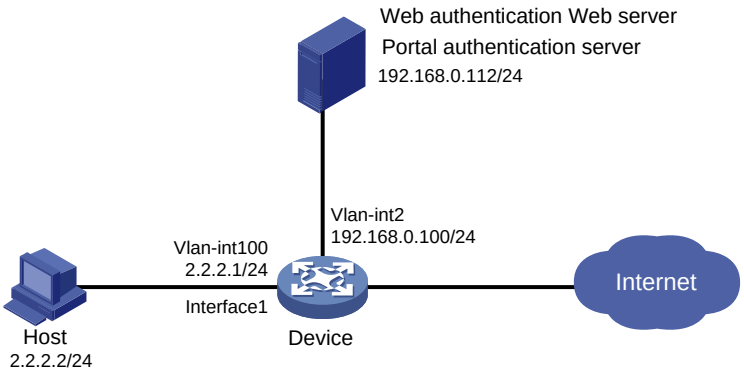

Table 4 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Prerequisites

- Configure the portal authentication server properly to provide normal portal functions for users.
- Create VLANs, assign IP addresses to the VLAN interfaces, and assign interfaces to the VLANs. Make sure the host, the RADIUS server, and the device can reach each other.

Procedure

1. Configure a local user:

   # Create a local network access user named **localuser**.

   ```
   <Device>system-view
   [Device] local-user localuser class network
   ```

   # Set the password for user **localuser.**

   ```
   [Device-luser-network-localuser] password simple 123456TESTplat&!
   ```

   # Authorize the user to use LAN access services.

   ```
   [Device-luser-network-localuser] service-type lan-access
   [Device-luser-network-localuser] quit
   ```

2. Configure an ISP domain:

   # Create an ISP domain named **local**.

   ```
   [Device] domain local
   ```

Configure the ISP domain to perform local authentication, authorization, and accounting for LAN access users.

```
[Device-isp-local] authentication lan-access local
[Device-isp-local] authorization lan-access local
[Device-isp-local] accounting lan-access local
[Device-isp-local] quit
```

3. Configure the portal authentication server:

```
[Device] portal server newpt
[Device-portal-server-newpt] ip 192.168.0.112 key simple portal
[Device-portal-server-newpt] port 50100
[Device-portal-server-newpt] quit
```

4. Configure remote Web authentication:

Create a remote Web server named **user** for Web authentication and enter its view.

```
[Device] web-auth remote server user
```

Configure the redirection URL of the remote Web server as **https://192.168.0.112:8080/portal/**.

```
[Device-web-auth-remote-server-user] url https://192.168.0.112:8080/portal/
```

Configure the IP address of the remote Web server as 192.168.0.112.

```
[Device-web-auth-remote-server-user] ip 192.168.0.112
[Device-web-auth-remote-server-user] quit
```

Specify an authentication domain for Web authentication users.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] web-auth domain local
```

Enable Web authentication that uses remote Web server **user**.

```
[Device-GigabitEthernet1/0/1] web-auth enable apply server user
[Device-GigabitEthernet1/0/1] quit
```

5. Configure the device to obtain user information from ARP entries.

```
[Device] portal access-info trust arp
```

Verifying the configuration

Display Web authentication user information after user **user1** passes Web authentication.

```
[Device] display web-auth user
  Total online web-auth users: 1

User Name: user1
  MAC address: acf1-df6c-f9ad
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 100
  Authorization VLAN: N/A
  Authorization ACL ID: N/A
  Authorization user profile: N/A
  Authorization microsegment ID: N/A
```

Example: Configuring remote Web authentication by using the AAA remote authentication method

Network configuration

As shown in Figure 8, the host is directly connected to the device through GigabitEthernet 1/0/1.

Configure remote Web authentication on GigabitEthernet 1/0/1, and use a remote RADIUS server to perform authentication, authorization, and accounting for the remote Web authentication users.

The remote Web server pushes Web authentication pages to users.

Figure 8 Network diagram

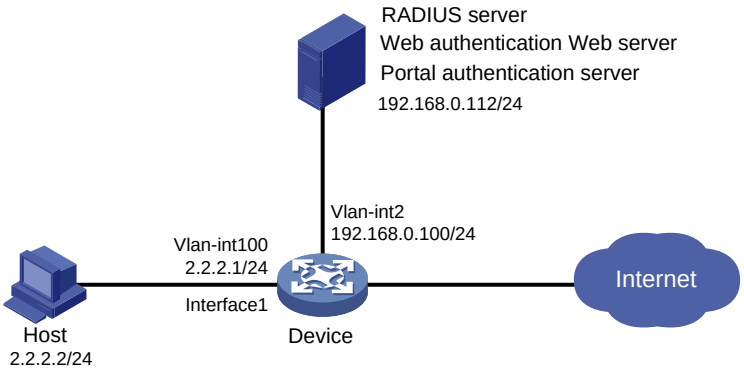

Table 5 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Prerequisites

- Configure the RADIUS server properly to provide authentication, authorization, and accounting functions for users. In this example, the username is configured as **user1** on the RADIUS server.
- Configure the portal authentication server properly to provide normal portal functions for users.
- Create VLANs, assign IP addresses to the VLAN interfaces, and assign interfaces to the VLANs. Make sure the host, the RADIUS server, and the device can reach each other.

Procedure

1. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rs1**.

   ```
   <Device> system-view
   [Device] radius scheme rs1
   ```

   # Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

   ```
   [Device-radius-rs1] primary authentication 192.168.0.112
   [Device-radius-rs1] primary accounting 192.168.0.112
   [Device-radius-rs1] key authentication simple radius
   [Device-radius-rs1] key accounting simple radius
   ```

   # Exclude the ISP domain name from the username sent to the RADIUS server.

   ```
   [Device-radius-rs1] user-name-format without-domain
   [Device-radius-rs1] quit
   ```

2. Configure an authentication domain:

   # Create an ISP domain named **dm1**.

   ```
   [Device] domain dm1
   ```

   # Configure AAA methods for the ISP domain

   ```
   [Device-isp-dm1] authentication lan-access radius-scheme rs1
   ```

```
[Device-isp-dm1] authorization lan-access radius-scheme rs1
[Device-isp-dm1] accounting lan-access radius-scheme rs1
[Device-isp-dm1] quit
```

3. Configure the portal authentication server:

```
[Device] portal server newpt
[Device-portal-server-newpt] ip 192.168.0.112 key simple portal
[Device-portal-server-newpt] port 50100
[Device-portal-server-newpt] quit
```

4. Configure remote Web authentication:

Create a remote Web server named **user** for Web authentication and enter its view.

```
[Device] web-auth remote server user
```

Configure the redirection URL of the remote Web server as **https://192.168.0.112:8080/portal/**.

```
[Device-web-auth-remote-server-user] url https://192.168.0.112:8080/portal/
```

Configure the IP address of the remote Web server as 192.168.0.112.

```
[Device-web-auth-remote-server-user] ip 192.168.0.112
[Device-web-auth-remote-server-user] quit
```

Specify an authentication domain for Web authentication users.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] web-auth domain dm1
```

Enable Web authentication that uses remote Web server **user**.

```
[Device-GigabitEthernet1/0/1] web-auth enable apply server user
[Device-GigabitEthernet1/0/1] quit
```

5. Configure the device to obtain user information from ARP entries.

```
[Device] portal access-info trust arp
```

Verifying the configuration

Display Web authentication user information after user **user1** passes Web authentication.

```
[Device] display web-auth user
  Total online web-auth users: 1

User Name: user1
  MAC address: acf1-df6c-f9ad
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 100
  Authorization VLAN: N/A
  Authorization ACL ID: N/A
  Authorization user profile: N/A
  Authorization microsegment ID: N/A
```

Troubleshooting Web authentication

Failure to come online (local authentication interface using the default ISP domain

Symptom

No authentication domain is specified for the local authentication interface. A user fails to pass Web authentication to come online.

Analysis

If no Web authentication domain is specified, the system default ISP domain (domain **system**) is used for Web authentication. The system default domain uses the local authentication method by default. Using these default domain settings, the local authentication should have operated correctly.

The local authentication fails might because that the authentication method of the system default domain is changed or the system default domain is changed.

Solution

To resolve the problem, perform the following tasks:

1. Use the **`display domain`** command to identify whether the AAA methods for Web users in the system default domain are local.
2. If the AAA methods for Web users in the system default domain are not local, reconfigure the AAA methods as local.

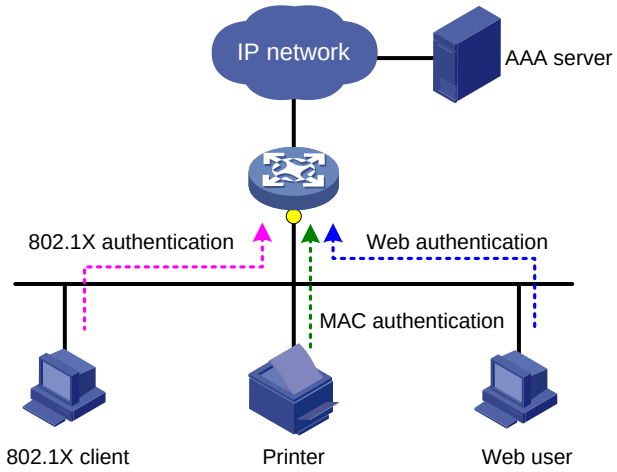
Configuring triple authentication



About triple authentication

Triple authentication enables an access port to perform Web, MAC, and 802.1X authentication. A terminal can access the network if it passes one type of authentication. For more information about 802.1X authentication, MAC authentication, and Web authentication, see "Configuring 802.1X authentication", "Configuring MAC authentication", and "Configuring Web authentication."

Typical network of triple authentication

Triple authentication is suitable for a LAN that comprises terminals that require different authentication services, as shown in Figure 1. The triple authentication-enabled access port can perform MAC authentication for the printer, 802.1X authentication for the PC installed with the 802.1X client, and Web authentication for the Web user.

Figure 1 Triple authentication network diagram

Triple authentication mechanism

The three types of authentication are triggered by different packets:

- The access port performs MAC authentication for a terminal when it receives an ARP or DHCP broadcast packet from the terminal for the first time. If the terminal passes MAC authentication, the terminal can access the network. If the MAC authentication fails, the access port performs 802.1X or Web authentication.
- The access port performs 802.1X authentication when it receives an EAP packet from an 802.1X client or a third-party client. If the unicast trigger feature of 802.1X is enabled on the access port, any packet from the client can trigger an 802.1X authentication.
- The access port performs Web authentication when it receives an HTTP packet from a terminal.

If a terminal triggers different types of authentication, the authentications are processed at the same time. The failure of one type of authentication does not affect the others. When a terminal passes one type of authentication, the other types of authentication are processed as follows:

- If the terminal first passes MAC authentication, Web authentication is terminated immediately, but 802.1X authentication will proceed. If the terminal also passes 802.1X authentication, the 802.1X authentication information will overwrite the MAC authentication information for the

terminal. If the terminal fails 802.1X authentication, the user stays online as a MAC authentication user, and only 802.1X authentication can be triggered again.

- If the terminal first passes 802.1X or Web authentication, the other types of authentication are terminated immediately and cannot be triggered again.

Triple authentication support for VLAN assignment

Authorization VLAN

After a user passes authentication, the authentication server assigns an authorization VLAN to the access port for the user. The user can then access the network resources in the authorized VLAN.

Authentication failure VLAN

The access port adds a user to an authentication failure VLAN configured on the port after the user fails authentication.

- For an 802.1X authentication user—Adds the user to the Auth-Fail VLAN configured for 802.1X authentication.
- For a Web authentication user—Adds the user to the Auth-Fail VLAN configured for Web authentication.
- For a MAC authentication user—Adds the user to the guest VLAN configured for MAC authentication.

If a user in the MAC authentication guest VLAN fails 802.1X authentication, the user is moved to the 802.1X Auth-Fail VLAN.

Server-unreachable VLAN

If a user fails authentication due to the unreachable server, the access port adds the user to an server-unreachable VLAN.

- For an 802.1X authentication user—Adds the user to the critical VLAN configured for 802.1X authentication.
- For a Web authentication user—Adds the user to the Auth-Fail VLAN configured for Web authentication.
- For a MAC authentication user—Adds the user to the critical VLAN configured for MAC authentication.

The access port supports configuring all types of server-unreachable VLANs at the same time. A user is added to the server-unreachable VLAN as follows:

- If the user does not undergo 802.1X authentication, the user is added to the server-unreachable VLAN configured for the last authentication.
- If the user in the Web Auth-Fail VLAN or MAC authentication critical VLAN also fails 802.1X authentication, the user is added to the 802.1X authentication critical VLAN.

Triple authentication support for ACL authorization

After a user passes authentication, the authentication server assigns an authorization ACL to the access port for the user. The access port uses the ACL to filter traffic for the user.

To use ACL authorization, you must specify authorization ACLs on the authentication server and configure the ACLs on the access device. You can change the user's access authorization by changing the authorization ACL on the authentication server or changing rules of the authorization ACL on the access device.

Triple authentication support for online user detection

You can configure the following features to detect the online status of users:

- Enable online user detection for Web authentication users.
- Enable the online user handshake or periodic online user reauthentication feature for 802.1X users.
- Enable offline detection for MAC authentication users.

Restrictions and guidelines: Triple authentication

In triple authentication, 802.1X authentication must use the MAC-based access control method.

If Web authentication is enabled on a port, configure the subnets of the server-unreachable VLANs of the port as Web authentication-free subnets. This ensures that an authentication-failed user can access the server-unreachable VLAN.

Do not configure both Web authentication-free IPs and 802.1X free IPs. If you do so, only 802.1X free IPs take effect.

Web authentication cannot be configured in conjunction with the following settings:

- Guest VLAN, Auth-Fail VLAN, and critical VLAN of 802.1 X authentication.
- Guest VLAN and critical VLAN of MAC authentication.

Triple authentication tasks at a glance

Choose the following tasks as needed:

- Configure 802.1X authentication

  For more information, see "Configuring 802.1X."
- Configure MAC authentication

  For more information, see "Configuring MAC authentication."
- Configure Web authentication

  For more information, see "Configuring Web authentication."

In triple authentication, if the above three authentication methods are configured, use the **`port-security triple-auth-order mac-dot1x-web`** command to specify the authentication order as MAC authentication, 802.1X authentication, and Web authentication. For more information about the **`port-security triple-auth-order mac-dot1x-web`** command, see port security commands in *Security Command Reference*.

Triple authentication configuration examples

Example: Configuring basic triple authentication

Network configuration

As shown in Figure 2, the terminals are connected to the device to access the IP network. Configure triple authentication on the device's Layer 2 interface that connects to the terminals. A terminal passing one of the three authentication methods, 802.1X authentication, Web authentication, and MAC authentication, can access the IP network.

- Assign IP addresses on subnet 192.168.1.0/24 to the terminals.

- Use the remote RADIUS server to perform authentication, authorization, and accounting. Configure the device to send usernames carrying no ISP domain names to the RADIUS server.
- Configure the local Web authentication server on the device to use listening IP address 4.4.4.4. Configure the device to send a default authentication page to the Web user and forward authentication data by using HTTP.

Figure 2 Network diagram

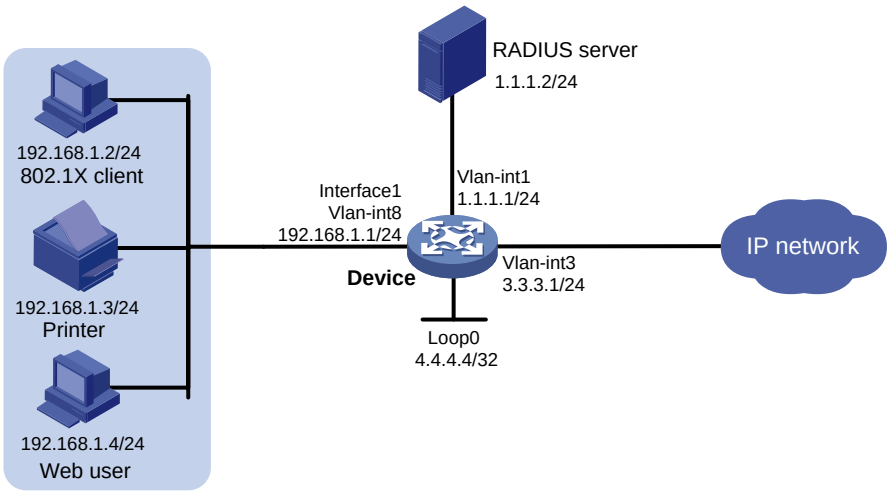


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

1. Make sure that the terminals, the server, and the device can reach each other. (Details not shown.)
2. Configure the RADIUS server to provide normal authentication, authorization, and accounting for users. In this example, configure the following on the RADIUS server:
   - An 802.1X user with username **userdot**.
   - A Web authentication user with username **userpt**.
   - A MAC authentication user with a username and password both being the MAC address of the printer **f07d6870725f**.
3. Configure Web authentication:

   # Configure VLANs and IP addresses for the VLAN interfaces, and add ports to specific VLANs. (Details not shown.)

   # Create an HTTP-based local portal Web service, and specify file **defaultfile.zip** as the default authentication page file of the local portal Web service. (Make sure the authentication page file already exists in the root directory of the storage medium on the device.)

   ```
   <Device> system-view
   [Device] portal local-web-server http
   [Device-portal-local-websvr-http] default-logon-page defaultfile.zip
   [Device-portal-local-websvr-http] quit
   ```

   # Assign IP address 4.4.4.4 to Loopback 0.

   ```
   [Device] interface loopback 0
   [Device-LoopBack0] ip address 4.4.4.4 32
   [Device-LoopBack0] quit
   ```

Create a Web authentication server named **webserver** and enter its view.

```
[Device] web-auth server webserver
```

Configure the redirection URL for the Web authentication server as **https://4.4.4.4/portal/**.

```
[Device-web-auth-server-webserver] url https://4.4.4.4/portal/
```

Specify 4.4.4.4 as the IP address and 80 as the port number of the Web authentication server.

```
[Device-web-auth-server-webserver] ip 4.4.4.4 port 80
[Device-web-auth-server-webserver] quit
```

Enable Web authentication on GigabitEthernet 1/0/1 and specify Web authentication server **webserver** on the interface.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] web-auth enable apply server webserver
[Device–GigabitEthernet1/0/1] quit
```

4. Configure 802.1X authentication:

Enable 802.1X authentication globally.

```
[Device] dot1x
```

Enable 802.1X authentication (MAC-based access control required) on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] dot1x port-method macbased
[Device–GigabitEthernet1/0/1] dot1x
[Device–GigabitEthernet1/0/1] quit
```

5. Configure MAC authentication:

Enable MAC authentication globally.

```
[Device] mac-authentication
```

Enable MAC authentication on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] mac-authentication
[Device–GigabitEthernet1/0/1] quit
```

6. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1**.

```
[Device] radius scheme rs1
```

Specify the primary authentication and accounting servers and keys.

```
[Device-radius-rs1] primary authentication 1.1.1.2
[Device-radius-rs1] primary accounting 1.1.1.2
[Device-radius-rs1] key authentication simple radius
[Device-radius-rs1] key accounting simple radius
```

Specify usernames sent to the RADIUS server to carry no domain names.

```
[Device-radius-rs1] user-name-format without-domain
[Device-radius-rs1] quit
```

7. Configure an ISP domain:

Create an ISP domain named **triple**.

```
[Device] domain triple
```

Configure the domain to use RADIUS scheme **rs1** for authentication, authorization and accounting of LAN access users.

```
[Device-isp-triple] authentication lan-access radius-scheme rs1
[Device-isp-triple] authorization lan-access radius-scheme rs1
[Device-isp-triple] accounting lan-access radius-scheme rs1
```

```
[Device-isp-triple] quit
```

Configure domain **triple** as the default domain. If a username entered by a user includes no ISP domain name, the AAA method of the default domain is used.

```
[Device] domain default enable triple
```

Verifying the configuration

1. Verify that the Web user can pass Web authentication.

   # On the Web user terminal, use a Web browser to access an external network and then enter the correct username and password on the authentication page **https://4.4.4.4/portal/logon.html**. (Details not shown.)

   # Display information about online Web authentication users.

```
[Device] display web-auth user
  Total online web-auth users: 1
User Name: localuser
  MAC address: acf1-df6c-f9ad
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 8
  Authorization VLAN: N/A
  Authorization ACL ID: N/A
  Authorization user profile: N/A
```

2. Verify that the printer can pass MAC authentication.

   # Connect the printer to the network. (Details not shown.)

   # Display information about online MAC authentication users.

```
[Device] display mac-authentication connection
Total connections: 1
Slot ID: 1
User MAC address: f07d-6870-725f
Access interface: GigabitEthernet1/0/1
Username: f07d6870725f
User access state: Successful
Authentication domain: triple
Initial VLAN: 8
Authorization untagged VLAN: N/A
Authorization tagged VLAN: N/A
Authorization ACL ID: N/A
Authorization user profile: N/A
Authorization CAR: N/A
Authorization URL: N/A
Termination action: Default
Session timeout period: N/A
Online from: 2015/01/04 18:01:43
Online duration: 0h 0m 2s
```

3. Verify that the 802.1X client can pass 802.1X authentication.

   # On the 802.1X client, initiate 802.1X authentication and then enter the correct username and password. (Details not shown.)

   # Display information about online 802.1X users.

```
[Device] display dot1x connection
Total connections: 1
Slot ID: 1
```

```
User MAC address: 7446-a091-84fe
Access interface: GigabitEthernet1/0/1
Username: userdot
User access state: Successful
Authentication domain: triple
IPv4 address: 192.168.1.2
Authentication method: CHAP
Initial VLAN: 8
Authorization untagged VLAN: N/A
Authorization tagged VLAN list: N/A
Authorization ACL ID: N/A
Authorization user profile: N/A
Authorization CAR: N/A
Authorization URL: N/A
Termination action: Default
Session timeout period: N/A
Online from: 2015/01/04 18:13:01
Online duration: 0h 0m 14s
```

Example: Configuring triple authentication to support authorization VLAN and authentication failure VLAN

Network configuration

As shown in Figure 3, the terminals are connected to the device to access the IP network. Configure triple authentication on the device's Layer 2 interface connected to the terminals. A terminal passing one of the three authentication methods, 802.1X authentication, Web authentication, and MAC authentication, can access the IP network.

- The Web authentication terminal uses DHCP to get an IP address in 192.168.1.0/24 before authentication and in 3.3.3.0/24 after passing authentication. If the terminal fails authentication, it requests IP addresses in 2.2.2.0/24 through DHCP.

  You can use the access device or an attached device as the DHCP server. In this example, the access device (the device) provides the DHCP service.
- The 802.1X terminal uses DHCP to get an IP address in 192.168.1.0/24 before authentication and in 3.3.3.0/24 after passing authentication. If the terminal fails authentication, it requests IP addresses in 2.2.2.0/24 through DHCP.
- After passing authentication, the printer obtains IP address 3.3.3.111/24 that is bound with its MAC address through DHCP.
- Use the remote RADIUS server to perform authentication, authorization, and accounting. Configure the device to remove the ISP domain names from usernames sent to the RADIUS server.
- Configure the local Web authentication server on the device to use listening IP address 4.4.4.4. Configure the device to forward authentication data by using HTTP.
- Configure VLAN 3 as the authorization VLAN. Users passing authentication are added to this VLAN.
- Configure VLAN 2 as the authentication failure VLAN. Users failing authentication are added to this VLAN.

Figure 3 Network diagram

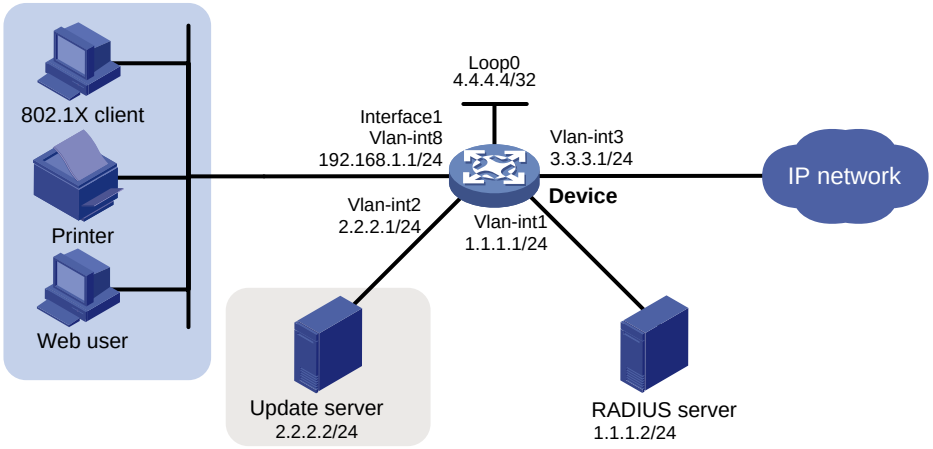

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

1. Make sure the terminals, the servers, and the device can reach each other. (Details not shown.)
2. Configure the RADIUS server to provide normal authentication, authorization, and accounting for users. In this example, configure the following on the RADIUS server:
   - An 802.1X user with username **userdot**.
   - A Web authentication user with username **userpt**.
   - A MAC authentication user with a username and password both being the MAC address of the printer **f07d6870725f**.
   - An authorization VLAN (VLAN 3).
3. Configure the IP address of the update server as an authentication-free IP address.

   ```
   <Device> system-view
   [Device] web-auth free-ip 2.2.2.2 24
   ```
4. Configure DHCP:

   # Configure VLANs and IP addresses for the VLAN interfaces, and add ports to specific VLANs. (Details not shown.)

   # Enable DHCP.

   ```
   [Device] dhcp enable
   ```

   # Exclude the IP address of the update server from dynamic address assignment.

   ```
   [Device] dhcp server forbidden-ip 2.2.2.2
   ```

   # Configure DHCP address pool 1 to assign IP addresses and other configuration parameters to clients on subnet 192.168.1.0.

   ```
   [Device] dhcp server ip-pool 1
   [Device-dhcp-pool-1] network 192.168.1.0 mask 255.255.255.0
   [Device-dhcp-pool-1] expired day 0 hour 0 minute 1
   [Device-dhcp-pool-1] gateway-list 192.168.1.1
   [Device-dhcp-pool-1] quit
   ```

   # Configure DHCP address pool 2 to assign IP address and other configuration parameters to clients on subnet 2.2.2.0.

```
[Device] dhcp server ip-pool 2
[Device-dhcp-pool-2] network 2.2.2.0 mask 255.255.255.0
[Device-dhcp-pool-2] expired day 0 hour 0 minute 1
[Device-dhcp-pool-2] gateway-list 2.2.2.1
[Device-dhcp-pool-2] quit
```

Configure DHCP address pool 3 to assign IP address and other configuration parameters to clients on subnet 3.3.3.0.

```
[Device] dhcp server ip-pool 3
[Device-dhcp-pool-3] network 3.3.3.0 mask 255.255.255.0
[Device-dhcp-pool-3] expired day 0 hour 0 minute 1
[Device-dhcp-pool-3] gateway-list 3.3.3.1
[Device-dhcp-pool-3] quit
```

Configure DHCP address pool 4, and bind the printer's MAC address f07d-6870-725f to IP address 3.3.3.111/24 in this address pool.

```
[Device] dhcp server ip-pool 4
[Device-dhcp-pool-4] static-bind ip-address 3.3.3.111 mask 255.255.255.0
client-identifier f07d-6870-725f
[Device-dhcp-pool-4] quit
```

5. Configure Web authentication:

Create an HTTP-based local portal Web service, and specify file **defaultfile.zip** as the default authentication page file of the local portal Web service. (Make sure the authentication page file already exists in the root directory of the storage medium on the device.)

```
[Device] portal local-web-server http
[Device-portal-local-websvr-http] default-logon-page defaultfile.zip
[Device-portal-local-websvr-http] quit
```

Assign IP address 4.4.4.4 to Loopback 0.

```
[Device] interface loopback 0
[Device-LoopBack0] ip address 4.4.4.4 32
[Device-LoopBack0] quit
```

Create a Web authentication server named **webserver**.

```
[Device] web-auth server webserver
```

Configure the redirection URL of the Web authentication server as **https://4.4.4.4/portal/**.

```
[Device-web-auth-server-webserver] url https://4.4.4.4/portal/
```

Specify 4.4.4.4 as the IP address and 80 as the port number of the Web authentication server.

```
[Device-web-auth-server-webserver] ip 4.4.4.4 port 80
[Device-web-auth-server-webserver] quit
```

Configure the IP address of the update server as an authentication-free IP address.

```
[Device] web-auth free-ip 2.2.2.2 24
```

Enable Web authentication on GigabitEthernet 1/0/1 and specify VLAN 2 as the Auth-Fail VLAN.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] port link-type hybrid
[Device–GigabitEthernet1/0/1] mac-vlan enable
[Device–GigabitEthernet1/0/1] web-auth enable apply server webserver
[Device–GigabitEthernet1/0/1] web-auth auth-fail vlan 2
[Device–GigabitEthernet1/0/1] quit
```

6. Configure 802.1X authentication:

Enable 802.1X authentication globally.

```
[Device] dot1x
```

Enable 802.1X authentication (MAC-based access control required) on GigabitEthernet 1/0/1, and specify VLAN 2 as the Auth-Fail VLAN.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] dot1x port-method macbased
[Device–GigabitEthernet1/0/1] dot1x
[Device–GigabitEthernet1/0/1] dot1x auth-fail vlan 2
[Device–GigabitEthernet1/0/1] quit
```

7. Configure MAC authentication:

Enable MAC authentication globally.

```
[Device] mac-authentication
```

Enable MAC authentication on GigabitEthernet 1/0/1, and specify VLAN 2 as the guest VLAN.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] mac-authentication
[Device–GigabitEthernet1/0/1] mac-authentication guest-vlan 2
[Device–GigabitEthernet1/0/1] quit
```

8. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1**.

```
[Device] radius scheme rs1
```

Specify the primary authentication and accounting servers and keys.

```
[Device-radius-rs1] primary authentication 1.1.1.2
[Device-radius-rs1] primary accounting 1.1.1.2
[Device-radius-rs1] key authentication simple radius
[Device-radius-rs1] key accounting simple radius
```

Specify usernames sent to the RADIUS server to carry no domain names.

```
[Device-radius-rs1] user-name-format without-domain
[Device-radius-rs1] quit
```

9. Configure an ISP domain:

Create an ISP domain named **triple**.

```
[Device] domain triple
```

Configure the domain to use RADIUS scheme **rs1** for authentication, authorization and accounting of LAN access users.

```
[Device-isp-triple] authentication lan-access radius-scheme rs1
[Device-isp-triple] authorization lan-access radius-scheme rs1
[Device-isp-triple] accounting lan-access radius-scheme rs1
[Device-isp-triple] quit
```

Configure domain **triple** as the default domain. If a username entered by a user includes no ISP domain name, the AAA methods of the default domain is used.

```
[Device] domain default enable triple
```

Verifying the configuration

1. Verify that the Web user can pass Web authentication.

On the Web user terminal, use a Web browser to access an external network and then enter the correct username and password on the authentication page **https://4.4.4.4/portal/logon.html**. (Details not shown.)

Use the **display web-auth user** command to display information about online users.

```
[Device] display web-auth user
  Total online web-auth users: 1
```

```
User Name: userpt
  MAC address: 6805-ca17-4a0b
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 8
  Authorization VLAN: 3
  Authorization ACL ID: N/A
  Authorization user profile: N/A
```

2. Verify that the printer can pass MAC authentication.

Connect the printer to the network. (Details not shown.)

Display information about online MAC authentication users.

```
[Device] display mac-authentication connection
Total connections: 1
Slot ID: 1
User MAC address: f07d-6870-725f
Access interface: GigabitEthernet1/0/1
Username: f07d6870725f
User access state: Successful
Authentication domain: triple
Initial VLAN: 8
Authorization untagged VLAN: 3
Authorization tagged VLAN: N/A
Authorization ACL ID: N/A
Authorization user profile: N/A
Authorization CAR: N/A
Authorization URL: N/A
Termination action: Default
Session timeout period: N/A
Online from: 2015/01/04 18:01:43
Online duration: 0h 0m 2s
```

3. Verify that the 802.1X user can pass 802.1X authentication.

On the 802.1X client, initiate 802.1X authentication and enter the correct username and password. (Details not shown.)

Display information about online 802.1X users.

```
[Device] display dot1x connection
Total connections: 1
Slot ID: 1
User MAC address: 7446-a091-84fe
Access interface: GigabitEthernet1/0/1
Username: userdot
User access state: Successful
Authentication domain: triple
IPv4 address: 3.3.3.3
Authentication method: CHAP
Initial VLAN: 8
Authorization untagged VLAN: 3
Authorization tagged VLAN list: N/A
Authorization ACL ID: N/A
```

```
Authorization user profile: N/A
Authorization CAR: N/A
Authorization URL: N/A
Termination action: Default
Session timeout period: N/A
Online from: 2015/01/04 18:13:01
Online duration: 0h 0m 14s
```

4. Verify that users that pass authentication have been assigned authorization VLANs.

Display MAC-VLAN entries of online users.

```
[Device] display mac-vlan all
  The following MAC VLAN addresses exist:
  S:Static  D:Dynamic
  MAC ADDR         MASK             VLAN ID   PRIO   STATE
  ------------------------------------------------------------
  6805-ca17-4a0b   ffff-ffff-ffff   3         0      D
  f07d-6870-725f   ffff-ffff-ffff   3         0      D
  7446-a091-84fe   ffff-ffff-ffff   3         0      D
  Total MAC VLAN address count:3
```

5. Verify that online users have been assigned IP addresses.

```
[Device] display dhcp server ip-in-use
IP address       Client-identifier/    Lease expiration          Type
                  Hardware address
 3.3.3.111        01f0-7d68-7072-5f     Jan  4 18:14:17 2015      Auto:(C)
 3.3.3.2          0168-05ca-174a-0b     Jan  4 18:15:01 2015      Auto:(C)
 3.3.3.3          0174-46a0-9184-fe     Jan  4 18:15:03 2015      Auto:(C)
```

6. When a terminal fails authentication, it is added to VLAN 2. You can use the previous display commands to display the MAC-VLAN entry and IP address of the terminal. (Details not shown.)

Configuring port security

About port security

Port security not only provides port security modes to enhance network access security, but also provides MAC-based network access control for 802.1X, MAC authentication, Web authentication, and static users.

Major port security functions

Port security provides multiple security modes, intrusion detection and port security protection, and unified management of access authentication.

Multiple port security modes

Port security provides different security modes to control MAC address learning on ports and define combinations of authentication methods. It enables the device to learn legitimate source MAC addresses and simplifies the procedure to configure basic port authentication for desired network management.

Intrusion detection and port security protection

Typically, you use the intrusion detection and port security protection features in conjunction with port security modes to enhance security.

NTK

The need to know (NTK) feature prevents traffic interception by checking the destination MAC address in the outbound frames. The feature ensures that frames are sent only to the following hosts:

- Hosts that have passed authentication.
- Hosts whose MAC addresses have been learned or configured on the access device.

The NTK feature supports the following modes:

- **ntk-withbroadcasts**—Forwards only broadcast and unicast frames with a known destination MAC address.
- **ntk-withmulticasts**—Forwards only broadcast, multicast, and unicast frames with a known destination MAC address.
- **ntkauto**—Forwards only broadcast, multicast, and unicast frames with a known destination MAC address, and only when the port has online users.
- **ntkonly**—Forwards only unicast frames with a known destination MAC address.

Intrusion protection

The intrusion protection feature checks the source MAC address in inbound frames for illegal frames, and takes a predefined action on each detected illegal frame. The action can be disabling the port temporarily, disabling the port permanently, or blocking frames from the illegal MAC address for a period set by the MAC block timer.

A frame is illegal if its source MAC address cannot be learned in a port security mode or it is from a client that has failed 802.1X or MAC authentication.

Intrusion protection takes one of the following actions on a port in response to illegal frames:

- **blockmac**—Adds the source MAC addresses of illegal frames to the blocked MAC address list, and then discards frames sourced from blocked MAC addresses for a period set by the block timer. A blocked MAC address will be unblocked when the block timer expires.

- **disableport**—Disables the port until you bring it up manually.
- **disableport-temporarily**—Disables the port for a period of time. The period can be configured with the **`port-security timer disableport`** command.

Unified management of access authentication on ports

Port security enables centralized configuration and management of authentication methods (802.1X, MAC authentication, Web authentication, and static users) on ports, as well as centralized management of access users.

Port security modes

Port security supports the following categories of security modes:

- **MAC learning control**—Includes two modes: autoLearn and secure. MAC address learning is permitted on a port in autoLearn mode and disabled in secure mode.
- **Authentication**—Security modes in this category implement MAC authentication, 802.1X authentication, or a combination of these two authentication methods.

Controlling MAC address learning

- autoLearn.

  A port in this mode can learn MAC addresses. The automatically learned MAC addresses are not added to the MAC address table as dynamic MAC address. Instead, these MAC addresses are added to the secure MAC address table as secure MAC addresses. You can also configure secure MAC addresses by using the **`port-security mac-address security`** command.

  A port in autoLearn mode allows frames sourced from the following MAC addresses to pass:

  - Secure MAC addresses.
  - MAC addresses configured by using the **`mac-address dynamic`** and **`mac-address static`** commands.

  When the number of secure MAC addresses reaches the upper limit, the port transitions to secure mode.

- secure.

  MAC address learning is disabled on a port in secure mode. You configure MAC addresses by using the **`mac-address static`** and **`mac-address dynamic`** commands. For more information about configuring MAC address table entries, see *Layer 2—LAN Switching Configuration Guide*.

  A port in secure mode allows only frames sourced from the following MAC addresses to pass:

  - Secure MAC addresses.
  - MAC addresses configured by using the **`mac-address dynamic`** and **`mac-address static`** commands.

Performing authentication

For the ease of memory, use the following conventions to interprete the names of port security modes for authentication:

- **userLogin** specifies 802.1X authentication and port-based access control. **userLogin** with **Secure** specifies 802.1X authentication and MAC-based access control. **Ext** indicates allowing multiple 802.1X users to be authenticated and serviced at the same time. A security mode without **Ext** allows only one user to pass 802.1X authentication.
- **macAddress** specifies MAC authentication.
- **Else** specifies that the authentication method before **Else** is applied first. If the authentication fails, whether to turn to the authentication method following **Else** depends on the protocol type of the authentication request.

- **Or** specifies that the authentication method following **Or** is applied first. If the authentication fails, the authentication method before **Or** is applied.
- **And** indicates that the authentication method before **And** is applied first. After the authentication succeeds, the system turns to the authentication method that follows **And** upon receiving the request of the authentication method.

Performing 802.1X authentication

- userLogin.

  A port in this mode performs 802.1X authentication and implements port-based access control. The port can service multiple 802.1X users. Once an 802.1X user passes authentication on the port, any subsequent 802.1X users can access the network through the port without authentication.

- userLoginMab

  Perform port-based 802.1X MAC bypass authentication for users. If the device does not receive an EAP message from a user on a port in userLoginMab mode, the device authenticates the user by using the MAC address of the client as the username. After a successful authentication, the user will come online as an 802.1X user. On a port in this mode, after an 802.1X user passes authentication, the subsequent users can access the network without authentication.

- userLoginSecure.

  A port in this mode performs 802.1X authentication and implements MAC-based access control. The port services only one user passing 802.1X authentication.

- userLoginSecureExt.

  This mode is similar to the userLoginSecure mode except that this mode supports multiple online 802.1X users.

- userLoginWithOUI.

  This mode is similar to the userLoginSecure mode. The difference is that a port in this mode also permits frames from one user whose MAC address contains a specific OUI.

  In this mode, the port performs OUI check at first. If the OUI check fails, the port performs 802.1X authentication. The port permits frames that pass OUI check or 802.1X authentication.

NOTE:

An OUI is a 24-bit number that uniquely identifies a vendor, manufacturer, or organization. In MAC addresses, the first three octets are the OUI.

Performing MAC authentication

macAddressWithRadius: A port in this mode performs MAC authentication, and services multiple users.

Performing a combination of MAC authentication and 802.1X authentication

- macAddressOrUserLoginSecure.

  This mode is the combination of the macAddressWithRadius and userLoginSecure modes. The mode allows one 802.1X authentication user and multiple MAC authentication users to log in.

  In this mode, the port performs 802.1X authentication first. By default, if 802.1X authentication fails, MAC authentication is performed.

  However, the port in this mode processes authentication differently when the following conditions exist:

  - The port is enabled with parallel processing of MAC authentication and 802.1X authentication.
  - The port is enabled with the 802.1X unicast trigger.
  - The port receives a packet from an unknown MAC address.

Under such conditions, the port sends a unicast EAP-Request/Identity packet to the MAC address to initiate 802.1X authentication. After that, the port immediately processes MAC authentication without waiting for the 802.1X authentication result.

- macAddressOrUserLoginSecureExt.

  This mode is similar to the macAddressOrUserLoginSecure mode, except that this mode supports multiple 802.1X and MAC authentication users.

- macAddressElseUserLoginSecure.

  This mode is the combination of the macAddressWithRadius and userLoginSecure modes, with MAC authentication having a higher priority as the **Else** keyword implies. The mode allows one 802.1X authentication user and multiple MAC authentication users to log in.

  In this mode, the port performs MAC authentication upon receiving non-802.1X frames. Upon receiving 802.1X frames, the port performs MAC authentication and then, if the authentication fails, 802.1X authentication.

- macAddressElseUserLoginSecureExt.

  This mode is similar to the macAddressElseUserLoginSecure mode except that this mode supports multiple 802.1X and MAC authentication users as the **Ext** keyword implies.

- macAddressAndUserLoginSecureExt.

  In this mode, a user must pass both MAC authentication and 802.1X authentication to access the authorized network resources.

  The device uses the following process to handle an access user on a port operating in this mode:

  a. Performs MAC authentication for the user.

  b. Marks the user as a temporary MAC authentication user when the user passes MAC authentication. A temporary MAC authentication user can access only resources in the 802.1X guest VLAN or VSI.

  c. After receiving 802.1X protocol packets from the user on the port, the device performs 802.1X authentication for the user.

  d. After the user passes 802.1X authentication on the port, the device removes the temporary MAC authentication user entry. Then, the user comes online as an 802.1X user.

- macAddressAndUserLoginSecureExt.

  In this mode, a user must pass both MAC authentication and 802.1X authentication to access the authorized network resources.

  The device uses the following process to handle an access user on a port operating in this mode:

  a. Performs MAC authentication for the user.

  b. Marks the user as a temporary MAC authentication user when the user passes MAC authentication. A temporary MAC authentication user can access only resources in the 802.1X guest VLAN.

  c. After receiving 802.1X protocol packets from the user on the port, the device performs 802.1X authentication for the user.

  d. After the user passes 802.1X authentication on the port, the device removes the temporary MAC authentication user entry. Then, the user comes online as an 802.1X user.

- macAddressAndUserLoginSecureExt.

  In this mode, a user must pass both MAC authentication and 802.1X authentication to access the authorized network resources.

  The device uses the following process to handle an access user on a port operating in this mode:

  a. Performs MAC authentication for the user.

b. Marks the user as a temporary MAC authentication user when the user passes MAC authentication. A temporary MAC authentication user can access only resources in the 802.1X guest VLAN.

c. After receiving 802.1X protocol packets from the user on the port, the device performs 802.1X authentication for the user.

d. After the user passes 802.1X authentication on the port, the device removes the temporary MAC authentication user entry. Then, the user comes online as an 802.1X user.

Workflow in a port security mode

Upon receiving a frame, the port in a security mode searches the MAC address table for the source MAC address.

- If a match is found, the port forwards the frame.
- If no match is found, the port learns the MAC address or performs authentication, depending on the security mode.
  - If MAC address learning or user authentication succeeds, the device adds the MAC address to the MAC address table and forwards the frame.
  - If MAC address learning or user authentication fails, the device determines that the frame is illegal. It then takes the predefined NTK or intrusion protection action on the port or sends SNMP notifications.

Outgoing frames are not restricted by port security's NTK action unless they trigger the NTK feature.

Table 1 describes the port security modes and the security features.

Table 1 Port security modes

Purpose	Security mode		Features that can be triggered
Turning off the port security feature	noRestrictions (the default mode) In this mode, port security is disabled on the port and access to the port is not restricted.		N/A
Controlling MAC address learning	autoLearn		NTK/intrusion protection
	secure		
Performing authentication	userLogin		NTK (**ntkauto** mode)
	userLoginMab		
	userLoginSecure		NTK/intrusion protection
	userLoginSecureExt		
	userLoginWithOUI		
Performing authentication	macAddressWithRadius		NTK/intrusion protection
Performing authentication	Or	macAddressOrUserLoginSecure	NTK/intrusion protection
		macAddressOrUserLoginSecureExt	
	Else	macAddressElseUserLoginSecure	
		macAddressElseUserLoginSecureExt	
	And	macAddressAndUserLoginSecureExt	

The mode names are illustrated as follows:

- **userLogin** specifies 802.1X authentication and port-based access control. **userLogin** with **Secure** specifies 802.1X authentication and MAC-based access control. **Ext** indicates allowing

multiple 802.1X users to be authenticated and serviced at the same time. A security mode without **Ext** allows only one user to pass 802.1X authentication.

- **macAddress** specifies MAC authentication.
- **Else** specifies that the authentication method before **Else** is applied first. If the authentication fails, whether to turn to the authentication method following **Else** depends on the protocol type of the authentication request.
- **Or** specifies that the authentication method following **Or** is applied first. If the authentication fails, the authentication method before **Or** is applied.
- **And** indicates that the authentication method before **And** is applied first. After the authentication succeeds, the system turns to the authentication method that follows **And** upon receiving the request of the authentication method.

Secure MAC addresses

When port security is enabled, a port in a port security mode for MAC learning control permits only packets from the following types of MAC addresses to pass through:

- The secure MAC addresses on the port.
- The MAC addresses manually configured by using the **`mac-address dynamic`** command or the **`mac-address static`** command.

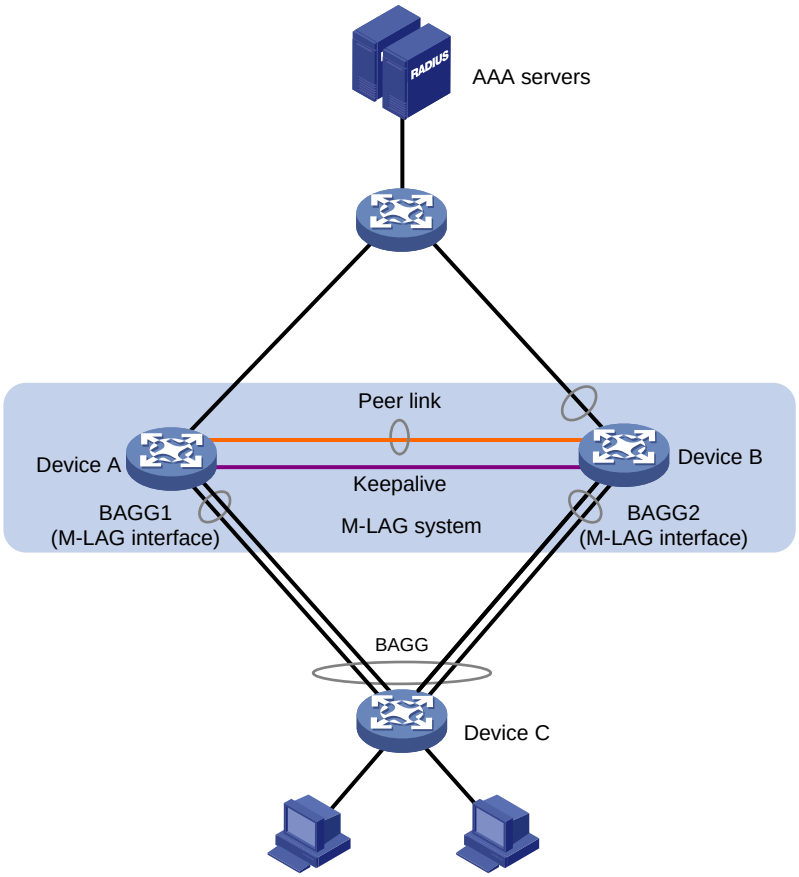
Secure MAC addresses include static, sticky, and dynamic secure MAC addresses, as shown in Table 2.

Table 2 Comparison of static, sticky, and dynamic secure MAC addresses

Type	Address sources	Can be saved and survive a device reboot?	Aging mechanism
Static	Manually added (by using the **`port-security mac-address security`** command without the **`sticky`** keyword).	Yes.	Not available. The static secure MAC addresses never age out unless you perform any of the following tasks: • Manually remove these MAC addresses. • Change the port security mode. • Disable the port security feature.
Sticky	• Manually added (by using the **`port-security mac-address security`** command with the **`sticky`** keyword). • Converted from dynamic secure MAC addresses. • Automatically learned when the dynamic secure MAC feature is disabled.	Yes. The secure MAC aging timer restarts at a reboot.	By default, sticky MAC addresses do not age out. However, you can configure an aging timer or use the aging timer together with the inactivity aging feature to remove old sticky MAC addresses. • If only the aging timer is configured, the aging timer counts up regardless of whether traffic data has been sent from the sticky MAC addresses. • If both the aging timer and the inactivity aging feature are configured, the aging timer restarts once traffic data is detected from the sticky MAC addresses.
Dynamic	• Converted from sticky MAC	No. All dynamic secure	Same as sticky MAC addresses.

Type	Address sources	Can be saved and survive a device reboot?	Aging mechanism
	addresses. • Automatically learned after the dynamic secure MAC feature is enabled.	MAC addresses are lost at reboot.	

Authentication load sharing modes in M-LAG environments



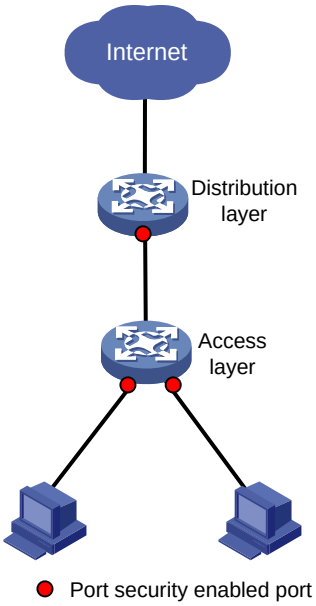
As shown in Figure 1, use M-LAG to configure Device A and Device B into an M-LAG system for load sharing and node redundancy. When one of the devices fails, traffic is switched to the other device to ensure service continuity.

For users attached to the M-LAG interfaces on an M-LAG system, port security provides the following authentication load sharing modes:

- **Centralized mode**—In this mode, the primary M-LAG member device processes authentication services for all users attached to any M-LAG interfaces in the system.
- **Distributed modes**—In a distributed mode, both M-LAG member devices provide authentication services for users attached to the M-LAG interfaces. Port security provides the following distributed authentication processing modes:
  - **Distributed local mode**—Each M-LAG member device processes authentication for users attached to their local M-LAG interfaces.
  - **Distributed even-/odd-MAC mode**—In this mode, one M-LAG member device processes authentication for packets with an even source MAC address and the other M-LAG member device processes authentication for packets with an odd source MAC address. In this mode, you must configure one M-LAG member device to process authentication for even source MAC addresses and configure the other M-LAG member device to process authentication for odd source MAC addresses.

One M-LAG member device automatically synchronizes user data to the other M-LAG member device upon each successful user authentication. This ensures that when one M-LAG member device fails, the other member device can take over to process authentication services for all users.

Figure 1 M-LAG network diagram



Port security application scenarios

Port security is typically used in the scenarios shown in Figure 2.

- Used on access devices to prevent fake users from launching attacks through ports other than those used by legitimate users.
  - If the access location of users is fixed but the link is unreliable, enable port security to convert their MAC addresses to sticky MAC addresses. This ensures that their MAC address bindings can be saved to the configuration file to persist throu gh device reboot or port state change between up and down.
  - If there are only a few users and their access location is fixed, manually configure their MAC addresses as static secure MAC addresses, which never age out.
  - If users frequently move between ports, configure port security to convert their MAC addresses to dynamic secure MAC addresses. This action ensures prompt removal of port and MAC bindings for inactive users, preventing unnecessary use of port and MAC binding resources. It also eliminates MAC entry conflicts to ensure that users can move between ports.
- Used on distribution devices to control the number of access users, preventing network congestion caused by excessive network accesses.

Figure 2 Port security application scenarios

Restrictions and guidelines: Port security configuration

This feature applies to networks, such as a WLAN, that require different authentication methods for different users on a port.

As a best practice, use the 802.1X authentication or MAC authentication feature rather than port security for scenarios that require only 802.1X authentication or MAC authentication. For more information about 802.1X and MAC authentication, see "Configuring 802.1X" and "Configuring MAC authentication."

The **`secure`** and **`userlogin-withoui`** port security modes are not supported on Layer 2 aggregate interfaces. Other port security settings are supported on both Layer 2 Ethernet interfaces and Layer 2 aggregate interfaces.

After a Layer 2 Ethernet interface is added to an aggregation group, port security settings on the interface do not take effect.

Do not delete a Layer 2 aggregate interface if the interface has online 802.1X or MAC authentication users.

When RADIUS DAS is enabled, an M-LAG system does not support the following operations:

- Shuts down or reboots the access ports for 802.1X, Web authentication, MAC authentication users by sending CoA messages.
- Reauthenticates these users by sending CoA messages.

For more information about RADIUS DAS, see "Configuring AAA."

In an M-LAG scenario with load sharing in even-/odd-MAC mode, make sure the port security settings match on both devices except for the different processing modes. For other load sharing modes, keep all port security settings identical on both devices.

To ensure a successful HTTPS redirect for users in either of the following situations, make sure VLAN interfaces exist for the VLANs that transport their packets:

- The users are assigned a redirect URL.

- EAD assistant is enabled.

The S5200-EI-G switch series does not support M-LAG-related functions or parameters.

The S5200-EI-G switch series does not support configuring port security on Layer 2 aggregate interfaces.

Port security tasks at a glance

To configure port security, perform the following tasks:

1. Configuring basic features of port security
   - Enabling port security
   - Setting the port security mode
2. Configuring port security detection and protection

   You typically use port security detection and protection features in conjunction with port security modes for enhanced security.
   - (Optional.) Configuring NTK
   - (Optional.) Configuring intrusion protection
3. (Optional) Configuring secure MAC addresses and their control settings
   - (Optional.) Setting port security's limit on the number of secure MAC addresses on a port
   - (Optional.) Configuring secure MAC addresses
     - Adding a static secure MAC address
     - Adding a sticky MAC address
     - Converting sticky MAC addresses to dynamic secure MAC addresses
     - Configuring secure MAC address aging
4. (Optional.) Configuring extended features of port security

   The following features are applicable when port security is enabled or when 802.1X, MAC authentication or Web authentication is enabled.
   - Configuring an authentication load sharing mode for users attached to M-LAG interfaces

     Perform this task on an M-LAG system.
   - Configuring static users for port access authentication
     - Configuring a static user range for port access authentication
     - Enabling static user IP update
     - Setting the maximum number of concurrent static users allowed on a port
     - Specifying an ACL to match the MAC addresses of static users
   - Configuring port security authentication profile settings
     - Configuring a port security authentication profile
     - Configuring the port security authentication order (port security authentication profile view)
   - Configuring port security access policies
   - Ignoring authorization information from the server
   - Configuring MAC move
   - Enabling overwrite of local MAC entries with remote MAC entries for MAC addresses moved to a remote device
   - Enabling the authorization-fail-offline feature
   - Setting port security's limit on the number of MAC addresses for specific VLANs on a port

- Enabling open authentication mode
- Configuring free VLANs for port security
- Applying a NAS-ID profile to port security
- Configuring single-access authentication
- Specifying a preauthentication domain for port security users on a port
- Specifying a domain for port security users redirected to an unavailable URL
- Setting port security timers
- Configuring the maximum number of reauthentication attempts for users in the preauthentication domain or Auth-Fail domain
- Enabling immediate reauthentication for users in the preauthentication domain or Auth-Fail domain when the authentication server becomes reachable
- Permitting MAC move between member ports in a TC group
- Enabling SNMP notifications for port security
- Enabling port security user logging

Enabling port security

Restrictions and guidelines

When you configure port security, follow these restrictions and guidelines:

- Executing the **`undo port-security enable`** command to disable port security will log off online users (if any).
- Enabling or disabling port security resets the following security settings to the default:
  - 802.1X access control mode, which is MAC-based.
  - Port authorization state, which is **auto**.

  These settings are not configurable after port security is enabled.

For more information about 802.1X authentication and MAC authentication configuration, see "Configuring 802.1X" and "Configuring MAC authentication."

Prerequisites

Before you enable port security, disable 802.1X and MAC authentication globally.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable port security.
   ```
   port-security enable
   ```
   By default, port security is disabled.

Setting the port security mode

Restrictions and guidelines

You can specify a port security mode when port security is disabled, but your configuration cannot take effect.

Changing the port security mode of a port logs off the online users of the port.

Do not enable 802.1X authentication or MAC authentication on a port where port security is enabled.

After enabling port security, you can change the port security mode of a port only when the port is operating in noRestrictions (the default) mode. To change the port security mode for a port in any other mode, first use the **undo port-security port-mode** command to restore the default port security mode.

The device supports the URL attribute assigned by a RADIUS server in the following port security modes:

- mac-authentication.
- mac-else-userlogin-secure.
- mac-else-userlogin-secure-ext.
- userlogin-secure.
- userlogin-secure-ext.
- userlogin-secure-or-mac.
- userlogin-secure-or-mac-ext.
- userlogin-withoui.

During authentication, the HTTP or HTTPS requests of a user are redirected to the Web interface specified by the server-assigned URL attribute. After the user passes the Web authentication, the RADIUS server records the MAC address of the user and uses a DM (Disconnect Message) to log off the user. When the user initiates 802.1X or MAC authentication again, it will pass the authentication and come online successfully.

When the port security mode is **macAddressAndUserLoginSecureExt** on a port, follow these restrictions and guidelines:

- To make sure the 802.1X clients attached to the port can initiate authentication, enable unicast trigger on the port by using the **dot1x unicast-trigger** command.
- The MAC authentication guest VLAN on the port does not take effect. For the temporary MAC authentication users to access a limited set of resources, configure an 802.1X guest VLAN on the port.
- If accounting is not required for the temporary MAC authentication users, configure different ISP domains for MAC authentication users and 802.1X users. In the ISP domain for MAC authentication users, set the accounting method to none.

To perform 802.1X MAC bypass authentication for clients incapable of sending EAP messages on a port in userLoginMab mode, enable 802.1X unicast trigger on the port by executing the **dot1x unicast-trigger** command.

To redirect the HTTPS requests of port security users, specify the HTTPS redirect listening port on the device. For more information, see HTTP redirect in *Layer 3—IP Services Configuration Guide*.

Prerequisites

Before you set a port security mode for a port, complete the following tasks:

- Disable 802.1X and MAC authentication.
- If you are configuring the autoLearn mode, set port security's limit on the number of secure MAC addresses. You cannot change the setting when the port is operating in autoLearn mode.

Procedure

1. Enter system view.

   system-view

2. Set an OUI value for user authentication.

   port-security oui index *index-value* **mac-address** *oui-value*

   By default, no OUI values are configured for user authentication.

   This command is required only for the **userlogin-withoui** mode.

You can set multiple OUIs, but when the port security mode is **userlogin-withoui**, the port allows one 802.1X user and only one user that matches one of the specified OUIs.

3. Enter interface view.

   interface *interface-type interface-number*

4. Set the port security mode.

   port-security port-mode { **autolearn** | **mac-and-userlogin-secure-ext** | **mac-authentication** | **mac-else-userlogin-secure** | **mac-else-userlogin-secure-ext** | **secure** | **userlogin** | **userlogin-mab** | **userlogin-secure** | **userlogin-secure-ext** | **userlogin-secure-or-mac** | **userlogin-secure-or-mac-ext** | **userlogin-withoui** }

   By default, a port operates in noRestrictions mode.

Setting port security's limit on the number of secure MAC addresses on a port

About this task

You can set the maximum number of secure MAC addresses that port security allows on a port for the following purposes:

- Controlling the number of concurrent users on the port.

  For a port operating in a security mode (except for autoLearn and secure), the upper limit equals the smaller of the following values:

  - The limit of the secure MAC addresses that port security allows.
  - The limit of concurrent users allowed by the authentication mode in use.

- Controlling the number of secure MAC addresses on the port in autoLearn mode.

  You can also set the maximum number of secure MAC addresses that port security allows for specific VLANs or each VLAN on a port. When the number of secure MAC addresses reaches the upper limit, the port transitions to secure mode. In secure mode, a port cannot learn MAC addresses.

Port security's limit on the number of secure MAC addresses on a port is independent of the MAC learning limit described in MAC address table configuration. For more information about MAC address table configuration, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the maximum number of secure MAC addresses allowed on a port.

   port-security max-mac-count *max-count*[**vlan** [*vlan-id-list*]]

   By default, port security does not limit the number of secure MAC addresses on a port.

Configuring secure MAC addresses

About secure MAC addresses

For more information about secure MAC addresses, see "Configuring secure MAC addresses."

Restrictions and guidelines

You can bind a secure MAC address to only one port in a VLAN.

You cannot add a MAC address to a VLAN as a static secure MAC address if it has been added as a sticky MAC address in that VLAN, and vice versa.

Prerequisites

Before you configure secure MAC addresses, complete the following tasks:

- Set port security's limit on the number of MAC addresses on the port. Perform this task before you enable autoLearn mode.
- Set the port security mode to autoLearn.
- Configure the port to permit packets of the specified VLAN to pass or add the port to the VLAN. Make sure the VLAN already exists.

Adding a static secure MAC address

1. Enter system view.

   system-view
2. Add a static secure MAC address.
   - Add a static secure MAC address in system view.

     port-security mac-address security *mac-address* **interface** *interface-type interface-number* **vlan** *vlan-id*
   - Execute the following commands in sequence to add a static secure MAC address in interface view:

     interface *interface-type interface-number*

     port-security mac-address security *mac-address* **vlan** *vlan-id*

   By default, no static secure MAC addresses exist.

Adding a sticky MAC address

About this task

When port security is enabled, the MAC addresses learned on a port in autoLearn mode are sticky MAC addresses by default. The following information describes the procedure to add a sticky MAC address manually.

Procedure

1. Enter system view.

   system-view
2. Add a sticky MAC address.
   - Add a sticky MAC address in system view.

     port-security mac-address security sticky *mac-address* **interface** *interface-type interface-number* **vlan** *vlan-id*
   - Execute the following commands in sequence to add a sticky MAC address in interface view:

     interface *interface-type interface-number*

     port-security mac-address security sticky *mac-address* **vlan** *vlan-id*

By default, no manually configured sticky MAC addresses exist.

Converting sticky MAC addresses to dynamic secure MAC addresses

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Convert sticky MAC addresses to dynamic secure MAC addresses.
   port-security mac-address dynamic

   By default, sticky MAC addresses can be saved to the configuration file. Once saved, they can survive a device reboot.

Configuring secure MAC address aging

About this task

By default, secure MAC addresses do not age out. This results in the following issues:

- If a legitimate user leaves a port and an illegitimate user uses the legitimate user's source MAC to access the network, the legitimate user cannot reconnect.
- When legitimate users move from one port to another port within the same VLAN, they cannot come online from the new port if their secure MAC entries on the original port do not age out.
- Legitimate users who have left still occupy the MAC address resources on the port, preventing other legitimate users from connecting to the network.

To enhance port security and improve port resource usage, you can have certain types of secure MAC addresses periodically age out.

Setting the secure MAC aging timer

1. Enter system view.
   system-view
2. Set the secure MAC aging timer.
   port-security timer autolearn aging [**second**] *time-value*

   By default, secure MAC addresses do not age out.

Enabling inactivity aging for secure MAC addresses

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable inactivity aging for secure MAC addresses.
   port-security mac-address aging-type inactivity

   By default, the inactivity aging feature is disabled for secure MAC addresses.

Configuring NTK

About this task

The NTK feature checks the destination MAC address in outbound frames to make sure frames are forwarded only to trustworthy devices. The device supports the **ntkauto** mode. In this mode, the device forwards only broadcast, multicast, and unicast frames with a known destination MAC address, and only when the port has online users.

Restrictions and guidelines

The NTK feature drops any unicast frame with an unknown destination MAC address.

Not all port security modes support triggering the NTK feature. For more information, see the port security modes table in "Workflow in a port security mode."

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the NTK feature.
   port-security ntk-mode ntkauto
   By default, NTK is disabled on a port and all frames are allowed to be sent.

Configuring intrusion protection

About this task

Intrusion protection takes one of the following actions on a port in response to illegal frames:

- **blockmac**—Adds the source MAC addresses of illegal frames to the blocked MAC address list, and then discards frames sourced from blocked MAC addresses for a period set by the block timer. A blocked MAC address will be unblocked when the block timer expires.
- **disableport**—Disables the port until you bring it up manually.
- **disableport-temporarily**—Disables the port for a period of time. The period can be configured with the **port-security timer disableport** command.

If the action is **disableport** or **disableport-temporarily**, you can also enable strict intrusion protection to enhance security. With strict intrusion protection, the port shuts down when it receives a frame whose source MAC address is a secure MAC address on another port in the same VLAN.

Restrictions and guidelines

On a port operating in either macAddressElseUserLoginSecure mode or macAddressElseUserLoginSecureExt mode, intrusion protection is triggered only after both MAC authentication and 802.1X authentication fail for the same frame.

Strict intrusion protection takes effect only when the intrusion protection action is **disableport** or **disableport-temporarily**. When strict intrusion protection is enabled on a port, you cannot change the intrusion protection action to **blockmac** on that port. To change the intrusion protection action to **blockmac**, you must first disable strict intrusion protection on that port.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.

interface *interface-type interface-number*

3. Configure the intrusion protection feature.

   port-security intrusion-mode { **blockmac** | **disableport** | **disableport-temporarily** }

   By default, intrusion protection is disabled.

4. (Optional.) Enable strict intrusion protection.

   port-security strict-intrusion-protection enable

   By default, strict intrusion protection is disabled.

5. Return to system view.

   quit

6. (Optional.) Set the silence timeout period during which a port remains disabled.

   port-security timer disableport *time-value*

   By default, the port silence timeout period is 20 seconds.

7. (Optional.) Set the block timer for blocked MAC addresses.

   port-security timer blockmac *time-value*

   By default, the block timer is 180 seconds.

Configuring an authentication load sharing mode for users attached to M-LAG interfaces

About this task

This feature takes effect only on 802.1X, Web authentication, and MAC authentication users attached to M-LAG interfaces in an M-LAG environment.

In an M-LAG system, the M-LAG member devices exchange configuration information with each other to check for configuration conflicts. If a configuration conflict exists, the M-LAG member devices do not allow new users to come online.

For more information about M-LAG, see *Layer 2—LAN Switching Configuration Guide*.

Restrictions and guidelines

CAUTION:

To avoid user logoffs caused by configuration conflicts, do not change the authentication load sharing mode for users on M-LAG interfaces when port security, 802.1X, Web authentication, or MAC authentication is enabled.

Make sure the M-LAG member devices are consistent in authentication load sharing settings for users attached to M-LAG interfaces.

- **Centralized mode**—Configure both devices to operate in centralized mode for user authentication.
- **Distributed local mode**—Configure both M-LAG member devices to operate in distributed local mode for user authentication.
- **Distributed even-/odd-MAC mode**—Configure one M-LAG member device in distributed even-MAC mode and the other to operate in distributed odd-MAC mode for user authentication.

To ensure correct user data processing, follow these guidelines when you configure the peer aggregate interfaces on each remote access device connected to the M-LAG interfaces:

- If the M-LAG system uses distributed local mode for user authentication, link-aggregation load sharing on the access device can only be based on one of the following criteria:

- Destination IP address.
- Destination MAC address.
- Source IP address.
- Source MAC address.

- In an 802.1X authentication scenario, you must configure the access device to ignore all packet fields except the source MAC if it uses the default link-aggregation load sharing mode.

In centralized mode, if all member ports of an M-LAG interface belong only to one M-LAG member device and the M-LAG interface forwards authentication traffic, users attached to the M-LAG interface cannot come online. To ensure that users attached to such M-LAG interfaces can come online, do not set the authentication load sharing mode to centralized mode.

For more information about M-LAG, see *Layer 2—LAN Switching Configuration Guide*. For more information about link aggregation load sharing, see Ethernet link aggregation in *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Set the authentication load sharing mode for users attached to M-LAG interfaces.
   port-security m-lag load-sharing-mode { **centralized** | **distributed** { **even-mac** | **local** | **odd-mac** } }
   By default, centralized mode applies.

Ignoring authorization information from the server

About this task

You can configure a port to ignore the authorization information received from the server (local or remote) after an 802.1X or MAC authentication user passes authentication.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Ignore the authorization information received from the authentication server.
   port-security authorization ignore
   By default, a port uses the authorization information received from the authentication server.

Configuring MAC move

About this task

Port security MAC move takes effect on online users authenticated through 802.1X authentication, MAC authentication, or Web authentication in the following scenarios:

- **Inter-port move on a device**—An authenticated online user moves between ports on the device. The user VLAN or authentication method might change or stay unchanged after the move.
- **Inter-VLAN move on a port**—An authenticated online user moves between VLANs on a trunk or hybrid port. This mode takes effect only when the packets that trigger authentication are VLAN tagged.

Port security MAC move allows an authenticated online user on one port or VLAN to be reauthenticated and come online on another port or VLAN without going offline first. After the user passes authentication on the new port or VLAN, the system removes the authentication session of the user on the original port or VLAN. This action ensures that the user stays online on only one port in one VLAN.

NOTE:

For MAC authentication, the MAC move feature applies only when MAC authentication single-VLAN mode is used. The MAC move feature does not apply to MAC authentication users that move between VLANs on a port with MAC authentication multi-VLAN mode enabled.

If this feature is disabled, authenticated users must go offline first before they can be reauthenticated successfully on a new port or VLAN to come online.

For a user moving between ports, the port from which the user moves is called the source port and the port to which the user moves is called the destination port.

On the destination port, an authenticated user will reauthenticate in the VLAN authorized on the source port if the source port is enabled with MAC-based VLAN. If that VLAN is not permitted to pass through on the destination port, reauthentication will fail. To avoid this situation, enable VLAN check bypass on the destination port.

Restrictions and guidelines

As a best practice to minimize security risks, enable MAC move only if user roaming between ports is required.

Authenticated users cannot move between ports on a device or between VLANs on a port if the maximum number of online users on the authentication server has been reached.

MAC authentication multi-VLAN mode has higher priority than MAC move for users moving between VLANs on a port. If MAC authentication multi-VLAN mode is enabled, these users can come online in the new VLAN without being reauthenticated. To enable MAC authentication multi-VLAN mode, use the **mac-authentication host-mode multi-vlan** command. For more information about MAC authentication multi-VLAN mode, see "Configuring MAC authentication."

When you configure VLAN check bypass for users moving between ports, follow these guidelines:

- To ensure a successful reauthentication, enable VLAN check bypass on a destination port if the source port is enabled with MAC-based VLAN.
- If the destination port is an 802.1X-enabled trunk port, you must configure it to send 802.1X protocol packets without VLAN tags. For more information, see "Configuring 802.1X."

Procedure

1. Enter system view.

   system-view
2. Enable MAC move.

   port-security mac-move permit [**port** | **vlan**]

   By default, MAC move is disabled.
3. (Optional.) Enable VLAN check bypass for users moving between ports.
   a. Enter interface view.

      interface *interface-type interface-number*
   b. Enable VLAN check bypass for users moving to the port from other ports.

      port-security mac-move bypass-vlan-check

      By default, the VLAN check bypass feature is disabled.

Enabling overwrite of local MAC entries with remote MAC entries for MAC addresses moved to a remote device

About this task

This feature is typically used in an M-LAG environment. It enables the device to overwrite local authenticated MAC entries with remote authenticated MAC entries received from remote devices over tunnels or the peer link immediately, without waiting for the local entries to age out. This overwrite mechanism ensures that the device can promptly update authenticated MAC entries to forward traffic correctly for port security users after they move to a remote device and reauthenticate to the network.

Hardware and feature compatibility

The S5200-EI-G switch series does not support this feature.

Procedure

1. Enter system view.

   `system-view`

2. Enable the device to overwrite the local MAC entry for a MAC address with the remote MAC entry for that MAC address after a MAC move

   `port-security mac-move overwrite-local`

   By default, the device overwrites the local MAC entry for a MAC address with the remote MAC entry for that MAC address after a MAC move.

Enabling the authorization-fail-offline feature

About the authorization-fail-offline feature

IMPORTANT:

The authorization-fail-offline feature takes effect only on port security users that have failed ACL authorization.

The authorization-fail-offline feature logs off port security users that have failed authorization.

A user fails authorization in the following situations:

- The device or server fails to assign the specified authorization attribute to the user.
- The device or server assigns authorization information that does not exist on the device to the user.

This feature does not apply to users that have failed VLAN authorization. The device logs off these users directly.

You can also enable the quiet timer feature for 802.1X or MAC authentication users that are logged off by the authorization-fail-offline feature. The device adds these users to the 802.1X or MAC authentication quiet queue. Within the quiet timer, the device does not process packets from these users or authenticate them. If you do not enable the quiet timer feature, the device immediately authenticates these users upon receiving packets from them.

Prerequisites

For the quiet timer feature to take effect, complete the following tasks:

- For 802.1X users, use the **dot1x quiet-period** command to enable the quiet timer and use the **dot1x timer quiet-period** command to set the timer.
- For MAC authentication users, use the **mac-authentication timer quiet** command to set the quiet timer for MAC authentication.

Procedure

1. Enter system view.

   system-view
2. Enable the authorization-fail-offline feature.

   port-security authorization-fail offline [**quiet-period**]

   By default, this feature is disabled, and the device does not log off users that have failed authorization.

Setting port security's limit on the number of MAC addresses for specific VLANs on a port

About this task

Typically, port security allows the access of the following types of MAC addresses on a port:

- MAC addresses that pass 802.1X authentication or MAC authentication.
- MAC addresses in the MAC authentication guest or critical VLAN.
- MAC addresses in the 802.1X guest, Auth-Fail, or critical VLAN.
- MAC addresses that pass Web authentication and MAC addresses in the Web authentication Auth-Fail VLAN.

This feature limits the number of MAC addresses that port security allows to access a port through specific VLANs. Use this feature to prevent resource contentions among MAC addresses and ensure reliable performance for each access user on the port. When the number of MAC addresses in a VLAN on the port reaches the upper limit, the device denies any subsequent MAC addresses in the VLAN on the port.

Restrictions and guidelines

On a port, the maximum number of MAC addresses in a VLAN cannot be smaller than the number of existing MAC addresses in the VLAN. If the specified maximum number is smaller, the setting does not take effect.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Set port security's limit on the number of MAC addresses for specific VLANs on the port.

   port-security mac-limit *max-number* **per-vlan** *vlan-id-list*

   By default, no limit is set to the number of MAC addresses for specific VLANs on the port.

Enabling open authentication mode

About this task

When planning for initial network deployment, administrators must estimate the number of users and determine their authentication methods. This information prepares them to configure user information on the RADIUS server for future access control. If 802.1X or MAC address authentication is enabled on ports prematurely, some users might fail to come online due to mismatching user information on the RADIUS server, preventing administrators from gathering sufficient user data.

This feature enables access users (802.1X or MAC authentication users) of a port to come online and access the network even if they use nonexistent usernames or incorrect passwords.

Access users that come online in open authentication mode are called open users. Authorization and accounting are not available for open users. To display open user information, use the following commands:

- **`display dot1x connection open`**.
- **`display mac-authentication connection open`**.

Open users do not include those users that are normally authenticated to come online from a port in open authentication mode.

Restrictions and guidelines

When you configure open authentication mode, follow these restrictions and guidelines:

- If global open authentication mode is enabled, all ports are enabled with open authentication mode regardless of the port-specific open authentication mode setting. If global open authentication mode is disabled, whether a port is enabled with open authentication mode depends on the port-specific open authentication mode setting.
- The open authentication mode setting has lower priority than the 802.1X Auth-Fail VLAN and the MAC authentication guest VLAN. Open authentication mode does not take effect on a port if the port is also configured with the 802.1X Auth-Fail VLAN or the MAC authentication guest VLAN. For information about 802.1X authentication and MAC authentication, see "802.1X overview," "Configuring 802.1X," and "Configuring MAC authentication."

Procedure

1. Enter system view.

   `system-view`
2. Enable global open authentication mode.

   `port-security authentication open global`

   By default, global open authentication mode is disabled.
3. Enter interface view.

   `interface` *`interface-type interface-number`*
4. Enable open authentication mode on the port.

   `port-security authentication open`

   By default, open authentication mode is disabled on a port.

Configuring free VLANs for port security

About this task

This feature allows packets from the specified VLANs to not trigger 802.1X or MAC authentication on a port configured with any of the following features:

- 802.1X authentication.
- MAC authentication.
- One of the following port security modes:
  - userLogin.
  - userLoginSecure.
  - userLoginWithOUI.
  - userLoginSecureExt.
  - macAddressWithRadius.
  - macAddressOrUserLoginSecure.
  - macAddressElseUserLoginSecure.
  - macAddressOrUserLoginSecureExt.
  - macAddressElseUserLoginSecureExt.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure free VLANs for port security.
   port-security free-vlan *vlan-id-list*
   By default, no free VLANs for port security exist on a port.

Applying a NAS-ID profile to port security

About this task

By default, the device sends its device name in the NAS-Identifier attribute of all RADIUS requests.

A NAS-ID profile enables you to send different NAS-Identifier attribute strings in RADIUS requests from different VLANs. The strings can be organization names, service names, or any user categorization criteria, depending on the administrative requirements.

For example, map the NAS-ID **companyA** to all VLANs of company A. The device will send **companyA** in the NAS-Identifier attribute for the RADIUS server to identify requests from any Company A users.

Restrictions and guidelines

You can apply a NAS-ID profile to port security globally or on a port. On a port, the device selects a NAS-ID profile in the following order:

1. The port-specific NAS-ID profile.
2. The NAS-ID profile applied globally.

If no NAS-ID profile is applied or no matching binding is found in the selected profile, the device uses the device name as the NAS-ID.

For more information about the NAS-ID profile configuration, see "Configuring AAA."

Procedure

1. Enter system view.
   system-view
2. Apply a NAS-ID profile.
   - Apply a NAS-ID profile globally.

port-security nas-id-profile *profile-name*

- Execute the following commands in sequence to apply a NAS-ID profile to an interface:
  interface *interface-type interface-number*
  port-security nas-id-profile *profile-name*

By default, no NAS-ID profile is applied in system view or in interface view.

Configuring the trigger order for authentication methods on a port

About this task

This feature takes effect only on ports with triple authentication enabled. Triple authentication allows Web authentication, MAC authentication, and 802.1X authentication to be enabled concurrently on a Layer 2 port for user access. Different types of endpoint packets trigger different types of authentication first. For more information, see "Configuring triple authentication."

By default, if 802.1X unicast trigger is enabled, any packdets from endpoints will trigger 802.1X authentication. To enable any endpoint packets to trigger MAC authentication first, use this feature.

A port can run authentication processes concurrently for multiple authentication methods. The failure of one authentication does not affect the processes for other authentication methods. However, if an endpoint passes one authentication on a port, the device handles processes for other authentication methods on the port as follows:

- If the endpoint passes MAC authentication, the device generates a MAC authentication user entry on the port and continues to perform 802.1X authentication for the endpoint on the port. However, the device cannot continue Web authentication for the endpoint on the port.
  - If the endpoint passes 802.1X authentication after MAC authentication, the device generates an 802.1X user entry for the endpoint on the port. The 802.1X user entry overwrites the MAC authentication user entry.
  - If the endpoint does not pass 802.1X authentication after MAC authentication, the MAC authentication user entry is retained on the port. The endpoint can trigger 802.1X authentication again, but it cannot trigger Web authentication.
- If the endpoint fails MAC authentication but passes 802.1X or Web authentication, the device immediately stops all authentication methods on the port except the one the endpoint has passed. In addition, the device can no longer trigger authentication processes for the stopped authentication methods for the endpoint on the port.

Restrictions and guidelines

This feature takes effect only on ports with triple authentication enabled.

This feature causes users that are being authenticated to fail authentication. The users must retrigger authentication to come online. As a best practice to avoid users failing to come online, use this feature with caution.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the trigger order for authentication methods on the port as MAC authentication, 802.1X authentication, and Web authentication.
   port-security triple-auth-order mac-dot1x-web

By default, the authentication that is triggered first depends on the type of packets sent from endpoints in a triple authentication environment.

Configuring single-access authentication

About this task

By default, when multiple authentication methods are configured on an interface, a user can proceed with other methods after passing one. For more information, see triple authentication configuration in Security Configuration Guide. For example, if a client sends an EAP message after the client user has come online through MAC authentication, the device performs 802.1X authentication for the user. If 802.1X authentication succeeds, the user will come online as an 802.1X user.

If single-access authentication is enabled, users will not undergo any other authentication methods after they have authenticated with one method.

Restrictions and guidelines

If multi-authentication mode is used, this feature does not take effect.

Procedure

1. Enter system view.

   `system-view`
2. Enter interface view.

   `interface` *`interface-type interface-number`*
3. Enable single-access authentication.

   `port-security single-access enable`

   By default, single-access authentication is disabled. When multiple authentication methods are configured on an interface, users can proceed with other methods of authentication after passing one.

Specifying a preauthentication domain for port security users on a port

About this task

A preauthentication domain accommodates 802.1X, Web authentication, and MAC authentication users that have not performed authentication. A preauthentication domain is applicable to the following scenarios:

- A user accesses the network for the first time. This scenario is applicable only to 802.1X and Web authentication users.
- A user fails authentication, but no Auth-Fail domain is configured.
- No server is reachable, but the critical domain is not configured.

When a port is configured with a preauthentication domain, authentication users that access that port will be assigned authorization attributes (including ACLand VLAN) in the preauthentication domain after they are assigned to the preauthentication domain. They can access only network resources permitted in the preauthentication domain. If they pass authentication, AAA will assign new authorization information to them.

Restrictions and guidelines

If the ACL and VLAN authorization settings in the current preauthentication domain have changes, the changes take effect only on users that are assigned to the preauthentication domain after the

changes are made. Users that have been assigned to the preauthentication domain before the changes are made still use the original settings.

On a port, port security preauthentication domain is mutually exclusive with the following settings:

- 802.1X guest VLAN, Auth-Fail VLAN, and critical VLAN settings.
- MAC authentication guest VLAN and critical VLAN settings.
- Web authentication Auth-Fail VLAN settings.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify a preauthentication domain for port security users.
   port-security pre-auth domain *isp-name*
   By default, no preauthentication domain is specified for port security users on a port.

Specifying a domain for port security users redirected to an unavailable URL

About this task

During user authentication, if the Web server specified by the redirect URL is unavailable, users cannot be redirected to the Web authentication page on the Web server. As a result, the users cannot come online. To allow users to access the resources in an ISP domain when the redirect URL is unavailable, use this feature to specify that ISP domain for the users.

Restrictions and guidelines

This feature is applicable only to MAC authentication and Web authentication users.

This feature is mutually exclusive with the following 802.1X, MAC authentication, and Web authentication settings:

- Guest VLAN settings.
- Auth-Fail VLAN settings.
- Critical VLAN settings.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify a domain for port security users redirected to an unavailable URL.
   port-security url-unavailable domain *isp-name*
   By default, no domain is specified for port security users redirected to an unavailable URL.

Configuring static users for port access authentication

Configuring a static user range for port access authentication

About this task

Typically, administrators assign static IP addresses to dumb terminals such as printers. For such users, you can configure them as static users to facilitate flexible authentication. After you configure a dumb terminal as a static user, the device can use the static user information such as the user IP address as the username to perform authentication for the dumb terminal on the user's access interface. For this purpose, make sure 802.1X, Web authentication, or MAC authentication is enabled on the user's access interface.

The device uses the following rules to handle static users:

- If two users have different IP addresses and MAC addresses, the users are different static user. They both can come online.
- If a user that has the same MAC address as an online static user attempts to come online, the device does not trigger authentication for the new user, regardless of whether the users use the same IP address. To update the IP addresses of static users, use the **port-security static-user update-ip enable** command.
- If users that have the same IP address but different MAC addresses come online, the device handles the users as follows:
  - If a MAC address has been bound to the IP address, the user that has the bound MAC address can come online. Users with other MAC addresses cannot trigger authentication to come online.
  - If no MAC address is bound to the IP address, the device allows all users that have IP addresses belonging to a static user IP range to trigger authentication to come online.

Restrictions and guidelines

Modification to a static user range does not affect static users that are already online. The modification takes effect only on static users that will come online.

In the public network or the same VPN instance, the IP address ranges for all static user ranges cannot overlap.

When the usernames of static users are their IP or MAC addresses, do not enable RESTful server-assisted automatic MAC authentication user recovery. If you enable RESTful server-assisted automatic MAC authentication user recovery, the device will recover static users as MAC authentication users after the device reboots or recovers from a failure. For more information about RESTful server-assisted automatic MAC authentication user recovery, see "Configuring MAC authentication."

Procedure

1. Enter system view.

   system-view

2. Configure a static user range for port access authentication.

   port-security static-user { **ip** | **ipv6** } *start-ip-address* [*end-ip-address*] [**vpn-instance** *vpn-instance-name*] [**domain** *isp-name* | [**interface** *interface-type interface-number* [**detect**]] **vlan** *vlan-id* | **mac** *mac-address* | **keep-online**] *

   By default, no static user ranges are configured for port access authentication.

3. (Optional.) Configure the username format used by static users when they come online.

port-security static-user user-name-format { **ip-address** | **mac-address** | **system-name** }

By default, the username of a static user is in the format of *SysnameIP*, in which *Sysname* is the name of the access device and *IP* is the user IP address.

4. (Optional.) Configure the user account format when MAC addresses of static users are used as their usernames.

   port-security static-user user-name-format mac-address { **one-section** | { **six-section** | **three-section** } **delimiter** { **colon** | **hyphen** } } [**uppercase**] [**password-with-mac**]

   By default, a static user does not have a password when its MAC address is used as its username. The MAC address contains three hyphen-separated sections and letters in the MAC address are in lower case.

5. (Optional.) Configure a password for static users.

   port-security static-user password { **cipher** | **simple** } *string*

   By default, no password is configured for static users.

6. (Optional.) Set the offline detect period for static users.

   port-security static-user timer offline-detect time-value

   By default, the offline detect period is 5 minutes for static users.

7. (Optional.) Set the interval at which the device actively sends ARP packets to trigger authentication for static users.

   port-security static-user timer detect-period *time-value*

   By default, the device actively sends ARP packets to trigger authentication for static users at intervals of 3 minutes.

Enabling static user IP update

About this task

After you use the **port-security static-user** command to configure an IP address range for a static user range, endpoints at IP addresses in the specified IP address range will come online as static users. If the IP address of an endpoint changes, the endpoint might send abnormal ARP packets to the access device when it comes online. The source IP address of these ARP packets does not belong to the specified IP address range. This issue triggers the device to update the IP address of the endpoint when static user IP update is enabled. After address update, the endpoint is no longer a static user. As a result, the endpoint is logged off.

By default, the device does not update IP addresses for static users when it receives ARP packets with source IP address not belonging to the specified IP address range from these users. This setting prevents the ARP packets from logging off online static users. To trace IP address changes for endpoints, you can enable static user IP update to allow the device to update the IP addresses of static users.

Restrictions and guidelines

Use static user IP update in conjunction with DHCP snooping, ARP snooping, DHCPv6 snooping, or ND snooping. To receive notifications about IP address changes from a snooping module, you must enable the corresponding snooping feature.

Procedure

1. Enter system view.

   system-view

2. Enable static user IP update.

   port-security static-user update-ip enable

By default, static user IP update is disabled.

Setting the maximum number of concurrent static users allowed on a port

About this task

Set the maximum number of concurrent static users on a port to prevent the system resources from being overused. When the maximum number is reached, the port denies subsequent static users.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the maximum number of concurrent static users allowed on the port.
   port-security static-user max-user *max-number*
   By default, a port supports a maximum of 4294967295 concurrent static users.

Specifying an ACL to match the MAC addresses of static users

About this task

Typically, endpoints that match static user IP ranges come online as static users. However, the device recognizes the endpoints as MAC authentication users instead of static users in the following situations:

- The first packet sent by an endpoint is a Layer 2 packet that does not contain an IP address. In this situation, the packet triggers MAC authentication first.
- An endpoint has both IPv4 and IPv6 addresses and the first packet sent by the endpoint is an IPv6 packet, but only static user IPv4 ranges are configured on the device. In this situation, the packet triggers MAC authentication first.

To resolve the issues, configure this feature to use MAC address as the criterion to match static users. With this feature, the device allows users that match the specified ACL to trigger authentication and come online only as static users. The users cannot trigger other authentication processes.

Restrictions and guidelines

The specified ACL must be a Layer 2 ACL. The ACL can contain only permit rules with the source MAC range criteria.

Procedure

1. Enter system view.
   system-view
2. Specify an ACL to match the MAC addresses of static users.
   port-security static-user match-mac acl *acl-number*
   By default, no ACL is specified to match the MAC addresses of static users.

Configuring a port security authentication profile

About this task

To implement fast port security authentication on users, the device uses port security authentication profiles for unified management of the access authentication configuration. In a port security authentication profile, you can bind 802.1X and MAC authentication access profiles and configure the authentication order to control user access.

After an interface is bound to a port security authentication profile, the interface uses the configuration of the bound profile to perform authentication for access users.

- For functions available in both interface view and port security authentication profile view (commands might differ), the functions configured in interface view are deleted regardless of whether they are configured in the profile view or not. To use those functions on the port, configure them in the bound port security authentication profile.
- For the functions available only in interface view, they can take effect on the interface after being configured.
- The authentication mode used on a port is determined by the 802.1X access profile and MAC authentication access profile bound to the port security authentication profile.

After an interface is bound to a port security authentication profile, the interface supports only MAC-based authentication. If you bind a MAC authentication access profile to the port security authentication profile, the interface will use MAC authentication. If you bind an 802.1X access profile to the port security authentication profile, the interface will use 802.1X authentication in MAC-based access control.

Restrictions and guidelines

A port security authentication profile can be bound to different interfaces. An interface can be bound to only one port security authentication profile. To change the bound port security authentication profile of an interface, you must first unbind the profile from the interface.

After the authentication profile bound to an interface takes effect, deleting the bound authentication profile will cause abnormal disconnection of online users on the interface.

To avoid authentication anomalies, do not execute the **dot1x port-method portbased** command on an interface that is bound to a port security authentication profile.

Procedure

1. Enter system view.

   system-view

2. Create a port security authentication profile and enter its view.

   port-security authentication-profile name *profile-name*

   By default, no port security authentication profiles exist.

3. Bind an 802.1X access profile to the port security authentication profile.

   dot1x access-profile *profile-name*

   By default, no 802.1X access profile is bound to a port security authentication profile.

4. Bind a MAC authentication access profile to the port security authentication profile.

   mac-authentication access-profile *profile-name*

   By default, no MAC authentication access profile is bound to a port security authentication profile.

5. Exit port security authentication profile view.

   quit

6. Enter interface view.

interface *interface-type interface-number*

7. Bind a port security authentication profile to the interface.

   port-security authentication-profile *profile-name*

   By default, no port security authentication profile is bound to an interface.

Configuring the port security authentication order (port security authentication profile view)

About this task

You can configure the access authentication order on a port enabled with both 802.1X and MAC authentication methods.

- In **dot1x-mac** order, for a port to perform MAC authentication and assign an authorization VLAN before it joins the 802.1X guest VLAN, enable parallel 802.1X and MAC authentication processing by using the **port-security auth-order dot1x-mac parallel** command and enable 802.1X guest VLAN assignment delay. For information about the commands for enabling 802.1X guest VLAN assignment delay, see 802.1X commands in Security Command Reference.
- In **mac-dot1x** order, to allow a user to go online only after the user passes both MAC and 802.1X authentication, enable multi-authentication mode by using the **port-security auth-order mac-dot1x multiple** command.

Restrictions and guidelines

Changing the access authentication order by using the **port-security auth-order** command will result in authentication failure for users that are currently being authenticated. The users must trigger authentication again in order to go online. To avoid such authentication failures, change the authentication order only when necessary.

If parallel 802.1X and MAC authentication processing is enabled, do not configure MAC authentication delay as a best practice.

Procedure

1. Enter system view.

   system-view

2. Enter port security authentication profile view.

   port-security authentication-profile name *profile-name*

   By default, no port security authentication profiles exist.

3. Configure the port security authentication order.

   port-security auth-order { **dot1x-mac** [**parallel**] | **mac-dot1x** [**multiple**] }

   By default, after a port receives a packet with unknown source MAC address, it performs 802.1X authentication and then MAC authentication for the user.

Configuring port security access policies

About this task

To simplify port security configuration, you can configure a port security access policy and uniformly apply it to all interfaces. By configuring match criteria and actions in port security access policy view, you can control port access users more granularly.

Restrictions and guidelines

A port security access policy only takes effect on users that come online for the first time, and does not affect the re-authentication process of existing online users.

Procedure

1. Enter system view.
   system-view
2. Create a port security access policy and enter its view.
   port-security access-policy *policy-name*
   By default, no port security access policy exists.
3. Configure the match criteria and actions for port security access users.
   if-match [**not**] **acl mac** *acl-number* **action access-type** { **dot1x** | **mac-auth** | **static** | **web-auth** } *
   By default, no match criteria and actions are configured for port security access users.
4. Apply the port security access policy globally.
   port-security apply access-policy *policy-name*
   By default, no port security access policy is applied globally.

Configuring the action to be taken on online users when their access ports go down

About this task

By default, the device immediately logs off online users when their access ports go down. When the ports come up, the users must be reauthenticated to come online. To prevent users from having to repeatedly be reauthenticated and come online in the event of frequent port flapping, you can configure the following actions for online users as needed:

- **keep-online**—Allows online users to stay online when their access ports go down. When the ports come up, the users can come online without being reauthenticated.
- **offline-delay**—Delays logging off online users when their access ports go down.
  - If the access ports come up before the delay time expires, the users can come online without being reauthenticated.
  - If the access ports do not come up before the delay time expires, the users are logged off when the delay time expires. When the ports come up, the users must be reauthenticated to come online.

Restrictions and guidelines

This feature takes effect for online users on a port only when the port automatically goes down due to link abnormalities. It does not take effect when the port goes down manually by executing the **shutdown** command.

This feature takes effect for online users on a port only if you configure it when that access port is up. It does not take effect for online users on a port if that access port is down when you configure it. In this case, any modification or deletion to the feature configuration cannot take effect on that access port.

Procedure

1. Enter system view.
   system-view
2. Enter port security authentication profile view.

port-security authentication-profile name *profile-name*

By default, no port security authentication profiles exist.

3. Configure the action to be taken on online users when their access ports go down.

   port-security link-down action { **keep-online** | **offline-delay** *delay-value* }

   By default, the device immediately logs off online users when their access ports go down.

Setting port security timers

About this task

Port security supports the following timers for users that have not performed authentication or that have failed authentication:

- **Periodic reauthentication timer**—Sets the interval at which the device initiates reauthentication for online 802.1X, Web authentication, or MAC authentication users in the specified domain.
- **User aging timer**—Sets the period that the device must wait before it can remove online 802.1X, Web authentication, or MAC authentication users from the specified domain.

Procedure

1. Enter system view.

   system-view

2. Set a port security timer for specific users.

   port-security timer { **reauth-period** { **auth-fail-domain** | **preauth-domain** } | **user-aging** { **auth-fail-domain** | **critical-domain** | **preauth-domain** } } *time-value*

   By default, the period for the periodic reauthentication timer is 600 seconds and the period for the user aging timer is 23 hours.

Configuring the maximum number of reauthentication attempts for users in the preauthentication domain or Auth-Fail domain

About this task

By default, the device performs periodic reauthentication for users in the preauthentication domain and Auth-Fail domain, and the number of reauthentications is not limited. Because of limited system resources, unlimited number of reauthentications without success can lead to resource contention and degraded device performance. To ensure device performance, use this feature to set the maximum number of reauthentication attempts, preventing users from occupying system resources for an extended period.

With this feature, after the maximum number of reauthentications is reached for a preauthentication or Auth-Fail domain user, the device will not trigger periodic reauthentication for that user. The user remains in the current domain and can initiate reauthentication from the client.

Restrictions and guidelines

This feature takes effect only on users who join the preauthentication domain or Auth-Fail domain after the feature command is executed.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the maximum number of reauthentication attempts for users in the preauthentication domain or Auth-Fail domain.

   port-security re-authenticate max-attempt { **auth-fail-domain | preauth-domain** } *max-attempt*

   By default, the device does not limit the number of reauthentication attempts for users in the preauthentication domain or Auth-Fail domain.

Enabling immediate reauthentication for users in the preauthentication domain or Auth-Fail domain when the authentication server becomes reachable

About this task

When all the authentication servers are unreachable or have failed, users might be assigned to the preauthentication domain or Auth-Fail domain. In normal conditions, when the periodic reauthentication feature is enabled for users in the preauthentication domain or Auth-Fail domain, the device triggers reauthentication for users only after the set reauthentication period ends. To have the device immediately trigger reauthentication for these users when any one of the authentication servers become reachable, use this feature.

When the device triggers reauthentication for preauthentication or Auth-Fail domain users, the device sets the maximum reauthentication attempts for them to the value set by using the **port-security re-authenticate max-attempt** command.

Procedure

1. Enter system view.

   system-view

2. Enable immediate reauthentication for users in the preauthentication domain or Auth-Fail domain when the authentication server becomes reachable.

   port-security reauth-trigger server-reachable { **auth-fail-domain** | **preauth-domain** }

   By default, when the authentication server changes from unreachable to reachable, the device does not immediately trigger reauthentication for users in the preauthentication domain or Auth-Fail domain.

Permitting MAC move between member ports in a TC group

About this task

Application scenarios

When the network topology changes, the STP module sends a topology change (TC) event message to notify relevant devices that the network topology has changed. TC events might cause traffic forwarding exceptions on a member port in a TC group.

To resolve this issue, use this feature to permit MAC move between member ports in a TC group when the network topology changes. MAC move allows authenticated online users on a member port in a TC group to move to the other member port in the same TC group without being authenticated again. The process is as described in "Operating mechanism."

Use this feature on the device if the device is connected to users that cannot actively send packets to trigger MAC move when the network topology changes.

Operating mechanism

The operating mechanism of this feature is as follows:

- If a member port in a TC group is up and receives a TC event message, the device searches for online authenticated users that come online from that port. In addition, the device sends ARP or NS detection packets to these users at detection intervals through the other member port in the same TC group.
  - If the other member port receives a response packet for a user, that user moves to the other member port and comes online without being authenticated.
  - If the other member port does not receive any response packets for a user after the device has made the maximum number of attempts for sending a detection packet, the device determines that the network topology of that TC group does not change. It does not move the user to the other member port.
- If the network topology changes because a member port in a TC group goes down, the device does not wait to receive TC event messages sent by the STP module or actively detect online authenticated users on that port from the other member port. Instead, it immediately moves the online authenticated users on that port to the other member port without authenticating them. To detect whether the users can come online correctly on the other member port, you can enable offline detection or ARP or NS packet detection on the other member port.

For more information about TC groups, see spanning tree configuration in *Layer 2—LAN Switching Configuration Guide*.

Restrictions and guidelines

This feature takes effect only on static users, MAC authentication users, and 802.1X users.

As a best practice to ensure successful MAC move between member ports in a TC group, the member ports in that TC group must use the same settings.

Procedure

1. Enter system view.

   `system-view`

2. Allow authenticated online users to move between member ports in the same TC group without being authenticated again.

   `port-security topology-change free-mac-move`

   By default, the device does not allow authenticated online users to move between member ports in the same TC group without being authenticated again.

3. Set the interval at which the device actively sends ARP or NS detection packets when the network topology changes.

   `port-security topology-change detect-period` *`time-value`*

   By default, the device actively sends ARP or NS detection packets at intervals of 5 seconds when the network topology changes.

4. Set the maximum number of attempts for sending an ARP or NS detection packet when the network topology changes.

   `port-security topology-change detect-retry` *`retries`*

By default, the device attempts to send an ARP or NS detection packet for a maximum of three times when the network topology changes.

Enabling SNMP notifications for port security

About this task

Use this feature to report critical port security events to an NMS. For port security event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for port security.

   snmp-agent trap enable port-security [**ac-creation-failure** | **acl-author-failure** | **acl-author-success** | **address-learned** | **dot1x-failure** | **dot1x-ip-change** | **dot1x-logoff** | **dot1x-logon** | **intrusion** | **intrusion-recover** | **mac-auth-failure** | **mac-auth-logoff** | **mac-auth-logon** | **mac-auth-ip-change** | **mac-auth-not-support** | **ntk-ineffective** | **port-mode-ineffective** | **url-author-failure** | **url-author-success**] *

   By default, SNMP notifications are disabled for port security.

Enabling port security user logging

About this task

This feature enables the device to generate logs about port security users and send the logs to the information center. For the logs to be output correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

To prevent excessive port security user log entries, use this feature only if you need to analyze abnormal port security user events.

Procedure

1. Enter system view.

   system-view

2. Enable port security user logging.

   port-security access-user log enable [**failed-authorization** | **mac-learning** | **violation** | **vlan-mac-limit**] *

   By default, port security user logging is disabled.

   If you do not specify any parameters, this command enables all types of port security user logs.

Display and maintenance commands for port security

Execute **display** commands in any view:

Task	Command
Display the port security configuration, operation information, and statistics.	**display port-security** [**interface** *interface-type interface-number*]
Display entries for online port security access users.	**display port-security access-user** [**m-lag** [**local** | **peer**]] [**access-type** { **dot1x** | **mac-auth** | **web-auth** | **static** } | **domain** *domain-name* | **online-type** { **auth-fail-domain** | **critical-domain** | **preauth-domain** | **success** | **url-unavailable-domain** } | **slot** *slot-number*] *
Display configuration information for port security authentication profiles	**display port-security authentication-profile** [**name** *profile-name*]
Display information about blocked MAC addresses.	**display port-security mac-address block** [**interface** *interface-type interface-number*] [**vlan** *vlan-id*] [**count**]
Display MAC address entries synchronized from the M-LAG peer.	**display port-security mac-address m-lag sync-from-peer** [**user-mac** *mac-address*]
Display MAC address entries synchronized to the M-LAG peer.	**display port-security mac-address m-lag sync-to-peer** [**interface** *interface-type interface-number* | **user-mac** *mac-address*]
Display information about secure MAC addresses.	**display port-security mac-address security** [**interface** *interface-type interface-number*] [**vlan** *vlan-id*] [**count**]
Display static user configuration information.	**display port-security static-user**
Display online static users.	**display port-security static-user connection** [[**m-lag** [**local** | **peer**]] [**interface** *interface-type interface-number* | **online-type** { **auth-fail-domain** | **critical-domain** | **preauth-domain** | **success** } | **slot** *slot-number* | **user-name** *user-name*] | { **ip** | **ipv6** } *ip-address* | **mac** *mac-address*]
Display port security statistics.	**display port-security statistics** [**slot** *slot-number*]
Log off online static users.	**reset port-security static-user** [**interface** *interface-type interface-number* | { **ip** | **ipv6** } *ip-address* | **mac** *mac-address* | **online-type** { **auth-fail-domain** | **critical-domain** | **preauth-domain** | **success** } | **user-name** *user-name*]
Clear port security statistics.	**reset port-security statistics**

Port security configuration examples

Example: Configuring port security in autoLearn mode

Network configuration

As shown in Figure 3, configure GigabitEthernet 1/0/1 on the device to meet the following requirements:

- Accept up to 64 users without authentication.
- Be permitted to learn and add MAC addresses as sticky MAC addresses, and set the secure MAC aging timer to 30 minutes.
- Stop learning MAC addresses after the number of secure MAC addresses reaches 64. If any frame with an unknown MAC address arrives, intrusion protection starts, and the port shuts down and stays silent for 30 seconds.

Figure 3 Network diagram

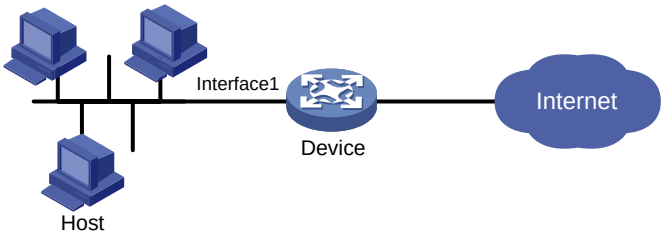


Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

Enable port security.

```
<Device> system-view
[Device] port-security enable
```

Set the secure MAC aging timer to 30 minutes.

```
[Device] port-security timer autolearn aging 30
```

Set port security's limit on the number of secure MAC addresses to 64 on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] port-security max-mac-count 64
```

Set the port security mode to autoLearn.

```
[Device-GigabitEthernet1/0/1] port-security port-mode autolearn
```

Configure the port to be silent for 30 seconds after the intrusion protection feature is triggered.

```
[Device-GigabitEthernet1/0/1] port-security intrusion-mode disableport-temporarily
[Device-GigabitEthernet1/0/1] quit
[Device] port-security timer disableport 30
```

Verifying the configuration

Verify the port security configuration.

```
[Device] display port-security interface gigabitethernet 1/0/1
Global port security parameters:
```

```
  Port security                              : Enabled

  Intrusion protection mode                  : DisablePortTemporarily
```

```
   Strict intrusion protection             : Disabled
   Security MAC address attribute
       Learning mode                       : Sticky
       Aging type                          : Periodical
   Max secure MAC addresses                : 64
   Current secure MAC addresses            : 0
   Authorization                           : Permitted
   NAS-ID profile                          : Not configured
   Free VLANs                              : Not configured
   Open authentication                     : Disabled
   MAC-move VLAN check bypass              : Disabled
   Server-reachable reauth
       Preauth domain                      : Disabled
       Auth-Fail domain                    : Disabled
```

The port allows for MAC address learning, and you can view the number of learned MAC addresses in the **Current secure MAC addresses** field.

Display additional information about the learned MAC addresses.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] display this
#
interface GigabitEthernet1/0/1
 port-security max-mac-count 64
 port-security port-mode autolearn
 port-security mac-address security sticky 0002-0000-0015 vlan 1
 port-security mac-address security sticky 0002-0000-0014 vlan 1
 port-security mac-address security sticky 0002-0000-0013 vlan 1
 port-security mac-address security sticky 0002-0000-0012 vlan 1
 port-security mac-address security sticky 0002-0000-0011 vlan 1
#
```

Use the **`display port-security interface`** command to verify that the port security mode changes to **secure** after the number of MAC addresses learned by the port reaches 64.

Use the **`display interface`** command to verify that the port will be disabled for 30 seconds after it receives a frame with an unknown MAC address. (Details not shown.)

After the port is re-enabled, delete several secure MAC addresses. (Details not shown.)

Verify that the port security mode of the port changes to **autoLearn**, and the port can learn MAC addresses again. (Details not shown.)

Example: Configuring port security in userLoginWithOUI mode

Network configuration

As shown in Figure 4, a client is connected to the device through GigabitEthernet 1/0/1. The device authenticates the client with a RADIUS server in ISP domain **sun**. If the authentication succeeds, the client is authorized to access the Internet.

- The RADIUS server at 192.168.1.2 acts as the primary authentication server and the secondary accounting server. The RADIUS server at 192.168.1.3 acts as the secondary authentication

server and the primary accounting server. The shared key for authentication is **name**, and the shared key for accounting is **money**.

- All users use the authentication, authorization, and accounting methods of ISP domain **sun**.
- The RADIUS server response timeout time is 5 seconds. The maximum number of RADIUS packet retransmission attempts is 5. The device sends real-time accounting packets to the RADIUS server at 15-minute intervals, and sends usernames without domain names to the RADIUS server.

Configure GigabitEthernet 1/0/1 to allow only one 802.1X user and a user that uses one of the specified OUI values to be authenticated.

Figure 4 Network diagram

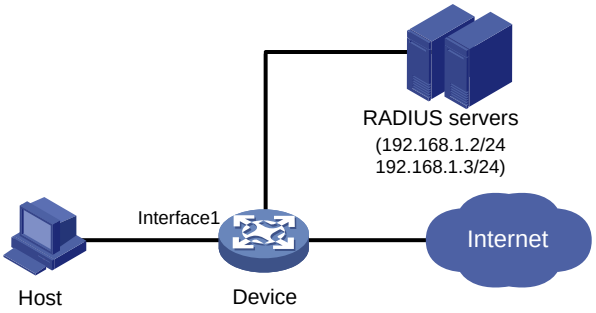

Table 4 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

The following configuration steps cover some AAA/RADIUS configuration commands. For more information about the commands, see *Security Command Reference*.

Make sure the host and the RADIUS server can reach each other.

1. Configure AAA:

Configure a RADIUS scheme named **radsun**.

```
<Device> system-view
[Device] radius scheme radsun
[Device-radius-radsun] primary authentication 192.168.1.2
[Device-radius-radsun] primary accounting 192.168.1.3
[Device-radius-radsun] secondary authentication 192.168.1.3
[Device-radius-radsun] secondary accounting 192.168.1.2
[Device-radius-radsun] key authentication simple name
[Device-radius-radsun] key accounting simple money
[Device-radius-radsun] timer response-timeout 5
[Device-radius-radsun] retry 5
[Device-radius-radsun] timer realtime-accounting 15
[Device-radius-radsun] user-name-format without-domain
[Device-radius-radsun] quit
```

Configure ISP domain **sun**.

```
[Device] domain sun
[Device-isp-sun] authentication lan-access radius-scheme radsun
[Device-isp-sun] authorization lan-access radius-scheme radsun
```

```
[Device-isp-sun] accounting lan-access radius-scheme radsun
[Device-isp-sun] quit
```

2. Configure 802.1X:

Set the 802.1X authentication method to CHAP. By default, the authentication method for 802.1X is CHAP.

```
[Device] dot1x authentication-method chap
```

Specify ISP domain **sun** as the mandatory authentication domain for 802.1X users on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] dot1x mandatory-domain sun
[Device-GigabitEthernet1/0/1] quit
```

3. Configure port security:

Enable port security.

```
[Device] port-security enable
```

Add five OUI values. (You can add up to 16 OUI values. The port permits only one user matching one of the OUIs to pass authentication.)

```
[Device] port-security oui index 1 mac-address 1234-0100-1111
[Device] port-security oui index 2 mac-address 1234-0200-1111
[Device] port-security oui index 3 mac-address 1234-0300-1111
[Device] port-security oui index 4 mac-address 1234-0400-1111
[Device] port-security oui index 5 mac-address 1234-0500-1111
```

Set the port security mode to userLoginWithOUI.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] port-security port-mode userlogin-withoui
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Verify that GigabitEthernet 1/0/1 allows only one 802.1X user to be authenticated.

```
[Device] display port-security interface gigabitethernet 1/0/1
Global port security parameters:
   Port security                          : Enabled

      Index :  2       Value : 123402
      Index :  3       Value : 123403
      Index :  4       Value : 123404
      Index :  5       Value : 123405

GigabitEthernet1/0/1 is link-up
  Port mode                               : userLoginWithOUI
  Pre-auth domain                         : Not configured
  URL-unavailable domain                  : Not configured
  NeedToKnow mode                         : Disabled
  Intrusion protection mode               : NoAction
  Strict intrusion protection             : Disabled
  Security MAC address attribute
      Learning mode                       : Sticky
      Aging type                          : Periodical
  Max secure MAC addresses                : Not configured
  Current secure MAC addresses            : 1
  Authorization                           :Permitted
  NAS-ID profile                          : Not configured
  Free VLANs                              : Not configured
  Open authentication                     : Disabled
  MAC-move VLAN check bypass              : Disabled
  Server-reachable reauth
      Preauth domain                      : Disabled
      Auth-Fail domain                    : Disabled
```

Use the **display dot1x** command to display information about the online 802.1X user to verify 802.1X configuration.

Verify that the port also allows one user whose MAC address has an OUI among the specified OUIs to pass authentication.

```
[Device] display mac-address interface gigabitethernet 1/0/1
MAC Address     VLAN ID   State          Port/Nickname            Aging
1234-0300-0011  1         Learned        GE1/0/1                  Y

```

Example: Configuring port security for M-LAG

Network configuration

As shown in Figure 5, Device A and Device B authenticate the host users to the Internet. Configure Device A and Device B as follows:

- Use RADIUS servers to perform authentication, authorization, and accounting for the users.
- Form an M-LAG system for node redundancy.
- Set the port security mode to **macAddressWithRadius** on their M-LAG interfaces. Set the authentication load sharing mode to distributed local mode for users attached to the M-LAG interfaces.
- To make sure the source IP address of the RADIUS packets sent for users attached to one member device does not change after a node failover, configure the following settings on each member device:
  - Configure one source IP address for local users and one for users attached to the peer member device. On each member device, use the active and standby M-LAG virtual IP addresses as the local and peer source IP addresses of the outgoing RADIUS packets, respectively.

Figure 5 Network diagram

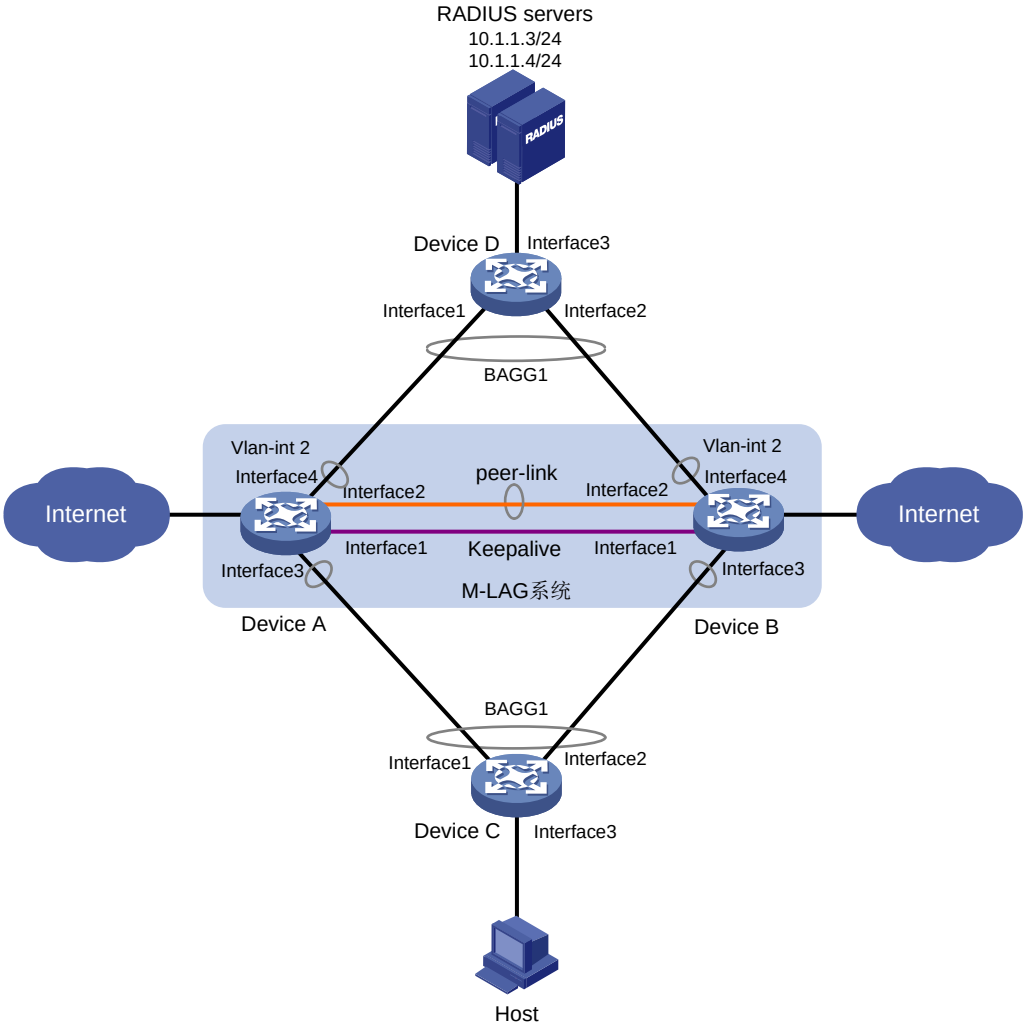

Table 5 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4

Table 6 IP assignment scheme

Device	Interface	M-LAG interface	IP address
Device A (M-LAG1)	GE1/0/1	Keepalive interface	1.1.1.2/24
	BAGG1 (GE1/0/2)	Peer link interface	-
	BAGG2 (GE1/0/4)	M-LAG interface	-
	BAGG3 (GE1/0/3)	M-LAG interface	-
	VLAN-interface 2	-	10.1.1.1/24
Device B (M-LAG2)	GE1/0/1	Keepalive interface	1.1.1.1/24
	BAGG1 (GE1/0/2)	Peer link interface	-

Device	Interface	M-LAG interface	IP address
	BAGG2 (GE1/0/4)	M-LAG interface	-
	BAGG3 (GE1/0/3)	M-LAG interface	-
	VLAN-interface 2	-	-

Restrictions and guidelines

The configuration procedure in this example uses some AAA and RADIUS commands. For more information about these commands, see *Security Command Reference*.

The configuration procedure in this example uses some M-LAG commands. For more information about these commands, see *Layer 2—LAN Switching Command Reference*.

Prerequisites

Make sure the host and RADIUS servers can reach each other.

Configure the RADIUS servers and add user accounts. Make sure the RADIUS servers can provide authentication, authorization, and accounting services.

Procedure

1. Configure Device A:

- Configure AAA:

  # Configure RADIUS scheme **radsun**.

```
<DeviceA> system-view
[DeviceA] radius scheme radsun
[DeviceA-radius-radsun] primary authentication 10.1.1.3
[DeviceA-radius-radsun] primary accounting 10.1.1.4
[DeviceA-radius-radsun] secondary authentication 10.1.1.4
[DeviceA-radius-radsun] secondary accounting 10.1.1.3
[DeviceA-radius-radsun] key authentication simple name
[DeviceA-radius-radsun] key accounting simple money
[DeviceA-radius-radsun] timer response-timeout 5
[DeviceA-radius-radsun] retry 5
[DeviceA-radius-radsun] timer realtime-accounting 15
[DeviceA-radius-radsun] user-name-format without-domain
```

  # Specify 10.1.1.1 as the source IP address of outgoing RADIUS packets for users attached to the local M-LAG interfaces. Specify 10.1.1.2 as the source IP address of outgoing RADIUS packets for users attached to the peer M-LAG interfaces.

```
[DeviceA-radius-radsun] nas-ip m-lag local 10.1.1.1
[DeviceA-radius-radsun] nas-ip m-lag peer 10.1.1.2
[DeviceA-radius-radsun] quit
```

  # Configure ISP domain **sun**.

```
[DeviceA] domain sun
[DeviceA-isp-sun] authentication lan-access radius-scheme radsun
[DeviceA-isp-sun] authorization lan-access radius-scheme radsun
[DeviceA-isp-sun] accounting lan-access radius-scheme radsun
[DeviceA-isp-sun] quit
```

- Configure M-LAG settings:

  # Configure M-LAG system settings.

```
[DeviceA] m-lag system-mac 1-1-1
[DeviceA] m-lag system-number 1
```

```
[DeviceA] m-lag system-priority 123
```

Configure the destination and source IP addresses of keepalive packets.

```
[DeviceA] m-lag keepalive ip destination 1.1.1.1 source 1.1.1.2
```

Configure port GigabitEthernet 1/0/1 to operate in Layer 3 mode and configure the source IP address of keepalive packets as the IP address of this port.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-mode route
[DeviceA-GigabitEthernet1/0/1] ip address 1.1.1.2 24
[DeviceA-GigabitEthernet1/0/1] quit
```

Exclude GigabitEthernet 1/0/1 (keepalive interface) from being shut down upon detection of multi-active collisions.

```
[DeviceA] m-lag mad exclude interface gigabitethernet 1/0/1
```

Create Layer 2 aggregate interface **Bridge-Aggregation 1** and set the aggregation mode to dynamic.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation1] quit
```

Assign GigabitEthernet 1/0/2 to aggregation group 1.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/2] quit
```

Configure Layer 2 aggregate interface **Bridge-Aggregation 1** as a peer link interface.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] port m-lag peer-link 1
[DeviceA-Bridge-Aggregation1] quit
```

On the VLAN interface, specify 10.1.1.1 as the M-LAG virtual IPv4 address in active state and specify 10.1.1.2 as the M-LAG virtual IPv4 address in standby state.

```
[DeviceA] vlan 2
[DeviceA-vlan2] quit
[DeviceA] interface vlan-interface 2
[DeviceA-Vlan-interface2] port m-lag virtual-ip 10.1.1.1 24 active virtual-mac
11-1-1
[DeviceA-Vlan-interface2] port m-lag virtual-ip 10.1.1.2 24 standby virtual-mac
11-1-2
[DeviceA-Vlan-interface2] quit
```

Create Layer 2 aggregate interface **Bridge-Aggregation 2** and set the aggregation mode to dynamic.

```
[DeviceA] interface bridge-aggregation 2
[DeviceA-Bridge-Aggregation2] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation2] quit
```

Assign GigabitEthernet 1/0/4 to aggregation group 2.

```
[DeviceA] interface gigabitethernet 1/0/4
[DeviceA-GigabitEthernet1/0/4] port link-aggregation group 2
[DeviceA-GigabitEthernet1/0/4] quit
```

Assign Bridge-Aggregation 2 to M-LAG group 2.

```
[DeviceA] interface bridge-aggregation 2
[DeviceA-Bridge-Aggregation2] port m-lag group 2
[DeviceA-Bridge-Aggregation2] port access vlan 2
[DeviceA-Bridge-Aggregation2] quit
```

Create Layer 2 aggregate interface **Bridge-Aggregation 3** and set the aggregation mode to dynamic.

```
[DeviceA] interface bridge-aggregation 3
[DeviceA-Bridge-Aggregation3] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation3] quit
```

Assign GigabitEthernet 1/0/3 to aggregation group 3.

```
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] port link-aggregation group 3
[DeviceA-GigabitEthernet1/0/3] quit
```

Assign Bridge-Aggregation 3 to M-LAG group 3.

```
[DeviceA] interface bridge-aggregation 3
[DeviceA-Bridge-Aggregation3] port m-lag group 3
[DeviceA-Bridge-Aggregation3] quit
```

- Configure port security settings:

  # Enable port security.

  ```
  [DeviceA] port-security enable
  ```

  # Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hyphenated hexadecimal notation, with letters in upper case.

  ```
  [DeviceA] mac-authentication user-name-format mac-address with-hyphen uppercase
  ```

  # Configure domain **sun** as the global MAC authentication domain on the device.

  ```
  [DeviceA] mac-authentication domain sun
  ```

  # Set the port security mode to **macAddressWithRadius** on Bridge-Aggregation 3.

  ```
  [DeviceA] interface bridge-aggregation 3
  [DeviceA-Bridge-Aggregation3] port-security port-mode mac-authentication
  ```

  # Configure domain **sun** as the MAC authentication domain on Bridge-Aggregation 3.

  ```
  [DeviceA-Bridge-Aggregation3] mac-authentication domain sun
  [DeviceA-Bridge-Aggregation3] quit
  ```

2. Configure Device B:

- Configure AAA settings:

  # Configure RADIUS scheme **radsun**.

  ```
  <DeviceB> system-view
  [DeviceB] radius scheme radsun
  [DeviceB-radius-radsun] primary authentication 10.1.1.3
  [DeviceB-radius-radsun] primary accounting 10.1.1.4
  [DeviceB-radius-radsun] secondary authentication 10.1.1.4
  [DeviceB-radius-radsun] secondary accounting 10.1.1.3
  [DeviceB-radius-radsun] key authentication simple name
  [DeviceB-radius-radsun] key accounting simple money
  [DeviceB-radius-radsun] timer response-timeout 5
  [DeviceB-radius-radsun] retry 5
  [DeviceB-radius-radsun] timer realtime-accounting 15
  [DeviceB-radius-radsun] user-name-format without-domain
  ```

  # Specify 10.1.1.2 as the source IP address of outgoing RADIUS packets for users attached to the local M-LAG interfaces. Specify 10.1.1.1 as the source IP address of outgoing RADIUS packets for users attached to the peer M-LAG interfaces.

  ```
  [DeviceB-radius-radsun] nas-ip m-lag local 10.1.1.2
  [DeviceB-radius-radsun] nas-ip m-lag peer 10.1.1.1
  ```

```
[DeviceB-radius-radsun] quit
```

Configure ISP domain **sun**.

```
[DeviceB] domain sun
[DeviceB-isp-sun] authentication lan-access radius-scheme radsun
[DeviceB-isp-sun] authorization lan-access radius-scheme radsun
[DeviceB-isp-sun] accounting lan-access radius-scheme radsun
[DeviceB-isp-sun] quit
```

- Configure M-LAG settings:

Configure M-LAG system settings.

```
[DeviceB] m-lag system-mac 1-1-1
[DeviceB] m-lag system-number 2
[DeviceB] m-lag system-priority 123
```

Configure the destination and source IP addresses of keepalive packets.

```
[DeviceB] m-lag keepalive ip destination 1.1.1.2 source 1.1.1.1
```

Configure GigabitEthernet 1/0/1 to operate in Layer 3 mode and configure the source IP address of keepalive packets as the IP address of this port.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-mode route
[DeviceB-GigabitEthernet1/0/1] ip address 1.1.1.1 24
[DeviceB-GigabitEthernet1/0/1] quit
```

Exclude GigabitEthernet 1/0/1 (keepalive interface) from being shut down upon detection of multi-active collisions.

```
[DeviceB] m-lag mad exclude interface gigabitethernet 1/0/1
```

Create Layer 2 aggregate interface **Bridge-Aggregation 1** and set the aggregation mode to dynamic.

```
[DeviceB] interface bridge-aggregation 1
[DeviceB-Bridge-Aggregation1] link-aggregation mode dynamic
[DeviceB-Bridge-Aggregation1] quit
```

Assign GigabitEthernet 1/0/2 to aggregation group 1.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-aggregation group 1
[DeviceB-GigabitEthernet1/0/2] quit
```

Configure Layer 2 aggregate interface **Bridge-Aggregation 1** as a peer link interface.

```
[DeviceB] interface bridge-aggregation 1
[DeviceB-Bridge-Aggregation1] port m-lag peer-link 1
[DeviceB-Bridge-Aggregation1] quit
```

Create VLAN-interface 2. On the VLAN interface, specify 10.1.1.2 as the M-LAG virtual IPv4 address in active state and specify 10.1.1.1 as the M-LAG virtual IPv4 address in standby state.

```
[DeviceB] vlan 2
[DeviceB-vlan2] quit
[DeviceB] interface vlan-interface 2
[DeviceB-Vlan-interface2] port m-lag virtual-ip 10.1.1.2 24 active virtual-mac
11-1-2
[DeviceB-Vlan-interface2] port m-lag virtual-ip 10.1.1.1 24 standby virtual-mac
11-1-1
[DeviceB-Vlan-interface2] quit
```

Create Layer 2 aggregate interface **Bridge-Aggregation 2** and set the aggregation mode to dynamic.

```
[DeviceB] interface bridge-aggregation 2
[DeviceB-Bridge-Aggregation2] link-aggregation mode dynamic
[DeviceB-Bridge-Aggregation2] quit
```

Assign GigabitEthernet 1/0/4 to aggregation group 2.

```
[DeviceB] interface gigabitethernet 1/0/4
[DeviceB-GigabitEthernet1/0/4] port link-aggregation group 2
[DeviceB-GigabitEthernet1/0/4] quit
```

Assign Bridge-Aggregation 2 to M-LAG group 2.

```
[DeviceB] interface bridge-aggregation 2
[DeviceB-Bridge-Aggregation2] port m-lag group 2
[DeviceB-Bridge-Aggregation2] port access vlan 2
[DeviceB-Bridge-Aggregation2] quit
```

Create Layer 2 aggregate interface **Bridge-Aggregation 3** and set the aggregation mode to dynamic.

```
[DeviceB] interface bridge-aggregation 3
[DeviceB-Bridge-Aggregation3] link-aggregation mode dynamic
[DeviceB-Bridge-Aggregation3] quit
```

Assign GigabitEthernet 1/0/3 to aggregation group 3.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-aggregation group 3
[DeviceB-GigabitEthernet1/0/3] quit
```

Assign Bridge-Aggregation 3 to M-LAG group 3.

```
[DeviceB] interface bridge-aggregation 3
[DeviceB-Bridge-Aggregation3] port m-lag group 3
[DeviceB-Bridge-Aggregation3] quit
```

- Configure port security settings:

  # Enable port security.

  ```
  [DeviceB] port-security enable
  ```

  # Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hyphenated hexadecimal notation, with letters in upper case.

  ```
  [DeviceB] mac-authentication user-name-format mac-address with-hyphen uppercase
  ```

  # Configure domain **sun** as the global MAC authentication domain on the device.

  ```
  [DeviceB] mac-authentication domain sun
  ```

  # Set the port security mode to **macAddressWithRadius** on Layer 2 aggregate interface **Bridge-Aggregation 3**.

  ```
  [DeviceB] interface bridge-aggregation 3
  [DeviceB-Bridge-Aggregation3] port-security port-mode mac-authentication
  ```

  # Configure domain **sun** as the MAC authentication domain on Bridge-Aggregation 3.

  ```
  [DeviceB-Bridge-Aggregation3] mac-authentication domain sun
  [DeviceB-Bridge-Aggregation3] quit
  ```

3. Configure Device C:

Create Layer 2 aggregate interface **Bridge-Aggregation 1** and set the aggregation mode to dynamic.

```
<DeviceC> system-view
[DeviceC] interface bridge-aggregation 1
[DeviceC-Bridge-Aggregation1] link-aggregation mode dynamic
[DeviceC-Bridge-Aggregation1] quit
```

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to aggregation group 1.

```
[DeviceC] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/2
[DeviceC-if-range] port link-aggregation group 1
[DeviceC-if-range] quit
```

4. Configure Device D:

Create Layer 2 aggregate interface **Bridge-Aggregation 1** and set the aggregation mode to dynamic.

```
<DeviceD> system-view
[DeviceD] interface bridge-aggregation 1
[DeviceD-Bridge-Aggregation1] link-aggregation mode dynamic
[DeviceD-Bridge-Aggregation1] quit
```

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to aggregation group 1.

```
[DeviceD] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/2
[DeviceD-if-range] port link-aggregation group 1
[DeviceD-if-range] quit
```

Verifying the configuration

1. On Device A:

Display M-LAG summary information on Device A to verify that Device A and Device B have formed an M-LAG system.

```
[DeviceA] display m-lag summary
Flags: A -- Aggregate interface down, B -- No peer M-LAG interface configured
       C -- Configuration consistency check failed

Peer-link interface: BAGG1
Peer-link interface state (cause): UP
Keepalive link state (cause): UP

                    M-LAG interface information
M-LAG IF      M-LAG group  Local state (cause)  Peer state  Remaining down time(s)
BAGG2         2            UP                   UP          -
BAGG3         3            UP                   UP          -
```

Display port security settings on Device A.

```
[DeviceA] display port-security interface bridge-aggregation 3
Global port security parameters:
   Port security                          : Enabled

Troubleshooting port security

Cannot set the port security mode

Symptom

Cannot set the port security mode for a port.

Analysis

For a port operating in a port security mode other than noRestrictions, you cannot change the port security mode by using the **`port-security port-mode`** command.

Solution

To resolve the issue:

1. Set the port security mode to noRestrictions.

   ```
   [Device-GigabitEthernet1/0/1] undo port-security port-mode
   ```

2. Set a new port security mode for the port, for example, autoLearn.

   ```
   [Device-GigabitEthernet1/0/1] port-security port-mode autolearn
   ```

3. If the issue persists, contact H3C Support.

Cannot configure secure MAC addresses

Symptom

Cannot configure secure MAC addresses.

Analysis

No secure MAC address can be configured on a port operating in a port security mode other than autoLearn.

Solution

To resolve the issue:

1. Set the port security mode to autoLearn.

   ```
   [Device-GigabitEthernet1/0/1] undo port-security port-mode
   [Device-GigabitEthernet1/0/1] port-security max-mac-count 64
   [Device-GigabitEthernet1/0/1] port-security port-mode autolearn
   [Device-GigabitEthernet1/0/1] port-security mac-address security 1-1-2 vlan 1
   ```

2. If the issue persists, contact H3C Support.

Configuring user profiles

About user profiles

A user profile defines a set of parameters, such as a QoS policy, for a user or a class of users. A user profile can be reused when a user connected to the network on a different interface.

The user profile application allows flexible traffic policing on a per-user basis. Each time a user passes authentication, the server sends the device the name of the user profile specified for the user. The device applies the parameters in the user profile to the user.

User profiles are typically used for resource allocation per user. For example, the interface-based traffic policing limits the total amount of bandwidth available to a group of users. However, user-profile-based traffic policing can limit the amount of bandwidth available to a single user.

Prerequisites for user profile

A user profile works with authentication methods. You must configure authentication for a user profile. For information about supported authentication methods, see the configuration guides for the related authentication modules.

Configuring a user profile

1. Enter system view.
   system-view
2. Create a user profile and enter user profile view.
   user-profile *profile-name*
3. Apply an existing QoS policy to the user profile.
   qos apply policy *policy-name* { **inbound** | **outbound** }
   By default, no QoS policy is applied to a user profile.
   For information about QoS policies, see *ACL and QoS Configuration Guide*.

Display and maintenance commands for user profiles

Execute **display** commands in any view.

Task	Command
Display configuration and online user information for the specified user profile or all user profiles.	**display user-profile** [**name** *profile-name*] [**slot** *slot-number*]

User profile configuration examples

Example: Configuring user profiles and QoS policies

Network configuration

As shown in Figure 1, the device performs local 802.1X authentication on the users in domain **user** for authentication and authorization efficiency.

Configure user profiles and QoS policies on the device to meet the following requirements:

- User A cannot access the Internet during 8: 30 and 12:00 every day even if User A passes 802.1X authentication.
- User B has an upload speed of 2 Mbps after passing 802.1X authentication.
- User C has a download speed of 4 Mbps after passing 802.1X authentication.

Figure 1 Network diagram

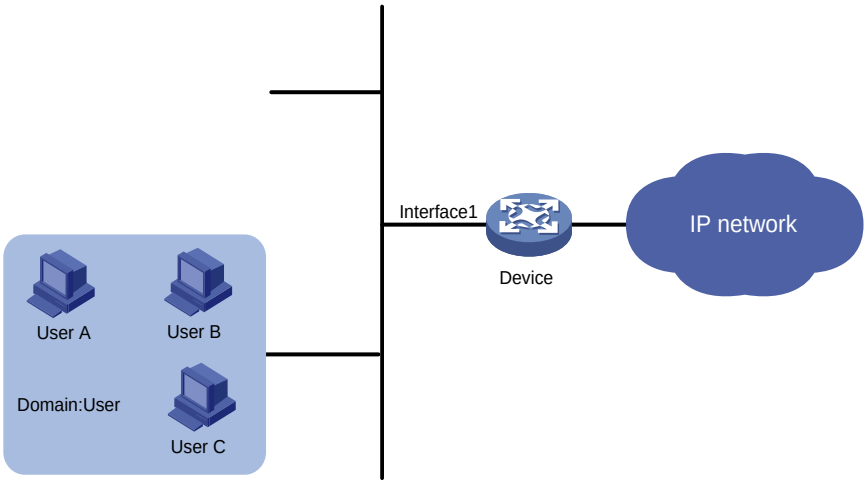

Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

1. Configure a QoS policy for User A:

   # Create a periodic time range from 8:30 to 12:00 every day.

   ```
   <Device> system-view
   [Device] time-range for_usera 8:30 to 12:00 daily
   ```

   # Create IPv4 basic ACL 2000, and configure a rule to match all packets during the time range **for_usera**.

   ```
   [Device] acl basic 2000
   [Device-acl-basic-2000] rule permit time-range for_usera
   [Device-acl-basic-2000] quit
   ```

   # Create a traffic class named **for_usera**, and use ACL 2000 as the match criterion.

   ```
   [Device] traffic classifier for_usera
   [Device-classifier-for_usera] if-match acl 2000
   [Device-classifier-for_usera] quit
   ```

Create a traffic behavior named **for_usera**, and configure the deny action.

```
[Device] traffic behavior for_usera
[Device-behavior-for_usera] filter deny
[Device-behavior-for_usera] quit
```

Create a QoS policy named **for_usera**, and associate traffic class **for_usera** and traffic behavior **for_usera** in the QoS policy.

```
[Device] qos policy for_usera
[Device-qospolicy-for_usera] classifier for_usera behavior for_usera
[Device-qospolicy-for_usera] quit
```

2. Create a user profile for User A and apply the QoS policy to the user profile:

Create a user profile named **usera**.

```
[Device] user-profile usera
```

Apply QoS policy **for_usera** to the inbound direction of user profile **usera**.

```
[[Device-user-profile-usera] qos apply policy for_usera inbound
[Device-user-profile-usera] quit
```

3. Configure a QoS policy for limiting the traffic rate for User B:

Create a traffic class named **class** to match all packets.

```
[Device] traffic classifier class
[Device-classifier-class] if-match any
[Device-classifier-class] quit
```

Create a traffic behavior named **for_userb**, and configure a traffic policing action (CIR 2000 kbps).

```
[Device] traffic behavior for_userb
[Device-behavior-for_userb] car cir 2000
[Device-behavior-for_userb] quit
```

Create a QoS policy named **for_userb**, and associate traffic class **class** and traffic behavior **for_userb** in the QoS policy.

```
[Device] qos policy for_userb
[Device-qospolicy-for_userb] classifier class behavior for_userb
[Device-qospolicy-for_userb] quit
```

4. Create a user profile for User B and apply the QoS policy to the user profile:

Create a user profile named **userb**.

```
[Device] user-profile userb
```

Apply QoS policy **for_userb** to the inbound direction of user profile **userb**.

```
[Device-user-profile-userb] qos apply policy for_userb inbound
[Device-user-profile-userb] quit
```

5. Configure a QoS policy for limiting the traffic rate for User C:

Create a traffic behavior named **for_userc**, and configure a traffic policing action (CIR 4000 kbps).

```
[Device] traffic behavior for_userc
[Device-behavior-for_userc] car cir 4000
[Device-behavior-for_userc] quit
```

Create a QoS policy named **for_userc**, and associate traffic class **class** and traffic behavior **for_userc** in the QoS policy.

```
[Device] qos policy for_userc
[Device-qospolicy-for_userc] classifier class behavior for_userc
[Device-qospolicy-for_userc] quit
```

6. Create a user profile for User C and apply the QoS policy to the user profile:

Create a user profile named **userc**.

```
[Device] user-profile userc
```

Apply QoS policy **for_userc** to the outbound direction of user profile **userc**.

```
[Device-user-profile-userc] qos apply policy for_userc outbound
[Device-user-profile-userc] quit
```

7. Configure local users:

Create a local user named **usera**.

```
[Device] local-user usera class network
New local user added.
```

Set the password to **123456TESTusera&!** for user **usera**.

```
[Device-luser-network-usera] password simple 123456TESTusera&!
```

Authorize user **usera** to use the LAN access service.

```
[Device-luser-network-usera] service-type lan-access
```

Specify user profile **usera** as the authorization user profile for user **usera**.

```
[Device-luser-network-usera] authorization-attribute user-profile usera
[Device-luser-network-usera] quit
```

Create a local user named **userb**.

```
[Device] local-user userb class network
New local user added.
```

Set the password to **123456TESTuserb&!** for user **userb**.

```
[Device-luser-network-userb] password simple 123456TESTuserb&!
```

Authorize user **userb** to use the LAN access service.

```
[Device-luser-network-userb] service-type lan-access
```

Specify user profile **userb** as the authorization user profile for user **userb**.

```
[Device-luser-network-userb] authorization-attribute user-profile userb
[Device-luser-network-userb] quit
```

Create a local user named **userc**.

```
[Device] local-user userc class network
New local user added.
```

Set the password to **123456TESTuserc&!** for user **userc**.

```
[Device-luser-network-userc] password simple 123456TESTuserc&!
```

Authorize user **userc** to use the LAN access service.

```
[Device-luser-network-userc] service-type lan-access
```

Specify user profile **userc** as the authorization user profile for user **userc**.

```
[Device-luser-network-userc] authorization-attribute user-profile userc
[Device-luser-network-userc] quit
```

8. Configure the authentication, authorization, and accounting methods for local users:

```
[Device] domain user
[Device-isp-user] authentication lan-access local
[Device-isp-user] authorization lan-access local
[Device-isp-user] accounting login none
[Device-isp-user] quit
```

9. Configure 802.1X:

Enable 802.1X on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] dot1x
```

Enable MAC-based access control on the port. By default, a port uses MAC-based access control.

```
[Device-GigabitEthernet1/0/1] dot1x port-method macbased
[Device-GigabitEthernet1/0/1] quit
```

Enable 802.1X globally.

```
[Device] dot1x
```

Verifying the configuration

Verify that the three users can pass 802.1X authentication and that QoS policies take effect on these users. (Details not shown.)

Display user profile information.

```
<Device> display user-profile
  User-Profile: usera
    Inbound:
      Policy: for_usera

    slot 1:
      User -:
        Authentication type: 802.1X

Configuring password control

About password control

Password control allows you to implement the following features:

- Manage login and super password setup, expirations, and updates for local users.
- Control user login status based on predefined policies.

For more information about local users, see "Configuring AAA." For information about super passwords, see RBAC in *Fundamentals Configuration Guide*.

Password setting

Minimum password length

You can define the minimum length of user passwords. The system rejects the setting of a password that is shorter than the configured minimum length.

Password composition policy

A password can be a combination of characters from the following types:

- Uppercase letters A to Z.
- Lowercase letters a to z.
- Digits 0 to 9.
- Special characters in Table 1.

Table 1 Special Characters

Character name	Symbol	Character name	Symbol
Ampersand sign	&	Apostrophe	'
Asterisk	*	At sign	@
Back quote	`	Back slash	\
Blank space	N/A	Caret	^
Colon	:	Comma	,
Dollar sign	$	Dot	.
Equal sign	=	Exclamation point	!
Left angle bracket	<	Left brace	{
Left bracket	[	Left parenthesis	(
Minus sign	-	Percent sign	%
Plus sign	+	Pound sign	#
Quotation marks	"	Right angle bracket	>
Right brace	}	Right bracket	]
Right parenthesis	)	Semi-colon	;
Slash	/	Tilde	~

Character name	Symbol	Character name	Symbol
Underscore	_	Vertical bar	|

Depending on the system's security requirements, you can set the minimum number of character types a password must contain and the minimum number of characters for each type, as shown in Table 2.

Table 2 Password composition policy

Password combination level	Minimum number of character types	Minimum number of characters for each type
Level 1	One	One
Level 2	Two	One
Level 3	Three	One
Level 4	Four	One

When a user sets or changes a password, the system checks if the password meets the combination requirement. If it does not, the operation fails.

Password complexity checking policy

A less complicated password is more likely to be cracked, such as a password containing the username or repeated characters. For higher security, you can configure a password complexity checking policy to ensure that all user passwords are relatively complicated. When a user configures a password, the system checks the complexity of the password. If the password is complexity-incompliant, the configuration will fail.

You can apply the following password complexity requirements:

- A password cannot contain the username, the reverse of the username, or part of the username or the reverse of the username. For example, if the username is **abc**, a password such as **abc982**, **2cba**, **ab**, or **cb** is not complex enough.
- A password cannot contain three or more identical consecutive characters. For example, password **a111** is not complex enough.
- A password cannot contain multiple horizontally-adjacent characters on the keyboard. For example, if a password can contain only two horizontally-adjacent characters on the keyboard, **QWE12** and **EWQ21** do not meet the complexity requirements.

Password updating and expiration

Password updating

This feature allows you to set the minimum interval at which users can change their passwords. A user can only change the password once within the specified interval.

The minimum interval does not apply to the following situations:

- A user is prompted to change the password at first login.
- The password aging time expires.

Password expiration

Password expiration imposes a lifecycle on a user password. After the password expires, the user needs to change the password.

The system displays an error message for a login attempt with an expired password. The user is asked to provide a new password. The new password must be valid, and the user must enter exactly the same password when confirming it.

Telnet users, SSH users, and console users can change their own passwords. FTP users must have their passwords changed by the administrator.

Early notice on pending password expiration

When a user logs in, the system checks whether the password will expire in a time equal to or less than the specified notification period. If so, the system notifies the user when the password will expire and provides a choice for the user to change the password.

- If the user sets a new valid password, the system records the new password and the setup time.
- If the user does not or fails to change the password, the system allows the user to log in by using the current password until the password expires.

Telnet users, SSH users, and console users can change their own passwords. FTP users must have their passwords changed by the administrator.

Login with an expired password

You can allow a user to log in a certain number of times within a period of time after the password expires. For example, if you set the maximum number of logins with an expired password to 3 and the time period to 15 days, a user can log in three times within 15 days after the password expires.

Password history

This feature allows the system to store passwords that a user has used.

When a network access user changes the password, the system compares the new password with the current password and those stored in the password history records. The new password must be different from the current one and those stored in the history records by a minimum of four different characters. Otherwise, the system will display an error message, and the new password is not successfully set.

The local passwords and super passwords for device management users are stored in hash form and cannot be converted to plain texts. When a device management user changes a local password or super password, follow these rules:

- If the new password is set by using the hash method, the system will not compare the new password with the current one and those stored in the history password records.
- If the new password is set in plain text, the system compares the new password with the current password and those stored in the password history records. A new password must be different from those stored in the history password records. If the current password is required, the new password must also be different from the current one by a minimum of four different characters. Otherwise, the system will display an error message, and the new password is not successfully set.

You can set the maximum number of history password records for the system to maintain for each user. When the number of history password records exceeds the setting, the most recent record overwrites the earliest one.

Current login passwords are not stored in the password history for device management users. Device management users have their passwords saved in cipher text, which cannot be recovered to plaintext passwords.

User login control

First login

By default, if the global password control feature is enabled, users must change the password at first login before they can access the system. In this situation, password changes are not subject to the minimum password update interval. If it is not necessary for users to change the password at first login, disable the password change at first login feature.

Password control blacklist

The password control blacklist prevents abnormal users from logging in by recording the login failures and maintaining the status of blacklisted user accounts.

If an FTP or VTY user fails to log in, the system adds the user account and the user's IP address to the password control blacklist. If a console user fails to log in, the system adds the user account to the password control blacklist.

If a user uses the same user account to log in to the device from different IP addresses and fails the logins, the device will create a blacklist entry for each IP address for the user account. When the maximum number of blacklist entries for the user account is reached, a blacklist entry for a new IP address of the user account will overwrite the earliest blacklist entry for the user account.

Login attempt limit

Limiting the number of consecutive login failures can effectively prevent password guessing.

When the number of consecutive failed attempts reaches the maximum limit, login attempt limit limits the user in any of the following ways:

- For an FTP or VTY user, the system prohibits the user from using the user account to log in through the user's IP address. For a console user, the system prohibits the user from logging in through console user line. The locked user can use their own account to log in to the device only after the account is manually removed from the password control blacklist.
- Allows the user to continue using the user account. The user account is removed from the password control blacklist when the user uses this account to successfully log in to the device.
- Locks the user account and the user's IP address for a period of time.

  The user can use the account to log in when either of the following conditions exists:

  - The locking timer expires.
  - The account is manually removed from the password control blacklist before the locking timer expires.

NOTE:

This account is locked only for the user at the locked IP address. A user from an unlocked IP address can still use this account, and the user at the locked IP address can use other unlocked user accounts.

Maximum account idle time

You can set the maximum account idle time for user accounts. When an account is idle for this period of time since the last successful login, the account becomes invalid.

Login control with a weak password

The system checks for weak passwords for Telnet, SSH, HTTP, or HTTPS device management users. A password is weak if it does not meet the following requirements:

- Password composition restriction.
- Minimum password length restriction.
- Password complexity username checking policy.

By default, the system displays a message about a weak password but does not force the user to change it. To improve the device security, you can enable the mandatory weak password change feature, which forces the users to change the identified weak passwords. The users can log in to the device only after their passwords meet the password requirements.

Password not displayed in any form

For security purposes, nothing is displayed when a user enters a password.

Logging

The system generates a log each time a user changes its password successfully or is added to the password control blacklist because of login failures.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

Restrictions and guidelines: Password control configuration

IMPORTANT:

To successfully enable the global password control feature and allow device management users to log in to the device, make sure the device have sufficient storage space.

The password control features can be configured in several different views, and different views support different features. The settings configured in different views or for different objects have the following application ranges:

- Settings for super passwords apply only to super passwords.
- Settings in local user view apply only to the password of the local user.
- Settings in user group view apply to the passwords of the local users in the user group if you do not configure password policies for these users in local user view.
- Global settings in system view apply to the passwords of the local users in all user groups if you do not configure password policies for these users in both local user view and user group view.

For local user passwords, the settings with a smaller application scope have higher priority. The system prefers to use the non-default setting in local user view for a local user.

- If the default setting is configured for the local user, the system uses the non-default setting for the user group to which the local user belongs.
- If the default setting is configured for the user group, the system uses the global setting.

Password control tasks at a glance

To configure password control, perform the following tasks:

1. Enabling password control
2. (Optional.) Setting global password control parameters
3. (Optional.) Setting user group password control parameters
4. (Optional.) Setting local user password control parameters
5. (Optional.) Setting super password control parameters
6. (Optional.) Enabling SNMP notifications for password control

Enabling password control

About this task

For device management users, enabling global password control is a prerequisite for password control functions to take effect except for password composition policy, minimum password length, and username checking. For a specific password restriction setting (password expiration or password history management) to take effect, make sure you enable both the global password control feature and the specific password restriction.

For network access users, all password control functions take effect only after the global password control feature is enabled.

Restrictions and guidelines

After global password control is enabled, follow these restrictions and guidelines:

- You cannot display the password and super password configurations for device management users by using the corresponding **display** commands.
- You cannot display the password configuration for network access users by using the corresponding **display** command.
- The passwords configured for local users must contain a minimum of four different characters.
- In FIPS mode, the global password control feature is enabled for device management users and cannot be disabled for them.
- To ensure correct function of password control, configure the device to use NTP to obtain the UTC time. After global password control is enabled, password control will record the UTC time when the password is set. The recorded UTC time might not be consistent with the actual UTC time due to power failure or device reboot. The inconsistency will cause the password expiration feature to malfunction. For information about NTP, see *Network Management and Monitoring Configuration Guide*.
- The device automatically generates a .dat file and saves the file to the storage media. The file is used to record authentication and login information of the local users. Do not manually delete or modify the file.
- The global password control feature enables the system to record history passwords. When the number of history password records of a user reaches the maximum number, the newest history record overwrites the earliest one. To delete the existing history password records, use one of the following methods:
  - Use the **undo password-control enable** command to disable the password control feature globally.
  - Use the **reset password-control history-record** command to clear the passwords manually.

Procedure

1. Enter system view.

   system-view

2. Enable the global password control feature.

   In non-FIPS mode:

   password-control enable [**network-class**]

   By default, the global password control feature is disabled for device management and network access users.

   In FIPS mode:

   password-control enable [**network-class**]

By default, the global password control feature is enabled for device management users and cannot be disabled. The global password control feature is disabled for network access users.

3. (Optional.) Enable a password restriction feature.

   password-control { **aging** | **composition** | **history** | **length** } **enable**

   By default, all four password restriction features are enabled.

Setting global password control parameters

Restrictions and guidelines

The global password control parameters in system view apply to all device management and network access local users.

You can configure all password control features for device management users. The password aging time, minimum password length, password complexity policy, password composition policy, and user login attempt limit can be configured in system view, user group view, and local user view.

You can configure only the following password control features for network access users:

- Minimum password length.
- Password complexity policy.
- Password composition policy.
- Minimum password update interval.
- Maximum number of history password records for each user.

Where, the minimum password length, password complexity policy, and password composition policy can be configured in system view, user group view, and local user view.

The password settings with a smaller application scope have higher priority. For local users, password settings configured in local user view have the highest priority, and global settings in system view have the lowest priority.

The **password-control login-attempt** command takes effect immediately and can affect the users already in the password control blacklist. Other password control configurations do not take effect on users that have been logged in or passwords that have been configured.

Procedure

1. Enter system view.

   system-view

2. Configure password settings.
   - Set the minimum password length.

     In non-FIPS mode:

     password-control length *length*

     The default setting is 10 characters.

     In FIPS mode:

     password-control length *length*

     The default length is 15 characters.
   - Configure the password composition policy.

     In non-FIPS mode:

     password-control composition type-number *type-number* [**type-length** *type-length*]

     By default, a password must contain a minimum of two character types and a minimum of one character for each type.

In FIPS mode:

password-control composition type-number *type-number* [**type-length** *type-length*]

By default, a password must contain a minimum of four character types and a minimum of one character for each type.

- Configure the password complexity checking policy.

  password-control complexity { **adjacent-character** | **same-character** | **user-name** } **check**

  In non-FIPS mode:

  By default, username checking is enabled but repeated character checking and horizontally-adjacent character checking are disabled.

  In FIPS mode:

  By default, the system does not perform password complexity checking.

- Specify the maximum number of horizontally-adjacent characters on the keyboard that can be included in a password.

  password-control adjacent-character max-number *number*

  By default, a maximum of three horizontally-adjacent characters on the keyboard can be included in a password.

- Set the maximum number of history password records for each user.

  password-control history *max-record-number*

  The default setting is 4.

3. Configure password updating and expiration.

- Set the minimum password update interval.

  password-control update interval *interval*

  The default setting is 24 hours.

- Set the password aging time.

  password-control aging *aging-time*

  The default setting is 90 days.

- Set the number of days during which a user is notified of the pending password expiration.

  password-control alert-before-expire *alert-time*

  The default setting is 7 days.

- Set the maximum number of days and maximum number of times that a user can log in after the password expires.

  password-control expired-user-login delay *delay* **times** *times*

  By default, a user can log in three times within 30 days after the password expires.

4. Configure user login control.

- Enable the password control blacklist feature for all user line types.

  password-control blacklist all-line

  By default, the password control blacklist feature is disabled for all user line types. The password control blacklist feature is enabled only for FTP and VTY users when you enable the global password control feature.

- Add only usernames to the password control blacklist for users failing authentication.

  password-control blacklist user-info username-only

  By default, both usernames and IP addresses are added to the password control blacklist when the users fail authentication.

- Set the maximum number of blacklist entries for a user account.

password-control per-user blacklist-limit *max-number*

By default, the maximum number of blacklist entries for a user account is 32.

- Configure the login attempt limit.

  password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

  By default, the maximum number of login attempts is 3 and a user failing to log in after the specified number of attempts must wait for 1 minute before trying again.

- Set the maximum account idle time.

  password-control login idle-time *idle-time*

  The default setting is 90 days.

  If a user account is idle for this period of time, the account becomes invalid and can no longer be used to log in to the device. To disable the account idle time restriction, set the idle time value to 0.

- Set the user authentication timeout time.

  password-control authentication-timeout *timeout*

  The default setting is 600 seconds.

  This command takes effect only on Telnet and terminal users.

- Disable password change at first login.

  undo password-control change-password first-login enable

  By default, the password change at first login feature is enabled.

  In FIPS mode, the password change at first login feature cannot be disabled.

- Enable mandatory weak password change.

  password-control change-password weak-password enable

  In non-FIPS mode:

  By default, the mandatory weak password change feature is disabled.

  In FIPS mode:

  By default, the mandatory weak password change feature is enabled, and cannot be disabled.

Setting user group password control parameters

1. Enter system view.

   system-view

2. Create a user group and enter its view.

   user-group *group-name*

   For information about how to configure a user group, see "Configuring AAA."

3. Configure the password aging time for the user group.

   password-control aging *aging-time*

   By default, the password aging time of the user group equals the global password aging time.

4. Configure the minimum password length for the user group.

   password-control length *length*

   By default, the minimum password length of the user group equals the global minimum password length.

5. Configure the password composition policy for the user group.

password-control composition type-number *type-number* [**type-length** *type-length*]

By default, the password composition policy of the user group equals the global password composition policy.

6. Configure the password complexity checking policy for the user group.

   password-control complexity { **adjacent-character** | **same-character** | **user-name** } **check**

   By default, the password complexity checking policy of the user group equals the global password complexity checking policy.

7. Configure the login attempt limit.

   password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

   By default, the login-attempt policy of the user group equals the global login-attempt policy.

Setting local user password control parameters

1. Enter system view.

   system-view

2. Create a device management or network access user and enter its view.
   - Create a device management user and enter its view.

     local-user *user-name* **class manage**
   - Create a network access user and enter its view.

     local-user *user-name* **class network**

   By default, no local user exists.

   For information about local user configuration, see "Configuring AAA."

3. Configure the password aging time for the local user.

   password-control aging *aging-time*

   By default, the setting equals that for the user group to which the local user belongs. If no aging time is configured for the user group, the global setting applies to the local user.

   This command is available only for device management users.

4. Configure the minimum password length for the local user.

   password-control length *length*

   By default, the setting equals that for the user group to which the local user belongs. If no minimum password length is configured for the user group, the global setting applies to the local user.

5. Configure the password composition policy for the local user.

   password-control composition type-number *type-number* [**type-length** *type-length*]

   By default, the settings equal those for the user group to which the local user belongs. If no password composition policy is configured for the user group, the global settings apply to the local user.

6. Configure the password complexity checking policy for the local user.

   password-control complexity { **adjacent-character** | **same-character** | **user-name** } **check**

   By default, the settings equal those for the user group to which the local user belongs. If no password complexity checking policy is configured for the user group, the global settings apply to the local user.

7. Configure the login attempt limit.

   password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

   By default, the settings equal those for the user group to which the local user belongs. If no login-attempt policy is configured for the user group, the global settings apply to the local user.

   This command is available only for device management users.

Setting super password control parameters

1. Enter system view.

   system-view

2. Set the password aging time for super passwords.

   password-control super aging *aging-time*

   The default setting is 90 days.

3. Configure the minimum length for super passwords.

   In non-FIPS mode:

   password-control super length *length*

   The default setting is 10 characters.

   In FIPS mode:

   password-control super length *length*

   The default setting is 15 characters.

4. Configure the password composition policy for super passwords.

   In non-FIPS mode:

   password-control super composition type-number *type-number* [**type-length** *type-length*]

   By default, a super password must contain a minimum of two character types and a minimum of one character for each type.

   In FIPS mode:

   password-control super composition type-number *type-number* [**type-length** *type-length*]

   By default, a super password must contain a minimum of four character types and a minimum of one character for each type.

5. Configure the super password complexity checking policy.

   password-control super complexity { **adjacent-character** | **same-character** } **check**

   By default, the system does not perform password complexity checking on super passwords. That is, a super password can contain consecutive identical characters and horizontally-adjacent characters on the keyboard.

6. Specify the maximum number of horizontally-adjacent characters on the keyboard that can be included in a super password.

   password-control super adjacent-character max-number *number*

   By default, a maximum of three horizontally-adjacent characters on the keyboard can be included in a super password.

Enabling SNMP notifications for password control

About this task

Password control supports the following SNMP notifications:

- **convert-format-failed**: Sends SNMP notifications when converting memory data to file storage fails before writing user password records to the password record file.
- **copy-file-failed**: Sends SNMP notifications when the password records failed to be copied to the record file on the subordinate device.
- **notify-write-file-failed**: Sends SNMP notifications when a request message to write user passwords to the password record file failed to be issued.
- **open-file-failed**: Sends SNMP notifications when a .dat file failed to be created or opened due to a file system error.
- **space-not-enough**: Sends SNMP notifications when the space of the storage medium (flash or CF card) where a .dat file is saved is insufficient.
- **write-password-failed**: Sends SNMP notifications when user passwords failed to be written to the password record file.

If you enable SNMP notifications for the password control module, the module will generate notifications to report key events on the module. The generated notifications will be sent to the SNMP module on the device. You can configure SNMP notification settings as needed.

For more information about notifications, see SNMP configuration in Network Management and Monitoring Configuration Guide.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for password control.

   snmp-agent trap enable password-control [**convert-format-failed** | **copy-file-failed** | **notify-write-file-failed** | **open-file-failed** | **space-not-enough** | **write-password-failed**] *

   By default, SNMP notifications are disabled for password control.

Display and maintenance commands for password control

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display password control configuration.	**display password-control** [**super**]
Display information about users in the password control blacklist.	**display password-control blacklist** [**user-name** *user-name* | **ip** *ipv4-address* | **ipv6** *ipv6-address*]
Delete users from the password control blacklist.	**reset password-control blacklist** [**user-name** *user-name*]
Clear history password records.	**reset password-control history-record** [**user-name** *user-name* | **super** [**role**

	role-name] | **network-class** [**user-name** *user-name*]]

Password control configuration examples

Example: Configuring password control

Network configuration

Configure a global password control policy to meet the following requirements:

- A password must contain a minimum of 16 characters.
- A password must contain a minimum of four character types and a minimum of four characters for each type.
- An FTP or VTY user failing to provide the correct password in two successive login attempts is permanently prohibited from logging in with the current IP address.
- A user can log in five times within 60 days after the password expires.
- A password expires after 30 days.
- The minimum password update interval is 36 hours.
- The maximum account idle time is 30 days.
- A password cannot contain the username or the reverse of the username, or part of the username or the reverse of the username.
- A password cannot contain three or more identical consecutive characters.
- A password cannot contain more than four horizontally-adjacent characters on the keyboard.

Configure a super password control policy for user role **network-operator** to meet the following requirements:

- A super password must contain a minimum of 24 characters.
- A super password must contain a minimum of four character types and a minimum of five characters for each type.
- A super password cannot contain more than four horizontally-adjacent characters on the keyboard.

Configure a password control policy for local Telnet user **test** to meet the following requirements:

- The password must contain a minimum of 24 characters.
- The password must contain a minimum of four character types and a minimum of five characters for each type.
- The password for the local user expires after 20 days.

Procedure

Enable the password control feature globally.

```
<Sysname> system-view
[Sysname] password-control enable
```

Allow a maximum of two consecutive login failures on a user account, and lock the user account and the user's IP address permanently if the limit is reached.

```
[Sysname] password-control login-attempt 2 exceed lock
```

Set all passwords to expire after 30 days.

```
[Sysname] password-control aging 30
```

Globally set the minimum password length to 16 characters.

```
[Sysname] password-control length 16
```

Set the minimum password update interval to 36 hours.

```
[Sysname] password-control update-interval 36
```

Specify that a user can log in five times within 60 days after the password expires.

```
[Sysname] password-control expired-user-login delay 60 times 5
```

Set the maximum account idle time to 30 days.

```
[Sysname] password-control login idle-time 30
```

Enable username checking.

```
[Sysname] password-control complexity user-name check
```

Enable repeated character checking.

```
[Sysname] password-control complexity same-character check
```

Enable horizontally-adjacent character checking in the password complexity checking policy.

```
[Sysname] password-control complexity adjacent-character check
```

Refuse a password that contains more than four horizontally-adjacent characters on the keyboard.

```
[Sysname] password-control adjacent-character max-number 4
```

Globally specify that all passwords must each contain a minimum of four character types and a minimum of four characters for each type.

```
[Sysname] password-control composition type-number 4 type-length 4
```

Set the minimum super password length to 24 characters.

```
[Sysname] password-control super length 24
```

Specify that a super password must contain a minimum of four character types and a minimum of five characters for each type.

```
[Sysname] password-control super composition type-number 4 type-length 5
```

Enable horizontally-adjacent character checking in the super password complexity checking policy.

```
[Sysname] password-control super complexity adjacent-character check
```

Refuse a super password that contains more than four horizontally-adjacent characters on the keyboard.

```
[Sysname] password-control super adjacent-character max-number 4
```

Configure a super password used for switching to user role **network-operator** as **123456789ABGFTweuix@#$%!** in plain text.

```
[Sysname] super password role network-operator simple 123456789ABGFTweuix@#$%!
```

Create a device management user named **test**.

```
[Sysname] local-user test class manage
```

Set the service type of the user to **Telnet**.

```
[Sysname-luser-manage-test] service-type telnet
```

Set the minimum password length to 24 for the local user.

```
[Sysname-luser-manage-test] password-control length 24
```

Specify that the password of the local user must contain a minimum of four character types and a minimum of five characters for each type.

```
[Sysname-luser-manage-test] password-control composition type-number 4 type-length 5
```

Set the password for the local user to expire after 20 days.

```
[Sysname-luser-manage-test] password-control aging 20
```

Configure the password of the local user in interactive mode.

```
[Sysname-luser-manage-test] password
```

```

Updating user information. Please wait ... ...
[Sysname-luser-manage-test] quit
```

Verifying the configuration

Display the global password control configuration.

```
<Sysname> display password-control
 Global password control configurations:
 Password control:                    Enabled(device management users)
                                      Disabled (network access users)
 Password aging:                      Enabled (30 days)
 Password length:                     Enabled (16 characters)
 Password composition:                Enabled (4 types, 4 characters per type)
 Password history:                    Enabled (max history record:4)
 Early notice on password expiration:  7 days
 User authentication timeout:         600 seconds
 Maximum login attempts:              2
 Action for exceeding login attempts:  Lock
 Minimum interval between two updates: 36 hours
 User account idle time:              30 days
 Logins with aged password:           5 times in 60 days
 Password complexity:                 Enabled (username checking)
                                      Enabled (repeated characters checking)
 Password change:                     Enabled (first login)
                                      Disabled (mandatory weak password change)
                                      Enabled (max adjacent characters:4)
 All line:                            Disabled (all line blacklist)
```

Display the password control configuration for super passwords.

```
<Sysname> display password-control super
 Super password control configurations:
 Password aging:                      Enabled (90 days)
 Password length:                     Enabled (24 characters)
 Password composition:                Enabled (4 types, 5 characters per type)
Password complexity:                 Disabled (repeated characters checking)
                                      Enabled (max adjacent characters:4)
```

Display the password control configuration for local user **test**.

```
<Sysname> display local-user user-name test class manage
Total 1 local users matched.

Device management user test:
  State:                     Active
  Service type:              Telnet
  User group:                system
  Bind attributes:
  Authorization attributes:
    Work directory:          flash:
```

```
  User role list:          network-operator
Password control configurations:
  Password aging:          20 days
  Password length:         24 characters
  Password composition:    4 types, 5 characters per type
  Password complexity:     username checking

Configuring keychains

About keychains

A keychain, a sequence of keys, provides dynamic authentication to ensure secure communication by periodically changing the key and authentication algorithm without service interruption.

A keychain operates in absolute time mode. In this mode, each time point during a key's lifetime is the UTC time and is not affected by the system's time zone or daylight saving time.

Each key in a keychain has a key string, authentication algorithm, sending lifetime, and receiving lifetime. When the system time is within the lifetime of a key in a keychain, an application uses the key to authenticate incoming and outgoing packets. The keys in the keychain take effect one by one according to the sequence of the configured lifetimes. In this way, the authentication algorithms and keys are dynamically changed to implement dynamic authentication.

Restrictions and guidelines: Keychain configuration

To make sure only one key in a keychain is used at a time to authenticate packets to a peer, set non-overlapping sending lifetimes for the keys in the keychain.

The keys used by the local device and the peer device must have the same authentication algorithm and key string.

Configuring a keychain

1. Enter system view.

   system-view

2. Create a keychain and enter keychain view.

   keychain *keychain-name* **mode absolute**

3. (Optional.) Configure TCP authentication.
   - Set the kind value in the TCP Enhanced Authentication Option.

     tcp-kind *kind-value*

     By default, the kind value is 254.
   - Set an algorithm ID for a TCP authentication algorithm.

     tcp-algorithm-id { **hmac-md5** | **hmac-sha-256** | **hamc-sm3** | **md5** | **sm3** } *algorithm-id*

     By default, the algorithm ID is 3 for the MD5 authentication algorithm, 51 for the SM3 authentication algorithm, 52 for the HMAC-SM3 authentication algorithm, 7 for the HMAC-SHA-256 authentication algorithm, and 5 for the HMAC-MD5 authentication algorithm.

   When the local device uses TCP to communicate with a peer device from another vendor, make sure both devices have the same kind value and algorithm ID settings. If they do not, modify the settings on the local device.

4. (Optional.) Set a tolerance time for accept keys in the keychain.

   accept-tolerance { *value* | **infinite** }

   By default, no tolerance time is configured for accept keys in a keychain.

If authentication information is changed, information mismatch occurs on the local and peer devices, and the service might be interrupted. Use this command to ensure continuous packet authentication.

5. Create a key and enter key view.

   key *key-id*

6. Configure the key.

   - Specify an authentication algorithm for the key.

     authentication-algorithm { **aes-128-cmac** | **aes-256-cmac** | **hmac-md5** | **hmac-sha-256** | **hmac-sm3** | **md5** | **sm3** }

     By default, no authentication algorithm is specified for a key.

   - Configure a key string for the key.

     key-string { **cipher** | **plain** } *string*

     By default, no key string is configured.

   - Set the sending lifetime in UTC mode for the key.

     send-lifetime utc *start-time start-date* { **duration** { *duration-value* | **infinite** } | **to** *end-time end-date* }

     By default, the sending lifetime is not configured for a key.

   - Set the receiving lifetime in UTC mode for the key.

     accept-lifetime utc *start-time start-date* { **duration** { *duration-value* | **infinite** } | **to** *end-time end-date* }

     By default, the receiving lifetime is not configured for a key.

   - (Optional.) Specify the key as the default send key.

     default-send-key

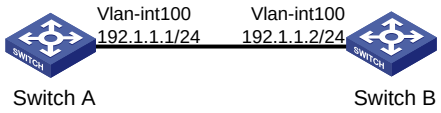
     By default, no default send key is configured for a keychain.

     You can specify only one key as the default send key in a keychain.

Display and maintenance commands for keychain

Execute **display** commands in any view.

Task	Command
Display keychain information.	**display keychain** [**name** *keychain-name* [**key** *key-id*]]



Keychain configuration example

Example: Configuring keychains

Network configuration

As shown in Figure 1, establish an OSPF neighbor relationship between Switch A and Switch B, and use a keychain to authenticate packets between the switches. Configure key 1 and key 2 for the keychain and make sure key 2 is used immediately when key 1 expires.

Figure 1 Network diagram

Procedure

1. Configure Switch A:

Configure IP addresses for interfaces. (Details not shown.)

Configure OSPF.

```
<SwitchA> system-view
[SwitchA] ospf 1 router-id 1.1.1.1
[SwitchA-ospf-1] area 0
[SwitchA-ospf-1-area-0.0.0.0] network 192.1.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] quit
[SwitchA-ospf-1] quit
```

Create a keychain named **abc**, and specify the absolute time mode for it.

```
[SwitchA] keychain abc mode absolute
```

Create key **1** for keychain **abc**, specify an authentication algorithm, and configure a key string and the sending and receiving lifetimes for the key.

```
[SwitchA-keychain-abc] key 1
[SwitchA-keychain-abc-key-1] authentication-algorithm md5
[SwitchA-keychain-abc-key-1] key-string plain 123456
[SwitchA-keychain-abc-key-1] send-lifetime utc 10:00:00 2015/02/06 to 11:00:00
2015/02/06
[SwitchA-keychain-abc-key-1] accept-lifetime utc 10:00:00 2015/02/06 to 11:00:00
2015/02/06
[SwitchA-keychain-abc-key-1] quit
```

Create key **2** for keychain **abc**, specify an authentication algorithm, and configure a key string and the sending and receiving lifetimes for the key.

```
[SwitchA-keychain-abc] key 2
[SwitchA-keychain-abc-key-2] authentication-algorithm hmac-md5
[SwitchA-keychain-abc-key-2] key-string plain pwd123
[SwitchA-keychain-abc-key-2] send-lifetime utc 11:00:00 2015/02/06 to 12:00:00
2015/02/06
[SwitchA-keychain-abc-key-2] accept-lifetime utc 11:00:00 2015/02/06 to 12:00:00
2015/02/06
[SwitchA-keychain-abc-key-2] quit
[SwitchA-keychain-abc] quit
```

Configure VLAN-interface 100 to use keychain **abc** for authentication.

```
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ospf authentication-mode keychain abc
[SwitchA-Vlan-interface100] quit
```

2. Configure Switch B:

Configure IP addresses for interfaces. (Details not shown.)

Configure OSPF.

```
[SwitchB] ospf 1 router-id 2.2.2.2
[SwitchB-ospf-1] area 0
```

```
[SwitchB-ospf-1-area-0.0.0.0] network 192.1.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] quit
```

Create a keychain named **abc**, and specify the absolute time mode for it.

```
[SwitchB] keychain abc mode absolute
```

Create key **1** for keychain **abc**, specify an authentication algorithm, and configure a key string and the sending and receiving lifetimes for the key.

```
[SwitchB-keychain-abc] key 1
[SwitchB-keychain-abc-key-1] authentication-algorithm md5
[SwitchB-keychain-abc-key-1] key-string plain 123456
[SwitchB-keychain-abc-key-1] send-lifetime utc 10:00:00 2015/02/06 to 11:00:00
2015/02/06
[SwitchB-keychain-abc-key-1] accept-lifetime utc 10:00:00 2015/02/06 to 11:00:00
2015/02/06
[SwitchB-keychain-abc-key-1] quit
```

Create key **2** for keychain **abc**, specify an authentication algorithm, and configure a key string and the sending and receiving lifetimes for the key.

```
[SwitchB-keychain-abc] key 2
[SwitchB-keychain-abc-key-2] authentication-algorithm hmac-md5
[SwitchB-keychain-abc-key-2] key-string plain pwd123
[SwitchB-keychain-abc-key-2] send-lifetime utc 11:00:00 2015/02/06 to 12:00:00
2015/02/06
[SwitchB-keychain-abc-key-2] accept-lifetime utc 11:00:00 2015/02/06 to 12:00:00
2015/02/06
[SwitchB-keychain-abc-key-2] quit
[SwitchB-keychain-abc] quit
```

Configure VLAN-interface 100 to use keychain **abc** for authentication.

```
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ospf authentication-mode keychain abc
[SwitchB-Vlan-interface100] quit
```

Verifying the configuration

1. When the system time is within the lifetime from 10:00:00 to 11:00:00 on the day 2015/02/06, verify the status of the keys in keychain **abc**.

   # Display keychain information on Switch A. The output shows that key 1 is the valid key.

```
[SwitchA] display keychain

 Keychain name          : abc
   Mode                 : absolute
   Accept tolerance     : 0
   TCP kind value       : 254
   TCP algorithm value
     HMAC-MD5           : 5
     HMAC-SHA-256       : 7
     MD5                : 3
     HMAC-SM3           : 52
     SM3                : 51
   Default send key ID  : None
   Active send key ID   : 1
```

```
  Active accept key IDs: 1

  Key ID              : 1
    Key string        : $c$3$dYTC8QeOKJkwFwP2k/rWL+1p6uMTw3MqNg==
    Algorithm         : md5
    Send lifetime     : 10:00:00 2015/02/06 to 11:00:00 2015/02/06
    Send status       : Active
    Accept lifetime   : 10:00:00 2015/02/06 to 11:00:00 2015/02/06
    Accept status     : Active

  Key ID              : 2
    Key string        : $c$3$7TSPbUxoP1ytOqkdcJ3K3x0BnXEWl4mOEw==
    Algorithm         : hmac-md5
    Send lifetime     : 11:00:00 2015/02/06 to 12:00:00 2015/02/06
    Send status       : Inactive
    Accept lifetime   : 11:00:00 2015/02/06 to 12:00:00 2015/02/06
    Accept status     : Inactive
```

Display keychain information on Switch B. The output shows that key 1 is the valid key.

```
[SwitchB] display keychain

 Keychain name          : abc
   Mode                 : absolute
   Accept tolerance     : 0
   TCP kind value       : 254
   TCP algorithm value
     HMAC-MD5           : 5
     HMAC-SHA-256       : 7
     MD5                : 3
     HMAC-SM3           : 52
     SM3                : 51
   Default send key ID  : None
   Active send key ID   : 1
   Active accept key IDs: 1

   Key ID               : 1
     Key string         : $c$3$/G/Shnh6heXWprlSQy/XDmftHa2JZJBSgg==
     Algorithm          : md5
     Send lifetime      : 10:00:00 2015/02/06 to 11:00:00 2015/02/06
     Send status        : Active
     Accept lifetime    : 10:00:00 2015/02/06 to 11:00:00 2015/02/06
     Accept status      : Active

   Key ID               : 2
     Key string         : $c$3$t4qHAw1hpZYN0JKIEpXPcMFMVT81u0hiOw==
     Algorithm          : hmac-md5
     Send lifetime      : 11:00:00 2015/02/06 to 12:00:00 2015/02/06
     Send status        : Inactive
     Accept lifetime    : 11:00:00 2015/02/06 to 12:00:00 2015/02/06
```

```
    Accept status      : Inactive
```

2. When the system time is within the lifetime from 11:00:00 to 12:00:00 on the day 2015/02/06, verify the status of the keys in keychain **abc**.

Display keychain information on Switch A. The output shows that key 2 becomes the valid key.

```
[SwitchA] display keychain

 Keychain name          : abc
   Mode                 : absolute

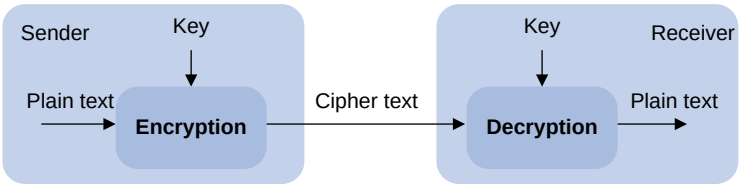
Managing public keys

About public key management



This chapter describes public key management for the following asymmetric key algorithms:

- Revest-Shamir-Adleman Algorithm (RSA).
- Digital Signature Algorithm (DSA).
- Elliptic Curve Digital Signature Algorithm (ECDSA).
- SM2 algorithm.

Asymmetric key algorithm overview

Asymmetric key algorithms are used by security applications to secure communications between two parties, as shown in Figure 1. Asymmetric key algorithms use two separate keys (one public and one private) for encryption and decryption. Symmetric key algorithms use only one key.

Figure 1 Encryption and decryption

A key owner can distribute the public key in plain text on the network but must keep the private key in privacy. It is mathematically infeasible to calculate the private key even if an attacker knows the algorithm and the public key.

The following asymmetric key algorithms are supported:

- Revest-Shamir-Adleman Algorithm (RSA).
- Digital Signature Algorithm (DSA).
- Elliptic Curve Digital Signature Algorithm (ECDSA).

Usage of asymmetric key algorithms

Security applications (such as SSH, SSL, and PKI) use the asymmetric key algorithms for the following purposes:

- **Encryption and decryption**—Any public key receiver can use the public key to encrypt information, but only the private key owner can decrypt the information.
- **Digital signature**—The key owner uses the private key to digitally sign information to be sent. The receiver decrypts the information with the sender's public key to verify information authenticity.

RSA, DSA, and ECDSA can all perform digital signature, but only RSA can perform encryption and decryption.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

Public key management tasks at a glance

To manage public keys, perform the following tasks:

1. Creating a local key pair
2. Distributing a local host public key

   Choose one of the following tasks:

   - Exporting a host public key
   - Displaying a host public key

   To enable the peer device to authenticate the local device, you must distribute the local device's public key to the peer device.
3. Configuring a peer host public key

   Choose one of the following tasks:

   - Importing a peer host public key from a public key file
   - Entering a peer host public key

   To encrypt information sent to a peer device or authenticate the digital signature of the peer device, you must configure the peer device's public key on the local device.
4. (Optional.) Destroying a local key pair
5. (Optional.) Configuring master keys

Creating a local key pair

Restrictions and guidelines

When you create a local key pair, follow these guidelines:

- The key algorithm must be the same as required by the security application.
- When you create an RSA or DSA key pair, enter an appropriate key modulus length at the prompt. The longer the key modulus length, the higher the security, and the longer the key generation time.

  When you create an ECDSA key pair, choose the appropriate elliptic curve. The elliptic curve determines the ECDSA key length. The longer the key length, the higher the security, and the longer the key generation time.

  See Table 1 for more information about key modulus lengths and key lengths.
- If you do not assign the key pair a name, the system assigns the default name to the key pair and marks the key pair as **default**. You can also assign the default name to another key pair, but the system does not mark the key pair as **default**. The key pair name must be unique among all manually named key pairs that use the same key algorithm. If a name conflict occurs, the system asks whether you want to overwrite the existing key pair.
- The key pairs are automatically saved and can survive system reboots.

Table 1 A comparison of different types of asymmetric key algorithms

Type	Generated key pairs	Modulus/key length
RSA	• In non-FIPS mode: ○ One host key pair, if you specify a key pair name. ○ One server key pair and one host key pair, if you do not specify a key pair name. Both key pairs use their default names. • In FIPS mode: One host key pair. **NOTE:** Only SSH 1.5 uses the RSA server key pair.	RSA key modulus length: • In non-FIPS mode: 512 to 4096 bits, 1024 bits by default. To ensure security, use a minimum of 768 bits. • In FIPS mode: A multiple of 256 bits in the range of 2048 to 4096 bits, 2048 bits by default.
DSA	One host key pair.	DSA key modulus length: • In non-FIPS mode: 512 to 2048 bits, 1024 bits by default. To ensure security, use a minimum of 768 bits. • In FIPS mode: The device does not support generating DSA host key pairs.
ECDSA	One host key pair.	ECDSA key length: • In non-FIPS mode: 192, 256, 384, or 521 bits. • In FIPS mode: 256, 384, or 521 bits.

Procedure

1. Enter system view.

   system-view

2. Create a local key pair.

   In non-FIPS mode:

   public-key local create { **dsa** | **ecdsa** [**secp192r1** | **secp256r1** | **secp384r1** | **secp521r1**] | **rsa** } [**name** *key-name*]

   In FIPS mode:

   public-key local create { **ecdsa** [**secp256r1** | **secp384r1** | **secp521r1**] | **rsa** } [**name** *key-name*]

   By default, no local key pairs exist.

Distributing a local host public key

About distribution of local host public keys

You must distribute a local host public key to a peer device so the peer device can perform the following operations:

- Use the public key to encrypt information sent to the local device.
- Authenticate the digital signature signed by the local device.

To distribute a local host public key, you must first export or display the key.

- Export a host public key:
  - Export a host public key to a file.

- Export a host public key to the monitor screen, and then save it to a file.

  After the key is exported to a file, transfer the file to the peer device. On the peer device, import the key from the file.

- Display a host public key.

  After the key is displayed, record the key, for example, copy it to an unformatted file. On the peer device, you must literally enter the key.

Exporting a host public key

Restrictions and guidelines

When you export a host public key, follow these restrictions and guidelines:

- If you specify a file name in the command, the command exports the key to the specified file.
- If you do not specify a file name, the command exports the key to the monitor screen. You must manually save the exported key to a file.

Procedure

1. Enter system view.

   system-view

2. Export a local host public key.
   - Export an RSA host public key:

     In non-FIPS mode:

     public-key local export rsa [**name** *key-name*] { **openssh** | **ssh1** | **ssh2** } [*filename*]

     In FIPS mode:

     public-key local export rsa [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]
   - Export an ECDSA host public key.

     public-key local export ecdsa [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]
   - Export a DSA host public key.

     public-key local export dsa [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]

     This command is supported only in non-FIPS mode.

Displaying a host public key

Perform the following tasks in any view:

- Display local RSA public keys.

  display public-key local rsa public [**name** *key-name*]

  Do not distribute the RSA server public key **serverkey (default)** to a peer device.

- Display local ECDSA public keys.

  display public-key local ecdsa public [**name** *key-name*]

- Display local DSA public keys.

  display public-key local dsa public [**name** *key-name*]

Configuring a peer host public key

About peer host public key configuration

To encrypt information sent to a peer device or authenticate the digital signature of the peer device, you must configure the peer device's public key on the local device.

You can configure the peer host public key by using the following methods:

- Import the peer host public key from a public key file (recommended).
- Manually enter (type or copy) the peer host public key.

For information about how to obtain the host public key of a device, see "Distributing a local host public key."

Restrictions and guidelines for peer host public key configuration

When you configure a peer host public key, follow these restrictions and guidelines:

- When you manually enter the peer host public key, make sure the entered key is in the correct format. To obtain the peer host public key in the correct format, use the **display public-key local public** command to display the public key on the peer device and record the key. The format of the public key displayed in any other way might be incorrect. If the key is not in the correct format, the system discards the key and displays an error message.
- Always import rather than enter the peer host public key if you are not sure whether the device supports the format of the recorded peer host public key.

Importing a peer host public key from a public key file

About this task

Before you perform this task, make sure you have exported the host public key to a file on the peer device and obtained the file from the peer device. For information about exporting a host public key, see "Exporting a host public key."

After you import the key, the system automatically converts the imported public key to a string in the Public Key Cryptography Standards (PKCS) format.

Procedure

1. Enter system view.

   system-view

2. Import a peer host public key from a public key file.

   public-key peer *keyname* **import sshkey** *filename*

   By default, no peer host public keys exist.

Entering a peer host public key

About this task

Before you perform this task, make sure you have displayed the key on the peer device and recorded the key. For information about displaying a host public key, see "Displaying a host public key."

Procedure

1. Enter system view.
   system-view
2. Specify a name for the peer host public key and enter public key view.
   public-key peer *keyname*
3. Type or copy the key.
   You can use spaces and carriage returns, but the system does not save them.
4. Exit public key view.
   peer-public-key end
   When you exit public key view, the system automatically saves the peer host public key.

Destroying a local key pair

About this task

To ensure security, destroy the local key pair and generate a new key pair in any of the following situations:

- The local key has leaked. An intrusion event might occur.
- The storage media of the device is replaced.
- The local certificate has expired. For more information about local certificates, see "Configuring PKI."

Procedure

1. Enter system view.
   system-view
2. Destroy a local key pair.
   In non-FIPS mode:
   public-key local destroy { **dsa** | **ecdsa** | **rsa** } [**name** *key-name*]
   In FIPS mode:
   public-key local destroy { **ecdsa** | **rsa** } [**name** *key-name*]

Configuring master keys

Setting a master key

About this task

By default, a device uses the unified default master key to encrypt the key strings configured for each service module on the device. After you load the exported configuration file of a device on another device, you can use the default master key to decrypt and obtain the configured key strings. In this way, keys can be copied between devices, bringing security risks.

To improve the security and reliability of data, you can set a master key for the device. After you configure this feature on the device, you need to configure the relevant settings as prompted:

1. Validate your identity:
   - If the login authentication mode is **password** or **scheme**, the CLI prompts you to enter your password for login. After you pass the authentication, you go to step 2.

- If the login authentication mode is **none**, you do not need to perform identity authentication but go to step 2 directly.

  For more information about login authentication modes, see login management in *Fundamentals Configuration Guide*.

2. Select whether to enter the master key:
   - If you enter **N** or **n**, the device will automatically and randomly generate a master key.
   - If you enter **Y** or **y**, manually enter the prepared master key and confirm it.

The device stores the master key in the hard disk. Power-off or reboot of the device will not affect the set master key. The device uses the master key to encrypt the key strings configured for each service module on the device.

You can only use the **display master-key type** command to view the type of the master key. You cannot view or obtain the value of the master key by any means. This prevents copying the keys on the device to another device.

Restrictions and guidelines

When the storage space for master keys is insufficient, the device prompts whether to overwrite the oldest master key.

When the login authentication mode is **password** or **scheme**, you will be logged off after three consecutive authentication failures and thus cannot perform master key-related operations.

The minimum interval between setting master keys is 3 minutes.

Prerequisites

To manually enter a master key, prepare the master key and keep it safe before configuring this feature.

Procedure

1. Enter system view.
   system-view
2. Set a master key.
   set master-key

Clearing master keys

About this task

You can configure this feature to clear master keys in the following situations:

- You do not need to use the master key feature.
- The storage space for master keys is insufficient, and you want to clear existing master keys to release storage space.

The default master key of the device uses the fixed factory default value. With the **clear master-key** command executed, all set master keys will be cleared and the default fixed master key will be restored.

Procedure

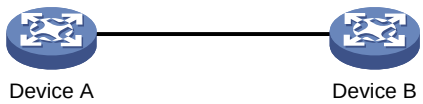
1. Enter system view.
   system-view
2. Clear master keys.
   clear master-key

Display and maintenance commands for public keys

Execute **display** commands in any view.

Task	Command
Display local public keys.	In non-FIPS mode: **display public-key local** { **dsa** | **ecdsa** | **rsa** } **public** [**name** *key-name*] In FIPS mode: **display public-key local** { **ecdsa** | **rsa** } **public** [**name** *key-name*]
Display peer host public keys.	**display public-key peer** [**brief** | **name** *publickey-name*]
Display the type of the current master key.	**display master-key type**

Examples of public key management



Example: Entering a peer host public key

Network configuration

As shown in Figure 2, to prevent illegal access, Device B authenticates Device A through a digital signature. Before configuring authentication parameters on Device B, use the following procedure to configure the public key of Device A on Device B:

- Create RSA key pairs on Device A and display the public keys of the RSA key pairs.
- Manually specify the RSA host public key of Device A on Device B.

Figure 2 Network diagram

Procedure

1. Configure Device A:

   # Create local RSA key pairs with the default names on Device A, and use the default key modulus length (1024 bits).

```
<DeviceA> system-view
[DeviceA] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
...
```

```
Create the key pair successfully.
```

Display all local RSA public keys.

```
[DeviceA] display public-key local rsa public

Example: Importing a public key from a public key file

Network configuration

As shown in Figure 3, Device B authenticates Device A through a digital signature. Before configuring authentication parameters on Device B, use the following procedure to configure the public key of Device A on Device B:

- Create RSA key pairs on Device A and export the RSA host public key to a file.
- Import the RSA host public key of Device A from the public key file to Device B.

Figure 3 Network diagram

Procedure

1. Configure Device A:

   # Create local RSA key pairs with the default names on Device A, and use the default key modulus length (1024 bits).

```
<DeviceA> system-view
[DeviceA] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
...
Create the key pair successfully.
```

   # Display all local RSA public keys.

```
[DeviceA] display public-key local rsa public

   AC41C80A15953FB22AA30203010001
```

Export the RSA host public key to file **devicea.pub**.

```
[DeviceA] public-key local export rsa ssh2 devicea.pub
```

Enable the FTP server, create an FTP user with username **ftp** and password **123456TESTplat&!**, and configure the FTP user role as **network-admin**.

```
[DeviceA] ftp server enable
[DeviceA] local-user ftp
[DeviceA-luser-manage-ftp] password simple 123456TESTplat&!
[DeviceA-luser-manage-ftp] service-type ftp
[DeviceA-luser-manage-ftp] authorization-attribute user-role network-admin
[DeviceA-luser-manage-ftp] quit
```

2. Configure Device B:

Use FTP in binary mode to get public key file **devicea.pub** from Device A.

```
<DeviceB> ftp 10.1.1.1
Connected to 10.1.1.1 (10.1.1.1).
220 FTP service ready.
User(10.1.1.1:(none)):ftp
331 Password required for ftp.
Password:
230 User logged in.
Remote system type is UNIX.
Using binary mode to transfer files.
ftp> binary
200 TYPE is now 8-bit binary
ftp> get devicea.pub
227 Entering Passive Mode (10,1,1,1,118,252)
150 Accepted data connection
226 File successfully transferred
301 bytes received in 0.003 seconds (98.0 kbyte/s)
ftp> quit
221-Goodbye. You uploaded 0 and downloaded 1 kbytes.
221 Logout.
```

Import the host public key from key file **devicea.pub**.

```
<DeviceB> system-view
```

```
[DeviceB] public-key peer devicea import sshkey devicea.pub
```

Verifying the configuration

Verify that the peer host public key configured on Device B is the same as the key displayed on Device A.

```
[DeviceB] display public-key peer name devicea

Configuring PKI

About PKI

Public Key Infrastructure (PKI) is an asymmetric key infrastructure to encrypt and decrypt data for securing network services.

PKI uses digital certificates to distribute and employ public keys, and provides network communication and e-commerce with security services such as user authentication, data confidentiality, and data integrity. For more information about public keys, see "Managing public keys."

PKI terminology

Digital certificate

A digital certificate is an electronic document signed by a CA that binds a public key with the identity of its owner.

A digital certificate includes the following information:

- Issuer name (name of the CA that issued the certificate).
- Subject name (name of the individual or group to which the certificate is issued).
- Identity information of the subject.
- Subject's public key.
- Signature of the CA.
- Validity period.

A digital certificate must comply with the international standards of ITU-T X.509, of which X.509 v3 is the most commonly used.

This chapter covers the following types of certificates:

- **CA certificate**—Certificate of a CA. Multiple CAs in a PKI system form a CA tree, with the root CA at the top. The root CA generates a self-signed certificate, and each lower level CA holds a CA certificate issued by the CA immediately above it. The chain of these certificates forms a chain of trust.
- **Registration authority (RA) certificate**—Certificate issued by a CA to an RA. RAs act as proxies for CAs to process enrollment requests in a PKI system.
- **Local certificate**—Certificate of a local PKI entity, which contains the entity's public key. Local certificates include the following types:
  - **CA-signed certificate**—Digital certificate signed and issued by a CA to the local PKI entity.
  - **Self-signed certificate**—Digital certificate signed and issued by the local PKI entity (the device) itself. When the device cannot request a local certificate from the CA, it can sign and issue a local certificate for communication with the peer to provide services. Using this type of certificate is simple in configuration but has low security. You can use self-signed certificates in scenarios with low security requirements.
- **Peer certificate**—CA-signed digital certificate of a peer, which contains the peer's public key.

Fingerprint of root CA certificate

Each root CA certificate has a unique fingerprint, which is the hash value of the certificate content. The fingerprint of a root CA certificate can be used to authenticate the validity of the root CA.

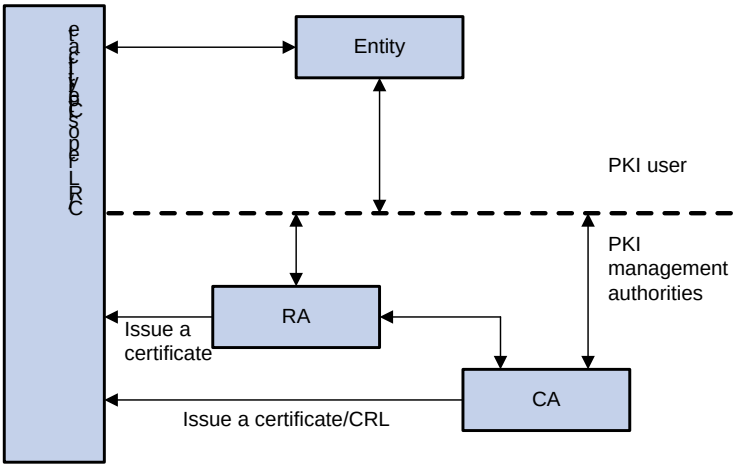
Certificate revocation list

A certificate revocation list (CRL) is a list of serial numbers for certificates that have been revoked. A CRL is created and signed by the CA that originally issued the certificates.

The CA publishes CRLs periodically to revoke certificates. Entities that are associated with the revoked certificates should not be trusted.

The CA must revoke a certificate when any of the following conditions occurs:

- The certificate subject name is changed.
- The private key is compromised.
- The association between the subject and CA is changed. For example, when an employee terminates employment with an organization.



CA policy

A CA policy is a set of criteria that a CA follows to process certificate requests, to issue and revoke certificates, and to publish CRLs. Typically, a CA advertises its policy in a certification practice statement (CPS). You can obtain a CA policy through out-of-band means such as phone, disk, and email. Make sure you understand the CA policy before you select a trusted CA for certificate request because different CAs might use different policies.

PKI architecture

A PKI system consists of PKI entities, CAs, RAs and a certificate/CRL repository, as shown in Figure 1.

Figure 1 PKI architecture

PKI entity

A PKI entity is an end user using PKI certificates. The PKI entity can be an operator, an organization, a device like a router or a switch, or a process running on a computer. PKI entities use SCEP to communicate with the CA or RA.

CA

Certification authority that grants and manages certificates. A CA issues certificates, defines the certificate validity periods, and revokes certificates by publishing CRLs.

RA

Registration authority, which offloads the CA by processing certificate enrollment requests. The RA accepts certificate requests, verifies user identity, and determines whether to ask the CA to issue certificates.

The RA is optional in a PKI system. In cases when there is security concern over exposing the CA to direct network access, it is advisable to delegate some of the tasks to an RA. Then, the CA can concentrate on its primary tasks of signing certificates and CRLs.

Certificate/CRL repository

A certificate distribution point that stores certificates and CRLs, and distributes these certificates and CRLs to PKI entities. It also provides the query function. A PKI repository can be a directory server using the LDAP or HTTP protocol, of which LDAP is commonly used.

Retrieval, usage, and maintenance of a digital certificate

The following workflow describes the retrieval, usage, and maintenance of a digital certificate. This example uses a CA which has an RA to process certificate enrollment requests.

1. A PKI entity generates an asymmetric key pair and submits a certificate request to the RA.

   The certificate request contains the public key and its identity information.
2. The RA verifies the identity of the entity and sends a digital signature containing the identity information and the public key to the CA.
3. The CA verifies the digital signature, approves the request, and issues a certificate.
4. After receiving the certificate from the CA, the RA sends the certificate to the certificate repository and notifies the PKI entity that the certificate has been issued.
5. The PKI entity obtains the certificate from the certificate repository.
6. To establish a secure connection for communication, two PKI entities exchange local certificates to authenticate each other. The connection can be established only if both entities verify that the peer's certificate is valid.
7. You can remove the local certificate of a PKI entity and request a new one when any of the following conditions occur:
   - The local certificate is about to expire.
   - The certificate's private key is compromised.

PKI applications

The PKI technology can meet security requirements of online transactions. As an infrastructure, PKI has a wide range of applications. H3C's PKI system can provide certificate management for IPsec and SSL.

The following are some application examples.

VPN

A VPN is a private data communication network built on the public communication infrastructure. A VPN can use network layer security protocols (for example, IPsec) in conjunction with PKI-based encryption and digital signature technologies for confidentiality.

Secure emails

PKI can address the email requirements for confidentiality, integrity, authentication, and non-repudiation. A common secure email protocol is Secure/Multipurpose Internet Mail Extensions (S/MIME), which is based on PKI and allows for transfer of encrypted mails with signature.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

PKI tasks at a glance

To configure PKI, perform the following tasks:

1. Configuring a PKI entity
2. Configuring a PKI domain
3. (Optional.) Specifying the storage path for certificates and CRLs
4. Requesting a certificate

   Choose one of the following tasks:

   - Enabling the automatic online certificate request mode
   - Manually submitting an online certificate request
   - Manually submitting a certificate request in offline mode
5. (Optional.) Aborting a certificate request
6. (Optional.) Obtaining certificates

   You can obtain the CA certificate, local certificates, and peer certificates related to a PKI domain from a CA and save them locally for higher lookup efficiency.
7. (Optional.) Verifying PKI certificates
8. (Optional.) Exporting certificates
9. (Optional.) Removing a certificate
10. (Optional.) Configuring a certificate-based access control policy

    Certificate-based access control policies allow you to authorize access to a device (for example, an HTTPS server) based on the attributes of an authenticated client's certificate.
11. (Optional.) Enabling local certificate expiration notification
12. (Optional.) Enabling SNMP notifications for PKI
13. (Optional.) Enabling PKI logging

Configuring a PKI entity

About this task

A certificate applicant uses an entity to provide its identity information to a CA. A valid PKI entity must include one or more of following identity categories:

- Distinguished name (DN) of the entity, which further includes the common name, country code, locality, organization, unit in the organization, and state. If you configure the DN for an entity, a common name is required.
- FQDN of the entity.
- IP address of the entity.

Restrictions and guidelines

Follow these restrictions and guidelines when you configure a PKI entity:

- Whether the identity categories are required or optional depends on the CA policy. Follow the CA policy to configure the entity settings. For example, if the CA policy requires the entity DN, but you configure only the IP address, the CA rejects the certificate request from the entity.
- The SCEP add-on on the Windows 2000 CA server has restrictions on the data length of a certificate request. If a request from a PKI entity exceeds the data length limit, the CA server does not respond to the certificate request. In this case, you can use an out-of-band means to submit the request. Other types of CA servers, such as RSA servers and OpenCA servers, do not have such restrictions.

Procedure

1. Enter system view.
   system-view
2. Create a PKI entity and enter its view.
   pki entity *entity-name*
3. Set a common name for the entity.
   common-name *common-name-sting*
   By default, the common name is not set.
4. Set the country code of the entity.
   country *country-code-string*
   By default, the country code is not set.
5. Set the locality of the entity.
   locality *locality-name*
   By default, the locality is not set.
6. Set the organization of the entity.
   organization *org-name*
   By default, the organization is not set.
7. Set the unit of the entity in the organization.
   organization-unit *org-unit-name*
   By default, the unit is not set.
8. Set the state where the entity resides.
   state *state-name*
   By default, the state is not set.
9. Set the FQDN of the entity.
   fqdn *fqdn-name-string*
   By default, the FQDN is not set.
10. Configure the IP address of the entity.
    ip { *ip-address* | **interface** *interface-type interface-number* }
    By default, the IP address is not configured.
11. Configure the title of the entity.
    title *title*
    By default, the title is not configured.

Configuring a PKI domain

About PKI domain

A PKI domain contains enrollment information for a PKI entity. It is locally significant and is intended only for use by other applications like IKE and SSL.

PKI domain tasks at a glance

To configure a PKI domain, perform the following tasks:

1. Creating a PKI domain

2. Specifying the trusted CA
3. Specifying the PKI entity name
4. Specifying the certificate request reception authority
5. Specifying the certificate request URL
6. (Optional.) Setting the SCEP polling interval and maximum polling attempts
7. Specifying the LDAP server

   This task is required when either of the following conditions is met:

   - The device must obtain certificates from the CA by using the LDAP protocol.
   - An LDAP URL which does not contain the host name of the LDAP server is specified as the CRL repository URL.
8. Specifying the fingerprint for root CA certificate verification

   This step is required if the auto certificate request mode is configured in the PKI domain.

   If the manual certificate request mode is configured, you can skip this step and manually verify the fingerprint displayed during verification of the root CA certificate.
9. Specifying the key pair for certificate request
10. (Optional.) Specifying the intended purpose for the certificate
11. (Optional.) Specifying the source IP address for PKI protocol packets

Creating a PKI domain

1. Enter system view.

   system-view
2. Create a PKI domain and enter its view.

   pki domain *domain-name*

Specifying the trusted CA

About this task

The PKI domain must have a CA certificate before you can request a local certificate. To obtain a CA certificate, the trusted CA name must be specified. The trusted CA name uniquely identifies the CA to be used if multiple CAs exist on the CA server.

Procedure

1. Enter system view.

   system-view
2. Enter PKI domain view.

   pki domain *domain-name*
3. Specify the trusted CA name.

   ca identifier *name*

   By default, no trusted CA name is specified.

Specifying the PKI entity name

1. Enter system view.

   system-view
2. Enter PKI domain view.

pki domain *domain-name*

3. Specify the PKI entity name.
   certificate request entity *entity-name*
   By default, no PKI entity name is specified.

Specifying the certificate request reception authority

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Specify the certificate request reception authority.
   certificate request from { **ca** | **ra** }
   By default, no certificate request reception authority is specified.

Specifying the certificate request URL

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Specify the URL of the certificate request reception authority to which the device sends certificate requests.
   certificate request url *url-string* [**vpn-instance** *vpn-instance-name*]
   By default, the certificate request URL is not specified.

Setting the SCEP polling interval and maximum polling attempts

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Set the SCEP polling interval and maximum number of polling attempts.
   certificate request polling { **count** *count* | **interval** *interval* }
   By default, the device polls the CA server for the certificate request status every 20 minutes. The maximum number of polling attempts is 50.

Specifying the LDAP server

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Specify the LDAP server.

ldap-server host *hostname* [**port** *port-number*] [**vpn-instance** *vpn-instance-name*]

By default, no LDAP server is specified.

Specifying the fingerprint for root CA certificate verification

1. Enter system view.

   system-view
2. Enter PKI domain view.

   pki domain *domain-name*
3. Configure the fingerprint for verifying the root CA certificate.

   In non-FIPS mode:

   root-certificate fingerprint { **md5** | **sha1** } *string*

   In FIPS mode:

   root-certificate fingerprint sha1 *string*

   By default, no fingerprint is configured.

Specifying the key pair for certificate request

Restrictions and guidelines

You can specify a nonexistent key pair for certificate request. The PKI entity automatically creates the key pair before submitting a certificate request.

Procedure

1. Enter system view.

   system-view
2. Enter PKI domain view.

   pki domain *domain-name*
3. Specify the key pair for certificate request.
   - Specify an RSA key pair.

     public-key rsa { { **encryption name** *encryption-key-name* [**length** *key-length*] | **signature name** *signature-key-name* [**length** *key-length*] } * | **general name** *key-name* [**length** *key-length*] }
   - Specify an ECDSA key pair.

     In non-FIPS mode:

     public-key ecdsa name *key-name* [**secp192r1** | **secp256r1** | **secp384r1** | **secp521r1**]

     In FIPS mode:

     public-key ecdsa name *key-name* [**secp256r1** | **secp384r1** | **secp521r1**]
   - Specify a DSA key pair.

     public-key dsa name *key-name* [**length** *key-length*]

     This command is supported only in non-FIPS mode.

   By default, no key pair is specified.

Specifying the intended purpose for the certificate

About this task

An issued certificate contains the extensions which restrict the usage of the certificate to specific purposes. You can specify the intended purposes for a certificate, which will be included in the certificate request sent to the CA. However, the actual extensions contained in an issued certificate depend on the CA policy, and they might be different from those specified in the PKI domain. Whether an application will use the certificate during authentication depends on the application's policy.

Supported certificate extensions include:

- **ike**—Certificates carrying this extension can be used by IKE peers.
- **ssl-client**—Certificates carrying this extension can be used by SSL clients.
- **ssl-server**—Certificates carrying this extension can be used by SSL servers.

Procedure

1. Enter system view.

   system-view
2. Enter PKI domain view.

   pki domain *domain-name*
3. Specify the intended use for the certificate.

   usage { **ike** | **ssl-client** | **ssl-server** } *

   By default, the certificate can be used by all supported applications, including IKE, SSL client, and SSL server.

Specifying the source IP address for PKI protocol packets

About this task

This task is required if the CA policy requires that the CA server accept certificate requests from a specific IP address or subnet.

Procedure

1. Enter system view.

   system-view
2. Enter PKI domain view.

   pki domain *domain-name*
3. Specify a source IP address for the PKI protocol packets.

   IPv4:

   source ip { *ip-address* | **interface** *interface-type interface-number* }

   IPv6:

   source ipv6 { *ipv6-address* | **interface** *interface-type interface-number* }

   By default, the source IP address of PKI protocol packets is the IP address of their outgoing interface.

Specifying the storage path for certificates and CRLs

About this task

The device has a default storage path for certificates and CRLs. You can change the storage path and specify different paths for the certificates and CRLs.

After you change the storage path for certificates or CRLs, the certificate files and CRL files in the original path are moved to the new path. Certificate files use the .cer or .p12 file extension and CRL files use the .crl file extension.

Restrictions and guidelines

If you change the storage path, save the configuration before you reboot or shut down the device to avoid loss of certificates or CRLs.

Procedure

1. Enter system view.

   system-view

2. Specify the storage path for certificates and CRLs.

   pki storage { **certificates** | **crls** } *dir-path*

   By default, the device stores certificates and CRLs in the PKI directory on the storage media of the device.

Requesting a certificate

About certificate request configuration

To request a certificate, a PKI entity must provide its identity information and public key to a CA.

A certificate request can be submitted to a CA in offline or online mode.

- **Offline mode**—A certificate request is submitted by using an out-of-band method, such as phone, disk, or email.
- **Online mode**—A certificate request can be automatically or manually submitted to a CA through the Simple Certificate Enrollment Protocol (SCEP).

Restrictions and guidelines for certificate request configuration

When you request a local certificate in a PKI domain, follow these restrictions and guidelines:

- To prevent an existing local certificate from becoming invalid, do not perform the following tasks:
  - Create a key pair with the same name as the key pair contained in the certificate.

    To create a key pair, use the **public-key local create** command.
  - Destroy the key pair contained in the certificate.

    To destroy a key pair, use the **public-key local destroy** command.
- To manually request a new certificate in a PKI domain that already has a local certificate, use the following procedure:

  a. Use the **pki delete-certificate** command to delete the existing local certificate.

b. Use the **public-key local create** command to generate a new key pair.

c. Manually submit a certificate request.

- A PKI domain can have local certificates using only one type of cryptographic algorithms (DSA, ECDSA, or RSA). If DSA or ECDSA is used, a PKI domain can have only one local certificate. If RSA is used, a PKI domain can have one local certificate for signature, and one local certificate for encryption.

Prerequisites for certificate request configuration

Make sure the device is time synchronized with the CA server. If the device is not time synchronized with the CA server, the certificate request might fail because the certificate might be considered to be outside of the validity period. For information about configuring the system time, see *Fundamentals Configuration Guide*.

Enabling the automatic online certificate request mode

About this task

In auto request mode, a PKI entity with no local certificates automatically submits a certificate request to the CA when an application works with the PKI entity. For example, when IKE negotiation uses a digital signature for identity authentication, but no local certificate is available, the entity automatically submits a certificate request. It saves the certificate locally after obtaining the certificate from the CA.

A CA certificate must be present before you request a local certificate. If no CA certificate exists in the PKI domain, the PKI entity automatically obtains a CA certificate before sending a certificate request.

Restrictions and guidelines

In auto request mode, the device does not automatically request a new certificate if the current certificate is about to expire or has expired, which might cause service interruptions.

Procedure

1. Enter system view.

system-view

2. Enter PKI domain view.

pki domain *domain-name*

3. Enable the automatic online certificate request mode.

certificate request mode auto [**password** { **cipher** | **simple** } *string*]

By default, the manual request mode applies.

If the CA policy requires a password for certificate revocation, specify the password in this command.

Manually submitting an online certificate request

About this task

In manual request mode, you must execute the **pki request-certificate domain** command to request a local certificate in a PKI domain. The certificate will be saved in the domain after it is obtained from the CA.

Procedure

1. Enter system view.

system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Set the certificate request mode to manual.

   certificate request mode manual

   By default, the manual request mode applies.

4. Return to system view.

   quit

5. Obtain a CA certificate.

   See "Obtaining certificates."

   This step is required if the PKI domain does not have a CA certificate. The CA certificate is used to verify the authenticity and validity of the obtained local certificate.

6. Manually submit an SCEP certificate request.

   pki request-certificate domain *domain-name* [**password** *password*]

   This command is not saved in the configuration file.

   If the CA policy requires a password for certificate revocation, specify the password in this command.

Manually submitting a certificate request in offline mode

About this task

Use this method if the CA does not support SCEP or if a network connection between the device and CA is not possible.

Procedure

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Set the certificate request mode to manual.

   certificate request mode manual

   By default, the manual request mode applies.

4. Return to system view.

   quit

5. Obtain the CA certificate.

   See "Obtaining certificates."

   This step is required if the PKI domain does not have a CA certificate. The CA certificate is used to verify the authenticity and validity of the obtained local certificate.

6. Print the certificate request in PKCS10 format on the terminal or save the certificate request to a PKCS10 file.

   pki request-certificate domain *domain-name* **pkcs10** [**filename** *filename*]

   This command is not saved in the configuration file.

7. Transfer certificate request information to the CA by using an out-of-band method.

8. Transfer the issued local certificate from the CA to the local device by using an out-of-band method.

9. Import the local certificate to the PKI domain.

   pki import domain *domain-name* { **der local filename** *filename* | **p12 local filename** *filename* | **pem local** [**filename** *filename*] }

Aborting a certificate request

About this task

Before the CA issues a certificate, you can abort a certificate request and change its parameters, such as the common name, country code, or FQDN. You can use the **display pki certificate request-status** command to display the status of a certificate request.

Alternatively, you also can remove a PKI domain to abort the associated certificate request.

Procedure

1. Enter system view.

   system-view

2. Abort a certificate request.

   pki abort-certificate-request domain *domain-name*

   This command is not saved in the configuration file.

Obtaining certificates

About this task

You can obtain the CA certificate, local certificates, and peer certificates related to a PKI domain from a CA and save them locally for higher lookup efficiency. To do so, use either the offline mode or the online mode:

- In offline mode, obtain the certificates by an out-of-band means like FTP, disk, or email, and then import them locally. Use this mode when the CRL repository is not specified, the CA server does not support SCEP, or the CA server generates the key pair for the certificates.
- In online mode, you can obtain the CA certificate through SCEP and obtain local certificates or peer certificates through LDAP.

Restrictions and guidelines

Follow these restrictions and guidelines when obtain certificates from a CA

- If a CA certificate already exists locally, you cannot obtain it again in online mode. If you want to obtain a new CA certificate, use the **pki delete-certificate** command to delete the existing CA certificate and local certificates first.
- If local or peer certificates already exist, you can obtain new local or peer certificates to overwrite the existing ones. If RSA is used, a PKI domain can have two local certificates, one for signature and the other for encryption.
- If CRL checking is enabled, obtaining a certificate triggers CRL checking. If the certificate to be obtained has been revoked, the certificate cannot be obtained.
- The device compares the validity period of a certificate with the local system time to determine whether the certificate is valid. Make sure the system time of the device is synchronized with the CA server.

Prerequisites

- Before you obtain local or peer certificates in online mode, make sure an LDAP server is correctly configured in the PKI domain.
- Before you import certificates in offline mode, complete the following tasks:

- Use FTP or TFTP to upload the certificate files to the storage media of the device.

  If FTP or TFTP is not available, display and copy the contents of a certificate to a file on the device. Make sure the certificate is in PEM format because only certificates in PEM format can be imported.
- Before you import a local certificate or peer certificate, obtain the CA certificate chain that signs the certificate.

  This step is required only if the CA certificate chain is neither available in the PKI domain nor contained in the certificate to be imported.
- Before you import a local certificate that contains an encrypted key pair, contact the CA administrator to obtain the password required for importing the certificate.

Procedure

1. Enter system view.

   system-view
2. Obtain certificates.
   - Import certificates in offline mode.

     pki import domain *domain-name* { **der** { **ca** | **local** | **peer** } **filename** *filename* | **p12 local filename** *filename* | **pem** { **ca** | **local** | **peer** } [**filename** *filename*] }
   - Obtain certificates in online mode.

     pki retrieve-certificate domain *domain-name* { **ca** | **local** | **peer** *entity-name* }

     This command is not saved in the configuration file.

Verifying PKI certificates

About certification verification

A certificate is automatically verified when it is requested, obtained, or used by an application. If the certificate expires, if it is not issued by a trusted CA, or if it is revoked, the certificate cannot be used You can also manually verify a certificate.

You can enable or disable CRL checking in a PKI domain. CRL checking checks whether a certificate is in the CRL. If it is, the certificate has been revoked and its home entity is not trusted.

To use CRL checking, a CRL must be obtained from a CRL repository. The device selects a CRL repository in the following order:

1. CRL repository specified in the PKI domain by using the **crl url** command.
2. CRL repository in the certificate that is being verified.
3. CRL repository in the CA certificate or CRL repository in the upper-level CA certificate if the certificate being verified is a CA certificate

If no CRL repository is found after the selection process, the device obtains the CRL through SCEP. In this scenario, the CA certificate and the local certificates must have been obtained.

A certificate fails CRL checking in the following situations:

- A CRL cannot be obtained during CRL checking of the certificate.
- CRL checking verifies that the certificate has been revoked.

Restrictions and guidelines for certificate verification

When verifying the CA certificate of a PKI domain, the system needs to verify all the certificates in the CA certificate chain. To ensure a successful certificate verification process, the device must have all the PKI domains to which the CA certificates in the certificate chain belong.

The system verifies the CA certificates in the CA certificate chain as follows:

1. Identifies the parent certificate of the lowest-level certificate.

   Each CA certificate contains an issuer field that identifies the parent CA that issued the certificate.
2. Locates the PKI domain to which the parent certificate belongs.
3. Performs CRL checking in the PKI domain to check whether the parent certificate has been revoked. If it has been revoked, the certificate cannot be used.

   This step will not be performed when CRL checking is disabled in the PKI domain.
4. Repeats the previous steps for upper-level certificates in the CA certificate chain until the root CA certificate is reached.
5. Verifies that each CA certificate in the certificate chain is issued by the named parent CA, starting from the root CA.

Verifying certificates with CRL checking

1. Enter system view.

   system-view
2. Enter PKI domain view.

   pki domain *domain-name*
3. (Optional.) Specify the URL of the CRL repository.

   crl url *url-string* [**vpn-instance** *vpn-instance-name*]

   By default, the URL of the CRL repository is not specified.
4. Enable CRL checking.

   crl check enable

   By default, CRL checking is enabled.
5. Return to system view.

   quit
6. Obtain the CA certificate.

   See "Obtaining certificates."

   The PKI domain must have a CA certificate before you can verify certificates in it.
7. (Optional.) Obtain the CRL.
   - Obtain the CRL from the CRL repository and save it locally.

     pki retrieve-crl domain *domain-name*

     To verify a non-root CA certificate and local certificates, the device automatically retrieves the CRL if the PKI domain has no CRL.

     The newly obtained CRL overwrites the old one, if any.

     The obtained CRL is issued by a CA in the CA certificate chain stored in the PKI domain.
   - Import a CRL file in the specified local path.

     pki retrieve-crl domain *domain-name*

     Use this method if no CRL repository exists in the environment.
8. Manually verify the validity of the certificates.

pki validate-certificate domain *domain-name* { **ca** | **local** }

Verifying certificates without CRL checking

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Disable CRL checking.
   undo crl check enable
   By default, CRL checking is enabled.
4. Return to system view.
   quit
5. Obtain a CA certificate for the PKI domain.
   See "Obtaining certificates."
   The PKI domain must have a CA certificate before you can verify certificates in it.
6. Manually verify the certificate validity.
   pki validate-certificate domain *domain-name* { **ca** | **local** }
   This command is not saved in the configuration file.

Exporting certificates

About this task

You can export the CA certificate and the local certificates in a PKI domain to certificate files. The exported certificate files can then be imported back to the device or other PKI applications.

Restrictions and guidelines

To export all certificates in PKCS12 format, the PKI domain must have a minimum of one local certificate. If the PKI domain does not have any local certificates, the certificates in the PKI domain cannot be exported.

If you do not specify a file name when you export a certificate in PEM format, this command displays the certificate content on the terminal.

When you export a local certificate with RSA key pairs to a file, the certificate file name might be different from the file name specified in the command. The actual certificate file name depends on the purpose of the key pair contained in the certificate. For more information about the file naming rule, see the **pki export** command in *Security Command Reference*.

Procedure

1. Enter system view.
   system-view
2. Export certificates.
   - Export certificates in DER format.
     pki export domain *domain-name* **der** { **all** | **ca** | **local** } **filename** *filename*
   - Export certificates in PKCS12 format.
     pki export domain *domain-name* **p12** { **all** | **local** } **passphrase** *p12-key* **filename** *filename*

- Export certificates in PEM format.

  pki export domain *domain-name* **pem** { { **all** | **local** } [{ **3des-cbc** | **aes-128-cbc** | **aes-192-cbc** | **aes-256-cbc** | **des-cbc** } *pem-key*] | **ca** } [**filename** *filename*]

Removing a certificate

About this task

You can remove certificates from a PKI domain in the following situations:

- Remove a CA certificate, local certificate, or peer certificate if the certificate has expired or is about to expire.
- Remove a local certificate if the certificate's private key is compromised, or if you want to request a new local certificate to replace the existing one.

Restrictions and guidelines

After you remove the CA certificate, the system automatically removes the local certificates, peer certificates, and CRLs from the domain.

To remove a local certificate and request a new certificate, perform the following tasks:

1. Remove the local certificate.
2. Use the **public-key local destroy** command to destroy the existing local key pair.
3. Use the **public-key local create** command to generate a new key pair.
4. Request a new certificate.

For more information about the **public-key local destroy** and **public-key local create** commands, see *Security Command Reference*.

Procedure

1. Enter system view.

   system-view
2. Remove a certificate.

   pki delete-certificate domain *domain-name* { **ca** | **local** | **peer** [**serial** *serial-num*] }

   If you use the **peer** keyword without specifying a serial number, this command removes all peer certificates.

Configuring a certificate-based access control policy

About certificate-based access control policies

Certificate-based access control policies allow you to authorize access to a device (for example, an HTTPS server) based on the attributes of an authenticated client's certificate.

Access control rules and certificate attribute groups

A certificate-based access control policy is a set of access control rules (permit or deny statements), each associated with a certificate attribute group. A certificate attribute group contains multiple attribute rules, each defining a matching criterion for an attribute in the certificate issuer name, subject name, or alternative subject name field.

Certificate matching mechanism

If a certificate matches all attribute rules in a certificate attribute group associated with an access control rule, the system determines that the certificate matches the access control rule. In this scenario, the match process stops, and the system performs the access control action defined in the access control rule.

The following conditions describe how a certificate-based access control policy verifies the validity of a certificate:

- If a certificate matches a permit statement, the certificate passes the verification.
- If a certificate matches a deny statement or does not match any statements in the policy, the certificate is regarded invalid.
- If a statement is associated with a non-existing attribute group, or the attribute group does not have attribute rules, the certificate matches the statement.
- If the certificate-based access control policy specified for a security application (for example, HTTPS) does not exist, all certificates in the application pass the verification.

Procedure

1. Enter system view.

   system-view
2. Create a certificate attribute group and enter its view.

   pki certificate attribute-group *group-name*
3. Configure an attribute rule for issuer name, subject name, or alternative subject name.

   attribute *id* { **alt-subject-name** { **fqdn** | **ip** } | { **issuer-name** | **subject-name** } { **dn** | **fqdn** | **ip** } } { **ctn** | **equ** | **nctn** | **nequ**} *attribute-value*

   By default, not attribute rules are configured.
4. Return to system view.

   quit
5. Create a certificate-based access control policy and enter its view.

   pki certificate access-control-policy *policy-name*

   By default, no certificate-based access control policies exist.
6. Create a certificate access control rule.

   rule [*id*] { **deny** | **permit** } *group-name*

   By default, no certificate access control rules are configured, and all certificates can pass the verification.

   You can create multiple certificate access control rules for a certificate-based access control policy.

Enabling local certificate expiration notification

About this task

After this feature is enabled, the system checks the validity date for local certificates every other hour. When a local certificate is about to expire in 30 days (included) or has expired, the system sends a notification log message for the certificate every other day.

Procedure

1. Enter system view.

system-view

2. Enable local certificate expiration notification.

   pki certificate logging { **local-will-expire** | **local-has-expired** } **enable**

   By default, local certificate expiration notification is disabled.

Enabling SNMP notifications for PKI

About this task

To report critical PKI events to an NMS, enable SNMP notifications for PKI. For PKI notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP notifications, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

For the device to generate and output certain types of PKI notifications, enable global PKI notifications and those types of PKI notifications. For the device to stop generating certain types of PKI notifications, disable those types of PKI notifications.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for PKI.

   snmp-agent trap enable pki [**ca-cert-invalid** | **ca-cert-valid** | **crl-http-failure** | **crl-http-success** | **crl-invalid** | **crl-ldap-failure** | **crl-ldap-success** | **crl-scep-failure** | **crl-scep-success** | **crl-valid** | **get-ca-failure** | **get-crl-failure** | **global** | **local-cert-has-expired** | **local-cert-invalid** | **local-cert-ldap-failure**| **local-cert-ldap-success** | **local-cert-nearly-expired** | **local-cert-scep-failure** | **local-cert-scep-success** | **local-cert-valid**] *

   By default, SNMP notifications for PKI are disabled.

Enabling PKI logging

About this task

PKI log messages help administrators easily locate and resolve issues. PKI logging allows the device to record the events and errors on the PKI module and output the corresponding log messages.

These PKI log messages will be sent to the information center. The configuration for the information center determines the output rules and destinations for the PKI log messages. For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

Recording PKI logs consumes memory resources. As a best practice to prevent excessive logging, do not enable this feature unless auditing or troubleshooting is needed.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for PKI.
   pki logging enable
   By default, PKI logging is disabled.

Display and maintenance commands for PKI

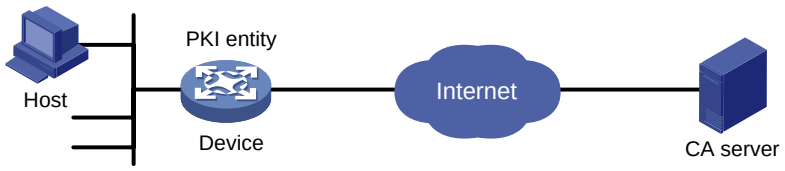
Execute **display** commands in any view.

Task	Command
Display certificate-based access control policy information.	**display pki certificate access-control-policy** [*policy-name*]
Display certificate attribute group information.	**display pki certificate attribute-group** [*group-name*]
Display the contents of a certificate.	**display pki certificate domain** *domain-name* { **ca** | **local** | **peer** [**serial** *serial-num*] }
Display certificate request status.	**display pki certificate request-status** [**domain** *domain-name*]
Display locally stored CRLs in a PKI domain.	**display pki crl domain** *domain-name*

PKI configuration examples

You can use different software applications, such as Windows server, RSA Keon, and OpenCA, to act as the CA server.

If you use Windows server or OpenCA, you must install the SCEP add-on for Windows server or enable SCEP for OpenCA. In either case, when you configure a PKI domain, you must use the **certificate request from ra** command to specify the RA to accept certificate requests.



If you use RSA Keon, the SCEP add-on is not required. When you configure a PKI domain, you must use the **certificate request from ca** command to specify the CA to accept certificate requests.

Example: Requesting a certificate from an RSA Keon CA server

Network configuration

Configure the PKI entity (the device) to request a local certificate from the CA server.

Figure 2 Network diagram

Configuring the RSA Keon CA server

1. Create a CA server named **myca**:

In this example, you must configure these basic attributes on the CA server:

- **Nickname**—Name of the trusted CA.
- **Subject DN**—DN attributes of the CA, including the common name (CN), organization unit (OU), organization (O), and country (C).

You can use the default values for other attributes.

2. Configure extended attributes:

   Configure parameters in the **Jurisdiction Configuration** section on the management page of the CA server:

   - Select the correct extension profiles.
   - Enable the SCEP autovetting function to enable the CA server to automatically approve certificate requests without manual intervention.
   - Specify the IP address list for SCEP autovetting.

Configuring the device

1. Synchronize the system time of the device with the CA server for the device to correctly request certificates or obtain CRLs. (Details not shown.)
2. Create an entity named **aaa** and set the common name to **Device**.

```
<Device> system-view
[Device] pki entity aaa
[Device-pki-entity-aaa] common-name Device
[Device-pki-entity-aaa] quit
```

3. Configure a PKI domain:

   # Create a PKI domain named **torsa** and enter its view.

```
[Device] pki domain torsa
```

   # Specify the name of the trusted CA. The setting must be the same as CA name configured on the CA server. This example uses **myca**.

```
[Device-pki-domain-torsa] ca identifier myca
```

   # Configure the URL of the CA server. The URL format is **http://***host:port***/***Issuing Jurisdiction ID*, where *Issuing Jurisdiction ID* is a hexadecimal string generated on the CA server.

```
[Device-pki-domain-torsa] certificate request url
http://1.1.2.22:446/80f6214aa8865301d07929ae481c7ceed99f95bd
```

   # Configure the device to send certificate requests to **ca**.

```
[Device-pki-domain-torsa] certificate request from ca
```

   # Set the PKI entity name to **aaa**.

```
[Device-pki-domain-torsa] certificate request entity aaa
```

   # Specify the URL of the CRL repository.

```
[Device-pki-domain-torsa] crl url ldap://1.1.2.22:389/CN=myca
```

   # Specify a 1024-bit general-purpose RSA key pair named **abc** for certificate request.

```
[Device-pki-domain-torsa] public-key rsa general name abc length 1024
[Device-pki-domain-torsa] quit
```

4. Generate the RSA key pair.

```
[Device] public-key local create rsa name abc
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512,it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
```

```
.........................++++++
.....................................++++++
Create the key pair successfully.
```

5. Request a local certificate:

Obtain the CA certificate and save it locally.

```
[Device] pki retrieve-certificate domain torsa ca
The trusted CA's finger print is:
    MD5  fingerprint:EDE9 0394 A273 B61A F1B3 0072 A0B1 F9AB
    SHA1 fingerprint: 77F9 A077 2FB8 088C 550B A33C 2410 D354 23B2 73A8
Is the finger print correct?(Y/N):y
Retrieved the certificates successfully.
```

Submit a certificate request manually and set the certificate revocation password to **1111**. The certificate revocation password is required when an RSA Keon CA server is used.

```
[Device] pki request-certificate domain torsa password 1111
Start to request general certificate ...
……
Request certificate of domain torsa successfully
```

Verifying the configuration

Display information about the local certificate in PKI domain **torsa**.

```
[Device] display pki certificate domain torsa local
Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number:

```

To display detailed information about the CA certificate, use the **display pki certificate domain** command.

Example: Requesting a certificate from a Windows Server 2003 CA server

Network configuration

Configure the PKI entity (the device) to request a local certificate from a Windows Server 2003 CA server.

Figure 3 Network diagram

Configuring the Windows Server 2003 CA server

1. Install the certificate service component:
   a. Select **Control Panel** > **Add or Remove Programs** from the start menu.
   b. Select **Add/Remove Windows Components** > **Certificate Services**.
   c. Click **Next** to begin the installation.
   d. Set the CA name. In this example, set the CA name to **myca**.
2. Install the SCEP add-on:

   By default, Windows Server 2003 does not support SCEP. You must install the SCEP add-on on the server for a PKI entity to register and obtain a certificate from the server. After the SCEP add-on installation is complete, you will see a URL. Specify this URL as the certificate request URL on the device.
3. Modify the certificate service attributes:
   a. Select **Control Panel** > **Administrative Tools** > **Certificate Authority** from the start menu.

      If the certificate service component and SCEP add-on have been installed successfully, there should be two certificates issued by the CA to the RA.
   b. Right-click the CA server in the navigation tree and select **Properties** > **Policy Module**.
   c. Click **Properties**, and then select **Follow the settings in the certificate template, if applicable. Otherwise, automatically issue the certificate**.
4. Modify the Internet information services attributes:

a. Select **Control Panel** > **Administrative Tools** > **Internet Information Services (IIS) Manager** from the start menu.
b. Select **Web Sites** from the navigation tree.
c. Right-click **Default Web Site** and select **Properties** > **Home Directory**.
d. Specify the path for certificate service in the **Local path** field.
e. Specify a unique TCP port number for the default website to avoid conflict with existing services. This example uses port 8080.

Configuring the device

1. Synchronize the device's system time with the CA server for the device to correctly request certificates. (Details not shown.)
2. Create an entity named **aaa** and set the common name to **test**.

```
<Device> system-view
[Device] pki entity aaa
[Device-pki-entity-aaa] common-name test
[Device-pki-entity-aaa] quit
```

3. Configure a PKI domain:

Create a PKI domain named **winserver** and enter its view.

```
[Device] pki domain winserver
```

Set the name of the trusted CA to **myca**.

```
[Device-pki-domain-winserver] ca identifier myca
```

Configure the certificate request URL. The URL format is **http://***host:port***/certsrv/mscep/mscep.dll**, where *host:port* is the host IP address and port number of the CA server.

```
[Device-pki-domain-winserver] certificate request url
http://4.4.4.1:8080/certsrv/mscep/mscep.dll
```

Configure the device to send certificate requests to **ra**.

```
[Device-pki-domain-winserver] certificate request from ra
```

Set the PKI entity name to **aaa**.

```
[Device-pki-domain-winserver] certificate request entity aaa
```

Configure a 1024-bit general-purpose RSA key pair named **abc** for certificate request.

```
[Device-pki-domain-winserver] public-key rsa general name abc length 1024
[Device-pki-domain-winserver] quit
```

4. Generate RSA key pair **abc**.

```
[Device] public-key local create rsa name abc
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512,it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.........................++++++
.....................................++++++
Create the key pair successfully.
```

5. Request a local certificate:

Obtain the CA certificate and save it locally.

```
[Device] pki retrieve-certificate domain winserver ca
The trusted CA's finger print is:
    MD5  fingerprint:766C D2C8 9E46 845B 4DCE 439C 1C1F 83AB
```

```
    SHA1 fingerprint:97E5 DDED AB39 3141 75FB DB5C E7F8 D7D7 7C9B 97B4
Is the finger print correct?(Y/N):y
Retrieved the certificates successfully.
```

Submit a certificate request manually.

```
[Device] pki request-certificate domain winserver
Start to request general certificate ...
…
Request certificate of domain winserver successfully
```

Verifying the configuration

Display information about the local certificate in PKI domain **winserver**.

```
[Device] display pki certificate domain winserver local
Certificate:
    Data:
        Version: 3 (0x2)

```

To display detailed information about the CA certificate, use the **display pki certificate domain** command.

Example: Requesting a certificate from an OpenCA server

Network configuration

Configure the PKI entity (the device) to request a local certificate from the CA server.

Figure 4 Network diagram

Configuring the OpenCA server

Configure the OpenCA server as instructed in related manuals. (Details not shown.)

Make sure the version of the OpenCA server is later than version 0.9.2 because the earlier versions do not support SCEP.

Configuring the device

1. Synchronize the device's system time with the CA server for the device to correctly request certificates. (Details not shown.)
2. Create a PKI entity named **aaa** and configure the common name, country code, organization name, and OU for the entity.

```
<Device> system-view
[Device] pki entity aaa
[Device-pki-entity-aaa] common-name rnd
[Device-pki-entity-aaa] country CN
[Device-pki-entity-aaa] organization test
[Device-pki-entity-aaa] organization-unit software
[Device-pki-entity-aaa] quit
```

3. Configure a PKI domain:

   # Create a PKI domain named **openca** and enter its view.

```
[Device] pki domain openca
```

   # Set the name of the trusted CA to **myca**.

```
[Device-pki-domain-openca] ca identifier myca
```

   # Configure the certificate request URL. The URL is in the format **http://***host***/cgi-bin/pki/scep**, where *host* is the host IP address of the OpenCA server.

```
[Device-pki-domain-openca] certificate request url
http://192.168.222.218/cgi-bin/pki/scep
```

   # Configure the device to send certificate requests to the RA.

```
[Device-pki-domain-openca] certificate request from ra
```

   # Specify PKI entity **aaa** for certificate request.

```
[Device-pki-domain-openca] certificate request entity aaa
```

   # Configure a 1024-bit general-purpose RSA key pair named **abc** for certificate request.

```
[Device-pki-domain-openca] public-key rsa general name abc length 1024
[Device-pki-domain-openca] quit
```

4. Generate RSA key pair **abc**.

```
[Device] public-key local create rsa name abc
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512,it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.........................++++++
.....................................++++++
Create the key pair successfully.
```

5. Request a local certificate:

   # Obtain the CA certificate and save it locally.

```
[Device] pki retrieve-certificate domain openca ca
The trusted CA's finger print is:
    MD5  fingerprint:5AA3 DEFD 7B23 2A25 16A3 14F4 C81C C0FA
```

```
    SHA1 fingerprint:9668 4E63 D742 4B09 90E0 4C78 E213 F15F DC8E 9122
Is the finger print correct?(Y/N):y
Retrieved the certificates successfully.
```

Submit a certificate request manually.

```
[Device] pki request-certificate domain openca
Start to request general certificate ...
…
Request certificate of domain openca successfully
```

Verifying the configuration

Display information about the local certificate in PKI domain **openca**.

```
[Device] display pki certificate domain openca local

```

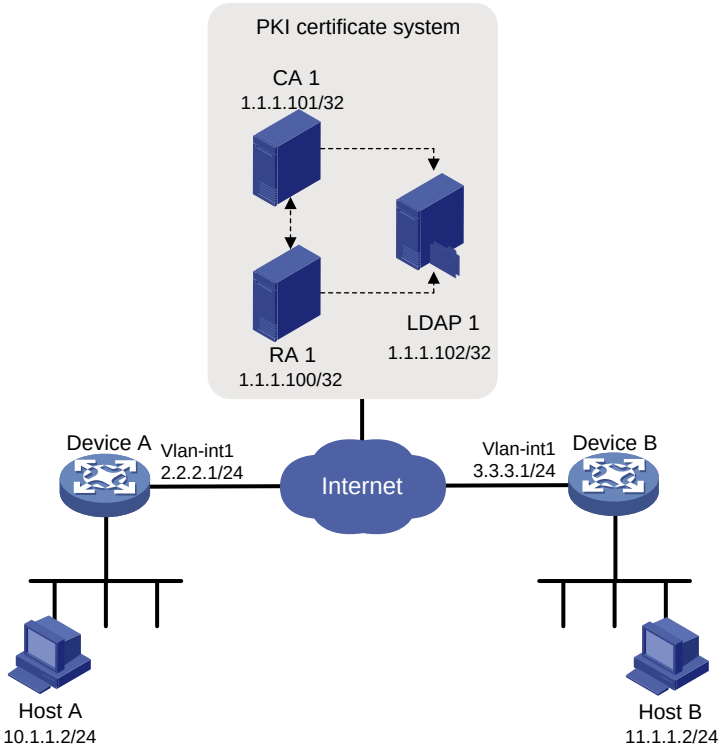
To display detailed information about the CA certificate, use the **display pki certificate domain** command.

Example: Configuring IKE negotiation with RSA digital signature from a Windows Server 2003 CA server



Network configuration

As shown in the network diagram, an IPsec tunnel is required to be established between Device A and Device B. The IPsec tunnel protects the traffic between Host A on subnet 10.1.1.0/24 and Host B on subnet 1.1.1.0/24.

Device A and Device B use IKE to set up SAs, and the IKE proposal uses RSA digital signature for identity authentication.

Device A and Device B use the same CA.

Figure 5 Network diagram

Configuring the Windows Server 2003 CA server

See "Example: Requesting a certificate from a Windows Server 2003 CA server."

Configuring Device A

Configure a PKI entity.

```
<DeviceA> system-view
[DeviceA] pki entity en
[DeviceA-pki-entity-en] ip 2.2.2.1
[DeviceA-pki-entity-en] common-name devicea
[DeviceA-pki-entity-en] quit
```

Configure a PKI domain.

```
[DeviceA] pki domain 1
[DeviceA-pki-domain-1] ca identifier CA1
[DeviceA-pki-domain-1] certificate request url http://1.1.1.100/certsrv/mscep/mscep.dll
[DeviceA-pki-domain-1] certificate request entity en
[DeviceA-pki-domain-1] ldap-server host 1.1.1.102
```

Configure the device to send certificate requests to **ra**.

```
[DeviceA-pki-domain-1] certificate request from ra
```

Configure a 1024-bit general-purpose RSA key pair named **abc** for certificate request.

```
[DeviceA-pki-domain-1] public-key rsa general name abc length 1024
[DeviceA-pki-domain-1] quit
```

Generate the RSA key pair.

```
[DeviceA] public-key local create rsa name abc
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512,it will take a few minutes.
```

```
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.........................++++++
.....................................++++++
Create the key pair successfully.
```

Obtain the CA certificate and save it locally.

```
[DeviceA] pki retrieve-certificate domain 1 ca
```

Submit a certificate request manually.

```
[DeviceA] pki request-certificate domain 1
```

Create IKE proposal 1, and configure the authentication method as RSA digital signature.

```
[DeviceA] ike proposal 1
[DeviceA-ike-proposal-1] authentication-method rsa-signature
[DeviceA-ike-proposal-1] quit
```

Specify the PKI domain used in IKE negotiation for IKE profile **peer**.

```
[DeviceA] ike profile peer
[DeviceA-ike-profile-peer] certificate domain 1
```

Configuring Device B

Configure a PKI entity.

```
<DeviceB> system-view
[DeviceB] pki entity en
[DeviceB-pki-entity-en] ip 3.3.3.1
[DeviceB-pki-entity-en] common-name deviceb
[DeviceB-pki-entity-en] quit
```

Configure a PKI domain.

```
[DeviceB] pki domain 1
[DeviceB-pki-domain-1] ca identifier CA1
[DeviceB-pki-domain-1] certificate request url http://1.1.1.100/certsrv/mscep/mscep.dll
[DeviceB-pki-domain-1] certificate request entity en
[DeviceB-pki-domain-1] ldap-server host 1.1.1.102
```

Configure the device to send certificate requests to **ra**.

```
[DeviceB-pki-domain-1] certificate request from ra
```

Configure a 1024-bit general-purpose RSA key pair named **abc** for certificate request.

```
[DeviceB-pki-domain-1] public-key rsa general name abc length 1024
[DeviceB-pki-domain-1] quit
```

Generate the RSA key pair.

```
[DeviceB] public-key local create rsa name abc
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512,it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.........................++++++
.....................................++++++
Create the key pair successfully.
```

Obtain the CA certificate and save it locally.

```
[DeviceB] pki retrieve-certificate domain 1 ca
The trusted CA's finger print is:
    MD5  fingerprint:5C41 E657 A0D6 ECB4 6BD6 1823 7473 AABC
    SHA1 fingerprint:1616 E7A5 D89A 2A99 9419 1C12 D696 8228 87BC C266
Is the finger print correct?(Y/N):y
Retrieved the certificates successfully.
```

Submit a certificate request manually.

```
[DeviceB] pki request-certificate domain 1
Start to request general certificate ...
...
Certificate requested successfully.
```

Create IKE proposal 1, and configure the authentication method as RSA digital signature.

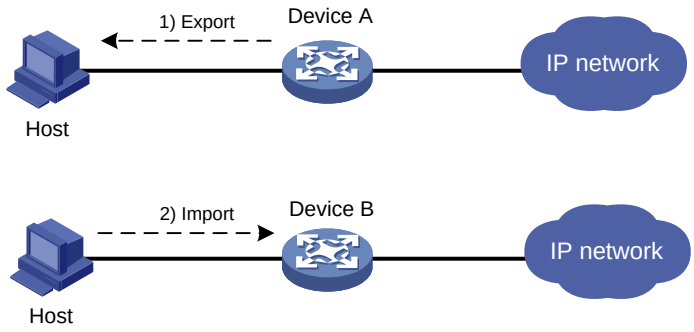
```
[DeviceB] ike proposal 1
[DeviceB-ike-proposal-1] authentication-method rsa-signature
[DeviceB-ike-proposal-1] quit
```

Specify the PKI domain used in IKE negotiation for IKE profile **peer**.

```
[DeviceB] ike profile peer
[DeviceB-ike-profile-peer] certificate domain 1
```

The configurations are for IKE negotiation with RSA digital signature. For information about how to configure IPsec SAs to be set up, see "Configuring IPsec."

Example: Importing and exporting certificates



Network configuration

As shown in Figure 6, Device B will replace Device A in the network. PKI domain **exportdomain** on Device A has two local certificates containing the private key and one CA certificate. To make sure the certificates are still valid after Device B replaces Device A, copy the certificates on Device A to Device B as follows:

1. Export the certificates in PKI domain **exportdomain** on Device A to .pem certificate files.

   During the export, encrypt the private key in the local certificates using 3DES_CBC with the password 11111.
2. Transfer the certificate files from Device A to Device B through the FTP host.
3. Import the certificate files to PKI domain **importdomain** on Device B.

Figure 6 Network diagram

Procedure

1. Export the certificates on Device A:

Export the CA certificate to a .pem file.

```
<DeviceA> system-view
[DeviceA] pki export domain exportdomain pem ca filename pkicachain.pem
```

Export the local certificate to a file named **pkilocal.pem** in PEM format, and use 3DES_CBC to encrypt the private key with the password **111111**.

```
[DeviceA] pki export domain exportdomain pem local 3des-cbc 111111 filename
pkilocal.pem
```

Now, Device A has three certificate files in PEM format:

- A CA certificate file named **pkicachain.pem**.
- A local certificate file named **pkilocal.pem-signature**, which contains the private key for signature.
- A local certificate file named **pkilocal.pem-encryption**, which contains the private key for encryption.

Display local certificate file **pkilocal.pem-signature**.

```
[DeviceA] quit
<DeviceA> more pkilocal.pem-signature

To display detailed information about the CA certificate, use the **`display pki certificate domain`** command.

Troubleshooting PKI configuration

This section provides troubleshooting information for common problems with PKI.

Failed to obtain the CA certificate

Symptom

The CA certificate cannot be obtained.

Analysis

- The network connection is down, for example, because the network cable is damaged or the connectors have bad contact.
- No trusted CA is specified.
- The certificate request URL is incorrect or not specified.
- The system time of the device is not synchronized with the CA server.
- The CA server does not accept the source IP address specified in the PKI domain, or no source IP address is specified.
- The fingerprint of the root CA certificate is illegal.

Solution

1. Fix the network connection problems, if any.
2. Configure the trusted CA and all other required parameters in the PKI domain.
3. Use the **ping** command to verify that the CA server is reachable.
4. Synchronize the system time of the device with the CA server.
5. Specify the correct source IP address that the CA server can accept. For the correct settings, contact the CA administrator.
6. Verify the fingerprint of the CA certificate on the CA server.
7. If the problem persists, contact H3C Support.

Failed to obtain local certificates

Symptom

The local certificates can be obtained.

Analysis

- The network connection is down.
- The PKI domain does not have a CA certificate before you submit the local certificate request.
- The LDAP server is not configured or is incorrectly configured.
- No key pair is specified for certificate request in the PKI domain, or the specified key pair does not match the one contained in the local certificates to the obtained.
- No PKI entity is configured in the PKI domain, or the PKI entity configuration is incorrect.
- CRL checking is enabled, but the PKI domain does not have a CRL and cannot obtain one.
- The CA server does not accept the source IP address specified in the PKI domain, or no source IP address is specified.
- The system time of the device is not synchronized with the CA server.

Solution

1. Fix the network connection problems, if any..
2. Obtain or import the CA certificate.
3. Configure the correct LDAP server parameters.
4. Specify the key pair for certificate request, or remove the existing key pair, specify a new key pair, and submit a local certificate request again.
5. Check the registration policy on the CA or RA, and make sure the attributes of the PKI entity meet the policy requirements.
6. Obtain the CRL from the CRL repository.
7. Specify the correct source IP address that the CA server can accept. For the correct settings, contact the CA administrator.
8. Synchronize the system time of the device with the CA server.
9. If the problem persists, contact H3C Support.

Failed to request local certificates

Symptom

Local certificate requests cannot be submitted.

Analysis

- The network connection is down, for example, because the network cable is damaged or the connectors have bad contact.
- The PKI domain does not have a CA certificate before the local certificate request is submitted.
- The certificate request URL is incorrect or is not specified.
- The certificate request reception authority is incorrect or is not specified.
- Required PKI entity parameters are not configured or are incorrectly configured.
- No key pair is specified in the PKI domain for certificate request, or the key pair is changed during a certificate request process.
- Exclusive certificate request applications are running in the PKI domain.
- The CA server does not accept the source IP address specified in the PKI domain, or no source IP address is specified.
- The system time of the device is not synchronized with the CA server.

Solution

1. Fix the network connection problems, if any.
2. Obtain or import the CA certificate.
3. Use the **ping** command to verify that the registration server is reachable.
4. Use the **certificate request from** command to specify the correct certificate request reception authority.
5. Configure the PKI entity parameters as required by the registration policy on the CA or RA.
6. Specify the key pair for certificate request, or remove the existing key pair, specify a new key pair, and submit a local certificate request again.
7. Use the **pki abort-certificate-request domain** command to abort the certificate request.
8. Specify the correct source IP address that the CA server can accept. For the correct settings, contact the CA administrator.
9. Synchronize the system time of the device with the CA server.
10. If the problem persists, contact H3C Support.

Failed to obtain CRLs

Symptom

CRLs cannot be obtained.

Analysis

- The network connection is down, for example, because the network cable is damaged or the connectors have bad contact.
- The PKI domain does not have a CA certificate before you try to obtain CRLs.
- The URL of the CRL repository is not configured and cannot be obtained from the CA certificate or local certificates in the PKI domain.
- The specified URL of the CRL repository is incorrect.
- The device tries to obtain CRLs through SCEP, but it experiences the following problems:
  - The PKI domain does not have local certificates.
  - The key pairs in the certificates have been changed.
  - The PKI domain has incorrect URL for certificate request.

- The CRL repository uses LDAP for CRL distribution. However, the IP address or host name of the LDAP server is neither contained in the CRL repository URL nor configured in the PKI domain.
- The CA does not issue CRLs.
- The CA server does not accept the source IP address specified in the PKI domain, or no source IP address is specified.

Solution

1. Fix the network connection problems, if any.
2. Obtain or import the CA certificate.
3. If the URL of the CRL repository cannot be obtained, verify that the following conditions exist:
   - The URL for certificate request is valid.
   - A local certificate has been successfully obtained.
   - The local certificate contains a public key that matches the locally stored key pair.
4. Make sure the LDAP server address is contained in the CRL repository URL, or is configured in the PKI domain.
5. Make sure the CA server support publishing CRLs.
6. Specify a correct source IP address that the CA server can accept. For the correct settings, contact the CA administrator.
7. If the problem persists, contact H3C Support.

Failed to import the CA certificate

Symptom

The CA certificate cannot be imported.

Analysis

- CRL checking is enabled, but the device does not have a CRL in the PKI domain and cannot obtain one.
- The specified format in which the CA certificate file is to be imported does not match actual certificate file format.

Solution

1. Use the **`undo crl check enable`** command to disable CRL checking in the PKI domain.
2. Make sure the format of the imported file is correct.
3. If the problem persists, contact H3C Support.

Failed to import the local certificate

Symptom

The local certificate cannot be imported.

Analysis

- The PKI domain does not have a CA certificate, and the local certificate file to be imported does not contain the CA certificate chain.
- CRL checking is enabled, but the device does not have a CRL in the PKI domain and cannot obtain one.
- The specified format in which the local certificate file is to be imported does not match actual certificate file format.

- The device and the certificate do not have the local key pair.
- The certificate has been revoked.
- The certificate is out of the validity period.
- The system time is incorrect.

Solution

1. Obtain or import the CA certificate.
2. Use the **undo crl check enable** command to disable CRL checking, or obtain the correct CRL before you import certificates.
3. Make sure the format of the file to be imported is correct.
4. Make sure the certificate file contains the private key.
5. Make sure the certificate is not revoked.
6. Make sure the certificate is valid.
7. Configure the correct system time for the device.
8. If the problem persists, contact H3C Support.

Failed to export certificates

Symptom

Certificates cannot be exported.

Analysis

- The PKI domain does not have local certificates when you export all certificates in PKCS12 format.
- The specified export path does not exist.
- The specified export path is illegal.
- The public key of the local certificate to be exported does not match the public key of the key pair configured in the PKI domain.
- The storage space of the device is full.

Solution

1. Obtain or request local certificates first.
2. Use the **mkdir** command to create the required path.
3. Specify a correct export path.
4. Configure the correct key pair in the PKI domain.
5. Clear up the storage space of the device.
6. If the problem persists, contact H3C Support.

Failed to set the storage path

Symptom

The storage path for certificates or CRLs cannot be set.

Analysis

- The specified storage path does not exist.
- The specified storage path is illegal.
- The storage space of the device is full.

Solution

1. Use the **mkdir** command to create the path.
2. Specify a valid storage path for certificates or CRLs.
3. Clear up the storage space of the device.
4. If the problem persists, contact H3C Support.

Configuring IPsec

About IPsec

IP Security (IPsec) is defined by the IETF to provide interoperable, high-quality, cryptography-based security for IP communications. It is a Layer 3 VPN technology that transmits data in a secure channel established between two endpoints (such as two security gateways). Such a secure channel is usually called an IPsec tunnel.

IPsec framework

IPsec is a security framework that has the following protocols and algorithms:

- Authentication Header (AH).
- Encapsulating Security Payload (ESP).
- Internet Key Exchange (IKE).
- Algorithms for authentication and encryption.

AH and ESP are security protocols that provide security services. IKE performs automatic key exchange. For more information about IKE, see "Configuring IKE."

IPsec security services

IPsec provides the following security services for data packets in the IP layer:

- **Confidentiality**—The sender encrypts packets before transmitting them over the Internet, protecting the packets from being eavesdropped en route.
- **Data integrity**—The receiver verifies the packets received from the sender to make sure they are not tampered with during transmission.
- **Data origin authentication**—The receiver verifies the authenticity of the sender.
- **Anti-replay**—The receiver examines packets and drops outdated and duplicate packets.

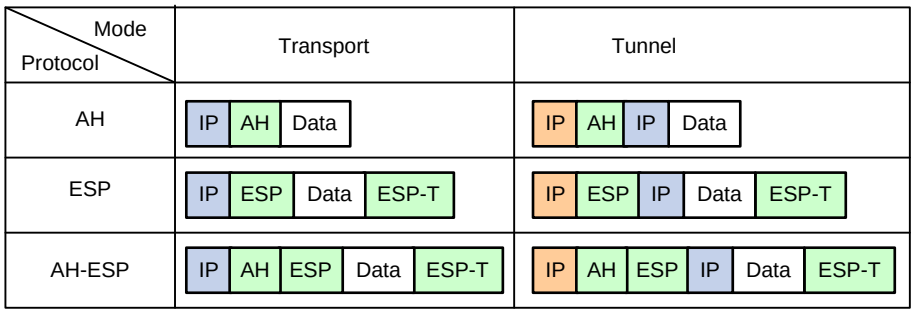
Benefits of IPsec

IPsec delivers the following benefits:

- Reduced key negotiation overhead and simplified maintenance by supporting the IKE protocol. IKE provides automatic key negotiation and automatic IPsec security association (SA) setup and maintenance.
- Good compatibility. You can apply IPsec to all IP-based application systems and services without modifying them.
- Encryption on a per-packet rather than per-flow basis. Per-packet encryption allows for flexibility and greatly enhances IP security.

Security protocols

IPsec comes with two security protocols, AH and ESP. They define how to encapsulate IP packets and the security services that they can provide.



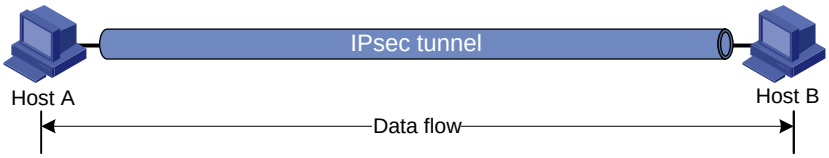
- AH (protocol 51) defines the encapsulation of the AH header in an IP packet, as shown in Figure 1. AH can provide data origin authentication, data integrity, and anti-replay services to

prevent data tampering, but it cannot prevent eavesdropping. Therefore, it is suitable for transmitting non-confidential data. The authentication algorithms supported by AH include HMAC-MD5 and HMAC-SHA1. AH does not support NAT traversal.

- ESP (protocol 50) defines the encapsulation of the ESP header and trailer in an IP packet, as shown in Figure 1. ESP can provide data encryption, data origin authentication, data integrity, and anti-replay services. Unlike AH, ESP can guarantee data confidentiality because it can encrypt the data before encapsulating the data to IP packets. ESP-supported encryption algorithms include DES, 3DES, and AES, and authentication algorithms include HMAC-MD5 and HMAC-SHA1.

Both AH and ESP provide authentication services, but the authentication service provided by AH is stronger. In practice, you can choose either or both security protocols. When both AH and ESP are used, an IP packet is encapsulated first by ESP and then by AH.

Figure 1 Security protocol encapsulations in different modes



Encapsulation modes

IPsec supports the following encapsulation modes: transport mode and tunnel mode.

Transport mode

The security protocols protect the upper layer data of an IP packet. Only the transport layer data is used to calculate the security protocol headers. The calculated security protocol headers and the encrypted data (only for ESP encapsulation) are placed after the original IP header. You can use the transport mode when end-to-end security protection is required (the secured transmission start and end points are the actual start and end points of the data). The transport mode is typically used for protecting host-to-host communications, as shown in Figure 2.

Figure 2 IPsec protection in transport mode

Tunnel mode

The security protocols protect the entire IP packet. The entire IP packet is used to calculate the security protocol headers. The calculated security protocol headers and the encrypted data (only for ESP encapsulation) are encapsulated in a new IP packet. In this mode, the encapsulated packet has two IP headers. The inner IP header is the original IP header. The outer IP header is added by the network device that provides the IPsec service. You must use the tunnel mode when the secured transmission start and end points are not the actual start and end points of the data packets (for example, when two gateways provide IPsec but the data start and end points are two hosts behind the gateways). The tunnel mode is typically used for protecting gateway-to-gateway communications, as shown in Figure 3.

Figure 3 IPsec protection in tunnel mode

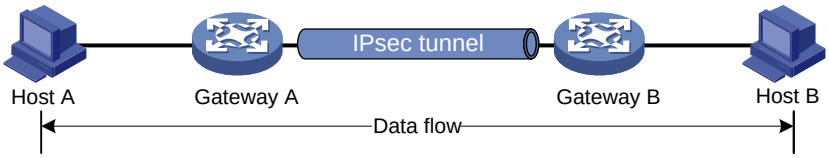


Figure 4 shows how the security protocols encapsulate an IP packet in different encapsulation modes.

Figure 4 Security protocol encapsulations in different modes

Mode / Protocol	Transport	Tunnel
AH	IP AH Data	IP AH IP Data
ESP	IP ESP Data ESP-T	IP ESP IP Data ESP-T
AH-ESP	IP AH ESP Data ESP-T	IP AH ESP IP Data ESP-T

Security association

A security association (SA) is an agreement negotiated between two communicating parties called IPsec peers. An SA includes the following parameters for data protection:

- Security protocols (AH, ESP, or both).
- Encapsulation mode (transport mode or tunnel mode).
- Authentication algorithm (HMAC-MD5 or HMAC-SHA1).
- Encryption algorithm (DES, 3DES, or AES).
- Shared keys and their lifetimes.

An SA is unidirectional. At least two SAs are needed to protect data flows in a bidirectional communication. If two peers want to use both AH and ESP to protect data flows between them, they construct an independent SA for each protocol in each direction.

An SA is uniquely identified by a triplet, which consists of the security parameter index (SPI), destination IP address, and security protocol identifier. An SPI is a 32-bit number. It is transmitted in the AH/ESP header.

An SA can be set up manually or through IKE.

- **Manual mode**—Configure all parameters for the SA through commands. This configuration mode is complex and does not support some advanced features (such as periodic key update), but it can implement IPsec without IKE. This mode is mainly used in small and static networks or when the number of IPsec peers in the network is small.
- **IKE negotiation mode**—The peers negotiate and maintain the SA through IKE. This configuration mode is simple and has good expansibility. As a best practice, set up SAs through IKE negotiations in medium- and large-scale dynamic networks.

A manually configured SA never ages out. An IKE-created SA has a lifetime, which comes in two types:

- **Time-based lifetime**—Defines how long the SA can be valid after it is created.
- **Traffic-based lifetime**—Defines the maximum traffic that the SA can process.

If both lifetime timers are configured for an SA, the SA becomes invalid when either of the lifetime timers expires. Before the SA expires, IKE negotiates a new SA, which takes over immediately after its creation.

Authentication and encryption

Authentication algorithms

IPsec uses hash algorithms to perform authentication. A hash algorithm produces a fixed-length digest for an arbitrary-length message. IPsec peers respectively calculate message digests for each packet. The receiver compares the local digest with that received from the sender. If the digests are identical, the receiver considers the packet intact and the sender's identity valid. IPsec uses the Hash-based Message Authentication Code (HMAC) based authentication algorithms, including HMAC-MD5 and HMAC-SHA1. Compared with HMAC-SHA1, HMAC-MD5 is faster but less secure.

Encryption algorithms

IPsec uses symmetric encryption algorithms, which encrypt and decrypt data by using the same keys. The following encryption algorithms are available for IPsec on the device:

- **DES**—Encrypts a 64-bit plaintext block with a 56-bit key. DES is the least secure but the fastest algorithm.
- **3DES**—Encrypts plaintext data with three 56-bit DES keys. The key length totals up to 168 bits. It provides moderate security strength and is slower than DES.
- **AES**—Encrypts plaintext data with a 128-bit, 192-bit, or 256-bit key. AES provides the highest security strength and is slower than 3DES.

IPsec-protected traffic

IPsec tunnels can protect the following types of traffic:

- Packets that match specific ACLs.
- Packets routed to a tunnel interface.
- Packets of IPv6 routing protocols.

Two peers use security policies (IPsec policies or IPsec profiles) to protect packets between them. A security policy defines the range of packets to be protected by IPsec and the security parameters used for the protection. For more information about IPsec policies and IPsec profiles, see "IPsec policy and IPsec profile."

The following information describes how IPsec protects packets:

- When an IPsec peer identifies the packets to be protected according to the security policy, it sets up an IPsec tunnel and sends the packet to the remote peer through the tunnel. The IPsec tunnel can be manually configured beforehand, or it can be set up through IKE negotiation triggered by the packet. The IPsec tunnels are actually the IPsec SAs. The inbound packets are protected by the inbound SA, and the outbound packets are protected by the outbound SA.
- When the remote IPsec peer receives the packet, it drops, de-encapsulates, or directly forwards the packet according to the configured security policy.

ACL-based IPsec

To implement ACL-based IPsec, configure an ACL to define the data flows to be protected, specify the ACL in an IPsec policy, and then apply the IPsec policy to an interface.

ACL-based IPsec works as follows:

- When packets sent by the interface match a permit rule of the ACL, the packets are protected by the outbound IPsec SA and encapsulated with IPsec.

- When the interface receives an IPsec packet destined for the local device, it searches for the inbound IPsec SA according to the SPI in the IPsec packet header for de-encapsulation. If the de-encapsulated packet matches a permit rule of the ACL, the device processes the packet. If the de-encapsulated packet does not match any permit rule of the ACL, the device drops the packet.

The device supports the following data flow protection modes:

- **Standard mode**—One IPsec tunnel protects one data flow. The data flow permitted by an ACL rule is protected by one IPsec tunnel that is established solely for it.
- **Aggregation mode**—One IPsec tunnel protects all data flows permitted by all the rules of an ACL. This mode is only used to communicate with old-version devices.
- **Per-host mode**—One IPsec tunnel protects one host-to-host data flow. One host-to-host data flow is identified by one ACL rule and protected by one IPsec tunnel established solely for it. This mode consumes more system resources when multiple data flows exist between two subnets to be protected.

IPv6 routing protocol-based IPsec

You can implement IPv6 routing protocol-based IPsec by binding an IPsec profile to an IPv6 routing protocol. All packets of the protocol are encapsulated with IPsec. Supported IPv6 routing protocols include OSPFv3, IPv6 BGP, and RIPng.

All packets of the applications that are not bound to IPsec and the IPsec packets that failed to be de-encapsulated are dropped.

In one-to-many communication scenarios, you must configure the IPsec SAs for an IPv6 routing protocol in manual mode because of the following reasons:

- The automatic key exchange mechanism protects communications between two points. In one-to-many communication scenarios, automatic key exchange cannot be implemented.
- One-to-many communication scenarios require that all the devices use the same SA parameters (SPI and key) to receive and send packets. IKE negotiated SAs cannot meet this requirement.

IPsec policy and IPsec profile

IPsec policies and IPsec profiles define the parameters used to establish IPsec tunnels between two peers and the range of packets to be protected.

IPsec policy

An IPsec policy is a set of IPsec policy entries that have the same name but different sequence numbers.

An IPsec policy contains the following settings:

- An ACL that defines the range of data flows to be protected.
- An IPsec transform set that defines the security parameters used for IPsec protection.
- IPsec SA establishment mode.

  IPsec SAs can be established through manual configuration or IKE negotiation.
- Local and remote IP addresses that define the start and end points of the IPsec tunnel.

In the same IPsec policy, an IPsec policy entry with a smaller sequence number has a higher priority. When sending a packet, the interface applied with an IPsec policy looks through the IPsec policy's entries in ascending order of sequence numbers. If the packet matches the ACL of an IPsec policy entry, the interface encapsulates the packet according to the IPsec policy entry. If no match is found, the interface sends the packet out without IPsec protection.

When the interface receives an IPsec packet destined for the local device, it searches for the inbound IPsec SA according to the SPI in the IPsec packet header for de-encapsulation. If the de-encapsulated packet matches a permit rule of the ACL, the device processes the packet. If the de-encapsulated packet does not match a permit rule of the ACL, the device drops the packet.

IPsec profile

An IPsec profile has similar settings as an IPsec policy. It is uniquely identified by a name and does not support ACL configuration.

IPsec profiles can be classified into the following types:

- **Manual IPsec profile**—A manual IPsec profile is used to protect IPv6 routing protocols. It specifies the IPsec transform set used for protecting data flows, and the SPIs and keys used by the SAs.
- **IKE-based IPsec profile**—An IKE-based IPsec profile is applied to tunnel interfaces to protect tunneled traffic. It specifies the IPsec transform sets used for protecting data flows, and the IKE profile used for IKE negotiation.

Protocols and standards

- RFC 2401, *Security Architecture for the Internet Protocol*
- RFC 2402, *IP Authentication Header*
- RFC 2406, *IP Encapsulating Security Payload*
- RFC 4552, *Authentication/Confidentiality for OSPFv3*

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

Restrictions and guidelines: IPsec configuration

IPsec supports encrypting and decrypting only software forwarded packets on the control plane. It does not handle the data packets on the user plane. For more information about the control plane and user plane, see QoS configuration in *ACL and QoS Configuration Guide*.

Typically, IKE uses UDP port 500 for communication, and AH and ESP use the protocol numbers 51 and 50, respectively. Make sure traffic of these protocols is not denied on the interfaces with IKE or IPsec configured.

Implementing ACL-based IPsec

ACLs for IPsec take effect only on traffic that is generated by the device and traffic that is destined for the device. They do not take effect on traffic forwarded through the device. For example, an ACL-based IPsec tunnel can protect log messages the device sends to a log server, but it does not protect data flows and voice flows that are forwarded by the device.

ACL-based IPsec tasks at a glance

To configure ACL-based IPsec, perform the following tasks:

1. Configuring an ACL

2. Configuring an IPsec transform set
3. Configuring an IPsec policy

   Choose one of the following tasks:
   - Configuring a manual IPsec policy
   - Configuring an IKE-based IPsec policy
4. Applying an IPsec policy to an interface
5. (Optional.) Configuring accessibility features for ACL-based IPsec
   - Enabling ACL checking for de-encapsulated packets
   - Configuring IPsec anti-replay
   - Configuring IPsec anti-replay redundancy
   - Binding a source interface to an IPsec policy
   - Enabling QoS pre-classify
   - Configuring the DF bit of IPsec packets
   - Configuring IPsec RRI
   - Configuring the global IPsec SA lifetime and idle timeout
   - Configuring IPsec fragmentation
6. (Optional.) Configuring logging and SNMP notification for IPsec.
   - Configuring IPsec logging
   - Configuring SNMP notifications for IPsec

Configuring an ACL

IPsec uses ACLs to identify the traffic to be protected.

Keywords in ACL rules

An ACL is a collection of ACL rules. Each ACL rule is a deny or permit statement. A permit statement identifies a data flow protected by IPsec, and a deny statement identifies a data flow that is not protected by IPsec. IPsec compares a packet against the ACL rules and processes the packet according to the first rule it matches.

- Each ACL rule matches both the outbound traffic and the returned inbound traffic. Suppose there is a rule **rule 0 permit ip source 1.1.1.0 0.0.0.255 destination 2.2.2.0 0.0.0.255**. This rule matches both traffic from 1.1.1.0 to 2.2.2.0 and traffic from 2.2.2.0 to 1.1.1.0.
- In the outbound direction, if a permit statement is matched, IPsec considers that the packet requires protection and continues to process it. If a deny statement is matched or no match is found, IPsec considers that the packet does not require protection and delivers it to the next module.
- In the inbound direction:
  - Non-IPsec packets that match a permit statement are dropped.
  - IPsec packets destined for the device itself are de-encapsulated. By default, the de-encapsulated packets are compared against the ACL rules. Only those that match a permit statement are processed. Other packets are dropped. If ACL checking for de-encapsulated IPsec packets is disabled, the de-encapsulated packets are not compared against the ACL rules and are directly processed by other modules.

When defining ACL rules for IPsec, follow these guidelines:

- Permit only data flows that need to be protected and use the **any** keyword with caution. With the **any** keyword specified in a permit statement, all outbound traffic matching the permit statement will be protected by IPsec. All inbound IPsec packets matching the permit statement will be received and processed, but all inbound non-IPsec packets will be dropped. This will cause all the inbound traffic that does not need IPsec protection to be dropped.

- Avoid statement conflicts in the scope of IPsec policy entries. When creating a deny statement, be careful with its match scope and match order relative to permit statements. The policy entries in an IPsec policy have different match priorities. ACL rule conflicts between them are prone to cause mistreatment of packets. For example, when configuring a permit statement for an IPsec policy entry to protect an outbound traffic flow, you must avoid the situation that the traffic flow matches a deny statement in a higher priority IPsec policy entry. Otherwise, the packets will be sent out as normal packets. If they match a permit statement at the receiving end, they will be dropped by IPsec.

The following example shows how an improper statement causes unexpected packet dropping. Only the ACL-related configuration is presented.

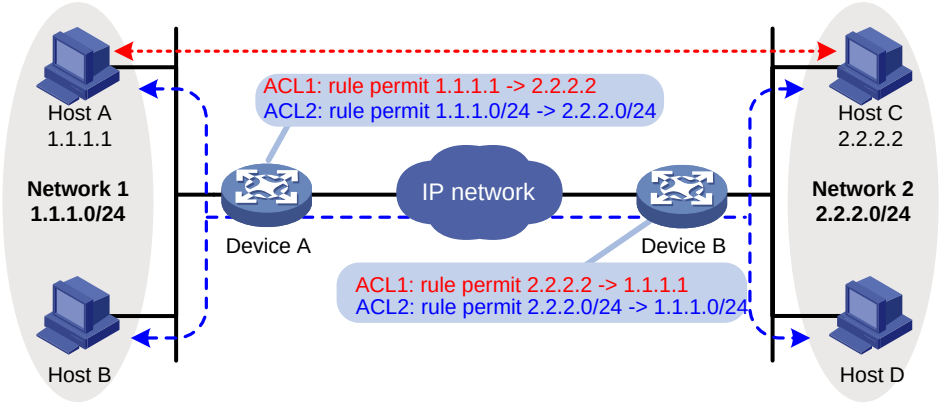
Assume Device A is connected to subnet 1.1.2.0/24 and Device B is connected to subnet 3.3.3.0/24, and the IPsec policy configuration on Device A and Device B is as follows:

- IPsec configuration on Device A:

```
acl advanced 3000
 rule 0 permit ip source 1.1.1.0 0.0.0.255 destination 2.2.2.0 0.0.0.255
 rule 1 deny ip
acl advanced 3001
 rule 0 permit ip source 1.1.2.0 0.0.0.255 destination 3.3.3.0 0.0.0.255
 rule 1 deny ip
#
ipsec policy testa 1 isakmp <---IPsec policy entry with a higher priority
 security acl 3000
 ike-profile aa
 transform-set 1
#
ipsec policy testa 2 isakmp <---IPsec policy entry with a lower priority
 security acl 3001
 ike-profile bb
 transform-set 1
```

- IPsec configuration on Device B:

```
acl advanced 3001
 rule 0 permit ip source 3.3.3.0 0.0.0.255 destination 1.1.2.0 0.0.0.255
 rule 1 deny ip
#
ipsec policy testb 1 isakmp
 security acl 3001
 ike-profile aa
 transform-set 1
```



On Device A, apply the IPsec policy **testa** to the outbound interface of Device A. The IPsec policy contains two policy entries, **testa 1** and **testa 2**. The ACLs used by the two policy entries each contain a rule that matches traffic from 1.1.2.0/24 to 3.3.3.0/24. The one used in the policy entry **testa 1** is a deny statement and the one used in the policy entry **testa 2** is a permit statement. Because **testa 1** is matched prior to **testa 2**, traffic from 1.1.2.0/24 to 3.3.3.0/24 will match the deny statement and be sent as normal traffic. When the traffic arrives at Device B, the traffic matches rule 0 (a permit statement) in ACL 3001 used in the applied IPsec policy **testb**. Because non-IPsec traffic that matches a permit statement must be dropped on the inbound interface, Device B drops the traffic.

To make sure subnet 1.1.2.0/24 can access subnet 3.3.3.0/24, you can delete the deny rule in ACL 3000 on Device A.

Mirror image ACLs

To make sure SAs can be set up and the traffic protected by IPsec can be processed correctly between two IPsec peers, create mirror image ACLs on the IPsec peers. As shown in Figure 5, ACL rules on Device B are mirror images of the rules on Device A. In this way, SAs can be created successfully for the traffic between Host A and Host C and for the traffic between Network 1 and Network 2.

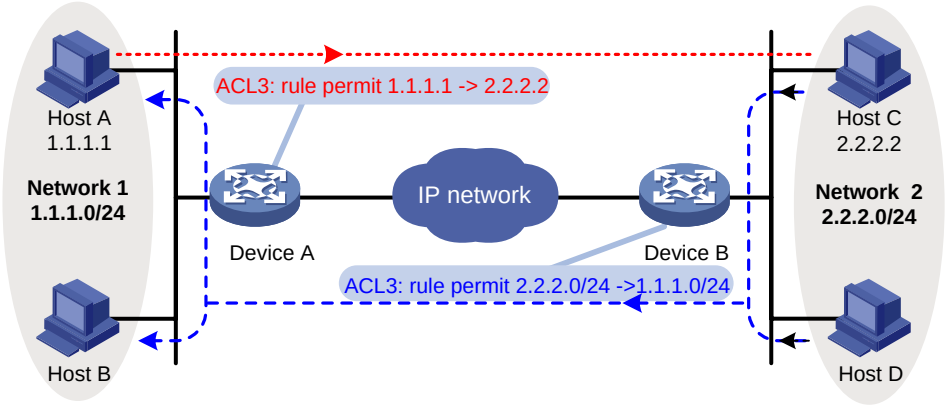


Figure 5 Mirror image ACLs

If the ACL rules on IPsec peers do not form mirror images of each other, SAs can be set up only when both of the following requirements are met:

- The range specified by an ACL rule on one peer is covered by its counterpart ACL rule on the other peer. As shown in Figure 6, the range specified by the ACL rule configured on Device A is covered by its counterpart on Device B.
- The peer with the narrower rule initiates SA negotiation. If a wider ACL rule is used by the SA initiator, the negotiation request might be rejected because the matching traffic is beyond the scope of the responder. As shown in Figure 6, the SA negotiation initiated by Host A to Host C is accepted but the SA negotiations from Host C to Host A, from Host C to Host B, and from Host D to Host A are rejected.

Figure 6 Non-mirror image ACLs

Configuring an IPsec transform set

About this task

An IPsec transform set, part of an IPsec policy, defines the security parameters for IPsec SA negotiation, including the security protocol, encryption algorithms, and authentication algorithms.

Restrictions and guidelines

Changes to an IPsec transform set affect only SAs negotiated after the changes. To apply the changes to existing SAs, execute the reset ipsec sa command to clear the SAs so that they can be set up by using the updated parameters.

In FIPS mode, you must specify both the ESP encryption algorithm and the ESP authentication algorithm for an IPsec transform set that uses the ESP security protocol.

When you set the packet encapsulation mode (tunnel or transport) for an IPsec transform set, follow these guidelines:

- The transport mode applies only when the source and destination IP addresses of data flows match those of the IPsec tunnel.
- IPsec for IPv6 routing protocols supports only the transport mode.

When you configure the Perfect Forward Secrecy (PFS) feature in an IPsec transform set, follow these guidelines:

- In IKEv1, the security level of the DH group of the initiator must be higher than or equal to that of the responder. This restriction does not apply to IKEv2.
- The end without the PFS feature performs SA negotiation according to the PFS requirements of the peer end.

You can specify multiple authentication or encryption algorithms for the same security protocol. The algorithm specified earlier has a higher priority.

Some algorithms are available only for IKEv2. See Table 1.

Table 1 Algorithms available only for IKEv2

Type	Algorithms
Encryption algorithm	aes-ctr-128 aes-ctr-192 aes-ctr-256 camellia-cbc-128 camellia-cbc-192 camellia-cbc-256 gmac-128 gmac-192 gmac-256 gcm-128 gcm-192 gcm-256
Authentication algorithm	aes-xcbc-mac

Procedure

1. Enter system view.
   system-view
2. Create an IPsec transform set and enter its view.
   ipsec transform-set *transform-set-name*
3. Specify the security protocol for the IPsec transform set.
   protocol { **ah** | **ah-esp** | **esp** }
   By default, the ESP security protocol is used.

4. Specify the encryption algorithms for ESP. Skip this step if the **protocol ah** command is configured.

   In non-FIPS mode:

   esp encryption-algorithm { **3des-cbc** | **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** | **aes-ctr-128** | **aes-ctr-192** | **aes-ctr-256** | **camellia-cbc-128** | **camellia-cbc-192** | **camellia-cbc-256** | **des-cbc** | **gmac-128** | **gmac-192** | **gmac-256** | **gcm-128** | **gcm-192** | **gcm-256** | **null** | **sm1-cbc-128** | **sm1-cbc-192** | **sm1-cbc-256** | **sm4-cbc** } *

   By default, no encryption algorithm is specified for ESP.

   In FIPS mode:

   esp encryption-algorithm { **gcm-128** | **gcm-192** | **gcm-256** } *

   By default, no encryption algorithm is specified for ESP.

5. Specify the authentication algorithms for ESP. Skip this step if the **protocol ah** command is configured.

   esp authentication-algorithm { **aes-xcbc-mac** | **md5** | **sha1** | **sha256** | **sha384** | **sha512** | **sm3** } *

   By default, no authentication algorithm is specified for ESP.

   The **aes-xcbc-mac** algorithm is available only for IKEv2.

6. Specify the authentication algorithms for AH. Skip this step if the **protocol esp** command is configured.

   In non-FIPS mode:

   ah authentication-algorithm { **aes-xcbc-mac** | **md5** | **sha1** | **sha256** | **sha384** | **sha512** | **sm3** } *

   By default, no authentication algorithm is specified for AH.

   The **aes-xcbc-mac** algorithm is available only for IKEv2.

   In FIPS mode:

   ah authentication-algorithm { **sha256** | **sha384** | **sha512** } *

   By default, no authentication algorithm is specified for AH.

7. Specify the packet encapsulation mode.

   encapsulation-mode { **transport** | **tunnel** }

   By default, the security protocol encapsulates IP packets in tunnel mode.

8. (Optional.) Enable the PFS feature.

   In non-FIPS mode:

   pfs { **dh-group1** | **dh-group2** | **dh-group5** | **dh-group14** | **dh-group24** | **dh-group19** | **dh-group20** }

   In FIPS mode:

   pfs { **dh-group19** | **dh-group20** | **dh-group24** }

   By default, the PFS feature is disabled.

   For more information about PFS, see "Configuring IKE."

9. (Optional.) Enable the Extended Sequence Number (ESN) feature.

   esn enable [**both**]

   By default, the ESN feature is disabled.

Configuring a manual IPsec policy

In a manual IPsec policy, the parameters are configured manually, such as the keys, the SPIs, and the IP addresses of the two ends in tunnel mode.

Restrictions and guidelines

When you configure a manual IPsec policy, make sure the IPsec configuration at both ends of the IPsec tunnel meets the following requirements:

- The IPsec policies at the two ends must have IPsec transform sets that use the same security protocols, security algorithms, and encapsulation mode.
- The remote IPv4 address configured on the local end must be the same as the primary IPv4 address of the interface applied with the IPsec policy at the remote end. The remote IPv6 address configured on the local end must be the same as the first IPv6 address of the interface applied with the IPsec policy at the remote end.
- At each end, configure parameters for both the inbound SA and the outbound SA, and make sure the SAs in each direction are unique: For an outbound SA, make sure its triplet (remote IP address, security protocol, and SPI) is unique. For an inbound SA, make sure its SPI is unique.
- The local inbound SA must use the same SPI and keys as the remote outbound SA. The same is true of the local outbound SA and remote inbound SA.
- The keys for the IPsec SAs at the two tunnel ends must be configured in the same format. For example, if the local end uses a key in hexadecimal format, the remote end must also use a key in hexadecimal format. If you configure a key in both the character and the hexadecimal formats, only the most recent configuration takes effect.
- If you configure a key in character format for ESP, the device automatically generates an authentication key and an encryption key for ESP.

Procedure

1. Enter system view.

   system-view

2. Create a manual IPsec policy entry and enter its view.

   ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* **manual**

3. (Optional.) Configure a description for the IPsec policy.

   description *text*

   By default, no description is configured.

4. Specify an ACL for the IPsec policy.

   security acl [**ipv6**] { *acl-number* | **name** *acl-name* }

   By default, no ACL is specified for an IPsec policy.

   You can specify only one ACL for an IPsec policy.

5. Specify an IPsec transform set for the IPsec policy.

   transform-set *transform-set-name*

   By default, no IPsec transform set is specified for an IPsec policy.

   You can specify only one IPsec transform set for a manual IPsec policy.

6. Specify the remote IP address of the IPsec tunnel.

   remote-address { *ipv4-address* | **ipv6** *ipv6-address* }

   By default, the remote IP address of the IPsec tunnel is not specified.

7. Configure an SPI for the inbound IPsec SA.

   sa spi inbound { **ah** | **esp** } *spi-number*

   By default, no SPI is configured for the inbound IPsec SA.

8. Configure an SPI for the outbound IPsec SA.

   sa spi outbound { **ah** | **esp** } *spi-number*

   By default, no SPI is configured for the outbound IPsec SA.

9. Configure keys for the IPsec SA.
   - Configure an authentication key in hexadecimal format for AH.

     sa hex-key authentication { **inbound** | **outbound** } **ah** { **cipher** | **simple** } *string*
   - Configure an authentication key in character format for AH.

     sa string-key { **inbound** | **outbound** } **ah** { **cipher** | **simple** } *string*
   - Configure a key in character format for ESP.

     sa string-key { **inbound** | **outbound** } **esp** { **cipher** | **simple** } *string*
   - Configure an authentication key in hexadecimal format for ESP.

     sa hex-key authentication { **inbound** | **outbound** } **esp** { **cipher** | **simple** }
   - Configure an encryption key in hexadecimal format for ESP.

     sa hex-key encryption { **inbound** | **outbound** } **esp** { **cipher** | **simple** } *string*

   By default, no keys are configured for the IPsec SA.

   Configure keys correctly for the security protocol (AH, ESP, or both) you have specified in the IPsec transform set used by the IPsec policy.

Configuring an IKE-based IPsec policy

About this task

In an IKE-based IPsec policy, the parameters are automatically negotiated through IKE.

To configure an IKE-based IPsec policy, use one of the following methods:

- Directly configure it by configuring the parameters in IPsec policy view.
- Configure it by using an existing IPsec policy template with the parameters to be negotiated configured.

  A device using an IPsec policy that is configured in this way cannot initiate an SA negotiation, but it can respond to a negotiation request. The parameters not defined in the template are determined by the initiator. For example, in an IPsec policy template, the ACL is optional. If you do not specify an ACL, the IPsec protection range has no limit. So the device accepts all ACL settings of the negotiation initiator.

  When the remote end's information (such as the IP address) is unknown, this method allows the remote end to initiate negotiations with the local end.

The configurable parameters for an IPsec policy template are the same as those when you directly configure an IKE-based IPsec policy. The difference is that more parameters are optional for an IPsec policy template. Except the IPsec transform sets and the IKE profile, all other parameters are optional.

Restrictions and guidelines for IKE-based IPsec policy configuration

The IPsec policies at the two tunnel ends must have IPsec transform sets that use the same security protocols, security algorithms, and encapsulation mode.

The IPsec policies at the two tunnel ends must have the same IKE profile parameters.

An IKE-based IPsec policy can use a maximum of six IPsec transform sets. During an IKE negotiation, IKE searches for a fully matched IPsec transform set at the two ends of the IPsec tunnel. If no match is found, no SA can be set up, and the packets expecting to be protected will be dropped.

The remote IP address of the IPsec tunnel is required on an IKE negotiation initiator and is optional on the responder. The remote IP address specified on the local end must be the same as the local IP address specified on the remote end.

The IPsec SA uses the local lifetime settings or those proposed by the peer, whichever are smaller.

The IPsec SA can have both a time-based lifetime and a traffic-based lifetime. The IPsec SA expires when either lifetime expires.

If you specify both an IKEv1 profile and an IKEv2 profile for an IPsec policy, the IKEv2 profile is used preferentially. For more information about IKEv1 and IKEv2 profiles, see "Configuring IKE" and "Configuring IKEv2."

Directly configuring an IKE-based IPsec policy

1. Enter system view.

   system-view

2. Create an IKE-based IPsec policy entry and enter its view.

   ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* **isakmp**

3. (Optional.) Configure a description for the IPsec policy.

   description *text*

   By default, no description is configured.

4. Specify an ACL for the IPsec policy.

   security acl [**ipv6**] { *acl-number* | **name** *acl-name* } [**aggregation** | **per-host**]

   By default, no ACL is specified for an IPsec policy.

   You can specify only one ACL for an IPsec policy.

5. Specify IPsec transform sets for the IPsec policy.

   transform-set *transform-set-name*&<1-6>

   By default, no IPsec transform sets are specified for an IPsec policy.

6. Specify an IKE profile or IKEv2 profile for the IPsec policy.
   - **Specify an IKE profile.**

     ike-profile *profile-name*

     By default, no IKE profile is specified for an IPsec policy.
   - **Specify an IKEv2 profile.**

     ikev2-profile *profile-name*

     By default, no IKEv2 profile is specified for an IPsec policy.

7. Specify the local IP address of the IPsec tunnel.

   local-address { *ipv4-address* | **ipv6** *ipv6-address* }

   By default, the local IPv4 address of the IPsec tunnel is the primary IPv4 address of the interface to which the IPsec policy is applied. The local IPv6 address of the IPsec tunnel is the first IPv6 address of the interface to which the IPsec policy is applied.

   The local IP address specified by this command must be the same as the IP address used as the local IKE identity.

   In a VRRP network, the local IP address must be the virtual IP address of the VRRP group to which the IPsec-applied interface belongs.

8. Specify the remote IP address of the IPsec tunnel.

   remote-address { [**ipv6**] *host-name* | *ipv4-address* | **ipv6** *ipv6-address* }

   By default, the remote IP address of the IPsec tunnel is not specified.

9. (Optional.) Set the lifetime or idle timeout for the IPsec SA.

- Set the IPsec SA lifetime.

  sa duration { **time-based** *seconds* | **traffic-based** *kilobytes* }

  By default, the global SA lifetime is used.
- Set the IPsec SA idle timeout.

  sa idle-time *seconds*

  By default, the global IPsec SA idle timeout is used.

10. (Optional.) Enable the Traffic Flow Confidentiality (TFC) padding feature.

tfc enable

By default, the TFC padding feature is disabled.

TFC padding applies only to IPsec SAs negotiated by IKEv2.

Configuring an IKE-based IPsec policy by using an IPsec policy template

1. Enter system view.

system-view

2. Create an IPsec policy template and enter its view.

ipsec { **ipv6-policy-template** | **policy-template** } *template-name seq-number*

3. (Optional.) Configure a description for the IPsec policy template.

description *text*

By default, no description is configured.

4. (Optional.) Specify an ACL for the IPsec policy template.

security acl [**ipv6**] { *acl-number* | **name** *acl-name* } [**aggregation** | **per-host**]

By default, no ACL is specified for an IPsec policy template.

You can specify only one ACL for an IPsec policy template.

5. Specify IPsec transform sets for the IPsec policy template.

transform-set *transform-set-name*&<1-6>

By default, no IPsec transform sets are specified for an IPsec policy template.

6. Specify an IKE profile or IKEv2 profile for the IPsec policy template.

- Specify an IKE profile.

  ike-profile *profile-name*

  By default, no IKE profile is specified for an IPsec policy template.

  Make sure the specified IKE profile is not used by another IPsec policy or IPsec policy template.
- Specify an IKEv2 profile.

  ikev2-profile *profile-name*

  By default, no IKEv2 profile is specified for an IPsec policy template.

7. Specify the local IP address of the IPsec tunnel.

local-address { *ipv4-address* | **ipv6** *ipv6-address* }

The default local IPv4 address and IPv6 address is the primary IPv4 address and first IPv6 address of the interface where the IPsec policy is applied.

The local IP address specified by this command must be the same as the IP address used as the local IKE identity.

In a VRRP network, the local IP address must be the virtual IP address of the VRRP group to which the IPsec-applied interface belongs.

8. Specify the remote IP address of the IPsec tunnel.

remote-address { [**ipv6**] *host-name* | *ipv4-address* | **ipv6** *ipv6-address* }

By default, the remote IP address of the IPsec tunnel is not specified.

9. (Optional.) Set the lifetime and idle timeout for the IPsec SA.
   - Set the IPsec SA lifetime.

     sa duration { **time-based** *seconds* | **traffic-based** *kilobytes* }

     By default, the global SA lifetime is used.
   - Set the IPsec SA idle timeout.

     sa idle-time *seconds*

     By default, the global IPsec SA idle timeout is used.
10. (Optional.) Enable the Traffic Flow Confidentiality (TFC) padding feature.

    tfc enable

    By default, the TFC padding feature is disabled.

    TFC padding applies only to IPsec SAs negotiated by IKEv2.
11. Return to system view.

    quit
12. Create an IPsec policy by using the IPsec policy template.

    ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* **isakmp template** *template-name*

Applying an IPsec policy to an interface

Restrictions and guidelines

You can apply an IPsec policy to interfaces to protect data flows.

- An IKE-based IPsec policy can be applied to multiple interfaces. As a best practice, apply an IKE-based IPsec policy to only one interface.
- A manual IPsec policy can be applied to only one interface.

To cancel the IPsec protection, remove the application of the IPsec policy.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Apply an IPsec policy to the interface.

   ipsec apply { **ipv6-policy** | **policy** } *policy-name*

   By default, no IPsec policy is applied to an interface.

   On one interface, you can apply a maximum of two IPsec policies: one IPv4 IPsec policy and one IPv6 IPsec policy.

   This feature is available only on Layer 3 interfaces.

   ○

Enabling ACL checking for de-encapsulated packets

About this task

This feature compares the de-encapsulated incoming IPsec packets against the ACL in the IPsec policy and discards those that do not match any permit rule of the ACL. This feature can protect networks against attacks using forged IPsec packets.

This feature applies only to tunnel-mode IPsec.

Procedure

1. Enter system view.
   system-view
2. Enable ACL checking for de-encapsulated packets.
   ipsec decrypt-check enable
   By default, ACL checking for de-encapsulated packets is enabled.

Configuring IPsec anti-replay

About this task

IPsec anti-replay protects networks against anti-replay attacks by using a sliding window mechanism called anti-replay window. This feature checks the sequence number of each received IPsec packet against the current IPsec packet sequence number range of the sliding window. If the sequence number is not in the current sequence number range, the packet is considered a replayed packet and is discarded.

IPsec packet de-encapsulation involves complicated calculation. De-encapsulation of replayed packets is not required, and the de-encapsulation process consumes large amounts of resources and degrades performance, resulting in DoS. IPsec anti-replay can check and discard replayed packets before de-encapsulation.

In some situations, service data packets are received in a different order than their original order. The IPsec anti-replay feature drops them as replayed packets, which impacts communications. If this happens, disable IPsec anti-replay checking or adjust the size of the anti-replay window as required.

Restrictions and guidelines

IPsec anti-replay does not affect manually created IPsec SAs. According to the IPsec protocol, only IKE-based IPsec SAs support anti-replay.

Set the anti-replay window size as small as possible to reduce the impact on system performance.

Failure to detect anti-replay attacks might result in denial of services. If you want to disable IPsec anti-replay, make sure you understand the impact of the operation on network security.

Procedure

1. Enter system view.
   system-view
2. Enable IPsec anti-replay.
   ipsec anti-replay check
   By default, IPsec anti-replay is enabled.
3. Set the size of the IPsec anti-replay window.
   ipsec anti-replay window *width*
   The default size is 64.

Configuring IPsec anti-replay redundancy

About this task

This feature synchronizes the following information from the active device to the standby device at configurable packet-based intervals:

- Lower bound values of the IPsec anti-replay window for inbound packets.
- IPsec anti-replay sequence numbers for outbound packets.

This feature, used together with IPsec redundancy, ensures uninterrupted IPsec traffic forwarding and anti-replay protection when the active device fails.

Procedure

1. Enter system view.

   system-view

2. Enable IPsec redundancy.

   ipsec redundancy enable

   By default, IPsec redundancy is disabled.

3. Enter IPsec policy view or IPsec policy template view.
   - Enter IPsec policy view.

     ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* [**isakmp** | **manual**]

   - Enter IPsec policy template view.

     ipsec { **ipv6-policy-template** | **policy-template** } *template-name seq-number*

4. Set the anti-replay window synchronization interval for inbound packets and the sequence number synchronization interval for outbound packets.

   redundancy replay-interval inbound *inbound-interval* **outbound** *outbound-interval*

   By default, the active device synchronizes the anti-replay window every time it receives 1000 packets and synchronizes the sequence number every time it sends 100000 packets.

Binding a source interface to an IPsec policy

About this task

For high availability, a core device is usually connected to an ISP through two links, which operate in backup or load sharing mode. The two interfaces negotiate with their peers to establish IPsec SAs respectively. When one interface fails and a link failover occurs, the other interface needs to take some time to renegotiate SAs, resulting in service interruption.

To solve these problems, bind a source interface to an IPsec policy and apply the policy to both interfaces. This enables the two physical interfaces to use the same source interface to negotiate IPsec SAs. As long as the source interface is up, the negotiated IPsec SAs will not be removed and will keep working, regardless of link failover.

Restrictions and guidelines

Only the IKE-based IPsec policies can be bound to a source interface.

An IPsec policy can be bound to only one source interface.

A source interface can be bound to multiple IPsec policies.

If the source interface bound to an IPsec policy is removed, the IPsec policy becomes a common IPsec policy.

If no local address is specified for an IPsec policy that has been bound to a source interface, the IPsec policy uses the IP address of the bound source interface to perform IKE negotiation. If a local address is specified, the IPsec policy uses the local address to perform IKE negotiation.

Procedure

1. Enter system view.

   system-view

2. Bind a source interface to an IPsec policy.

   ipsec { **ipv6-policy** | **policy** } *policy-name* **local-address** *interface-type interface-number*

   By default, no source interface is bound to an IPsec policy.

Enabling QoS pre-classify

About this task

When both an IPsec policy and a QoS policy are applied to an interface, QoS classifies packets by using the new headers added by IPsec. If you want QoS to classify packets by using the headers of the original IP packets, enable the QoS pre-classify feature.

Restrictions and guidelines

If you configure both IPsec and QoS on an interface, make sure the IPsec traffic classification rules match the QoS traffic classification rules. If the rules do not match, QoS might classify the packets of one IPsec SA to different queues, causing packets to be sent out of order. When IPsec anti-replay is enabled, IPsec will drop the incoming packets that are out of the anti-replay window, resulting in packet loss.

IPsec traffic classification rules are determined by the rules of the specified ACL. For more information about QoS policy and classification, see *ACL and QoS Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter IPsec policy view or IPsec policy template view.

   - Enter IPsec policy view.

     ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* [**isakmp** | **manual**]

   - Enter IPsec policy template view.

     ipsec { **ipv6-policy-template** | **policy-template** } *template-name seq-number*

3. Enable QoS pre-classify.

   qos pre-classify

   By default, QoS pre-classify is disabled.

Configuring the DF bit of IPsec packets

About this task

Perform this task to configure the Don't Fragment (DF) bit in the new IP header of IPsec packets in one of the following ways:

- **clear**—Clears the DF bit in the new header.
- **set**—Sets the DF bit in the new header.

- **copy**—Copies the DF bit in the original IP header to the new IP header.

You can configure the DF bit in system view and interface view. The interface-view DF bit setting takes precedence over the system-view DF bit setting. If the interface-view DF bit setting is not configured, the interface uses the system-view DF bit setting.

Restrictions and guidelines for DF bit configuration for IPsec packets

The DF bit setting takes effect only in tunnel mode, and it changes the DF bit in the new IP header rather than the original IP header.

This feature is available only on Layer 3 interfaces.

Configure the same DF bit setting on the interfaces where the same IPsec policy bound to a source interface is applied.

If the DF bit is set, the devices on the path cannot fragment the IPsec packets. To prevent IPsec packets from being discarded, make sure the path MTU is larger than the IPsec packet size. As a best practice, clear the DF bit if you cannot make sure the path MTU is larger than the IPsec packet size.

Configuring the DF bit of IPsec packets on an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the DF bit of IPsec packets on the interface.
   ipsec df-bit { **clear** | **copy** | **set** }
   By default, the interface uses the global DF bit setting.

Configuring the DF bit of IPsec packets globally

1. Enter system view.
   system-view
2. Configure the DF bit of IPsec packets globally.
   ipsec global-df-bit { **clear** | **copy** | **set** }
   By default, IPsec copies the DF bit in the original IP header to the new IP header.

Configuring IPsec RRI

Restrictions and guidelines

Enabling IPsec RRI for an IPsec policy deletes all existing IPsec SAs created by this IPsec policy. IPsec RRI creates static routes according to new IPsec SAs.

Disabling IPsec RRI for an IPsec policy deletes all existing IPsec SAs created by this IPsec policy and the associated static routes.

IPsec RRI is supported in both tunnel mode and transport mode.

If you change the preference value or tag value for an IPsec policy, the device deletes all IPsec SAs created by this IPsec policy, and the associated static routes. The change takes effect for future IPsec RRI-created static routes.

IPsec RRI does not generate a static route to a destination address to be protected if the destination address is not defined in the ACL used by an IPsec policy or an IPsec policy template. You must manually configure a static route to the destination address.

Procedure

1. Enter system view.

system-view

2. Enter IPsec policy view or IPsec policy template view.
   - Enter IPsec policy view.
     ipsec { **policy** | **ipv6-policy** } *policy-name seq-number* **isakmp**
   - Enter IPsec policy template view.
     ipsec { **ipv6-policy-template** | **policy-template** } *template-name seq-number*
3. Enable IPsec RRI.
   reverse-route dynamic
   By default, IPsec RRI is disabled.
4. (Optional.) Set the preference value for the static routes created by IPsec RRI.
   reverse-route preference *number*
   The default value is 60.
5. (Optional.) Set the tag value for the static routes created by IPsec RRI.
   reverse-route tag *tag-value*
   The default value is 0.

Configuring IPsec for IPv6 routing protocols

IPsec protection for IPv6 routing protocols tasks at a glance

To configure IPsec protection for IPv6 routing protocols, perform the following tasks:

1. Configuring an IPsec transform set
2. Configuring a manual IPsec profile
3. Applying the IPsec profile to an IPv6 routing protocol
4. (Optional.) Configuring IPsec fragmentation
5. (Optional.) Configuring SNMP notifications for IPsec

Configuring a manual IPsec profile

About this task

A manual IPsec profile specifies the IPsec transform set used for protecting data flows, and the SPIs and keys used by the SAs.

Restrictions and guidelines

When you configure a manual IPsec profile, make sure the IPsec profile configuration at both tunnel ends meets the following requirements:

- The IPsec transform set specified in the IPsec profile at the two tunnel ends must have the same security protocol, encryption and authentication algorithms, and packet encapsulation mode.
- The local inbound and outbound IPsec SAs must have the same SPI and key.
- The IPsec SAs on the devices in the same scope must have the same key. The scope is defined by protocols. For OSPFv3, the scope consists of OSPFv3 neighbors or an OSPFv3 area. For RIPng, the scope consists of directly-connected neighbors or a RIPng process. For BGP, the scope consists of BGP peers or a BGP peer group.
- The keys for the IPsec SAs at the two tunnel ends must be configured in the same format. For example, if the local end uses a key in hexadecimal format, the remote end must also use a key

in hexadecimal format. If you configure a key in both the character and the hexadecimal formats, only the most recent configuration takes effect.

- If you configure a key in character format for ESP, the device automatically generates an authentication key and an encryption key for ESP.

Procedure

1. Enter system view.
   system-view
2. Create a manual IPsec profile and enter its view.
   ipsec profile *profile-name* **manual**
   The **manual** keyword is not needed if you enter the view of an existing IPsec profile.
3. (Optional.) Configure a description for the IPsec profile.
   description *text*
   By default, no description is configured.
4. Specify an IPsec transform set.
   transform-set *transform-set-name*
   By default, no IPsec transform set is specified in an IPsec profile.
   The specified IPsec transform set must use the transport mode.
5. Configure an SPI for an SA.
   sa spi { **inbound** | **outbound** } { **ah** | **esp** } *spi-number*
   By default, no SPI is configured for an SA.
6. Configure keys for the IPsec SA.
   - Configure an authentication key in hexadecimal format for AH.
     sa hex-key authentication { **inbound** | **outbound** } **ah** { **cipher** | **simple** } *string*
   - Configure an authentication key in character format for AH.
     sa string-key { **inbound** | **outbound** } **ah** { **cipher** | **simple** } *string*
   - Configure a key in character format for ESP.
     sa string-key { **inbound** | **outbound** } **esp** { **cipher** | **simple** } *string*
   - Configure an authentication key in hexadecimal format for ESP.
     sa hex-key authentication { **inbound** | **outbound** } **esp** { **cipher** | **simple** }
   - Configure an encryption key in hexadecimal format for ESP.
     sa hex-key encryption { **inbound** | **outbound** } **esp** { **cipher** | **simple** } *string*

   By default, no keys are configured for the IPsec SA.
   Configure a key for the security protocol (AH, ESP, or both) you have specified.

Applying the IPsec profile to an IPv6 routing protocol

For information about the configuration procedure, see IPv6 BGP, OSPFv3, and RIPng configuration in *Layer 3—IP Routing Configuration Guide*.

Configuring the global IPsec SA lifetime and idle timeout

About this task

If the IPsec SA lifetime and idle timeout are not configured in an IPsec policy, IPsec policy template, or IPsec profile, the global settings are used.

When IKE negotiates IPsec SAs, it uses the local lifetime settings or those proposed by the peer, whichever are smaller.

An IPsec SA can have both a time-based lifetime and a traffic-based lifetime. The IPsec SA expires when either lifetime expires.

Procedure

1. Enter system view.

   system-view
2. Set the global IPsec SA lifetime or idle timeout.
   - Set the global IPsec SA lifetime.

     ipsec sa global-duration { **time-based** *seconds* | **traffic-based** *kilobytes* }

     By default, the time-based SA lifetime is 3600 seconds, and the traffic-based SA lifetime is 1843200 kilobytes.
   - Set the global SA idle timeout.

     ipsec sa idle-time *seconds*

     By default, the global IPsec SA idle timeout feature is disabled.

Configuring IPsec fragmentation

About this task

Perform this task to configure the device to fragment packets before or after IPsec encapsulation.

If you configure the device to fragment packets before IPsec encapsulation, the device predetermines the encapsulated packet size before the actual encapsulation. If the encapsulated packet size exceeds the MTU of the output interface, the device fragments the packets before encapsulation. If a packet's DF bit is set, the device drops the packet and sends an ICMP error message.

If you configure the device to fragment packets after IPsec encapsulation, the device directly encapsulates the packets and fragments the encapsulated packets in subsequent service modules.

Restrictions and guidelines

This feature takes effect on IPsec protected IPv4 packets.

Procedure

1. Enter system view.

   system-view
2. Configure IPsec fragmentation.

   ipsec fragmentation { **after-encryption** | **before-encryption** }

   By default, the device fragments packets before IPsec encapsulation.

Setting the maximum number of IPsec tunnels

Restrictions and guidelines

To maximize concurrent performance of IPsec when memory is sufficient, increase the maximum number of IPsec tunnels. To ensure service availability when memory is insufficient, decrease the maximum number of IPsec tunnels.

Procedure

1. Enter system view.
   system-view
2. Set the maximum number of IPsec tunnels.
   ipsec limit max-tunnel *tunnel-limit*
   The number of IPsec tunnels is not limited.

Configuring IPsec logging

About this task

IPsec logging provides you with records of important IPsec configuration, negotiation, and packet events.

- After you enable configuration event logging, the device generates log entries when configuration events such as adding or deleting IPsec policies occur. A configuration event log entry primarily includes the name of the IPsec policy being configured, template number, and the number of IPsec policies that have been configured.
- After you enable negotiation logging, the device generates a log entry when negotiation succeeds or fails, for example, when IPsec SA creation succeeds or fails. A negotiation log entry primarily includes the source and destination IP addresses, SPI value, and sequence number of the negotiation packets. If the device drops a negotiation packet, the log entry also includes the reason for the packet drop.
- After you enable IPsec packet logging, the device generates a log entry when it drops a packet because of failure to find an inbound SA, AH or ESP authentication failure, ESP encryption failure, or any other issue. An IPsec packet log entry primarily includes the source and destination IP addresses, SPI value, and sequence number of the negotiation packets. If the device drops a negotiation packet, the log entry also includes the reason for the packet drop.

If you execute this command multiple times, the most recent configuration takes effect.

Procedure

1. Enter system view.
   system-view
2. Enable logging for IPsec packets.
   ipsec logging { **config** | **negotiation** | **packet** } **enable**
   By default, logging for IPsec packets is disabled.

Configuring SNMP notifications for IPsec

About this task

After you enable SNMP notifications for IPsec, the IPsec module notifies the NMS of important module events. The notifications are sent to the device's SNMP module. For the notifications to be

sent correctly, you must also configure SNMP on the device. For more information about SNMP notifications, see *Network Management and Monitoring Configuration Guide*.

To generate and output SNMP notifications for a specific IPsec failure or event type, perform the following tasks:

1. Enable SNMP notifications for IPsec globally.
2. Enable SNMP notifications for the failure or event type.

Procedure

1. Enter system view.

   system-view
2. Enable SNMP notifications for IPsec globally.

   snmp-agent trap enable ipsec global

   By default, SNMP notifications for IPsec are disabled.
3. Enable SNMP notifications for the specified failure or event types.

   snmp-agent trap enable ipsec [**auth-failure** | **decrypt-failure** | **encrypt-failure** | **invalid-sa-failure** | **no-sa-failure** | **policy-add** | **policy-attach** | **policy-delete** | **policy-detach** | **sa-establish** | **sa-establish-failure** | **sa-initiate** | **sa-terminate** | **tunnel-start** | **tunnel-stop**] *

   By default, SNMP notifications for all failure and event types are disabled.

Display and maintenance commands for IPsec

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display IPsec policy information.	**display ipsec** { **ipv6-policy** | **policy** } [*policy-name* [*seq-number*]]
Display IPsec policy template information.	**display ipsec** { **ipv6-policy-template** | **policy-template** } [*template-name* [*seq-number*]]
Display IPsec profile information.	**display ipsec profile** [*profile-name*]
Display IPsec SA information.	**display ipsec sa** [**brief** | **count** | **interface** *interface-type interface-number* | { **ipv6-policy** | **policy** } *policy-name* [*seq-number*] | **profile** *profile-name* | **remote** [**ipv6**] *ip-address*]
Display IPsec statistics.	**display ipsec statistics** [**tunnel-id** *tunnel-id*]
Display IPsec transform set information.	**display ipsec transform-set** [*transform-set-name*]
Display IPsec tunnel information.	**display ipsec tunnel** { **brief** | **count** | **tunnel-id** *tunnel-id* }

Task	Command
Clear IPsec SAs.	**reset ipsec sa** [{ **ipv6-policy** | **policy** } *policy-name* [*seq-number*] | **profile** *policy-name* | **remote** { *ipv4-address* | **ipv6** *ipv6-address* } | **spi** { *ipv4-address* | **ipv6** *ipv6-address* } { **ah** | **esp** } *spi-num*]
Clear IPsec statistics.	**reset ipsec statistics** [**tunnel-id** *tunnel-id*]

IPsec configuration examples

Example: Configuring a manual mode IPsec tunnel for IPv4 packets

Network configuration

As shown in Figure 7, establish an IPsec tunnel between Switch A and Switch B to protect data flows between the switches. Configure the tunnel as follows:

- Specify the encapsulation mode as tunnel, the security protocol as ESP, the encryption algorithm as AES-CBC-192, and the authentication algorithm as HMAC-SHA1.
- Manually set up IPsec SAs.

Figure 7 Network diagram

Procedure

1. Configure Switch A:

   # Assign IP addresses to interfaces, as shown in Figure 7.

   ```
   <Sysname> system-view
   [Sysname] sysname SwitchA
   [SwitchA] vlan 1

   ```
   [SwitchA] acl advanced 3101
   [SwitchA-acl-ipv4-adv-3101] rule 0 permit ip source 2.2.2.1 0 destination 2.2.3.1 0
   [SwitchA-acl-ipv4-adv-3101] quit
   ```

   # Create an IPsec transform set named **tran1**.

```
[SwitchA] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchA-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create a manual IPsec policy entry. Specify the policy name as **map1** and set the sequence number to 10.

```
[SwitchA] ipsec policy map1 10 manual
```

Specify ACL 3101.

```
[SwitchA-ipsec-policy-manual-map1-10] security acl 3101
```

Specify IPsec transform set **tran1**.

```
[SwitchA-ipsec-policy-manual-map1-10] transform-set tran1
```

Specify the remote IP address of the IPsec tunnel as 2.2.3.1.

```
[SwitchA-ipsec-policy-manual-map1-10] remote-address 2.2.3.1
```

Configure inbound and outbound SPIs for ESP.

```
[SwitchA-ipsec-policy-manual-map1-10] sa spi outbound esp 12345
[SwitchA-ipsec-policy-manual-map1-10] sa spi inbound esp 54321
```

Configure the inbound and outbound SA keys for ESP.

```
[SwitchA-ipsec-policy-manual-map1-10] sa string-key outbound esp simple abcdefg
[SwitchA-ipsec-policy-manual-map1-10] sa string-key inbound esp simple gfedcba
[SwitchA-ipsec-policy-manual-map1-10] quit
```

Apply IPsec policy **map1** to VLAN-interface 1.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ipsec apply policy map1
```

2. Configure Switch B:

Assign IP addresses to interfaces, as shown in Figure 7.

```
<Sysname> system-view
[Sysname] sysname SwitchB
[SwitchB] vlan 1
[SwitchB-vlan1] quit
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ip address 2.2.3.1 255.255.255.0
[SwitchB-Vlan-interface1] quit
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] port access vlan 1
[SwitchB-GigabitEthernet1/0/2] quit
```

Configure an IPv4 advanced ACL to identify the data flows between Switch B and Switch A.

```
[SwitchB] acl advanced 3101
[SwitchB-acl-ipv4-adv-3101] rule 0 permit ip source 2.2.3.1 0 destination 2.2.2.1 0
[SwitchB-acl-ipv4-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchB] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchB-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Create a manual IPsec policy entry. Specify the policy name as **use1** and set the sequence number to 10.

```
[SwitchB] ipsec policy use1 10 manual
```

Specify ACL 3101.

```
[SwitchB-ipsec-policy-manual-use1-10] security acl 3101
```

Specify IPsec transform set **tran1**.

```
[SwitchB-ipsec-policy-manual-use1-10] transform-set tran1
```

Specify the remote IP address of the IPsec tunnel as 2.2.2.1.

```
[SwitchB-ipsec-policy-manual-use1-10] remote-address 2.2.2.1
```

Configure the inbound and outbound SPIs for ESP.

```
[SwitchB-ipsec-policy-manual-use1-10] sa spi outbound esp 54321
[SwitchB-ipsec-policy-manual-use1-10] sa spi inbound esp 12345
```

Configure the inbound and outbound SA keys for ESP.

```
[SwitchB-ipsec-policy-manual-use1-10] sa string-key outbound esp simple gfedcba
[SwitchB-ipsec-policy-manual-use1-10] sa string-key inbound esp simple abcdefg
[SwitchB-ipsec-policy-manual-use1-10] quit
```

Apply IPsec policy **use1** to VLAN-interface 1.

```
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ipsec apply policy use1
```

Verifying the configuration

After the configuration is completed, an IPsec tunnel between Switch A and Switch B is established, and the traffic between the switches is IPsec-protected. This example uses Switch A to verify the configuration.

Use the **display ipsec sa** command to display IPsec SAs on Switch A.

```
[SwitchA] display ipsec sa
-------------------------------
Interface: Vlan-interface 1
-------------------------------

  -----------------------------
  IPsec policy: map1
  Sequence number: 10
  Mode: manual
  -----------------------------
    Tunnel id: 549
    Encapsulation mode: tunnel
    Path MTU: 1443
    Tunnel:
        local  address: 2.2.2.1
        remote address: 2.2.3.1
```

```
    Flow:
        as defined in ACL 3101
    [Inbound ESP SA]
      SPI: 54321 (0x0000d431)
      Transform set: ESP-ENCRYPT-AES-CBC-192 ESP-AUTH-SHA1
      No duration limit for this SA
    [Outbound ESP SA]
      SPI: 12345 (0x00003039)
      Transform set: ESP-ENCRYPT-AES-CBC-192 ESP-AUTH-SHA1
      No duration limit for this SA
```

Example: Configuring an IKE-based IPsec tunnel for IPv4 packets

Network configuration

As shown in Figure 8, establish an IPsec tunnel between Switch A and Switch B to protect data flows between them. Configure the IPsec tunnel as follows:

- Specify the encapsulation mode as tunnel, the security protocol as ESP, the encryption algorithm as AES-CBC-192, and the authentication algorithm as HMAC-SHA1.
- Set up SAs through IKE negotiation.

Figure 8 Network diagram

Procedure

1. Configure Switch A:

Assign IP addresses to interfaces, as shown in Figure 8.

```
<Sysname> system-view
[Sysname] sysname SwitchA
[SwitchA] vlan 1
[SwitchA-vlan1] quit
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ip address 2.2.2.1 255.255.255.0
[SwitchA-Vlan-interface1] quit
[SwitchA] interface gigabitethernet 1/0/2
[SwitchA-GigabitEthernet1/0/2] port access vlan 1
[SwitchA-GigabitEthernet1/0/2] quit
```

Configure an IPv4 advanced ACL to identify data flows from Switch A to Switch B.

```
[SwitchA] acl number 3101
[SwitchA-acl-adv-3101] rule 0 permit ip source 2.2.2.1 0 destination 2.2.3.1 0
[SwitchA-acl-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchA] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchA-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchA] ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 2.2.3.1.

```
[SwitchA-ike-keychain-keychain1] pre-shared-key address 2.2.3.1 255.255.255.0 key
simple 12345zxcvb!@#$%ZXCVB
[SwitchA-ike-keychain-keychain1] quit
```

Create and configure the IKE profile named **profile1**.

```
[SwitchA] ike profile profile1
[SwitchA-ike-profile-profile1] keychain keychain1
[SwitchA-ike-profile-profile1] match remote identity address 2.2.3.1 255.255.255.0
[SwitchA-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **map1** and set the sequence number to 10.

```
[SwitchA] ipsec policy map1 10 isakmp
```

Apply ACL 3101.

```
[SwitchA-ipsec-policy-isakmp-map1-10] security acl 3101
```

Apply IPsec transform set **tran1**.

```
[SwitchA-ipsec-policy-isakmp-map1-10] transform-set tran1
```

Specify the local and remote IP addresses of the IPsec tunnel as 2.2.2.1 and 2.2.3.1.

```
[SwitchA-ipsec-policy-isakmp-map1-10] local-address 2.2.2.1
[SwitchA-ipsec-policy-isakmp-map1-10] remote-address 2.2.3.1
```

Apply IKE profile **profile1**.

```
[SwitchA-ipsec-policy-isakmp-map1-10] ike-profile profile1
[SwitchA-ipsec-policy-isakmp-map1-10] quit
```

Apply IPsec policy **map1** to VLAN interface 1.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ipsec apply policy map1
```

2. Configure Switch B:

Assign IP addresses to interfaces, as shown in Figure 8.

```
<Sysname> system-view
[Sysname] sysname SwitchB
[SwitchB] vlan 1
[SwitchB-vlan1] quit
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ip address 2.2.3.1 255.255.255.0
[SwitchB-Vlan-interface1] quit
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] port access vlan 1
[SwitchB-GigabitEthernet1/0/2] quit
```

Configure an IPv4 advanced ACL to identify data flows from Switch B to Switch A.

```
[SwitchB] acl number 3101
[SwitchB-acl-adv-3101] rule 0 permit ip source 2.2.3.1 0 destination 2.2.2.1 0
[SwitchB-acl-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchB] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchB-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchB] ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 2.2.2.1.

```
[SwitchB-ike-keychain-keychain1] pre-shared-key address 2.2.2.1 255.255.255.0 key
simple 12345zxcvb!@#$%ZXCVB
[SwitchB-ike-keychain-keychain1] quit
```

Create and configure the IKE profile named **profile1**.

```
[SwitchB] ike profile profile1
[SwitchB-ike-profile-profile1] keychain keychain1
[SwitchB-ike-profile-profile1] match remote identity address 2.2.2.1 255.255.255.0
[SwitchB-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **use1** and set the sequence number to 10.

```
[SwitchB] ipsec policy use1 10 isakmp
```

Apply ACL 3101.

```
[SwitchB-ipsec-policy-isakmp-use1-10] security acl 3101
```

Apply IPsec transform set **tran1**.

```
[SwitchB-ipsec-policy-isakmp-use1-10] transform-set tran1
```

Specify the local and remote IP addresses of the IPsec tunnel as 2.2.3.1 and 2.2.2.1.

```
[SwitchB-ipsec-policy-isakmp-use1-10] local-address 2.2.3.1
[SwitchB-ipsec-policy-isakmp-use1-10] remote-address 2.2.2.1
```

Apply IKE profile **profile1**.

```
[SwitchB-ipsec-policy-isakmp-use1-10] ike-profile profile1
[SwitchB-ipsec-policy-isakmp-use1-10] quit
```

Apply IPsec policy **use1** to VLAN-interface 1.

```
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ipsec apply policy use1
```

Verifying the configuration

Initiate a connection between Switch A and Switch B to trigger IKE negotiation. After IPsec SAs are successfully negotiated by IKE, the traffic between the two switches is IPsec-protected.

Configuration files

Example: Configuring IPsec for RIPng

Network configuration

As shown in Figure 9, Switch A, Switch B, and Switch C learn IPv6 routes through RIPng.

Establish an IPsec tunnel between the switches to protect the RIPng packets transmitted in between. Specify the security protocol as ESP, the encryption algorithm as 128-bit AES, and the authentication algorithm as HMAC-SHA1 for the IPsec tunnel.

Figure 9 Network diagram

Requirements analysis

To meet the network configuration requirements, perform the following tasks:

1. Configure basic RIPng.

   For more information about RIPng configurations, see *Layer 3—IP Routing Configuration Guide*.

2. Configure an IPsec profile.
   - The IPsec profiles on all the switches must have IPsec transform sets that use the same security protocol, authentication and encryption algorithms, and encapsulation mode.
   - The SPI and key configured for the inbound SA and those for the outbound SA must be the same on each switch.
   - The SPI and key configured for the SAs on all the switches must be the same.
3. Apply the IPsec profile to a RIPng process or to an interface.

Procedure

1. Configure Switch A:

   # Assign IP addresses to interfaces,as shown in Figure 9.

```
<Sysname> system-view
[Sysname] sysname SwitchA
[SwitchA] vlan 100
[SwitchA-vlan100] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ipv6 address 1::1/64
[SwitchA-Vlan-interface100] quit
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] port access vlan 100
[SwitchA-GigabitEthernet1/0/1] quit
```

   # Configure basic RIPng.

```
[SwitchA] ripng 1
[SwitchA-ripng-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ripng 1 enable
[SwitchA-Vlan-interface100] quit
```

   # Create and configure the IPsec transform set named **tran1**.

```
[SwitchA] ipsec transform-set tran1
```

```
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode transport
[SwitchA-ipsec-transform-set-tran1] protocol esp
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-128
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create and configure the IPsec profile named **profile001**.

```
[SwitchA] ipsec profile profile001 manual
[SwitchA-ipsec-profile-manual-profile001] transform-set tran1
[SwitchA-ipsec-profile-manual-profile001] sa spi outbound esp 123456
[SwitchA-ipsec-profile-manual-profile001] sa spi inbound esp 123456
[SwitchA-ipsec-profile-manual-profile001] sa string-key outbound esp simple abcdefg
[SwitchA-ipsec-profile-manual-profile001] sa string-key inbound esp simple abcdefg
[SwitchA-ipsec-profile-manual-profile001] quit
```

Apply the IPsec profile to RIPng process 1.

```
[SwitchA] ripng 1
[SwitchA-ripng-1] enable ipsec-profile profile001
[SwitchA-ripng-1] quit
```

2. Configure Switch B:

Assign IP addresses to interfaces,as shown in Figure 9.

```
<Sysname> system-view
[Sysname] sysname SwitchB
[SwitchB] vlan 100
[SwitchB-vlan100] quit
[SwitchB] vlan 200
[SwitchB-vlan200] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] ipv6 address 3::1/64
[SwitchB-Vlan-interface200] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ipv6 address 1::2/64
[SwitchB-Vlan-interface100] quit
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] port access vlan 100
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] port access vlan 200
[SwitchB-GigabitEthernet1/0/2] quit
```

Configure basic RIPng.

```
[SwitchB] ripng 1
[SwitchB-ripng-1] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] ripng 1 enable
[SwitchB-Vlan-interface200] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ripng 1 enable
[SwitchB-Vlan-interface100] quit
```

Create and configure the IPsec transform set named **tran1**.

```
[SwitchB] ipsec transform-set tran1
```

```
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode transport
[SwitchB-ipsec-transform-set-tran1] protocol esp
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-128
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Create and configure the IPsec profile named **profile001**.

```
[SwitchB] ipsec profile profile001 manual
[SwitchB-ipsec-profile-manual-profile001] transform-set tran1
[SwitchB-ipsec-profile-manual-profile001] sa spi outbound esp 123456
[SwitchB-ipsec-profile-manual-profile001] sa spi inbound esp 123456
[SwitchB-ipsec-profile-manual-profile001] sa string-key outbound esp simple abcdefg
[SwitchB-ipsec-profile-manual-profile001] sa string-key inbound esp simple abcdefg
[SwitchB-ipsec-profile-manual-profile001] quit
```

Apply the IPsec profile to RIPng process 1.

```
[SwitchB] ripng 1
[SwitchB-ripng-1] enable ipsec-profile profile001
[SwitchB-ripng-1] quit
```

3. Configure Switch C:

Assign IP addresses to interfaces,as shown in Figure 9.

```
<Sysname> system-view
[Sysname] sysname SwitchC
[SwitchC] vlan 100
[SwitchC-vlan100] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] ipv6 address 3::2/64
[SwitchC-Vlan-interface200] quit
[SwitchC] interface gigabitethernet 1/0/1
[SwitchC-GigabitEthernet1/0/1] port access vlan 200
[SwitchC-GigabitEthernet1/0/1] quit
```

Configure basic RIPng.

```
[SwitchC] ripng 1
[SwitchC-ripng-1] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] ripng 1 enable
[SwitchC-Vlan-interface200] quit
```

Create and configure the IPsec transform set named **tran1**.

```
[SwitchC] ipsec transform-set tran1
[SwitchC-ipsec-transform-set-tran1] encapsulation-mode transport
[SwitchC-ipsec-transform-set-tran1] protocol esp
[SwitchC-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-128
[SwitchC-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchC-ipsec-transform-set-tran1] quit
```

Create and configure the IPsec profile named **profile001**.

```
[SwitchC] ipsec profile profile001 manual
[SwitchC-ipsec-profile-manual-profile001] transform-set tran1
[SwitchC-ipsec-profile-manual-profile001] sa spi outbound esp 123456
[SwitchC-ipsec-profile-manual-profile001] sa spi inbound esp 123456
[SwitchC-ipsec-profile-manual-profile001] sa string-key outbound esp simple abcdefg
```

```
[SwitchC-ipsec-profile-manual-profile001] sa string-key inbound esp simple abcdefg
[SwitchC-ipsec-profile-manual-profile001] quit
```

Apply the IPsec profile to RIPng process 1.

```
[SwitchC] ripng 1
[SwitchC-ripng-1] enable ipsec-profile profile001
[SwitchC-ripng-1] quit
```

Verifying the configuration

After the configuration is completed, Switch A, Switch B, and Switch C learn IPv6 routing information through RIPng. IPsec SAs are set up successfully on the switches to protect RIPng packets. This example uses Switch A to verify the configuration.

Display the RIPng configuration. The output shows that IPsec profile **profile001** has been applied to RIPng process 1.

```
[SwitchA] display ripng 1
    RIPng process : 1
       Preference : 100
       Checkzero : Enabled
       Default Cost : 0
       Maximum number of load balanced routes : 8
       Update time   :   30 secs  Timeout time         :  180 secs
       Suppress time :  120 secs  Garbage-Collect time :  120 secs
       Update output delay:   20(ms)  Output count:    3
       Graceful-restart interval:   60 secs
       Triggered Interval : 5 50 200
       Number of periodic updates sent : 186
       Number of triggered updates sent : 1
       IPsec profile name: profile001
```

Display the established IPsec SAs.

```
[SwitchA] display ipsec sa
------------------------------

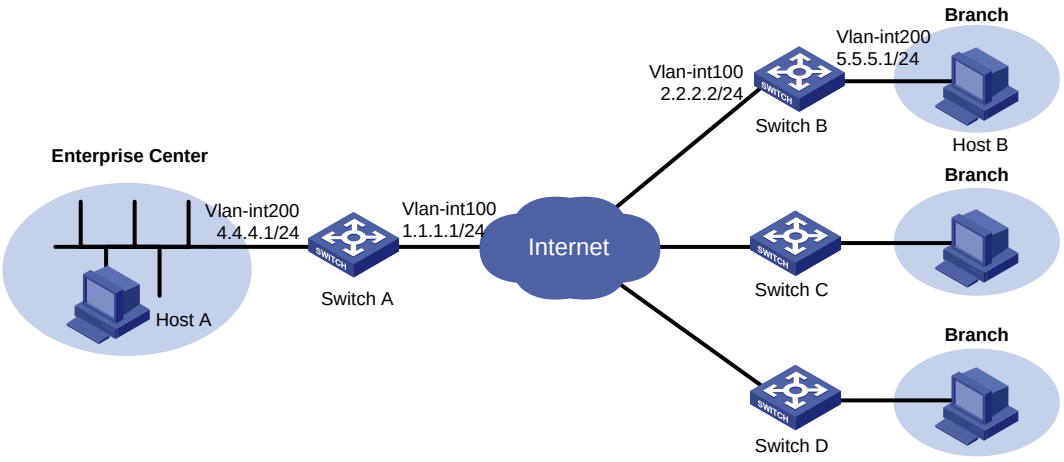
Example: Configuring IPsec RRI



Network configuration

As shown in Figure 10, branches access the enterprise center through an IPsec VPN.

Configure the IPsec VPN as follows:

- Configure an IPsec tunnel between Switch A and each branch gateway (Switch B, Switch C, and Switch D) to protect traffic between subnets 4.4.4.0/24 and 5.5.5.0/24.
- Configure the tunnels to use security protocol ESP, encryption algorithm DES, and authentication algorithm SHA1-HMAC-96. Use IKE for IPsec SA negotiation.
- Configure IKE proposal to use the preshared key authentication method, encryption algorithm 3DES, and authentication algorithm HMAC-SHA1.
- Configure IPsec RRI on Switch A to automatically create static routes to the branches based on the established IPsec SAs.

Figure 10 Network diagram

Procedure

1. Configure Switch A:

   # Assign IP addresses to interfaces, as shown in Figure 10.

```
<Sysname> system-view
[Sysname] sysname SwitchA
[SwitchA] vlan 100
[SwitchA-vlan100] quit
[SwitchA] vlan 200
[SwitchA-vlan200] quit
[SwitchA] interface vlan-interface 200
[SwitchA-Vlan-interface200] ip address 4.4.4.1 255.255.255.0
[SwitchA-Vlan-interface200] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ip address 1.1.1.1 255.255.255.0
[SwitchA-Vlan-interface100] quit
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] port access vlan 100
[SwitchA-GigabitEthernet1/0/1] quit
[SwitchA] interface gigabitethernet 1/0/2
[SwitchA-GigabitEthernet1/0/2] port access vlan 200
[SwitchA-GigabitEthernet1/0/2] quit
```

Configure settings for routing. This example configures a static route, and the next hop in the route is 1.1.1.2.

```
[SwitchA] ip route-static 2.2.2.0 24 1.1.1.2
```

Create an IPsec transform set named **tran1**, and specify **ESP** as the security protocol, **DES** as the encryption algorithm, and **HMAC-SHA-1-96** as the authentication algorithm.

```
[SwitchA] ipsec transform-set tran1
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode tunnel
[SwitchA-ipsec-transform-set-tran1] protocol esp
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm des
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create and configure the IKE profile named **profile1**.

```
[SwitchA] ike profile profile1
[SwitchA-ike-profile-profile1] keychain key1
[SwitchA-ike-profile-profile1] match remote identity address 2.2.2.2 255.255.255.0
[SwitchA-ike-profile-profile1] quit
```

Create an IPsec policy template named **temp1**. Specify IPsec transform set **tran1** and IKE profile **profile1** for the IPsec policy template.

```
[SwitchA] ipsec policy-template temp1 1
[SwitchA-ipsec-policy-template-temp1-1] transform-set tran1
[SwitchA-ipsec-policy-template-temp1-1] ike-profile profile1
```

Enable IPsec RRI, set the preference to 100 and the tag to 1000 for the static routes created by IPsec RRI.

```
[SwitchA-ipsec-policy-template-temp1-1] reverse-route dynamic
[SwitchA-ipsec-policy-template-temp1-1] reverse-route preference 100
[SwitchA-ipsec-policy-template-temp1-1] reverse-route tag 1000
[SwitchA-ipsec-policy-template-temp1-1] quit
```

Create an IKE-based IPsec policy entry by using IPsec policy template **temp1**. Specify the policy name as **map1** and set the sequence number to 10.

```
[SwitchA] ipsec policy map1 10 isakmp template temp1
```

Create an IKE proposal named **1**, and specify **3DES** as the encryption algorithm, **HMAC-SHA1** as the authentication algorithm, and **pre-share** as the authentication method.

```
[SwitchA] ike proposal 1
[SwitchA-ike-proposal-1] encryption-algorithm 3des-cbc
[SwitchA-ike-proposal-1] authentication-algorithm sha
[SwitchA-ike-proposal-1] authentication-method pre-share
[SwitchA-ike-proposal-1] quit
```

Create an IKE keychain named **key1** and specify **123** in plain text as the preshared key to be used with the remote peer at 2.2.2.2.

```
[SwitchA] ike keychain key1
[SwitchA-ike-keychain-key1] pre-shared-key address 2.2.2.2 key simple 123
[SwitchA-ike-keychain-key1] quit
```

Apply IPsec policy **map1** to VLAN-interface 100.

```
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ipsec apply policy map1
[SwitchA-Vlan-interface100] quit
```

2. Configure Switch B:

Assign IP addresses to interfaces, as shown in Figure 10.

```
<Sysname> system-view
[Sysname] sysname SwitchB
[SwitchB] vlan 100
[SwitchB-vlan100] quit
[SwitchB] vlan 200
[SwitchB-vlan200] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] ip address 5.5.5.1 255.255.255.0
[SwitchB-Vlan-interface200] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ip address 2.2.2.2 255.255.255.0
[SwitchB-Vlan-interface100] quit
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] port access vlan 100
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] port access vlan 200
[SwitchB-GigabitEthernet1/0/2] quit
```

Configure static routes. In this example, the next hop in the routes is 2.2.2.3.

```
[SwitchB] ip route-static 1.1.1.0 24 2.2.2.3
[SwitchB] ip route-static 4.4.4.0 24 2.2.2.3
```

Create an IPsec transform set named **tran1**, and specify **ESP** as the security protocol, **DES** as the encryption algorithm, and **HMAC-SHA-1-96** as the authentication algorithm.

```
[SwitchB] ipsec transform-set tran1
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode tunnel
[SwitchB-ipsec-transform-set-tran1] protocol esp
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm des
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Configure IPv4 advanced ACL 3000 to identify traffic from subnet 5.5.5.0/24 to subnet 4.4.4.0/24.

```
[SwitchB] acl advanced 3000
[SwitchB-acl-ipv4-adv-3000] rule permit ip source 5.5.5.0 0.0.0.255 destination 4.4.4.0 0.0.0.255
[SwitchB-acl-ipv4-adv-3000] quit
```

Create and configure the IKE profile named **profile1**.

```
[SwitchB] ike profile profile1
[SwitchB-ike-profile-profile1] keychain key1
[SwitchB-ike-profile-profile1] match remote identity address 1.1.1.1 255.255.255.0
[SwitchB-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry named **map1** and configure the following settings for the policy entry:

- Set the sequence number to 10.
- Specify transform set **tran1** and ACL 3000.
- Specify the remote IP address for the tunnel as 1.1.1.1.
- Specify IKE profile **profile1**.

```
[SwitchB] ipsec policy map1 10 isakmp
[SwitchB-ipsec-policy-isakmp-map1-10] transform-set tran1
[SwitchB-ipsec-policy-isakmp-map1-10] security acl 3000
[SwitchB-ipsec-policy-isakmp-map1-10] remote-address 1.1.1.1
[SwitchB-ipsec-policy-isakmp-map1-10] ike-profile profile1
[SwitchB-ipsec-policy-isakmp-map1-10] quit
```

Create an IKE proposal named **1**, and specify **3DES** as the encryption algorithm, **HMAC-SHA1** as the authentication algorithm, and **pre-share** as the authentication method.

```
[SwitchB] ike proposal 1
[SwitchB-ike-proposal-1] encryption-algorithm 3des-cbc
[SwitchB-ike-proposal-1] authentication-algorithm sha
[SwitchB-ike-proposal-1] authentication-method pre-share
[SwitchB-ike-proposal-1] quit
```

Create an IKE keychain named **key1** and specify **123** in plain text as the preshared key to be used with the remote peer at 1.1.1.1.

```
[SwitchB] ike keychain key1
[SwitchB-ike-keychain-key1] pre-shared-key address 1.1.1.1 key simple 123
[SwitchB-ike-keychain-key1] quit
```

Apply IPsec policy **map1** to VLAN-interface 100.

```
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ipsec apply policy map1
[SwitchB-Vlan-interface100] quit
```

Make sure Switch B has a route to the peer private network, with the outgoing interface as VLAN-interface 100.

3. Configure Switch C and Switch D in the same way Switch B is configured.

Verifying the configuration

1. Verify that IPsec RRI can automatically create a static route from Switch A to Switch B:

   # Initiate a connection from subnet 5.5.5.0/24 to subnet 4.4.4.0/24. IKE negotiation is triggered to establish IPsec SAs between Switch A and Switch B. (Details not shown.)

   # Verify that IPsec SAs are established on Switch A.

```
[SwitchA] display ipsec sa
```

```
------------------------------
Interface: Vlan-interface100
------------------------------

  ----------------------------
  IPsec policy: map1
  Sequence number: 10

      Anti-replay window size: 64
      UDP encapsulation used for NAT traversal: N
      Status: Active

    [Outbound ESP SAs]
      SPI: 4011716027 (0xef1dedbb)
      Connection ID: 64424509441
      Transform set: ESP-ENCRYPT-DES-CBC ESP-AUTH-SHA1
      SA duration (kilobytes/sec): 1843200/3600
      SA remaining duration (kilobytes/sec): 1843199/3590
      Max sent sequence-number: 4
      UDP encapsulation used for NAT traversal: N
      Status: Active
```

Verify that IPsec RRI has created a static route to reach Switch B.

```
[SwitchA] display ip routing-table verbose
```

2. Verify that Switch A can automatically create static routes to Switch C and Switch D in the same way that you verify the IPsec RRI feature by using Switch A and Switch B. (Details not shown.)

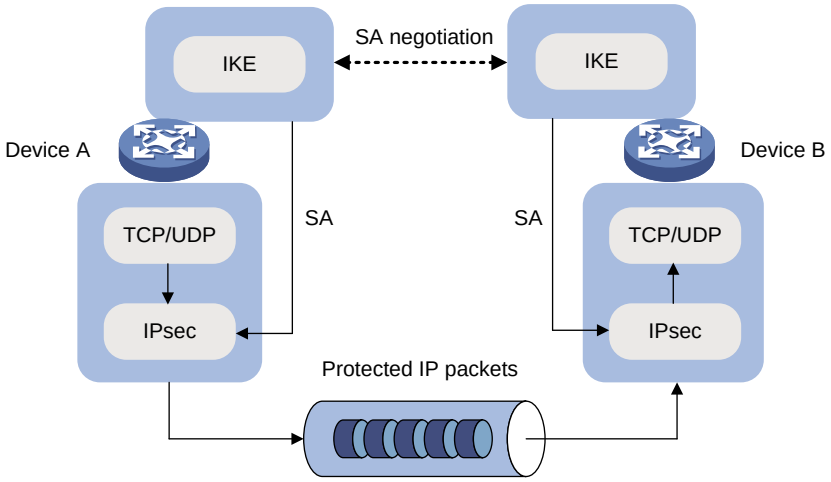
Configuring IKE

Unless otherwise specified, the term "IKE" in this chapter refers to IKEv1.

About IKE

Built on a framework defined by ISAKMP, Internet Key Exchange (IKE) provides automatic key negotiation and SA establishment services for IPsec.

Benefits of IKE



IKE provides the following benefits for IPsec:

- Automatically negotiates IPsec parameters.
- Performs DH exchanges to calculate shared keys, making sure each SA has a key that is independent of other keys.
- Automatically negotiates SAs when the sequence number in the AH or ESP header overflows, making sure IPsec can provide the anti-replay service by using the sequence number.

Relationship between IPsec and IKE

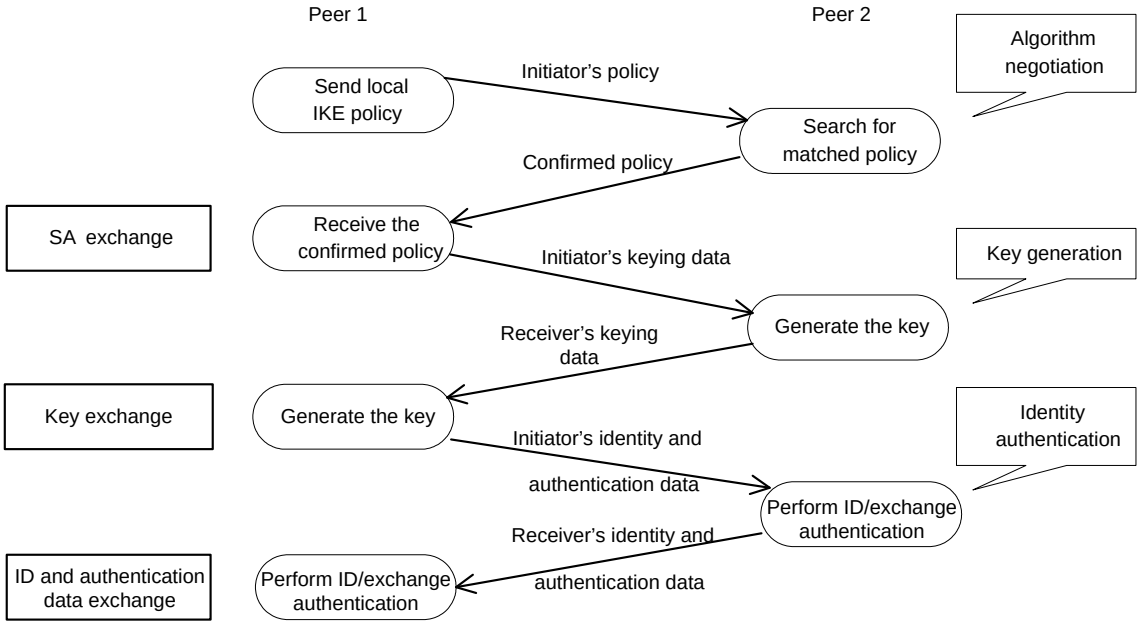
As shown in Figure 11, IKE negotiates SAs for IPsec and transfers the SAs to IPsec, and IPsec uses the SAs to protect IP packets.

Figure 11 Relationship between IKE and IPsec

IKE negotiation process

IKE negotiates keys and SAs for IPsec in two phases:

1. **Phase 1**—The two peers establish an IKE SA, a secure, authenticated channel for communication.
2. **Phase 2**—Using the IKE SA established in phase 1, the two peers negotiate to establish IPsec SAs.



Phase 1 negotiation can use either main mode or aggressive mode.

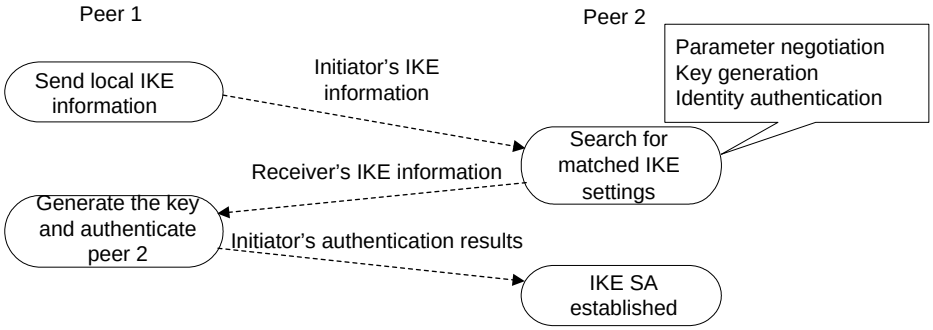
IKE exchange process in main mode

As shown in Figure 12, the main mode of IKE negotiation in phase 1 involves three pairs of messages:

- **SA exchange**—Used for negotiating the IKE security policy.
- **Key exchange**—Used for exchanging the DH public value and other values, such as the random number. The two peers use the exchanged data to generate key data and use the encryption key and authentication key to ensure the security of IP packets.
- **ID and authentication data exchange**—Used for identity authentication.

Figure 12 IKE exchange process in main mode

IKE exchange process in aggressive mode



As shown in Figure 13, the process of phase 1 IKE negotiation in aggressive mode is as follows:

1. The initiator (peer 1) sends a message containing the local IKE information to peer 2. The message includes parameters used for IKE SA establishment, keying data, and peer 1's identity information.
2. Peer 2 chooses the IKE establishment parameters to use, generate the key, and authenticate peer 1's identity. Then it sends the IKE data to peer 1.
3. Peer 1 generates the key, authenticates peer 2's identity, and sends the results to peer 1.

After the preceding process, an IKE SA is established between peer 1 and peer 2.

The aggressive mode is faster than the main mode but it does not provide identity information protection. The main mode provides identity information protection but is slower. Choose the appropriate negotiation mode according to your requirements.

Figure 13 IKE exchange process in aggressive mode

IKE security mechanism

IKE has a series of self-protection mechanisms and supports secure identity authentication, key distribution, and IPsec SA establishment on insecure networks.

Identity authentication

The IKE identity authentication mechanism is used to authenticate the identity of the communicating peers. The device supports the following identity authentication methods:

- **Preshared key authentication**—Two communicating peers use the pre-configured shared key for identity authentication.
- **RSA signature authentication** and **DSA signature authentication**—Two communicating peers use the digital certificates issued by the CA for identity authentication.

The preshared key authentication method does not require certificates and is easy to configure. It is usually deployed in small networks.

The signature authentication methods provide higher security and are usually deployed in networks with the headquarters and some branches. When deployed in a network with many branches, a signature authentication method can simplify the configuration because only one PKI domain is required. If you use the preshared key authentication method, you must configure a preshared key for each branch on the Headquarters node.

DH algorithm

The DH algorithm is a public key algorithm. With this algorithm, two peers can exchange keying material and then use the material to calculate the shared keys. Due to the decryption complexity, a third party cannot decrypt the keys even after intercepting all keying materials.

PFS

The Perfect Forward Secrecy (PFS) feature is a security feature based on the DH algorithm. After PFS is enabled, an additional DH exchange is performed in IKE phase 2 to make sure IPsec keys have no derivative relations with IKE keys and a broken key brings no threats to other keys.

Protocols and standards

- RFC 2408, *Internet Security Association and Key Management Protocol (ISAKMP)*
- RFC 2409, *The Internet Key Exchange (IKE)*
- RFC 2412, *The OAKLEY Key Determination Protocol*
- Internet Draft, *draft-ietf-ipsec-isakmp-xauth-06*
- Internet Draft, *draft-dukes-ike-mode-cfg-02*

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

IKE tasks at a glance

To configure IKE, perform the following tasks:

1. (Optional.) Configuring an IKE profile
   a. Configuring an IKE profile
   b. Configuring peer IDs for the IKE profile
   c. Specifying the IKE keychain or PKI domain
   d. Configuring the IKE phase 1 negotiation mode
   e. Specifying IKE proposals for the IKE profile
   f. Configuring the local ID for the IKE profile
   g. Configuring optional features for the IKE profile
2. Configuring an IKE proposal
3. Configuring an IKE keychain
4. (Optional.) Configuring the global identity information
5. (Optional.) Configuring the IKE keepalive feature
6. (Optional.) Configuring the IKE NAT keepalive feature
7. (Optional.) Configuring global IKE DPD
8. (Optional.) Enabling invalid SPI recovery
9. (Optional.) Setting the maximum number of IKE SAs
10. (Optional.) Configuring an IKE IPv4 address pool
11. (Optional.) Configuring SNMP notifications for IKE

Prerequisites for IKE configuration

Determine the following parameters prior to IKE configuration:

- The algorithms to be used during IKE negotiation, including the identity authentication method, encryption algorithm, authentication algorithm, and DH group.
  - Different algorithms provide different levels of protection. A stronger algorithm provides more resistance to decryption but uses more resources.
  - A DH group that uses more bits provides higher security but needs more time for processing.
- The preshared key or PKI domain for IKE negotiation. For more information about PKI, see "Configuring PKI."
- The IKE-based IPsec policies for the communicating peers. If you do not specify an IKE profile in an IPsec policy, the device selects an IKE profile for the IPsec policy. If no IKE profile is configured, the globally configured IKE settings are used. For more information about IPsec, see "Configuring IPsec."

Configuring an IKE profile

Creating an IKE profile

About this task

Perform this task to create an IKE profile.

An IKE profile is intended to provide a set of parameters for IKE negotiation.

Procedure

1. Enter system view.
   system-view
2. Create an IKE profile and enter its view.
   ike profile *profile-name*

Configuring peer IDs for the IKE profile

About this task

Perform this task to configure the peer IDs for IKE profile matching. When the device needs to select an IKE profile for IKE negotiation with a peer, it compares the received peer ID with the peer IDs of its local IKE profiles. If a match is found, it uses the IKE profile with the matching peer ID for IKE negotiation.

Restrictions and guidelines

For an IKE profile, you can configure multiple peer IDs. A peer ID configured earlier has a higher priority.

Two IKE peers must both have or both not have peer IDs configured.

Procedure

1. Enter system view.
   system-view
2. Enter IKE profile view.
   ike profile *profile-name*
3. Configure a peer ID for the IKE profile.
   match remote { **certificate** *policy-name* | **identity** { **address** { { *ipv4-address* [*mask* | *mask-length*] | **range** *low-ipv4-address high-ipv4-address* } | **ipv6** { *ipv6-address* [*prefix-length*] | **range** *low-ipv6-address high-ipv6-address* } } [**vpn-instance** *vpn-instance-name*] | **fqdn** *fqdn-name* | **user-fqdn** *user-fqdn-name* } }

Specifying the IKE keychain or PKI domain

Restrictions and guidelines

Configure the IKE keychain or PKI domain for the IKE proposals to use. To use digital signature authentication, configure a PKI domain. To use preshared key authentication, configure an IKE keychain.

Procedure

1. Enter system view.

system-view

2. Enter IKE profile view.

   ike profile *profile-name*

3. Specify the keychain for preshared key authentication or the PKI domain used to request a certificate for digital signature authentication.

   - Specify the keychain.

     keychain *keychain-name*

   - Specify the PKI domain.

     certificate domain *domain-name*

   By default, no IKE keychain or PKI domain is specified in an IKE profile.

Configuring the IKE phase 1 negotiation mode

Restrictions and guidelines

Specify the IKE phase 1 negotiation mode (main or aggressive) that the device uses as the initiator. When the device acts as the responder, it uses the IKE negotiation mode of the initiator.

Procedure

1. Enter system view.

   system-view

2. Enter IKE profile view.

   ike profile *profile-name*

3. Specify the IKE negotiation mode for phase 1.

   In non-FIPS mode:

   exchange-mode { **aggressive** | **main** }

   In FIPS mode:

   exchange-mode main

   By default, IKE negotiation in phase 1 uses the main mode.

Specifying IKE proposals for the IKE profile

Restrictions and guidelines

Specify the IKE proposals that the device can use as the initiator. An IKE proposal specified earlier has a higher priority. When the device acts as the responder, it uses the IKE proposals configured in system view to match the IKE proposals received from the initiator. If no matching proposal is found, the negotiation fails.

Procedure

1. Enter system view.

   system-view

2. Enter IKE profile view.

   ike profile *profile-name*

3. Specify IKE proposals for the IKE profile.

   proposal *proposal-number*&<1-6>

   By default, no IKE proposals are specified for an IKE profile and the IKE proposals configured in system view are used for IKE negotiation.

Configuring the local ID for the IKE profile

Restrictions and guidelines

For digital signature authentication, the device can use an ID of any type. If the local ID is an IP address that is different from the IP address in the local certificate, the device uses the FQDN (the device name configured by using the **sysname** command) instead.

For preshared key authentication, the device can use an ID of any type other than the DN.

Procedure

1. Enter system view.

   system-view

2. Enter IKE profile view.

   ike profile *profile-name*

3. Configure the local ID.

   local-identity { **address** { *ipv4-address* | **ipv6** *ipv6-address* } | **dn** | **fqdn** [*fqdn-name*] | **user-fqdn** [*user-fqdn-name*] }

   By default, no local ID is configured for an IKE profile, and an IKE profile uses the local ID configured in system view. If the local ID is not configured in system view, the IKE profile uses the IP address of the interface to which the IPsec policy or IPsec policy template is applied as the local ID.

Configuring optional features for the IKE profile

1. Enter system view.

   system-view

2. Enter IKE profile view.

   ike profile *profile-name*

3. Configure optional features as needed.

   - Configure IKE DPD.

     dpd interval *interval* [**retry** *seconds*] { **on-demand** | **periodic** }

     By default, IKE DPD is not configured for an IKE profile and an IKE profile uses the DPD settings configured in system view. If IKE DPD is not configured in system view either, the device does not perform dead IKE peer detection.

     The IKE DPD settings configured in the IKE profile view take precedence over those configured in system view.

   - Specify the local interface or IP address to which the IKE profile can be applied.

     match local address { *interface-type interface-number* | { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] }

     By default, an IKE profile can be applied to any local interface or IP address.

     An IKE profile configured with this command has a higher priority over those not configured with this command.

   - Specify a priority for the IKE profile.

     priority *priority*

     By default, the priority of an IKE profile is 100.

     The device selects a local IKE profile for IKE negotiation as follows:

     – First, it selects an IKE profile with the **match local address** command configured.

- If a tie exists, it selects the IKE profile with a smaller priority number.
- If a tie still exists, it selects the IKE profile configured earlier.

- Enable client authentication.

  client-authentication xauth

  By default, client authentication is disabled.

  This feature is typically used on the IPsec gateway at the enterprise center. It enables the IPsec gateway to perform extended (XAUTH) authentication on remote users through AAA after IKE phase 1 negotiation. AAA configuration is also required on the IPsec gateway for client authentication.

- Enable AAA authorization.

  aaa authorization domain *domain-name* **username** *user-name*

  By default, AAA authorization is disabled.

  The AAA authorization feature enables IKE to request authorization attributes, such as the IKE IPv4 address pool, from AAA. IKE uses the address pool to assign IPv4 addresses to remote users. For more information about AAA authorization, see "Configuring AAA."

Configuring an IKE proposal

About this task

An IKE proposal defines a set of attributes describing how IKE negotiation in phase 1 should take place. You can create multiple IKE proposals with different priorities. The priority of an IKE proposal is represented by its sequence number. The lower the sequence number, the higher the priority.

Two peers must have at least one matching IKE proposal for successful IKE negotiation. During IKE negotiation:

- The initiator sends its IKE proposals to the peer.
  - If the initiator is using an IPsec policy with an IKE profile, the initiator sends all IKE proposals specified in the IKE profile to the peer. An IKE proposal specified earlier for the IKE profile has a higher priority.
  - If the initiator is using an IPsec policy with no IKE profile, the initiator sends all its IKE proposals to the peer. An IKE proposal with a smaller number has a higher priority.
- The peer searches its own IKE proposals for a match. The search starts from the IKE proposal with the highest priority and proceeds in descending order of priority until a match is found. The matching IKE proposals are used to establish the IKE SA. If all user-defined IKE proposals are found mismatching, the two peers use their default IKE proposals to establish the IKE SA.

Two matching IKE proposals have the same encryption algorithm, authentication method, authentication algorithm, and DH group. The SA lifetime takes the smaller one of the two proposals' SA lifetime settings.

Procedure

1. Enter system view.

   system-view

2. Create an IKE proposal and enter its view.

   ike proposal *proposal-number*

   By default, a default IKE proposal exists.

3. Configure a description for the IKE proposal.

   description

   By default, an IKE proposal does not have a description.

4. Specify an encryption algorithm for the IKE proposal.

In non-FIPS mode:

encryption-algorithm { **3des-cbc** | **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** | **des-cbc** | **sm1-cbc-128** | **sm1-cbc-192** | **sm1-cbc-256** | **sm4-cbc** }

By default, the 56-bit DES encryption algorithm in CBC mode is used .

In FIPS mode:

encryption-algorithm { **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** }

By default, the 128-bit AES encryption algorithm in CBC mode is used.

5. Specify an authentication method for the IKE proposal.

   In non-FIPS mode:

   authentication-method { **dsa-signature** | **ecdsa-signature** | **pre-share** | **rsa-signature** }

   In FIPS mode:

   authentication-method { **ecdsa-signature** | **pre-share** | **rsa-signature** }

   By default, the preshared key authentication method is used.

6. Specify an authentication algorithm for the IKE proposal.

   authentication-algorithm { **md5** | **sha** | **sha256** | **sha384** | **sha512** | **sm3** }

   By default, the HMAC-SHA1 authentication algorithm is used.

7. Specify a DH group for key negotiation in phase 1.

   In non-FIPS mode:

   dh { **group1** | **group14** | **group19** | **group2** | **group20** | **group24** | **group5** }

   DH group 1 (the 768-bit DH group) is used by default.

   In FIPS mode:

   dh { **group14** | **group19** | **group20** | **group24** }

   DH group 14 (the 2048-bit DH group) is used by default.

8. (Optional.) Set the IKE SA lifetime for the IKE proposal.

   sa duration *seconds*

   By default, the IKE SA lifetime is 86400 seconds.

Configuring an IKE keychain

About this task

Perform this task when you configure the IKE to use the preshared key for authentication.

Follow these guidelines when you configure an IKE keychain:

- Two peers must be configured with the same preshared key to pass preshared key authentication.
- You can specify the local address configured in IPsec policy or IPsec policy template view (using the **local-address** command) for the IKE keychain to be applied. If no local address is configured, specify the IP address of the interface that uses the IPsec policy.
- The device determines the priority of an IKE keychain as follows:
  a. The device examines the existence of the **match local address** command. An IKE keychain with the **match local address** command configured has a higher priority.
  b. If a tie exists, the device compares the priority numbers. An IKE keychain with a smaller priority number has a higher priority.
  c. If a tie still exists, the device prefers an IKE keychain configured earlier.

Procedure

1. Enter system view.

   system-view

2. Create an IKE keychain and enter its view.

   ike keychain *keychain-name* [**vpn-instance** *vpn-instance-name*]

3. Configure a preshared key.

   In non-FIPS mode:

   pre-shared-key { **address** { *ipv4-address* [*mask* | *mask-length*] | **ipv6** *ipv6-address* [*prefix-length*] } | **hostname** *host-name* } **key** { **cipher** | **simple** } *string*

   In FIPS mode:

   pre-shared-key { **address** { *ipv4-address* [*mask* | *mask-length*] | **ipv6** *ipv6-address* [*prefix-length*] } | **hostname** *host-name* } **key** [**cipher** *string*]

   By default, no preshared key is configured.

4. (Optional.) Specify a local interface or IP address to which the IKE keychain can be applied.

   match local address { *interface-type interface-number* | { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] }

   By default, an IKE keychain can be applied to any local interface or IP address.

5. (Optional.) Specify a priority for the IKE keychain.

   priority *priority*

   The default priority is 100.

Configuring the global identity information

Restrictions and guidelines

The global identity can be used by the device for all IKE SA negotiations, and the local identity (set by the **local-identity** command) can be used only by the device that uses the IKE profile.

When signature authentication is used, you can set any type of the identity information.

When preshared key authentication is used, you cannot set the DN as the identity.

Procedure

1. Enter system view.

   system-view

2. Configure the global identity to be used by the local end.

   ike identity { **address** { *ipv4-address* | **ipv6** *ipv6-address* }| **dn** | **fqdn** [*fqdn-name*] | **user-fqdn** [*user-fqdn-name*] }

   By default, the IP address of the interface to which the IPsec policy or IPsec policy template is applied is used as the IKE identity.

3. (Optional.) Configure the local device to always obtain the identity information from the local certificate for signature authentication.

   ike signature-identity from-certificate

   By default, the local end uses the identity information specified by **local-identity** or **ike identity** for signature authentication.

Configure this command when the aggressive mode and signature authentication are used and the device interconnects with a Comware 5-based peer device. Comware 5 supports only DN for signature authentication.

Configuring the IKE keepalive feature

About this task

IKE sends keepalive packets to query the liveness of the peer. If the peer is configured with the keepalive timeout time, you must configure the keepalive interval on the local device. If the peer receives no keepalive packets during the timeout time, the IKE SA is deleted along with the IPsec SAs it negotiated.

Restrictions and guidelines

Configure IKE DPD instead of IKE keepalive unless IKE DPD is not supported on the peer. The IKE keepalive feature sends keepalives at regular intervals, which consumes network bandwidth and resources.

The keepalive timeout time configured on the local device must be longer than the keepalive interval configured at the peer. Since it seldom occurs that more than three consecutive packets are lost on a network, you can set the keepalive timeout three times as long as the keepalive interval.

Procedure

1. Enter system view.
   `system-view`
2. Set the IKE SA keepalive interval.
   `ike keepalive interval` *`interval`*
   By default, no keepalives are sent to the peer.
3. Set the IKE SA keepalive timeout time.
   `ike keepalive timeout` *`seconds`*
   By default, IKE SA keepalive never times out.

Configuring the IKE NAT keepalive feature

About this task

If IPsec traffic passes through a NAT device, you must configure the NAT traversal feature. If no packet travels across an IPsec tunnel in a period of time, the NAT sessions are aged and deleted, disabling the tunnel from transmitting data to the intended end. To prevent NAT sessions from being aged, configure the NAT keepalive feature on the IKE gateway behind the NAT device to send NAT keepalive packets to its peer periodically to keep the NAT session alive.

Procedure

1. Enter system view.
   `system-view`
2. Set the IKE NAT keepalive interval.
   `ike nat-keepalive` *`seconds`*
   The default interval is 20 seconds.

Configuring global IKE DPD

About this task

DPD detects dead peers. It can operate in periodic mode or on-demand mode.

- **Periodic DPD**—Sends a DPD message at regular intervals. It features an earlier detection of dead peers, but consumes more bandwidth and CPU.
- **On-demand DPD**—Sends a DPD message based on traffic. When the device has traffic to send and is not aware of the liveness of the peer, it sends a DPD message to query the status of the peer. If the device has no traffic to send, it never sends DPD messages. As a best practice, use the on-demand mode.

The IKE DPD works as follows:

1. The local device sends a DPD message to the peer, and waits for a response from the peer.
2. If the peer does not respond within the retry interval specified by the **retry** *seconds* parameter, the local device resends the message.
3. If still no response is received within the retry interval, the local end sends the DPD message again. The system allows a maximum of four retries.
4. If the local device receives no response after two retries, the device considers the peer to be dead, and deletes the IKE SA along with the IPsec SAs it negotiated.
5. If the local device receives a response from the peer during the detection process, the peer is considered alive. The local device performs a DPD detection again when the triggering interval is reached or it has traffic to send, depending on the DPD mode.

Restrictions and guidelines

When DPD settings are configured in both IKE profile view and system view, the DPD settings in IKE profile view apply. If DPD is not configured in IKE profile view, the DPD settings in system view apply.

It is a good practice to set the triggering interval longer than the retry interval so that a DPD detection is not triggered during a DPD retry.

Procedure

1. Enter system view.

   system-view

2. Enable sending IKE DPD messages.

   ike dpd interval *interval* [**retry** *seconds*] { **on-demand** | **periodic** }

   By default, IKE DPD is disabled.

Enabling invalid SPI recovery

About this task

An IPsec "black hole" occurs when one IPsec peer fails (for example, a peer can fail if a reboot occurs). One peer fails and loses its SAs with the other peer. When an IPsec peer receives a data packet for which it cannot find an SA, an invalid SPI is encountered. The peer drops the data packet and tries to send an SPI invalid notification to the data originator. This notification is sent by using the IKE SA. Because no IKE SA is available, the notification is not sent. The originating peer continues sending the data by using the IPsec SA that has the invalid SPI, and the receiving peer keeps dropping the traffic.

The invalid SPI recovery feature enables the receiving peer to set up an IKE SA with the originator so that an SPI invalid notification can be sent. Upon receiving the notification, the originating peer deletes the IPsec SA that has the invalid SPI. If the originator has data to send, new SAs will be set up.

Restrictions and guidelines

Use caution when you enable the invalid SPI recovery feature because using this feature can result in a DoS attack. Attackers can make a great number of invalid SPI notifications to the same peer.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable invalid SPI recovery.
   ```
   ike invalid-spi-recovery enable
   ```
   By default, the invalid SPI recovery is disabled.

Setting the maximum number of IKE SAs

About this task

You can set the maximum number of half-open IKE SAs and the maximum number of established IKE SAs.

- The supported maximum number of half-open IKE SAs depends on the device's processing capability. Adjust the maximum number of half-open IKE SAs to make full use of the device's processing capability without affecting the IKE SA negotiation efficiency.
- The supported maximum number of established IKE SAs depends on the device's memory space. Adjust the maximum number of established IKE SAs to make full use of the device's memory space without affecting other applications in the system.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Set the maximum number of half-open IKE SAs and the maximum number of established IKE SAs.
   ```
   ike limit { max-negotiating-sa negotiation-limit | max-sa sa-limit }
   ```
   By default, there is no limit to the maximum number of IKE SAs.

Configuring an IKE IPv4 address pool

About this task

To perform centralized management on remote users, an IPsec gateway can use an IPv4 address pool to assign private IPv4 addresses to remote users.

You must use an IKE IPv4 address pool together with AAA authorization by specifying the IKE IPv4 address pool as an AAA authorization attribute. For more information about AAA authorization, see "Configuring AAA."

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Configure an IKE IPv4 address pool.
   ```
   ike address-group group-name start-ipv4-address end-ipv4-address
   [ mask | mask-length ]
   ```

Configuring IKE logging

About this task

IKE logging provides you with records of important IKE configuration and negotiation events.

- IKE negotiation event logging generates log entries at the beginning and end of IKE negotiation phases and during key exchange and security parameters negotiation. An IKE negotiation event log entry primarily includes the source and destination IP addresses, source and destination ports, and initiator and responder. If the negotiation fails, the log entry also includes the reason for negotiation failure.
- IKE configuration event logging primarily records IKE proposal creation and deletion events. An IKE configuration log entry primarily includes proposal number information.

If you execute this command multiple times, the most recent configuration takes effect.

Restrictions and guidelines

This command is not available in FIPS mode.

Procedure

1. Enter system view.

   system-view
2. Enable IKE logging for event types of interest.

   ike logging { **config** | **negotiation** } * **enable**

   By default, IKE logging is disabled.

Configuring SNMP notifications for IKE

About this task

After you enable SNMP notifications for IKE, the IKE module notifies the NMS of important module events. The notifications are sent to the device's SNMP module. For the notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP notifications, see *Network Management and Monitoring Configuration Guide*.

To generate and output SNMP notifications for a specific IKE failure or event type, perform the following tasks:

1. Enable SNMP notifications for IKE globally.
2. Enable SNMP notifications for the failure or event type.

Procedure

1. Enter system view

   system-view
2. Enable SNMP notifications for IKE globally.

   snmp-agent trap enable ike global

   By default, SNMP notifications for IKE are disabled.
3. Enable SNMP notifications for the specified failure or event types.

   snmp-agent trap enable ike [**attr-not-support** | **auth-failure** | **cert-type-unsupport** | **cert-unavailable** | **cert-verify-failure** | **decrypt-failure** | **encrypt-failure** | **invalid-cert-auth** | **invalid-cookie** | **invalid-id** | **invalid-proposal** | **invalid-protocol** | **invalid-sign** | **no-sa-failure** | **p1sa-failure** | **p2sa-failure** |

p2sa-terminate | **proposal-add** | **proposal-delete** | **tunnel-start** | **tunnel-stop** | **unsupport-exch-type**] *

By default, SNMP notifications for all failure and event types are disabled.

Display and maintenance commands for IKE

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display configuration information about all IKE proposals.	**display ike proposal**
Display information about the current IKE SAs.	**display ike sa** [**verbose** [**connection-id** *connection-id*	**remote-address** [**ipv6**] *remote-address* [**vpn-instance** *vpn-instance-name*]]]
Display IKE statistics.	**display ike statistics**
Delete IKE SAs.	**reset ike sa** [**connection-id** *connection-id*]
Clear IKE MIB statistics.	**reset ike statistics**

IKE configuration examples

Example: Configuring main-mode IKE with preshared key authentication

Network configuration

As shown in Figure 14, configure an IKE-based IPsec tunnel between Switch A and Switch B to secure the communication between the switches.

- Configure the two switches to use the default IKE proposal for the IKE negotiation.
- Configure the two switches to use the preshared key authentication method for the IKE negotiation.

Figure 14 Network diagram

Procedure

1. Make sure Switch A and Switch B can reach each other.
2. Configure Switch A:

   # Assign IP addresses to interfaces.

   ```
   <SwitchA> system-view
   [SwitchA] vlan 1
   ```

```
[SwitchA-vlan1] quit
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] port access vlan 1
[SwitchA-GigabitEthernet1/0/1] quit
[SwitchA] interface vlan-interface 1
[SwitchA-vlan-interface1] ip address 1.1.1.1 255.255.0.0
[SwitchA-vlan-interface1] quit
```

Configure a static route to Switch B. In this example, the next hop in the route is 1.1.1.2.

```
[SwitchA] ip route-static 2.2.0.0 255.255.0.0 1.1.1.2
```

Configure IPv4 advanced ACL 3101 to identify the traffic from Switch A to Switch B.

```
[SwitchA] acl advanced 3101
[SwitchA-acl-ipv4-adv-3101] rule 0 permit ip source 1.1.1.1 0 destination 2.2.2.2 0
[SwitchA-acl-ipv4-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchA] ipsec transform-set tran1
```

Set the packet encapsulation mode to **tunnel**.

```
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Use the ESP protocol for the IPsec transform set.

```
[SwitchA-ipsec-transform-set-tran1] protocol esp
```

Specify the encryption and authentication algorithms.

```
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchA] ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 2.2.2.2.

```
[SwitchA-ike-keychain-keychain1] pre-shared-key address 2.2.2.2 255.255.0.0 key
simple 12345zxcvb!@#$%ZXCVB
[SwitchA-ike-keychain-keychain1] quit
```

Create an IKE profile named **profile1**.

```
[SwitchA] ike profile profile1
```

Specify IKE keychain **keychain1**.

```
[SwitchA-ike-profile-profile1] keychain keychain1
```

Configure a peer ID with the identity type as IP address and the value as **2.2.2.2/16**.

```
[SwitchA-ike-profile-profile1] match remote identity address 2.2.2.2 255.255.0.0
[SwitchA-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **map1** and set the sequence number to 10.

```
[SwitchA] ipsec policy map1 10 isakmp
```

Specify the remote IP address 2.2.2.2 for the IPsec tunnel.

```
[SwitchA-ipsec-policy-isakmp-map1-10] remote-address 2.2.2.2
```

Specify ACL 3101 to identify the traffic to be protected.

```
[SwitchA-ipsec-policy-isakmp-map1-10] security acl 3101
```

Specify IPsec transform set **tran1** for the IPsec policy.

```
[SwitchA-ipsec-policy-isakmp-map1-10] transform-set tran1
```

Specify IKE profile **profile1** for the IPsec policy.

```
[SwitchA-ipsec-policy-isakmp-map1-10] ike-profile profile1
[SwitchA-ipsec-policy-isakmp-map1-10] quit
```

Apply IPsec policy **map1** to VLAN-interface 1.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ipsec apply policy map1
```

3. Configure Switch B:

Assign IP addresses to interfaces.

```
<SwitchB> system-view
[SwitchB] vlan 1
[SwitchB-vlan1] quit
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] port access vlan 1
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface Vlan-interface1
[SwitchB-Vlan-interface1] ip address 2.2.2.2 255.255.0.0
[SwitchB-Vlan-interface1] quit
```

Configure a static route to Switch A. In this example, the next hop in the route is 2.2.2.3.

```
[SwitchB] ip route-static 1.1.0.0 255.255.0.0 2.2.2.3
```

Configure IPv4 advanced ACL 3101 to identify the traffic from Switch B to Switch A.

```
[SwitchB] acl number 3101
[SwitchB-acl-adv-3101] rule 0 permit ip source 2.2.2.2 0 destination 1.1.1.1 0
[SwitchB-acl-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchB] ipsec transform-set tran1
```

Set the packet encapsulation mode to **tunnel**.

```
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Use the ESP protocol for the IPsec transform set.

```
[SwitchB-ipsec-transform-set-tran1] protocol esp
```

Specify the encryption and authentication algorithms.

```
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchB]ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 1.1.1.1.

```
[SwitchB-ike-keychain-keychain1] pre-shared-key address 1.1.1.1 255.255.0.0 key
simple 12345zxcvb!@#$%ZXCVB
[SwitchB-ike-keychain-keychain1] quit
```

Create an IKE profile named **profile1**.

```
[SwitchB] ike profile profile1
```

Specify IKE keychain **keychain1**

```
[SwitchB-ike-profile-profile1] keychain keychain1
```

Configure a peer ID with the identity type as IP address and the value as **1.1.1.1/16**.

```
[SwitchB-ike-profile-profile1] match remote identity address 1.1.1.1 255.255.0.0
[SwitchB-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **use1** and set the sequence number to 10.

```
[SwitchB] ipsec policy use1 10 isakmp
```

Specify the remote IP address 1.1.1.1 for the IPsec tunnel.

```
[SwitchB-ipsec-policy-isakmp-use1-10] remote-address 1.1.1.1
```

Specify ACL 3101 to identify the traffic to be protected.

```
[SwitchB-ipsec-policy-isakmp-use1-10] security acl 3101
```

Specify IPsec transform set **tran1** for the IPsec policy.

```
[SwitchB-ipsec-policy-isakmp-use1-10] transform-set tran1
```

Specify IKE profile **profile1** for the IPsec policy.

```
[SwitchB-ipsec-policy-isakmp-use1-10] ike-profile profile1
[SwitchB-ipsec-policy-isakmp-use1-10] quit
```

Apply IPsec policy **use1** to VLAN-interface 1.

```
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ipsec apply policy use1
```

Verifying the configuration

Initiate a connection between Switch A and Switch B to trigger IKE negotiation. After IPsec SAs are successfully negotiated by IKE, the traffic between the two switches is IPsec-protected.

Configuration files

Switch A

```
#
sysname SwitchA
#
vlan 1
#
interface gigabitethernet 1/0/1
port access vlan 1
#

#
```

Example: Configuring an IKE-based IPsec tunnel for IPv4 packets

Network configuration

As shown in Figure 15, establish an IPsec tunnel between Switch A and Switch B to protect data flows between the switches. Configure the IPsec tunnel as follows:

- Specify the encapsulation mode as tunnel, the security protocol as ESP, the encryption algorithm as AES-CBC-192, and the authentication algorithm as HMAC-SHA1.
- Set up SAs through IKE negotiation.

Figure 15 Network diagram

Procedure

1. Configure Switch A:

Assign IP addresses to interfaces.

```
<SwitchA> system-view
[SwitchA] vlan 1
[SwitchA-vlan1] quit
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] port access vlan 1
[SwitchA-GigabitEthernet1/0/1] quit
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ip address 2.2.2.1 255.255.255.0
[SwitchA-Vlan-interface1] quit
```

Configure a static route to Switch B. In this example, the next hop in the route is 2.2.2.3.

```
[SwitchA] ip route-static 2.2.3.0 255.255.255.0 2.2.2.3
```

Configure an IPv4 advanced ACL to identify the data flows from Switch A to Switch B.

```
[SwitchA] acl advanced 3101
[SwitchA-acl-ipv4-adv-3101] rule 0 permit ip source 2.2.2.1 0 destination 2.2.3.1 0
[SwitchA-acl-ipv4-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchA] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchA-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchA] ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 2.2.3.1.

```
[SwitchA-ike-keychain-keychain1] pre-shared-key address 2.2.3.1 255.255.255.0 key simple 12345zxcvb!@#$%ZXCVB
[SwitchA-ike-keychain-keychain1] quit
```

Create and configure an IKE profile named **profile1**.

```
[SwitchA] ike profile profile1
[SwitchA-ike-profile-profile1] keychain keychain1
[SwitchA-ike-profile-profile1] match remote identity address 2.2.3.1 255.255.255.0
[SwitchA-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **map1** and set the sequence number to 10.

```
[SwitchA] ipsec policy map1 10 isakmp
```

Specify ACL 3101.

```
[SwitchA-ipsec-policy-isakmp-map1-10] security acl 3101
```

Specify IPsec transform set **tran1**.

```
[SwitchA-ipsec-policy-isakmp-map1-10] transform-set tran1
```

Specify the local and remote IP addresses of the IPsec tunnel as 2.2.2.1 and 2.2.3.1.

```
[SwitchA-ipsec-policy-isakmp-map1-10] local-address 2.2.2.1
[SwitchA-ipsec-policy-isakmp-map1-10] remote-address 2.2.3.1
```

Specify IKE profile **profile1**.

```
[SwitchA-ipsec-policy-isakmp-map1-10] ike-profile profile1
[SwitchA-ipsec-policy-isakmp-map1-10] quit
```

Apply IPsec policy **map1** to VLAN-interface 1.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ipsec apply policy map1
```

2. Configure Switch B:

Assign IP addresses to interfaces.

```
<SwitchB> system-view
[SwitchB] vlan 1
[SwitchB-vlan1] quit
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] port access vlan 1
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ip address 2.2.3.1 255.255.255.0
[SwitchB-Vlan-interface1] quit
```

Configure a static route to Switch A. In this example, the next hop in the route is 3.3.3.2.

```
[SwitchB] ip route-static 2.2.2.0 255.255.255.0 3.3.3.2
```

Configure an IPv4 advanced ACL to identify the data flows from Switch B to Switch A.

```
[SwitchB] acl advanced 3101
[SwitchB-acl-ipv4-adv-3101] rule 0 permit ip source 2.2.3.1 0 destination 2.2.2.1 0
[SwitchB-acl-ipv4-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchB] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchB-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchB] ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 2.2.2.1.

```
[SwitchB-ike-keychain-keychain1] pre-shared-key address 2.2.2.1 255.255.255.0 key
simple 12345zxcvb!@#$%ZXCVB
[SwitchB-ike-keychain-keychain1] quit
```

Create and configure an IKE profile named **profile1**.

```
[SwitchB] ike profile profile1
[SwitchB-ike-profile-profile1] keychain keychain1
[SwitchB-ike-profile-profile1] match remote identity address 2.2.2.1 255.255.255.0
[SwitchB-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **use1** and set the sequence number to 10.

```
[SwitchB] ipsec policy use1 10 isakmp
```

Specify ACL 3101.

```
[SwitchB-ipsec-policy-isakmp-use1-10] security acl 3101
```

Specify IPsec transform set **tran1**.

```
[SwitchB-ipsec-policy-isakmp-use1-10] transform-set tran1
```

Specify the local and remote IP addresses of the IPsec tunnel as 2.2.3.1 and 2.2.2.1.

```
[SwitchB-ipsec-policy-isakmp-use1-10] local-address 2.2.3.1
[SwitchB-ipsec-policy-isakmp-use1-10] remote-address 2.2.2.1
```

Specify IKE profile **profile1**.

```
[SwitchB-ipsec-policy-isakmp-use1-10] ike-profile profile1
[SwitchB-ipsec-policy-isakmp-use1-10] quit
```

Apply IPsec policy **use1** to VLAN-interface 1.

```
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ipsec apply policy use1
```

Verifying the configuration

Initiate a connection between Switch A and Switch B to trigger IKE negotiation. After IPsec SAs are successfully negotiated by IKE, the traffic between the two switches is IPsec-protected.

Configuration files

Switch A

```
#
sysname SwitchA
#
vlan 1
#
interface gigabitethernet 1/0/1
port access vlan 1
#
```

```

ipsec apply policy use1
#
```

Troubleshooting IKE

IKE negotiation failed because no matching IKE proposals were found

Symptom

1. The IKE SA is in Unknown state.

```
<Sysname> display ike sa
    Connection-ID   Remote                Flag         DOI
-----------------------------------------------------------------
    1               192.168.222.5         Unknown      IPsec
Flags:
RD--READY RL--REPLACED FD-FADING RK-REKEY
```

2. When IKE event debugging and packet debugging are enabled, the following messages appear:

   IKE event debugging message:

   ```
   The attributes are unacceptable.
   ```

   IKE packet debugging message:

   ```
   Construct notification packet: NO_PROPOSAL_CHOSEN.
   ```

Analysis

Certain IKE proposal settings are incorrect.

Solution

1. Examine the IKE proposal configuration to see whether the two ends have matching IKE proposals.

2. Modify the IKE proposal configuration to make sure the two ends have matching IKE proposals.

IKE negotiation failed because no IKE proposals or IKE keychains are specified correctly

Symptom

1. The IKE SA is in Unknown state.

```
<Sysname> display ike sa
    Connection-ID   Remote                Flag         DOI
-----------------------------------------------------------------
    1               192.168.222.5         Unknown      IPsec
Flags:
RD--READY RL--REPLACED FD-FADING RK-REKEY
```

2. The following IKE event debugging or packet debugging message appeared:

   IKE event debugging message:

```
Notification PAYLOAD_MALFORMED is received.
```

   IKE packet debugging message:

```
Construct notification packet: PAYLOAD_MALFORMED.
```

Analysis

- If the following debugging information appeared, the matched IKE profile is not using the matched IKE proposal:

```
Failed to find proposal 1 in profile profile1.
```

- If the following debugging information appeared, the matched IKE profile is not using the matched IKE keychain:

```
Failed to find keychain keychain1 in profile profile1.
```

Solution

- Verify that the matched IKE proposal (IKE proposal 1 in this debugging message example) is specified for the IKE profile (IKE profile 1 in the example).
- Verify that the matched IKE keychain (IKE keychain 1 in this debugging message example) is specified for the IKE profile (IKE profile 1 in the example).

IPsec SA negotiation failed because no matching IPsec transform sets were found

Symptom

1. The **`display ike sa`** command shows that the IKE SA negotiation succeeded and the IKE SA is in RD state, but the **`display ipsec sa`** command shows that the expected IPsec SA has not been negotiated yet.
2. The following IKE debugging message appeared:

```
The attributes are unacceptable.
```

   Or:

```
Construct notification packet: NO_PROPOSAL_CHOSEN.
```

Analysis

Certain IPsec policy settings are incorrect.

Solution

1. Examine the IPsec configuration to see whether the two ends have matching IPsec transform sets.
2. Modify the IPsec configuration to make sure the two ends have matching IPsec transform sets.

IPsec SA negotiation failed due to invalid identity information

Symptom

1. The **display ike sa** command shows that the IKE SA negotiation succeeded and the IKE SA is in RD state, but the **display ipsec sa** command shows that the expected IPsec SA has not been negotiated yet.
2. The following IKE debugging message appeared:

   ```
   Notification INVALID_ID_INFORMATION is received.
   ```

   Or:

   ```
   Failed to get IPsec policy when renegotiating IPsec SA. Delete IPsec SA.
   Construct notification packet: INVALID_ID_INFORMATION.
   ```

Analysis

Certain IPsec policy settings of the responder are incorrect. Verify the settings as follows:

1. Use the **display ike sa verbose** command to verify that matching IKE profiles were found in IKE negotiation phase 1. If no matching IKE profiles were found and the IPsec policy is using an IKE profile, the IPsec SA negotiation fails.

   # Identify whether matching IKE profiles were found in IKE negotiation phase 1. The following output shows that no matching IKE profile was found:

   ```
   <Sysname> display ike sa verbose
      ---------------------------------------------
      Connection ID: 3
      Outside VPN:
      Inside VPN:
      Profile:
      Transmitting entity: Responder
      ---------------------------------------------
      Local IP: 192.168.222.5
      Local ID type: IPV4_ADDR
      Local ID: 192.168.222.5

      Remote IP: 192.168.222.71
      Remote ID type: IPV4_ADDR
      Remote ID: 192.168.222.71

      Authentication-method: PRE-SHARED-KEY
      Authentication-algorithm: MD5
      Encryption-algorithm: 3DES-CBC

      Life duration(sec): 86400
      Remaining key duration(sec): 85847
      Exchange-mode: Main
      Diffie-Hellman group: Group 1
   ```

```
   NAT traversal: Not detected
```

Identify whether the IPsec policy is using an IKE profile. The following output shows that the IPsec policy is using an IKE profile.

```
[Sysname] display ipsec policy
-----------------------------------------
IPsec Policy: policy1
Interface: GigabitEthernet1/0/1
-----------------------------------------

  ----------------------------
  Sequence number: 1
  Mode: ISAKMP
  ----------------------------
  Description:
  Security data flow: 3000
  Selector mode: aggregation
  Local address: 192.168.222.5
  Remote address: 192.168.222.71
  Transform set:  transform1
  IKE profile: profile1
  SA duration(time based):
  SA duration(traffic based):
  SA idle time:
```

2. Verify that the ACL specified for the IPsec policy is correctly configured. If the flow range defined by the responder's ACL is smaller than that defined by the initiator's ACL, IPsec proposal matching will fail.

For example, if the initiator's ACL defines a flow from one network segment to another but the responder's ACL defines a flow from one host to another host, IPsec proposal matching will fail.

On the initiator:

```
[Sysname] display acl 3000
Advanced IPv4 ACL 3000, 1 rule,
ACL's step is 5
 rule 0 permit ip source 192.168.222.0 0.0.0.255 destination 192.168.222.0 0.0.0.255
```

On the responder:

```
[Sysname] display acl 3000
Advanced IPv4 ACL 3000, 1 rule,
ACL's step is 5
 rule 0 permit ip source 192.168.222.71 0 destination 192.168.222.5 0
```

3. Verify that the IPsec policy has a remote address and an IPsec transform set configured and that the IPsec transform set has all necessary settings configured.

If, for example, the IPsec policy has no remote address configured, the IPsec SA negotiation will fail:

```
[Sysname] display ipsec policy
-----------------------------------------
IPsec Policy: policy1
Interface: GigabitEthernet1/0/1
-----------------------------------------

  ----------------------------
```

```
Sequence number: 1
Mode: ISAKMP
-----------------------------
Security data flow: 3000
Selector mode: aggregation
Local address: 192.168.222.5
Remote address:
Transform set:  transform1
IKE profile: profile1
SA duration(time based):
SA duration(traffic based):
SA idle time:
```

Solution

1. If the IPsec policy specifies an IKE profile but no matching IKE profiles was found in IKE negotiation, perform one of the following tasks on the responder:
   - Remove the specified IKE profile from the IPsec policy.
   - Modify the specified IKE profile to match the IKE profile of the initiator.
2. If the flow range defined by the responder's ACL is smaller than that defined by the initiator's ACL, modify the responder's ACL so the ACL defines a flow range equal to or greater than that of the initiator's ACL.

   For example:

   ```
   [Sysname] display acl 3000
   Advanced IPv4 ACL 3000, 2 rules,
   ACL's step is 5
    rule 0 permit ip source 192.168.222.0 0.0.0.255 destination 192.168.222.0 0.0.0.255
   ```
3. Configure the missing settings (for example, the remote address).

Configuring IKEv2

About IKEv2

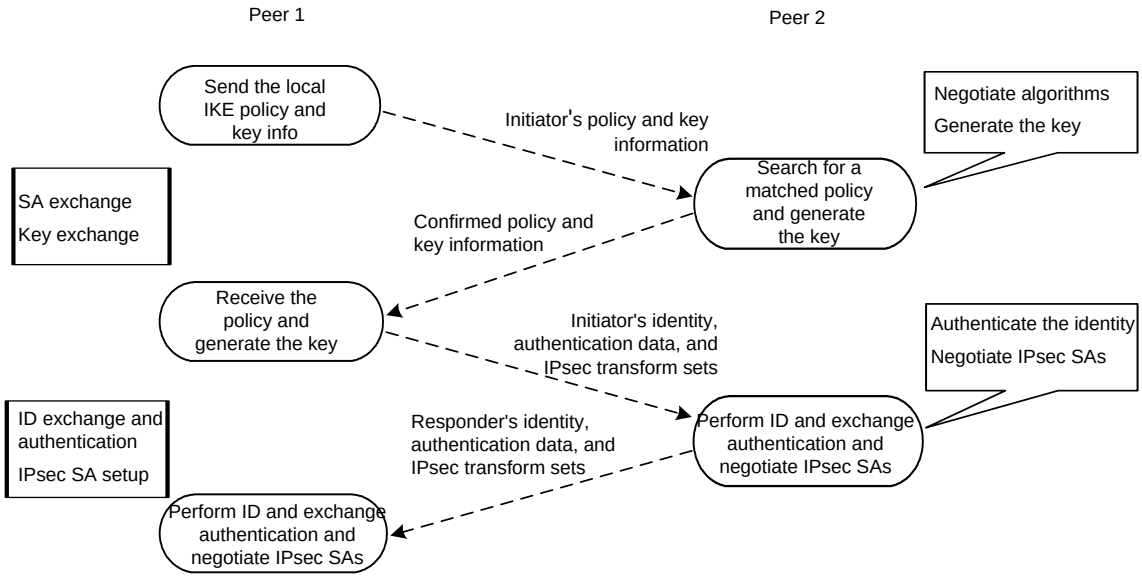
Internet Key Exchange version 2 (IKEv2) is an enhanced version of IKEv1. The same as IKEv1, IKEv2 has a set of self-protection mechanisms and can be used on insecure networks for reliable identity authentication, key distribution, and IPsec SA negotiation. IKEv2 provides stronger protection against attacks and higher key exchange ability and needs fewer message exchanges than IKEv1.

IKEv2 negotiation process

Compared with IKEv1, IKEv2 simplifies the negotiation process and is much more efficient.

IKEv2 defines three types of exchanges: initial exchanges, CREATE_CHILD_SA exchange, and INFORMATIONAL exchange.

As shown in Figure 16, IKEv2 uses two exchanges during the initial exchange process: IKE_SA_INIT and IKE_AUTH, each with two messages.



- **IKE_SA_INIT exchange**—Negotiates IKE SA parameters and exchanges keys.
- **IKE_AUTH exchange**—Authenticates the identity of the peer and establishes IPsec SAs.

After the four-message initial exchanges, IKEv2 sets up one IKE SA and one pair of IPsec SAs. For IKEv1 to set up one IKE SA and one pair of IPsec SAs, it must go through two phases that use a minimum of six messages.

To set up one more pair of IPsec SAs within the IKE SA, IKEv2 goes on to perform an additional two-message exchange—the CREATE_CHILD_SA exchange. One CREATE_CHILD_SA exchange creates one pair of IPsec SAs. IKEv2 also uses the CREATE_CHILD_SA exchange to rekey IKE SAs and Child SAs.

IKEv2 uses the INFORMATIONAL exchange to convey control messages about errors and notifications.

Figure 16 IKEv2 Initial exchange process

New features in IKEv2

DH guessing

In the IKE_SA_INIT exchange, the initiator guesses the DH group that the responder is most likely to use and sends it in an IKE_SA_INIT request message. If the initiator's guess is correct, the responder responds with an IKE_SA_INIT response message and the IKE_SA_INIT exchange is finished. If the guess is wrong, the responder responds with an INVALID_KE_PAYLOAD message that contains the DH group that it wants to use. The initiator then uses the DH group selected by the responder to reinitiate the IKE_SA_INIT exchange. The DH guessing mechanism allows for more flexible DH group configuration and enables the initiator to adapt to different responders.

Cookie challenging

Messages for the IKE_SA_INIT exchange are in plain text. An IKEv1 responder cannot confirm the validity of the initiators and must maintain half-open IKE SAs, which makes the responder susceptible to DoS attacks. An attacker can send a large number of IKE_SA_INIT requests with forged source IP addresses to the responder, exhausting the responder's system resources.

IKEv2 introduces the cookie challenging mechanism to prevent such DoS attacks. When an IKEv2 responder maintains a threshold number of half-open IKE SAs, it starts the cookie challenging mechanism. The responder generates a cookie and includes it in the response sent to the initiator. If the initiator initiates a new IKE_SA_INIT request that carries the correct cookie, the responder considers the initiator valid and proceeds with the negotiation. If the carried cookie is incorrect, the responder terminates the negotiation.

The cookie challenging mechanism automatically stops working when the number of half-open IKE SAs drops below the threshold.

IKEv2 SA rekeying

For security purposes, both IKE SAs and IPsec SAs have a lifetime and must be rekeyed when the lifetime expires. An IKEv1 SA lifetime is negotiated. An IKEv2 SA lifetime, in contrast, is configured. If two peers are configured with different lifetimes, the peer with the shorter lifetime always initiates the SA rekeying. This mechanism reduces the possibility that two peers will simultaneously initiate a rekeying. Simultaneous rekeying results in redundant SAs and SA status inconsistency on the two peers.

IKEv2 message retransmission

Unlike IKEv1 messages, IKEv2 messages appear in request/response pairs. IKEv2 uses the Message ID field in the message header to identify the request/response pair. If an initiator sends a request but receives no response with the same Message ID value within a specific period of time, the initiator retransmits the request.

It is always the IKEv2 initiator that initiates the retransmission, and the retransmitted message must use the same Message ID value.

Protocols and standards

- RFC 2412, *The OAKLEY Key Determination Protocol*
- RFC 5996, *Internet Key Exchange Protocol Version 2 (IKEv2)*

IKEv2 tasks at a glance

To configure IKEv2, perform the following tasks:

1. Configuring an IKEv2 profile
   a. Creating an IKEv2 profileSpecifying the local and remote identity authentication methodsConfiguring the IKEv2 keychain or PKI domain
   b. Configuring the local ID for the IKEv2 profile
   c. Configuring peer IDs for the IKEv2 profile
   d. Specifying a VPN instance for the IKEv2 profile
   e. Configuring optional features for the IKEv2 profile
2. Configuring an IKEv2 policy
3. Configuring an IKEv2 proposal

   If you specify an IKEv2 proposal in an IKEv2 policy, you must configure the IKEv2 proposal.
4. Configuring an IKEv2 keychain

   This task is required when either end or both ends use the preshared key authentication method.
5. (Optional.) Enabling the cookie challenging feature

   The cookie challenging feature takes effect only on IKEv2 responders.
6. (Optional.) Configuring the IKEv2 DPD feature
7. (Optional.) Configuring the IKEv2 NAT keepalive feature
8. (Optional.) Configuring IKEv2 address pools

Prerequisites for IKEv2 configuration

Determine the following parameters prior to IKEv2 configuration:

- The strength of the algorithms for IKEv2 negotiation, including the encryption algorithms, integrity protection algorithms, PRF algorithms, and DH groups. Different algorithms provide different levels of protection. A stronger algorithm means better resistance to decryption of protected data but requires more resources. Typically, the longer the key, the stronger the algorithm.
- The local and remote identity authentication methods.
  - To use the preshared key authentication method, you must determine the preshared key.
  - To use the RSA digital signature authentication method, you must determine the PKI domain for the local end to use. For information about PKI, see "Configuring PKI."

Configuring an IKEv2 profile

Creating an IKEv2 profile

About this task

An IKEv2 profile is intended to provide a set of parameters for IKEv2 negotiation.

Procedure

1. Enter system view.

   `system-view`
2. Create an IKEv2 profile and enter its view.

   `ikev2 profile` *`profile-name`*

Specifying the local and remote identity authentication methods

Restrictions and guidelines

The local and remote identity authentication methods must both be specified and they can be different. You can specify only one local identity authentication method and multiple remote identity authentication methods.

Procedure

1. Enter system view.

   system-view

2. Enter IKEv2 profile view.

   ikev2 profile *profile-name*

3. Specify the local and remote identity authentication methods.

   In non-FIPS mode:

   authentication-method { **local** | **remote** } { **dsa-signature** | **ecdsa-signature** | **pre-share** | **rsa-signature** }

   In FIPS mode:

   authentication-method { **local** | **remote** } { **ecdsa-signature** | **pre-share** | **rsa-signature** }

   By default, no local or remote identity authentication method is configured.

Configuring the IKEv2 keychain or PKI domain

Restrictions and guidelines

Configure the IKEv2 keychain or PKI domain for the IKEv2 profile to use. To use digital signature authentication, configure a PKI domain. To use preshared key authentication, configure an IKEv2 keychain.

Procedure

1. Enter system view.

   system-view

2. Enter IKEv2 profile view.

   ikev2 profile *profile-name*

3. Specify the keychain for preshared key authentication or the PKI domain used to request a certificate for digital signature authentication.

   - Specify the keychain.

     keychain *keychain-name*

   - Specify the PKI domain.

     certificate domain *domain-name* [**sign** | **verify**]

   By default, no IKEv2 keychain or PKI domain is specified for an IKEv2 profile.

Configuring the local ID for the IKEv2 profile

Restrictions and guidelines

For digital signature authentication, the device can use an ID of any type. If the local ID is an IP address that is different from the IP address in the local certificate, the device uses the FQDN as the local ID. The FQDN is the device name configured by using the **sysname** command.

For preshared key authentication, the device can use an ID of any type other than the DN.

Procedure

1. Enter system view.

   system-view

2. Enter IKEv2 profile view.

   ikev2 profile *profile-name*

3. Configure the local ID.

   identity local { **address** { *ipv4-address* | **ipv6** *ipv6-address* } | **dn** | **email** *email-string* | **fqdn** *fqdn-name* | **key-id** *key-id-string* }

   By default, no local ID is configured, and the device uses the IP address of the interface where the IPsec policy applies as the local ID.

Configuring peer IDs for the IKEv2 profile

About this task

Perform this task to configure the peer ID for IKEv2 profile matching. When the device needs to select an IKEv2 profile for IKEv2 negotiation with a peer, it compares the received peer ID with the peer IDs of its local IKE profiles. If a match is found, it uses the IKEv2 profile with the matching peer ID for negotiation. IKEv2 profiles will be compared in descending order of their priorities.

Procedure

1. Enter system view.

   system-view

2. Enter IKEv2 profile view.

   ikev2 profile *profile-name*

3. Configure a peer ID.

   match remote { **certificate** *policy-name* | **identity** { **address** { { *ipv4-address* [*mask* | *mask-length*] | **range** *low-ipv4-address high-ipv4-address* } | **ipv6** { *ipv6-address* [*prefix-length*] | **range** *low-ipv6-address high-ipv6-address* } } | **fqdn** *fqdn-name* | **email** *email-string* | **key-id** *key-id-string* } }

   You must configure a minimum of one peer ID on each of the two peers.

Specifying a VPN instance for the IKEv2 profile

About this task

After you specify a VPN instance for an IKEv2 profile, the IKEv2 profile can be used for IKEv2 negotiation only on the interfaces that belong to the VPN instance.

Procedure

1. Enter system view.

system-view

2. Enter IKEv2 profile view.
   ikev2 profile *profile-name*
3. Specify a VPN instance for the IKEv2 profile.
   match vrf { **name** *vrf-name* | **any** }
   By default, an IKEv2 profile belongs to the public network.

Configuring optional features for the IKEv2 profile

1. Enter system view.
   system-view
2. Enter IKEv2 profile view.
   ikev2 profile *profile-name*
3. Configure optional features as needed.
   - Configure IKEv2 DPD.
     dpd interval *interval* [**retry** *seconds*] { **on-demand** | **periodic** }
     By default, IKEv2 DPD is not configured for an IKEv2 profile and an IKEv2 profile uses the DPD settings configured in system view. If IKEv2 DPD is not configured in system view either, the device does not perform dead IKEv2 peer detection.
   - Specify the local interface or IP address to which the IKEv2 profile can be applied.
     match local address { *interface-type interface-number* | *ipv4-address* | **ipv6** *ipv6-address* }
     By default, an IKEv2 profile can be applied to any local interface or local IP address.
     Use this command to specify which address or interface can use the IKEv2 profile for IKEv2 negotiation. Specify the local address configured in IPsec policy or IPsec policy template view (using the **local-address** command) for this command. If no local address is configured, specify the IP address of the interface that uses the IPsec policy.
   - Specify a priority for the IKEv2 profile.
     priority *priority*
     By default, the priority of an IKEv2 profile is 100.
     When the device needs to select an IKEv2 profile for IKEv2 negotiation with a peer, it compares the received peer ID with the peer ID of its local IKEv2 profiles in descending order of their priorities
   - Set the IKEv2 SA lifetime for the IKEv2 profile.
     sa duration *seconds*
     By default, the IKEv2 SA lifetime is 86400 seconds.
     The local and remote ends can use different IKEv2 SA lifetimes and they do not negotiate the lifetime. The end with a smaller SA lifetime will initiate an SA negotiation when the lifetime expires.
   - Set the IKEv2 NAT keepalive interval.
     nat-keepalive *seconds*
     By default, the global IKEv2 NAT keepalive setting is used.
     Configure this command when the device is behind a NAT gateway. The device sends NAT keepalive packets regularly to its peer to prevent the NAT session from being aged because of no matching traffic.
   - Enable the configuration exchange feature.
     config-exchange { **request** | **set** { **accept** | **send** } }

By default, all configuration exchange options are disabled.

This feature applies to scenarios where the headquarters and branches communicate through virtual tunnels. It enables exchanges of IP address request and set messages between the IPsec gateway at a branch and the IPsec gateway at the headquarters.

Table 2 Parameter descriptions

Parameter	Description
request	Enables the IPsec gateway at a branch to submit IP address request messages to the IPsec gateway at the headquarters.
set accept	Enables the IPsec gateway at a branch to accept the IP addresses pushed by the IPsec gateway at the headquarters.
set send	Enables the IPsec gateway at the headquarters to push IP addresses to IPsec gateways at branches.

- Enable AAA authorization.

  aaa authorization domain *domain-name* **username** *user-name*

  By default, AAA authorization is disabled.

  The AAA authorization feature enables IKEv2 to request authorization attributes, such as the IKEv2 address pool, from AAA. IKEv2 uses the address pool to assign IP addresses to remote users. For more information about AAA authorization, see "Configuring AAA."

Configuring an IKEv2 policy

About this task

During the IKE_SA_INIT exchange, each end tries to find a matching IKEv2 policy, using the IP address of the local security gateway as the matching criterion.

- If IKEv2 policies are configured, IKEv2 searches for an IKEv2 policy that uses the IP address of the local security gateway. If no IKEv2 policy uses the IP address or the policy is using an incomplete proposal, the IKE_SA_INIT exchange fails.
- If no IKEv2 policy is configured, IKEv2 uses the system default IKEv2 policy **default**.

The device matches IKEv2 policies in the descending order of their priorities. To determine the priority of an IKEv2 policy:

1. First, the device examines the existence of the **match local address** command. An IKEv2 policy with the **match local address** command configured has a higher priority.
2. If a tie exists, the device compares the priority numbers. An IKEv2 policy with a smaller priority number has a higher priority.
3. If a tie still exists, the device prefers an IKEv2 policy configured earlier.

Procedure

1. Enter system view.

   system-view
2. Create an IKEv2 policy and enter its view.

   ikev2 policy *policy-name*

   By default, an IKEv2 policy named **default** exists.
3. Specify the local interface or address used for IKEv2 policy matching.

   match local address { *interface-type interface-number* | *ipv4-address* | **ipv6** *ipv6-address* }

By default, no local interface or address is used for IKEv2 policy matching, and the policy matches any local interface or address.

4. Specify a VPN instance for IKEv2 policy matching.

   match vrf { **name** *vrf-name* | **any** }

   By default, no VPN instance is specified for IKEv2 policy matching. The IKEv2 policy matches all local addresses in the public network.

5. Specify an IKEv2 proposal for the IKEv2 policy.

   proposal *proposal-name*

   By default, no IKEv2 proposal is specified for an IKEv2 policy.

6. Specify a priority for the IKEv2 policy.

   priority *priority*

   By default, the priority of an IKEv2 policy is 100.

Configuring an IKEv2 proposal

About this task

An IKEv2 proposal contains security parameters used in IKE_SA_INIT exchanges, including the encryption algorithms, integrity protection algorithms, PRF algorithms, and DH groups. An algorithm specified earlier has a higher priority.

Restrictions and guidelines

A complete IKEv2 proposal must have at least one set of security parameters, including one encryption algorithm, one integrity protection algorithm, one PRF algorithm, and one DH group.

You can specify multiple IKEv2 proposals for an IKEv2 policy. A proposal specified earlier has a higher priority.

Procedure

1. Enter system view.

   system-view

2. Create an IKEv2 proposal and enter its view.

   ikev2 proposal *proposal-name*

   By default, an IKEv2 proposal named **default** exists.

   In non-FIPS mode, the default proposal uses the following settings:

   - Encryption algorithms AES-CBC-128 and 3DES.
   - Integrity protection algorithms HMAC-SHA1 and HMAC-MD5.
   - PRF algorithms HMAC-SHA1 and HMAC-MD5.
   - DH groups 2 and 5.

   In FIPS mode, the default proposal uses the following settings:

   - Encryption algorithms AES-CBC-128 and AES-CTR-128.
   - Integrity protection algorithms HMAC-SHA1 and HMAC-SHA256.
   - PRF algorithms HMAC-SHA1 and HMAC-SHA256.
   - DH groups 14 and 19.

3. Specify the encryption algorithms.

   In non-FIPS mode:

   encryption { **3des-cbc** | **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** | **aes-ctr-128** | **aes-ctr-192** | **aes-ctr-256** | **camellia-cbc-128** |

camellia-cbc-192 | **camellia-cbc-256** | **des-cbc** | **aes-gcm-128** | **aes-gcm-192** | **aes-gcm-256** } *

In FIPS mode:

encryption { **aes-gcm-128** | **aes-gcm-192** | **aes-gcm-256** } *

By default, an IKEv2 proposal does not have any encryption algorithms.

4. Specify the integrity protection algorithms.

   In non-FIPS mode:

   integrity { **aes-xcbc-mac** | **md5** | **sha1** | **sha256** | **sha384** | **sha512** } *

   By default, an IKEv2 proposal does not have any integrity protection algorithms.

5. Specify the DH groups.

   In non-FIPS mode:

   dh { **group1** | **group14** | **group19** | **group2** | **group20** | **group24** | **group5** } *

   In FIPS mode:

   dh { **group19** | **group20** | **group24** } *

   By default, an IKEv2 proposal does not have any DH groups.

6. Specify the PRF algorithms.

   In non-FIPS mode:

   prf { **aes-xcbc-mac** | **md5** | **sha1** | **sha256** | **sha384** | **sha512** } *

   In FIPS mode:

   prf { **sha256** | **sha384** | **sha512** } *

   By default, an IKEv2 proposal uses the integrity protection algorithms as the PRF algorithms.

Configuring an IKEv2 keychain

About this task

An IKEv2 keychain specifies the preshared keys used for IKEv2 negotiation.

An IKEv2 keychain can have multiple IKEv2 peers. Each peer has a symmetric preshared key or an asymmetric preshared key pair, and information for identifying the peer (such as the peer's host name, IP address or address range, or ID).

An IKEv2 negotiation initiator uses the peer host name or IP address/address range as the matching criterion to search for a peer. A responder uses the peer host IP address/address range or ID as the matching criterion to search for a peer.

Procedure

1. Enter system view.

   system-view

2. Create an IKEv2 keychain and enter its view.

   ikev2 keychain *keychain-name*

3. Create an IKEv2 peer and enter its view.

   peer *name*

4. Configure a host name for the peer:

   hostname *name*

   By default, no host name is configured for an IKEv2 peer.

5. Configure a host IP address or address range for the peer:

address { *ipv4-address* [*mask* | *mask-length*] | **ipv6** *ipv6-address* [*prefix-length*] }

By default, no host IP address or address range is configured for an IKEv2 peer.

You must configure different host IP addresses/address ranges for different peers.

6. Configure an ID for the peer:

   identity { **address** { *ipv4-address* | **ipv6** { *ipv6-address* } } | **fqdn** *fqdn-name* | **email** *email-string* | **key-id** *key-id-string* }

   By default, no identity information is configured for an IKEv2 peer.

7. Configure a preshared key for the peer.

   pre-shared-key [**local** | **remote**] { **ciphertext** | **plaintext** } *string*

   By default, an IKEv2 peer does not have a preshared key.

Configure global IKEv2 parameters

Enabling the cookie challenging feature

About this task

Enable cookie challenging on responders to protect them against DoS attacks that use a large number of source IP addresses to forge IKE_SA_INIT requests.

Procedure

1. Enter system view.

   system-view

2. Enable IKEv2 cookie challenging.

   ikev2 cookie-challenge *number*

   By default, IKEv2 cookie challenging is disabled.

Configuring the IKEv2 DPD feature

About this task

IKEv2 DPD detects dead IKEv2 peers in periodic or on-demand mode.

- **Periodic IKEv2 DPD**—Verifies the liveness of an IKEv2 peer by sending DPD messages at regular intervals.
- **On-demand IKEv2 DPD**—Verifies the liveness of an IKEv2 peer by sending DPD messages before sending data.
  - Before the device sends data, it identifies the time interval for which the last IPsec packet has been received from the peer. If the time interval exceeds the DPD interval, it sends a DPD message to the peer to detect its liveliness.
  - If the device has no data to send, it never sends DPD messages.

Restrictions and guidelines

If you configure IKEv2 DPD in both IKEv2 profile view and system view, the IKEv2 DPD settings in IKEv2 profile view apply. If you do not configure IKEv2 DPD in IKEv2 profile view, the IKEv2 DPD settings in system view apply.

Procedure

1. Enter system view.

   system-view

2. Configure global IKEv2 DPD.

   ikev2 dpd interval *interval* [**retry** *seconds*] { **on-demand** | **periodic** }

   By default, global DPD is disabled.

Configuring the IKEv2 NAT keepalive feature

About this task

Configure this feature on the IKEv2 gateway behind the NAT device. The gateway then sends NAT keepalive packets regularly to its peer to keep the NAT session alive, so that the peer can access the device.

The NAT keepalive interval must be shorter than the NAT session lifetime.

This feature takes effect after the device detects the NAT device.

Procedure

1. Enter system view.

   system-view

2. Set the IKEv2 NAT keepalive interval.

   ikev2 nat-keepalive *seconds*

   By default, the IKEv2 NAT keepalive interval is 10 seconds.

Configuring IKEv2 address pools

About this task

To perform centralized management on remote users, an IPsec gateway can use an address pool to assign private IP addresses to remote users.

You must use an IKEv2 address pool together with AAA authorization by specifying the IKEv2 address pool as an AAA authorization attribute. For more information about AAA authorization, see "Configuring AAA."

Procedure

1. Enter system view.

   system-view

2. Configure an IKEv2 IPv4 address pool.

   ikev2 address-group *group-name start-ipv4-address end-ipv4-address* [*mask* | *mask-length*]

3. Configure an IKEv2 IPv6 address pool.

   ikev2 ipv6-address-group *group-name* **prefix** *prefix/prefix-len* **assign-len** *assign-len*

Display and maintenance commands for IKEv2

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the IKEv2 policy configuration.	**display ikev2 policy** [*policy-name* | **default**]

Task	Command
Display the IKEv2 profile configuration.	**display ikev2 profile** [*profile-name*]
Display the IKEv2 proposal configuration.	**display ikev2 proposal** [*name* | **default**]
Display the IKEv2 SA information.	**display ikev2 sa** [**count** | [{ **local** | **remote** } { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] [**verbose** [**tunnel** *tunnel-id*]]]
Display IKEv2 statistics.	**display ikev2 statistics**
Delete IKEv2 SAs and the child SAs negotiated through the IKEv2 SAs.	**reset ikev2 sa** [[{ **local** | **remote** } { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] | **tunnel** *tunnel-id*] [**fast**]
Clear IKEv2 statistics.	**reset ikev2 statistics**

Troubleshooting IKEv2

IKEv2 negotiation failed because no matching IKEv2 proposals were found

Symptom

The IKEv2 SA is in IN-NEGO status.

```
<Sysname> display ikev2 sa
Tunnel ID   Local                       Remote                      Status
  ------------------------------------------------------------------------------
  5           123.234.234.124/500         123.234.234.123/500         IN-NEGO
Status:
IN-NEGO: Negotiating, EST: Established, DEL:Deleting
```

Analysis

Certain IKEv2 proposal settings are incorrect.

Solution

1. Examine the IKEv2 proposal configuration to see whether the two ends have matching IKEv2 proposals.
2. Modify the IKEv2 proposal configuration to make sure the two ends have matching IKEv2 proposals.

IPsec SA negotiation failed because no matching IPsec transform sets were found

Symptom

The **display ikev2 sa** command shows that the IKEv2 SA negotiation succeeded and the IKEv2 SA is in EST status. The **display ipsec sa** command shows that the expected IPsec SAs have not been negotiated yet.

Analysis

Certain IPsec policy settings are incorrect.

Solution

1. Examine the IPsec configuration to see whether the two ends have matching IPsec transform sets.
2. Modify the IPsec configuration to make sure the two ends have matching IPsec transform sets.

IPsec tunnel establishment failed

Symptom

The ACLs and IKEv2 proposals are correctly configured on both ends. The two ends cannot establish an IPsec tunnel or cannot communicate through the established IPsec tunnel.

Analysis

The IKEv2 SA or IPsec SAs on either end are lost. The reason might be that the network is unstable and the device reboots.

Solution

1. Use the **display ikev2 sa** command to examine whether an IKEv2 SA exists on both ends. If the IKEv2 SA on one end is lost, delete the IKEv2 SA on the other end by using the **reset ikev2 sa** command and trigger new negotiation. If an IKEv2 SA exists on both ends, go to the next step.
2. Use the **display ipsec sa** command to examine whether IPsec SAs exist on both ends. If the IPsec SAs on one end are lost, delete the IPsec SAs on the other end by using the **reset ipsec sa** command and trigger new negotiation.

Configuring SSH

About SSH

Secure Shell (SSH) is a network security protocol. Using encryption and authentication, SSH can implement secure remote access and file transfer over an insecure network.

SSH uses the typical client-server model to establish a channel for secure data transfer based on TCP.

SSH includes two versions: SSH1.x and SSH2.0 (hereinafter referred to as SSH1 and SSH2), which are not compatible. SSH2 is better than SSH1 in performance and security.

SSH applications

The device supports the following SSH applications:

- **Secure Telnet**—Stelnet provides secure and reliable network terminal access services. Through Stelnet, a user can securely log in to a remote server. Stelnet can protect devices against attacks, such as IP spoofing and plain text password interception. The device can act as an Stelnet server or an Stelnet client.
- **Secure File Transfer Protocol**—Based on SSH2, SFTP uses SSH connections to provide secure file transfer. The device can act as an SFTP server, allowing a remote user to log in to the SFTP server for secure file management and transfer. The device can also act as an SFTP client, enabling a user to log in from the device to a remote device for secure file transfer.
- **Secure Copy**—Based on SSH2, SCP offers a secure method to copy files. The device can act as an SCP server, allowing a user to log in to the device for file upload and download. The device can also act as an SCP client, enabling a user to log in from the device to a remote device for secure file transfer.
- **NETCONF over SSH**—Based on SSH2, it enables users to securely log in to the device through SSH and perform NETCONF operations on the device through the NETCONF-over-SSH connections. The device can act only as a NETCONF-over-SSH server. For more information about NETCONF, see *Network Management and Monitoring Configuration Guide*.

The device supports different SSH versions depending on its role:

- When acting as an Stelnet server, the device supports both SSH2 and SSH1 in non-FIPS mode and only SSH2 in FIPS mode.
- When acting as an SSH client, the device supports only SSH2.
- When acting as an SFTP, SCP, or NETCONF-over-SSH server, the device supports only SSH2.

How SSH works

This section uses SSH2 as an example to describe the stages to establish an SSH session.

Table 1 Stages to establish an SSH session

Stages	Description
Connection establishment	The SSH server listens to connection requests on port 22. After a client initiates a connection request, the server and the client establish a TCP connection.
Version negotiation	The two parties determine a version to use.

Stages	Description
Algorithm negotiation	SSH supports multiple algorithms. Based on the local algorithms, the two parties negotiate the following algorithms: • Key exchange algorithm for generating session keys. • Encryption algorithm for encrypting data. • Public key algorithm for the digital signature and authentication. • HMAC algorithm for protecting data integrity.
Key exchange	The two parties use the DH exchange algorithm to dynamically generate the session keys and session ID. • The session keys are used for protecting data transfer. • The session ID is used for identifying the SSH connection. In this stage, the client also authenticates the server.
Authentication	The SSH server authenticates the client in response to the client's authentication request.
Session request	After passing the authentication, the client sends a session request to the server to request the establishment of a session for the Stelnet, NETCONF, SCP, or SFTP service.
Interaction	After the server grants the request, the client and the server start to communicate with each other in the session. In this stage, you can paste commands in text format and execute them at the CLI. The text pasted at one time must be no more than 2000 bytes. As a best practice to ensure the correct execution of commands, paste commands that are in the same view. To execute commands of more than 2000 bytes, save the commands in a configuration file, upload the file to the server through SFTP, and use it to restart the server.

SSH authentication methods

This section describes authentication methods that are supported by the device when it acts as an SSH server.

Password authentication

The SSH server authenticates a client through the AAA mechanism. The password authentication process is as follows:

1. The client sends the server an authentication request that includes the encrypted username and password.
2. The server performs the following operations:
   a. Decrypts the request to get the username and password in plain text.
   b. Verifies the username and password locally or through remote AAA authentication.
   c. Informs the client of the authentication result.

If the remote AAA server requires the user to enter a password for secondary authentication, it send the SSH server an authentication response carrying a prompt. The prompt is transparently transmitted to the client to notify the user to enter a specific password. When the user enters the correct password, the AAA sever examines the password validity. If the password is valid, the SSH server returns an authentication success message to the client.

SSH1 clients do not support secondary password authentication initiated by the AAA server.

For more information about AAA, see "Configuring AAA."

Keyboard-interactive authentication

In keyboard-interactive authentication, the remote authentication server and user exchanges information for authentication as follows:

1. The remote authentication server sends a prompt to the SSH server in an authentication response.
2. The prompt indicates the information required to be provided by the user.
3. The SSH server transparently transmits the prompt to the client terminal.
4. The user enters the required information as prompted.

This process repeats multiple times if the remote authentication server requires more interactive information. The remote authentication server returns an authentication success message after the user provides all required interactive information.

If the remote authentication server does not require interactive information, the keyboard-interactive authentication process is the same as the password authentication.

Publickey authentication

The server authenticates a client by verifying the digital signature of the client. The publickey authentication process is as follows:

1. The client sends the server a publickey authentication request that includes the username, public key, and public key algorithm name.

   If the digital certificate of the client is required in authentication, the client also encapsulates the digital certificate in the authentication request. The digital certificate carries the public key information of the client.
2. The server verifies the client's public key.
   - If the public key is invalid, the server informs the client of the authentication failure.
   - If the public key is valid, the server requests the digital signature of the client. After receiving the signature, the server uses the public key to verify the signature and informs the client of the authentication result.

When acting as an SSH server, the device supports using the public key algorithms DSA, ECDSA, and RSA to verify digital signatures.

When acting as an SSH client, the device supports using the public key algorithms DSA, ECDSA, and RSA to generate digital signatures.

For more information about public key configuration, see "Managing public keys."

Password-publickey authentication

The server requires SSH2 clients to pass both password authentication and publickey authentication. However, an SSH1 client only needs to pass either authentication.

Any authentication

The server requires clients to pass keyboard-interactive authentication, password authentication, or publickey authentication. Success with any one authentication method is sufficient to connect to the server.

SSH support for Suite B

Suite B contains a set of encryption and authentication algorithms that meet high security requirements. Table 2 lists all algorithms in Suite B.

The SSH server and client support using the X.509v3 certificate for identity authentication in compliance with the algorithm, negotiation, and authentication specifications defined in RFC 6239.

Table 2 Suite B algorithms

Security level	Key exchange algorithm	Encryption algorithm and HMAC algorithm	Public key algorithm
128-bit	ecdh-sha2-nistp256	AES128-GCM	x509v3-ecdsa-sha2-nistp256
192-bit	ecdh-sha2-nistp384	AES256-GCM	x509v3-ecdsa-sha2-nistp384
Both	ecdh-sha2-nistp256 ecdh-sha2-nistp384	AES128-GCM AES256-GCM	x509v3-ecdsa-sha2-nistp256 x509v3-ecdsa-sha2-nistp384

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see "Configuring FIPS."

Configuring the device as an SSH server

SSH server tasks at a glance

To configure an SSH server, perform the following tasks:

1. Generating local key pairs
2. (Optional.) Specifying the SSH service port
3. Enabling the SSH server
   - Enabling the Stelnet server
   - Enabling the SFTP server
   - Enabling the SCP server
   - Enabling NETCONF over SSH
4. Configuring the user lines for SSH login

   Required only for Stelnet and NETCONF-over-SSH servers.
5. Configuring a client's host public key

   Required for authentication method **publickey**, **password-publickey,** or **any**.
6. Configuring an SSH user
   - Required for authentication method **keyboard-interactive**, **publickey**, **password-publickey,** or **any**.
   - Optional for the **password** authentication method.
7. (Optional.) Configuring the SSH management parameters

   SSH management settings, such as authentication and connection control settings, help improve security of SSH connections.
8. (Optional.) Specifying a PKI domain for the SSH server
9. (Optional.) Disconnecting SSH sessions

Generating local key pairs

About this task

The DSA, ECDSA, or RSA key pairs on the SSH server are required for generating the session keys and session ID in the key exchange stage. They can also be used by a client to authenticate the server. When a client authenticates the server, it compares the public key received from the server with the server's public key that the client saved locally. If the keys are consistent, the client uses the locally saved server's public key to decrypt the digital signature received from the server. If the decryption succeeds, the server passes the authentication.

To support SSH clients that use different types of key pairs, generate DSA, ECDSA, and RSA key pairs on the SSH server.

- **RSA key pairs**—The SSH server generates a server key pair and a host key pair for RSA. The RSA server key pair is only used in SSH1 to encrypt the session key for secure transmission of the session key. It is not used in SSH2, because no session key transmission is required in SSH2.
- **DSA key pair**—The SSH server generates only one DSA host key pair. SSH1 does not support the DSA algorithm.
- **ECDSA key pair**—The SSH server generates only one ECDSA host key pair.

Restrictions and guidelines

Local DSA, ECDSA, and RSA key pairs for SSH use default names. You cannot assign names to the key pairs. For more information about the command for generating key pairs, see public key management commands in *Security Command Reference*.

If the device does not have RSA key pairs with default names, it automatically generates one RSA server key pair and one RSA host key pair when SSH starts. Both key pairs use their default names. The SSH application starts when you execute an SSH server command on the device.

The key modulus length must be less than 2048 bits when you generate the DSA key pair on the SSH server.

When you generate an ECDSA key pair, you can generate only a **secp256r1** or **secp384r1** ECDSA key pair.

The SSH server operating in FIPS mode supports only ECDSA and RSA key pairs. Do not generate a DSA key pair on the SSH server in FIPS mode.

Procedure

1. Enter system view.

   system-view
2. Generate local key pairs.

   public-key local create { **dsa** | **ecdsa** { **secp256r1** | **secp384r1** } | **rsa** }

Specifying the SSH service port

About this task

The default port of the SSH service is 22. You can specify another port for the SSH service to improve security of SSH connections.

Restrictions and guidelines

If you modify the SSH port number when the SSH server is enabled, the SSH service is restarted and all SSH connections are terminated after the modification. SSH users must reconnect to the SSH server to access the server.

If you set the SSH port to a well-known port number, the service that uses the well-known port number might fail to start. Well-known port numbers are in the range of 1 to 1024.

Procedure

1. Enter system view.
   system-view
2. Specify the SSH service port.
   ssh server port *port-number*
   By default, the SSH service port is 22.

Enabling the Stelnet server

About this task

After you enable the Stelnet server on the device, a client can log in to the device through Stelnet.

Procedure

1. Enter system view.
   system-view
2. Enable the Stelnet server.
   ssh [**ipv4** | **ipv6**] **server enable**
   By default, the Stelnet server is disabled.

Enabling the SFTP server

About this task

After you enable the SFTP server on the device, a client can log in to the device through SFTP.

Restrictions and guidelines

When acting as an SFTP server, the device does not support SFTP connections initiated by SSH1 clients.

Procedure

1. Enter system view.
   system-view
2. Enable the SFTP server.
   sftp [**ipv4** | **ipv6**] **server enable**
   By default, the SFTP server is disabled.

Enabling the SCP server

About this task

After you enable the SCP server on the device, a client can log in to the device through SCP.

Restrictions and guidelines

When acting as an SCP server, the device does not support SCP connections initiated by SSH1 clients.

Procedure

1. Enter system view.

system-view

2. Enable the SCP server.

   scp [**ipv4** | **ipv6**] **server enable**

   By default, the SCP server is disabled.

Enabling NETCONF over SSH

About this task

After you enable NETCONF over SSH on the device, a client can perform NETCONF operations on the device through a NETCONF-over-SSH connection.

Restrictions and guidelines

When acting as a server in the NETCONF-over-SSH connection, the device does not support connection requests initiated by SSH1 clients.

Procedure

1. Enter system view.

   system-view

2. Enable NETCONF over SSH.

   netconf ssh server enable

   By default, NETCONF over SSH is disabled.

   For more information about NETCONF over SSH commands, see *Network Management and Monitoring Command Reference*.

Configuring the user lines for SSH login

About this task

Depending on the SSH application, an SSH client can be an Stelnet client, SFTP client, SCP client, or NETCONF-over-SSH client.

Only Stelnet and NETCONF-over-SSH clients require the user line configuration. The user line configuration takes effect on the clients at the next login.

Procedure

1. Enter system view.

   system-view

2. Enter VTY user line view.

   line vty *number* [*ending-number*]

3. Set the login authentication mode to scheme.

   authentication-mode scheme

   By default, the authentication mode is **password**.

   For more information about this command, see *Fundamentals Command Reference*.

Configuring a client's host public key

About this task

In publickey authentication, the server compares the SSH username and the client's host public key received from the client with the locally saved SSH username and the client's host public key. If they

are the same, the server checks the digital signature that the client sends. The client generates the digital signature by using the private key that is paired with the client's host public key.

For publickey authentication, password-publickey authentication, or any authentication, you must perform the following tasks:

1. Configure the client's DSA, ECDSA, or RSA host public key on the server.
2. Specify the associated host private key on the client to generate the digital signature.

   If the device acts as an SSH client, specify the public key algorithm on the client. The algorithm determines the associated host private key for generating the digital signature.

Client public key configuration methods

You can configure the client host public key by using the following methods:

- Manually enter the content of a client's host public key on the server.
  a. Display the host public key on the client and record the key.
  b. Type the client's host public key character by character on the server, or use the copy and paste method.

  The manually entered key must be in DER format without being converted. For the displayed key to meet the requirement when the client is an H3C device, use the **display public-key local public** command. The format of the public key displayed in any other way (for example, by using the **public-key local export** command) might be incorrect. If the key is not in correct format, the system discards the key.
- Import the client host public key from a public key file.
  c. Save the client public key file to the server. For example, transfer the client public key file to the server in binary mode through FTP or TFTP.
  d. Import the client public key from the locally saved public key file.

  During the import process, the server automatically converts the host public key to a string in PKCS format.

Restrictions and guidelines

As a best practice, configure no more than 20 SSH client's host public keys on an SSH server.

Import the client's host public key as a best practice.

Entering a client's host public key

1. Enter system view.

   system-view
2. Enter public key view.

   public-key peer *keyname*
3. Configure a client's host public key.

   Enter the content of the client's host public key character by character, or use the copy and paste method.

   When you enter the content of a client's host public key, you can use spaces and carriage returns between characters but the system does not save them. For more information, see "Managing public keys."
4. Exit public key view and save the key.

   peer-public-key end

Importing a client's host public key from the public key file

1. Enter system view.

   system-view
2. Import a client's public key from the public key file.

public-key peer *keyname* **import sshkey** *filename*

Configuring an SSH user

About this task

Configure an SSH user and a local user depending on the authentication method.

- If the authentication method is **publickey**, you must create an SSH user and a local user on the SSH server. The two users must have the same username, so that the SSH user can be assigned the correct working directory and user role.
- If the authentication method is **password**, you must perform one of the following tasks:
  - For local authentication, configure a local user on the SSH server.
  - For remote authentication, configure an SSH user on a remote authentication server, for example, a RADIUS server.

  You do not need to create an SSH user by using the **ssh user** command. However, if you want to display all SSH users, including the password-only SSH users, for centralized management, you can use this command to create them. If such an SSH user has been created, make sure you have specified the correct service type and authentication method.
- If the authentication method is **keyboard-interactive**, **password-publickey**, or **any**, you must create an SSH user on the SSH server and perform one of the following tasks:
  - For local authentication, configure a local user on the SSH server.
  - For remote authentication, configure an SSH user on a remote authentication server, for example, a RADIUS server.

  In either case, the local user or the SSH user configured on the remote authentication server must have the same username as the SSH user.

For information about configuring local users and remote authentication, see "Configuring AAA."

Restrictions and guidelines

If you change the authentication parameters for a logged-in SSH user, the change takes effect on the user at the next login.

When the device operates as an SSH server in FIPS mode, the device does not support authentication method **any** or **publickey**.

For an SFTP or SCP user, the working directory depends on the authentication method.

- If the authentication method is **publickey** or **password-publickey**, the working folder is specified by the **authorization-attribute** command in the associated local user view.
- If the authentication method is **keyboard-interactive** or **password**, the working directory is authorized by AAA.

For an SSH user, the user role also depends on the authentication method.

- If the authentication method is **publickey** or **password-publickey**, the user role is specified by the **authorization-attribute** command in the associated local user view.
- If the authentication method is **keyboard-interactive** or **password**, the user role is authorized by AAA.

For all authentication methods except keyboard-interactive authentication and password authentication, you must specify a client's host public key or digital certificate.

- For a client that sends the user's public key information directly to the server, specify the client's host public key on the server. The specified public key must already exist. For more information about public keys, see "Configuring a client's host public key." If you specify multiple client public keys, the device verifies the user identity by using the public keys in the order they are specified. The user is valid if the user passes one public key check.

- For a client that sends the user's public key information to the server through a digital certificate, specify the PKI domain on the server. This PKI domain verifies the client's digital certificate. For successful verification, the specified PKI domain must have the correct CA certificate. To specify the PKI domain, use the **ssh user** or **ssh server pki-domain** command. For more information about configuring a PKI domain, see "Configuring PKI."

Procedure

1. Enter system view.

   system-view

2. Create an SSH user, and specify the service type and authentication method.

   In non-FIPS mode:

   ssh user *username* **service-type** { **all** | **netconf** | **scp** | **sftp** | **stelnet** } **authentication-type** { **keyboard-interactive** | **password** | { **any** | **password-publickey** | **publickey** } [**assign** { **pki-domain** *domain-name* | **publickey** *keyname*&<1-6> }] }

   In FIPS mode:

   ssh user *username* **service-type** { **all** | **netconf** | **scp** | **sftp** | **stelnet** } **authentication-type** { **keyboard-interactive** | **password** | **password-publickey** [**assign** { **pki-domain** *domain-name* | **publickey** *keyname*&<1-6> }] }

   An SSH server supports up to 1024 SSH users.

Configuring the SSH management parameters

Enabling the SSH server to support SSH1 clients

1. Enter system view.

   system-view

2. Enable the SSH server to support SSH1 clients.

   ssh server compatible-ssh1x enable

   By default, the SSH server does not support SSH1 clients.

   This command is not available in FIPS mode.

Enabling SSH algorithm renegotiation and key re-exchange

1. Enter system view.

   system-view

2. Use one of the following methods or both at the same time to trigger SSH algorithm renegotiation and key re-exchange:

   - Enable SSH algorithm renegotiation and key re-exchange.
     - In non-FIPS mode:

       ssh server key-re-exchange enable [**interval** *interval*]

     - In FIPS mode:

       ssh server key-re-exchange enable [**interval-minutes** *interval*]

     By default, SSH algorithm renegotiation and key re-exchange are disabled.

     The command takes effect only on new SSH connections that are established after the command is executed, and it does not affect existing SSH connections.

   - Configure the traffic threshold that triggers SSH algorithm renegotiation and key re-exchange

     ssh server key-re-exchange traffic-threshold *traffic-threshold*

By default, the traffic threshold that enables SSH algorithm renegotiation and key re-exchange depends on the encryption algorithm for the negotiation:

- For DES and 3DESC encryption algorithms, the traffic threshold that triggers SSH algorithm renegotiation and key re-exchange is 1 GB.
- For AES and SM4 encryption algorithms, the traffic threshold that triggers SSH algorithm renegotiation and key re-exchange is 64 GB.

This feature does not affect the existing SSH connections.

Setting the minimum interval for updating the RSA server key pair

1. Enter system view.

   system-view

2. Set the minimum interval for updating the RSA server key pair.

   ssh server rekey-interval *interval*

   By default, the device does not update the RSA server key pair.

   This command is not available in FIPS mode.

   This configuration takes effect only on SSH1 clients.

Setting the SSH user authentication timeout timer

1. Enter system view.

   system-view

2. Set the SSH user authentication timeout timer.

   ssh server authentication-timeout *time-out-value*

   The default setting is 60 seconds.

   Perform this task to prevent malicious occupation of TCP connections. If a user does not finish the authentication when the timeout timer expires, the connection cannot be established.

Setting the maximum number of SSH authentication attempts

1. Enter system view.

   system-view

2. Set the maximum number of SSH authentication attempts.

   ssh server authentication-retries *retries*

   The default setting is 3.

   Perform this task to prevent malicious hacking of usernames and passwords. If the authentication method is **any**, the total number of publickey authentication attempts and password authentication attempts cannot exceed the upper limit.

Specifying an SSH login control ACL

1. Enter system view.

   system-view

2. Specify an SSH login control ACL.

   IPv4:

   ssh server acl { *advanced-acl-number* | *basic-acl-number* | **mac** *mac-acl-number* }

   IPv6:

   ssh server ipv6 acl { **ipv6** { *advanced-acl-number* | *basic-acl-number* } | **mac** *mac-acl-number* }

   This feature uses an ACL to filter SSH clients that initiate SSH connections to the server. By default, no ACLs are specified and all SSH users can initiate SSH connections to the server.

Only SSH users that match the ACL's permit rules can initiate SSH connections to the server. If the specified ACL does not exist or the ACL contains no rules, no SSH users can initiate SSH connections to the server.

This configuration takes effect only on new SSH connections. It does not affect the existing SSH connections.

Enabling logging for SSH login attempts that are denied by the SSH login control ACL

1. Enter system view.

   system-view

2. Enable logging for SSH login attempts that are denied by the SSH login control ACL.

   ssh server acl-deny-log enable

   By default, logging is disabled for login attempts that are denied by the SSH login control ACL.

   This command enables SSH to generate log messages for SSH login attempts that are denied by the SSH login control ACL and send the messages to the information center.

Setting the DSCP value in the packets that the SSH server sends to SSH clients

1. Enter system view.

   system-view

2. Set the DSCP value in the packets that the SSH server sends to the SSH clients.

   IPv4:

   ssh server dscp *dscp-value*

   IPv6:

   ssh server ipv6 dscp *dscp-value*

   By default, the DSCP value of SSH packets is 48.

   The DSCP value is carried in the ToS field of an IPv4 packet and in the Traffic Class field of an IPv6 packet. It defines the priority of a packet and affects the transmission priority of the packet. A bigger DSCP value represents a higher priority.

Setting the SFTP connection idle timeout timer

1. Enter system view.

   system-view

2. Set the SFTP connection idle timeout timer.

   sftp server idle-timeout *time-out-value*

   By default, the SFTP connection idle timeout is 10 minutes.

   When the SFTP connection idle timeout timer expires, the system automatically tears the connection down and releases the connection resources.

Setting the maximum number of online SSH users

1. Enter system view.

   system-view

2. Set the maximum number of online SSH users.

   aaa session-limit ssh *max-sessions*

   The default setting is 32.

   When the number of online SSH users reaches the upper limit, the system denies new SSH connection requests. Changing the upper limit does not affect online SSH users.

   For more information about this command, see AAA commands in *Security Command Reference*.

Setting the maximum number of records for SSH user login exceptions

1. Enter system view.

   system-view

2. Set the maximum number of records for SSH user login exceptions.

   ssh exception-record max-number *max-number*

   By default, the maximum number of records for SSH user login exceptions is 10.

   To view more records for SSH user login exceptions, you can use this command to set the maximum number of records.

Setting alarm and recovery thresholds for SSH user login failures in the specified statistics period

1. Enter system view.

   system-view

2. Set alarm and recovery thresholds for SSH user login failures in the specified statistics period.

   ssh server login-failed threshold-alarm upper-limit *report-time* **lower-limit** *resume-time* **period** *period-time*

   By default, the statistics period is 5 minutes, and the SSH user login failure alarm threshold and alarm recovery threshold are 30 and 20, respectively.

   Configure this feature to monitor the SSH user login situation. With this feature configured, the device generates alarms as follows:

   - Generates an alarm when the number of login failures in the specified statistics period reaches or exceeds the alarm threshold.
   - Generates a recovery alarm when the number of login failures in the specified statistics period drops below the alarm recovery threshold from the alarm threshold or a higher value.

Specifying a PKI domain for the SSH server

About this task

The PKI domain specified for the SSH server has the following functions:

- The SSH server uses the PKI domain to send its certificate to the client in the key exchange stage.
- The SSH server uses the PKI domain to authenticate the client's certificate if no PKI domain is specified for the client authentication by using the **ssh user** command.

Procedure

1. Enter system view.

   system-view

2. Specify a PKI domain for the SSH server.

   ssh server pki-domain *domain-name*

   By default, no PKI domain is specified for the SSH server.

Disconnecting SSH sessions

About this task

The device supports concurrent login sessions. To avoid an SSH login user interfering with your configuration, you can disconnect that SSH login user.

Procedure

Execute the following command in user view to disconnect SSH sessions:

free ssh { **user-ip** { *ip-address* | **ipv6** *ipv6-address* } [**port** *port-number*] | **user-pid** *pid-number* | **username** *username* }

Configuring the device as an Stelnet client

Stelnet client tasks at a glance

To configure an Stelnet client, perform the following tasks:

1. Generating local key pairs

   Only required for authentication method **publickey**, **password-publickey**, or **any**.
2. (Optional.) Specifying the source IP address for outgoing SSH packets
3. Establishing a connection to an Stelnet server
4. (Optional.) Deleting server public keys saved in the public key file on the Stelnet client
5. (Optional.) Establishing a connection to an Stelnet server based on Suite B

Generating local key pairs

About this task

You must generate local key pairs on Stelnet clients when the Stelnet server uses the **publickey**, **password-publickey**, or **any** authentication method.

Restrictions and guidelines

Local DSA, ECDSA, and RSA key pairs for SSH use default names. You cannot assign names to the key pairs. For more information about the command for generating key pairs, see public key management commands in *Security Command Reference*.

The key modulus length must be less than 2048 bits when you generate a DSA key pair.

When you generate an ECDSA key pair, you can generate only a **secp256r1** or **secp384r1** ECDSA key pair.

The Stelnet client operating in FIPS mode supports only ECDSA and RSA key pairs.

Procedure

1. Enter system view.

   system-view
2. Generate local key pairs.

   public-key local create { **dsa** | **ecdsa** { **secp256r1** | **secp384r1** } | **rsa** }

Specifying the source IP address for outgoing SSH packets

About this task

After you specify the source IP address for outgoing SSH packets on an Stelnet client, the client uses the specified IP address to communicate with the Stelnet server.

Restrictions and guidelines

As a best practice, specify the IP address of a loopback interface as the source address of outgoing SSH packets for the following purposes:

- Ensuring the communication between the Stelnet client and the Stelnet server.
- Improving the manageability of Stelnet clients in authentication service.

Procedure

1. Enter system view.

   system-view

2. Specify the source address for outgoing SSH packets.

   IPv4:

   ssh client source { **interface** *interface-type interface-number* | **ip** *ip-address* }

   By default, an IPv4 Stelnet client uses the primary IPv4 address of the output interface in the matching route as the source address of the outgoing SSH packets.

   IPv6:

   ssh client ipv6 source { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

   By default, an IPv6 Stelnet client automatically selects a source IPv6 address for outgoing SSH packets in compliance with RFC 3484.

Establishing a connection to an Stelnet server

About this task

Perform this task to enable the Stelnet client feature on the device and establish a connection to the Stelnet server. You can specify the public key algorithm and the preferred encryption, HMAC, and key exchange algorithms to be used during the connection.

To access the server, a client must use the server's host public key to authenticate the server. As a best practice, configure the server's host public key on the device in an insecure network. If the server's host public key is not configured on the client, the client will notify you to confirm whether to continue with the access.

- If you choose to continue, the client accesses the server and downloads the server's host public key. The downloaded public key will be used to authenticate the server in subsequent accesses.

  If the server public key is not specified the when you connect to the server, the device saves the server public key to the public key file. It does not save the server public key to the configuration file.
- If you choose to not continue, the connection cannot be established.

Restrictions and guidelines for establishing a connection to an Stelnet server

An Stelnet client cannot establish connections to both IPv4 and IPv6 Stelnet servers.

Establishing a connection to an IPv4 Stelnet server

Execute the following command in user view to establish a connection with an IPv4 Stelnet server:

In non-FIPS mode:

ssh2 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** |

aes128-ctr | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** }] * [**dscp** *dscp-value* | **escape** *character* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

In FIPS mode:

ssh2 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-ctos-hmac** { **sha2-256** | **sha2-512** } | **prefer-kex** { **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-stoc-hmac** { **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | **escape** *character* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

Establishing a connection to an IPv6 Stelnet server

Execute the following command in user view to establish a connection to an IPv6 Stelnet server:

In non-FIPS mode:

ssh2 ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** }] * [**dscp** *dscp-value* | **escape** *character* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

In FIPS mode:

ssh2 ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-ctos-hmac** { **sha2-256** | **sha2-512** } | **prefer-kex** { **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-stoc-hmac** { **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | **escape** *character* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Deleting server public keys saved in the public key file on the Stelnet client

About this task

When the Stelnet client switches to FIPS mode but the locally saved server public key does not comply with FIPS, the client cannot connect to the server. To connect to the server, delete the server public key saved on the client and make sure a FIPS-compliant public key has been generated on the server.

Procedure

1. Enter system view.
   system-view
2. Delete server public keys saved in the public key file on the Stelnet client.
   delete ssh client server-public-key [**server-ip** *ip-address*]

Establishing a connection to an Stelnet server based on Suite B

Execute the following command in user view to establish a connection to an Stelnet server based on Suite B:

IPv4:

ssh2 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**dscp** *dscp-value* | **escape** *character* | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

IPv6:

ssh2 ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**dscp** *dscp-value* | **escape** *character* | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Configuring the device as an SFTP client

SFTP client tasks at a glance

To configure an SFTP client, perform the following tasks:

1. Generating local key pairs
   Only required for authentication method **publickey**, **password-publickey**, or **any**.
2. (Optional.) Specifying the source IP address for outgoing SFTP packets
3. Establishing a connection to an SFTP server
4. (Optional.) Deleting server public keys saved in the public key file on the SFTP client
5. (Optional.) Establishing a connection to an SFTP server based on Suite B
6. (Optional.) Working with SFTP directories
7. (Optional.) Working with SFTP files

8. (Optional.) Displaying help information
9. (Optional.) Terminating the connection with the SFTP server

Generating local key pairs

About this task

You must generate local key pairs on SFTP clients when the SFTP server uses the **publickey**, **password-publickey**, or **any** authentication method.

Restrictions and guidelines

Local DSA, ECDSA, and RSA key pairs for SSH use default names. You cannot assign names to the key pairs. For more information about the command for generating key pairs, see public key management commands in *Security Command Reference*.

The key modulus length must be less than 2048 bits when you generate a DSA key pair.

When you generate an ECDSA key pair, you can generate only a **secp256r1** or **secp384r1** ECDSA key pair.

The SFTP client operating in FIPS mode supports only ECDSA and RSA key pairs.

Procedure

1. Enter system view.

   system-view
2. Generate local key pairs.

   public-key local create { **dsa** | **ecdsa** { **secp256r1** | **secp384r1** } | **rsa** }

Specifying the source IP address for outgoing SFTP packets

About this task

After you specify the source IP address for outgoing SFTP packets on an SFTP client, the client uses the specified IP address to communicate with the SFTP server.

Restrictions and guidelines

As a best practice, specify the IP address of a loopback interface as the source address of outgoing SFTP packets for the following purposes:

- Ensuring the communication between the SFTP client and the SFTP server.
- Improving the manageability of SFTP clients in authentication service.

Procedure

1. Enter system view.

   system-view
2. Specify the source address for outgoing SFTP packets.

   IPv4:

   sftp client source { **ip** *ip-address* | **interface** *interface-type interface-number* }

   By default, an SFTP client uses the primary IPv4 address of the output interface in the matching route as the source address of the outgoing SFTP packets.

   IPv6:

   sftp client ipv6 source { **ipv6** *ipv6-address* | **interface** *interface-type interface-number* }

By default, an IPv6 SFTP client automatically selects a source IPv6 address for the outgoing SFTP packets in compliance with RFC 3484.

Establishing a connection to an SFTP server

About this task

Perform this task to enable the SFTP client feature on the device and establish a connection to the SFTP server. You can specify the public key algorithm and the preferred encryption, HMAC, and key exchange algorithms to be used during the connection.

To access the server, a client must use the server's host public key to authenticate the server. As a best practice, configure the server's host public key on the device in an insecure network. If the server's host public key is not configured on the client, the client will notify you to confirm whether to continue with the access.

- If you choose to continue, the client accesses the server and downloads the server's host public key. The downloaded public key will be used to authenticate the server in subsequent accesses.

  If the server public key is not specified when you connect to the server, the device saves the server public key to the public key file. It does not save the server public key to the configuration file.
- If you choose to not continue, the connection cannot be established.

Restrictions and guidelines for establishing a connection to an SFTP server

An SFTP client cannot establish connections to both IPv4 and IPv6 SFTP servers.

Establishing a connection to an IPv4 SFTP server

Execute the following command in user view to establish a connection to an IPv4 SFTP server:

In non-FIPS mode:

sftp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** }] * [**dscp** *dscp-value* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

In FIPS mode:

sftp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-ctos-hmac** { **sha2-256** | **sha2-512** } | **prefer-kex** { **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-stoc-hmac** { **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | { **public-key** *keyname* |

server-pki-domain *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

Establishing a connection to an IPv6 SFTP server

Execute the following command in user view to establish a connection to an IPv6 SFTP server:

In non-FIPS mode:

sftp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** }] * [**dscp** *dscp-value* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

In FIPS mode:

sftp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-ctos-hmac** { **sha2-256** | **sha2-512** } | **prefer-kex** { **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-stoc-hmac** { **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Deleting server public keys saved in the public key file on the SFTP client

About this task

When the SFTP client switches to FIPS mode but the locally saved server public key does not comply with FIPS, the client cannot connect to the server. To connect to the server, delete the server public key saved on the client and make sure a FIPS-compliant public key has been generated on the server.

Procedure

1. Enter system view.

   system-view

2. Delete server public keys saved in the public key file on the SFTP client.

   delete ssh client server-public-key [**server-ip** *ip-address*]

Establishing a connection to an SFTP server based on Suite B

Execute the following command in user view to establish a connection to an SFTP server based on Suite B:

IPv4:

sftp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress** **zlib**] [**dscp** *dscp-value* | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

IPv6:

sftp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress** **zlib**] [**dscp** *dscp-value* | **escape** *character* | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Working with SFTP directories

About this task

After you establish a connection to an SFTP server, you can operate directories of the SFTP server.

Changing the working directory on the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Change the working directory on the SFTP server.

   cd [*remote-path*]
3. (Optional.) Return to the upper-level directory.

   cdup

Displaying the current working directory on the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Display the current working directory on the SFTP server.

   pwd

Displaying files under a directory

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Display files under a directory.
   - **dir** [**-a** | **-l**] [*remote-path*]
   - **ls** [**-a** | **-l**] [*remote-path*]

   The **dir** command has the same function as the **ls** command.

Changing the name of a directory on the SFTP server

1. Enter SFTP client view.

For more information, see "Establishing a connection to an SFTP server."

2. Change the name of a directory on the SFTP server.
   rename *oldname newname*

Creating a new directory on the SFTP server

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Create a new directory on the SFTP server.
   mkdir *remote-path*

Deleting directories on the SFTP server

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Delete one or more directories from the SFTP server.
   rmdir *remote-path*

Working with SFTP files

About this task

After you establish a connection to an SFTP server, you can operate files on the SFTP server.

Changing the name of a file on the SFTP server

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Change the name of a file on the SFTP server.
   rename *old-name new-name*

Downloading a file from the SFTP server and save it locally

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Download a file from the SFTP server and save it locally.
   get *remote-file* [*local-file*]

Uploading a local file to the SFTP server

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Upload a local file to the SFTP server.
   put *local-file* [*remote-file*]

Display files under a directory

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Display files under a directory.
   - **dir** [**-a** | **-l**] [*remote-path*]
   - **ls** [**-a** | **-l**] [*remote-path*]

   The **dir** command has the same function as the **ls** command.

Deleting a file from the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Delete a file from the SFTP server.
   - **`delete`** *`remote-file`*
   - **`remove`** *`remote-file`*

   The **`delete`** command has the same function as the **`remove`** command.

Displaying help information

About this task

After you establish a connection to the SFTP server, you can display the help information of SFTP client commands, including the command syntax and parameter configuration.

Procedure

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Display SFTP client command help information.
   - **`help`**
   - **`?`**

   The **`help`** command has the same function as the **`?`** command.

Terminating the connection with the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Terminate the connection with the SFTP server and return to user view.
   - **`bye`**
   - **`exit`**
   - **`quit`**

   The three commands have the same function.

Configuring the device as an SCP client

SCP client tasks at a glance

To configure an SCP client, perform the following tasks:

1. Generating local key pairs

   Only required for the **publickey**, **password-publickey**, or **any** authentication method.
2. (Optional.) Specifying the source IP address for outgoing SCP packets
3. Establishing a connection to an SCP server
4. (Optional.) Deleting server public keys saved in the public key file on the SCP client
5. (Optional.) Establishing a connection to an SCP server based on Suite B

Generating local key pairs

About this task

You must generate local key pairs on SCP clients when the SCP server uses the **publickey**, **password-publickey**, or **any** authentication method.

Restrictions and guidelines

Local DSA, ECDSA, and RSA key pairs for SSH use default names. You cannot assign names to the key pairs. For more information about the command for generating key pairs, see public key management commands in *Security Command Reference*.

The key modulus length must be less than 2048 bits when you generate a DSA key pair.

When you generate an ECDSA key pair, you can generate only a **secp256r1** or **secp384r1** ECDSA key pair.

The SCP client operating in FIPS mode supports only ECDSA and RSA key pairs.

Procedure

1. Enter system view.

   system-view

2. Generate local key pairs.

   public-key local create { **dsa** | **ecdsa** { **secp256r1** | **secp384r1** } | **rsa** }

Specifying the source IP address for outgoing SCP packets

About this task

After you specify the source IP address for outgoing SCP packets on an SCP client, the client uses the specified IP address to communicate with the SCP server.

Restrictions and guidelines

As a best practice, specify the IP address of a loopback interface as the source address of outgoing SCP packets for the following purposes:

- Ensuring the communication between the SCP client and the SCP server.
- Improving the manageability of SCP clients in authentication service.

Procedure

1. Enter system view.

   system-view

2. Specify the source address for outgoing SCP packets.

   IPv4:

   scp client source { **interface** *interface-type interface-number* | **ip** *ip-address* }

   By default, an SCP client uses the primary IPv4 address of the output interface in the matching route as the source address of the outgoing SCP packets.

   IPv6:

   scp client ipv6 source { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

   By default, an SCP client automatically selects an IPv6 address as the source address of the outgoing packets in compliance with RFC 3484.

Establishing a connection to an SCP server

About this task

Perform this task to enable the SCP client feature on the device, establish a connection to the SCP server, and transfer files with the server. You can specify the public key algorithm and the preferred encryption, HMAC, and key exchange algorithms to be used during the connection.

To access the server, a client must use the server's host public key to authenticate the server. As a best practice, configure the server's host public key on the device in an insecure network. If the server's host public key is not configured on the client, the client will notify you to confirm whether to continue with the access.

- If you choose to continue, the client accesses the server and downloads the server's host public key. The downloaded public key will be used to authenticate the server in subsequent accesses.

  If the server public key is not specified when you connect to the server, the device saves the server public key to the public key file. It does not save the server public key to the configuration file.
- If you choose to not continue, the connection cannot be established.

Restrictions and guidelines for establishing a connection to an SCP server

An SCP client cannot establish connections to both IPv4 and IPv6 SCP servers.

Establishing a connection to an IPv4 SCP server

Execute the following command in user view to connect to an IPv4 SCP server, and transfer files with the server:

In non-FIPS mode:

scp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] { **put** | **get** } *source-file-name* [*destination-file-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** }] * [{ **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

In FIPS mode:

scp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] { **put** | **get** } *source-file-name* [*destination-file-name*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-ctos-hmac** { **sha2-256** | **sha2-512** } | **prefer-kex** { **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-stoc-hmac** { **sha2-256** | **sha2-512** }] * [{ **public-key** *keyname* | **server-pki-domain**

domain-name } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

Establishing a connection to an IPv6 SCP server

Execute the following command in user view to connect to an IPv6 SCP server, and transfer files with the server.

In non-FIPS mode:

scp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] { **put** | **get** } *source-file-name* [*destination-file-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress** **zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** | **sm4-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** }] * [{ **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

In FIPS mode:

scp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] { **put** | **get** } *source-file-name* [*destination-file-name*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress** **zlib** | **prefer-ctos-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-ctos-hmac** { **sha2-256** | **sha2-512** } | **prefer-kex** { **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } | **prefer-stoc-hmac** { **sha2-256** | **sha2-512** }] * [{ **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

Deleting server public keys saved in the public key file on the SCP client

About this task

When the SCP client switches to FIPS mode but the locally saved server public key does not comply with FIPS, the client cannot connect to the server. To connect to the server, delete the server public key saved on the client and make sure a FIPS-compliant public key has been generated on the server.

Procedure

1. Enter system view.

   system-view

2. Delete server public keys saved in the public key file on the SCP client.

   delete ssh client server-public-key [**server-ip** *ip-address*]

Establishing a connection to an SCP server based on Suite B

Execute the following command in user view to establish a connection to an SCP server based on Suite B:

IPv4:

scp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] { **put** | **get** } *source-file-name* [*destination-file-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

IPv6:

scp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] { **put** | **get** } *source-file-name* [*destination-file-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

Specifying algorithms for SSH2

About algorithms for SSH2

The SSH2 client and server use the following types of algorithms for algorithm negotiation during the Stelnet, SFTP, or SCP session establishment:

- Key exchange algorithms.
- Public key algorithms.
- Encryption algorithms.
- MAC algorithms.

If you specify algorithms, SSH2 uses only the specified algorithms for algorithm negotiation. The client uses the specified algorithms to initiate the negotiation, and the server uses the matching algorithms to negotiate with the client. If multiple algorithms of the same type are specified, the algorithm specified earlier has a higher priority during negotiation.

Specifying key exchange algorithms for SSH2

1. Enter system view.

   system-view

2. Specify key exchange algorithms for SSH2.

   In non-FIPS mode:

   ssh2 algorithm key-exchange { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } *

   By default, SSH2 uses the **ecdh-sha2-nistp256**, **ecdh-sha2-nistp384**, **dh-group-exchange-sha1**, **dh-group14-sha1**, and **dh-group1-sha1** key exchange algorithms in descending order of priority for algorithm negotiation.

   In FIPS mode:

ssh2 algorithm key-exchange { **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } *

By default, SSH2 uses the **ecdh-sha2-nistp256** and **ecdh-sha2-nistp384** key exchange algorithms in descending order of priority for algorithm negotiation.

Specifying public key algorithms for SSH2

1. Enter system view.

   system-view

2. Specify public key algorithms for SSH2.

   In non-FIPS mode:

   ssh2 algorithm public-key { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } *

   By default, SSH2 uses the **x509v3-ecdsa-sha2-nistp256**, **x509v3-ecdsa-sha2-nistp384**, **ecdsa-sha2-nistp256**, **ecdsa-sha2-nistp384**, **rsa**, and **dsa** public key algorithms in descending order of priority for algorithm negotiation.

   In FIPS mode:

   ssh2 algorithm public-key { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } *

   By default, SSH2 uses the **x509v3-ecdsa-sha2-nistp256**, **x509v3-ecdsa-sha2-nistp384**, **ecdsa-sha2-nistp256**, **ecdsa-sha2-nistp384**, and **rsa** public key algorithms in descending order of priority for algorithm negotiation.

Specifying encryption algorithms for SSH2

1. Enter system view.

   system-view

2. Specify encryption algorithms for SSH2.

   In non-FIPS mode:

   ssh2 algorithm cipher { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes128-gcm@openssh** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **aes256-gcm@openssh** | **des-cbc** | **sm4-cbc** } *

   By default, SSH2 uses the **aes128-ctr**, **aes192-ctr**, **aes256-ctr**, **aes128-gcm@openssh**, **aes256-gcm@openssh**, **aes128-gcm**, **aes256-gcm**, **aes128-cbc**, **3des-cbc**, **aes256-cbc**, **des-cbc**, and **sm4-cbc** encryption algorithms in descending order of priority for algorithm negotiation.

   In FIPS mode:

   ssh2 algorithm cipher { **aes128-gcm** | **aes128-gcm@openssh** | **aes256-gcm** | **aes256-gcm@openssh** } *

   By default, SSH2 uses the **aes128-gcm@openssh**, **aes256-gcm@openssh**, **aes128-gcm**, and **aes256-gcm** encryption algorithms in descending order of priority for algorithm negotiation.

Specifying MAC algorithms for SSH2

1. Enter system view.

   system-view

2. Specify MAC algorithms for SSH2.

   In non-FIPS mode:

   ssh2 algorithm mac { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** | **sm3** } *

   By default, SSH2 uses the **sha2-256**, **sha2-512**, **sha1**, **md5**, **sha1-96**, **md5-96**, and **sm3** MAC algorithms in descending order of priority for algorithm negotiation.

   In FIPS mode:

   ssh2 algorithm mac { **sha2-256** | **sha2-512** } *

   By default, SSH2 uses the **sha2-256** and **sha2-512** MAC algorithms in descending order of priority for algorithm negotiation.

Display and maintenance commands for SSH

Execute **display** commands in any view.

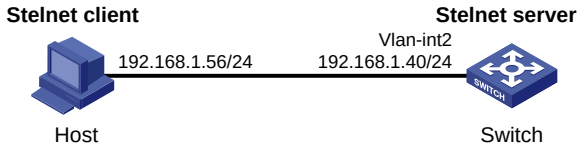
Task	Command
Display the public keys of the local key pairs.	**display public-key local** { **dsa** | **ecdsa** | **rsa** } **public** [**name** *publickey-name*]
Display information about peer public keys.	**display public-key peer** [**brief** | **name** *publickey-name*]
Display the source IP address configuration of the SCP client.	**display scp client source**
Display the source IP address configuration of the SFTP client.	**display sftp client source**
Display server public key information saved in the public key file on the SSH client.	**display ssh client server-public-key** [**server-ip** *ip-address*]
Display the source IP address configuration of the Stelnet client.	**display ssh client source**
Display SSH server status or sessions.	**display ssh server** { **session** | **status** }
Display SSH user information on the SSH server.	**display ssh user-information** [*username*]
Display algorithms used by SSH2 in the algorithm negotiation stage.	**display ssh2 algorithm**
Display records for SSH user login exceptions.	**display ssh exception-record**

For more information about the **display public-key local** and **display public-key peer** commands, see public key management commands in *Security Command Reference*.

Stelnet configuration examples

Unless otherwise noted, devices in the configuration examples operate in non-FIPS mode.

When the device acts as an Stelnet server operating in FIPS mode, only ECDSA and RSA key pairs are supported. Do not generate a DSA key pair on the Stelnet server.



Example: Configuring the device as an Stelnet server (password authentication)

Network configuration

As shown in Figure 1:

- The switch acts as the Stelnet server and uses password authentication to authenticate the Stelnet client. The username and password of the client are saved on the switch.
- The host acts as the Stelnet client, using Stelnet client software (SSH2). After the user on the host logs in to the switch through Stelnet, the user can configure and manage the switch as a network administrator.

Figure 1 Network diagram

Procedure

1. Configure the Stelnet server:

   # Generate RSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

   # Generate a DSA key pair.

```
[Switch] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
...+.................+..........+...+.
Create the key pair successfully.
```

   # Generate an ECDSA key pair.

```
[Switch] public-key local create ecdsa secp256r1
Generating Keys...
.
```

```
Create the key pair successfully.
```

Enable the Stelnet server.

```
[Switch] ssh server enable
```

Assign an IP address to VLAN-interface 2. The Stelnet client uses this address as the destination for SSH connection.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[Switch-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Create a local device management user named **client001**.

```
[Switch] local-user client001 class manage
```

Set a password for local user **client001**.

```
[Switch-luser-manage-client001] password simple 123456TESTplat&!
```

Authorize local user **client001** to use the **SSH** service.

```
[Switch-luser-manage-client001] service-type ssh
```

Assign the **network-admin** user role to local user **client001**.

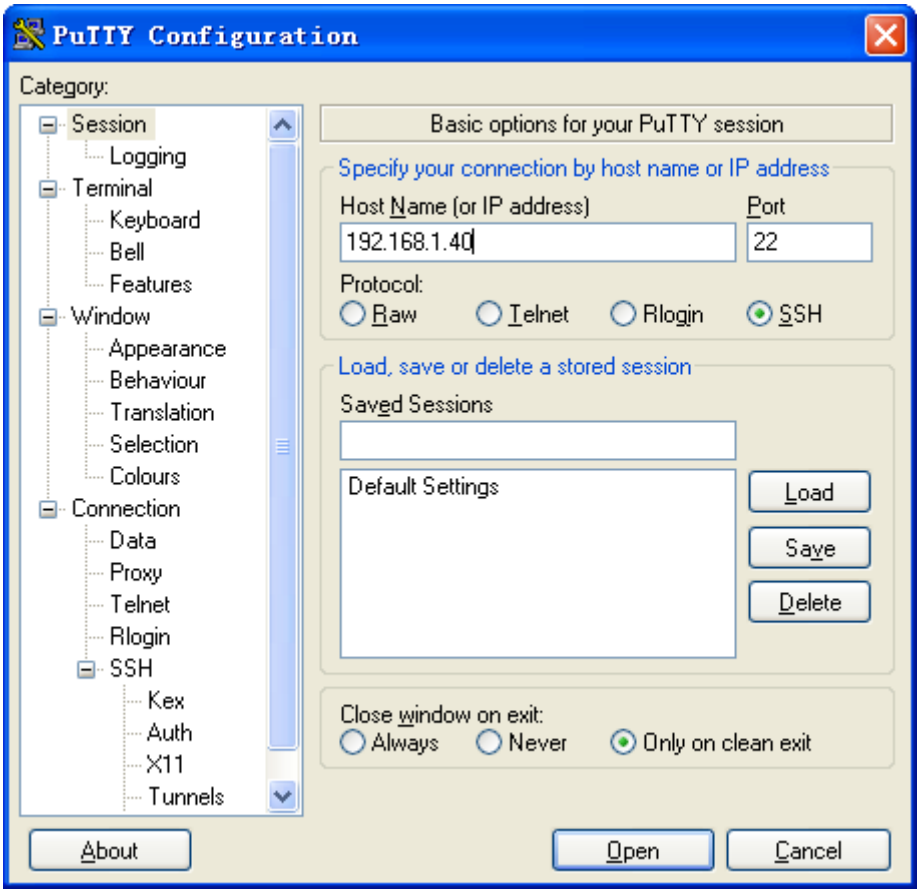
```
[Switch-luser-manage-client001] authorization-attribute user-role network-admin
[Switch-luser-manage-client001] quit
```

Create an SSH user named **client001**. Specify the service type as **stelnet** and the authentication method as **password** for the user.

```
[Switch] ssh user client001 service-type stelnet authentication-type password
```

2. Establish a connection to the Stelnet server:

There are different types of Stelnet client software, such as PuTTY and OpenSSH. This example uses an Stelnet client that runs PuTTY version 0.58.



To establish a connection to the Stelnet server:

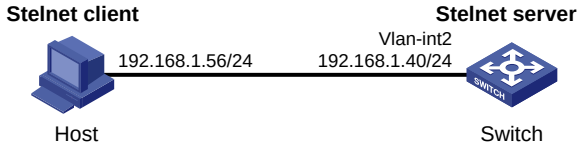
a. Launch PuTTY.exe to enter the interface shown in Figure 2.

b. In the **Host Name (or IP address)** field, enter IP address **192.168.1.40** of the Stelnet server.

c. Click **Open**.

Figure 2 Specifying the host name (or IP address)

a. Enter username **client001** and the password to log in to the Stelnet server.



Example: Configuring the device as an Stelnet server (publickey authentication)

Network configuration

As shown in Figure 3:

- The switch acts as the Stelnet server, and it uses publickey authentication and the RSA public key algorithm.
- The host acts as the Stelnet client, using Stelnet client software (SSH2). After the user on the host logs in to the switch through Stelnet, the user can configure and manage the switch as a network administrator.

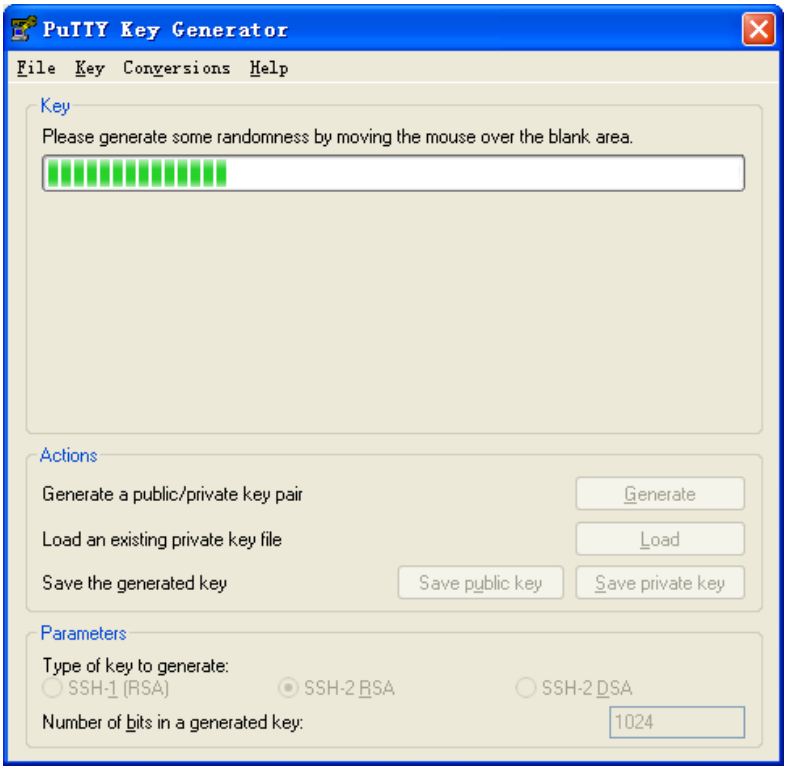
Figure 3 Network diagram

Procedure

In the server configuration, the client's host public key is required. Use the client software to generate RSA key pairs on the client before configuring the Stelnet server.

There are different types of Stelnet client software, such as PuTTY and OpenSSH. This example uses an Stelnet client that runs PuTTY version 0.58.

The configuration procedure is as follows:



1. Generate RSA key pairs on the Stelnet client:
   a. Run PuTTYGen.exe on the client, select **SSH-2 RSA** and click **Generate**.

Figure 4 Generating a key pair on the client

   a. Continue moving the mouse during the key generating process, but do not place the mouse over the green progress bar shown in Figure 5. Otherwise, the progress bar stops moving and the key pair generating progress stops.

Figure 5 Generating process

a. After the key pair is generated, click **Save public key** to save the public key. A file saving window appears.

Figure 6 Saving a key pair on the client

a. Enter a file name (**key.pub** in this example), and click **Save**.

b. On the page shown in Figure 6, click **Save private key** to save the private key.

A confirmation dialog box appears.

c. Click **Yes**.

A file saving window appears.

d. Enter a file name (**private.ppk** in this example), and click **Save**.

e. Transmit the public key file to the server through FTP or TFTP. (Details not shown.)

2. Configure the Stelnet server:

Generate RSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

Generate a DSA key pair.

```
[Switch] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.................................+
...+.................+..........+...+
Create the key pair successfully.
```

Generate an ECDSA key pair.

```
[Switch] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

Enable the Stelnet server.

```
[Switch] ssh server enable
```

Assign an IP address to VLAN-interface 2. The Stelnet client uses this IP address as the destination for SSH connection.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[Switch-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
```

```
[Switch-line-vty0-63] quit
```

Import the client's public key from the public key file **key.pub** and name it **switchkey**.

```
[Switch] public-key peer switchkey import sshkey key.pub
```

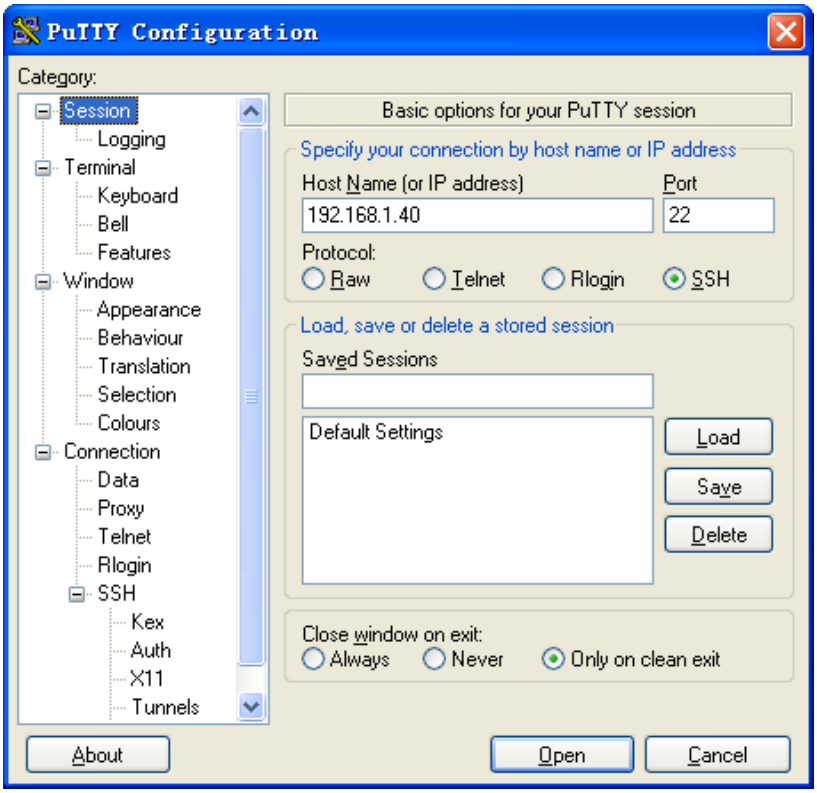
Create an SSH user named **client002**. Specify the authentication method as **publickey** for the user, and assign the public key **switchkey** to the user.

```
[Switch] ssh user client002 service-type stelnet authentication-type publickey assign publickey switchkey
```

Create a local device management user named **client002**.

```
[Switch] local-user client002 class manage
```

Authorize local user **client002** to use the **SSH** service.



```
[Switch-luser-manage-client002] service-type ssh
```

Assign the **network-admin** user role to local user **client002**.

```
[Switch-luser-manage-client002] authorization-attribute user-role network-admin
[Switch-luser-manage-client002] quit
```

3. Specify the private key file and establish a connection to the Stelnet server:
   a. Launch PuTTY.exe on the Stelnet client to enter the interface shown in Figure 7.
   b. In the **Host Name (or IP address)** field, enter IP address **192.168.1.40** of the Stelnet server.

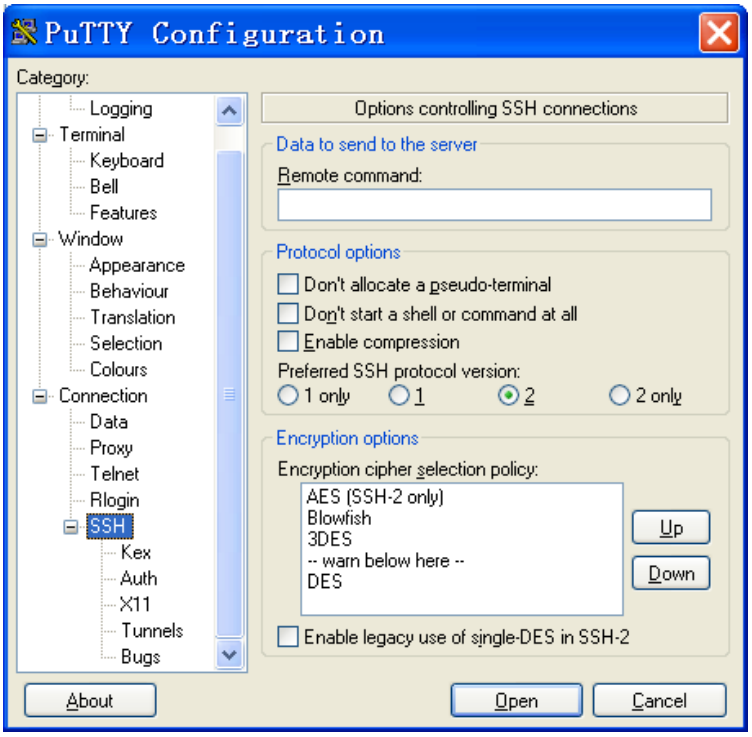


Figure 7 Specifying the host name (or IP address)

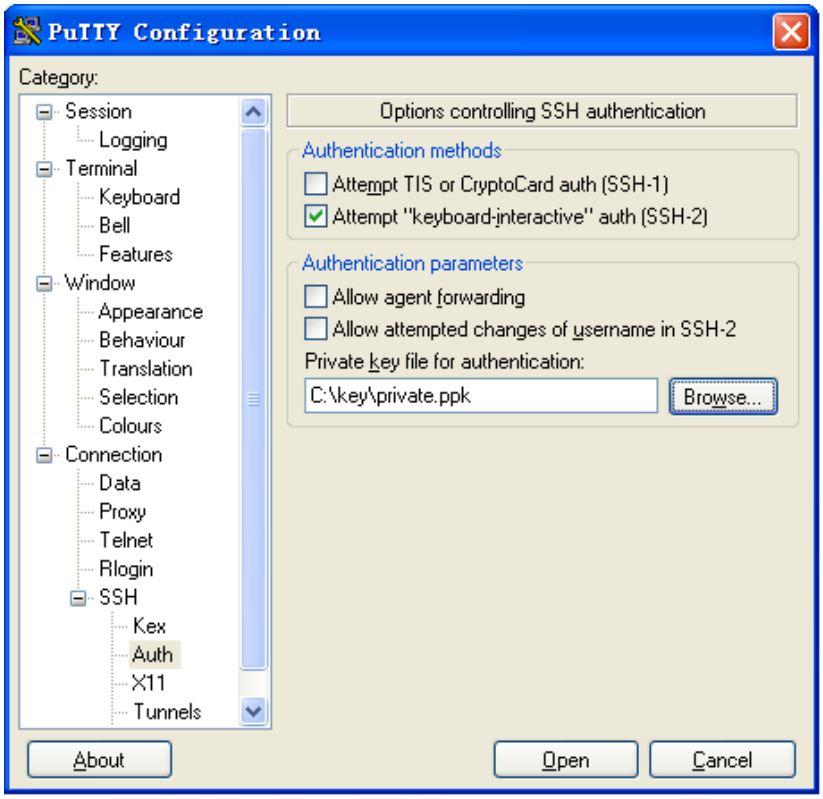
   a. From the navigation tree, select **Connection** > **SSH**.

      The window shown in Figure 8 appears.
   b. Set **Preferred SSH protocol version** to **2**.

Figure 8 Setting the preferred SSH version



a. From the navigation tree, select **Connection** > **SSH** > **Auth**.

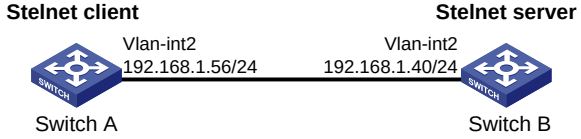
The window shown in Figure 9 appears.

b. Click **Browse…** to open the file selection window, and then select the private key file (**private.ppk** in this example).

c. Click **Open**.

Figure 9 Specifying the private key file

a. Entering username **client002** to log in to the Stelnet server.



Example: Configuring the device as an Stelnet client (password authentication)

Network configuration

As shown in Figure 10:

- Switch B acts as the Stelnet server and uses password authentication to authenticate the Stelnet client. The username and password of the client are saved on Switch B.
- Switch A acts as the Stelnet client. After the user on Switch A logs in to Switch B through Stelnet, the user can configure and manage Switch B as a network administrator.

Figure 10 Network diagram

Procedure

1. Configure the Stelnet server:

Generate RSA key pairs.

```
<SwitchB> system-view
[SwitchB] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
```

```
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

Generate a DSA key pair.

```
[SwitchB] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.................................+
...+.............+.........+...+
Create the key pair successfully.
```

Generate an ECDSA key pair.

```
[SwitchB] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

Enable the Stelnet server.

```
[SwitchB] ssh server enable
```

Assign an IP address to VLAN-interface 2. The Stelnet client uses this address as the destination address of the SSH connection.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[SwitchB] line vty 0 63
[SwitchB-line-vty0-63] authentication-mode scheme
[SwitchB-line-vty0-63] quit
```

Create a local device management user named **client001**.

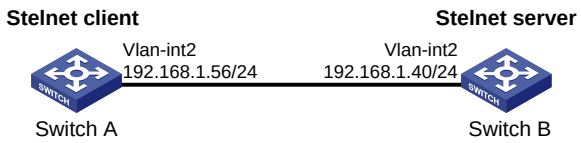
* no decompiling or reverse-engineering shall be allowed.              *
************************************************************************
<SwitchB>
```

After you enter the correct username and password, you can successfully log in to Switch B.



Example: Configuring the device as an Stelnet client (publickey authentication)

Network configuration

As shown in Figure 11:

- Switch B acts as the Stelnet server, and it uses publickey authentication and the DSA public key algorithm.
- Switch A acts as the Stelnet client. After the user on Switch A logs in to Switch B through Stelnet, the user can configure and manage Switch B as a network administrator.

Figure 11 Network diagram

Procedure

In the server configuration, the client's host public key is required. Generate a DSA key pair on the client before configuring the Stelnet server.

1. Configure the Stelnet client:

   # Assign an IP address to VLAN-interface 2.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ip address 192.168.1.56 255.255.255.0
   [SwitchA-Vlan-interface2] quit
   ```

   # Generate a DSA key pair.

   ```
   [SwitchA] public-key local create dsa
   The range of public key modulus is (512 ~ 2048).
   If the key modulus is greater than 512, it will take a few minutes.
   Press CTRL+C to abort.
   Input the modulus length [default = 1024]:
   Generating Keys...
   ```

```
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
...+................+.........+...+
Create the key pair successfully.
```

Export the DSA host public key to a public key file named **key.pub**.

```
[SwitchA] public-key local export dsa ssh2 key.pub
[SwitchA] quit
```

Transmit the public key file **key.pub** to the server through FTP or TFTP. (Details not shown.)

2. Configure the Stelnet server:

Generate RSA key pairs.

```
<SwitchB> system-view
[SwitchB] public-key local create rsa
The range of public key modulus is (512 ~ 4096)
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.......................++++++
...................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

Generate a DSA key pair.

```
[SwitchB] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
...+................+.........+...+
Create the key pair successfully.
```

Generate an ECDSA key pair.

```
[SwitchB] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

Enable the Stelnet server.

```
[SwitchB] ssh server enable
```

Assign an IP address to VLAN-interface 2. The Stelnet client uses this address as the destination address for SSH connection.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[SwitchB] line vty 0 63
[SwitchB-line-vty0-63] authentication-mode scheme
```

```
[SwitchB-line-vty0-63] quit
```

Import the peer public key from the public key file **key.pub**, and name it **switchkey**.

```
[SwitchB] public-key peer switchkey import sshkey key.pub
```

Create an SSH user named **client002**. Specify the authentication method as **publickey** for the user. Assign the public key **switchkey** to the user.

```
[SwitchB] ssh user client002 service-type stelnet authentication-type publickey
assign publickey switchkey
```

Create a local device management user named **client002**.

```
[SwitchB] local-user client002 class manage
```

Authorize local user **client002** to use the **SSH** service.

```
[SwitchB-luser-manage-client002] service-type ssh
```

Assign the **network-admin** user role to local user **client002**.

```
[SwitchB-luser-manage-client002] authorization-attribute user-role network-admin
[SwitchB-luser-manage-client002] quit
```

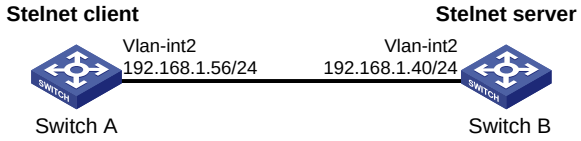
3. Establish an SSH connection to the Stelnet server.

```
<SwitchA> ssh2 192.168.1.40 identity-key dsa
Username: client002
Press CTRL+C to abort.
Connecting to 192.168.1.40 port 22.
The server is not authenticated. Continue? [Y/N]:y
Do you want to save the server public key? [Y/N]:n
Enter a character ~ and a dot to abort.

*****************************************************************************
* Copyright (c) 2004-2017 New H3C Technologies Co., Ltd. All rights reserved.*
* Without the owner's prior written consent,                                *
* no decompiling or reverse-engineering shall be allowed.                   *
*****************************************************************************

<SwitchB>
```

After you enter username **client002** and then enter **y** to continue accessing the server, you can log in to the server successfully.



Example: Configuring Stelnet based on 128-bit Suite B algorithms

Network configuration

As shown in Figure 12:

- Switch B acts as the Stelnet Suite B server (SSH2), and it uses publickey authentication to authenticate the Stelnet client.
- Switch A acts as an Stelnet Suite B client (SSH2). After the user on Switch A logs in to Switch B through the Stelnet Suite B client software, the user can configure and manage Switch B as an administrator.

Figure 12 Network diagram

Procedure

1. Generate the client's certificate and the server's certificate. (Details not shown.)

   You must first configure the certificates of the server and the client because they are required for identity authentication between the two parties.

   In this example, the server's certificate file is **ssh-server-ecdsa256.p12** and the client's certificate file is **ssh-client-ecdsa256.p12**.

2. Configure the Stelnet client:

   You can modify the pkix version of the client software OpenSSH to support Suite B. This example uses an H3C switch as an Stelnet client.

   # Upload the server's certificate file **ssh-server-ecdsa256.p12** and the client's certificate file **ssh-client-ecdsa256.p12** to the Stelnet client through FTP or TFTP. (Details not shown.)

   # Create a PKI domain named **server256** for verifying the server's certificate and enter its view.

   ```
   <SwitchA> system-view
   [SwitchA] pki domain server256
   ```

   # Disable CRL checking.

   ```
   [SwitchA-pki-domain-server256] undo crl check enable
   [SwitchA-pki-domain-server256] quit
   ```

   # Import local certificate file **ssh-server-ecdsa256.p12** to PKI domain **server256**.

   ```
   [SwitchA] pki import domain server256 p12 local filename ssh-server-ecdsa256.p12
   The system is going to save the key pair. You must specify a key pair name, which is
   a case-insensitive string of 1 to 64 characters. Valid characters include a to z, A
   to Z, 0 to 9, and hyphens (-).
   Please enter the key pair name[default name: server256]:
   ```

   # Display information about local certificates in PKI domain **server256**.

   ```
   [SwitchA] display pki certificate domain server256 local
   Certificate:

```

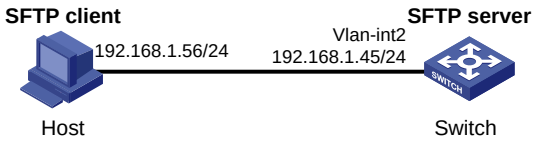
SFTP configuration examples

Unless otherwise noted, devices in the configuration examples operate in non-FIPS mode.

When the device acts as an SFTP server operating in FIPS mode, only ECDSA and RSA key pairs are supported. Do not generate a DSA key pair on the SFTP server.

Example: Configuring the device as an SFTP server (password authentication)



Network configuration

As shown in Figure 13:

- The switch acts as the SFTP server and uses password authentication to authenticate the SFTP client. The username and password of the client are saved on the switch.

- The host acts as the SFTP client. After the user on the client logs in to the switch through SFTP, the user can perform file management and transfer operations on the switch as a network administrator.

  Figure 13 Network diagram

Procedure

1. Configure the SFTP server:

   # Generate RSA key pairs.

   ```
   <Switch> system-view
   [Switch] public-key local create rsa
   The range of public key modulus is (512 ~ 4096).
   If the key modulus is greater than 512, it will take a few minutes.
   Press CTRL+C to abort.
   Input the modulus length [default = 1024]:
   Generating Keys...
   ........................++++++
   ...................++++++
   ..++++++++
   ............++++++++
   Create the key pair successfully.
   ```

   # Generate a DSA key pair.

   ```
   [Switch] public-key local create dsa
   The range of public key modulus is (512 ~ 2048).
   If the key modulus is greater than 512, it will take a few minutes.
   Press CTRL+C to abort.
   Input the modulus length [default = 1024]:
   Generating Keys...
   .++++++++++++++++++++++++++++++++++++++++++++++++++*
   ........+......+.....+.....................................+
   ...+................+..........+...+
   Create the key pair successfully.
   ```

   # Generate an ECDSA key pair.

   ```
   [Switch] public-key local create ecdsa secp256r1
   Generating Keys...
   .
   Create the key pair successfully.
   ```

   # Enable the SFTP server.

   ```
   [Switch] sftp server enable
   ```

   # Assign an IP address to VLAN-interface 2. The client uses this address as the destination for SSH connection.

   ```
   [Switch] interface vlan-interface 2
   [Switch-Vlan-interface2] ip address 192.168.1.45 255.255.255.0
   [Switch-Vlan-interface2] quit
   ```

Create a local device management user named **client002**.

```
[Switch] local-user client002 class manage
```

Set a password for local user **client002**.

```
[Switch-luser-manage-client002] password simple 123456TESTplat&!
```

Authorize local user **client002** to use the **SSH** service.

```
[Switch-luser-manage-client002] service-type ssh
```

Assign the **network-admin** user role and working directory **flash:/** to local user **client002**.

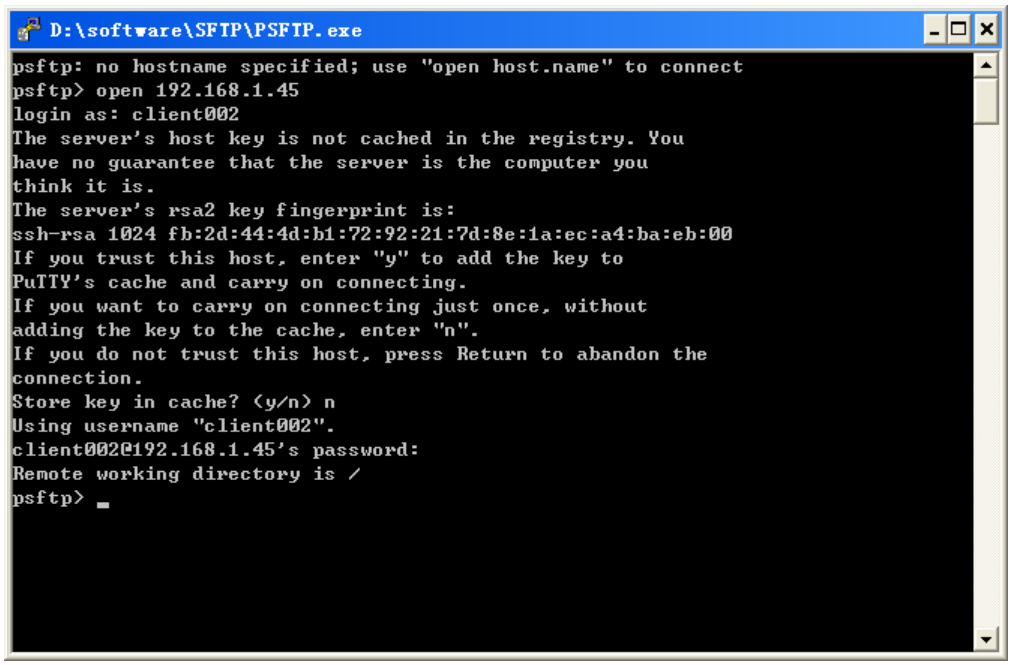
```
[Switch-luser-manage-client002] authorization-attribute user-role network-admin
work-directory flash:/
[Switch-luser-manage-client002] quit
```

Create an SSH user named **client002**. Specify the authentication method as **password** and service type as **sftp** for the user.

```
[Switch] ssh user client002 service-type sftp authentication-type password
```

2. Establish a connection between the SFTP client and the SFTP server:

This example uses an SFTP client that runs PSFTP of PuTTy version 0.58. PSFTP supports only password authentication.



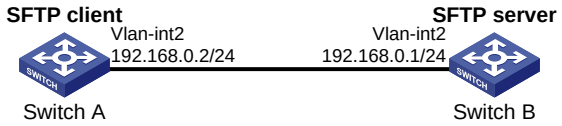
To establish a connection to the SFTP server:

a. Run the **psftp.exe** to launch the client interface shown in Figure 14, and enter the following command:

```
open 192.168.1.45
```

b. Enter username **client002** and the password to log in to the SFTP server.

Figure 14 SFTP client interface



Example: Configuring the device as an SFTP client (publickey authentication)

Network configuration

As shown in Figure 15:

- Switch B acts as the SFTP server, and it uses publickey authentication and the RSA public key algorithm.
- Switch A acts as the SFTP client. After the user on Switch A logs in to Switch B through SFTP, the user can perform file management and transfer operations on Switch B as a network administrator.

Figure 15 Network diagram

Procedure

In the server configuration, the client's host public key is required. Generate RSA key pairs on the client before configuring the SFTP server.

1. Configure the SFTP client:

   # Assign an IP address to VLAN-interface 2.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 192.168.0.2 255.255.255.0
[SwitchA-Vlan-interface2] quit
```

   # Generate RSA key pairs.

```
[SwitchA] public-key local create rsa
The range of public key size is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

   # Export the host public key to a public key file named **pubkey**.

```
[SwitchA] public-key local export rsa ssh2 pubkey
[SwitchA] quit
```

   # Transmit the public key file **pubkey** to the server through FTP or TFTP. (Details not shown.)

2. Configure the SFTP server:

   # Generate RSA key pairs.

```
<SwitchB> system-view
[SwitchB] public-key local create rsa
The range of public key size is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
```

```
.............++++++++
Create the key pair successfully.
```

Generate a DSA key pair.

```
[SwitchB] public-key local create dsa
The range of public key size is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
...+.................+..........+...+
Create the key pair successfully.
```

Generate an ECDSA key pair.

```
[SwitchB] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

Enable the SFTP server.

```
[SwitchB] sftp server enable
```

Assign an IP address to VLAN-interface 2. The SSH client uses this address as the destination for SSH connection.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 192.168.0.1 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Import the peer public key from the public key file **pubkey**, and name it **switchkey**.

```
[SwitchB] public-key peer switchkey import sshkey pubkey
```

Create an SSH user named **client001**. Specify the service type as **sftp** and the authentication method as **publickey** for the user. Assign the public key **switchkey** to the user.

```
[SwitchB] ssh user client001 service-type sftp authentication-type publickey assign
publickey switchkey
```

Create a local device management user named **client001**.

```
[SwitchB] local-user client001 class manage
```

Authorize local user **client001** to use the **SSH** service.

```
[SwitchB-luser-manage-client001] service-type ssh
```

Assign the **network-admin** user role and working directory **flash:/** to local user **client001**.

```
[SwitchB-luser-manage-client001] authorization-attribute user-role network-admin
work-directory flash:/
[SwitchB-luser-manage-client001] quit
```

3. Establish a connection to the SFTP server:

Establish a connection to the SFTP server and enter SFTP client view.

```
<SwitchA> sftp 192.168.0.1 identity-key rsa
Username: client001
Press CTRL+C to abort.
Connecting to 192.168.0.1 port 22.
The server is not authenticated. Continue? [Y/N]:y
Do you want to save the server public key? [Y/N]:n
sftp>
```

Display files under the current directory of the server, delete file **z**, and verify the result.

```
sftp> dir -l
-rwxrwxrwx   1 noone    nogroup      1759 Aug 23 06:52 config.cfg
-rwxrwxrwx   1 noone    nogroup       225 Aug 24 08:01 pubkey2
-rwxrwxrwx   1 noone    nogroup       283 Aug 24 07:39 pubkey
drwxrwxrwx   1 noone    nogroup         0 Sep 01 06:22 new
-rwxrwxrwx   1 noone    nogroup       225 Sep 01 06:55 pub
-rwxrwxrwx   1 noone    nogroup         0 Sep 01 08:00 z
sftp> delete z
Removing /z
sftp> dir -l
-rwxrwxrwx   1 noone    nogroup      1759 Aug 23 06:52 config.cfg
-rwxrwxrwx   1 noone    nogroup       225 Aug 24 08:01 pubkey2
-rwxrwxrwx   1 noone    nogroup       283 Aug 24 07:39 pubkey
drwxrwxrwx   1 noone    nogroup         0 Sep 01 06:22 new
-rwxrwxrwx   1 noone    nogroup       225 Sep 01 06:55 pub
```

Add a directory named **new1** and verify the result.

```
sftp> mkdir new1
sftp> dir -l
-rwxrwxrwx   1 noone    nogroup      1759 Aug 23 06:52 config.cfg
-rwxrwxrwx   1 noone    nogroup       225 Aug 24 08:01 pubkey2
-rwxrwxrwx   1 noone    nogroup       283 Aug 24 07:39 pubkey
drwxrwxrwx   1 noone    nogroup         0 Sep 01 06:22 new
-rwxrwxrwx   1 noone    nogroup       225 Sep 01 06:55 pub
drwxrwxrwx   1 noone    nogroup         0 Sep 02 06:30 new1
```

Change the name of directory **new1** to **new2** and verify the result.

```
sftp> rename new1 new2
sftp> dir -l
-rwxrwxrwx   1 noone    nogroup      1759 Aug 23 06:52 config.cfg
-rwxrwxrwx   1 noone    nogroup       225 Aug 24 08:01 pubkey2

```

```
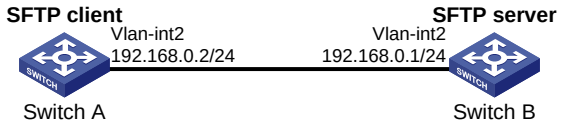
-rwxrwxrwx   1 noone    nogroup       283 Sep 02 06:36 puk
sftp>
```

Exit SFTP client view.

```
sftp> quit
<SwitchA>
```



Example: Configuring SFTP based on 192-bit Suite B algorithms

Network configuration

As shown in Figure 16:

- Switch B acts as the SFTP Suite B server (SSH2), and it uses publickey authentication to authenticate the SFTP client.
- Switch A acts as an SFTP Suite B client (SSH2). After the user on Switch A logs in to Switch B based on the SFTP Suite B client software, the user can manage and transfer files on Switch B as an administrator.

Figure 16 Network diagram

Procedure

1. Generate the client's certificate and the server's certificate. (Details not shown.)

   You must first configure the certificates of the server and the client because they are required for identity authentication between the two parties.

   In this example, the server's certificate file is **ssh-server-ecdsa384.p12** and the client's certificate file is **ssh-client-ecdsa384.p12**.

2. Configure the SFTP client:

   You can modify the pkix version of the client software OpenSSH to support Suite B. This example uses an H3C switch as an SFTP client.

   # Upload the server's certificate file **ssh-server-ecdsa384.p12** and the client's certificate file **ssh-client-ecdsa384.p12** to the SFTP client through FTP or TFTP. (Details not shown.)

   # Create a PKI domain named **server384** for verifying the server's certificate and enter its view.

   ```
   <SwitchA> system-view
   [SwitchA] pki domain server384
   ```

   # Disable CRL checking.

   ```
   [SwitchA-pki-domain-server384] undo crl check enable
   [SwitchA-pki-domain-server384] quit
   ```

   # Import local certificate file **ssh-server-ecdsa384.p12** to PKI domain **server384**.

   ```
   [SwitchA] pki import domain server384 p12 local filename ssh-server-ecdsa384.p12
   The system is going to save the key pair. You must specify a key pair name, which is
   a case-insensitive string of 1 to 64 characters. Valid characters include a to z, A
   to Z, 0 to 9, and hyphens (-).
   Please enter the key pair name[default name: server384]:
   ```

   # Display information about local certificates in PKI domain **server384**.

   ```
   [SwitchA] display pki certificate domain server384 local
   ```

```

[SwitchA] quit
```

3. Configure the SFTP server:

   # Upload the server's certificate file **ssh-server-ecdsa384.p12** and the client's certificate file **ssh-client-ecdsa384.p12** to the SFTP server through FTP or TFTP. (Details not shown.)

   # Create a PKI domain named **client384** for verifying the client's certificate and import the file of the client's certificate to this domain. (Details not shown.)

   # Create a PKI domain named **server384** for the server's certificate and import the file of the server's certificate to this domain. (Details not shown.)

   # Specify Suite B algorithms for algorithm negotiation.

   ```
   [SwitchB] ssh2 algorithm key-exchange ecdh-sha2-nistp384
   [SwitchB] ssh2 algorithm cipher aes256-gcm
   [SwitchB] ssh2 algorithm public-key x509v3-ecdsa-sha2-nistp384
   ```

   # Specify **server384** as the PKI domain of the server's certificate.

   ```
   [SwitchB] ssh server pki-domain server384
   ```

   # Enable the SFTP server.

   ```
   [SwitchB] sftp server enable
   ```

   # Assign an IP address to VLAN-interface 2.

   ```
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] ip address 192.168.0.1 255.255.255.0
   [SwitchB-Vlan-interface2] quit
   ```

   # Set the authentication mode to AAA for user lines.

   ```
   [SwitchB] line vty 0 63
   [SwitchB-line-vty0-63] authentication-mode scheme
   [SwitchB-line-vty0-63] quit
   ```

   # Create a local device management user named **client001**. Authorize the user to use the **SSH** service and assign the **network-admin** user role to the user.

   ```
   [SwitchB] local-user client001 class manage
   [SwitchB-luser-manage-client001] service-type ssh
   [SwitchB-luser-manage-client001] authorization-attribute user-role network-admin
   [SwitchB-luser-manage-client001] quit
   ```

   # Create an SSH user named **client001**. Specify the **publickey** authentication method for the user and specify **client384** as the PKI domain for verifying the client's certificate.

   ```
   [SwitchB] ssh user client001 service-type sftp authentication-type publickey assign
   pki-domain client384
   ```

4. Establish an SFTP connection to the SFTP server based on the 192-bit Suite B algorithms:

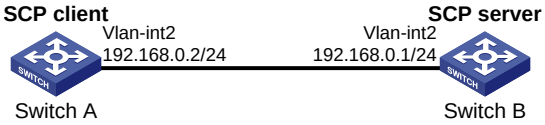
   # Establish an SFTP connection to the server at 192.168.0.1.

   ```
   <SwitchA> sftp 192.168.0.1 suite-b 192-bit pki-domain client384 server-pki-domain
   server384
   Username: client001
   Press CTRL+C to abort.
   Connecting to 192.168.0.1 port 22.
   sftp>
   ```

SCP configuration examples

Unless otherwise noted, devices in the configuration examples operate in non-FIPS mode.

When the device acts as an SCP server operating in FIPS mode, only ECDSA and RSA key pairs are supported. Do not generate a DSA key pair on the SCP server.



Example: Configuring SCP with password authentication

Network configuration

As shown in Figure 17:

- Switch B acts as the SCP server and uses password authentication to authenticate the SCP client. The client's username and password are saved on Switch B.
- Switch A acts as the SCP client. After the user on Switch A logs in to Switch B through SCP, the user can transfer files between switches as a network administrator.

Figure 17 Network diagram

Procedure

1. Configure the SCP server:

   # Generate RSA key pairs.

```
<SwitchB> system-view
[SwitchB] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

   # Generate a DSA key pair.

```
[SwitchB] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
...+.................+..........+...+.
Create the key pair successfully.
```

   # Generate an ECDSA key pair.

```
[SwitchB] public-key local create ecdsa secp256r1
Generating Keys...
.
```

```
Create the key pair successfully.
```

Enable the SCP server.

```
[SwitchB] scp server enable
```

Configure an IP address for VLAN-interface 2. The client uses this address as the destination for SCP connection.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 192.168.0.1 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Create a local device management user named **client001**.

```
[SwitchB] local-user client001 class manage
```

Set a password for local user **client001**.

```
[SwitchB-luser-manage-client001] password simple 123456TESTplat&!
```

Authorize local user **client001** to use the **SSH** service.

```
[SwitchB-luser-manage-client001] service-type ssh
```

Assign the **network-admin** user role to local user **client001**.

```
[SwitchB-luser-manage-client001] authorization-attribute user-role network-admin
[SwitchB-luser-manage-client001] quit
```

Create an SSH user named **client001**. Specify the service type as **scp** and the authentication method as **password** for the user.

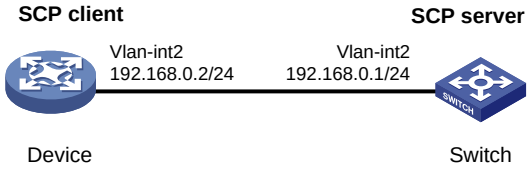
```
[SwitchB] ssh user client001 service-type scp authentication-type password
```

2. Configure an IP address for VLAN-interface 2 on the SCP client.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 192.168.0.2 255.255.255.0
[SwitchA-Vlan-interface2] quit
[SwitchA] quit
```

3. Connect to the SCP server, download file **remote.bin** from the server, and save it as a local file named **local.bin**.

```
<SwitchA> scp 192.168.0.1 get remote.bin local.bin
Username: client001
Press CTRL+C to abort.
Connecting to 192.168.0.1 port 22.
The server is not authenticated. Continue? [Y/N]:y
Do you want to save the server public key? [Y/N]:n
client001@192.168.0.1's password:
remote.bin                                    100% 2875     2.8KB/s   00:00
```



Example: Configuring SCP file transfer with a Linux SCP client

Network configuration

As shown in Figure 18, the switch acts as the SCP server and uses password authentication to authenticate the SCP client. The client's username and password are saved on the switch.

The device acts as the SCP client. After the user on the device logs in to the switch through SCP, the user can transfer files with the switch as a network administrator.

Figure 18 Network diagram

Procedure

1. Configure the SCP server:

   # Generate an RSA key pair.

```
<Switch> system-view
[Switch] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

   # Generate a DSA key pair.

```
[Switch] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.................................+
...+.................+..........+...+.
Create the key pair successfully.
```

   # Generate an ECDSA key pair.

```
[Switch] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

   # Enable the SCP server.

```
[Switch] scp server enable
```

   # Configure an IP address for VLAN interface 2. The SCP client uses this IP address as the destination address of the SCP connection.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.0.1 255.255.255.0
[Switch-Vlan-interface2] quit
```

   # Create a local device management user named **client001**. Set a password for the user, authorize the user to use the SSH service, assign the **network-admin** user role to the user, and specify the working directory as **flash:/**.

```
[Switch] local-user client001 class manage
[Switch-luser-manage-client001] password simple 123456TESTplat&!
[Switch-luser-manage-client001] service-type ssh
[Switch-luser-manage-client001] authorization-attribute user-role network-admin
work-directory flash:/
[Switch-luser-manage-client001] quit
```

Configure an SSH user named **client001**, specify the SCP service for the SSH user, and set the authentication method as password. (This step is optional.)

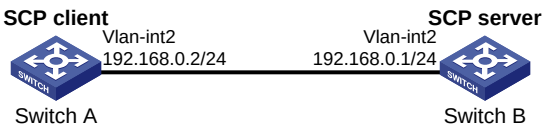
```
[Switch] ssh user client001 service-type scp authentication-type password
```

2. Configure the SCP client:

   The following uses the SCP client running on a Linux system as an example:

   # Connect to the SCP server, download the **remote.bin** file from the server, and save it as a local file named **local.bin**.

```
admin@device:~# scp client001@192.168.0.1:remote.bin local.bin
client001@192.168.0.1's password:
remote.bin                                                    100%   15
     0.0KB/s   00:00
```



Example: Configuring SCP based on Suite B algorithms

Network configuration

As shown in Figure 19:

- Switch B acts as the SCP Suite B server (SSH2), and it uses publickey authentication to authenticate the SCP client.
- Switch A acts as an SCP Suite B client (SSH2). After the user on Switch A logs in to Switch B through the SCP Suite B client software, the user can transfer files between switches as a network administrator.

Figure 19 Network diagram

Procedure

1. Generate the client's certificates and the server's certificates. (Details not shown.)

   You must first configure the certificates of the server and the client because they are required for identity authentication between the two parties.

   In this example, the server's certificate files are **ssh-server-ecdsa256.p12** and **ssh-server-ecdsa384.p12**. The client's certificate files are **ssh-client-ecdsa256.p12** and **ssh-client-ecdsa384.p12**.

2. Configure the SCP client:

   You can modify the pkix version of the client software OpenSSH to support Suite B. This example uses an H3C switch as an SCP client.

   # Upload the server's certificate files (**ssh-server-ecdsa256.p12** and **ssh-server-ecdsa384.p12**) and the client's certificate files (**ssh-client-ecdsa256.p12** and **ssh-client-ecdsa384.p12**) to the SCP client through FTP or TFTP. (Details not shown.)

   # Create a PKI domain named **server256** for verifying the server's certificate **ecdsa256** and enter its view.

```
<SwitchA> system-view
[SwitchA] pki domain server256
```

Disable CRL checking.

```
[SwitchA-pki-domain-server256] undo crl check enable
[SwitchA-pki-domain-server256] quit
```

Import local certificate file **ssh-server-ecdsa256.p12** to PKI domain **server256**.

```
[SwitchA] pki import domain server256 p12 local filename ssh-server-ecdsa256.p12
The system is going to save the key pair. You must specify a key pair name, which is
a case-insensitive string of 1 to 64 characters. Valid characters include a to z, A
to Z, 0 to 9, and hyphens (-).
Please enter the key pair name[default name: server256]:
```

Display information about local certificates in PKI domain **server256**.

```
[SwitchA] display pki certificate domain server256 local

Assign an IP address to VLAN-interface 2.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 192.168.0.2 255.255.255.0
[SwitchA-Vlan-interface2] quit
```

3. Configure the SCP server:

Upload the server's certificate files (**ssh-server-ecdsa256.p12** and **ssh-server-ecdsa384.p12**) and the client's certificate files (**ssh-client-ecdsa256.p12** and **ssh-client-ecdsa384.p12**) to the SCP server through FTP or TFTP. (Details not shown.)

Create a PKI domain named **client256** for verifying the client's certificate **ecdsa256** and import the file of this certificate to this domain. Create a PKI domain named **server256** for the server's certificate **ecdsa256** and import the file of this certificate to this domain. (Details not shown.)

Create a PKI domain named **client384** for verifying the client's certificate **ecdsa384** and import the file of this certificate to this domain. Create a PKI domain named **server384** for the server's certificate **ecdsa384** and import the file of this certificate to this domain. (Details not shown.)

Specify Suite B algorithms for algorithm negotiation.

```
<SwitchB> system-view
[SwitchB] ssh2 algorithm key-exchange ecdh-sha2-nistp256 ecdh-sha2-nistp384
[SwitchB] ssh2 algorithm cipher aes128-gcm aes256-gcm
[SwitchB] ssh2 algorithm public-key x509v3-ecdsa-sha2-nistp256
x509v3-ecdsa-sha2-nistp384
```

Enable the SCP server.

```
[SwitchB] scp server enable
```

Assign an IP address to VLAN-interface 2.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 192.168.0.1 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[SwitchB] line vty 0 63
[SwitchB-line-vty0-63] authentication-mode scheme
[SwitchB-line-vty0-63] quit
```

Create a local device management user named **client001**. Authorize the user to use the **SSH** service and assign the **network-admin** user role to the user.

```
[SwitchB] local-user client001 class manage
[SwitchB-luser-manage-client001] service-type ssh
[SwitchB-luser-manage-client001] authorization-attribute user-role network-admin
[SwitchB-luser-manage-client001] quit
```

Create a local device management user named **client002**. Authorize the user to use the **SSH** service and assign the **network-admin** user role to the user.

```
[SwitchB] local-user client002 class manage
[SwitchB-luser-manage-client002] service-type ssh
[SwitchB-luser-manage-client002] authorization-attribute user-role network-admin
[SwitchB-luser-manage-client002] quit
```

4. Establish an SCP connection to the SCP server:

- Based on the 128-bit Suite B algorithms:

  # Specify **server256** as the PKI domain of the server's certificate.

  ```
  [SwitchB]ssh server pki-domain server256
  ```

  # Create an SSH user **client001**. Specify the **publickey** authentication method for the user and specify **client256** as the PKI domain for verifying the client's certificate.

  ```
  [SwitchB] ssh user client001 service-type scp authentication-type publickey assign pki-domain client256
  ```

  # Establish an SCP connection to the SCP server at 192.168.0.1 based on the 128-bit Suite B algorithms.

  ```
  <SwitchA> scp 192.168.0.1 get src.cfg suite-b 128-bit pki-domain client256 server-pki
  -domain server256
  Username: client001
  Press CTRL+C to abort.
  Connecting to 192.168.0.1 port 22.
  src.cfg                                       100% 4814     4.7KB/s   00:00
  <SwitchA>
  ```

- Based on the 192-bit Suite B algorithms:

  # Specify **server384** as the PKI domain of the server's certificate.

  ```
  [SwitchB] ssh server pki-domain server384
  ```

  # Create an SSH user **client002**. Specify the **publickey** authentication method for the user and specify **client384** as the PKI domain for verifying the client's certificate.

  ```
  [Switch] ssh user client002 service-type scp authentication-type publickey assign pki-domain client384
  ```

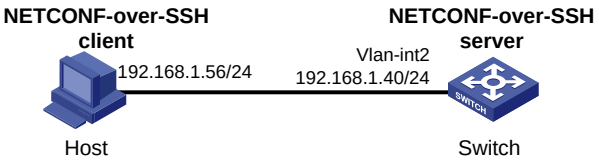
  # Establish an SCP connection to the SCP server at 192.168.0.1 based on the 192-bit Suite B algorithms.

  ```
  <SwitchA> scp 192.168.0.1 get src.cfg suite-b 192-bit pki-domain client384 server-pki
  -domain server384
  Username: client002
  Press CTRL+C to abort.
  Connecting to 192.168.0.1 port 22.
  src.cfg                                       100% 4814     4.7KB/s   00:00
  <SwitchA>
  ```

NETCONF over SSH configuration examples

Unless otherwise noted, devices in the configuration examples are in non-FIPS mode.

When the device acts as a NETCONF-over-SSH server operating in FIPS mode, only ECDSA and RSA key pairs are supported. Do not generate a DSA key pair on the NETCONF-over-SSH server.



Example: Configuring NETCONF over SSH with password authentication

Network configuration

As shown in Figure 20:

- The switch acts as the NETCONF-over-SSH server and uses password authentication to authenticate the client. The client's username and password are saved on the switch.
- The host acts as the NETCONF-over-SSH client, using SSH2 client software. After the user on the host logs in to the switch through NETCONF over SSH, the user can perform NETCONF operations on the switch as a network administrator.

Figure 20 Network diagram

Procedure

Generate RSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

Generate a DSA key pair.

```
[Switch] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
```

```
...+.................+.........+...+.
Create the key pair successfully.
```

Generate an ECDSA key pair.

```
[Switch] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

Enable NETCONF over SSH.

```
[Switch] netconf ssh server enable
```

Configure an IP address for VLAN-interface 2. The client uses this address as the destination for NETCONF-over-SSH connection.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[Switch-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Create a local device management user named **client001**.

```
[Switch] local-user client001 class manage
```

Set a password for local user **client001**.

```
[Switch-luser-manage-client001] password simple 123456TESTplat&!
```

Authorize local user **client001** to use the **SSH** service.

```
[Switch-luser-manage-client001] service-type ssh
```

Assign the **network-admin** user role to local user **client001**.

```
[Switch-luser-manage-client001] authorization-attribute user-role network-admin
[Switch-luser-manage-client001] quit
```

Create an SSH user named **client001**. Specify the service type as **NETCONF** and the authentication method as **password** for the user.

```
[Switch] ssh user client001 service-type netconf authentication-type password
```

Verifying the configuration

Verify that you can perform NETCONF operations after logging in to the switch. (Details not shown.)

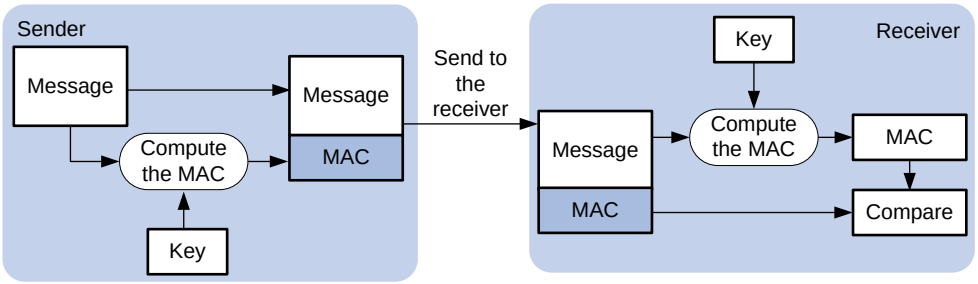
Configuring SSL

About SSL



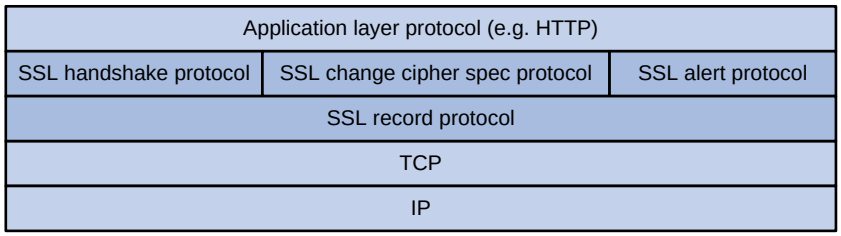
Secure Sockets Layer (SSL) is a cryptographic protocol that provides communication security for TCP-based application layer protocols such as HTTP. SSL has been widely used in applications such as e-business and online banking to provide secure data transmission over the Internet.

SSL security services

SSL provides the following security services:

- **Privacy**—SSL uses a symmetric encryption algorithm to encrypt data. It uses the asymmetric key algorithm of RSA to encrypt the key used by the symmetric encryption algorithm. For more information about RSA, see "Managing public keys."
- **Authentication**—SSL uses certificate-based digital signatures to authenticate the SSL server and client. The SSL server and client obtain digital certificates through PKI. For more information about PKI and digital certificates, see "Configuring PKI."
- **Integrity**—SSL uses the message authentication code (MAC) to verify message integrity. It uses a MAC algorithm and a key to transform a message of any length to a fixed-length message. Any change to the original message will result in a change to the calculated fixed-length message. As shown in Figure 1, the message integrity verification process is as follows:
  - **a.** The sender uses a MAC algorithm and a key to calculate a MAC value for a message. Then, it appends the MAC value to the message and sends the message to the receiver.
  - **b.** The receiver uses the same key and MAC algorithm to calculate a MAC value for the received message, and compares it with the MAC value appended to the message.
  - **c.** If the two MAC values match, the receiver considers the message intact. Otherwise, the receiver considers that the message was tampered with and it discards the message.

Figure 1 MAC algorithm diagram



SSL protocol stack

The SSL protocol stack includes the following protocols:

- SSL record protocol at the lower layer.
- SSL handshake protocol, SSL change cipher spec protocol, and SSL alert protocol at the upper layer.

Figure 2 SSL protocol stack

The following describes the major functions of SSL protocols:

- **SSL record protocol**—Fragments data received from the upper layer, computes and adds MAC to the data, and encrypts the data.
- **SSL handshake protocol**—Negotiates the cipher suite used for secure communication, authenticates the server and client, and securely exchanges the keys between the server and client. The cipher suite that needs to be negotiated includes the symmetric encryption algorithm, key exchange algorithm, and MAC algorithm.
- **SSL change cipher spec protocol**—Notifies the receiver that subsequent packets are to be protected based on the negotiated cipher suite and key.
- **SSL alert protocol**—Sends alert messages to the receiving party. An alert message contains the alert severity level and a description.

SSL protocol versions

SSL protocol versions include SSL 2.0, SSL 3.0, TLS 1.0 (or SSL 3.1), TLS 1.1, and TLS 1.2. Because SSL 3.0 is known to be insecure, you can disable SSL 3.0 for the SSL server to ensure security.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

Restrictions and guidelines: SSL configuration

By default, the SSL server can communicate with clients running all SSL protocol versions. When the server receives an SSL 2.0 Client Hello message from a client, it notifies the client to use a later version for communication.

SSL tasks at a glance

To configure SSL, perform the following tasks:

1. Configuring SSL server settings
   - Configuring an SSL server policy
   - (Optional.) Disabling SSL protocol versions for the SSL server
   - (Optional.) Disabling SSL session renegotiation
2. Configuring SSL client settings

   Configuring an SSL client policy

Configuring an SSL server policy

About this task

An SSL server policy is a set of SSL parameters used by the device when the device acts as the SSL server. An SSL server policy takes effect only after it is associated with an application such as HTTPS.

Procedure

1. Enter system view.

   system-view

2. Create an SSL server policy and enter its view.

   ssl server-policy *policy-name*

3. Specify a PKI domain for the SSL server policy.

   pki-domain *domain-name*

   By default, no PKI domain is specified for an SSL server policy.

   If SSL server authentication is required, you must specify a PKI domain and request a local certificate for the SSL server in the domain.

   For information about configuring a PKI domain, see "Configuring PKI."

4. Specify the cipher suites that the SSL server policy supports.

   In non-FIPS mode:

   ciphersuite { **dhe_rsa_aes_128_cbc_sha** | **dhe_rsa_aes_128_cbc_sha256** | **dhe_rsa_aes_256_cbc_sha** | **dhe_rsa_aes_256_cbc_sha256** | **ecdhe_ecdsa_aes_128_cbc_sha256** | **ecdhe_ecdsa_aes_128_gcm_sha256** | **ecdhe_ecdsa_aes_256_cbc_sha384** | **ecdhe_ecdsa_aes_256_gcm_sha384** | **ecdhe_rsa_aes_128_cbc_sha256** | **ecdhe_rsa_aes_128_gcm_sha256** | **ecdhe_rsa_aes_256_cbc_sha384** | **ecdhe_rsa_aes_256_gcm_sha384** | **exp_rsa_des_cbc_sha** | **exp_rsa_rc2_md5** | **exp_rsa_rc4_md5** | **rsa_3des_ede_cbc_sha** | **rsa_aes_128_cbc_sha** | **rsa_aes_128_cbc_sha256** | **rsa_aes_128_gcm_sha256** | **rsa_aes_256_cbc_sha** | **rsa_aes_256_cbc_sha256** | **rsa_aes_256_gcm_sha384** | **rsa_des_cbc_sha** | **rsa_rc4_128_md5** | **rsa_rc4_128_sha** } *

   In FIPS mode:

   ciphersuite { **ecdhe_ecdsa_aes_128_cbc_sha256** | **ecdhe_ecdsa_aes_256_cbc_sha384** | **ecdhe_ecdsa_aes_128_gcm_sha256** | **ecdhe_ecdsa_aes_256_gcm_sha384** | **ecdhe_rsa_aes_128_cbc_sha256** | **ecdhe_rsa_aes_128_gcm_sha256** | **ecdhe_rsa_aes_256_cbc_sha384** | **ecdhe_rsa_aes_256_gcm_sha384** | **rsa_aes_128_cbc_sha** | **rsa_aes_128_cbc_sha256**| **rsa_aes_128_gcm_sha256** | **rsa_aes_256_cbc_sha** | **rsa_aes_256_cbc_sha256** | **rsa_aes_256_gcm_sha384** } *

   By default, an SSL server policy supports all cipher suites.

5. (Optional.) Set the maximum number of sessions that the SSL server can cache and the session cache timeout time.

   session { **cachesize** *size* | **timeout** *time* } *

   By default, the SSL server can cache a maximum of 500 sessions, and the session cache timeout time is 3600 seconds.

6. Enable mandatory or optional SSL client authentication.

   client-verify { **enable** | **optional** }

By default, SSL client authentication is disabled. The SSL server does not perform digital certificate-based authentication on SSL clients.

When authenticating a client by using the digital certificate, the SSL server verifies the certificate chain presented by the client. It also verifies that the certificates in the certificate chain (except the root CA certificate) are not revoked.

7. (Optional.) Enable the SSL server to send the complete certificate chain to the client during SSL negotiation.

   certificate-chain-sending enable

   By default, the SSL server sends the server certificate rather than the complete certificate chain to the client during negotiation.

Configuring an SSL client policy

About this task

An SSL client policy is a set of SSL parameters used by the device when the device acts as the SSL client. The SSL client uses the settings in the client policy to establish a connection to the server. An SSL client policy takes effect only after it is associated with an application such as DDNS. For information about DDNS, see the DNS configuration in *Layer 3—IP Services Configuration Guide*.

Restrictions and guidelines

As a best practice to enhance system security, do not specify SSL 3.0 for the SSL client policy.

Procedure

1. Enter system view.

   system-view

2. Create an SSL client policy and enter its view.

   ssl client-policy *policy-name*

3. Specify a PKI domain for the SSL client policy.

   pki-domain *domain-name*

   By default, no PKI domain is specified for an SSL client policy.

   If SSL client authentication is required, you must specify a PKI domain and request a local certificate for the SSL client in the PKI domain.

   For information about configuring a PKI domain, see "Configuring PKI."

4. Specify the preferred cipher suite for the SSL client policy.

   In non-FIPS mode:

   prefer-cipher { **dhe_rsa_aes_128_cbc_sha** | **dhe_rsa_aes_128_cbc_sha256** | **dhe_rsa_aes_256_cbc_sha** | **dhe_rsa_aes_256_cbc_sha256** | **ecdhe_ecdsa_aes_128_cbc_sha256** | **ecdhe_ecdsa_aes_128_gcm_sha256** | **ecdhe_ecdsa_aes_256_cbc_sha384** | **ecdhe_ecdsa_aes_256_gcm_sha384** | **ecdhe_rsa_aes_128_cbc_sha256** | **ecdhe_rsa_aes_128_gcm_sha256** | **ecdhe_rsa_aes_256_cbc_sha384** | **ecdhe_rsa_aes_256_gcm_sha384** | **exp_rsa_des_cbc_sha** | **exp_rsa_rc2_md5** | **exp_rsa_rc4_md5** | **rsa_3des_ede_cbc_sha** | **rsa_aes_128_cbc_sha** | **rsa_aes_128_cbc_sha256** | **rsa_aes_128_gcm_sha256** | **rsa_aes_256_cbc_sha** | **rsa_aes_256_cbc_sha256** | **rsa_aes_256_gcm_sha384** | **rsa_des_cbc_sha** | **rsa_rc4_128_md5** | **rsa_rc4_128_sha** }

   In FIPS mode:

   prefer-cipher { **ecdhe_ecdsa_aes_128_cbc_sha256** | **ecdhe_ecdsa_aes_128_gcm_sha256** | **ecdhe_ecdsa_aes_256_cbc_sha384** | **ecdhe_ecdsa_aes_256_gcm_sha384** | **ecdhe_rsa_aes_128_cbc_sha256** |

ecdhe_rsa_aes_128_gcm_sha256 | **ecdhe_rsa_aes_256_cbc_sha384** | **ecdhe_rsa_aes_256_gcm_sha384** | **rsa_aes_128_cbc_sha** | **rsa_aes_128_cbc_sha256** | **rsa_aes_128_gcm_sha256** | **rsa_aes_256_cbc_sha** | **rsa_aes_256_cbc_sha256** | **rsa_aes_256_gcm_sha384** }

By default:

- In non-FIPS mode, the preferred cipher suite is **rsa_rc4_128_md5**.
- In FIPS mode, the preferred cipher suite is **rsa_aes_128_cbc_sha**.

5. Specify the SSL protocol version for the SSL client policy.

   In non-FIPS mode:

   version { **ssl3.0** | **tls1.0** | **tls1.1** | **tls1.2** }

   In FIPS mode:

   version { **tls1.0** | **tls1.1** | **tls1.2** }

   By default, an SSL client policy uses TLS 1.0.

6. Enable the SSL client to authenticate servers through digital certificates.

   server-verify enable

   By default, SSL server authentication is enabled.

Disabling SSL protocol versions for the SSL server

About this task

To enhance system security, you can disable the SSL server from using specific SSL protocol versions (SSL 3.0, TLS 1.0, and TLS 1.1) for session negotiation.

Restrictions and guidelines

Disabling an SSL protocol version does not affect the availability of earlier SSL protocol versions. For example, if you execute the **ssl version tls1.1 disable** command, TLS 1.1 is disabled but TLS 1.0 is still available for the SSL server.

Procedure

1. Enter system view.

   system-view

2. Disable SSL protocol versions for the SSL server.

   In non-FIPS mode:

   ssl version { **ssl3.0** | **tls1.0** | **tls1.1** } * **disable**

   In FIPS mode:

   ssl version { **tls1.0** | **tls1.1** } * **disable**

   By default:

   - In non-FIPS mode, the SSL server supports SSL 3.0, TLS 1.0, TLS 1.1, and TLS 1.2.
   - In FIPS mode, the SSL server supports TLS 1.0, TLS 1.1, and TLS 1.2.

Disabling SSL session renegotiation

About this task

The SSL session renegotiation feature enables the SSL client and server to reuse a previously negotiated SSL session for an abbreviated handshake.

Disabling session renegotiation causes more computational overhead to the system but it can avoid potential risks.

Restrictions and guidelines

Disable SSL session renegotiation only when explicitly required.

Procedure

1. Enter system view.
   `system-view`
2. Disable SSL session renegotiation.
   `ssl renegotiation disable`
   By default, SSL session renegotiation is enabled.

Display and maintenance commands for SSL

Execute **`display`** commands in any view.

Task	Command
Display SSL client policy information.	**`display ssl client-policy`** [*`policy-name`*]
Display SSL server policy information.	**`display ssl server-policy`** [*`policy-name`*]

Configuring TCP attack prevention 1
About TCP attack prevention 1
Configuring Naptha attack prevention 1

Configuring TCP attack prevention

About TCP attack prevention

TCP attack prevention can detect and prevent attacks that exploit the TCP connection establishment process.

Configuring Naptha attack prevention

About this task

Naptha is a DDoS attack that targets operating systems. It exploits the resources consuming vulnerability in TCP/IP stack and network application process. The attacker establishes a large number of TCP connections in a short period of time and leaves them in certain states without requesting any data. These TCP connections starve the victim of system resources, resulting in a system breakdown.

After you enable Naptha attack prevention, the device periodically checks the number of TCP connections in each state (CLOSING, ESTABLISHED, FIN_WAIT_1, FIN_WAIT_2, and LAST_ACK). If the number of TCP connections in a state exceeds the limit, the device will accelerate the aging of the TCP connections in that state to mitigate the Naptha attack.

Procedure

1. Enter system view.

   system-view

2. Enable Naptha attack prevention.

   tcp anti-naptha enable

   By default, Naptha attack prevention is disabled.

3. (Optional.) Set the maximum number of TCP connections in a state.

   tcp state { **closing** | **established** | **fin-wait-1** | **fin-wait-2** | **last-ack** } **connection-limit** *number*

   By default, the maximum number of TCP connections in each state (CLOSING, ESTABLISHED, FIN_WAIT_1, FIN_WAIT_2, and LAST_ACK) is 50.

   To disable the device from accelerating the aging of the TCP connections in a state, set the value to 0.

4. (Optional.) Set the interval for checking the number of TCP connections in each state.

   tcp check-state interval *interval*

   By default, the interval for checking the number of TCP connections in each state is 30 seconds.

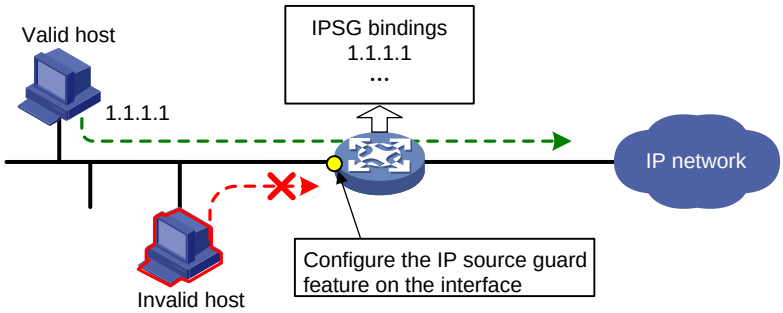
Configuring IP source guard

About IPSG

IP source guard (IPSG) prevents spoofing attacks by using an IPSG binding table to filter out illegitimate packets. This feature is typically configured on user-side interfaces.

IPSG operating mechanism



The IPSG binding table contains bindings that bind IP address, MAC address, VLAN, or any combinations. IPSG uses the bindings to match an incoming packet. If a match is found, the packet is forwarded. If no match is found, the packet is discarded.

IPSG is a per-interface packet filter. Configuring this feature on one interface does not affect packet forwarding on another interface.

IPSG bindings can be static or dynamic.

As shown in Figure 1, IPSG forwards only the packets that match an IPSG binding.

Figure 1 IPSG application

Static IPSG bindings

Static IPSG bindings are configured manually. They are suitable for scenarios where few hosts exist on a LAN and their IP addresses are manually configured. For example, you can configure a static IPSG binding on an interface that connects to a server. This binding allows the interface to receive packets only from the server.

Static IPSG bindings on an interface implement the following functions:

- Filter incoming IPv4 or IPv6 packets on the interface.
- Cooperate with ARP attack detection in IPv4 for user validity checking. For information about ARP attack detection, see "Configuring ARP attack protection."
- Cooperate with ND attack detection in IPv6 for user validity checking. For information about ND attack detection, see "Configuring ND attack defense."

Static IPSG bindings can be global or interface-specific.

- **Global static binding**—Binds the IP address and MAC address in system view. The binding takes effect on all interfaces to filter packets for user spoofing attack prevention.
- **Interface-specific static binding**—Binds the IP address, MAC address, VLAN, or any combination of the items in interface view. The binding takes effect only on the interface to check the validity of users who are attempting to access the interface.

Dynamic IPSG bindings

IPSG automatically obtains user information from other modules to generate dynamic bindings. A dynamic IPSG binding can contain MAC address, IPv4 or IPv6 address, VLAN tag, ingress interface, and binding type. The binding type identifies the source module for the binding, such as DHCP snooping, DHCPv6 snooping, DHCP relay agent, or DHCPv6 relay agent.

For example, DHCP-based IPSG bindings are suitable for scenarios where hosts on a LAN obtain IP addresses through DHCP. IPSG is configured on the DHCP server, the DHCP snooping device, or the DHCP relay agent. It generates dynamic bindings based on the client bindings on the DHCP server, the DHCP snooping entries, or the DHCP relay entries. IPSG allows only packets from the DHCP clients to pass through.

Dynamic IPv4SG

Dynamic bindings generated based on different source modules are for different usages:

Interface types	Source modules	Binding usage
Layer 2 Ethernet interface	DHCP snooping 802.1X	Packet filtering.
	ARP snooping	For cooperation with modules (such as the MFF module) to provide security services.
Layer 3 Ethernet interface VLAN interface	DHCP relay agent	Packet filtering.
	DHCP server	For cooperation with modules (such as the authorized ARP module) to provide security services.

For more information about 802.1X, see "Configuring 802.1X." For information about ARP snooping, DHCP snooping, DHCP relay, and DHCP server, see *Layer 3—IP Services Configuration Guide*.

Dynamic IPv6SG

Dynamic IPv6SG bindings generated based on different source modules are for different usages:

Interface types	Source modules	Binding usage
Layer 2 Ethernet interface	DHCPv6 snooping ND snooping 802.1X	Packet filtering.
Layer 3 Ethernet interface VLAN interface	DHCPv6 relay agent ND RA prefix entry recording	Packet filtering.
	DHCPv6 server	Reporting bindings to the controller to provide online and offline user information.

For more information about DHCPv6 snooping, see *Layer 3—IP Services Configuration Guide*. For more information about ND snooping, see IPv6 basics configuration in *Layer 3—IP Services Configuration Guide*. For more information about ND RA prefix entry recording, see IPv6 neighbor discovery in *Layer 3—IP Services Configuration Guide.* For more information about DHCPv6 relay agent, see *Layer 3—IP Services Configuration Guide*. For more information about DHCPv6 server, see *Layer 3—IP Services Configuration Guide.*

IPSG bindings synchronized by routing protocols

In addition to static and dynamic IPSG bindings, the device also supports IPSG bindings synchronized by routing protocols (such as BGP) from remote devices. These bindings are called remote IPSG bindings. By default, the remote IPSG bindings do not have interface information and cannot be used for packet filtering. When users roam from remote devices to the local device, the device learns interface information for the remote IPSG bindings through ARP or ND entries of the users. Then, the device converts the remote IPSG bindings into local IPSG bindings and uses these bindings for packet filtering.

For more information about BGP, see BGP overview in *Layer 3—IP Routing Configuration Guide*.

IPSG tasks at a glance

To configure IPSG, perform the following tasks:

1. To configure IPv4SG, perform the following tasks:
   a. Enabling IPv4SG
   b. (Optional.) Configuring a static IPv4SG binding
   c. (Optional.) Excluding IPv4 packets from IPSG filtering
   d. (Optional.) Enabling IPv4SG alarming
2. To configure IPv6SG, perform the following tasks:
   a. Enabling IPv6SG
   b. (Optional.) Configuring a static IPv6SG binding
   c. (Optional.) Enabling IPv6SG alarming
3. Enabling SNMP notifications for IPSG

Configuring the IPv4SG feature

Enabling IPv4SG

About this task

When you enable IPSG on an interface, the static and dynamic IPSG are both enabled.

- Static IPv4SG uses static bindings configured by using the **ip source binding** command. For more information, see "Configuring a static IPv4SG binding."
- Dynamic IPv4SG generates dynamic bindings from related source modules. IPv4SG uses the bindings to filter incoming IPv4 packets based on the matching criteria specified in the **ip verify source** command.

Restrictions and guidelines

To implement dynamic IPv4SG, make sure 802.1X, ARP snooping, DHCP snooping, DHCP relay agent, or DHCP server operates correctly on the network.

Enabling IPv4SG on an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
   The following interface types are supported:

- Layer 2 Ethernet interface.
- Layer 3 Ethernet interface.
- VLAN interface.

3. Enable the IPv4SG feature.

   ip verify source { **ip-address** | **ip-address** **mac-address** | **mac-address** }

   By default, the IPv4SG feature is disabled on an interface.

Configuring a static IPv4SG binding

About this task

You can configure global static and interface-specific static IPv4SG bindings. Interface-specific static and dynamic bindings take priority over global static bindings. An interface first uses the static and dynamic bindings on the interface to match packets. If no match is found, the interface uses the global bindings.

Restrictions and guidelines

Global static bindings take effect on all interfaces on the device.

To configure a static IPv4SG binding for the ARP attack detection feature, make sure the following conditions are met:

- The **ip-address** *ip-address* option, the **mac-address** *mac-address* option, and the **vlan** *vlan-id* option must be specified.
- ARP attack detection must be enabled for the specified VLAN.

Configuring a global static IPv4SG binding

1. Enter system view.

   system-view

2. Configure a global static IPv4SG binding.

   ip source binding ip-address *ip-address* **mac-address** *mac-address*

Configuring a static IPv4SG binding on an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

   The following interface types are supported:

   - Layer 2 Ethernet interface.
   - Layer 3 Ethernet interface.
   - VLAN interface.

3. Configure a static IPv4SG binding.

   ip source binding { **ip-address** *ip-address* | **ip-address** *ip-address* **mac-address** *mac-address* | **mac-address** *mac-address* } [**vlan** *vlan-id*]

   You can configure the same static IPv4SG binding on different interfaces.

Excluding IPv4 packets from IPSG filtering

About this task

By default, IPv4SG processes all incoming IPv4 packets on an interface and discards the packets that do not match IPSG bindings. To allow specific IPv4 packets that do not match any IPSG binding to pass through the interface, you can specify source items of the packets for IPSG filtering exemption. All IPv4 packets with the specified source items are forwarded without being processed by IPSG.

Procedure

1. Enter system view.

   system-view

2. Exclude IPv4 packets with the specified source items from IPSG filtering.

   ip verify source exclude vlan *start-vlan-id* [to *end-vlan-id*]

   By default, no excluded source items are configured.

   You can execute this command multiple times to specify multiple excluded VLANs. The specified excluded VLANs cannot overlap.

Enabling IPv4SG alarming

About this task

This feature monitors the number of packets dropped by IPv4SG per second. When the packet dropping rate reaches or exceeds the alarm threshold, the device generates an alarm log. When the packet dropping rate drops below the alarm threshold, the device generates an alarm-cleared log.

Restrictions and guidelines

Do not enable this feature in a VLAN and an Ethernet interface belonging to the VLAN at the same time.

Procedure

1. Enter system view.

   system-view

2. Enter interface view or VLAN view.

   - Enter interface view.

     interface *interface-type interface-number*

   - Enter VLAN view.

     vlan *vlan-id*

3. Enable IPv4SG alarming on the interface.

   ip verify source alarm [*alarm-threshold*]

   By default, IPv4SG alarming is disabled on an interface.

Configuring the IPv6SG feature

Enabling IPv6SG

About this task

When you enable IPv6SG on an interface, the static and dynamic IPv6SG are both enabled.

- Static IPv6SG uses static bindings configured by using the **ipv6 source binding** command. For more information, see "Configuring a static IPv6SG binding."
- Dynamic IPv6SG generates dynamic bindings from related source modules. IPv6SG uses the bindings to filter incoming IPv6 packets based on the matching criteria specified in the **ipv6 verify source** command.

Restrictions and guidelines

To implement dynamic IPv6SG, make sure DHCPv6 snooping, DHCPv6 relay agent, or ND snooping operates correctly on the network.

Enabling IPv6SG on an interface

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*

   The following interface types are supported:

   - Layer 2 Ethernet interface.
   - Layer 3 Ethernet interface.
   - VLAN interface.
3. Enable the IPv6SG feature.

   ipv6 verify source { **ip-address** | **ip-address mac-address** | **mac-address** }

   By default, the IPv6SG feature is disabled on an interface.

Configuring a static IPv6SG binding

About this task

You can configure global static and interface-specific static IPv6SG bindings. Interface-specific static and dynamic bindings take priority over global static bindings. An interface first uses the static and dynamic bindings on the interface to match packets. If no match is found, the interface uses the global bindings.

Restrictions and guidelines

Global static bindings take effect on all interfaces on the device.

To configure a static IPv6SG binding for the ND attack detection feature, the **vlan** *vlan-id* option must be specified, and ND attack detection must be enabled for the specified VLAN.

If you configure both a static IPv6SG binding and VLAN mapping on a Layer 2 Ethernet interface, the interface forwards packets as follows:

- If you configure VLAN mapping and then configure a static IPv6SG binding and specify the original VLAN for the binding, the interface forwards packets based on the original VLAN.
- If you configure a static IPv6SG binding and specify a VLAN for the binding and then configure VLAN mapping, the interface forwards packets without considering the VLAN.

Configuring a global static IPv6SG binding

1. Enter system view.

   system-view
2. Configure a global static IPv6SG binding.

   ipv6 source binding ip-address *ipv6-address* **mac-address** *mac-address*

Configuring a static IPv6SG binding on an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
   The following interface types are supported:
   - Layer 2 Ethernet interface.
   - Layer 3 Ethernet interface.
   - VLAN interface.
3. Configure a static IPv6SG binding.
   ipv6 source binding { **ip-address** *ipv6-address* | **ip-address** *ipv6-address* **mac-address** *mac-address* | **mac-address** *mac-address* } [**vlan** *vlan-id*]
   You can configure the same static IPv6SG binding on different interfaces.

Setting the maximum number of IPv6SG bindings on an interface

About this task

You can set the maximum number of IPv6SG bindings on an interface to limit the total number of static and dynamic IPv6SG bindings on the interface. If the upper limit is reached, no more IPv6SG bindings can be added on the interface.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view.
   interface *interface-type interface-number*
3. Set the maximum number of IPv6SG bindings on the interface.
   ipv6 verify source max-entries *number*
   By default, the maximum number of IPv6SG bindings is not limited on an interface.

Enabling IPv6SG alarming

About this task

This feature enables the device to monitor the number of packets dropped by IPv6SG per second. When the packet dropping rate reaches or exceeds the alarm threshold, the device generates an alarm log. When the packet dropping rate drops below the alarm threshold, the device generates an alarm-cleared log.

Restrictions and guidelines

Do not enable this feature in a VLAN and an Ethernet interface belonging to the VLAN at the same time.

Procedure

1. Enter system view.
   system-view
2. Enter interface view or VLAN view.

- Enter interface view.
  interface *interface-type interface-number*
- *Enter VLAN view.*
  vlan *vlan-id*

3. Enable IPv6SG alarming on the interface.
   ipv6 verify source alarm [*alarm-threshold*]
   By default, IPv6SG alarming is disabled on an interface.

Enabling SNMP notifications for IPSG

About this task

To report critical IPSG events to an NMS, enable SNMP notifications for IPSG. For example, If you enable the device to generate notifications when the number of packets dropped by IPSG per second on an interface has reached, exceeded, or dropped below the alarm threshold, the device works as follows:

- When the number of packets dropped by IPSG per second on an interface is equal to or greater than the IPv4SG or IPv6SG alarm threshold, the device sends a notification.
- When the number of packets dropped by IPSG per second on an interface drops below the IPv4SG or IPv6SG alarm threshold, the device reports a threshold recovery event.

To set the IPv4 or IPv6SG alarm threshold, execute the **ip verify source alarm** or **ipv6 verify source alarm** command, respectively.

For SNMP notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP and information center configuration, see *Network Management and Monitoring Guide*.

Procedure

1. Enter system view.
   system-view
2. Enable SNMP notifications for IPSG.
   snmp-agent trap enable ipsg [**drop-threshold**]
   By default, SNMP notifications for IPSG are enabled.

Display and maintenance commands for IPSG

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display IPv4SG bindings.	**display ip source binding** [**static** | [**vpn-instance** *vpn-instance-name*] [**arp-snooping-vlan** | **dhcp-relay** | **dhcp-server** | **dhcp-snooping** | **dot1x** | **remote**]] [**ip-address** *ip-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display local IPv4SG bindings that can be synchronized by routing protocols.	**display ip source binding-local** [**interface** *interface-type interface-number*] [**dhcp-relay**] [**ip-address** *ip-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**slot** *slot-number*]

Task	Command
Display remote IPv4SG bindings synchronized by routing protocols.	**display ip source binding-remote** [**router-id** *router-id*] [**dhcp-relay**] [**ip-address** *ip-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**slot** *slot-number*]
Display statistics about local and remote IPv4SG bindings that routing protocols synchronize.	**display ip source binding statistics**
Display source items that have been configured to be excluded from IPSG filtering.	**display ip verify source excluded** [**vlan** *start-vlan-id* [**to** *end-vlan-id*]] [**slot** *slot-number*]
Display IPv6SG address bindings.	**display ipv6 source binding** [**static** | [**vpn-instance** *vpn-instance-name*] [**dhcpv6-relay** | **dhcpv6-server** | **dhcpv6-snooping** | **dot1x** | **nd-snooping-vlan** | **remote**]] [**ip-address** *ipv6-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display local IPv6SG bindings that can be synchronized by routing protocols.	**display ipv6 source binding-local** [**interface** *interface-type interface-number*] [**dhcpv6-relay** | **nd-snooping-vlan**] [**ip-address** *ipv6-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**slot** *slot-number*]
Display remote IPv6SG bindings synchronized by routing protocols.	**display ipv6 source binding-remote** [**router-id** *router-id*] [**dhcpv6-relay** | **nd-snooping-vlan**] [**ip-address** *ipv6-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**slot** *slot-number*]
Display IPv6SG prefix bindings.	**display ipv6 source binding pd** [**vpn-instance** *vpn-instance-name*] [**prefix** *prefix/prefix-length*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display statistics about local and remote IPv6SG bindings that routing protocols synchronize.	**display ipv6 source binding statistics**

IPSG configuration examples

Example: Configuring static IPv4SG

Network configuration

As shown in Figure 2, all hosts use static IP addresses.

Configure static IPv4SG bindings on Device A and Device B to meet the following requirements:

- All interfaces of Device A allow IP packets from Host A to pass.
- GigabitEthernet 1/0/1 of Device A allows IP packets from Host B to pass.

Figure 2 Network diagram

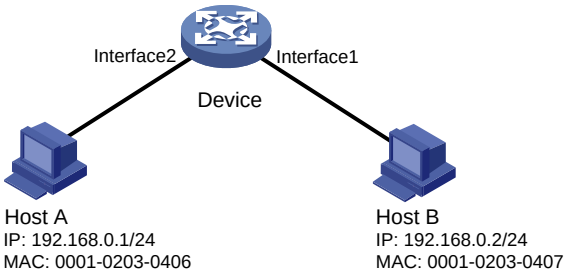


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

Configure IP addresses for the interfaces. (Details not shown.)

Enable IPv4SG on GigabitEthernet 1/0/2.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] ip verify source ip-address mac-address
[DeviceA-GigabitEthernet1/0/2] quit
```

Configure a static IPv4SG binding for Host A.

```
[DeviceA] ip source binding ip-address 192.168.0.1 mac-address 0001-0203-0406
```

Enable IPv4SG on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ip verify source ip-address mac-address
```

On GigabitEthernet 1/0/1, configure a static IPv4SG binding for Host B.

```
[DeviceA-GigabitEthernet1/0/1] ip source binding mac-address 0001-0203-0407
[DeviceA-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Verify that the static IPv4SG bindings are configured successfully on Device A.

```
<DeviceA> display ip source binding static
Total entries found: 2
IP address      MAC address    Interface              VLAN Type
192.168.0.1     0001-0203-0406 N/A                    N/A  Static
N/A             0001-0203-0407 GE1/0/1                N/A  Static
```

Example: Configuring DHCP snooping-based dynamic IPv4SG

Network configuration

As shown in Figure 3, the host (the DHCP client) obtains an IP address from the DHCP server. Perform the following tasks:

- Enable DHCP snooping on the device to make sure the DHCP client obtains an IP address from the authorized DHCP server. To generate a DHCP snooping entry for the DHCP client, enable recording of client information in DHCP snooping entries.
- Enable dynamic IPv4SG on GigabitEthernet 1/0/1 to filter incoming packets by using the IPv4SG bindings generated based on DHCP snooping entries. Only packets from the DHCP client are allowed to pass.

Figure 3 Network diagram

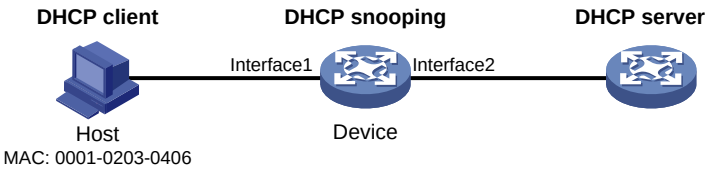

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure the DHCP server.

   For information about DHCP server configuration, see *Layer 3—IP Services Configuration Guide*.

2. Configure the device:

   # Configure IP addresses for the interfaces. (Details not shown.)

   # Enable DHCP snooping.

   ```
   <Device> system-view
   [Device] dhcp snooping enable
   ```

   # Configure GigabitEthernet 1/0/2 as a trusted interface.

   ```
   [Device] interface gigabitethernet 1/0/2
   [Device-GigabitEthernet1/0/2] dhcp snooping trust
   [Device-GigabitEthernet1/0/2] quit
   ```

   # Enable IPv4SG on GigabitEthernet 1/0/1 and verify the source IP address and MAC address for dynamic IPSG.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip verify source ip-address mac-address
   ```

   # Enable recording of client information in DHCP snooping entries on GigabitEthernet 1/0/1.

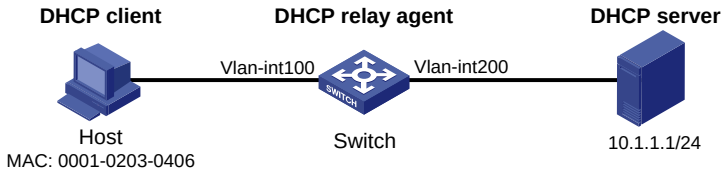
   ```
   [Device-GigabitEthernet1/0/1] dhcp snooping binding record
   [Device-GigabitEthernet1/0/1] quit
   ```

Verifying the configuration

Display dynamic IPv4SG bindings generated based on DHCP snooping entries.

```
[Device] display ip source binding dhcp-snooping
Total entries found: 1
IP address      MAC address    Interface               VLAN Type
192.168.0.1     0001-0203-0406 GE1/0/1                 1    DHCP snooping
```

GigabitEthernet 1/0/1 will filter packets based on the IPv4SG binding.



Example: Configuring DHCP relay agent-based dynamic IPv4SG

Network configuration

As shown in Figure 4, DHCP relay agent is enabled on the switch. The host obtains an IP address from the DHCP server through the DHCP relay agent.

Enable dynamic IPv4SG on VLAN-interface 100 to filter incoming packets by using the IPv4SG bindings generated based on DHCP relay entries.

Figure 4 Network diagram

Procedure

1. Configure dynamic IPv4SG:

   # Configure IP addresses for the interfaces. (Details not shown.)

   # Enable IPv4SG on VLAN-interface 100 and verify the source IP address and MAC address for dynamic IPSG.

   ```
   <Switch> system-view
   [Switch] interface vlan-interface 100
   [Switch-Vlan-interface100] ip verify source ip-address mac-address
   [Switch-Vlan-interface100] quit
   ```

2. Configure the DHCP relay agent:

   # Enable the DHCP service.

   ```
   [Switch] dhcp enable
   ```

   # Enable recording DHCP relay entries.

   ```
   [Switch] dhcp relay client-information record
   ```

   # Configure VLAN-interface 100 to operate in DHCP relay mode.

   ```
   [Switch] interface vlan-interface 100
   [Switch-Vlan-interface100] dhcp select relay
   ```

   # Specify the IP address of the DHCP server.

   ```
   [Switch-Vlan-interface100] dhcp relay server-address 10.1.1.1
   [Switch-Vlan-interface100] quit
   ```

Verifying the configuration

Display dynamic IPv4SG bindings generated based on DHCP relay entries.

```
[Switch] display ip source binding dhcp-relay
Total entries found: 1
IP address      MAC address    Interface               VLAN Type
192.168.0.1     0001-0203-0406 Vlan100                 100  DHCP relay
```

VLAN-interface 100 will filter packets based on the IPv4SG binding.

Example: Configuring static IPv6SG

Network configuration

As shown in Figure 5, configure a static IPv6SG binding on GigabitEthernet 1/0/1 of the device to allow only IPv6 packets from the host to pass.

Figure 5 Network diagram

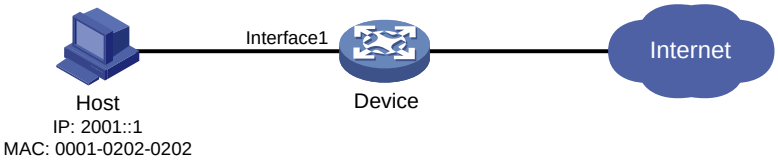


Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

Enable IPv6SG on GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ipv6 verify source ip-address mac-address
```

On GigabitEthernet 1/0/1, configure a static IPv6SG binding for the host.

```
[Device-GigabitEthernet1/0/1] ipv6 source binding ip-address 2001::1 mac-address
0001-0202-0202
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Verify that the static IPv6SG binding is configured successfully on the device.

```
[Device] display ipv6 source binding static
Total entries found: 1
IPv6 address         MAC address    Interface             VLAN Type
2001::1              0001-0202-0202 GE1/0/1               N/A  Static
```

Example: Configuring DHCPv6 snooping-based dynamic IPv6SG address bindings

Network configuration

As shown in Figure 6, the host (the DHCPv6 client) obtains an IP address from the DHCPv6 server. Perform the following tasks:

- Enable DHCPv6 snooping on the device to make sure the DHCPv6 client obtains an IPv6 address from the authorized DHCPv6 server. To generate a DHCPv6 snooping entry for the DHCPv6 client, enable recording of client information in DHCPv6 snooping entries.
- Enable dynamic IPv6SG on GigabitEthernet 1/0/1 to filter incoming packets by using the IPv6SG bindings generated based on DHCPv6 snooping entries. Only packets from the DHCPv6 client are allowed to pass.

Figure 6 Network diagram

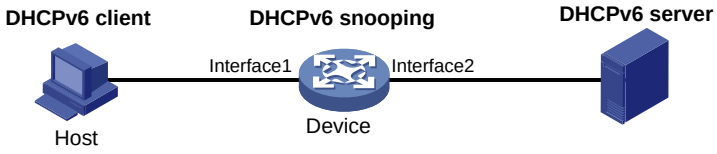

Table 4 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure DHCPv6 snooping:

   # Enable DHCPv6 snooping globally.

   ```
   <Device> system-view
   [Device] ipv6 dhcp snooping enable
   ```

   # Configure GigabitEthernet 1/0/2 as a trusted interface.

   ```
   [Device] interface gigabitethernet 1/0/2
   [Device-GigabitEthernet1/0/2] ipv6 dhcp snooping trust
   [Device-GigabitEthernet1/0/2] quit
   ```

2. Enable IPv6SG:

   # Enable IPv6SG on GigabitEthernet 1/0/1 and verify the source IP address and MAC address for dynamic IPv6SG.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ipv6 verify source ip-address mac-address
   ```

   # Enable recording of client information in DHCPv6 snooping entries on GigabitEthernet 1/0/1.

   ```
   [Device-GigabitEthernet1/0/1] ipv6 dhcp snooping binding record
   [Device-GigabitEthernet1/0/1] quit
   ```

Verifying the configuration

Display dynamic IPv6SG bindings generated based on DHCPv6 snooping entries.

```
[Device] display ipv6 source binding dhcpv6-snooping
Total entries found: 1
IPv6 address         MAC address    Interface             VLAN Type
2001::1              040a-0000-0001 GE1/0/1               1    DHCPv6 snooping
```

GigabitEthernet 1/0/1 will filter packets based on the IPv6SG binding.

Example: Configuring DHCPv6 snooping-based dynamic IPv6SG prefix bindings

Network configuration

As shown in Figure 7, the host (the DHCPv6 client) obtains an IPv6 prefix from the DHCPv6 server. Perform the following tasks:

- Enable DHCPv6 snooping on the device to make sure the DHCPv6 client obtains an IPv6 prefix from the authorized DHCPv6 server. To generate a DHCPv6 snooping prefix entry for the DHCPv6 client, enable recording IPv6 prefix information in DHCPv6 snooping entries.

- Enable dynamic IPv6SG on GigabitEthernet 1/0/1 to filter incoming packets by using the IPv6SG bindings generated based on DHCPv6 snooping prefix entries. Only packets from the DHCPv6 client are allowed to pass.

Figure 7 Network diagram

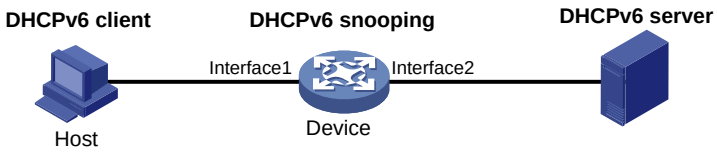

Table 5 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure DHCPv6 snooping.

   # Enable DHCPv6 snooping globally.

   ```
   <Device> system-view
   [Device] ipv6 dhcp snooping enable
   ```

   # Configure GigabitEthernet 1/0/2 as a trusted interface.

   ```
   [Device] interface gigabitethernet 1/0/2
   [Device-GigabitEthernet1/0/2] ipv6 dhcp snooping trust
   [Device-GigabitEthernet1/0/2] quit
   ```

   # Enable recording DHCPv6 snooping prefix entries on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ipv6 dhcp snooping pd binding record
   ```

2. Enable IPv6SG.

   # Enable IPv6SG on GigabitEthernet 1/0/1 and verify the source IP address and MAC address for dynamic IPv6SG.

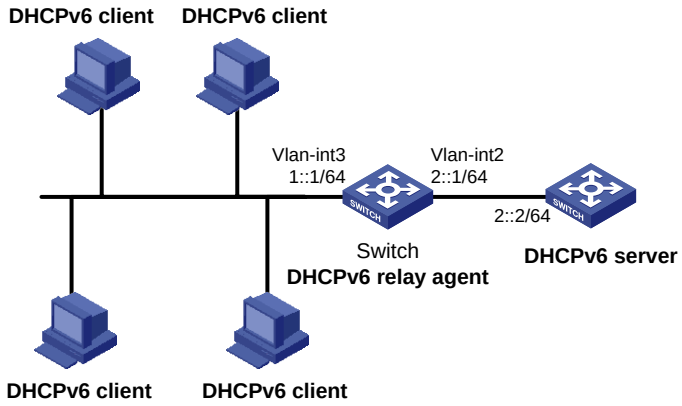
   ```
   [Device-GigabitEthernet1/0/1] ipv6 verify source ip-address mac-address
   [Device-GigabitEthernet1/0/1] quit
   ```

Verifying the configuration

Display dynamic IPv6SG bindings generated based on DHCPv6 snooping entries.

```
[Device] display ipv6 source binding pd
Total entries found: 1
IPv6 address         MAC address    Interface              VLAN Type
2001:410:1::/48      0010-9400-0004 GE1/0/1                1
```

GigabitEthernet 1/0/1 will filter packets based on the IPv6SG binding.



Example: Configuring DHCPv6 relay agent-based dynamic IPv6SG

Network configuration

As shown in Figure 8, DHCPv6 relay agent is enabled on the switch. The clients obtain IPv6 addresses from the DHCPv6 server through the DHCPv6 relay agent.

Enable dynamic IPv6SG on VLAN-interface 3 to filter incoming packets by using the IPv6SG bindings generated based on DHCPv6 relay entries.

Figure 8 Network diagram

Procedure

1. Configure the DHCPv6 relay agent:

   # Create VLAN 2 and VLAN 3, assign interfaces to the VLANs, and specify IP addresses for VLAN-interface 2 and VLAN-interface 3. (Details not shown.)

   # Enable the DHCPv6 relay agent on VLAN-interface 3.

   ```
   <Switch> system-view
   [Switch] interface vlan-interface 3
   [Switch-Vlan-interface3] ipv6 dhcp select relay
   ```

   # Enable recording of DHCPv6 relay entries on the interface.

   ```
   [Switch-Vlan-interface3] ipv6 dhcp relay client-information record
   ```

   # Specify the DHCPv6 server address 2::2 on the relay agent.

   ```
   [Switch-Vlan-interface3] ipv6 dhcp relay server-address 2::2
   ```

2. Enable IPv6SG on VLAN-interface 3 and verify the source IP address and MAC address for dynamic IPv6SG.

   ```
   [Switch-Vlan-interface3] ipv6 verify source ip-address mac-address
   [Switch-Vlan-interface3] quit
   ```

Verifying the configuration

Display dynamic IPv6SG bindings generated based on DHCPv6 relay entries.

```
[Switch] display ipv6 source binding dhcpv6-relay
Total entries found: 1
IP Address      MAC Address    Interface               VLAN Type
1::2            0001-0203-0406 Vlan3                   3    DHCPv6 relay
```

VLAN-interface 3 will filter packets based on the IPv6SG binding.

Configuring ARP attack protection

About ARP attack protection

The device can provide multiple features to detect and prevent ARP attacks and viruses in the LAN. An attacker can exploit ARP vulnerabilities to attack network devices in the following ways:

- Sends a large number of unresolvable IP packets to have the receiving device busy with resolving IP addresses until its CPU is overloaded. Unresolvable IP packets refer to IP packets for which ARP cannot find corresponding MAC addresses.
- Sends a large number of ARP packets to overload the CPU of the receiving device.
- Acts as a trusted user or gateway to send ARP packets so the receiving devices obtain incorrect ARP entries.

ARP attack protection tasks at a glance

All ARP attack protection tasks are optional.

- Preventing flood attacks
  - Configuring unresolvable IP attack protection
  - Configuring source MAC-based ARP packet rate limiting
  - Configuring source MAC-based ARP attack detection
- Preventing user and gateway spoofing attacks
  - Configuring ARP packet source MAC consistency check
  - Configuring ARP active acknowledgement
  - Configuring authorized ARP
  - Configuring ARP attack detection
  - Configuring ARP scanning and fixed ARP
  - Configuring ARP keepalive entry scanning
  - Configuring ARP gateway protection
  - Configuring ARP filtering
  - Configuring ARP sender IP address checking
  - Configuring ARP entry fixing
- Enabling SNMP notifications for ARP

Configuring unresolvable IP attack protection

About unresolvable IP attack protection

If a device receives a large number of unresolvable IP packets from a host, the following situations can occur:

- The device sends a large number of ARP requests, overloading the target subnets.
- The device keeps trying to resolve the destination IP addresses, overloading its CPU.

To protect the device from such IP attacks, you can configure the following features:

- **ARP source suppression**—This feature is applicable if the attack packets have the same source addresses.
- **ARP blackhole routing**—This feature is applicable regardless of whether the attack packets have the same source addresses.

Configuring ARP source suppression

About this task

This feature stops resolving packets from an IP address if the number of unresolvable IP packets from the IP address exceeds the upper limit within 5 seconds. The device continues ARP resolution when the interval elapses.

For a gateway or server trusted by the device, you can configure an ARP source suppression rule so that the device always permits IP packets sourced from the IP address of the gateway or server.

Restrictions and guidelines

To have the configured ARP source suppression rules take effect, you must enable ARP source suppression by using the **arp source-suppression enable** command.

Procedure

1. Enter system view.

   system-view
2. Enable ARP source suppression.

   arp source-suppression enable

   By default, ARP source suppression is disabled.
3. Set the maximum number of unresolvable packets that the device can process per source IP address within 5 seconds.

   arp source-suppression limit *limit-value*

   By default, the maximum number is 10.
4. Configure ARP source suppression rules.

   arp source-suppression rule *rule-id* **permit** *ip-address* [*mask*]

   By default, no ARP source suppression rules exist.

Configuring ARP blackhole routing

About this task

This feature creates a blackhole route destined for an unresolved IP address. The device drops all matching packets until the blackhole route is deleted. A blackhole route is deleted when its aging timer is reached or the route becomes reachable.

After a blackhole route is created for an unresolved IP address, the device immediately starts the first ARP blackhole route probe by sending an ARP request. If the resolution fails, the device continues probing according to the probe settings. If the IP address resolution succeeds in a probe, the device converts the blackhole route to a normal route. If an ARP blackhole route ages out before the device finishes all probes, the device deletes the blackhole route and does not perform the remaining probes.

Restrictions and guidelines

Set the ARP blackhole route probe count to a big value, for example, 25. If the device fails to reach the destination IP address temporarily and the probe count is too small, all probes might finish before the problem is resolved. As a result, non-attack packets will be dropped. This setting can avoid such situation.

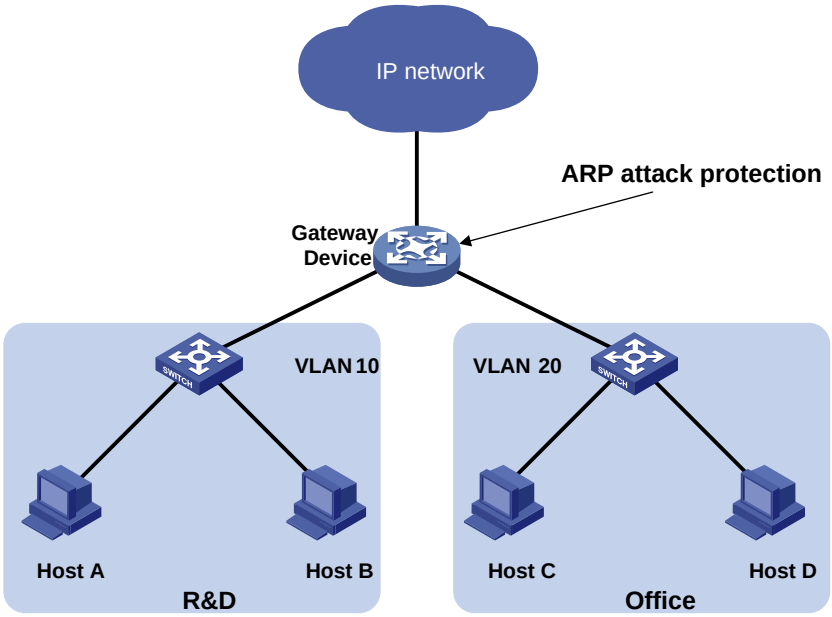
Procedure

1. Enter system view.
   system-view
2. Enable ARP blackhole routing.
   arp resolving-route enable
   By default, ARP blackhole routing is enabled.
3. (Optional.) Set the number of ARP blackhole route probes for each unresolved IP address.
   arp resolving-route probe-count *count*
   The default setting is three probes.
4. (Optional.) Set the interval at which the device probes ARP blackhole routes.
   arp resolving-route probe-interval *interval*
   The default setting is 1 second.

Display and maintenance commands for unresolvable IP attack protection

Execute **display** commands in any view.

Task	Command
Display ARP source suppression configuration information.	**display arp source-suppression**
Display ARP source suppression entries.	**display arp source-suppression cache** [**slot** *slot-number*]



Example: Configuring unresolvable IP attack protection

Network configuration

As shown in Figure 1, a LAN contains two areas: an R&D area in VLAN 10 and an office area in VLAN 20. Each area connects to the gateway (Device) through an access switch.

A large number of ARP requests are detected in the office area and are considered an attack caused by unresolvable IP packets. To prevent the attack, configure ARP source suppression or ARP blackhole routing.

Figure 1 Network diagram

Procedure

- If the attack packets have the same source address, configure ARP source suppression:

  # Enable ARP source suppression.

  ```
  <Device> system-view
  [Device] arp source-suppression enable
  ```

  # Configure the device to process a maximum of 100 unresolvable packets per source IP address within 5 seconds.

  ```
  [Device] arp source-suppression limit 100
  ```

- If the attack packets have different source addresses, configure ARP blackhole routing:

  # Enable ARP blackhole routing.

  ```
  [Device] arp resolving-route enable
  ```

Configuring ARP packet rate limiting

About this task

The ARP packet rate limiting feature allows you to limit the rate of ARP packets delivered to the CPU. An ARP attack detection-enabled device will send all received ARP packets to the CPU for inspection. Processing excessive ARP packets will make the device malfunction or even crash. To solve this problem, configure ARP packet rate limiting. When the receiving rate of ARP packets on the interface exceeds the rate limit, those packets are discarded.

You can enable sending notifications to the SNMP module or enable logging for ARP packet rate limiting.

- If notification sending is enabled, the device sends the highest threshold-crossed ARP packet rate within the sending interval in a notification to the SNMP module. You must use the **`snmp-agent target-host`** command to set the notification type and target host. For more information about notifications, see *Network Management and Monitoring Command Reference*.
- If logging for ARP packet rate limiting is enabled, the device sends the highest threshold-crossed ARP packet rate within the sending interval in a log message to the

information center. You can configure the information center module to set the log output rules. For more information about information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

As a best practice, configure this feature when ARP attack detection is enabled, or when ARP flood attacks are detected.

If excessive notifications and log messages are sent for ARP packet rate limiting, you can increase notification and log message sending interval.

If you enable notification sending and logging for ARP packet rate limiting on an aggregate interface, the features apply to all aggregation member ports.

The ARP packet rate limit configured in Ethernet interface view or aggregate interface view takes effect only on the current interface. The limit on an aggregation member port takes effect only when the member port leaves the aggregation group.

Only the S5200-HI-G switch series supports the ARP packet rate limiting feature.

Procedure

1. Enter system view.
   system-view
2. (Optional.) Enable SNMP notifications for ARP packet rate limiting.
   snmp-agent trap enable arp [**rate-limit**]
   By default, SNMP notifications for ARP packet rate limiting are disabled.
3. (Optional.) Enable logging for ARP packet rate limiting.
   arp rate-limit log enable
   By default, logging for ARP packet rate limiting is disabled.
4. (Optional.) Set the notification and log message sending interval.
   arp rate-limit log interval *interval*
   By default, the device sends notifications and log messages every 60 seconds.
5. Enter interface view.
   interface *interface-type interface-number*
   Supported interface types include Layer 2 Ethernet interface, Layer 3 Ethernet interface, Layer 3 aggregate interface, and Layer 2 aggregate interface.
6. Enable ARP packet rate limiting.
   arp rate-limit [*pps*]
   By default, ARP packet rate limiting is enabled.

Configuring source MAC-based ARP packet rate limiting

About this task

A client might send a large number of ARP requests, which might cause high CPU usage on the gateway, adversely affect other services, and even crash the device. To resolve the issue, use the source MAC-based ARP packet rate limit to limit the receiving rate of ARP packets from the client. When the receiving rate of ARP requests from the client exceeds the limit, the device will discard subsequent ARP requests.

You can use the **debugging arp packet** command to view the source MAC addresses from which the rate of ARP packets is high.

Restrictions and guidelines

You can configure both global rate limit for all ARP packets and MAC-specific rate limit for ARP packets from specific MAC addresses. For the ARP packets from a specific MAC address, the global limit rate or MAC-specific limit rate whichever is smaller applies. If you execute the **undo arp rate-limit source-mac** command without specifying the *mac-address* argument, the command disables only global rate limit. MAC-specific rate limit for ARP packets still takes effect.

Procedure

1. Enter system view.
   system-view
2. Enable source MAC-based ARP packet rate limiting and set the limit rate.
   arp rate-limit source-mac [*mac-address*] *pps*
   By default, source MAC-based ARP packet rate limiting is disabled.

Configuring source MAC-based ARP attack detection

About this task

This feature checks the number of ARP packets delivered to the CPU. If the number of packets from the same MAC address within 5 seconds exceeds a threshold, the device generates an ARP attack detection entry for the MAC address. If logging is enabled for source MAC-based ARP attack detection, the device handles the attack by using either of the following methods before the ARP attack detection entry ages out:

- **Monitor**—Only generates log messages.
- **Filter**—Generates log messages and filters out subsequent ARP packets from the MAC address and data packets sourced from or destined for the MAC address.

When an ARP attack detection entry ages out, ARP packets sourced from the MAC address in the entry can be processed correctly.

Some security devices or servers might send a large number of ARP packets for security check. To prevent such ARP packets from being filtered out, exclude the MAC addresses of these devices from source MAC-based ARP attack detection. The device will directly permit the packets sourced from the MAC addresses.

Restrictions and guidelines

When you change the handling method from monitor to filter, the configuration takes effect immediately. When you change the handling method from filter to monitor, the device continues filtering packets that match existing ARP attack detection entries, and uses the monitor method to process packets that match the new ARP attack detection entries.

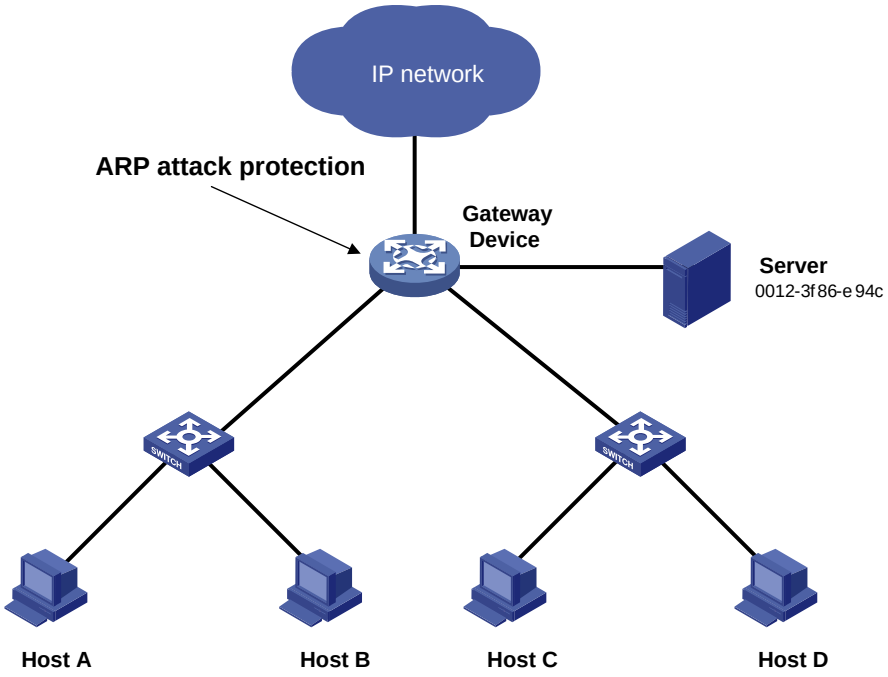
Procedure

1. Enter system view.
   system-view
2. Enable source MAC-based ARP attack detection and specify the handling method.
   arp source-mac { **filter** | **monitor** }
   By default, this feature is disabled.

3. Set the threshold.
   arp source-mac threshold *threshold-value*
   By default, the threshold is 30.
4. Set the aging timer for ARP attack detection entries.
   arp source-mac aging-time *time*
   By default, the lifetime is 300 seconds.
5. (Optional.) Exclude specific MAC addresses from this detection.
   arp source-mac exclude-mac *mac-address*&<1-10>
   By default, no MAC address is excluded.
6. Enable logging for source MAC-based ARP attack detection.
   arp source-mac log enable
   By default, logging for source MAC-based ARP attack detection is disabled.

Display and maintenance commands for source MAC-based ARP attack detection

Execute **display** commands in any view.



Task	Command
Display ARP attack detection entries generated by source MAC-based ARP attack detection.	**display arp source-mac** { **interface** *interface-type interface-number* [**slot** *slot-number*] | **slot** *slot-number* }

Example: Configuring source MAC-based ARP attack detection

Network configuration

As shown in Figure 2, the hosts access the Internet through a gateway (Device). If malicious users send a large number of ARP requests to the gateway, the gateway might crash and cannot process requests from the clients. To solve this problem, configure source MAC-based ARP attack detection on the gateway.

Figure 2 Network diagram

Procedure

Enable source MAC-based ARP attack detection, and specify the handling method as filter.

```
<Device> system-view
[Device] arp source-mac filter
```

Set the threshold to 30.

```
[Device] arp source-mac threshold 30
```

Set the lifetime for source MAC-based ARP attack detection entries to 60 seconds.

```
[Device] arp source-mac aging-time 60
```

Exclude MAC address 0012-3f86-e94c from this detection.

```
[Device] arp source-mac exclude-mac 0012-3f86-e94c
```

Configuring ARP packet source MAC consistency check

About ARP packet source MAC consistency check

This feature enables a gateway to filter ARP packets whose source MAC address in the Ethernet header is different from the sender MAC address in the message body. This feature allows the gateway to learn correct ARP entries.

Procedure

1. Enter system view.
   `system-view`
2. Enable ARP packet source MAC address consistency check.

arp valid-check enable

By default, ARP packet source MAC address consistency check is disabled.

Configuring ARP active acknowledgement

About this task

Use the ARP active acknowledgement feature on gateways to prevent user spoofing.

This feature enables the device to perform active acknowledgement before creating an ARP entry.

- Upon receiving an ARP request that requests the MAC address of the device, the device sends an ARP reply. Then, it sends an ARP request for the sender IP address in the received ARP request to determine whether to create an ARP entry for the sender IP address.
  - If the device receives an ARP reply within the probe interval, it creates the ARP entry.
  - If the device does not receive an ARP reply within the probe interval, it does not create the ARP entry.
- Upon receiving an ARP reply, the device examines whether it was the reply to the request that the device has sent.
  - If it was, the device creates an ARP entry for the sender IP address in the ARP reply.
  - If it was not, the device sends an ARP request for the sender IP address to determine whether to create an ARP entry for the sender IP address.
    - If the device receives an ARP reply within the probe interval, it creates the ARP entry.
    - If the device does not receive an ARP reply within the probe interval, it does not create the ARP entry.

To improve validity and reliability of ARP entries, you can enable ARP active acknowledgement in strict mode. In this mode, the device creates ARP entries only for the IP addresses that the device actively initiates the ARP resolution.

Procedure

1. Enter system view.

   system-view
2. Enable ARP active acknowledgement.

   arp active-ack [**strict**] **enable**

   By default, ARP active acknowledgement is disabled.

   For ARP active acknowledgement to take effect in strict mode, make sure ARP blackhole routing is enabled.

Configuring authorized ARP

About authorized ARP

Authorized ARP entries are generated based on the DHCP clients' address leases on the DHCP server or dynamic client entries on the DHCP relay agent. For more information about DHCP server and DHCP relay agent, see *Layer 3—IP Services Configuration Guide*.

Use this feature to prevent user spoofing and to allow only authorized clients to access network resources.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

   Supported interface types include Layer 3 Ethernet interface, Layer 3 Ethernet subinterface, Layer 3 aggregate interface, Layer 3 aggregate subinterface, and VLAN interface.

3. Enable authorized ARP on the interface.

   arp authorized enable

   By default, authorized ARP is disabled.

Example: Configuring authorized ARP on a DHCP server

Network configuration

As shown in Figure 3, configure authorized ARP on Vlan-interface2 of Switch A (a DHCP server) to ensure user validity.

Figure 3 Network diagram

Procedure

1. Configure Switch A:

   # Specify the IP address for Vlan-interface2.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ip address 10.1.1.1 24
   [SwitchA-Vlan-interface2] quit
   ```

   # Configure DHCP.

   ```
   [SwitchA] dhcp enable
   [SwitchA] dhcp server ip-pool 1
   [SwitchA-dhcp-pool-1] network 10.1.1.0 mask 255.255.255.0
   [SwitchA-dhcp-pool-1] quit
   ```

   # Enter VLAN interface view.

   ```
   [SwitchA] interface vlan-interface 2
   ```

   # Enable authorized ARP.

   ```
   [SwitchA-Vlan-interface2] arp authorized enable
   [SwitchA-Vlan-interface2] quit
   ```

2. Configure Switch B:

   ```
   <SwitchB> system-view
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] ip address dhcp-alloc
   [SwitchB-Vlan-interface2] quit
   ```

Verifying the configuration

Display authorized ARP entry information on Switch A.

```
[SwitchA] display arp all
  Type: S-Static   D-Dynamic   O-Openflow   R-Rule   M-Multiport  I-Invalid
IP address      MAC address    VLAN/VSI name Interface               Aging Type
10.1.1.2        0012-3f86-e94c 2             GE1/0/1                 960   D
```

The output shows that IP address 10.1.1.2 has been assigned to Switch B.

Switch B must use the IP address and MAC address in the authorized ARP entry to communicate with Switch A. Otherwise, the communication fails. Thus user validity is ensured.

Example: Configuring authorized ARP on a DHCP relay agent

Network configuration

As shown in Figure 4, configure authorized ARP on GigabitEthernet 1/0/2 of Device B (a DHCP relay agent) to ensure user validity.

Figure 4 Network diagram

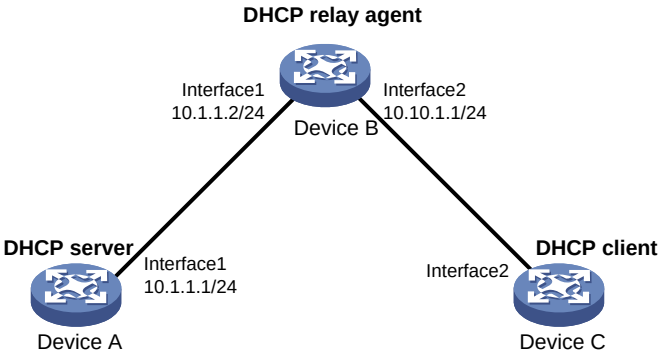


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure Device A:

   # Specify the IP address for GigabitEthernet 1/0/1.

   ```
   <DeviceA> system-view
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ip address 10.1.1.1 24
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Configure DHCP.

   ```
   [DeviceA] dhcp enable
   [DeviceA] dhcp server ip-pool 1
   [DeviceA-dhcp-pool-1] network 10.10.1.0 mask 255.255.255.0
   [DeviceA-dhcp-pool-1] gateway-list 10.10.1.1
   ```

```
[DeviceA-dhcp-pool-1] quit
[DeviceA] ip route-static 10.10.1.0 24 10.1.1.2
```

2. Configure Device B:

   # Enable DHCP.

```
<DeviceB> system-view
[DeviceB] dhcp enable
```

   # Specify the IP addresses of GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ip address 10.1.1.2 24
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] ip address 10.10.1.1 24
```

   # Enable DHCP relay agent on GigabitEthernet 1/0/2.

```
[DeviceB-GigabitEthernet1/0/2] dhcp select relay
```

   # Add the DHCP server 10.1.1.1 to DHCP server group 1.

```
[DeviceB-GigabitEthernet1/0/2] dhcp relay server-address 10.1.1.1
```

   # Enable authorized ARP.

```
[DeviceB-GigabitEthernet1/0/2] arp authorized enable
[DeviceB-GigabitEthernet1/0/2] quit
```

   # Enable recording of relay entries on the relay agent.

```
[DeviceB] dhcp relay client-information record
```

3. Configure Device C:

```
<DeviceC> system-view
[DeviceC] ip route-static 10.1.1.0 24 10.10.1.1
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] ip address dhcp-alloc
[DeviceC-GigabitEthernet1/0/2] quit
```

Verifying the configuration

Display authorized ARP information on Device B.

```
[DeviceB] display arp all
  Type: S-Static   D-Dynamic   O-Openflow   R-Rule   M-Multiport  I-Invalid
IP address      MAC address    VLAN/VSI name Interface               Aging Type
10.10.1.2       0012-3f86-e94c --            GE1/0/2                  960   D
```

The output shows that Device A assigned the IP address 10.10.1.2 to Device C.

Device C must use the IP address and MAC address in the authorized ARP entry to communicate with Device B. Otherwise, the communication fails. Thus the user validity is ensured.

Configuring ARP attack detection

About ARP attack detection

ARP attack detection enables access devices to block ARP packets from unauthorized clients to prevent user spoofing and gateway spoofing attacks.

ARP attack detection provides the following features:

- User validity check.

- ARP packet validity check.
- ARP restricted forwarding.
- ARP packet ingress port ignoring during user validity check
- ARP attack detection logging.

If both ARP packet validity check and user validity check are enabled, the former one applies first, and then the latter applies.

Do not configure ARP attack detection together with ARP snooping. Otherwise, ARP snooping entries cannot be generated.

Configuring user validity check

About this task

User validity check does not check ARP packets received on ARP trusted interfaces. This feature compares the sender IP and sender MAC in the ARP packet received on an ARP untrusted interface with the matching criteria in the following order:

1. User validity check rules.
   - If a match is found, the device processes the ARP packet according to the rule.
   - If no match is found or no user validity check rule is configured, proceeds to step 2.
2. Static IPSG bindings, 802.1X security entries, and DHCP snooping entries.
   - If a match is found, the device determines that the ARP packet is valid, and then forwards the ARP packet.
     - If a match is found and the receiving interface is different from the interface in the entry with a matching sender IP address, the device performs Layer 3 forwarding.
     - If a match is found but the receiving interface is the same as the interface in the entry with a matching sender IP address, the device performs Layer 2 forwarding.
     - If no match is found, the device performs Layer 2 forwarding.
   - If no match is found, the device discards the ARP packet.

Static IP source guard bindings are created by using the **`ip source binding`** command. For more information, see "Configuring IP source guard."

DHCP snooping entries are automatically generated by DHCP snooping. For more information, see *Layer 3—IP Services Configuration Guide*.

802.1X security entries record the IP-to-MAC mappings for 802.1X clients. After a client passes 802.1X authentication and uploads its IP address to an ARP attack detection enabled device, the device automatically generates an 802.1X security entry. The 802.1X client must be enabled to upload its IP address to the device. For more information, see "Configuring 802.1X."

Restrictions and guidelines

When you configure user validity check, make sure one or more of the following items are configured:

- User validity check rules.
- Static IP source guard bindings.
- DHCP snooping.
- 802.1X.

If none of the items is configured, no incoming ARP packets on ARP untrusted interfaces can be forwarded normally.

Specify an IP address, a MAC address, and a VLAN where ARP attack detection is enabled for an IP source guard binding. Otherwise, no ARP packets can match the IP source guard binding.

Configuring user validity check rules

1. Enter system view.

   system-view

2. Configure a user validity check rule.

   arp detection rule *rule-id* { **deny** | **permit** } **ip** { *ip-address* [*mask*] | **any** } **mac** { *mac-address* [*mask*] | **any** } [**vlan** *vlan-id*]

   By default, no user validity check rules are configured.

Enabling ARP attack detection in a VLAN

1. Enter system view.

   system-view

2. Enter VLAN view.

   vlan *vlan-id*

3. Enable ARP attack detection.

   arp detection enable

   By default, ARP attack detection is disabled. The device does not perform ARP user validity check.

4. (Optional.) Configure an interface that does not require ARP user validity check as a trusted interface.

   a. Return to system view.

      quit

   b. Enter interface view.

      interface *interface-type interface-number*

      Supported interface types include Layer 2 Ethernet interface and Layer 2 aggregate interface.

   c. Configure the interface as a trusted interface excluded from ARP attack detection.

      arp detection trust

      By default, an interface is untrusted.

Configuring ARP packet validity check

About this task

ARP packet validity check does not check ARP packets received on ARP trusted interfaces. To check ARP packets received on untrusted interfaces, you can specify the following objects to be checked:

- **src-mac**—Checks whether the sender MAC address in the message body is identical to the source MAC address in the Ethernet header. If they are identical, the packet is forwarded. Otherwise, the packet is discarded.
- **dst-mac**—Checks the target MAC address of ARP replies. If the target MAC address is all-zero, all-one, or inconsistent with the destination MAC address in the Ethernet header, the packet is considered invalid and discarded.
- **ip**—Checks the sender and target IP addresses of ARP replies, and the sender IP address of ARP requests. All-one or multicast IP addresses are considered invalid and the corresponding packets are discarded.

Prerequisites

Before you configure ARP packet validity check, you must first configure user validity check. For more information about user validity check configuration, see "Configuring user validity check."

Enabling ARP packet validity check

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable ARP attack detection.
   arp detection enable
   By default, ARP attack detection is disabled. The device does not perform ARP packet validity check.
4. Enable ARP packet validity check.
   a. Return to system view.
      quit
   b. Enable ARP packet validity check and specify the objects to be checked.
      arp detection validate { **dst-mac** | **ip** | **src-mac** } *
      By default, ARP packet validity check is disabled.

Enabling ARP attack detection in a VLAN

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable ARP attack detection.
   arp detection enable
   By default, ARP attack detection is disabled. The device does not perform ARP packet validity check.
4. (Optional.) Configure the interface that does not require ARP packet validity check as a trusted interface.
   a. Return to system view.
      quit
   b. Enter interface view.
      interface *interface-type interface-number*
      Supported interface types include Layer 2 Ethernet interface and Layer 2 aggregate interface.
   c. Configure the interface as a trusted interface excluded from ARP attack detection.
      arp detection trust
      By default, an interface is untrusted.

Configuring ARP restricted forwarding

About this task

ARP restricted forwarding does not take effect on ARP packets received on ARP trusted interfaces and forwards the ARP packets correctly. This feature controls the forwarding of ARP packets that are received on untrusted interfaces and have passed user validity check as follows:

- If the packets are ARP requests, they are forwarded through the trusted interface.
- If the packets are ARP replies, they are forwarded according to their destination MAC address. If no match is found in the MAC address table, they are forwarded through the trusted interface.

Restrictions and guidelines

ARP restricted forwarding does not apply to ARP packets that use multiport destination MAC addresses.

Prerequisites

Configure user validity check before you configure ARP restricted forwarding. For information about user validity check configuration, see "Configuring user validity check."

Procedure

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable ARP restricted forwarding.
   arp restricted-forwarding enable
   By default, ARP restricted forwarding is disabled.

Ignoring ingress ports of ARP packets during user validity check

About this task

ARP attack detection performs user validity check on ARP packets from ARP untrusted interfaces. The sender IP and sender MAC in the received ARP packet are compared with the entries used for user validity check. In addition, user validity check compares the ingress port of the ARP packet with the port in the entries. If no matching port is found, the ARP packet is discarded. For more information about user validity check, see "Configuring user validity check."

You can configure the device to ignore the ingress ports of ARP packets during user validity check. If an ARP packet passes user validity check, the device directly performs Layer 2 forwarding for the packet. It no longer searches for a matching static IPSG binding, 802.1X security entry, or DHCP snooping entry by the target IP address of the ARP packet.

Procedure

1. Enter system view.
   system-view
2. Ignore ingress ports of ARP packets during user validity check.
   arp detection port-match-ignore
   By default, ingress ports of ARP packets are checked during user invalidity.

Enabling ARP attack detection logging

About this task

The ARP attack detection logging feature enables a device to generate ARP attack detection log messages when illegal ARP packets are detected. An ARP attack detection log message contains the following information:

- Receiving interface of the ARP packets.
- Sender IP address.
- Total number of dropped ARP packets.

Procedure

1. Enter system view.

   system-view

2. Enable ARP attack detection logging.

   arp detection log enable [**interval** *interval* | **number** *number* | **threshold** *threshold-value*]*

   By default, ARP attack detection logging is disabled.

Display and maintenance commands for ARP attack detection

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the VLANs enabled with ARP attack detection.	**display arp detection**
Display ARP attack source statistics.	**display arp detection statistics attack-source slot** *slot-number*
Display statistics for packets dropped by ARP attack detection.	**display arp detection statistics packet-drop** [**interface** *interface-type interface-number*]
Clear ARP attack source statistics.	**reset arp detection statistics attack-source** [**slot** *slot-number*]
Clear statistics for packets dropped by ARP attack detection.	**reset arp detection statistics packet-drop** [**interface** *interface-type interface-number*]

Example: Configuring user validity check

Network configuration

As shown in Figure 5, configure Device B to perform user validity check based on 802.1X security entries for connected hosts.

Figure 5 Network diagram

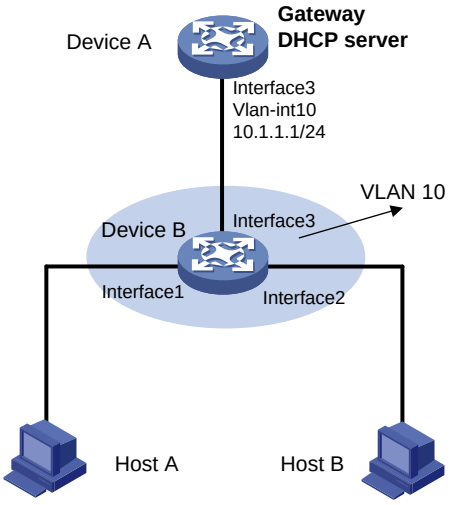

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Add all interfaces on Device B to VLAN 10, and specify the IP address of VLAN-interface 10 on Device A. (Details not shown.)
2. Configure the DHCP server on Device A, and configure DHCP address pool 0.

```
<DeviceA> system-view
[DeviceA] dhcp enable
[DeviceA] dhcp server ip-pool 0
[DeviceA-dhcp-pool-0] network 10.1.1.0 mask 255.255.255.0
```

3. Configure Host A and Host B as 802.1X clients and configure them to upload IP addresses for ARP attack detection. (Details not shown.)
4. Configure Device B:

   # Enable 802.1X.

```
<DeviceB> system-view
[DeviceB] dot1x
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] dot1x
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] dot1x
[DeviceB-GigabitEthernet1/0/2] quit
```

   # Add a local user **test**.

```
[DeviceB] local-user test class network
[DeviceB-luser-network-test] service-type lan-access
[DeviceB-luser-network-test] password simple test
```

```
[DeviceB-luser-network-test] quit
```

Enable ARP attack detection for VLAN 10 to check user validity based on 802.1X entries.

```
[DeviceB] vlan 10
[DeviceB-vlan10] arp detection enable
```

Configure the upstream interface as an ARP trusted interface. By default, an interface is an untrusted interface.

```
[DeviceB-vlan10] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] arp detection trust
[DeviceB-GigabitEthernet1/0/3] quit
```

Verifying the configuration

Verify that ARP packets received on interfaces GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are checked against 802.1X entries.

Example: Configuring user validity check and ARP packet validity check

Network configuration

As shown in Figure 6, configure Device B to perform ARP packet validity check and user validity check based on static IP source guard bindings and DHCP snooping entries for connected hosts.

Figure 6 Network diagram

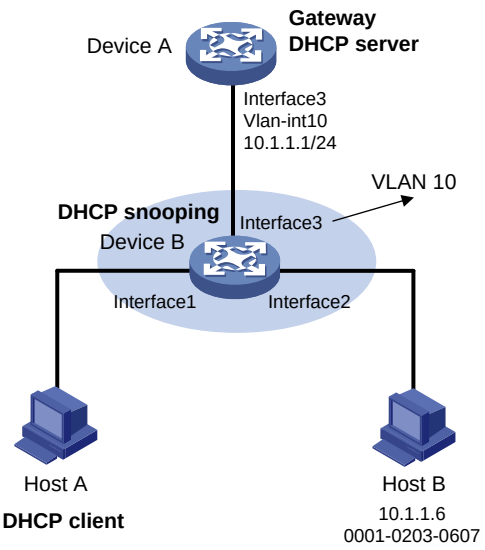

Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Add all interfaces on Device B to VLAN 10, and specify the IP address of VLAN-interface 10 on Device A. (Details not shown.)

2. Configure the DHCP server on Device A, and configure DHCP address pool 0.

```
<DeviceA> system-view
[DeviceA] dhcp enable
[DeviceA] dhcp server ip-pool 0
[DeviceA-dhcp-pool-0] network 10.1.1.0 mask 255.255.255.0
```

3. Configure Host A (DHCP client) and Host B. (Details not shown.)
4. Configure Device B:

   # Enable DHCP snooping.

```
<DeviceB> system-view
[DeviceB] dhcp snooping enable
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] dhcp snooping trust
[DeviceB-GigabitEthernet1/0/3] quit
```

   # Enable recording of client information in DHCP snooping entries on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] dhcp snooping binding record
[DeviceB-GigabitEthernet1/0/1] quit
```

   # Enable ARP attack detection for VLAN 10.

```
[DeviceB] vlan 10
[DeviceB-vlan10] arp detection enable
```

   # Configure the upstream interface as a trusted interface. By default, an interface is an untrusted interface.

```
[DeviceB-vlan10] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] arp detection trust
[DeviceB-GigabitEthernet1/0/3] quit
```

   # Configure a static IP source guard binding entry on interface GigabitEthernet 1/0/2 for user validity check.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] ip source binding ip-address 10.1.1.6 mac-address
0001-0203-0607 vlan 10
[DeviceB-GigabitEthernet1/0/2] quit
```

   # Enable ARP packet validity check by checking the MAC addresses and IP addresses of ARP packets.

```
[DeviceB] arp detection validate dst-mac ip src-mac
```

Verifying the configuration

Verify that Device B first checks the validity of ARP packets received on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2. If the ARP packets are confirmed valid, Device B performs user validity check by using the static IP source guard bindings and finally DHCP snooping entries.

Example: Configuring ARP restricted forwarding

Network configuration

As shown in Figure 7, configure ARP restricted forwarding on Device B where ARP attack detection is configured. Port isolation configured on Device B can take effect for broadcast ARP requests.

Figure 7 Network diagram

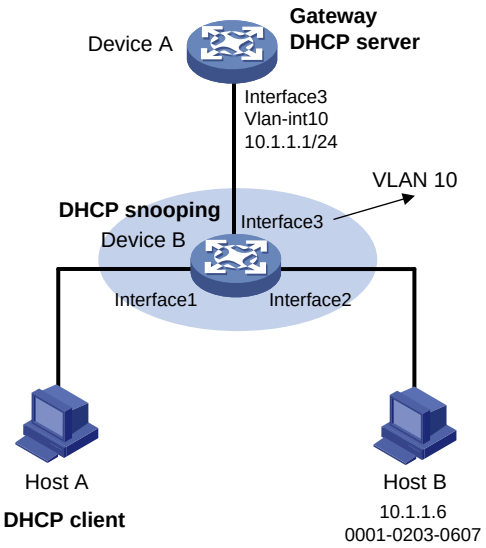

Table 4 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure VLAN 10, add interfaces to VLAN 10, and specify the IP address of VLAN-interface 10 on Device A. (Details not shown.)
2. Configure the DHCP server on Device A, and configure DHCP address pool 0.

```
<DeviceA> system-view
[DeviceA] dhcp enable
[DeviceA] dhcp server ip-pool 0
[DeviceA-dhcp-pool-0] network 10.1.1.0 mask 255.255.255.0
```

3. Configure Host A (DHCP client) and Host B. (Details not shown.)
4. Configure Device B:

   # Enable DHCP snooping, and configure GigabitEthernet 1/0/3 as a DHCP trusted interface.

```
<DeviceB> system-view
[DeviceB] dhcp snooping enable
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] dhcp snooping trust
[DeviceB-GigabitEthernet1/0/3] quit
```

   # Enable ARP attack detection for user validity check.

```
[DeviceB] vlan 10
[DeviceB-vlan10] arp detection enable
```

   # Configure GigabitEthernet 1/0/3 as an ARP trusted interface.

```
[DeviceB-vlan10] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] arp detection trust
[DeviceB-GigabitEthernet1/0/3] quit
```

Configure a static IP source guard entry on interface GigabitEthernet 1/0/2.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] ip source binding ip-address 10.1.1.6 mac-address
0001-0203-0607 vlan 10
[DeviceB-GigabitEthernet1/0/2] quit
```

Enable ARP packet validity check by checking the MAC addresses and IP addresses of ARP packets.

```
[DeviceB] arp detection validate dst-mac ip src-mac
```

Configure port isolation.

```
[DeviceB] port-isolate group 1
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port-isolate enable group 1
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port-isolate enable group 1
[DeviceB-GigabitEthernet1/0/2] quit
```

After the configurations are completed, Device B first checks the validity of ARP packets received on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2. If the ARP packets are confirmed valid, Device B performs user validity check by using the static IP source guard bindings and finally DHCP snooping entries. However, ARP broadcast requests sent from Host A can pass the check on Device B and reach Host B. Port isolation fails.

Enable ARP restricted forwarding.

```
[DeviceB] vlan 10
[DeviceB-vlan10] arp restricted-forwarding enable
[DeviceB-vlan10] quit
```

Verifying the configuration

Verify that Device B forwards ARP broadcast requests from Host A to Device A through the trusted interface GigabitEthernet 1/0/3. Host B cannot receive such packets. Port isolation operates correctly.

Configuring ARP scanning and fixed ARP

About this task

ARP scanning is typically used together with the fixed ARP feature in small-scale and stable networks.

ARP scanning automatically creates ARP entries for devices in an address range. The device performs ARP scanning in the following steps:

1. Sends ARP requests for each IP address in the address range.
2. Obtains their MAC addresses through received ARP replies.
3. Creates dynamic ARP entries.

You can manually trigger ARP scanning or enable automatic ARP scanning. Automatic ARP scanning periodically sends ARP requests for all IP addresses in the range at the specified rate set by using the **arp scan auto send-rate** command.

Fixed ARP converts existing dynamic ARP entries (including those generated through ARP scanning) to static ARP entries. These static ARP entries are of the same attributes as the ARP entries that are manually configured. This feature prevents ARP entries from being modified by attackers.

You can set the ARP packet sending rate if the scanning range has a large number of IP addresses. This setting can avoid high CPU usage and heavy network load caused by a burst of ARP traffic.

Restrictions and guidelines

IP addresses in existing ARP entries are not scanned.

If you trigger ARP scanning and enable automatic ARP scanning, both of them take effect. As a best practice, use automatic ARP scanning only on networks where users come online and go offline frequently.

Due to the limit on the total number of static ARP entries, some dynamic ARP entries might fail the conversion.

The **arp fixup** command is a one-time operation. You can use this command again to convert the dynamic ARP entries learned later to static.

To delete a static ARP entry converted from a dynamic one, use the **undo arp** *ip-address* [*vpn-instance-name*] command. You can also use the **reset arp all** command to delete all ARP entries or the **reset arp static** command to delete all static ARP entries.

Triggering ARP scanning

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Trigger ARP scanning.
   arp scan [*start-ip-address* **to** *end-ip-address*] [**send-rate** { **ppm** *ppm* | *pps* }]

CAUTION:

ARP scanning will take some time and occupy a lot of system and network resources. To stop an ongoing scan, press **Ctrl** + **C**. Dynamic ARP entries are created based on ARP replies received before the scan is terminated.

Configuring automatic ARP scanning

1. Enter system view.
   system-view
2. Set the ARP packet sending rate for automatic ARP scanning.
   arp scan auto send-rate { **ppm** *ppm* | **pps** *pps* }
   By default, the device sends ARP packets at the rate of 48 pps during automatic ARP scanning.
3. Enter interface view.
   interface *interface-type interface-number*
4. Enable automatic ARP scanning.
   arp scan auto enable [*start-ip-address* **to** *end-ip-address*]
   By default, automatic ARP scanning is disabled.

Configuring fixed ARP

1. Enter system view.
   system-view
2. Convert existing dynamic ARP entries to static ARP entries.
   arp fixup

Configuring ARP keepalive entry scanning

About ARP keepalive entry scanning

In a large-scale network, it takes a long time for ARP scanning to identify the hosts that go offline abnormally if you specify a large scanning range. After you enable ARP keepalive entry scanning, the system can quickly locate those hosts and monitor the host status within the aging time.

You can set the aging time for ARP keepalive entries in both system view and interface view. The aging time set in interface view takes precedence over the aging time set in system view. In interface view, the default aging time for ARP keepalive entries is the aging time set in system view.

When users come online, the system generates dynamic APR entries and IPSG binding entries. Enabled with ARP keepalive entry scanning, the system also creates online keepalive entries when users come online. If users go offline, the corresponding APR entries are deleted and the status of the keepalive entries is set to offline. The device sends ARP requests at intervals to the IP addresses in the offline keepalive entries until the keepalive entries become online again or are deleted when the aging time expires. The interval varies with the number of ARP requests that have been sent to the IP address in an offline keepalive entry. For more information about IP source guard configuration, see *Security Configuration Guide*.

Configuring ARP keepalive entry scanning

1. Enter system view.
   system-view
2. (Optional.) Set the ARP request sending rate for keepalive entry scanning.
   arp scan keepalive send-rate *pps*
   By default, the device sends ARP requests at a rate of 48 pps during keepalive entry scanning.
3. (Optional.) Set the aging time for ARP keepalive entries.
   arp scan keepalive aging-time *time*
   By default, the aging time for ARP keepalive entries in system view is 60 minutes. The aging time for ARP keepalive entries in interface view is the aging time set in system view.
4. Enter interface view.
   interface *interface-type interface-number*
5. Enable the ARP keepalive entry scanning feature.
   arp scan keepalive enable
   By default, the ARP keepalive entry scanning is disabled on an interface.

Display and maintenance commands for ARP keepalive entry scanning

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display ARP keepalive entries.	**display arp scan keepalive entry** [**interface** *interface-type interface-number*] [**count**]
Display statistics about ARP requests sent to the IP addresses in offline keepalive entries for an interface.	**display arp scan keepalive statistics** [**slot** *slot-number*] [**interface** *interface-type interface-number*]
Clear statistics about ARP requests sent to the IP addresses in offline keepalive entries.	**reset arp scan keepalive statistics** [**slot** *slot-number*]

Configuring ARP gateway protection

About ARP gateway protection

Configure this feature on interfaces not connected with a gateway to prevent gateway spoofing attacks.

When such an interface receives an ARP packet, it checks whether the sender IP address in the packet is consistent with that of any protected gateway. If yes, it discards the packet. If not, it handles the packet correctly.

Restrictions and guidelines

You can enable ARP gateway protection for a maximum of eight gateways on an interface or in an Ethernet service instance.

Do not configure both the **arp filter source** and **arp filter binding** commands on an interface. You can configure both the **arp filter binding** command on an interface and the **arp filter source** command in an Ethernet service instance.

If ARP gateway protection works with ARP attack detection, MFF, ARP snooping, and ARP fast-reply, ARP gateway protection applies first.

Procedure

1. Enter system view.
   system-view
2. Enter interface view or Ethernet service instance view.
   - Enter interface view.
     interface *interface-type interface-number*
     Supported interface types include Layer 2 Ethernet interface and Layer 2 aggregate interface.
   - Enter Ethernet service instance view.
     interface *interface-type interface-number*
     service-instance *instance-id*
3. Enable ARP gateway protection for the specified gateway.
   arp filter source *ip-address*
   By default, ARP gateway protection is disabled.

Example: Configuring ARP gateway protection

Network configuration

As shown in Figure 8, Host B launches gateway spoofing attacks to Device B. As a result, traffic that Device B intends to send to Device A is sent to Host B.

Configure Device B to block such attacks.

Figure 8 Network diagram

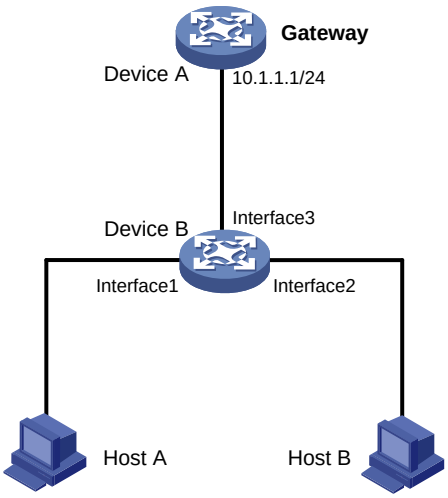

Table 5 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

Configure ARP gateway protection on Device B.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] arp filter source 10.1.1.1
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] arp filter source 10.1.1.1
```

Verifying the configuration

Verify that GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 discard the incoming ARP packets whose sender IP address is the IP address of the gateway.

Configuring ARP filtering

About ARP filtering

The ARP filtering feature can prevent gateway spoofing and user spoofing attacks.

An interface enabled with this feature checks the sender IP and MAC addresses in a received ARP packet against permitted entries. If a match is found, the packet is handled correctly. If not, the packet is discarded.

Restrictions and guidelines

You can configure a maximum of eight permitted entries on an interface.

Do not configure both the **arp filter source** and **arp filter binding** commands on an interface.

If ARP filtering works with ARP attack detection, MFF, ARP snooping, and ARP fast-reply, ARP filtering applies first.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
   Supported interface types include Ethernet interface and Layer 2 aggregate interface.
3. Enable ARP filtering and configure a permitted entry.
   arp filter binding *ip-address mac-address*
   By default, ARP filtering is disabled.

Example: Configuring ARP filtering

Network configuration

As shown in Figure 9, the IP and MAC addresses of Host A are 10.1.1.2 and 000f-e349-1233, respectively. The IP and MAC addresses of Host B are 10.1.1.3 and 000f-e349-1234, respectively.

Configure ARP filtering on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 of Device B to permit ARP packets from only Host A and Host B.

Figure 9 Network diagram

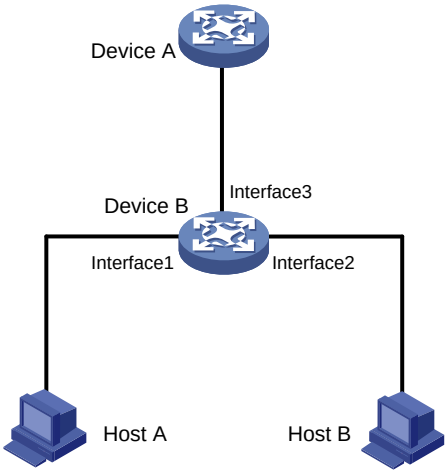

Table 6 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

Configure ARP filtering on Device B.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] arp filter binding 10.1.1.2 000f-e349-1233
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] arp filter binding 10.1.1.3 000f-e349-1234
```

Verifying the configuration

Verify that GigabitEthernet 1/0/1 permits ARP packets from Host A and discards other ARP packets.

Verify that GigabitEthernet 1/0/2 permits ARP packets from Host B and discards other ARP packets.

Configuring ARP sender IP address checking

About ARP sender IP address checking

This feature allows a gateway to check the sender IP address of an ARP packet in a VLAN before ARP learning. If the sender IP address is within the allowed IP address range, the gateway continues ARP learning. If the sender IP address is out of the range, the gateway determines the ARP packet as an attack packet and discards it.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable the ARP sender IP address checking feature and specify the IP address range.
   arp sender-ip-range *start-ip-address end-ip-address*
   By default, the ARP sender IP address checking feature is disabled.

Configuring ARP entry fixing

About this task

Upon receiving the first ARP packet from a user, the device adds an ARP entry to the ARP table. If it receives another ARP packet from the same user, it dynamically refreshes the ARP entry based on

the new ARP packet. To prevent attackers from interrupting legitimate user services by sending forged ARP packets that tamper with their ARP entries, enable this feature.

ARP entry fixing supports the following modes:

- **all**—Fixes all information in ARP entries. When the device receives an ARP packet in which the IP address is the same as an ARP entry, it works as follows:
  - If the MAC address, output interface, or VLAN in the ARP packet does not match the ARP entry, the device directly drops the packet and does not update the ARP entry.
  - If the MAC address, output interface, and VLAN in the ARP packet match the ARP entry, the device updates the aging time of the ARP entry.
- **mac**—Fixes only the MAC addresses in ARP entries. When the device receives an ARP packet in which the IP address is the same as an ARP entry, it works as follows:
  - If the MAC address in the ARP packet does not match the ARP entry, the device directly drops the packet and does not update the ARP entry.
  - If the MAC address in the ARP packet matches the ARP entry, the device updates the output interface, VLAN, and aging time of the ARP entry.

Restrictions and guidelines

The global ARP entry fixing feature takes effect on all interfaces.

An interface is enabled with ARP entry fixing once you enable ARP entry fixing in system view or the view of that interface.

To enable ARP entry fixing on a specific interface, make sure global ARP entry fixing is disabled..

If global ARP entry fixing and interface-specific ARP entry fixing are in different modes, the interface-specific ARP entry fixing configuration takes effect.

Enabling global ARP entry fixing

1. Enter system view.
   system-view
2. Enable global ARP entry fixing.
   arp anti-attack entry-fixing { **all** | **mac** } **enable**
   By default, global ARP entry fixing is disabled.

Enabling ARP entry fixing on an interface

1. Enter system view.
   system-view
2. (Optional.) Disable global ARP entry fixing.
   undo arp anti-attack entry-fixing { **all** | **mac** } **enable**
   By default, global ARP entry fixing is disabled.
3. Enter interface view.
   interface *interface-type interface-number*
4. Enable ARP entry fixing on the interface.
   arp anti-attack entry-fixing { **all** | **mac** } **enable**
   By default, ARP entry fixing is disabled on an interface.

Enabling SNMP notifications for ARP

About this task

Enable SNMP notifications for ARP as required.

- If you enable ARP active acknowledgement notifications, the device sends a notification to the SNMP module when it does not establish an ARP entry due to active acknowledgement. The notification includes the sender IP address in the received ARP packet and the interface that receives the ARP packet.
- If you enable rate limit notifications for sending ARP Miss messages and ARP packets, the device sends the highest threshold-crossed rate as a notification to the SNMP module when the sending rate exceeds the custom threshold.
- If you enable notifications for packet dropping due to ARP attack detection, the device sends a notification to the SNMP module when a packet is dropped by ARP attack detection. The notification includes the VLAN ID, service ID, and drop reason for the dropped packet.
- If you enable ARP entry modification notifications, the device sends a notification to the SNMP module when it detects that the ARP entry for a user might be changed to the attacker's ARP entry. The notification includes the sender IP and MAC addresses in the ARP attack packet.
- If you enable ARP entry limit notifications, the device sends the current number of ARP entries as a notification to the SNMP module when the number of global ARP entries exceeds the alarm threshold.
- If you enable ARP gateway protection notifications, the device sends a notification to the SNMP module when it is attacked by gateway spoofing attacks. The notification includes the sender IP and MAC addresses in the ARP attack packet dropped by ARP gateway protection, and index of the interface that receives the ARP attack packet. When an ARP packet with the same sender IP address triggers the SNMP notification again within 3 minutes, the device sends a recovery notification to the SNMP module.
- If you enable endpoint and local device conflict notifications, the device sends a notification to the SNMP module when an endpoint and local device conflict occurs. The notification includes the sender IP address, sender MAC address, target IP address, and target MAC address in the conflicting ARP packet.
- If you enable MAC address inconsistency notifications, the device sends a notification to the SNMP module when the MAC address in the configured static ARP entry and user's actual MAC address are inconsistent. The notification includes the IP address, VPN instance, and MAC address in the ARP entry.
- An invalid ARP packet contains an invalid hardware address type, protocol address type, hardware address length, protocol address length, operation code, or VLAN. For example, when the operation code value is not 1 (ARP request) or 2 (ARP reply), the operation code is invalid and the ARP packet is invalid. If you enable invalid ARP packet check notifications, the device sends a notification to the SNMP module when it receives an invalid ARP packet. The notification includes the name of the interface that receives the ARP packet, sender MAC and IP addresses, user VLAN ID, and VLAN ID of the service provider.
- If you enable ARP packet queue limit notifications, the device sends the number of packets in the queue as a notification to the SNMP module when the number exceeds 80% of the upper limit.
- If you enable rate limit notifications for receiving ARP packets, the device sends the highest threshold-crossed rate as a notification to the SNMP module. For more information about ARP packet rate limiting, see "Configuring ARP packet rate limiting."
- If you enable user IP address conflict notifications, the device sends a notification to the SNMP module when a user IP address conflict occurs. The notification includes the sender IP and MAC addresses in the conflicting ARP packet, and MAC address in the corresponding local ARP entry. For more information about enabling recording user IP address conflicts, see ARP configuration in *Layer 3—IP Services Configuration Guide*.
- If you enable user port migration notifications, the device sends a notification to the SNMP module when a user port changes. The notification includes the IP address, MAC address, port before migration, and port after migration of the user. For more information about enabling recording user port migrations, see *ARP configuration in Layer 3—IP Services Configuration Guide*.

For ARP event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for ARP.

   snmp-agent trap enable arp [**active-ack** | **arp-miss** | **detection-drop** | **entry-check** | **entry-limit** | **gateway-check** | **local-conflict** | **mac-mismatch** | **packet-check** | **pkt-threshold** | **rate-limit** | **user-ip-conflict** | **user-move**] *

   By default, SNMP notifications for ARP are disabled.

   If you do not specify any keywords, this command enables all SNMP notifications for ARP.

   Only the S5200-HI-G switch series supports the **rate-limit** keyword.

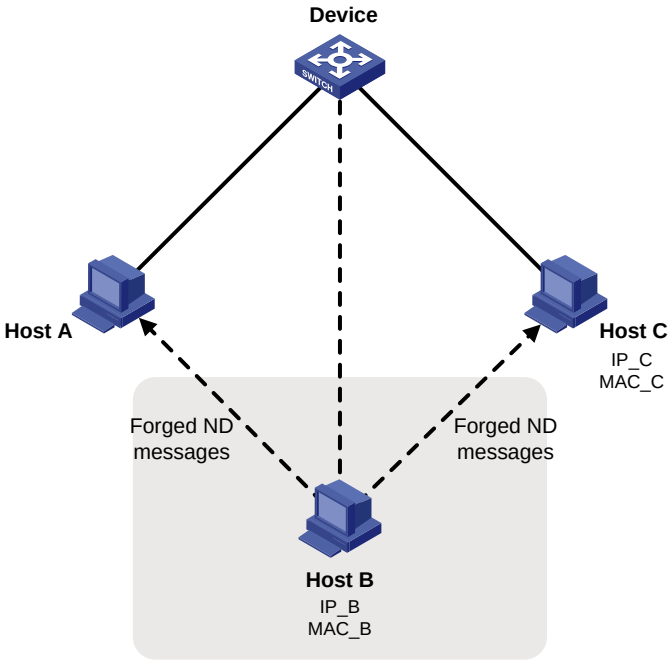
Configuring ND attack defense



About ND attack defense

IPv6 Neighbor Discovery (ND) attack defense is able to identify forged ND messages to prevent ND attacks.

The IPv6 ND protocol does not provide any security mechanisms and is vulnerable to network attacks. As shown in Figure 1, an attacker can send the following forged ICMPv6 messages to perform ND attacks:

- Forged NS/NA/RS messages with an IPv6 address of a victim host. The gateway and other hosts update the ND entry for the victim with incorrect address information. As a result, all packets intended for the victim are sent to the attacking terminal.
- Forged RA messages with the IPv6 address of a victim gateway. As a result, all hosts attached to the victim gateway maintain incorrect IPv6 configuration parameters and ND entries.

Figure 1 ND attack diagram

ND attack defense tasks at a glance

All ND attack defense tasks are optional.

- Configuring ND packet rate limit
- Enabling source MAC consistency check for ND messages
- Configuring ND attack detection
- Configuring RA guard
- Configuring ND keepalive entry scanning
- Enabling SNMP notifications for ND
- Configuring ND blackhole routing

Configuring ND packet rate limit

About this task

This feature limits the receiving rate of ND packets that are to be delivered to the CPU, preventing the CPU from being overwhelmed by ND packets.

Enabled with ND attack detection, the device redirects the received ND packets to the CPU for security check. If attackers send a large number of forged ND packets to the device, the CPU will be overloaded. As a result, other features might malfunction and the device might crash. To avoid this situation, configure ND packet rate limit on ND packet receiving interfaces. When the receiving rate of ND packets on the interfaces exceeds the rate limit, the packets that exceed the limit will be discarded.

When logging for ND packet rate limit is enabled, the device sends the highest threshold-crossed ND packet rate within the sending interval in a log message to the information center. You can configure the information center module to set the log output rules. For more information about information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

As a best practice, configure this feature if the device is configured with ND attack detection or ND snooping or has detected ND flood attacks.

To prevent the device from sending log messages frequently, set the log message sending interval to a high value.

On a Layer 2 aggregate interface, if you enable ND packet rate limit and the logging for this feature, the device sends log messages upon limit violations on its member ports.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Enable logging for ND packet rate limit.

   ipv6 nd rate-limit log enable

   By default, logging for ND packet rate limit is disabled.

3. (Optional.) Set the log message sending interval.

   ipv6 nd rate-limit log interval *interval*

   By default, the device sends log messages every 60 seconds.

4. Enter interface view.

   interface *interface-type interface-number*

   Supported interfaces include Layer 2 Ethernet interfaces, Layer 2 aggregate interfaces, Layer 3 Ethernet interfaces, and Layer 3 aggregate interfaces.

5. Enable ND packet rate limit.

   ipv6 nd rate-limit [*pps*]

   By default, ND packet rate limit is enabled.

Enabling source MAC consistency check for ND messages

About this task

The source MAC consistency check feature is typically configured on gateways to prevent ND attacks.

This feature checks the source MAC address and the source link-layer address for consistency for each arriving ND message.

- If the source MAC address and the source link-layer address are not the same, the device drops the packet.
- If the addresses are the same, the device continues learning ND entries.

The ND logging feature logs source MAC inconsistency events, and it sends the log messages to the information center. The information center can then output log messages from different source modules to different destinations. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   `system-view`
2. Enable source MAC consistency check for ND messages.
   `ipv6 nd mac-check enable`
   By default, source MAC consistency check is disabled for ND messages.
3. (Optional.) Enable the ND logging feature.
   `ipv6 nd check log enable`
   By default, the ND logging feature is disabled.
   As a best practice, disable the ND logging feature to avoid excessive ND logs.

Configuring ND attack detection

About ND attack detection

ND attack detection checks incoming ND messages for user validity to prevent spoofing attacks. It is typically configured on access devices.

ND attack detection defines the following types of interfaces on a VLAN network:

- **ND trusted interface**—Performs no user validity check on the received ND messages.
- **ND untrusted interface**—Discards incoming RA and redirect messages, and performs the user validity check on other types of incoming ND messages.

ND attack detection compares the source IPv6 address and the source MAC address in an incoming ND message against security entries from other modules.

- If a match is found, the device verifies the user as legal, and it forwards the ND message.
- If no match is found, the device verifies the user as illegal, and it discards the ND message.

The security entries used by ND attack detection for user validity check vary by the specified keyword when you enable this feature.

- If you do not specify the **`dhcpv6-relay`** or **`nd-ra-prefix`** keyword, ND attack detection uses static IPv6 source guard binding entries, ND snooping entries, and DHCPv6 snooping entries for user validity check.
- If you specify the **`dhcpv6-relay`** keyword, ND attack detection uses static IPv6 source guard binding entries, ND snooping entries, DHCPv6 snooping entries, and DHCPv6 relay agent entries for user validity check.
- If you specify the **`nd-ra-prefix`** keyword, ND attack detection uses static IPv6 source guard binding entries, ND snooping entries, DHCPv6 snooping entries, and IPv6 source guard binding entries with prefixes advertised in RA messages for user validity check.

The entries are generated as follows:

- Static IPv6 source guard binding entries are created by using the **ipv6 source binding** command. For information about IPv6 source guard, see "Configuring IP source guard."
- ND snooping entries are automatically generated by the ND snooping feature. For information about ND snooping, see IPv6 basics configuration in *Layer 3–IP Services Configuration Guide*.
- DHCPv6 snooping entries are automatically generated by the DHCPv6 snooping feature. For more information, see DHCPv6 configuration in *Layer 3–IP Services Configuration Guide*.
- DHCPv6 relay entries are automatically generated by the DHCPv6 relay entry recording feature. For more information, see DHCPv6 configuration in *Layer 3–IP Services Configuration Guide*.
- IPv6 source guard binding entries with prefixes advertised in RA messages are created by using the **ipv6 nd ra prefix source binding** command. For more information, see IPv6 basics configuration in *Layer 3–IP Services Configuration Guide*.

Restrictions and guidelines for ND attack detection configuration

When you configure ND attack detection, follow these restrictions and guidelines:

- To prevent ND untrusted interfaces from dropping all received ND messages, make sure one or more of the these features are configured: IPv6 source guard static bindings, DHCPv6 snooping, and ND snooping.
- To make the IPv6 source guard static bindings effective for ND attack detection, you must perform the following operations:
  - Specify the **vlan** *vlan-id* option in the **ipv6 source binding** command.
  - Enable ND attack detection for the same VLAN.

Configuring ND attack detection for a VLAN

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable ND attack detection.
   ipv6 nd detection enable [**dhcpv6-relay** | **nd-ra-prefix**]
   By default, ND attack detection is disabled.
4. (Optional.) Configure the interface as ND trusted interface:
   a. Return to system view.
      quit
   b. Enter Layer 2 Ethernet or aggregate interface view.
      interface *interface-type interface-number*
   c. Configure the interface as ND trusted interface.
      ipv6 nd detection trust
      By default, all interfaces are ND untrusted interfaces.

Ignoring ingress ports of ND packets

About this task

With ND attack detection enabled, the device can perform security check on received packets based on the local and remote IPSG bindings. Remote IPSG bindings do not contain port information. The device drops ND packets that match remote IPSG bindings because it does not find matching ingress ports for these packets. To prevent the device from dropping these packets, you can configure the device to ignore ingress ports of ND packets. This feature does not examine the ingress ports of ND packets, so that ND packets that match remote IPSG bindings will not be dropped.

Procedure

1. Enter system view.
   `system-view`
2. Ignore ingress ports of ND packets in ND attack detection.
   `ipv6 nd detection port-match-ignore`
   By default, ingress ports of ND packets are examined in ND attack detection.

Enabling ND attack detection logging

About this task

This feature allows a device to generate logs when it detects invalid ND packets. The log information helps administrators locate and solve problems. Each log records the following information:

- Victim port numbers in a VLAN.
- Source IP address of the invalid ND packets.
- Source MAC address of the invalid ND packets.
- VLAN ID of the invalid ND packets.
- Total number of dropped ND packets.

Procedure

1. Enter system view.
   `system-view`
2. Enable ND attack detection logging.
   `ipv6 nd detection log enable`
   By default, ND attack detection logging is disabled.

Display and maintenance commands for ND attack detection

Execute **`display`** commands in any view and **`reset`** commands in user view.

Task	Command
Display statistics for ND messages dropped by ND attack detection.	**`display ipv6 nd detection statistics`** [**`interface`** *`interface-type interface-number`*]
Clear ND attack detection statistics.	**`reset ipv6 nd detection statistics`** [**`interface`** *`interface-type interface-number`*]

Example: Configuring ND attack detection

Network configuration

As shown in Figure 2, configure ND attack detection on Device B to check user validity for ND messages from Host A and Host B.

Figure 2 Network diagram

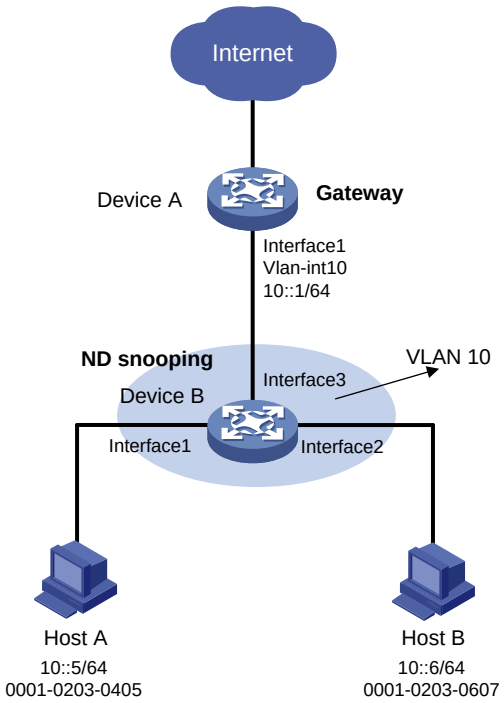


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure Device A:

   # Create VLAN 10.

   ```
   <DeviceA> system-view
   [DeviceA] vlan 10
   [DeviceA-vlan10] quit
   ```

   # Configure GigabitEthernet 1/0/1 to trunk VLAN 10.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] port link-type trunk
   [DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 10
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Assign IPv6 address 10::1/64 to VLAN-interface 10.

   ```
   [DeviceA] interface vlan-interface 10
   ```

```
[DeviceA-Vlan-interface10] ipv6 address 10::1/64
[DeviceA-Vlan-interface10] quit
```

2. Configure Device B:

   # Create VLAN 10.

```
<DeviceB> system-view
[DeviceB] vlan 10
[DeviceB-vlan10] quit
```

   # Configure GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 to trunk VLAN 10.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type access
[DeviceB-GigabitEthernet1/0/1] port access vlan 10
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type access
[DeviceB-GigabitEthernet1/0/2] port access vlan 10
[DeviceB-GigabitEthernet1/0/2] quit
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan 10
[DeviceB-GigabitEthernet1/0/3] quit
```

   # Enable ND attack detection for VLAN 10.

```
[DeviceB] vlan 10
[DeviceB-vlan10] ipv6 nd detection enable
```

   # Enable ND snooping for IPv6 global unicast addresses and ND snooping for IPv6 link-local addresses in VLAN 10.

```
[DeviceB-vlan10] ipv6 nd snooping enable global
[DeviceB-vlan10] ipv6 nd snooping enable link-local
[DeviceB-vlan10] quit
```

   # Configure GigabitEthernet 1/0/3 as ND trusted interface.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] ipv6 nd detection trust
```

Verifying the configuration

Verify that Device B inspects all ND messages received by GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 based on the ND snooping entries. (Details not shown.)

Configuring RA guard

About RA guard

RA guard allows Layer 2 access devices to analyze and block unwanted and forged RA messages.

Upon receiving an RA message, the device makes the forwarding or dropping decision based on the role of the attached device or the RA guard policy.

1. If the role of the device attached to the receiving interface is **router**, the device forwards the RA message. If the role is **host**, the device drops the RA message.
2. If no attached device role is set, the device uses the RA guard policy applied to the VLAN of the receiving interface to match the RA message.

- If the policy does not contain match criteria, the policy will not take effect and the device forwards the RA message.
- If the RA message content matches every criterion in the policy, the device forwards the message. Otherwise, the device drops the message.

Specifying the role of the attached device

Restrictions and guidelines

Make sure your setting is consistent with the type of the attached device. If you are not aware of the device type, do not specify a role for the device.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter aggregate interface view.
     interface bridge-aggregation *interface-number*
3. Specify the role of the device attached to the interface.
   ipv6 nd raguard role { **host** | **router** }
   By default, the role of the device attached to the interface is not specified.

Configuring and applying an RA guard policy

About this task

Configure an RA guard policy if you do not specify a role for the attached device or if you want to filter the RA messages sent by a router.

Procedure

1. Enter system view.
   system-view
2. Create an RA guard policy and enter its view.
   ipv6 nd raguard policy *policy-name*
3. Configure the RA guard policy.
   Choose the following tasks as needed:
   - Specify an ACL match criterion.
     if-match acl { *ipv6-acl-number* | **name** *ipv6-acl-name* }
   - Specify a prefix match criterion.
     if-match prefix acl { *ipv6-acl-number* | **name** *ipv6-acl-name* }
   - Specify a router preference match criterion.
     if-match router-preference maximum { **high** | **low** | **medium** }
   - Specify an M flag match criterion.
     if-match autoconfig managed-address-flag { **off** | **on** }
   - Specify an O flag match criterion.
     if-match autoconfig other-flag { **off** | **on** }

- Specify a maximum or minimum hop limit match criterion.
  if-match hop-limit { **maximum** | **minimum** } *limit*

By default, the RA guard policy is not configured.

4. Quit RA guard policy view.
   quit
5. Enter VLAN view.
   vlan *vlan-number*
6. Apply an RA guard policy to the VLAN.
   ipv6 nd raguard apply policy [*policy-name*]
   By default, no RA guard policy is applied to the VLAN.

Enabling the RA guard logging feature

About this task

This feature allows a device to generate logs when it detects forged RA messages. The log information helps administrators locate and solve problems. Each log records the following information:

- Name of the interface that received the forged RA message.
- Source IP address of the forged RA message.
- Number of RA messages dropped on the interface.

The RA guard logging feature sends the log messages to the information center. The information center can then output log messages from different source modules to different destinations. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enable the RA guard logging feature.
   ipv6 nd raguard log enable
   By default, the RA guard logging feature is disabled.

Display and maintenance commands for RA guard

Execute **display** commands in any view.

Task	Command
Display the RA guard policy configuration.	**display ipv6 nd raguard policy** [*policy-name*]
Display RA guard statistics.	**display ipv6 nd raguard statistics** [**interface** *interface-type interface-number*]
Clear RA guard statistics.	**reset ipv6 nd raguard statistics** [**interface** *interface-type interface-number*]

Example: Configuring RA guard

Network configuration

As shown in Figure 3, GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 of Device B are in VLAN 10.

Configure RA guard on Device B to filter forged and unwanted RA messages.

- Configure an RA policy in VLAN 10 for GigabitEthernet 1/0/2 to filter all RA messages received from the unknown device.
- Specify **host** as the role of the host. All RA messages received on GigabitEthernet 1/0/1 are dropped.
- Specify **router** as the role of the Device A. All RA messages received on GigabitEthernet 1/0/3 are forwarded.

Figure 3 Network diagram

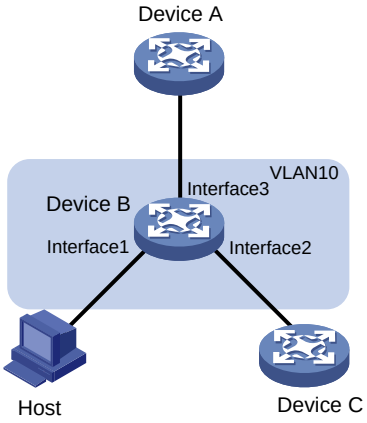

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

Create an RA guard policy named **policy1**.

```
<DeviceB> system-view
[DeviceB] ipv6 nd raguard policy policy1
```

Set the maximum router preference to **high** for the RA guard policy.

```
[DeviceB-raguard-policy-policy1] if-match router-preference maximum high
```

Specify **on** as the M flag match criterion for the RA guard policy.

```
[DeviceB-raguard-policy-policy1] if-match autoconfig managed-address-flag on
```

Specify **on** as the O flag match criterion for the RA guard policy.

```
[DeviceB-raguard-policy-policy1] if-match autoconfig other-flag on
```

Set the maximum advertised hop limit to 120 for the RA guard policy.

```
[DeviceB-raguard-policy-policy1] if-match hop-limit maximum 120
```

Set the minimum advertised hop limit to 100 for the RA guard policy.

```
[DeviceB-raguard-policy-policy1] if-match hop-limit minimum 100
[DeviceB-raguard-policy-policy1] quit
```

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to VLAN 10.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type access
[DeviceB-GigabitEthernet1/0/1] port access vlan 10
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type access
[DeviceB-GigabitEthernet1/0/2] port access vlan 10
[DeviceB-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 to trunk VLAN 10.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan 10
[DeviceB-GigabitEthernet1/0/3] quit
```

Apply the RA guard policy **policy1** to VLAN 10.

```
[DeviceB] vlan 10
[DeviceB-vlan10] ipv6 nd raguard apply policy policy1
[DeviceB-vlan10] quit
```

Specify **host** as the role of the device attached to GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ipv6 nd raguard role host
[DeviceB-GigabitEthernet1/0/1] quit
```

Specify **router** as the role of the device attached to GigabitEthernet 1/0/3.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] ipv6 nd raguard role router
[DeviceB-GigabitEthernet1/0/3] quit
```

Verifying the configuration

Verify that the device forwards or drops RA messages received on GigabitEthernet 1/0/2 based on the RA guard policy. (Details not shown.)

Verify that the device drops RA messages received on GigabitEthernet 1/0/1. (Details not shown.)

Verify that the device forwards RA messages received on GigabitEthernet 1/0/3 to other interfaces in VLAN 10. (Details not shown.)

Configuring ND keepalive entry scanning

About ND keepalive entry scanning

In a large-scale network, it takes a long time for ND scanning to identify the hosts that go offline abnormally if you specify a large scanning range. After you enable ND keepalive entry scanning, the system can quickly locate those hosts and monitor the host status within the aging time.

You can set the aging time for ND keepalive entries in both system view and interface view. The aging time set in interface view takes precedence over the aging time set in system view. In interface view, the default aging time for ND keepalive entries is the aging time set in system view.

When users come online, the system generates dynamic ND entries and IPSG binding entries. Enabled with ND keepalive entry scanning, the system also creates online keepalive entries when users come online. If users go offline, the corresponding ND entries are deleted and the status of the keepalive entries is set to offline. The device sends NS packets at intervals to the IPv6 addresses in the offline keepalive entries until the keepalive entries become online again or are deleted when the aging time expires. The interval varies with the number of NS packets that have been sent to the IPv6 address in an offline keepalive entry. For more information about IP source guard configuration, see *Security Configuration Guide*.

Configuring ND keepalive entry scanning

1. Enter system view.
   system-view
2. (Optional.) Set the NS packet sending rate for keepalive entry scanning.
   ipv6 nd scan keepalive send-rate *pps*
   By default, the device sends NS packets at a rate of 48 pps during keepalive entry scanning.
3. (Optional.) Set the aging time for ND keepalive entries.
   ipv6 nd scan keepalive aging-time *time*
   By default, the aging time for ND keepalive entries in system view is 60 minutes. The aging time for ND keepalive entries in interface view is the aging time set in system view.
4. Enter interface view.
   interface *interface-type interface-number*
5. Enable the ND keepalive entry scanning feature.
   ipv6 nd scan keepalive enable
   By default, the ND keepalive entry scanning is disabled on an interface.

Display and maintenance commands for ND keepalive entry scanning

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display ND keepalive entries.	**display ipv6 nd scan keepalive entry** [**interface** *interface-type interface-number*] [**count**]
Display statistics about NS packets sent to the IPv6 addresses in offline keepalive entries.	**display ipv6 nd scan keepalive statistics** [**slot** *slot-number*] [**interface** *interface-type interface-number*]
Clear statistics about NS packets sent to the IPv6 addresses in offline keepalive entries.	**reset ipv6 nd scan keepalive statistics** [**slot** *slot-number*]

Enabling SNMP notifications for ND

About this task

Enable SNMP notifications for ND as required.

- If you enable ND entry limit notifications, the device sends the current ND entry information as a notification to the SNMP module when the number of ND entries exceeds the alarm threshold.
- If you enable endpoint and local device conflict notifications, the device sends a notification to the SNMP module when an endpoint and local device conflict occurs. The notification includes the source IPv6 address, source MAC address, destination IPv6 address, and destination MAC address in the conflicting ND packet.
- If you enable rate limit notifications for sending ND Miss messages and ND packets, the device sends the highest threshold-crossed rate as a notification to the SNMP module. When the device receives an IP packet in which the destination IP address is unresolvable, it sends a ND Miss message to the CPU.
- If you enable ND packet queue limit notifications, the device sends the number of packets in the queue as a notification to the SNMP module when the number exceeds 80% of the upper limit.
- If you enable user IPv6 address conflict notifications, the device sends a notification to the SNMP module when a user IPv6 address conflict occurs. The notification includes the source IPv6 and MAC addresses in the conflicting ND packet, and MAC address in the corresponding local ND entry.

For ND event notifications to be sent correctly, you must also configure SNMP on the device. For more information, see SNMP configuration in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for ND.

   snmp-agent trap enable nd [**entry-limit** | **local-conflict** | **nd-miss** | **pkt-threshold** | **user-ip-conflict**] *

   By default, SNMP notifications for ND are disabled.

   If you do not specify any keywords, this command enables all SNMP notifications for ND.

Configuring ND blackhole routing

About this task

If the device receives a large number of unresolvable IPv6 packets from a host, it frequently sends NS messages and keeps trying to resolve the destination IPv6 addresses, overloading its CPU.

Enabled with ND blackhole routing, the device creates a blackhole route for an unresolved IPv6 address and sends NS messages to the IPv6 address. If the IPv6 address is resolved before the blackhole route ages out, the device immediately deletes the blackhole route and starts forwarding packets destined for the IPv6 address. If the IPv6 address remains unresolvable before the blackhole route is deleted, the device directly drops the packets destined for the IPv6 address.

Procedure

1. Enter system view.

   system-view

2. Enable ND blackhole routing.

   ipv6 nd resolving-route enable

   By default, ND blackhole routing is enabled.

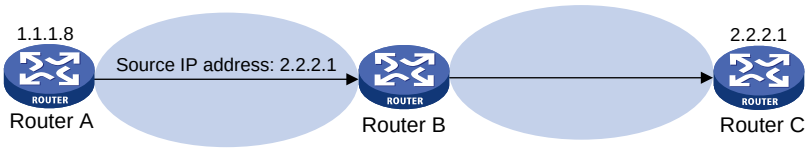
Configuring uRPF



About uRPF

Unicast Reverse Path Forwarding (uRPF) protects a network against source address spoofing attacks, such as DoS and DDoS attacks.

uRPF application scenario

Attackers send packets with a forged source address to access a system that uses IPv4-based authentication, in the name of authorized users or even the administrator. Even if the attackers or other hosts cannot receive any response packets, the attacks are still disruptive to the attacked target.

Figure 1 Source address spoofing attack

As shown in Figure 1, an attacker on Router A sends the server (Router B) requests with a forged source IP address 2.2.2.1 at a high rate. Router B sends response packets to IP address 2.2.2.1 (Router C). Consequently, both Router B and Router C are attacked. If the administrator disconnects Router C by mistake, the network service is interrupted.

Attackers can also send packets with different forged source addresses or attack multiple servers simultaneously to block connections or even break down the network.

uRPF can prevent these source address spoofing attacks. It checks whether an interface that receives a packet is the output interface of the FIB entry that matches the source address of the packet. If not, uRPF considers it a spoofing attack and discards the packet.

uRPF check modes

uRPF supports strict and loose modes.

Strict uRPF check

To pass strict uRPF check, the source address of a packet and the receiving interface must match the destination address and output interface of a FIB entry. In some scenarios (for example, asymmetrical routing), strict uRPF might discard valid packets.

Strict uRPF is often deployed between a PE and a CE.

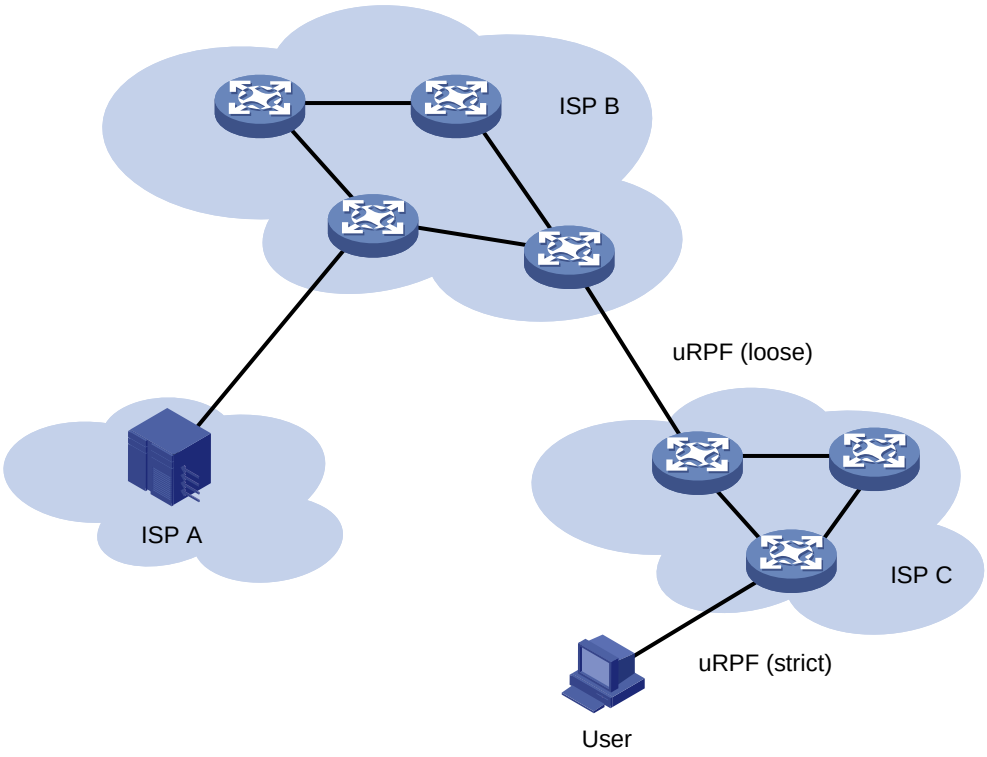
Loose uRPF check

To pass loose uRPF check, the source address of a packet must match the destination address of a FIB entry. Loose uRPF can avoid discarding valid packets, but might let go attack packets.

Loose uRPF is often deployed between ISPs, especially in asymmetrical routing.

uRPF extended functions

Using the default route in uRPF check



When a default route exists, all packets that fail to match a specific FIB entry match the default route during uRPF check and thus are permitted to pass. To avoid this situation, you can disable uRPF from using any default route to discard such packets. If you allow using the default route (set by using **`allow-default-route`**), uRPF permits packets that only match the default route.

By default, uRPF discards packets that can only match a default route. Typically, you do not need to configure the **`allow-default-route`** keyword on a PE device because it has no default route pointing to the CE. If you enable uRPF on a CE interface and the CE interface has a default route pointing to the PE, specify the **`allow-default-route`** keyword.

Network application

As shown in Figure 2, strict uRPF check is configured between an ISP network and a customer network. Loose uRPF check is configured between ISPs.

Figure 2 Network diagram

Restrictions and guidelines: uRPF configuration

If you enable uRPF on an interface, you can use the **`display ip interface`** command to display statistics about packets discarded by uRPF (displayed as "Drops" and "Suppressed drops").

Do not configure the **`allow-default-route`** keyword for loose uRPF check. Otherwise, uRPF might fail to work.

Do not configure both strict uRPF check and loose IPv6 uRPF check, or loose uRPF check and strict IPv6 uRPF check on an interface.

Do not use strict uRPF if ECMP routing is available in the network. Service packets that travel along ECMP routes cannot pass the strict uRPF check and will be dropped.

Enabling uRPF on an interface

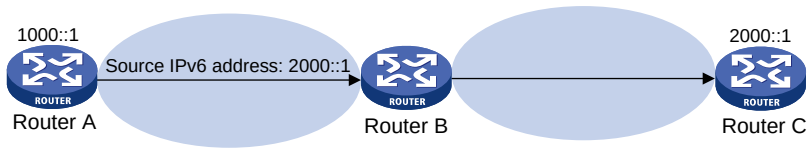
1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Enable uRPF.
   ip urpf { **loose** [**allow-default-route**] | **strict** [**allow-default-route**] }
   By default, uRPF is disabled.

Display and maintenance commands for uRPF

Execute **display** commands in any view.

Task	Command
Display uRPF configuration.	**display ip urpf interface** *interface-type interface-number* [**slot** *slot-number*]

Configuring IPv6 uRPF



About IPv6 uRPF

IPv6 Unicast Reverse Path Forwarding (uRPF) protects a network against source address spoofing attacks, such as DoS and DDoS attacks.

IPv6 uRPF application scenario

Attackers send packets with a forged source address to access a system that uses IPv6-based authentication, in the name of authorized users or even the administrator. Even if the attackers or other hosts cannot receive any response packets, the attacks are still disruptive to the attacked target.

Figure 3 Source address spoofing attack

As shown in Figure 3, an attacker on Router A sends the server (Router B) requests with a forged source IPv6 address 2000::1 at a high rate. Router B sends response packets to IPv6 address 2000::1 (Router C). Consequently, both Router B and Router C are attacked. If the administrator disconnects Router C by mistake, the network service is interrupted.

Attackers can also send packets with different forged source addresses or attack multiple servers simultaneously to block connections or even break down the network.

IPv6 uRPF can prevent these source address spoofing attacks. It checks whether an interface that receives a packet is the output interface of the FIB entry that matches the source address of the packet. If not, IPv6 uRPF considers it a spoofing attack and discards the packet.

IPv6 uRPF check modes

IPv6 uRPF supports strict and loose check modes.

Strict IPv6 uRPF check

To pass strict IPv6 uRPF check, the source address of a packet and the receiving interface must match the destination address and output interface of an IPv6 FIB entry. In some scenarios (for example, asymmetrical routing), strict IPv6 uRPF might discard valid packets.

Strict IPv6 uRPF is often deployed between a PE and a CE.

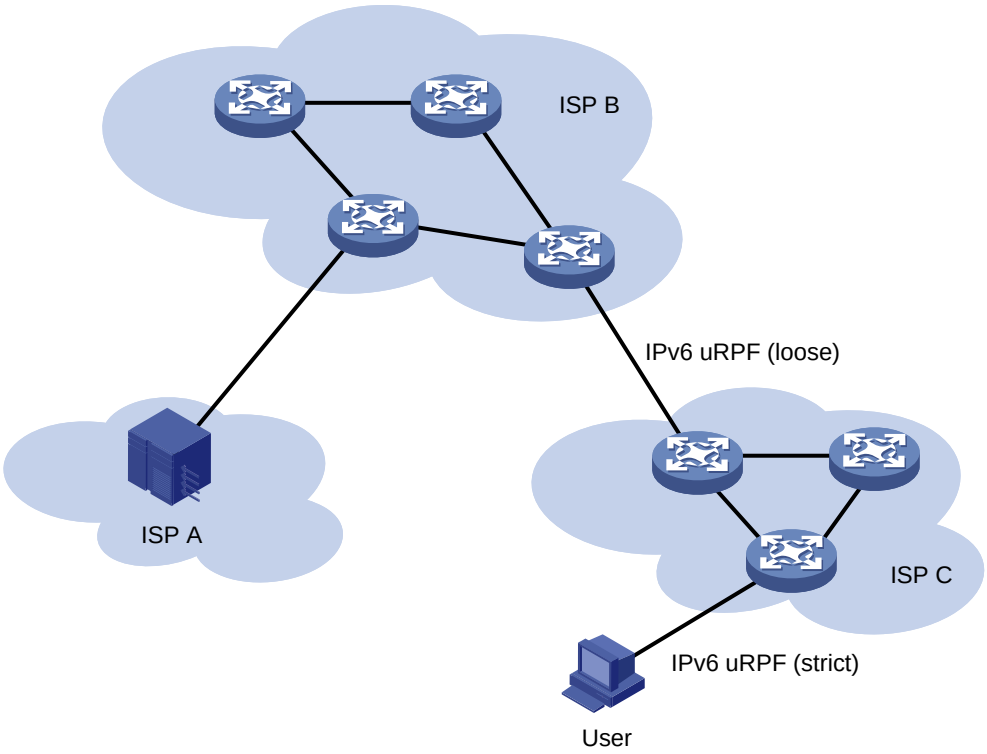
Loose IPv6 uRPF check

To pass loose IPv6 uRPF check, the source address of a packet must match the destination address of an IPv6 FIB entry. Loose IPv6 uRPF can avoid discarding valid packets, but might let go attack packets.

Loose IPv6 uRPF is often deployed between ISPs, especially in asymmetrical routing.

IPv6 uRPF extended functions

Using the default route in IPv6 uRPF check



When a default route exists, all packets that fail to match a specific IPv6 FIB entry match the default route during IPv6 uRPF check and thus are permitted to pass. If you allow using the default route (by using **`allow-default-route`**), IPv6 uRPF permits packets that only match the default route.

By default, IPv6 uRPF discards packets that can only match a default route. Typically, you do not need to configure the **`allow-default-route`** keyword on a PE device because it has no default route pointing to the CE device. If you enable IPv6 uRPF on a CE interface and the CE interface has a default route pointing to the PE, specify the **`allow-default-route`** keyword.

Network application

As shown in Figure 4, strict IPv6 uRPF check is configured between an ISP network and a customer network. Loose IPv6 uRPF check is configured between ISPs.

Figure 4 Network diagram

Restrictions and guidelines: IPv6 uRPF configuration

If you enable IPv6 uRPF on an interface, you can use the **display ipv6 interface** command to view statistics about packets discarded by IPv6 uRPF (displayed as "Drops" and "Suppressed drops").

Do not configure the **allow-default-route** keyword for loose IPv6 uRPF check. Otherwise, IPv6 uRPF might fail to work.

Do not configure both strict IPv6 uRPF check and loose uRPF check, or loose IPv6 uRPF check and strict uRPF check on an interface.

Do not use strict IPv6 uRPF if ECMP routing is available in the network. Service packets that travel along ECMP routes cannot pass the strict uRPF check and will be dropped.

Enabling IPv6 uRPF on an interface

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Enable IPv6 uRPF.
   ipv6 urpf { **loose** | **strict** } [**allow-default-route**]
   By default, IPv6 uRPF is disabled.

Display and maintenance commands for IPv6 uRPF

Execute **display** commands in any view.

Task	Command
Display IPv6 uRPF configuration.	**display ipv6 urpf interface** *interface-type interface-number***interface** *interface-type interface-number* [**slot** *slot-number*]

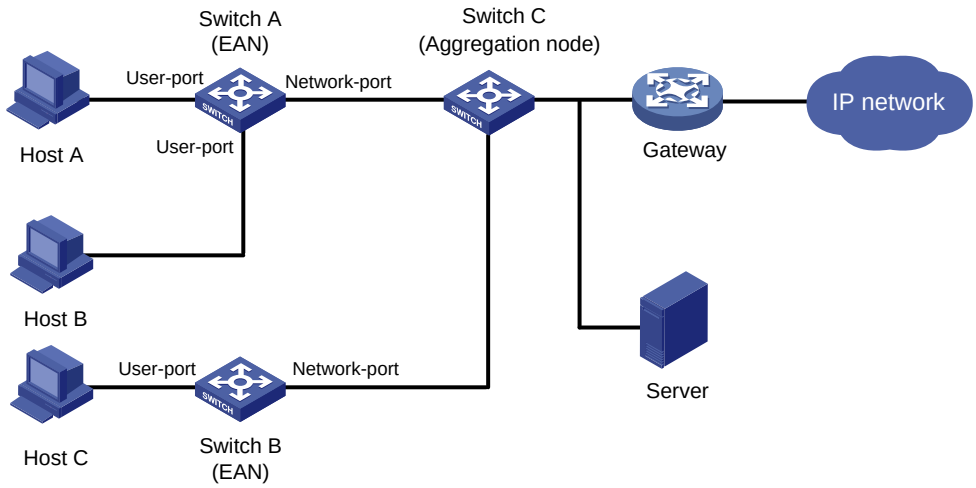
Configuring MFF

About MFF



MAC-forced forwarding (MFF) implements Layer 2 isolation and Layer 3 communication between hosts in the same broadcast domain.

An MFF-enabled device intercepts ARP requests and returns the MAC address of a gateway (or server) to the senders. In this way, the senders are forced to send packets to the gateway for traffic monitoring and attack prevention.

MFF network model

As shown in Figure 1, hosts are connected to Switch C through Switch A and Switch B, which are called Ethernet access nodes (EANs). The MFF-enabled EANs forward packets from hosts to the gateway for further forwarding. The hosts are isolated at Layer 2, but they can communicate at Layer 3.

Figure 1 Network diagram for MFF

MFF works with any of the following features to implement traffic filtering and Layer 2 isolation on the EANs:

- ARP snooping (see *Layer 3—IP Services Configuration Guide*).
- IP source guard (see "Configuring IP source guard").
- ARP detection (see "Configuring ARP attack protection").
- VLAN mapping (see *Layer 2—LAN Switching Configuration Guide*).

Port roles

Two types of ports, user port and network port, exist in an MFF-enabled VLAN.

User port

An MFF user port is directly connected to a host and processes the following packets differently:

- Allows multicast packets to pass.
- Delivers ARP packets to the CPU.

- Processes unicast packets as follows:
  - If gateways' MAC addresses have been learned, the user port allows only the unicast packets with the gateways' MAC addresses as the destination MAC addresses to pass.
  - If no gateways' MAC addresses have been learned, the user port discards all received unicast packets.

Network port

An MFF network port is connected to any of the following networking devices:

- An access switch.
- A distribution switch.
- A gateway.
- A server.

A network port processes the following packets differently:

- Allows multicast packets to pass.
- Delivers ARP packets to the CPU.
- Denies broadcast packets other than DHCP and ARP packets.

Processing of ARP packets in MFF

An MFF-enabled device implements Layer 3 communication between hosts by intercepting ARP requests from the hosts and replies with the MAC address of a gateway. This mechanism helps reduce the number of broadcast messages.

The MFF device processes ARP packets as follows:

- After receiving an ARP request from a host, the MFF device sends the MAC address of the corresponding gateway to the host. In this way, hosts in the network have to communicate at Layer 3 through a gateway.
- After receiving an ARP request from a gateway, the MFF device sends the requested host's MAC address to the gateway if the corresponding entry is available. If the entry is not available, the MFF device forwards the ARP request.
- The MFF device forwards ARP replies between hosts and gateways.
- If the source MAC addresses of ARP requests from gateways are different from those recorded, the MFF device updates and broadcasts the IP and MAC addresses of the gateways.

MFF default gateway

MFF applies to only networks where the hosts' IP addresses are manually configured. Because the hosts cannot obtain the gateway information through DHCP, the default gateway must be specified by the **`mac-forced-forwarding default-gateway`** command. MFF maintains only one default gateway for each VLAN. MFF updates the MAC address of the default gateway upon receiving an ARP packet with a different sender MAC address from the default gateway.

Protocols and standards

RFC 4562, *MAC-Forced Forwarding*

MFF tasks at a glance

To configure MFF, perform the following tasks:

1. Enabling MFF
2. Configuring a network port
3. (Optional.) Enabling periodic gateway probe
4. Specifying the IP addresses of servers

   If servers exist in the network, you must perform this task to ensure communication between the servers and hosts.

Enabling MFF

Restrictions and guidelines

- An MFF-enabled device and a host cannot ping each other.
- When MFF works with static IP source guard bindings, you must configure VLAN IDs in the static bindings. Otherwise, IP packets allowed by IP source guard are permitted even if their destination MAC addresses are not the MAC address of the gateway.
- MFF is not supported in a network where VRRP load balancing mode is configured.

Prerequisites

For MFF to take effect, make sure ARP snooping is enabled on the VLAN where MFF is enabled.

Procedure

1. Enter system view.

   system-view
2. Enter VLAN view.

   vlan *vlan-id*
3. Enable MFF.

   mac-forced-forwarding default-gateway *gateway-ip*

   By default, MFF is disabled.

Configuring a network port

Restrictions and guidelines

In a VLAN with MFF enabled, you need to configure the following ports as network ports:

- Upstream ports connected to the gateway.
- Ports connected to other MFF devices.

Link aggregation is supported by network ports in an MFF-enabled VLAN, but it is not supported by user ports in the VLAN. You can add the network ports to link aggregation groups, but cannot add the user ports to link aggregation groups. For more information about link aggregation, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.
   - **interface** *interface-type interface-number*
3. Configure the port as a network port.

   mac-forced-forwarding network-port

   By default, the port is a user port.

Enabling periodic gateway probe

About this task

You can configure the MFF device to detect gateways every 30 seconds for the change of MAC addresses by sending forged ARP packets. The ARP packets use 0.0.0.0 as the sender IP address and bridge MAC address as the sender MAC address.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable periodic gateway probe.
   mac-forced-forwarding gateway probe
   By default, this feature is disabled.

Specifying the IP addresses of servers

About this task

Server IP addresses can be those of the interfaces on a router in a VRRP group and those of the servers collaborating with MFF, such as a RADIUS server.

When the MFF device receives an ARP request from a server, the device searches IP-to-MAC address entries it has stored. Then the device replies with the requested MAC address to the server.

As a result, packets from a host to a server are forwarded by the gateway. However, packets from a server to a host are not forwarded by the gateway.

MFF does not check whether the IP address of a server is on the same network segment as that of a gateway. Instead, it checks whether the IP address of a server is all-zero or all-one. An all-zero or all-one server IP address is invalid.

Restrictions and guidelines

If the server's interface connecting to the MFF device uses secondary IP addresses to send ARP packets, include all these IP addresses in the server IP address list.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Specify the IP addresses of servers.
   mac-forced-forwarding server *server-ip*&<1-10>
   By default, no server IP address is specified.

Display and maintenance commands for MFF

Execute **display** commands in any view.

Task	Command
Display MFF port configuration.	**display mac-forced-forwarding interface**
Display the MFF configuration for a VLAN.	**display mac-forced-forwarding vlan** *vlan-id*

MFF configuration examples

Example: Configuring MFF in a tree network

Network configuration

As shown in Figure 2, all the devices are in VLAN 100. Hosts A, B, and C are assigned IP addresses manually.

Configure MFF to isolate the hosts at Layer 2 and allow them to communicate with each other through the gateway at Layer 3.

Figure 2 Network diagram

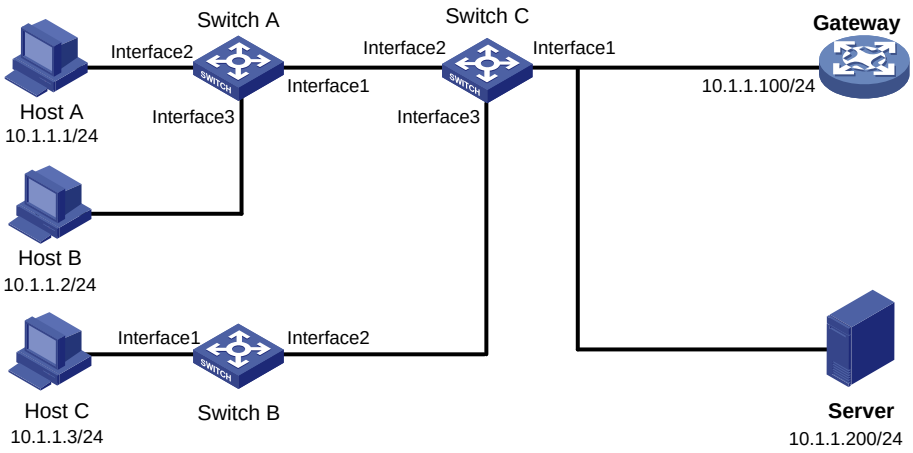


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure the IP addresses of the hosts and the gateway, as shown in Figure 2.
2. Configure Switch A:

   # Configure MFF on VLAN 100.

   ```
   [SwitchA] vlan 100
   [SwitchA-vlan100] mac-forced-forwarding default-gateway 10.1.1.100
   ```

   # Specify the IP address of the server.

```
[SwitchA-vlan100] mac-forced-forwarding server 10.1.1.200
```

Enable ARP snooping on VLAN 100.

```
[SwitchA-vlan100] arp snooping enable
[SwitchA-vlan100] quit
```

Configure GigabitEthernet 1/0/1 as a network port.

```
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] mac-forced-forwarding network-port
```

3. Configure Switch B:

Configure MFF on VLAN 100.

```
[SwitchB] vlan 100
[SwitchB-vlan100] mac-forced-forwarding default-gateway 10.1.1.100
```

Specify the IP address of the server.

```
[SwitchB-vlan100] mac-forced-forwarding server 10.1.1.200
```

Enable ARP snooping on VLAN 100.

```
[SwitchB-vlan100] arp snooping enable
[SwitchB-vlan100] quit
```

Configure GigabitEthernet 1/0/2 as a network port.

```
[SwitchB] interface gigabitethernet 1/0/2 1/0/6
[SwitchB-GigabitEthernet1/0/2] mac-forced-forwarding network-port
```

Example: Configuring MFF in a ring network

Network configuration

As shown in Figure 3, all the devices are in VLAN 100, and the switches form a ring. Hosts A, B, and C are assigned IP addresses manually.

Configure MFF to isolate the hosts at Layer 2 and allow them to communicate with each other through the gateway at Layer 3.

Figure 3 Network diagram

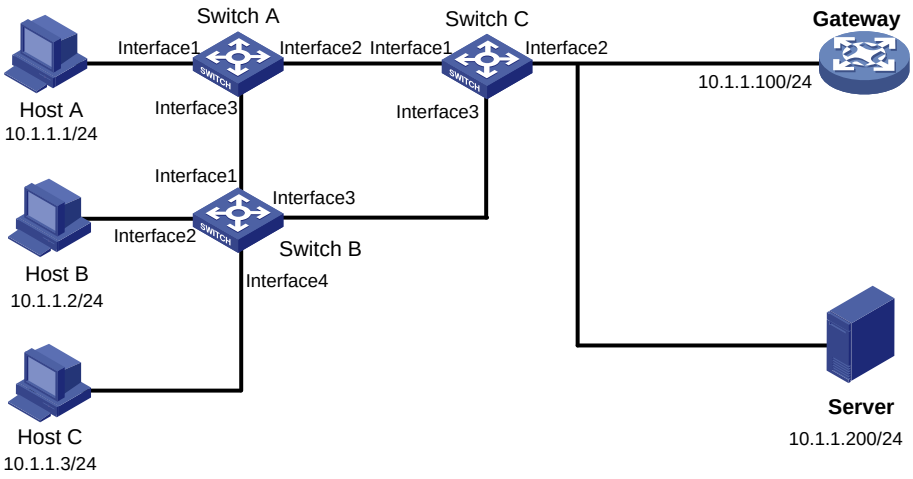

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4

Procedure

1. Configure the IP addresses of the hosts and the gateway, as in shown in Figure 3.
2. Configure Switch A:

   # Enable STP globally to make sure STP is enabled on interfaces.

   ```
   [SwitchA] stp global enable
   ```

   # Configure MFF on VLAN 100.

   ```
   [SwitchA] vlan 100
   [SwitchA-vlan100] mac-forced-forwarding default-gateway 10.1.1.100
   ```

   # Specify the IP address of the server.

   ```
   [SwitchA-vlan100] mac-forced-forwarding server 10.1.1.200
   ```

   # Enable ARP snooping on VLAN 100.

   ```
   [SwitchA-vlan100] arp snooping enable
   [SwitchA-vlan100] quit
   ```

   # Configure GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3 as network ports.

   ```
   [SwitchA] interface gigabitethernet 1/0/2
   [SwitchA-GigabitEthernet1/0/2] mac-forced-forwarding network-port
   [SwitchA-GigabitEthernet1/0/2] quit
   [SwitchA] interface gigabitethernet 1/0/3
   [SwitchA-GigabitEthernet1/0/3] mac-forced-forwarding network-port
   ```

3. Configure Switch B:

   # Enable STP globally to make sure STP is enabled on interfaces.

   ```
   [SwitchB] stp global enable
   ```

   # Configure MFF on VLAN 100.

   ```
   [SwitchB] vlan 100
   [SwitchB-vlan100] mac-forced-forwarding default-gateway 10.1.1.100
   ```

   # Specify the IP address of the server.

   ```
   [SwitchB-vlan100] mac-forced-forwarding server 10.1.1.200
   ```

   # Enable ARP snooping on VLAN 100.

   ```
   [SwitchB-vlan100] arp snooping enable
   [SwitchB-vlan100] quit
   ```

   # Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/3 as network ports.

   ```
   [SwitchB] interface gigabitethernet 1/0/1
   [SwitchB-GigabitEthernet1/0/1] mac-forced-forwarding network-port
   [SwitchB-GigabitEthernet1/0/1] quit
   [SwitchB] interface gigabitethernet 1/0/3
   [SwitchB-GigabitEthernet1/0/3] mac-forced-forwarding network-port
   ```

4. Enable STP on Switch C globally to make sure STP is enabled on interfaces.

   ```
   <SwitchC> system-view
   [SwitchC] stp global enable
   ```

Configuring an 802.1X client

About 802.1X clients

As shown in Figure 1, the 802.1X client feature allows the access device to act as the supplicant in the 802.1X architecture. For information about the 802.1X architecture, see "802.1X overview."

Figure 1 802.1X client network diagram

Restrictions: Hardware compatibility with 802.1X client

The S5200-EI-G switch series does not support the 802.1X client feature.

802.1X client tasks at a glance

To configure an 802.1X client, perform the following tasks:

1. Enabling the 802.1X client feature
2. Configuring an 802.1X client username and password
3. Specifying an 802.1X client EAP authentication method
4. (Optional.) Configuring an 802.1X client MAC address
5. (Optional.) Specifying an 802.1X client mode for sending EAP-Response and EAPOL-Logoff packets
6. (Optional.) Configuring an 802.1X client anonymous identifier
7. Specifying an SSL client policy

   This task is required when you specify PEAP-MSCHAPv2, PEAP-GTC, TTLS-MSCHAPv2, or TTLS-GTC authentication as the 802.1X client EAP authentication method.

Enabling the 802.1X client feature

Enabling the 802.1X client feature in Ethernet interface view

1. Enter system view.

system-view

2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Enable the 802.1X client feature.
   dot1x supplicant enable
   By default, the 802.1X client feature is disabled.

Configuring an 802.1X client username and password

Restrictions and guidelines

To ensure successful authentication, make sure the username and password configured on the 802.1X client is consistent with the username and password configured on the authentication server.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Configure an 802.1X client username.
   dot1x supplicant username *username*
   By default, no 802.1X client username is configured.
4. Set an 802.1X client password.
   dot1x supplicant password { **cipher** | **simple** } *string*
   By default, no 802.1X client password is configured.

Specifying an 802.1X client EAP authentication method

About this task

The following EAP authentication methods are available for the 802.1X client feature:

- MD5-Challenge.
- PEAP-MSCHAPv2.
- PEAP-GTC.
- TTLS-MSCHAPv2.
- TTLS-GTC.

Restrictions and guidelines

The following matrix shows the restrictions for the selection of authentication methods on the 802.1X client and the authenticator:

Authentication method specified on the 802.1X client	Packet exchange method specified on the authenticator
MD5-Challenge	• CHAP • EAP
• PEAP-MSCHAPv2 • PEAP-GTC • TTLS-MSCHAPv2 • TTLS-GTC	EAP

For information about 802.1X packet exchange methods, see "Configuring 802.1X."

Make sure the specified 802.1X client EAP authentication method is supported by the authentication server.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Specify an 802.1X client EAP authentication method.
   dot1x supplicant eap-method { **md5** | **peap-gtc** | **peap-mschapv2** | **ttls-gtc** | **ttls-mschapv2** }
   By default, the EAP authentication method is MD5-Challenge.

Configuring an 802.1X client MAC address

About this task

The authenticator adds the MAC address of an authenticated 802.1X client to the MAC address table and then assigns access rights to the client.

If the device has multiple Ethernet interfaces that act as 802.1X clients to seek MACsec protection, configure a unique MAC address for each interface to ensure successful 802.1X client authentication. For information about MACsec, see "Configuring MACsec."

You can use either of the following methods to configure a unique MAC address for each interface:

- Execute the **mac-address** command in Ethernet interface view. For information about this command, see *Layer 2—LAN Switching Command Reference*.
- Configure an 802.1X client MAC address.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Configure an 802.1X client MAC address.
   dot1x supplicant mac-address *mac-address*

By default, the 802.1X client on an Ethernet interface uses the MAC address of the interface for 802.1X authentication. If the interface's MAC address is unavailable, the client uses the device's MAC address for 802.1X authentication.

Specifying an 802.1X client mode for sending EAP-Response and EAPOL-Logoff packets

About this task

802.1X client authentication supports unicast and multicast modes to send EAP-Response and EAPOL-Logoff packets. As a best practice, use multicast mode to avoid 802.1X client authentication failures if the NAS device in the network does not support receiving unicast EAP-Response or EAPOL-Logoff packets.

Procedure

1. Enter system view.

   system-view

2. Enter Ethernet interface view.

   interface *interface-type interface-number*

3. Specify a mode for 802.1X client authentication to send EAP-Response and EAPOL-Logoff packets.

   dot1x supplicant transmit-mode { **multicast** | **unicast** }

   By default, 802.1X client authentication uses unicast mode to send EAP-Response and EAPOL-Logoff packets.

Configuring an 802.1X client anonymous identifier

About this task

At phase 1, packets sent to the authenticator are not encrypted. The use of an 802.1X client anonymous identifier prevents the 802.1X client username from being disclosed at phase 1. The 802.1X client sends the anonymous identifier to the authenticator instead of the 802.1X client username. The 802.1X client username will be sent to the authenticator in encrypted packets at phase 2.

If no 802.1X client anonymous identifier is configured, the 802.1X client sends the 802.1X client username at phase 1.

The configured 802.1X client anonymous identifier takes effect only if one of the following EAP authentication methods is used:

- PEAP-MSCHAPv2.
- PEAP-GTC.
- TTLS-MSCHAPv2.
- TTLS-GTC.

If the MD5-Challenge EAP authentication is used, the configured 802.1X client anonymous identifier does not take effect. The 802.1X client uses the 802.1X client username at phase 1.

Restrictions and guidelines

Do not configure the 802.1X client anonymous identifier if the vendor-specific authentication server cannot identify anonymous identifiers.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Configure an 802.1X client anonymous identifier.
   dot1x supplicant anonymous identify *identifier*
   By default, no 802.1X client anonymous identifier is configured.

Specifying an SSL client policy

About this task

If the PEAP-MSCHAPv2, PEAP-GTC, TTLS-MSCHAPv2, or TTLS-GTC authentication is used, the 802.1X client authentication process is as follows:

- **Phase 1**—The 802.1X client acts as an SSL client to negotiate with the SSL server.
  The SSL client uses the SSL parameters defined in the specified SSL client policy to establish a connection with the SSL server for negotiation. The SSL parameters include a PKI domain, supported cipher suites, and the SSL version. For information about SSL client policy configuration, see "Configuring SSL."
- **Phase 2**—The 802.1X client uses the negotiated result to encrypt and transmit the interchanged authentication packets.

If the MD5-Challenge authentication is used, the 802.1X client does not use an SSL client policy during the authentication process.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Specify an SSL client policy.
   dot1x supplicant ssl-client-policy *policy-name*
   By default, the default SSL client policy is used.

Display and maintenance commands for 802.1X client

Execute **display** commands in any view.

Task	Command
Display 802.1X client information.	**display dot1x supplicant** [**interface** *interface-type interface-number*]

Configuring attack detection and prevention

About attack detection and prevention

Attack detection and prevention enables a device to detect attacks by inspecting arriving packets, and to take prevention actions to protect a private network. Prevention actions include:

- Logging.
- Packet dropping.
- Client verification.

Attacks that the device can prevent

This section describes the attacks that the device can detect and prevent.

Single-packet attacks

Single-packet attacks are also known as malformed packet attacks. An attacker typically launches single-packet attacks by using the following methods:

- An attacker sends defective packets to a device, which causes the device to malfunction or crash.
- An attacker sends normal packets to a device, which interrupts connections or probes network topologies.
- An attacker sends a large number of forged packets to a target device, which consumes network bandwidth and causes denial of service (DoS).

Table 1 lists the single-packet attack types that the device can detect and prevent.

Table 1 Types of single-packet attacks

Single-packet attack	Description
ICMP redirect	An attacker sends ICMP redirect messages to modify the victim's routing table. The victim cannot forward packets correctly.
ICMP destination unreachable	An attacker sends ICMP destination unreachable messages to cut off the connections between the victim and its destinations.
ICMP type	A receiver responds to an ICMP packet according to its type. An attacker sends forged ICMP packets of a specific type to affect the packet processing of the victim.
ICMPv6 type	A receiver responds to an ICMPv6 packet according to its type. An attacker sends forged ICMPv6 packets of specific types to affect the packet processing of the victim.
Land	An attacker sends the victim a large number of TCP SYN packets, which contain the victim's IP address as the source and destination IP addresses. This attack exhausts the half-open connection resources on the victim, and locks the victim's system.
Large ICMP packet	An attacker sends large ICMP packets to crash the victim. Large ICMP packets can cause memory allocation error and crash the protocol stack.

Single-packet attack	Description
Large ICMPv6 packet	An attacker sends large ICMPv6 packets to crash the victim. Large ICMPv6 packets can cause memory allocation error and crash the protocol stack.
IP options	An attacker sends IP datagrams in which the IP options are abnormal. This attack intends to probe the network topology. The target system will break down if it is incapable of processing error packets.
IP fragment	An attacker sends the victim an IP datagram with an offset smaller than 5, which causes the victim to malfunction or crash.
IP impossible packet	An attacker sends IP packets whose source IP address is the same as the destination IP address, which causes the victim to malfunction.
Tiny fragment	An attacker makes the fragment size small enough to force Layer 4 header fields into the second fragment. These fragments can pass the packet filtering because they do not hit any match.
Smurf	An attacker sends an ICMP echo request to target networks. In these requests, the destination IP address is a network or broadcast address of a Class A, B, or C subnet, and the source IP address is the victim's IP address. Every receiver on the target networks will send an ICMP echo reply to the victim. The victim will be flooded with replies, and will be unable to provide services. Network congestion might occur.
TCP flag	An attacker sends packets with defective TCP flags to probe the operating system of the target host. Different operating systems process unconventional TCP flags differently. The target system will break down if it processes this type of packets incorrectly.
Traceroute	An attacker uses traceroute tools to probe the topology of the victim network.
WinNuke	An attacker sends Out-Of-Band (OOB) data to the TCP port 139 (NetBIOS) on the victim that runs Windows system. The malicious packets contain an illegal Urgent Pointer, which causes the victim's operating system to crash.
UDP bomb	An attacker sends a malformed UDP packet. The length value in the IP header is larger than the IP header length plus the length value in the UDP header. When the target system processes the packet, a buffer overflow can occur, which causes a system crash.
UDP Snork	An attacker sends a UDP packet with destination port 135 (the Microsoft location service) and source port 135, 7, or 19. This attack causes an NT system to exhaust its CPU.
UDP Fraggle	An attacker sends a large number of packets with source UDP port 7 and destination UDP port 19 (UDP chargen port) to a network. These packets use the victim's IP address as the source IP address. Replies will flood the victim, resulting in DoS.
Teardrop	An attacker sends a stream of overlapping fragments. The victim will crash when it tries to reassemble the overlapping fragments.
Ping of death	An attacker sends the victim an ICMP echo request larger than 65535 bytes that violates the IP protocol. When the victim reassembles the packet, a buffer overflow can occur, which causes a system crash.

Scanning attacks

Scanning is a preintrusion activity used to prepare for intrusion into a network. The scanning allows the attacker to find a way into the target network and to disguise the attacker's identity.

Attackers use scanning tools to probe a network, find vulnerable hosts, and discover services that are running on the hosts. Attackers can use the information to launch attacks.

The device can detect and prevent the IP sweep and port scan attacks. If an attacker performs port scanning from multiple hosts to the target host, distributed port scan attacks occur.

Flood attacks

An attacker launches a flood attack by sending a large number of forged requests to the victim in a short period of time. The victim is too busy responding to these forged requests to provide services for legal users, and a DoS attack occurs.

The device can detect and prevent the following types of flood attacks.

SYN flood attack

A SYN flood attacker exploits the TCP three-way handshake characteristics and makes the victim unresponsive to legal users. An attacker sends a large number of SYN packets with forged source addresses to a server. This causes the server to open a large number of half-open connections and respond to the requests. However, the server will never receive the expected ACK packets. The server is unable to accept new incoming connection requests because all of its resources are bound to half-open connections.

ACK flood attack

An ACK packet is a TCP packet only with the ACK flag set. Upon receiving an ACK packet from a client, the server must search half-open connections for a match.

An ACK flood attacker sends a large number of ACK packets to the server. This causes the server to be busy searching for half-open connections, and the server is unable to process packets for normal services.

SYN-ACK flood attack

Upon receiving a SYN-ACK packet, the server must search for the matching SYN packet it has sent. A SYN-ACK flood attacker sends a large number of SYN-ACK packets to the server. This causes the server to be busy searching for SYN packets, and the server is unable to process packets for normal services.

FIN flood attack

FIN packets are used to shut down TCP connections.

A FIN flood attacker sends a large number of forged FIN packets to a server. The victim might shut down correct connections, or be unable to provide services because it is busy searching for matching connections.

RST flood attack

RST packets are used to abort TCP connections when TCP connection errors occur.

An RST flood attacker sends a large number of forged RST packets to a server. The victim might shut down correct connections, or be unable to provide services because it is busy searching for matching connections.

DNS flood attack

The DNS server processes and replies all DNS queries that it receives.

A DNS flood attacker sends a large number of forged DNS queries. This attack consumes the bandwidth and resources of the DNS server, which prevents the server from processing and replying legal DNS queries.

HTTP flood attack

Upon receiving an HTTP GET request, the HTTP server performs complex operations, including character string searching, database traversal, data reassembly, and format switching. These operations consume a large amount of system resources.

An HTTP flood attacker sends a large number of HTTP GET requests that exceed the processing capacity of the HTTP server, which causes the server to crash.

ICMP flood attack

An ICMP flood attacker sends ICMP request packets, such as ping packets, to a host at a fast rate. Because the target host is busy replying to these requests, it is unable to provide services.

ICMPv6 flood attack

An ICMPv6 flood attacker sends ICMPv6 request packets, such as ping packets, to a host at a fast rate. Because the target host is busy replying to these requests, it is unable to provide services.

UDP flood attack

A UDP flood attacker sends UDP packets to a host at a fast rate. These packets consume a large amount of the target host's bandwidth, so the host cannot provide other services.

TCP fragment attack

An attacker launches TCP fragment attacks by sending attack TCP fragments defined in RFC 1858:

- First fragments in which the TCP header is smaller than 20 bytes.
- Non-first fragments with a fragment offset of 8 bytes (FO=1).

Typically, packet filter detects the source and destination IP addresses, source and destination ports, and transport layer protocol of the first fragment of a TCP packet. If the first fragment passes the detection, all subsequent fragments of the TCP packet are allowed to pass through.

Because the first fragment of attack TCP packets does not hit any match in the packet filter, the subsequent fragments can all pass through. After the receiving host reassembles the fragments, a TCP fragment attack occurs.

To prevent TCP fragment attacks, enable TCP fragment attack prevention to drop attack TCP fragments.

Login dictionary attack

The login dictionary attack is an automated process to attempt to log in by trying all possible passwords from a pre-arranged list of values (the dictionary). Multiple login attempts can occur in a short period of time.

You can configure the login delay feature to slow down the login dictionary attacks. This feature enables the device to delay accepting another login request after detecting a failed login attempt for a user.

Blacklist feature

IP blacklist

The IP blacklist feature is an attack prevention method that filters packets by source IP addresses in blacklist entries. Compared with ACL-based packet filtering, IP blacklist filtering is simpler and provides effective screening at a faster speed.

User blacklist

The user blacklist feature is an attack prevention method that filters packets by source users in blacklist entries. Compared with IP blacklist filtering, user blacklist filtering performs access control on the user level and makes the filtering easy to use.

The user blacklist feature must be used together with the user identification feature. User identification provides the mappings between usernames and IP addresses for the user blacklist.

Attack detection and prevention tasks at a glance

To configure attack detection and prevention, perform the following tasks:

1. Configuring and applying an attack defense policy
   a. Creating an attack defense policy
   b. Configuring an attack defense policy
      Choose the following tasks as needed:
      - Configuring a single-packet attack defense policy
      - Configuring a scanning attack defense policy
      - Configuring a flood attack defense policy
   c. (Optional.) Configuring attack detection exemption
   d. Applying an attack defense policy
      Choose the following tasks as needed:
      - Applying an attack defense policy to an interface
      - Applying an attack defense policy to the device
2. (Optional.) Enabling log non-aggregation for single-packet attack events
3. (Optional.) Configuring TCP fragment attack prevention
   Typically, this feature is separately used.
4. (Optional.) Configuring the blacklist feature
   Use this feature separately or jointly with a scanning attack defense policy.
   - Configuring the IP blacklist feature
   - Configuring the user blacklist feature
5. (Optional.) Configuring the login attack prevention feature
   Typically, this feature is separately used.
   - Configuring login attack prevention
   - Enabling the login delay

Configuring and applying an attack defense policy

Creating an attack defense policy

About this task

An attack defense policy contains a set of attack detection and prevention configuration.

To configure attack defense configuration such as detection signatures and protection actions, you must first create an attack defense policy and enter its view.

Restrictions and guidelines

CAUTION:

The default thresholds for triggering attack prevention might not be appropriate for your network. Set appropriate according to the actual application scenarios. Small thresholds might affect the Internet or webpage access speed. Large thresholds might make your network vulnerable to attacks.

Procedure

1. Enter system view.

   system-view

2. Create an attack defense policy and enter its view.

   attack-defense policy *policy-name*

Configuring a single-packet attack defense policy

About this task

Apply the single-packet attack defense policy to the interface that is connected to the external network.

Single-packet attack detection inspects incoming packets based on the packet signature. If an attack packet is detected, the device can take the following actions:

- Output logs (the default action).
- Drop attack packets.

You can also configure the device to not take any actions.

Procedure

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Configure signature detection for specific single-packet attack types, and specify the actions against the attacks.
   - Configure signature detection for well-known single-packet attacks, and specify the actions against the attacks.

     signature detect { **fraggle** | **fragment** | **impossible** | **land** | **large-icmp** | **large-icmpv6** | **smurf** | **snork** | **tcp-all-flags** | **tcp-fin-only** | **tcp-invalid-flags** | **tcp-null-flag** | **tcp-syn-fin** | **tiny-fragment** | **traceroute** | **udp-bomb** | **winnuke** } [**action** { { **drop** | **logging** } * | **none** }]

     signature detect { **ip-option-abnormal** | **ping-of-death** | **teardrop** } **action** { **drop** | **logging** } *

   - Configure signature detection for ICMP packet attacks, and specify the actions against the attacks.

     signature detect icmp-type { *icmp-type-value* | **address-mask-reply** | **address-mask-request** | **destination-unreachable** | **echo-reply** | **echo-request** | **information-reply** | **information-request** | **parameter-problem** | **redirect** | **source-quench** | **time-exceeded** | **timestamp-reply** | **timestamp-request** } [**action** { { **drop** | **logging** } * | **none** }]

- Configure signature detection for ICMPv6 packet attacks, and specify the actions against the attacks.

  signature detect icmpv6-type { *icmpv6-type-value* | **destination-unreachable** | **echo-reply** | **echo-request** | **group-query** | **group-reduction** | **group-report** | **packet-too-big** | **parameter-problem** | **time-exceeded** } [**action** { { **drop** | **logging** } * | **none** }]

- Configure signature detection for IP option attacks, and specify the actions against the attacks.

  signature detect ip-option { *option-code* | **internet-timestamp** | **loose-source-routing** | **record-route** | **route-alert** | **security** | **stream-id** | **strict-source-routing** } [**action** { { **drop** | **logging** } * | **none** }]

- Configure signature detection for abnormal IPv6 extension header attacks, and specify the actions against the attacks.

  signature detect ipv6-ext-header *ext-header-value* [**action** { { **drop** | **logging** } * | **none** }]

By default, signature detection is not configured for single-packet attacks.

4. (Optional.) Set the maximum length of safe ICMP or ICMPv6 packets.

   signature { **large-icmp** | **large-icmpv6** } **max-length** *length*

   By default, the maximum length of safe ICMP or ICMPv6 packets is 4000 bytes.

5. (Optional.) Specify the actions against single-packet attacks of a specific level.

   signature level { **high** | **info** | **low** | **medium** } **action** { { **drop** | **logging** } * | **none** }

   The default action is **logging** for single-packet attacks of the informational and low levels.

   The default actions are **logging** and **drop** for single-packet attacks of the medium and high levels.

6. (Optional.) Enable signature detection for single-packet attacks of a specific level.

   signature level { **high** | **info** | **low** | **medium** } **detect**

   By default, signature detection is disabled for all levels of single-packet attacks.

Configuring a scanning attack defense policy

About this task

Apply a scanning attack defense policy to the interface that is connected to the external network.

Scanning attack detection inspects the incoming packet rate of connections to the target system. If a source initiates connections at a rate equal to or exceeding the pre-defined threshold, the device can take the following actions:

- Output logs.
- Drop subsequent packets from the IP address of the attacker.

Procedure

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Configure scanning attack detection.

   scan detect level { **high** | **low** | **medium** } **action** { **drop** | **logging** } *

   By default, scanning attack detection is not configured.

Configuring a flood attack defense policy

About this task

Apply a flood attack defense policy to the interface that is connected to the external network to protect internal servers.

Flood attack detection monitors the rate at which connections are initiated to the internal servers.

With flood attack detection enabled, the device is in attack detection state. When the packet sending rate to an IP address reaches the threshold, the device enters prevention state and takes defensive actions, such as logging and dropping subsequent packets. When the rate is below the silence threshold (three-fourths of the threshold), the device returns to the attack detection state.

Restrictions and guidelines for flood attack detection and prevention

If a device has multiple service cards, the global trigger threshold you set takes effect on each service card. The global trigger threshold of the device is the product of multiplying the value you set by the service card quantity.

You can configure flood attack detection and prevention for a specific IP address. For non-specific IP addresses, the device uses the global attack prevention settings.

Configuring a SYN flood attack defense policy

1. Enter system view.

   system-view
2. Enter attack defense policy view.

   attack-defense policy *policy-name*
3. Enable global SYN flood attack detection.

   syn-flood detect non-specific

   By default, global SYN flood attack detection is disabled.
4. Set the global trigger threshold for SYN flood attack prevention.

   syn-flood threshold *threshold-value*

   The default setting is 1000.
5. Specify global actions against SYN flood attacks.

   syn-flood action { **drop** | **logging** } *

   By default, no global action is specified for SYN flood attacks.
6. Configure IP address-specific SYN flood attack detection.

   syn-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

   By default, IP address-specific SYN flood attack detection is not configured.

Configuring an ACK flood attack defense policy

1. Enter system view.

   system-view
2. Enter attack defense policy view.

   attack-defense policy *policy-name*
3. Enable global ACK flood attack detection.

   ack-flood detect non-specific

   By default, global ACK flood attack detection is disabled.
4. Set the global trigger threshold for ACK flood attack prevention.

ack-flood threshold *threshold-value*

The default setting is 1000.

5. Specify global actions against ACK flood attacks.

ack-flood action { **drop** | **logging** } *

By default, no global action is specified for ACK flood attacks.

6. Configure IP address-specific ACK flood attack detection.

ack-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

By default, IP address-specific ACK flood attack detection is not configured.

Configuring a SYN-ACK flood attack defense policy

1. Enter system view.

system-view

2. Enter attack defense policy view.

attack-defense policy *policy-name*

3. Enable global SYN-ACK flood attack detection.

syn-ack-flood detect non-specific

By default, global SYN-ACK flood attack detection is disabled.

4. Set the global trigger threshold for SYN-ACK flood attack prevention.

syn-ack-flood threshold *threshold-value*

The default setting is 1000.

5. Specify global actions against SYN-ACK flood attacks.

syn-ack-flood action { **drop** | **logging** }*

By default, no global action is specified for SYN-ACK flood attacks.

6. Configure IP address-specific SYN-ACK flood attack detection.

syn-ack-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

By default, IP address-specific SYN-ACK flood attack detection is not configured.

Configuring a FIN flood attack defense policy

1. Enter system view.

system-view

2. Enter attack defense policy view.

attack-defense policy *policy-name*

3. Enable global FIN flood attack detection.

fin-flood detect non-specific

By default, global FIN flood attack detection is disabled.

4. Set the global trigger threshold for FIN flood attack prevention.

fin-flood threshold *threshold-value*

The default setting is 1000.

5. Specify global actions against FIN flood attacks.

fin-flood action { **drop** | **logging** } *

By default, no global action is specified for FIN flood attacks.

6. Configure IP address-specific FIN flood attack detection.

fin-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

By default, IP address-specific FIN flood attack detection is not configured.

Configuring an RST flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global RST flood attack detection.

   rst-flood detect non-specific

   By default, global RST flood attack detection is disabled.

4. Set the global trigger threshold for RST flood attack prevention.

   rst-flood threshold *threshold-value*

   The default setting is 1000.

5. Specify global actions against RST flood attacks.

   rst-flood action { **drop** | **logging** } *

   By default, no global action is specified for RST flood attacks.

6. Configure IP address-specific RST flood attack detection.

   rst-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

   By default, IP address-specific RST flood attack detection is not configured.

Configuring an ICMP flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global ICMP flood attack detection.

   icmp-flood detect non-specific

   By default, global ICMP flood attack detection is disabled.

4. Set the global trigger threshold for ICMP flood attack prevention.

   icmp-flood threshold *threshold-value*

   The default setting is 1000.

5. Specify global actions against ICMP flood attacks.

   icmp-flood action { **drop** | **logging** } *

   By default, no global action is specified for ICMP flood attacks.

6. Configure IP address-specific ICMP flood attack detection.

   icmp-flood detect ip *ip-address* [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

   By default, IP address-specific ICMP flood attack detection is not configured.

Configuring an ICMPv6 flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.
   attack-defense policy *policy-name*
3. Enable global ICMPv6 flood attack detection.
   icmpv6-flood detect non-specific
   By default, global ICMPv6 flood attack detection is disabled.
4. Set the global trigger threshold for ICMPv6 flood attack prevention.
   icmpv6-flood threshold *threshold-value*
   The default setting is 1000.
5. Specify global actions against ICMPv6 flood attacks.
   icmpv6-flood action { **drop** | **logging** } *
   By default, no global action is specified for ICMPv6 flood attacks.
6. Configure IP address-specific ICMPv6 flood attack detection.
   icmpv6-flood detect ipv6 *ipv6-address* [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]
   By default, IP address-specific ICMPv6 flood attack detection is not configured.

Configuring a UDP flood attack defense policy

1. Enter system view.
   system-view
2. Enter attack defense policy view.
   attack-defense policy *policy-name*
3. Enable global UDP flood attack detection.
   udp-flood detect non-specific
   By default, global UDP flood attack detection is disabled.
4. Set the global trigger threshold for UDP flood attack prevention.
   udp-flood threshold *threshold-value*
   The default setting is 1000.
5. Specify global actions against UDP flood attacks.
   udp-flood action { **drop** | **logging** } *
   By default, no global action is specified for UDP flood attacks.
6. Configure IP address-specific UDP flood attack detection.
   udp-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]
   By default, IP address-specific UDP flood attack detection is not configured.

Configuring a DNS flood attack defense policy

1. Enter system view.
   system-view
2. Enter attack defense policy view.
   attack-defense policy *policy-name*
3. Enable global DNS flood attack detection.
   dns-flood detect non-specific
   By default, global DNS flood attack detection is disabled.
4. Set the global trigger threshold for DNS flood attack prevention.

dns-flood threshold *threshold-value*

The default setting is 1000.

5. (Optional.) Specify the global ports to be protected against DNS flood attacks.

   dns-flood port *port-list*

   By default, DNS flood attack prevention protects port 53.

6. Specify global actions against DNS flood attacks.

   dns-flood action { **drop** | **logging** } *

   By default, no global action is specified for DNS flood attacks.

7. Configure IP address-specific DNS flood attack detection.

   dns-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**port** *port-list*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

   By default, IP address-specific DNS flood attack detection is not configured.

Configuring an HTTP flood attack defense policy

1. Enter system view.

   system-view

2. Enter attack defense policy view.

   attack-defense policy *policy-name*

3. Enable global HTTP flood attack detection.

   http-flood detect non-specific

   By default, global HTTP flood attack detection is disabled.

4. Set the global trigger threshold for HTTP flood attack prevention.

   http-flood threshold *threshold-value*

   The default setting is 1000.

5. (Optional.) Specify the global ports to be protected against HTTP flood attacks.

   http-flood port *port-list*

   By default, HTTP flood attack prevention protects port 80.

6. Specify global actions against HTTP flood attacks.

   http-flood action { **drop** | **logging** } *

   By default, no global action is specified for HTTP flood attacks.

7. Configure IP address-specific HTTP flood attack detection.

   http-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**port** *port-list*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]

   By default, IP address-specific HTTP flood attack detection is not configured.

Configuring attack detection exemption

About this task

The attack defense policy uses the ACL to identify exempted packets. The policy does not check the packets permitted by the ACL. You can configure the ACL to identify packets from trusted servers. The exemption feature reduces the false alarm rate and improves packet processing efficiency. For example, the attack defense policy identifies multicast packets with the same source addresses and different destination addresses as scanning attack packets (for example, OSPF or PIM packets). You can configure an ACL to exempt such packets from attack detection.

Restrictions and guidelines

If an ACL is used for attack detection exemption, only the following match criteria in the ACL permit rules take effect:

- Source IP address.
- Destination IP address.
- Source port.
- Destination port.
- Protocol.
- The **fragment** keyword for matching non-first fragments.

Procedure

1. Enter system view.
   system-view
2. Enter attack defense policy view.
   attack-defense policy *policy-name*
3. Configure attack detection exemption.
   exempt acl [**ipv6**] { *acl-number* | **name** *acl-name* }
   By default, attack detection exemption is not configured.

Applying an attack defense policy to an interface

1. Enter system view.
   system-view
2. Enter system view.
   interface *interface-type interface-number*
3. Apply an attack defense policy to the interface.
   attack-defense apply policy *policy-name*
   By default, no attack defense policy is applied to the interface.

Applying an attack defense policy to the device

About this task

An attack defense policy applied to the device itself rather than the interfaces detects packets destined for the device and prevents attacks targeted at the device.

A switch uses hardware to implement packet forwarding and uses software to process packets if the packets are destined for the switch. The software does not provide any attack defense features, so you must apply an attack defense policy to the switch to prevent attacks aimed at the switch.

If a device and its interfaces have attack defense policies applied, a packet destined for the device is processed as follows:

1. The policy applied to the receiving interface processes the packet.
2. If the packet is not dropped by the receiving interface, the policy applied to the device processes the packet.

Procedure

1. Enter system view.
   system-view

2. Apply an attack defense policy to the device.
   attack-defense local apply policy *policy-name*
   By default, no attack defense policy is applied to the device.

Enabling log non-aggregation for single-packet attack events

About this task

Log aggregation aggregates multiple logs generated during a period of time and sends one log. Logs that are aggregated must have the following attributes in common:

- Attacks are detected on the same interface or are destined for the device.
- Attack type.
- Attack defense action.
- Source and destination IP addresses.
- VPN instance to which the victim IP address belongs.

Restrictions and guidelines

As a best practice, do not disable log aggregation. A large number of logs will consume the display resources of the console.

Procedure

1. Enter system view.
   system-view
2. Enable log non-aggregation for single-packet attack events.
   attack-defense signature log non-aggregate
   By default, log non-aggregation is disabled for single-packet attack events.

Configuring TCP fragment attack prevention

About this task

The TCP fragment attack prevention feature detects the length and fragment offset of received TCP fragments and drops attack TCP fragments.

Restrictions and guidelines

TCP fragment attack prevention takes precedence over single-packet attack prevention. When both are used, incoming TCP packets are processed first by TCP fragment attack prevention and then by the single-packet attack defense policy.

Procedure

1. Enter system view.
   system-view
2. Enable TCP fragment attack prevention.
   attack-defense tcp fragment enable
   By default, TCP fragment attack prevention is enabled.

Configuring the IP blacklist feature

About this task

The IP blacklist feature filters packets sourced from IP addresses in blacklist entries. If the global blacklist feature is enabled, the blacklist feature is enabled on all interfaces or security zones.

IP blacklist entries can be manually added or dynamically learned:

- You can manually add an IP blacklist entry by using the **blacklist ip** or **blacklist ipv6** command. These entries do not age out by default. You can set an aging time for each entry.
- The device can automatically add IP blacklist entries when collaborating with scanning attack detection. Each dynamically learned IP blacklist entry has an aging time, which is user configurable. Make sure the **block-source** keyword is specified as the scanning attack prevention action. For more information about the scanning attack detection and prevention, see "Configuring a scanning attack defense policy."

Hardware and feature compatibility

The S5200-EI-G switch series does not support this feature.

Restrictions and guidelines

If the global blacklist feature is enabled, the blacklist feature is enabled on all interfaces.

If the global blacklist feature is disabled, you can enable the blacklist feature on specific interfaces to meet your network requirements.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Enable the global blacklist feature.

   blacklist global enable

   By default, the global blacklist feature is disabled.

3. (Optional.) Add an IP blacklist entry.
   - Add an IPv4 blacklist entry.

     blacklist ip *source-ip-address* [**vpn-instance** *vpn-instance-name*] [**ds-lite-peer** *ds-lite-peer-address*] [**timeout** *minutes*]
   - Add an IPv6 blacklist entry.

     blacklist ipv6 *source-ipv6-address* [**vpn-instance** *vpn-instance-name*] [**timeout** *minutes*]

4. (Optional.) Enable logging for the blacklist feature.

   blacklist logging enable

   By default, logging is disabled for the blacklist feature.

5. Enter interface view.

   interface *interface-type interface-number*

6. Enable the blacklist feature on the interface.

   blacklist enable

   By default, the blacklist feature is disabled on the interface.

Configuring the user blacklist feature

About this task

The user blacklist feature filters packets sourced from users in blacklist entries.

A user blacklist entry can only be manually added by using the **blacklist user** command. A user blacklist entry does not age out by default. You can set an aging time for the entry.

Procedure

1. Enter system view.
   system-view
2. Enable the global blacklist feature.
   blacklist global enable
   By default, the global blacklist feature is disabled.
3. Add a user blacklist entry.
   blacklist user *user-name* [**timeout** *minutes*]
4. (Optional.) Enable logging for the blacklist feature.
   blacklist logging enable
   By default, logging is disabled for the blacklist feature.

Configuring login attack prevention

About this task

The login attack prevention feature detects a login DoS attack if a user fails the maximum number of successive login attempts. The feature triggers the blacklist feature to add the user's IP to the blacklist. Following login attempts from the user is blocked for the block period. For login attack prevention to take effect, you must enable the global blacklist feature.

This feature can effectively prevent login DoS attacks.

Hardware and feature compatibility

The S5200-EI-G switch series does not support this feature.

Procedure

1. Enter system view.
   system-view
2. Enable login attack prevention.
   attack-defense login enable
   By default, login attack prevention is disabled.
3. Set the maximum number of successive login failures.
   attack-defense login max-attempt *max-attempt*
   The default value is three.
4. Set the block period during which a login attempt is blocked.
   attack-defense login block-timeout *minutes*
   The default value is 60 minutes.
5. Enable the global blacklist feature.
   blacklist global enable
   By default, the global blacklist feature is disabled.

Enabling the login delay

About this task

The login delay feature delays the device from accepting a login request from a user after the user fails a login attempt. This feature can slow down login dictionary attacks.

The login delay feature is independent of the login attack prevention feature.

Procedure

1. Enter system view.

   `system-view`

2. Enable the login delay feature.

   `attack-defense login reauthentication-delay` *seconds*

   By default, the login delay feature is disabled. The device does not delay accepting a login request from a user who has failed a login attempt.

Display and maintenance commands for attack detection and prevention

The S5200-EI-G switch series does not support the blacklist feature.

Use the **`display`** commands in any view and the **`reset`** commands in user view.

To display and maintain attack detection and prevention:

Task	Command
Display flood attack detection and prevention statistics for an IPv4 address.	**display attack-defense** { **ack-flood** | **dns-flood** | **fin-flood** | **flood** | **http-flood** | **icmp-flood** | **rst-flood** | **syn-ack-flood** | **syn-flood** | **udp-flood** } **statistics ip** [*ip-address* [**vpn** *vpn-instance-name*]] [[**interface** *interface-type interface-number* | **local**] [**slot** *slot-number*]] [**count**]

Task	Command
Display flood attack detection and prevention statistics for an IPv6 address.	**display attack-defense** { **ack-flood** | **dns-flood** | **fin-flood** | **flood** | **http-flood** | **icmpv6-flood** | **rst-flood** | **syn-flood** | **syn-ack-flood** | **udp-flood** } **statistics ipv6** [*ipv6-address* [**vpn** *vpn-instance-name*]] [[**interface** *interface-type interface-number* | **local**] [**slot** *slot-number*]] [**count**]
Display attack defense policy configuration.	**display attack-defense policy** [*policy-name*]

Task	Command
Display information about IPv4 addresses protected by flood attack detection and prevention.	**display attack-defense policy** *policy-name* { **ack-flood** | **dns-flood** | **fin-flood** | **flood** | **http-flood** | **icmp-flood** | **rst-flood** | **syn-ack-flood** | **syn-flood** | **udp-flood** } **ip** [*ip-address* [**vpn** *vpn-instance-name*]] [**slot** *slot-number*] [**count**]
Display information about IPv6 addresses protected by flood attack detection and prevention.	**display attack-defense policy** *policy-name* { **ack-flood** | **dns-flood** | **fin-flood** | **flood** | **http-flood** | **icmpv6-flood** | **rst-flood** | **syn-ack-flood** | **syn-flood** | **udp-flood** } **ipv6** [*ipv6-address* [**vpn** *vpn-instance-name*]] [**slot** *slot-number*] [**count**]

Task	Command
Display information about IPv4 scanning attackers.	**display attack-defense scan attacker ip** [[**interface** *interface-type interface-number* | **local**] [**slot** *slot-number*]] [**count**]
Display information about IPv6 scanning attackers.	**display attack-defense scan attacker ipv6** [[**interface** *interface-type interface-number* | **local**] [**slot** *slot-number*]] [**count**]
Display information about IPv4 scanning attack victims.	**display attack-defense scan victim ip** [[**interface** *interface-type interface-number* | **local**] [**slot** *slot-number*]] [**count**]
Display information about IPv6 scanning attack victims.	**display attack-defense scan victim ipv6** [[**interface** *interface-type interface-number* | **local**] [**slot** *slot-number*]] [**count**]

Task	Command
Display attack detection and prevention statistics on an interface.	**display attack-defense statistics interface** *interface-type interface-number* [**slot** *slot-number*]
Display attack detection and prevention statistics for the device.	**display attack-defense statistics local** [**slot** *slot-number*]
Display manually added IPv4 blacklist entries.	**display blacklist ip** [*source-ip-address* [**vpn-instance** *vpn-instance-name*] [**ds-lite-peer** *ds-lite-peer-address*] | **count**]
Display manually added IPv6 blacklist entries.	**display blacklist ipv6** [*source-ipv6-address* [**vpn-instance** *vpn-instance-name*] | **count**]
Clear flood attack detection and prevention statistics.	**reset attack-defense policy** *policy-name* **flood protected** { **ip** | **ipv6** } **statistics**
Clear attack detection and prevention statistics for an interface.	**reset attack-defense statistics interface** *interface-type interface-number*
Clear attack detection and prevention statistics for the device.	**reset attack-defense statistics local**
Clear dynamic IPv4 blacklist entries.	**reset blacklist ip** { *source-ip-address* [**vpn-instance** *vpn-instance-name*] [**ds-lite-peer** *ds-lite-peer-address*] | **all** }
Clear dynamic IPv6 blacklist entries.	**reset blacklist ipv6** { *source-ipv6-address* [**vpn-instance** *vpn-instance-name*] | **all** }
Clear blacklist statistics.	**reset blacklist statistics**

Attack detection and prevention configuration examples

Example: Configuring attack detection and prevention on the device

Network configuration

Configure attack detection and prevention on the switch (the gateway) to protect against network attacks from the user side or the network side.

- To prevent TCP flag attacks and low level scanning attacks that aim at the switch, enable TCP flag attack prevention and scanning attack prevention. Configure the device to output logs if it detects such attacks.
- To prevent the SYN flood attacks that aim at the external interface of the switch, enable IP address-specific SYN flood attack detection for 192.168.2.1/24. When the device receives 5000 or more SYN packets sent to the protected IP address per second, it outputs logs and drops the packets.
- To prevent the SYN flood attacks that aim at the internal interface of the switch, enable global SYN flood attack detection. When the device receives 2000 or more SYN packets that are destined to the switch but not to the protected IP address per second, it outputs logs.

Figure 1 Network diagram

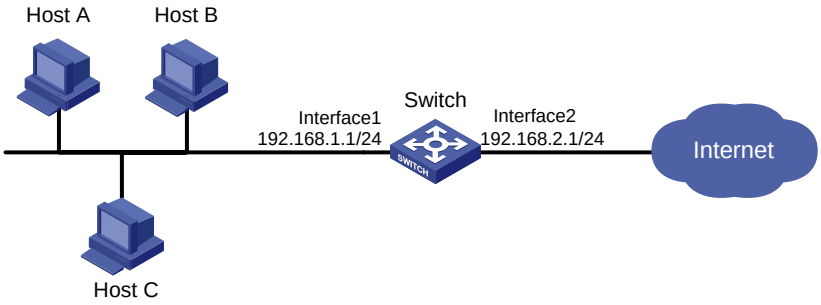

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

Assign IP addresses to interfaces according to the network diagram.

```
<Sysname> system-view
[Sysname] sysname Switch
[Switch] interface gigabitethernet 1/0/1
[Switch-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.255.0
[Switch-GigabitEthernet1/0/1] quit
[Switch] interface gigabitethernet 1/0/2
[Switch-GigabitEthernet1/0/2] ip address 192.168.2.1 255.255.255.0
[Switch-GigabitEthernet1/0/2] quit
```

Create attack defense policy **a1**.

```
[Switch] attack-defense policy a1
```

Enable signature detection for TCP single packet attacks and specify **logging** as the attack prevention action. A TCP packet is identified as an attack packet if it has all flags set, only FIN flag set, invalid flags, no TCP flags set, or both SYN and FIN flags set.

```
[Switch-attack-defense-policy-a1] signature detect tcp-all-flags action logging
[Switch-attack-defense-policy-a1] signature detect tcp-fin-only action logging
[Switch-attack-defense-policy-a1] signature detect tcp-invalid-flags action logging
[Switch-attack-defense-policy-a1] signature detect tcp-null-flag action logging
[Switch-attack-defense-policy-a1] signature detect tcp-syn-fin action logging
```

Enable low level scanning attack detection and specify **logging** as the attack prevention action.

```
[Switch-attack-defense-policy-a1] scan detect level low action logging
```

Enable SYN flood attack detection for 192.168.2.1. Set the threshold for triggering SYN flood attack prevention to 5000 and specify **logging** and **drop** as the attack prevention actions.

```
[Switch-attack-defense-policy-a1] syn-flood detect ip 192.168.2.1 threshold 5000 action
logging drop
```

Enable global SYN flood attack detection, set the global threshold for triggering SYN flood attack prevention to 2000, and specify **logging** as the global attack prevention action.

```
[Switch-attack-defense-policy-a1] syn-flood detect non-specific
[Switch-attack-defense-policy-a1] syn-flood threshold 2000
[Switch-attack-defense-policy-a1] syn-flood action logging
[Switch-attack-defense-policy-a1] quit
```

Apply the attack defense policy to the device.

```
[Switch] attack-defense local apply policy a1
```

Verifying the configuration

Verify that attack defense policy **a1** is correctly configured.

```
[Switch] display attack-defense policy a1
          Attack-defense Policy Information
------------------------------------------------------------------------------
Policy name                       : a1
Applied list                      : Local
------------------------------------------------------------------------------
Exempt IPv4 ACL                   : Not configured
Exempt IPv6 ACL                   : Not configured
------------------------------------------------------------------------------
  Actions: CV-Client verify  BS-Block source  L-Logging  D-Drop  N-None

Signature attack defense configuration:
Signature name                    Defense     Level            Actions
Fragment                          Disabled    low              L
Impossible                        Disabled    medium           L,D
Teardrop                          Disabled    medium           L,D
Tiny fragment                     Disabled    low              L
IP option abnormal                Disabled    medium           L,D

Example: Configuring IP blacklist

Network configuration

As shown in Figure 2, configure the IP blacklist feature on the router to block packets from the attacker Host D permanently and from Host C for 50 minutes.

Figure 2 Network diagram

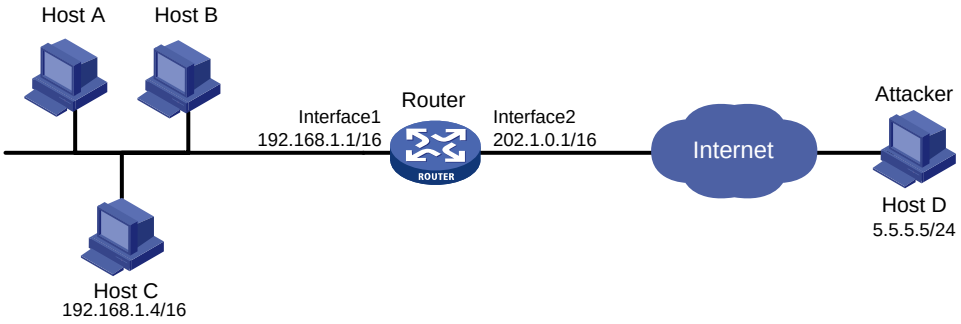

Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

The S5200-EI-G switch series does not support the blacklist feature.

Assign IP addresses to interfaces according to the network diagram.

```
<Sysname> system-view
[Sysname] sysname Router
[Router] interface gigabitethernet 1/0/1
[Router-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.0.0
[Router-GigabitEthernet1/0/1] quit
[Router] interface gigabitethernet 1/0/2
[Router-GigabitEthernet1/0/2] ip address 202.1.0.1 255.255.0.0
```

```
[Router-GigabitEthernet1/0/2] quit
```

Enable the global blacklist feature.

```
<Router> system-view
[Router] blacklist global enable
```

Add an IPv4 blacklist entry for Host D.

```
[Router] blacklist ip 5.5.5.5
```

Add an IPv4 blacklist entry for Host C and set the blacklist entry aging time to 50 minutes.

```
[Router] blacklist ip 192.168.1.4 timeout 50
```

Verifying the configuration

Verify that the IPv4 blacklist entries are successfully added.

```
<Router> display blacklist ip
IP address      VPN instance   DS-Lite tunnel peer  Type    TTL(sec) Dropped
5.5.5.5         --             --                   Manual  Never    0
192.168.1.4     --             --                   Manual  2989     0
```

Verify that the router drops packets from Host D. (Details not shown.)

Execute the **`undo blacklist ip 5.5.5.5`** command and verify that the router forwards packets from Host D. (Details not shown.)

Verify that the router drops packets from Host C for 50 minutes and forwards packets from Host C after 50 minutes. (Details not shown.)

Configuration files

```
#
interface GigabitEthernet1/0/1
 port link-mode route
 ip address 192.168.1.1 255.255.0.0
#
interface GigabitEthernet1/0/2
 port link-mode route
 ip address 202.1.0.1 255.255.0.0
#
 blacklist ip 5.5.5.5
 blacklist global enable
#
```

Example: Configuring user blacklist

Network configuration

As shown in Figure 3, configure the user blacklist feature on the router to block packets from User C for 50 minutes. The IP address of User C is 1.2.3.4 and the MAC address of User C is 0001-0001-0001.

Figure 3 Network diagram

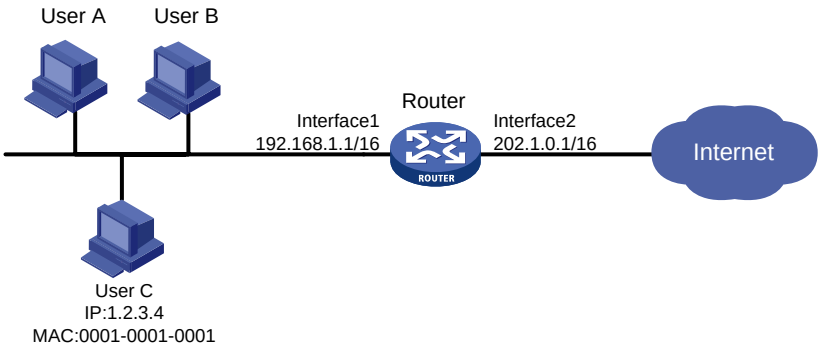

Table 4 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

The S5200-EI-G switch series does not support the blacklist feature.

1. Assign IP addresses to interfaces according to the network diagram.

```
<Sysname> system-view
[Sysname] sysname Router
[Router] interface gigabitethernet 1/0/1
[Router-GigabitEthernet1/0/1] ip address 192.168.1.1 255.255.0.0
[Router-GigabitEthernet1/0/1] quit
[Router] interface gigabitethernet 1/0/2
[Router-GigabitEthernet1/0/2] ip address 202.1.0.1 255.255.0.0
[Router-GigabitEthernet1/0/2] quit
```

2. Configure user identification:

   # Add a network access user named **userc**.

```
<Router> system-view
[Router] local-user userc class network
[Router-luser-network-userc] quit
```

   # Configure a static identity user with username **userc**, IP address 1.2.3.4, and MAC address 0001-0001-0001.

```
[Router] user-identity static-user userc bind ipv4 1.2.3.4 mac 0001-0001-0001
```

   # Enable user identification.

```
[Router] user-identity enable
```

3. Configure the user blacklist feature:

   # Enable the global blacklist feature.

```
[Router] blacklist global enable
```

   # Add a user blacklist entry for user **userc** and set the blacklist entry aging time to 50 minutes.

```
[Router] blacklist user userc timeout 50
```

Verifying the configuration

Verify that the user blacklist entry is successfully added.

```
[Router] display blacklist user
```

```
User name       Type    TTL(sec) Dropped
userc           Manual  2987     0
```

Verify that the router drops packets from User C for 50 minutes and forwards packets from User C after 50 minutes. (Details not shown.)

Configuration files

```
#
interface GigabitEthernet1/0/1
 port link-mode route
 ip address 192.168.1.1 255.255.0.0
#
interface GigabitEthernet1/0/2
 port link-mode route
 ip address 202.1.0.1 255.255.0.0
#
local-user userc class network
 authorization-attribute user-role network-operator
#
 blacklist global enable
#
 user-identity enable
 user-identity static-user userc bind ipv4 1.2.3.4 mac 0001-0001-0001
#
```

Configuring TCP attack prevention 1
About TCP attack prevention 1
Configuring Naptha attack prevention 1

Configuring TCP attack prevention

About TCP attack prevention

TCP attack prevention can detect and prevent attacks that exploit the TCP connection establishment process.

Configuring Naptha attack prevention

About this task

Naptha is a DDoS attack that targets operating systems. It exploits the resources consuming vulnerability in TCP/IP stack and network application process. The attacker establishes a large number of TCP connections in a short period of time and leaves them in certain states without requesting any data. These TCP connections starve the victim of system resources, resulting in a system breakdown.

After you enable Naptha attack prevention, the device periodically checks the number of TCP connections in each state (CLOSING, ESTABLISHED, FIN_WAIT_1, FIN_WAIT_2, and LAST_ACK). If the number of TCP connections in a state exceeds the limit, the device will accelerate the aging of the TCP connections in that state to mitigate the Naptha attack.

Procedure

1. Enter system view.

   system-view

2. Enable Naptha attack prevention.

   tcp anti-naptha enable

   By default, Naptha attack prevention is disabled.

3. (Optional.) Set the maximum number of TCP connections in a state.

   tcp state { **closing** | **established** | **fin-wait-1** | **fin-wait-2** | **last-ack** } **connection-limit** *number*

   By default, the maximum number of TCP connections in each state (CLOSING, ESTABLISHED, FIN_WAIT_1, FIN_WAIT_2, and LAST_ACK) is 50.

   To disable the device from accelerating the aging of the TCP connections in a state, set the value to 0.

4. (Optional.) Set the interval for checking the number of TCP connections in each state.

   tcp check-state interval *interval*

   By default, the interval for checking the number of TCP connections in each state is 30 seconds.

Configuring SAVI

About SAVI

Source Address Validation Improvement (SAVI) checks the validity of the source addresses of global unicast IPv6 packets. It implements the validity check by using the ND snooping, DHCPv6 snooping, ND attack detection, and IP source guard features. SAVI checks only global unicast addresses and forwards the packets that pass the validity check. Packets sourced from an invalid address are dropped.

SAVI application scenarios

DHCPv6-only

The hosts connected to the SAVI-enabled device obtain addresses only through DHCPv6. DHCPv6 messages, ND messages (RA and RR messages excluded), and IPv6 data packets are checked based on DHCPv6 snooping entries and static IPv6 source guard binding entries.

SLAAC-only

The hosts connected to the SAVI-enabled device obtain addresses only through Stateless Address Autoconfiguration (SLAAC). In this scenario, SAVI drops all DHCPv6 messages. Only ND messages and IPv6 data packets are checked based on DHCPv6 snooping entries and static IPv6 source guard binding entries.

DHCPv6+SLAAC

The hosts connected to the SAVI-enabled device obtain addresses through DHCPv6 and SLAAC. In this scenario, SAVI checks all DHCPv6 messages, ND messages, and IPv6 data packets based on DHCPv6 snooping entries, ND snooping entries, and static IPv6 source guard binding entries.

SAVI tasks at a glance

To configure SAVI, perform the following tasks:

1. Enabling SAVI
2. Configuring IPv6 source guard
3. Configuring DHCPv6 snooping
4. Configuring ND parameters
5. (Optional.) Setting the entry deletion delay
6. (Optional.) Enabling packet spoofing logging and filtering entry logging

Enabling SAVI

1. Enter system view.
   `system-view`
2. Enable SAVI.
   `ipv6 savi strict`
   By default, SAVI is disabled.

Configuring IPv6 source guard

1. Enable IPv6 source guard on an interface.
2. (Optional.) Configure static IPv6SG bindings.

For more information about IPv6 source guard configuration, see "Configuring IP source guard."

Configuring DHCPv6 snooping

Restrictions and guidelines

Enable only DHCPv6 snooping for the SLAAC-only scenario.

Procedure

1. Enable DHCPv6 snooping.
2. Specify DHCPv6 snooping trusted ports.
3. Enable recording client information in DHCPv6 snooping entries.

For more information about DHCPv6 snooping configuration, see *Layer 3—IP Services Configuration Guide*.

Configuring ND parameters

Restrictions and guidelines

Enable only ND attack detection for the DHCPv6-only scenario.

Procedure

1. Enable ND snooping for global unicast addresses.

   For more information about ND snooping, see IPv6 basics in *Layer 3—IP Services Configuration Guide*.
2. Enable ND attack detection.

   For more information about ND attack detection, see "Configuring ND attack defense."
3. Specify ND trusted ports.

   For more information about ND trusted ports, see "Configuring ND attack defense."

Setting the entry deletion delay

About this task

The entry deletion delay is the period of time that the device waits before deleting the DHCPv6 snooping entries and ND snooping entries for a down port.

Procedure

1. Enter system view.

   system-view
2. Set the entry deletion delay.

   ipv6 savi down-delay *delay-time*

   By default, the entry deletion delay is 30 seconds.

Enabling packet spoofing logging and filtering entry logging

About this task

Packet spoofing logging enables the device to generate log messages for the spoofed packets detected by SAVI.

Filtering entries are effective bindings used for filtering IPv6 packets by the source IPv6 address. Filtering entry logging enables the device to generate log messages for filtering entries. A log message contains the IPv6 address, MAC address, VLAN, and interface of a filtering entry.

The device sends packet spoofing and filtering entry log messages to the information center. With the information center, you can set log message filtering and output rules, including output destinations. For more information about using the information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable packet spoofing logging.

   ipv6 savi log enable spoofing-packet [**interval** *interval* | **total-number** *number*] *

   By default, packet spoofing logging is disabled.

3. Enable filtering entry logging.

   ipv6 savi log enable filter-entry

   By default, filtering entry logging is disabled.

SAVI configuration examples

Example: Configuring DHCPv6-only SAVI

Network configuration

As shown in Figure 1, configure SAVI on the switch to meet the following requirements:

- Clients obtain IPv6 addresses only through DHCPv6.
- SAVI checks the source addresses of DHCPv6 messages, ND messages (RA and RR messages excluded), and IPv6 data packets on GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3.

Figure 1 Network diagram

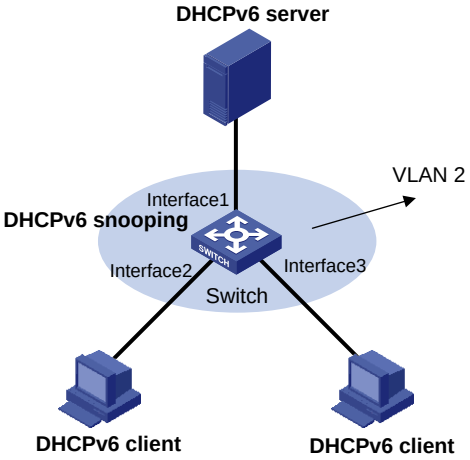

Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

Enable SAVI.

```
<Switch> system-view
[Switch] ipv6 savi strict
```

Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to VLAN 2.

```
[Switch] vlan 2
[Switch-vlan2] port gigabitethernet 1/0/1 gigabitethernet 1/0/2 gigabitethernet 1/0/3
[Switch-vlan2] quit
```

Enable DHCPv6 snooping.

```
[Switch] ipv6 dhcp snooping enable
```

Configure GigabitEthernet 1/0/1 as a DHCPv6 snooping trusted port.

```
[Switch] interface gigabitethernet 1/0/1
[Switch-GigabitEthernet1/0/1] ipv6 dhcp snooping trust
[Switch-GigabitEthernet1/0/1] quit
```

Enable recording DHCPv6 snooping entries on GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3.

```
[Switch] interface gigabitethernet 1/0/2
[Switch-GigabitEthernet1/0/2] ipv6 dhcp snooping binding record
[Switch-GigabitEthernet1/0/2] quit
[Switch] interface gigabitethernet 1/0/3
[Switch-GigabitEthernet1/0/3] ipv6 dhcp snooping binding record
[Switch-GigabitEthernet1/0/3] quit
```

Enable ND attack detection.

```
[Switch] vlan 2
[Switch-vlan2] ipv6 nd detection enable
```

```
[Switch-vlan2] quit
```

Enable IPv6 source guard on GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3.

```
[Switch] interface gigabitethernet 1/0/2
[Switch-GigabitEthernet1/0/2] ipv6 verify source ip-address mac-address
[Switch-GigabitEthernet1/0/2] quit
[Switch] interface gigabitethernet 1/0/3
[Switch-GigabitEthernet1/0/3] ipv6 verify source ip-address mac-address
[Switch-GigabitEthernet1/0/3] quit
```

Example: Configuring SLAAC-only SAVI

Network configuration

As shown in Figure 2, configure SAVI on Switch B to meet the following requirements:

- Hosts obtain IPv6 addresses only through SLAAC.
- DHCPv6 messages are dropped on GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 in VLAN 2.
- SAVI checks the source addresses of ND messages and IPv6 data packets on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

Figure 2 Network diagram

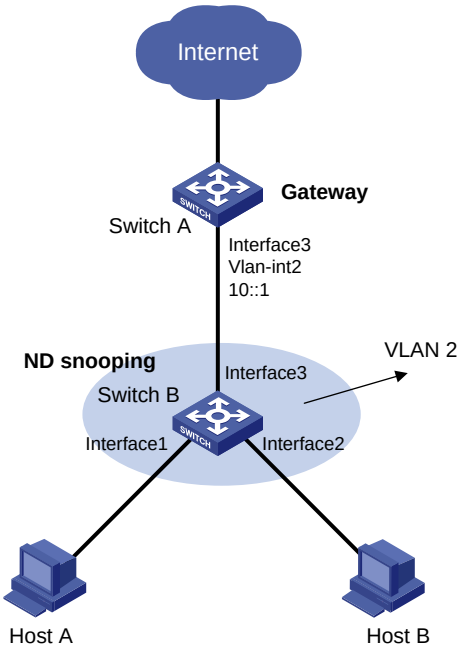

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

Enable SAVI.

```
<SwitchB> system-view
[SwitchB] ipv6 savi strict
```

Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to VLAN 2.

```
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/1 gigabitethernet 1/0/2 gigabitethernet 1/0/3
[SwitchB-vlan2] quit
```

Enable ND snooping for global unicast addresses in VLAN 2.

```
[SwitchB] vlan 2
[SwitchB-vlan2] ipv6 nd snooping enable global
```

Enable ND attack detection for VLAN 2.

```
[SwitchB-vlan2] ipv6 nd detection enable
[SwitchB-vlan2] quit
```

Enable DHCPv6 snooping.

```
[SwitchB] ipv6 dhcp snooping enable
```

Configure GigabitEthernet 1/0/3 as an ND trusted port.

```
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] ipv6 nd detection trust
[SwitchB-GigabitEthernet1/0/3] quit
```

Enable IPv6 source guard on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] ipv6 verify source ip-address mac-address
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] ipv6 verify source ip-address mac-address
[SwitchB-GigabitEthernet1/0/2] quit
```

Example: Configuring DHCPv6+SLAAC SAVI

Network configuration

As shown in Figure 3, configure SAVI on Switch B to meet the following requirements:

- Hosts obtain IP addresses through DHCPv6 or SLAAC.
- SAVI checks the source addresses of DHCPv6 messages, ND messages, and IPv6 data packets on GigabitEthernet 1/0/3 through GigabitEthernet 1/0/5.

Figure 3 Network diagram

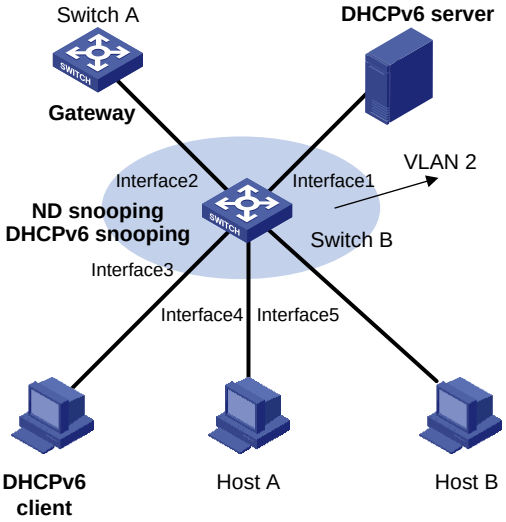

Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4
Interface5	GigabitEthernet1/0/5

Procedure

Enable SAVI.

```
<SwitchB> system-view
[SwitchB] ipv6 savi strict
```

Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/5 to VLAN 2.

```
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/1 gigabitethernet 1/0/2 gigabitethernet 1/0/3
gigabitethernet 1/0/4 gigabitethernet 1/0/5
```

Enable DHCPv6 snooping.

```
[SwitchB] ipv6 dhcp snooping enable
```

Enable recording DHCPv6 snooping entries on GigabitEthernet 1/0/3 through GigabitEthernet 1/0/5.

```
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] ipv6 dhcp snooping binding record
[SwitchB-GigabitEthernet1/0/3] quit
[SwitchB] interface gigabitethernet 1/0/4
[SwitchB-GigabitEthernet1/0/4] ipv6 dhcp snooping binding record
[SwitchB-GigabitEthernet1/0/4] quit
[SwitchB] interface gigabitethernet 1/0/5
[SwitchB-GigabitEthernet1/0/5] ipv6 dhcp snooping binding record
[SwitchB-GigabitEthernet1/0/5] quit
```

Configure GigabitEthernet 1/0/1 as a DHCPv6 snooping trusted port.

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] ipv6 dhcp snooping trust
[SwitchB-GigabitEthernet1/0/1] quit
```

Enable ND snooping for global unicast addresses in VLAN 2.

```
[SwitchB] vlan 2
[SwitchB-vlan2] ipv6 nd snooping enable global
```

Enable ND attack detection for VLAN 2.

```
[SwitchB-vlan2] ipv6 nd detection enable
[SwitchB-vlan2] quit
```

Configure GigabitEthernet 1/0/2 as an ND trusted port.

```
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] ipv6 nd detection trust
[SwitchB-GigabitEthernet1/0/2] quit
```

Enable IPv6 source guard on GigabitEthernet 1/0/3 through GigabitEthernet 1/0/5.

```
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] ipv6 verify source ip-address mac-address
[SwitchB-GigabitEthernet1/0/3] quit
[SwitchB] interface gigabitethernet 1/0/4
[SwitchB-GigabitEthernet1/0/4] ipv6 verify source ip-address mac-address

Configuring FIPS

About FIPS

Federal Information Processing Standards (FIPS) was developed by the National Institute of Standards and Technology (NIST) of the United States. FIPS specifies the requirements for cryptographic modules.

FIPS security levels

FIPS 140-2 defines four levels of security, named Level 1 to Level 4, from low to high. The device supports Level 2.

Unless otherwise noted, the term "FIPS" refers to Level-2 FIPS 140-2 in this document.

FIPS functionality

In FIPS mode, the device has strict security requirements. It performs self-tests on cryptography modules to verify that the modules are operating correctly.

A FIPS device also meets the functionality requirements defined in Network Device Protection Profile (NDPP) of Common Criteria (CC).

FIPS self-tests

To ensure correct operation of cryptography modules, FIPS provides self-test mechanisms, including power-up self-tests and conditional self-tests.

If a power-up self-test fails, the device where the self-test process exists reboots. If a conditional self-test fails, the system outputs a self-test failure message.

NOTE:
If a self-test fails, contact H3C Support.

Power-up self-tests

The power-up self-test examines the availability of FIPS-allowed cryptographic algorithms.

The device supports the following types of power-up self-tests:

- Known-answer test (KAT)

  A cryptographic algorithm is run on data for which the correct output is already known. The calculated output is compared with the known answer. If they are not identical, the KAT test fails.

- Pairwise conditional test (PWCT)
  - **Signature and authentication test**—The test is run when a DSA, RSA, or ECDSA asymmetrical key pair is generated. The system uses the private key to sign the specific data, and then uses the public key to authenticate the signed data. If the authentication is successful, the test succeeds.
  - **Encryption and decryption test**—The test is run when an RSA asymmetrical key pair is generated. The system uses the public key to encrypt a plain text string, and then uses the private key to decrypt the encrypted text. If the decryption result is the same as the original plain text string, the test succeeds.

The power-up self-test examines the cryptographic algorithms listed in Table 1.

Table 1 Power-up self-tests list

Type	Operations
KAT	Tests the following algorithms: • SHA1, SHA224, SHA256, SHA384, and SHA512. • HMAC-SHA1, HMAC-SHA224, HMAC-SHA256, HMAC-SHA384, and HMAC-SHA512. • AES. • RSA (signature and authentication). • ECDH. • DRBG. • GCM. • GMAC.
PWCT	Tests the following algorithms: • RSA (signature and authentication). • RSA (encryption and decryption). • DSA (signature and authentication). • ECDSA (signature and authentication).

Conditional self-tests

A conditional self-test runs when an asymmetrical cryptographic module or a random number generator module is invoked. Conditional self-tests include the following types:

- **PWCT signature and authentication**—This test is run when a DSA or RSA asymmetrical key pair is generated. The system uses the private key to sign the specific data, and then uses the public key to authenticate the signed data. If the authentication is successful, the test succeeds.
- **Continuous random number generator test**—Runs when a random number is generated. The system compares the generated random number with the previously generated random number. If the two numbers are the same, the test fails. This test also runs when a DSA or RSA asymmetrical key pair is generated.

Restrictions: Hardware compatibility with FIPS

The S5200-EI-G switch series does not support FIPS.

Restrictions and guidelines: FIPS

Requirements for key pairs and passwords

Before you reboot the device to enter FIPS mode, the system automatically removes all key pairs configured in non-FIPS mode and all FIPS-incompliant digital certificates. FIPS-incompliant digital certificates are MD5-based certificates with a key modulus length less than 2048 bits. You cannot log in to the device through SSH after the device enters FIPS mode. To log in to the device in FIPS mode through SSH, log in to the device through a console port and create a key pair for the SSH server.

The password for entering the device in FIPS mode must comply with the password control policies, such as password length, complexity, and aging policy. When the aging timer for a password expires, the system prompts you to change the password. If you adjust the system time after the device enters FIPS mode, the login password might expire before the next login, because the original system time is typically much earlier than the actual time.

Configuration rollback guidelines

Configuration rollback is supported in FIPS mode and also during a switch between FIPS mode and non-FIPS mode. After a configuration rollback between FIPS mode and non-FIPS mode, perform the following tasks:

1. Delete the local user and configure a new local user. Local user attributes include password, user role, and service type.
2. Save the current configuration file.
3. Specify the current configuration file as the startup configuration file.
4. Reboot the device. The new configuration takes effect after the reboot. During this process, do not exit the system or perform other operations.

If a device enters FIPS or non-FIPS mode through automatic reboot, configuration rollback fails. To support configuration rollback, you must execute the **save** command after the device enters FIPS or non-FIPS mode.

IRF compatibility

All devices in an IRF fabric must be operating in the same mode, whether in FIPS mode or non-FIPS mode.

To enable FIPS mode for an IRF fabric, you must reboot the entire IRF fabric.

Feature changes in FIPS mode

After the system enters FIPS mode, the following feature changes occur:

- The user login authentication mode can only be scheme.
- The FTP/TFTP server and client are disabled.
- The Telnet server and client are disabled.
- The HTTP server is disabled.

- SNMPv1 and SNMPv2c are disabled. Only SNMPv3 is available.
- The SSL server supports only TLS1.0, TLS1.1, and TLS1.2.
- The SSH server does not support SSHv1 clients or DSA key pairs.
- The generated RSA and DSA key pairs must have a modulus length of 2048 bits.

  When the device acts as a server to authenticate a client through the public key, the key pair for the client must also have a modulus length of 2048 bits.
- The generated ECDSA key pairs must have a modulus length of more than 256 bits.

  When the device acts as a server to authenticate a client through the public key, the key pair for the client must also have a modulus length of more than 256 bits.
- SSH, SNMPv3, IPsec, and SSL do not support DES, 3DES, RC4, or MD5.
- The password control feature cannot be disabled globally. The **`undo password-control enable`** command does not take effect.
- An AAA shared key, IKE pre-shared key, or SNMPv3 authentication key must have at least 15 characters and must contain uppercase and lowercase letters, digits, and special characters.
- The password for a device management local user and password for switching user roles must comply with the password control policies. By default, the password must have at least 15 characters and must contain uppercase and lowercase letters, digits, and special characters.

Entering FIPS mode

About entering FIPS mode

For the device to enter FIPS mode, you can use one of the following methods:

- **Automatic reboot**—The system automatically performs the following operations:
  a. Prompts you to specify the username and password for the next login.
  b. Creates a default FIPS configuration file named **fips-startup.cfg**.
  c. Specifies the default FIPS configuration file as the startup configuration file.
  d. Reboots and loads the default FIPS configuration file to enter the FIPS mode.
- **Manual reboot**—You must complete the required configuration tasks and reboot the device manually.

Restrictions and guidelines

After you execute the **`fips mode enable`** command, the system prompts you to choose a reboot method.

- If you do not make a choice within 30 seconds or press **Ctrl**+**C**, the system enables FIPS mode and waits for you to manually complete the FIPS mode configuration tasks. You must complete

the tasks or execute the **undo fips mode enable** command before saving the running configuration and rebooting the device.

- If you select the automatic reboot method, you can press **Ctrl**+**C** to abort both the interactive FIPS mode configuration process and the **fips mode enable** command.

Using the automatic reboot method to enter FIPS mode

Prerequisites

To ensure login password effectiveness under the password control policies, set the correct system time.

Procedure

1. **Enter system view.**

   system-view

   - Enable FIPS mode.

     fips mode enable

     By default, the FIPS mode is disabled.

   - After the reboot method choice prompt appears, enter **Y** within 30 minutes.

     The system starts the interactive FIPS mode configuration process.

CAUTION:
System reboot might interrupt ongoing services. Please perform the previous operations with caution.

   - Enter the login username and password as prompted.

     The password must have a minimum of 15 characters and must contain uppercase and lowercase letters, digits, and special characters. After you enter the username and password, the device performs the following operations:

1. Creates a device management local user that uses the entered username and password.
2. Assigns the user the terminal service and the network-admin user role.
3. Saves the running configuration and specifies the configuration file as the startup configuration file.
4. Reboots, loads the startup configuration file, and enters FIPS mode.

To log in to the device, you must enter the configured username and password. After login, you are identified as the FIPS mode crypto officer.

a Using the manual reboot method to enter FIPS mode

Prerequisites

1. **To ensure login password effectiveness under the password control policies, set the correct system time.**

Configure the password control feature.

Enable the password control feature globally.

Configure password control policies.

2. Set the number of character types a password must contain to 4.
3. Set the minimum number of characters for each type to one character.
4. Set the minimum length for a user password to 15 characters.

For more information about the password control feature, see password control in *Security Configuration Guide*.

Configure a local user.

5. Create a device management local user.
6. Specify a password that complies with the password control policies.
7. Assign the terminal service to the user.
8. Assign the network-admin user role to the user.

Procedure

1. **Enter system view.**

```
system-view
```

Enable FIPS mode.

```
fips mode enable
```

By default, the FIPS mode is disabled.

After the reboot method choice prompt appears, enter **N**.

The system enables FIPS mode and waits for you to complete the FIPS mode configuration tasks. Before rebooting the device to enter FIPS mode, do not execute any commands except for **save** and commands used to prepare for entering FIPS mode. If you execute any other commands, the commands might not take effect.

CAUTION:

1. When you enable or disable FIPS mode, the system prompts you to select the reboot method before it reboots. System reboot might interrupt ongoing services. Perform this operation with caution.
2. If you select the manual reboot method to enable FIPS mode, you must manually complete the

configurations for entering FIPS mode. Otherwise, you cannot log in to the system correctly.

Save the running configuration and specify the configuration file as the startup configuration file.

Delete the .mdb startup configuration file.

When loading a .mdb configuration file, the device loads all settings in the file. The settings that are not supported in FIPS mode might affect device operation.

Reboot the device.

The device reboots, loads the startup configuration file, and enters FIPS mode. To log in to the device, you must enter the configured username and password. After login, you are identified as the FIPS mode crypto officer.

Manually triggering self-tests

About this task

You can manually trigger FIPS self-tests to verify operation of cryptography modules anytime as required. The triggered self-tests are the same as the power-up self-tests.

Procedure

1. **Enter system view.**

```
system-view
```

Table 2 Trigger self-tests.

```
fips self-test
```

CAUTION:
A successful self-test requires that all cryptographic algorithms pass the self-test. If the self-test fails, the device where the self-test process exists reboots.

1. Exiting FIPS mode

1. About this task

After you disable FIPS mode and reboot the device, the device operates in non-FIPS mode.

For the device to exit FIPS mode, you can use one of the following reboot methods:

2. **Automatic reboot**—The system automatically creates a default non-FIPS configuration file named **non-fips-startup.cfg**, specifies the file as the startup configuration file, and reboots to enter non-FIPS mode. You can log in to the device without providing username or password.

3. **Manual reboot**—You must manually complete the configuration tasks for entering non-FIPS mode, and then reboot the device. To log in to the device after the reboot, you must enter user information as required by the authentication mode settings.

   The following are the default authentication mode settings:

   1. **VTY line**—Password authentication.
      - **AUX line**—Authentication is disabled.

   You can modify the authentication settings as needed.

   1. Using the automatic reboot method to exit FIPS mode

   1. Enter system view.

   ```
   system-view
   ```

   2. Disable FIPS mode.

      ```
      undo fips mode enable
      ```

      By default, the FIPS mode is disabled.

   3. Select the automatic reboot method.

   CAUTION:
   System reboot might interrupt ongoing services. Please perform the previous operations with caution.

   2. Using the manual reboot method to exit FIPS mode

   1. Enter system view.

   ```
   system-view
   ```

   2. Disable FIPS mode.

      ```
      undo fips mode enable
      ```

      By default, the FIPS mode is disabled.

   3. Select the manual reboot method.

   CAUTION:
   System reboot might interrupt ongoing services. Please perform the previous operations with caution.

   4. Configure login authentication settings.

2. If you logged in to the device through SSH, perform the following tasks without disconnecting the current user line:

   1. Set the authentication mode to **scheme** for VTY lines.

2. Specify the username and password. If you do not specify the username or password, the device uses the current username and password.

3. If you logged in to the device through a console port, configure login authentication settings for the current type of user lines as described in the following table:

Current login method	Login authentication requirements
Scheme	Set the authentication to scheme and specify the username and password. If you do not specify the username or password, the device uses the current username and password.
Password	Set the authentication to password and specify the password. If you do not specify the password, the device uses the current password.
None	Set the authentication to none.

1. Save the running configuration and specify the file as the startup configuration file.
2. Delete the .mdb startup configuration file.
3. Reboot the device.

Display and maintenance commands for FIPS

Execute **display** commands in any view.

Task	Command
Display the version number of the device algorithm base.	**display crypto version**
Display the FIPS mode state.	**display fips status**

FIPS configuration examples

Example: Entering FIPS mode through automatic reboot

Network configuration

Use the automatic reboot method to enter FIPS mode, and use a console port to log in to the device in FIPS mode.

Procedure

If you want to save the current configuration, execute the **save** command before you enable FIPS mode.

Enable FIPS mode and choose the automatic reboot method to enter FIPS mode. Set the username to **root** and the password to **12345zxcvb!@#$%ZXCVB**.

```
<Sysname> system-view
[Sysname] fips mode enable
FIPS mode change requires a device reboot. Continue? [Y/N]:y
Reboot the device automatically? [Y/N]:y
The system will create a new startup configuration file for FIPS mode. After you set the login username and password for FIPS mode, the device will reboot automatically.
Enter username(1-55 characters):root
Enter password(15-63 characters):
Confirm password:
Waiting for reboot... After reboot, the device will enter FIPS mode.
```

Verifying the configuration

After the device reboots, enter a username of **root** and a password of **12345zxcvb!@#$%ZXCVB**. The system prompts you to configure a new password. After you configure the new password, the device enters FIPS mode. The new password must be different from the previous password. It must include at least 15 characters, and contain uppercase and lowercase letters, digits, and special characters. For more information about the requirements for the password, see the system output.

```
Press ENTER to get started.
login: root
Password:
First login or password reset. For security reason, you need to change your password. Please enter your password.
old password:
new password:
confirm:
Updating user information. Please wait ... ...
…
<Sysname>
```

Display the FIPS mode state.

```
<Sysname> display fips status
FIPS mode is enabled.
```

Display the default configuration file.

```
<Sysname> more fips-startup.cfg
#
 password-control enable
#
local-user root class manage
 service-type terminal
 authorization-attribute user-role network-admin
#
 fips mode enable
#
return

<Sysname>
```

Example: Entering FIPS mode through manual reboot

Network configuration

Use the manual reboot method to enter FIPS mode, and use a console port to log in to the device in FIPS mode.

Procedure

Enable the password control feature globally.

```
<Sysname> system-view
[Sysname] password-control enable
```

Set the number of character types a password must contain to 4, and set the minimum number of characters for each type to one character.

```
[Sysname] password-control composition type-number 4 type-length 1
```

Set the minimum length of user passwords to 15 characters.

```
[Sysname] password-control length 15
```

Add a local user account for device management, including a username of **test**, a password of **12345zxcvb!@#$%ZXCVB**, a user role of **network-admin**, and a service type of **terminal**.

```
[Sysname] local-user test class manage
[Sysname-luser-manage-test] password simple 12345zxcvb!@#$%ZXCVB
[Sysname-luser-manage-test] authorization-attribute user-role network-admin
[Sysname-luser-manage-test] service-type terminal
[Sysname-luser-manage-test] quit
```

Enable FIPS mode, and choose the manual reboot method to enter FIPS mode.

```
[Sysname] fips mode enable
FIPS mode change requires a device reboot. Continue? [Y/N]:y
Reboot the device automatically? [Y/N]:n
Change the configuration to meet FIPS mode requirements, save the configuration to the
next-startup configuration file, and then reboot to enter FIPS mode.
```

Save the current configuration to the root directory of the storage medium, and specify it as the startup configuration file.

```
[Sysname] save
The current configuration will be written to the device. Are you sure? [Y/N]:y
Please input the file name(*.cfg)[flash:/startup.cfg]
(To leave the existing filename unchanged, press the enter key):
flash:/startup.cfg exists, overwrite? [Y/N]:y
Validating file. Please wait...
Saved the current configuration to mainboard device successfully.
[Sysname] quit
```

Delete the startup configuration file in binary format.

```
<Sysname> delete flash:/startup.mdb
Delete flash:/startup.mdb?[Y/N]:y
Deleting file flash:/startup.mdb...Done.
```

Reboot the device.

```
<Sysname> reboot
```

Verifying the configuration

After the device reboots, enter a username of **test** and a password of **12345zxcvb!@#$%ZXCVB**. The system prompts you to configure a new password. After you configure the new password, the device enters FIPS mode. The new password must be different from the previous password. It must include at least 15 characters, and contain uppercase and lowercase letters, digits, and special characters. For more information about the requirements for the password, see the system output.

```
Press ENTER to get started.
login: test
Password:
First login or password reset. For security reason, you need to change your pass
word. Please enter your password.
old password:
new password:
confirm:
Updating user information. Please wait ... ...
…
<Sysname>
```

Display the FIPS mode state.

```
<Sysname> display fips status
FIPS mode is enabled.
```

Example: Exiting FIPS mode through automatic reboot

Network configuration

After logging in to the device in FIPS mode through a console port, use the automatic reboot method to exit FIPS mode.

Procedure

Disable FIPS mode.

```
[Sysname] undo fips mode enable
FIPS mode change requires a device reboot. Continue? [Y/N]:y
The system will create a new startup configuration file for non-FIPS mode and then reboot
automatically. Continue? [Y/N]:y
Waiting for reboot... After reboot, the device will enter non-FIPS mode.
```

Verifying the configuration

After the device reboots, you can enter the system.

```
<Sysname>
```

Display the FIPS mode state.

```
<Sysname> display fips status
FIPS mode is disabled.
```

Example: Exiting FIPS mode through manual reboot

Network configuration

After logging in to the device in FIPS mode through the console port with username **test** and password **12345zxcvb!@#$%ZXCVB**, use the manual reboot method to exit FIPS mode.

Procedure

Disable FIPS mode.

```
[Sysname] undo fips mode enable
FIPS mode change requires a device reboot. Continue? [Y/N]:y
The system will create a new startup configuration file for non-FIPS mode, and then reboot automatically. Continue? [Y/N]:n
Change the configuration to meet non-FIPS mode requirements, save the configuration to the next-startup configuration file, and then reboot to enter non-FIPS mode.
```

Save the current configuration to the root directory of the storage medium, and specify it as the startup configuration file.

```
[Sysname] save
The current configuration will be written to the device. Are you sure? [Y/N]:y
Please input the file name(*.cfg)[flash:/startup.cfg]
(To leave the existing filename unchanged, press the enter key):
flash:/startup.cfg exists, overwrite? [Y/N]:y
Validating file. Please wait...
Saved the current configuration to mainboard device successfully.
[Sysname] quit
```

Delete the startup configuration file in binary format.

```
<Sysname> delete flash:/startup.mdb
Delete flash:/startup.mdb?[Y/N]:y
Deleting file flash:/startup.mdb...Done.
```

Reboot the device.

```
<Sysname> reboot
```

Verifying the configuration

After the device reboots, authentication is disabled for console login by default. You can press **Enter** to enter non-FIPS mode without authentication.

```
Press ENTER to get started.
login: test
Password:
Last successfully login time:…
…
<Sysname>
```

Display the FIPS mode state.

```
<Sysname> display fips status
FIPS mode is disabled.
```

Configuring MACsec

About MACsec

Media Access Control Security (MACsec) secures data communication on IEEE 802 LANs. MACsec provides services such as data encryption, frame integrity check, and data origin validation for frames on the MAC sublayer of the Data Link Layer.

Basic concepts

MKA

MACsec Key Agreement (MKA) protocol is used for encryption key negotiation.

CA

Connectivity association (CA) is a group of participants that use the same key and key algorithm.

CAK

The key used by the CA participants is called a connectivity association key (CAK). The CAK is not directly used for data packet encryption. It and other parameters generate the encryption key. A CAK can be a key generated during 802.1X authentication or a user-configured preshared key. The user-configured preshared key takes precedence over the 802.1X-generated key.

The following types of CAKs are available:

- **Pairwise CAK**—Used by CAs that have two participants.
- **Group CAK**—Used by CAs that have more than two participants.

The pairwise CAK is used most often because MACsec is typically applied to point-to-point networks.

CKN

Connectivity Association Key Name (CKN) is the name of a CAK.

SC

Security Channel (SC) transmits secure data between CA participants.

SCI

Security Channel Identifier (SCI) includes the MAC address and ID of a port, which uniquely identifies an SC.

SA

Secure association (SA) is an agreement negotiated by CA participants. The agreement includes a cipher suite and keys for integrity check.

SAK

Security Association Key (SAK) is generated from the CAK based on an algorithm, which encrypts data transmitted along the SC. An SC can contain multiple SAs, and each SA uses a unique SAK.

MKA limits the number of packets that can be encrypted by an SAK. When the limit is exceeded, the SAK will be refreshed. For example, when packets with the minimum size are sent on a 10 Gbps link, an SAK rekey occurs about every 300 seconds.

ICV

The packet sender calculates an Integrity Check Value (ICV) from packet data units by using an algorithm and includes the ICV in the frame trailer. The packet receiver recalculates an ICV and compares the calculated ICV with the ICV in the frame trailer to check packet data integrity.

Security mechanisms

Data encryption

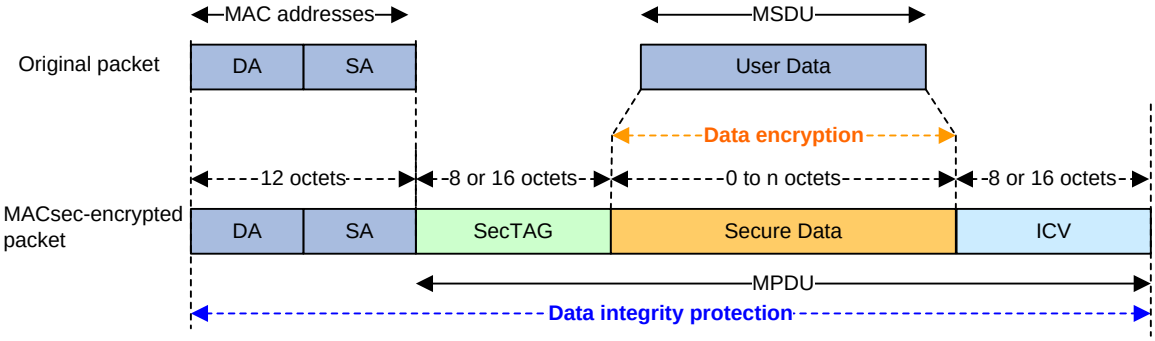
MACsec enables a port to encrypt outbound frames and decrypt MACsec-encrypted inbound frames. The keys for encryption and decryption are negotiated by MKA.

Integrity check

MACsec performs integrity check when the device receives a MACsec-encrypted frame. The integrity check uses the following process:

- Uses a key negotiated by MKA to calculate an ICV for the frame.
- Compares the calculated ICV with the ICV in the frame trailer.
  - If the ICVs are the same, the device verifies the frame as legal.
  - If the ICVs are different, the device determines whether to drop the frame based on the validation mode. The device supports the following validation modes:
    - **check**—Performs validation only, and does not drop illegal frames.
    - **disabled**—Does not perform validation.
    - **strict**—Performs validation, and drops illegal frames.

Replay protection



When MACsec frames are transmitted over the network, frame disorder might occur. MACsec replay protection allows the device to accept the out-of-order packets within the replay protection window size and drop other out-of-order packets. Suppose the replay protection window size is **a** on a port. After the port receives a packet with PN **x**, it can accept only packets whose PN is greater than or equal to **x-a**.

Packet structure

After SAK negotiation and installation between CA participants are completed, the negotiated key will be used for data packet forwarding.

- The data packet sender performs the following tasks:
  a. Uses an SAK and an encryption algorithm to encrypt the MAC Service Data Unit (MSDU) of the original packet. The encrypted part is called secure data.
  b. Uses the SAK and a validity algorithm to calculate an ICV from the source MAC address, destination MAC address, SecTAG, and secure data, and then includes the ICV in the packet trailer.
  c. Sends the complete MACsec-encrypted packet to the peer end.
- The packet receiver performs the following tasks:
  d. Uses the SAK and a decryption algorithm to obtain the plaintext from the encrypted packet.
  e. Uses a validity algorithm to calculate an ICV, and compares the calculated ICV with the ICV in the packet trailer. If the ICVs are the same, the packet has not been modified.

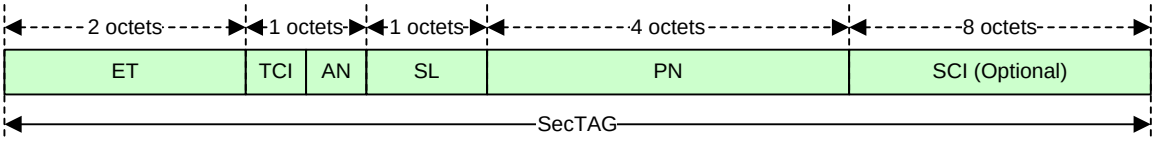


Figure 1 MACsec-encrypted packet

A MACsec-encrypted packet has the following key fields:

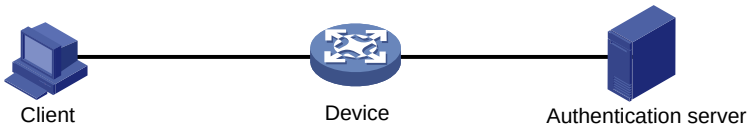
- **DA**—Destination MAC address in the packet. The length is 6 bytes.
- **SecTAG**—Security tag. The length is 8 or 16 bytes.
- **Secure Data**—Packet payload after MACsec encryption. MACsec can encrypt only the bytes after the MACsec confidentiality offset in a frame. The offset value can be 0, 30, or 50.
- **ICV**—Integrity check value. The length is 8 to 16 bytes. If a packet has been tampered with, the ICV value will change. This protects the packet from malicious modification.

Figure 2 SecTAG field

- **Ethertype (ET)**—Ethernet type of the MACsec protocol. The length is 2 bytes and the value is 0x88E5.
- **TAG control information (TCI)**—Provides information including the MACsec version number, whether the packet has been encrypted, whether integrity calculation has been performed, and whether the packet trailer carries an ICV. The length is 6 bits.
- **Association Number (AN)**—Number of an SA in the SC that transmits the packet. The length is 2 bits. An SC can include four SAs.
- **Short Length (SL)**—The length is 1 byte. If the length of the **Secure Data** field is less than 48 bytes, the value for this field is the length of **Secure Data** field. if the length of the **Secure Data** field is greater than 48 bytes, the value for this field is 0.
- **Packet Number (PN)**—Number of the packet. The length is 4 bytes. Every time the packet sender sends a packet, the value for this field increases by 1 to prevent packet replay attacks.
- **Secure Channel Identifier (SCI)**—8-byte identifier for the SC, including a 6-byte MAC address and a 2-byte port number.

MACsec application modes

MACsec supports client-oriented and device-oriented modes.



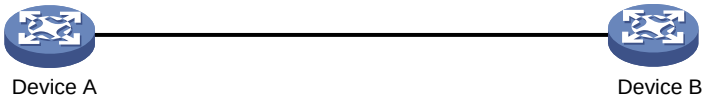
Client-oriented mode

As shown in Figure 3, MACsec secures data transmission between the client and the access device. In this mode, MACsec must operate with 802.1X authentication.

Client-oriented MACsec includes the following entities:

- **Client (supplicant)**—A user terminal seeking access to the LAN or a device that supports the 802.1X client feature. The terminal must have 802.1X software to authenticate to the access device. The terminal also performs CAK negotiation and packet encryption.
- **Access device (authenticator)**—Authenticates the client to control access to the LAN and performs CAK negotiation and packet encryption.
- **Authentication server**—Provides AAA services for the access device. The authentication server is typically a RADIUS server. After the client passes authentication, the authentication server generates and distributes the CAK to the client and the access device.

Figure 3 Client-oriented mode



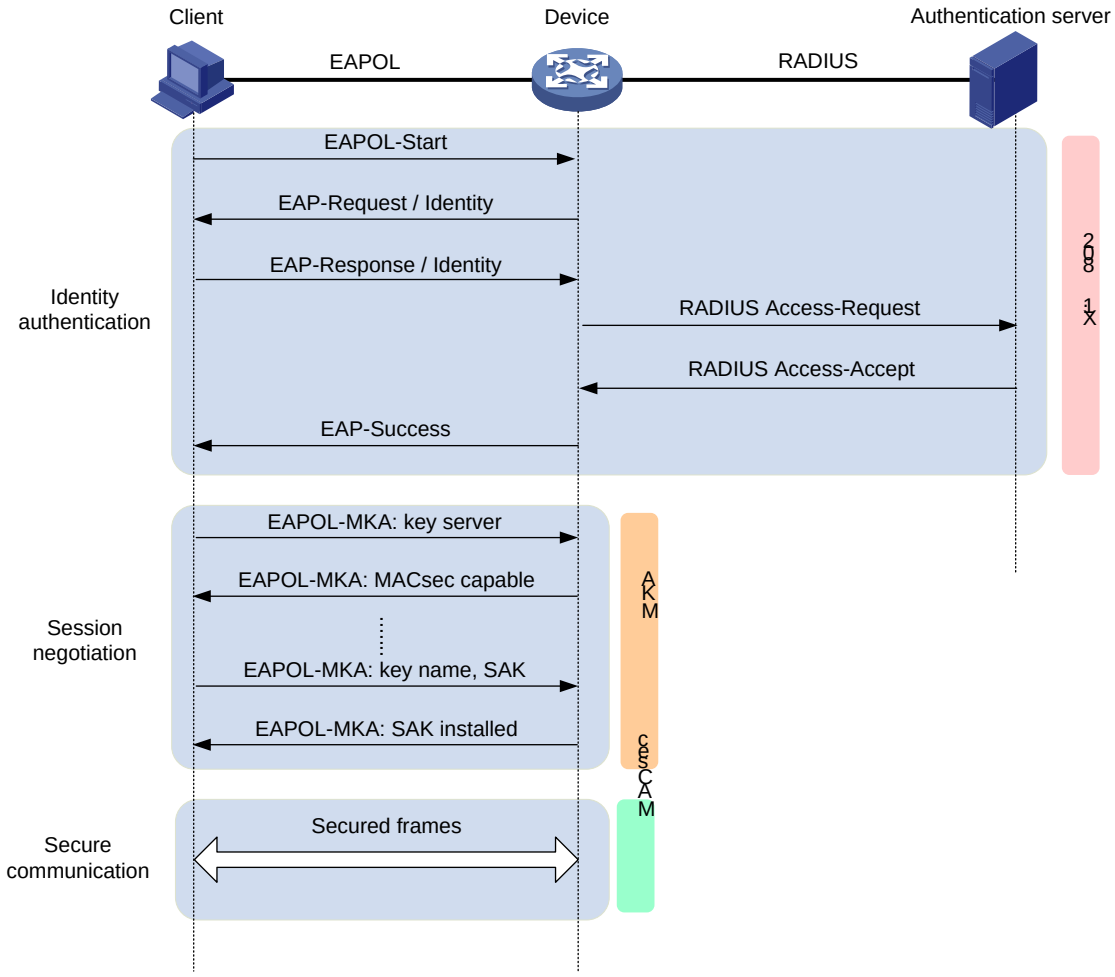
NOTE:

In client-oriented mode, an MKA-enabled port on the access device must perform port-based 802.1X access control. The authentication method must be EAP relay.

Device-oriented mode

As shown in Figure 4, MACsec secures data transmission between devices. In this mode, the same preshared key must be configured on the MACsec ports that connect the devices. The devices use the configured preshared key as the CAK.

Figure 4 Device-oriented mode

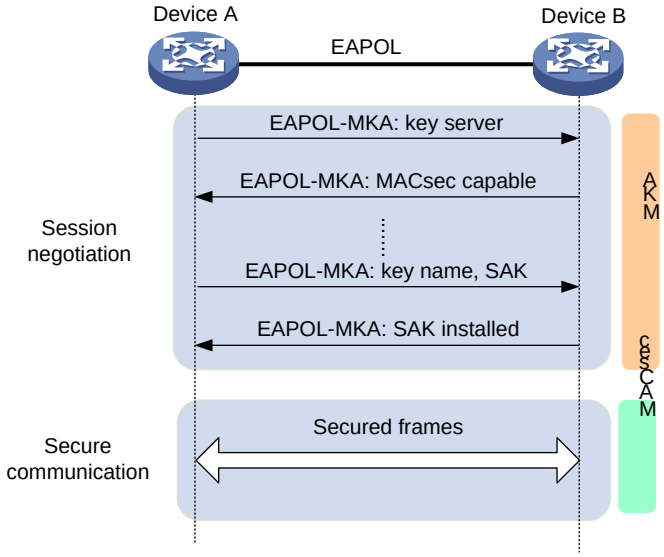


MACsec operating mechanism

Operating mechanism for client-oriented mode

Figure 5 illustrates how MACsec operates in client-oriented mode.

Figure 5 MACsec interactive process in client-oriented mode



The following shows the MACsec process:

2. After the client passes 802.1X authentication, the RADIUS server distributes the generated CAK to the client and the access device.
3. After receiving the CAK, the client and the access device exchange EAPOL-MKA packets.
4. The client and the access device exchange the MACsec capability and required parameters for session establishment. The parameters include MKA key server priority and MACsec desire.
5. During the negotiation process, the access device with a higher priority automatically becomes the key server.
6. The key server generates an SAK from the CAK for packet encryption, and it distributes the SAK to the client.
7. The client and the access device use the SAK to encrypt packets, and they send and receive the encrypted packets in secure channels.
8. When the access device receives a logoff request from the client, it immediately removes the associated secure session from the port. The remove operation prevents an unauthorized client from using the secure session established by the previous authorized client to access the network.

Operating mechanism for device-oriented mode

As shown in Figure 6, the devices use the configured preshared key to start session negotiation.

Figure 6 MACsec interactive process in device-oriented mode

The following shows the MACsec process:

2. The devices use the configured preshared key as the CAK to exchange EAPOL-MKA packets.
3. The devices exchange the MACsec capability and required parameters for session establishment. The parameters include MKA key server priority and MACsec desire.
4. During the negotiation process, the port with higher MKA key server priority becomes the key server. The key server generates and distributes an SAK.
5. The devices use the SAK to encrypt packets, and they send and receive the encrypted packets in secure channels.
6. When a device receives a logoff request from the peer, it immediately deletes the associated secure session.

Protocols and standards

IEEE 802.1X-2010, *Port-Based Network Access Control*

IEEE 802.1AE-2006, *Media Access Control (MAC) Security*

Restrictions and guidelines: MACsec configuration

To avoid packet dropping, make sure MACsec traffic speed is below 100 Gbps.

You can enable MACsec on a maximum of 32 ports.

If you enable MKA on multiple ports in a serpentine topology, one port will occupy two encryption/decryption hardware resources, and one of these resources will be deleted by the platform later. The current number of encryption/decryption hardware resources is 32. Therefore, in a serpentine network, you can enable MKA on a maximum of 16 ports simultaneously. If this number is exceeded, channels cannot be created until other ports release encryption/decryption hardware resources.

Before the MACsec encryption/decryption channel is stable, traffic might not be forwarded normally.

If ports belong to the same VLAN, you can enable MACsec for a maximum of 5 ports in bulk when establishing channels between each two ports.

MACsec tasks at a glance

To configure MACsec, perform the following tasks:

1. Configuring basic MACsec parameters
   - Enabling MKA
   - Enabling MACsec desire
   - Specifying the cipher suite for MACsec encryption

     This task is applicable only to device-oriented mode.
   - Configuring a preshared key

     This task is required in device-oriented mode. Do not perform this task in client-oriented mode.
2. (Optional.) Configuring extended MACsec features
   - Configuring the MKA key server priority
   - Setting the MKA life time

     This task is applicable only in device-oriented mode.
   - Configuring MACsec protection parameters

     Choose one of the following tasks:
     - Configuring MACsec protection parameters in interface view
     - Configuring MACsec protection parameters by MKA policy
   - Enabling inclusion of the SCI in the SecTAG field of MACsec frames on an interface
   - Enabling MACsec maintenance mode on an interface
   - Enabling MKA session logging

Enabling MKA

About this task

MKA establishes and manages MACsec secure channels on a port. It also negotiates keys used by MACsec.

Procedure

1. Enter system view.

   `system-view`
2. Enter interface view.

   `interface` *`interface-type interface-number`*
3. Enable MKA.

   `mka enable`

   By default, MKA is disabled on the port.

Enabling MACsec desire

About this task

The MACsec desire feature expects MACsec protection for outbound frames. The key server determines whether MACsec protects the outbound frames.

MACsec protects the outbound frames of a port when the following requirements are met:

- The key server is MACsec capable.
- Both the local participant and its peer are MACsec capable.
- A minimum of one participant is enabled with MACsec desire.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable MACsec desire.
   macsec desire
   By default, the port does not expect MACsec protection for outbound frames.

Specifying the cipher suite for MACsec encryption

About this task

MACsec uses the GCM-AES-128, GCM-AES-256, GCM-AES-XPN-128, or GCM-AES-XPN-256 cipher suite to encrypt, validate, and decrypt protected data frames.

H3C's implementations of GCM-AES-256 and GCM-AES-XPN-256 cipher suites differ from their standard open source counterparts. To successfully establish MKA sessions with a peer that uses the standard open source GCM-AES-256 or GCM-AES-XPN-256 cipher suite, you must specify the standard cipher suite for MACsec encryption.

Restrictions and guidelines

This feature is supported only in device-oriented mode. Do not configure this feature on an 802.1X-enabled port.

Make sure the connected MACsec ports are configured with the same cipher suite. If the ports are configured with different cipher suites, they cannot successfully establish MKA sessions.

Specifying the cipher suite for MACsec encryption (interface view)

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify the cipher suite for MACsec encryption.
   macsec cipher-suite { **gcm-aes-128** | **gcm-aes-256** [**standard**] | **gcm-aes-xpn-128** | **gcm-aes-xpn-256** [**standard**] }
   By default, MACsec uses the GCM-AES-128 cipher suite for encryption.

Configuring a preshared key

Restrictions and guidelines

In device-oriented mode, configure a preshared key as the CAK. To successfully establish an MKA session between two devices, make sure the following requirements are met:

- The connected MACsec ports are configured with the same CAK name (CKN) and CAK.
- Only the ports are configured with the same CKN in the network.

A user-configured preshared key has higher priority than the 802.1X-generated CAK. To ensure a successful MKA session establishment, do not configure a preshared key in client-oriented mode.

Different cipher suites for MACsec encryption have different requirements for the CKN and CAK configuration.

- The GCM-AES-128 or GCM-AES-XPN-128 cipher suite requires that the CKN and CAK each must be 32 characters long. If the configured CKN or CAK is not 32 characters long, the system performs the following operations when it runs the cipher suite:
  - Automatically increases the length of the CKN or CAK by zero padding if the CKN or CAK contains less than 32 characters.
  - Uses only the first 32 characters if the CKN or CAK contains more than 32 characters.
- The GCM-AES-256 or GCM-AES-XPN-256 cipher suite requires that the CKN and CAK each must be 64 characters long. If the configured CKN or CAK contains less than 64 characters, the system automatically increases the length of the CKN or CAK by zero padding when it runs the cipher suite.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Set a preshared key.

   mka psk ckn *name* **cak** { **cipher** | **simple** } *string*

   By default, no MKA preshared key exists.

Configuring the MKA key server priority

Restrictions and guidelines

When you configure the MKA key server priority, follow these restrictions and guidelines:

- In client-oriented mode, the access device port automatically becomes the key server. You do not have to configure the MKA key server priority.
- In device-oriented mode, the port that has higher priority becomes the key server. The lower the priority value, the higher the priority. If a port and its peers have the same priority, MACsec compares the secure channel identifier (SCI) values on the ports. The port with the lowest SCI value (a combination of MAC address and port ID) becomes the key server.
- A port with priority 255 cannot become the key server. For a successful key server selection, make sure a minimum of one participant's key server priority is not 255.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Set the MKA key server priority.

   mka priority *priority-value*

   The default setting is 0.

Setting the MKA life time

Restrictions and guidelines

This task is applicable only in device-oriented mode.

Make sure the participants at each end of a secure session have the same MKA life time.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the MKA life time.
   mka timer mka-life *seconds*
   By default, the MKA life time is 6 seconds.

Configuring MACsec protection parameters

About MACsec protection parameters

You can set the following MACsec protection parameters:

- **MACsec confidentiality offset**—Specifies the number of bytes starting from the frame header. MACsec encrypts only the bytes after the offset in a frame. The offset value can be 0, 30, or 50.
- **MACsec replay protection**—Allows a MACsec port to accept a number of out-of-order or repeated inbound frames.
- **MACsec validation**—Allows a port to perform integrity check based on the validation modes.

Restrictions and guidelines for MACsec protection parameter configuration

You can configure MACsec protection parameters either in interface view or through MKA policies.

The use of MKA policies provides a centralized method to configure MACsec protection parameters. When you need to configure the same settings for MACsec protection parameters on multiple ports, you can configure them in an MKA policy and apply the policy to the ports.

If you configure a protection parameter in interface view after applying an MKA policy, the configuration in interface view overwrites the configuration of that parameter in the MKA policy. The other protection parameters in the MKA policy still take effect.

If you apply an MKA policy to a port after configuring protection parameters on the port, the settings in the policy overwrite all protection parameter settings in interface view. The protection parameters not configured in the policy are restored to the default.

The configured MACsec confidentiality offset does not take effect on the GCM-AES-XPN-128 or GCM-AES-XPN-256 cipher suite. The confidentiality offset is fixed at 0 for these two suites.

Configuring MACsec protection parameters in interface view

1. Enter system view.
   system-view

2. Enter interface view.
   interface *interface-type interface-number*
3. Set the MACsec confidentiality offset.
   macsec confidentiality-offset *offset-value*
   The default setting is 0, and the entire frame needs to be encrypted.
   MACsec uses the confidentiality offset propagated by the key server.
4. Configure MACsec replay protection:
   a. Enable MACsec replay protection.
      macsec replay-protection enable
      By default, MACsec replay protection is enabled on the port.
   b. Set the MACsec replay protection window size.
      macsec replay-protection window-size *size-value*
      The default setting is 0. The device accepts only frames that arrive in the correct order. Out-of-order or duplicated frames will be dropped.
      The configured replay protection window size takes effect only when MACsec replay protection is enabled.
5. Set a MACsec validation mode.
   macsec validation mode { **check** | **disabled** | **strict** }
   The default setting is **check**.
   To avoid data loss, use the **display macsec** command to verify that MKA negotiation with the peer device has succeeded before you change the mode to **strict**.

Parameter	Description
check	Verifies incoming frames but does not drop illegal frames.
disabled	Disables MACsec validation for incoming frames.
strict	Verifies incoming frames and drops illegal frames.

Configuring MACsec protection parameters by MKA policy

Restrictions and guidelines

An MKA policy can be applied to a port or multiple ports. When you apply an MKA policy to a port, follow these restrictions and guidelines:

- The settings in the MKA policy overwrite all protection parameter settings configured in interface view. The protection parameters not configured in the policy are restored to the default.
- Any modifications to the MKA policy take effect immediately.
- When you remove an MKA policy application from the port, the MACsec parameter settings on the port restore to the default.
- When you apply a nonexistent MKA policy to the port, the port automatically uses the system-defined MKA policy named **default-policy**. If you create the policy, the policy will be automatically applied to the port.
- The configured MACsec confidentiality offset does not take effect on the GCM-AES-XPN-128 or GCM-AES-XPN-256 cipher suite. The confidentiality offset is fixed at 0 for these two suites.

Procedure

1. Enter system view.

system-view

2. Create an MKA policy and enter its view.

   mka policy *policy-name*

   By default, a system-defined MKA policy exists. The policy name is **default-policy**.

   The settings for parameters in the system-defined policy are the same as the default settings for the parameters on a port.

   You cannot delete or modify the system-defined MKA policy.

   You can create multiple MKA policies.

3. Set the MACsec confidentiality offset.

   confidentiality-offset *offset-value*

   The default setting is 0, and the entire frame needs to be encrypted.

   MACsec uses the confidentiality offset propagated by the key server.

4. Configure MACsec replay protection:

   a. Enable MACsec replay protection.

      replay-protection enable

      By default, MACsec replay protection is enabled.

   b. Set the replay protection window size.

      replay-protection window-size *size-value*

      The default replay protection window size is 0. The device accepts only frames that arrive in the correct order. Out-of-order or duplicated frames will be dropped.

5. Set a MACsec validation mode.

   validation mode { **check** | **disabled** | **strict** }

   The default setting is **check**.

Parameter	Description
check	Verifies incoming frames but does not drop illegal frames.
disabled	Disables MACsec validation for incoming frames.
strict	Verifies incoming frames and drops illegal frames.

6. Apply an MKA policy:

   a. Return to system view.

      quit

   b. Enter interface view.

      interface *interface-type interface-number*

   c. Apply the MKA policy to the port.

      mka apply policy *policy-name*

      By default, no MKA policy is applied to a port.

Enabling inclusion of the SCI in the SecTAG field of MACsec frames on an interface

About this task

The secure channel identifier (SCI) identifies the source of a MACsec frame. It contains the MAC address and ID of the port that sends the frame.

To have an interface send encrypted MACsec frames with the SCI included in the SecTAG field, perform this task.

Restrictions and guidelines

To forward traffic between a pair of peer MACsec interfaces, you must make sure inclusion of the SCI in the SecTAG field is enabled or disabled on both of them.

Procedure

1. Enter system view.

   `system-view`
2. Enter interface view.

   `interface` *`interface-type interface-number`*
3. Enable inclusion of the SCI in the SecTAG field of MACsec frames sent out of the interface.

   `macsec include-sci`

   By default, a MACsec port sends MACsec frames with the SCI included in the SecTAG field.

Enabling MACsec maintenance mode on an interface

About this task

To protect data security, a MACsec port is blocked by default until it establishes an MKA session with its peer port. In blocked state, the MACsec port can send and receive MKA protocol packets, but it cannot send or receive data packets. On a network that uses a controller to deploy configuration, this might cause a configuration deployment failure if the configuration delivered to a device must traverse a MACsec port.

To make sure a device can always receive its configuration from a controller over the link between a pair of MACsec ports, enable MACsec maintenance mode on the MACsec ports. In this mode, a MACsec port is unblocked regardless of whether it has established an MKA session with its peer port.

For security purposes, a MACsec port in MACsec maintenance mode will still be blocked when it receives frames that contain its own SCI (identified by its MAC address and port ID).

A MACsec port in MACsec maintenance mode issues its SCI information only after it receives MKA protocol packets from its peer port.

Restrictions and guideline

△ **CAUTION:**

If you enable MACsec maintenance mode on an interface before it establishes an MKA session with its peer end, data frames are exposed to security risks. Before you perform this operation, make sure you fully understand this impact on security.

Prerequisites

Before you enable or disable MACsec maintenance mode on a MACsec port:

- Disable MKA on that port.
- Use the **link-delay down** command to increase the delay to report a link down event to CPU. Transient link state flapping might occur after you enable MACsec maintenance mode. This step prevents a link down event from causing MKA packet exchange failure during this period.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable MACsec maintenance mode.
   macsec maintenance-mode enable
   By default, MACsec maintenance mode is disabled.

CAUTION:
Enabling this feature before MKA session establishment reduces security of data packets. Please be cautious.

Enabling MKA session logging

About this task

This feature enables the device to generate logs for MKA session changes, such as peer aging and SAK updates. The logs are sent to the information center of the device. For the logs to be output correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

As a best practice, disable this feature to prevent excessive MKA session log output.

Procedure

1. Enter system view.
   system-view
2. Enable MKA session logging.
   macsec mka-session log enable
   By default, MKA session logging is disabled.

Display and maintenance commands for MACsec

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display MACsec information on ports.	**display macsec** [**interface** *interface-type interface-number*] [**verbose**]

Task	Command
Display MKA policy information.	**display mka** { **default-policy** | **policy** [**name** *policy-name*] }
Display MKA session information.	**display mka session** [**interface** *interface-type interface-number* | **local-sci** *sci-id*] [**verbose**]
Display MKA statistics on ports.	**display mka statistics** [**interface** *interface-type interface-number*]
Reset MKA sessions on ports.	**reset mka session** [**interface** *interface-type interface-number*]
Clear MKA statistics on ports.	**reset mka statistics** [**interface** *interface-type interface-number*]

MACsec configuration examples

Example: Configuring client-oriented MACsec (host as client)

Network configuration

As shown in Figure 7, the host accesses the network through GigabitEthernet 1/0/1. The device performs RADIUS-based 802.1X authentication for the host to control user access to the Internet.

To ensure secure communication between the host and device, perform the following tasks on the device:

- Enable MACsec desire, and configure MKA to negotiate SAKs for packet encryption.
- Set the MACsec confidentiality offset to 30 bytes.
- Enable MACsec replay protection, and set the replay protection window size to 100.
- Set the MACsec validation mode to **strict**.

Figure 7 Network diagram

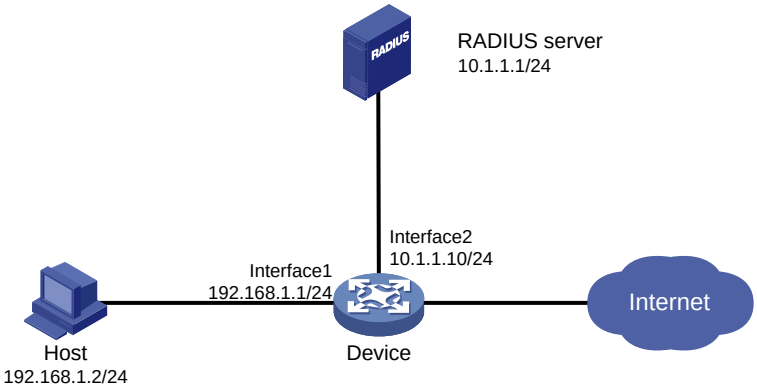


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure IP addresses for the Ethernet ports. (Details not shown.)
2. Configure the RADIUS server to provide authentication, authorization, and accounting services. Add a user account for the host. (Details not shown.)
3. Configure AAA:

   # Enter system view.

   ```
   <Device> system-view
   ```

   # Configure RADIUS scheme **radius1**.

   ```
   [Device] radius scheme radius1
   [Device-radius-radius1] primary authentication 10.1.1.1
   [Device-radius-radius1] primary accounting 10.1.1.1
   [Device-radius-radius1] key authentication simple name
   [Device-radius-radius1] key accounting simple name
   [Device-radius-radius1] user-name-format without-domain
   [Device-radius-radius1] quit
   ```

   # Configure authentication domain **bbb** for 802.1X users.

   ```
   [Device] domain bbb
   [Device-isp-bbb] authentication lan-access radius-scheme radius1
   [Device-isp-bbb] authorization lan-access radius-scheme radius1
   [Device-isp-bbb] accounting lan-access radius-scheme radius1
   [Device-isp-bbb] quit
   ```

4. Configure 802.1X:

   # Enable 802.1X on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] dot1x
   ```

   # Implement port-based access control on GigabitEthernet 1/0/1.

   ```
   [Device-GigabitEthernet1/0/1] dot1x port-method portbased
   ```

   # Specify **bbb** as the mandatory authentication domain for 802.1X users on GigabitEthernet 1/0/1.

   ```
   [Device-GigabitEthernet1/0/1] dot1x mandatory-domain bbb
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Enable 802.1X globally, and sets the device to relay EAP packets.

   ```
   [Device] dot1x
   [Device] dot1x authentication-method eap
   ```

5. Configure MACsec:

   # Create an MKA policy named **pls**.

   ```
   [Device] mka policy pls
   ```

   # Set the MACsec confidentiality offset to 30 bytes.

   ```
   [Device-mka-policy-pls] confidentiality-offset 30
   ```

   # Enable MACsec replay protection.

   ```
   [Device-mka-policy-pls] replay-protection enable
   ```

   # Set the MACsec replay protection window size to 100.

   ```
   [Device-mka-policy-pls] replay-protection window-size 100
   ```

   # Set the MACsec validation mode to **strict**.

   ```
   [Device-mka-policy-pls] validation mode strict
   [Device-mka-policy-pls] quit
   ```

Apply the MKA policy to GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] mka apply policy pls
```

Configure MACsec desire and enable MKA on GigabitEthernet 1/0/1.

```
[Device-GigabitEthernet1/0/1] macsec desire
[Device-GigabitEthernet1/0/1] mka enable
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Display MACsec information on GigabitEthernet 1/0/1.

```
[Device] display macsec interface gigabitethernet 1/0/1 verbose
Interface GigabitEthernet1/0/1

Example: Configuring device-oriented MACsec

Network configuration

As shown in Figure 8, Device A is the MACsec key server.

To secure data transmission between the two devices by MACsec, perform the following tasks on Device A and Device B, respectively:

- Set the MACsec confidentiality offset to 30 bytes.
- Enable MACsec replay protection, and set the replay protection window size to 100.
- Set the MACsec validation mode to **strict**.
- Configure the CAK name (CKN) and the CAK as **E9AC** and **09DB3EF1**, respectively.

Figure 8 Network diagram

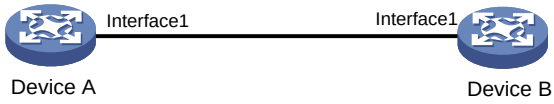

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

1. Configure Device A:

   # Enter system view.

   ```
   <DeviceA> system-view
   ```

   # Enter GigabitEthernet 1/0/1 interface view.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   ```

   # Enable MACsec desire on GigabitEthernet 1/0/1.

   ```
   [DeviceA-GigabitEthernet1/0/1] macsec desire
   ```

   # Set the MKA key server priority to 5.

   ```
   [DeviceA-GigabitEthernet1/0/1] mka priority 5
   ```

   # Configure the CKN as **E9AC** and the CAK as **09DB3EF1** in plain text.

   ```
   [DeviceA-GigabitEthernet1/0/1] mka psk ckn E9AC cak simple 09DB3EF1
   ```

   # Set the MACsec confidentiality offset to 30 bytes.

   ```
   [DeviceA-GigabitEthernet1/0/1] macsec confidentiality-offset 30
   ```

   # Enable MACsec replay protection.

   ```
   [DeviceA-GigabitEthernet1/0/1] macsec replay-protection enable
   ```

Set the MACsec replay protection window size to 100.

```
[DeviceA-GigabitEthernet1/0/1] macsec replay-protection window-size 100
```

Set the MACsec validation mode to **strict**.

```
[DeviceA-GigabitEthernet1/0/1] macsec validation mode strict
```

Enable MKA on GigabitEthernet 1/0/1.

```
[DeviceA-GigabitEthernet1/0/1] mka enable
[DeviceA-GigabitEthernet1/0/1] quit
```

2. Configure Device B:

Enter system view.

```
<DeviceB> system-view
```

Enter GigabitEthernet 1/0/1 interface view.

```
[DeviceB] interface gigabitethernet 1/0/1
```

Enable MACsec desire on GigabitEthernet 1/0/1.

```
[DeviceB-GigabitEthernet1/0/1] macsec desire
```

Set the MKA key server priority to 10.

```
[DeviceB-GigabitEthernet1/0/1] mka priority 10
```

Configure the CKN as **E9AC** and the CAK as **09DB3EF1** in plain text.

```
[DeviceB-GigabitEthernet1/0/1] mka psk ckn E9AC cak simple 09DB3EF1
```

Set the MACsec confidentiality offset to 30 bytes.

```
[DeviceB-GigabitEthernet1/0/1] macsec confidentiality-offset 30
```

Enable MACsec replay protection.

```
[DeviceB-GigabitEthernet1/0/1] macsec replay-protection enable
```

Set the MACsec replay protection window size to 100.

```
[DeviceB-GigabitEthernet1/0/1] macsec replay-protection window-size 100
```

Set the MACsec validation mode to **strict**.

```
[DeviceB-GigabitEthernet1/0/1] macsec validation mode strict
```

Enable MKA on GigabitEthernet 1/0/1.

```
[DeviceB-GigabitEthernet1/0/1] mka enable
[DeviceB-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Display MACsec information on GigabitEthernet 1/0/1 of Device A.

```
[DeviceA] display macsec interface gigabitethernet 1/0/1 verbose

Troubleshooting MACsec

Cannot establish MKA sessions between MACsec devices

Symptom

The devices cannot establish MKA sessions when the following conditions exist:

- The link connecting the devices is up.
- The ports at the ends of the link are MACsec capable.

Analysis

The symptom might occur for the following reasons:

- The ports at the link are not enabled with MKA.
- A port at the link is not configured with a preshared key or configured with a preshared key different from the peer.

Solution

To resolve the issue:

1. Enter interface view.
2. Use the **display this** command to check the MACsec configuration:
   - If MKA is not enabled on the port, execute the **mka enable** command.
   - If a preshared key is not configured or the preshared key is different from the peer, use the **mka psk** command to configure a preshared key. Make sure the preshared key is the same as the preshared key on the peer.
3. If the issue persists, contact H3C Support.

Preface

This configuration guide describes the high availability fundamentals and configuration procedures. The high availability technologies include fault detection and fault failover. Failure detection technologies focus on fault detection and isolation. Failover technologies focus on network recovery.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** >

Convention	Description
	Folder.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

Configuring DLDP

About DLDP

Physical layer detection mechanisms, such as auto-negotiation, can detect physical signals and faults. However, they cannot detect communication failures for unidirectional links where the physical layer is in connected state.

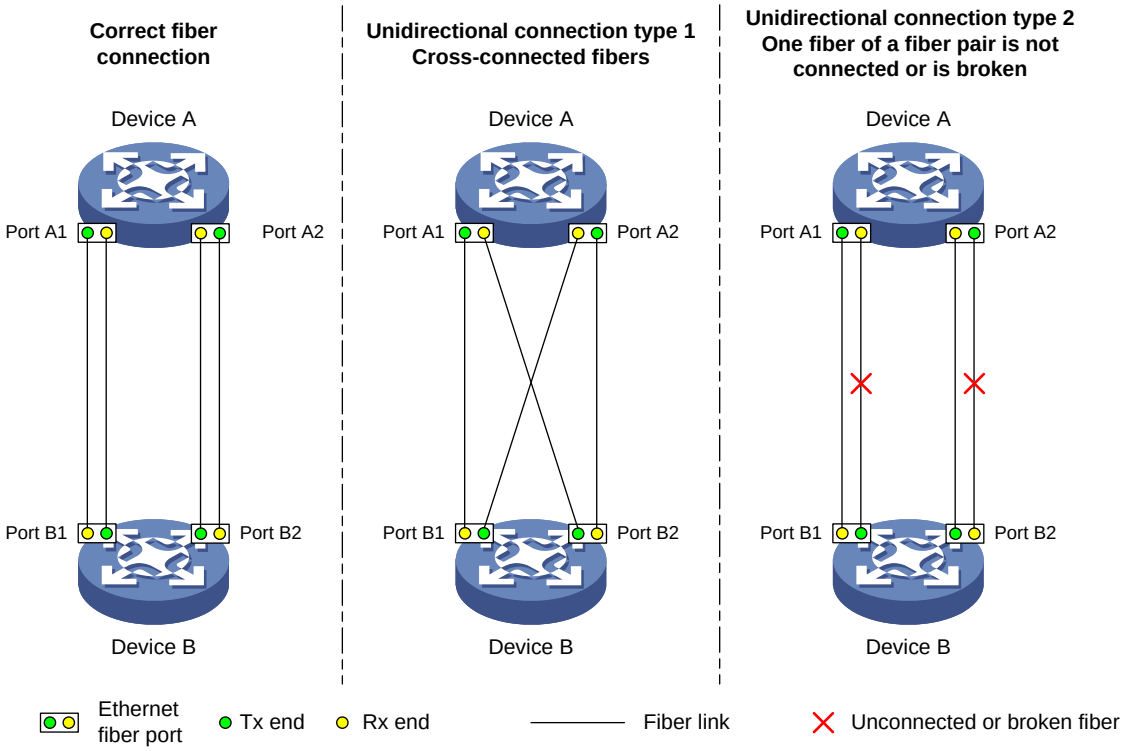
As a data link layer protocol, the H3C-proprietary Device Link Detection Protocol (DLDP) can do the following:

- Monitor status of the fiber link or twisted-pair link at the link layer.
- Cooperate with physical layer protocols to detect whether the link is correctly connected and whether the two ends of the link can exchange packets correctly.

When DLDP detects unidirectional links, it can automatically shut down the faulty port to avoid network problems. Alternatively, a user can manually shut down the faulty port.

Application scenario

A link becomes unidirectional when only one end of the link can receive packets from the other end.



Unidirectional fiber links occur in the following cases:

- Fibers are cross-connected.
- A fiber is not connected at one end or one fiber of a fiber pair is broken.

Figure 1 shows a correct fiber connection and two types of unidirectional fiber connections.

When DLDP detects unidirectional links, it can automatically shut down the faulty port to avoid network problems. Alternatively, a user can manually shut down the faulty port.

Figure 1 Correct and incorrect fiber connections

Basic concepts

DLDP neighbor states

If port A can receive link-layer packets from port B on the same link, port B is a DLDP neighbor of port A. Two ports that can exchange packets are neighbors.

Table 1 DLDP neighbor states

DLDP timer	Description
Confirmed	The link to a DLDP neighbor is bidirectional.
Unconfirmed	The state of the link to a newly discovered neighbor is not determined.

DLDP port states

A DLDP-enabled port is called a DLDP port. A DLDP port can have multiple neighbors, and its state varies by the DLDP neighbor state.

Table 2 DLDP port states

State	Description
Initial	DLDP is enabled on the port, but is disabled globally.
Inactive	DLDP is enabled on the port and globally, and the link is physically down.
Bidirectional	DLDP is enabled on the port and globally, and at least one neighbor in Confirmed state exists.
Unidirectional	DLDP is enabled on the port and globally, and no neighbor in Confirmed state exists. In this state, a port does not send or receive packets other than DLDP packets any more.

DLDP timers

Table 3 DLDP timers

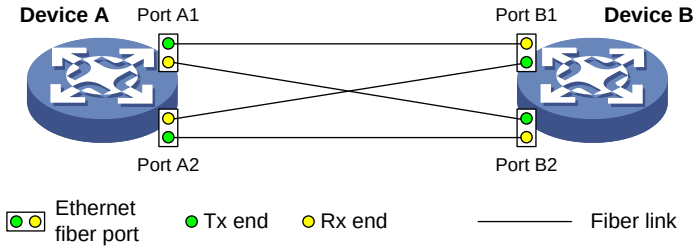
DLDP timer	Description
Advertisement timer	Advertisement packet sending interval (the default is 5 seconds and is configurable).
Probe timer	Probe packet sending interval. This timer is set to 1 second.
Echo timer	The Echo timer is triggered when a probe is launched for a new neighbor. The neighbor information is deleted when the timer expires. This timer is set to 10 seconds.
Entry timer	When a new neighbor joins, a neighbor entry is created and the corresponding Entry timer is triggered if the neighbor is in Confirmed state. When an Advertisement is received, the device updates the corresponding neighbor entry and the Entry timer. When the Entry timer expires, the Enhanced timer and Echo timer are triggered for the neighbor. The value of an Entry timer is three times that of the Advertisement timer.
Enhanced timer	Probe packet sending interval. This timer is set to 1 second. When the Entry timer expires, the Enhanced timer is triggered and probe packets are sent. At the same time, the Echo timer is triggered.
DelayDown timer	If a port is physically down, the device triggers the DelayDown timer, rather than removing the corresponding neighbor entry. The default DelayDown timer is 1 second and is configurable. When the DelayDown timer expires, the device removes the corresponding DLDP neighbor information if the port is down, and does not perform any operation if the port is up.
RecoverProbe timer	This timer is set to 2 seconds. A port in unidirectional state regularly sends RecoverProbe packets to detect whether a unidirectional link has been restored to bidirectional.

DLDP authentication mode

You can use DLDP authentication to prevent network attacks and illegal detecting.

Table 4 DLDP authentication mode

Authentication mode	Processing at the DLDP packet sending side	Processing at the DLDP packet receiving side
Non-authentication	The sending side sets the Authentication field of DLDP packets to 0.	The receiving side examines the authentication information of received DLDP packets and drops packets where the authentication information conflicts with the local configuration.
Plaintext authentication	The sending side sets the Authentication field to the password configured in plain text.	
MD5 authentication	The sending side encrypts the user configured password by using MD5 algorithm, and assigns the digest to the Authentication field.	



How DLDP works

Detecting one neighbor

When two devices are connected through an optical fiber or a network cable, enable DLDP to detect unidirectional links to the neighbor. The following illustrates the unidirectional link detection process in two cases:

- Unidirectional links occur before you enable DLDP.

  Figure 2 Cross-connected fibers

  As shown in Figure 2, before you enable DLDP, the optical fibers between Device A and Device B are cross-connected. After you enable DLDP, the four ports are all up and in unidirectional state, and they send RecoverProbe packets. Take Port A1 as an example to illustrate the unidirectional link detection process.

  a. Port A1 receives the RecoverProbe packet from Port B2, and returns a RecoverEcho packet.

  b. Port B2 cannot receive any RecoverEcho packet from Port A1, so Port B2 cannot become the neighbor of Port A1.

  c. Port B1 can receive the RecoverEcho packet from Port A1, but Port B1 is not the intended destination, so Port B1 cannot become the neighbor of Port A1.

  The same process occurs on the other three ports. The four ports are all in unidirectional state.

- Unidirectional links occur after you enable DLDP.

  Figure 3 Broken fiber

  As shown in Figure 3, Device A and Device B are connected through an optical fiber. After you enable DLDP, Port A1 and Port B1 establish the bidirectional neighborship in the following way:

  a. Port A1 that is physically up enters the unidirectional state and sends a RecoverProbe packet.

  b. After receiving the RecoverProbe packet, Port B1 returns a RecoverEcho packet.

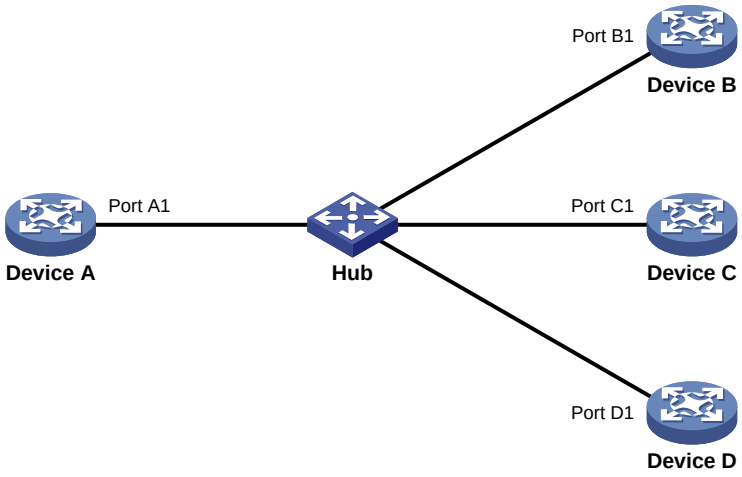
  c. After Port A1 receives the RecoverEcho packet, it examines the neighbor information in the packet. If the neighbor information matches the local information, Port A1 establishes the neighborship with Port B1 and transits to bidirectional state. Port A1 then starts the Entry timer and periodically sends Advertisement packets.

d. After Port B1 receives the Advertisement packet, it establishes the Unconfirmed neighborship with Port A1. Port B1 then starts the Echo timer and Probe timer, and periodically sends Probe packets.

e. After receiving the Probe packet, Port A1 returns an Echo packet.

f. After Port B1 receives the Echo packet, it examines the neighbor information in the packet. If the neighbor information matches the local information, the neighbor state of Port A1 becomes Confirmed. Port B1 then transits to bidirectional state, starts the Entry timer, and periodically sends Advertisement packets.

The bidirectional neighborship between Port A1 and Port B1 is now established.



After that, when Port B1's Rx end fails to receive signals, Port B1 is physically down and enters the Inactive state. Because Port B1's Tx end can still send signals to Port A1, Port A1 stays up. After the Entry timer for Port B1 expires, Port A1 starts the Enhanced timer and Echo timer, and sends a probe packet to Port B1. Because Port A1's Tx line is broken, Port A1 cannot receive the Echo packet from Port B1 after the Echo timer expires. Port A1 then enters the unidirectional state, and sends a Disable packet to Port B1. At the same time, Port A1 deletes the neighborship with Port B1, and starts the RecoverProbe timer. Port B1 stays in Inactive state during this process.

When an interface is physically down, but the Tx end of the interface is still operating, DLDP sends a LinkDown packet to inform the peer to delete the relevant neighbor entry.

Detecting multiple neighbors

When multiple devices are connected through a hub, enable DLDP on all interfaces connected to the hub to detect unidirectional links among the neighbors. When no Confirmed neighbor exists, an interface enters the unidirectional state.

Figure 4 Network diagram

As shown in Figure 4, Device A through Device D are connected through a hub, and enabled with DLDP. When Port A1, Port B1, and Port C1 detect that the link to Port D1 fails, they delete the neighborship with Port D1, but stay in bidirectional state.

Restrictions and guidelines: DLDP configuration

When you configure DLDP, follow these configuration restrictions and guidelines:

- For DLDP to operate correctly, enable DLDP on both sides and make sure the following settings are consistent:
  - Interval to send Advertisement packets.
  - DLDP authentication mode.

- Password.

- For DLDP to operate correctly, configure the full duplex mode for the ports at the two ends of the link, and configure the same speed for the two ports.

DLDP tasks at a glance

To configure DLDP, perform the following tasks:

1. Enabling DLDP
2. (Optional.) Setting the interval to send advertisement packets
3. (Optional.) Setting the DelayDown timer
4. (Optional.) Setting the port shutdown mode
5. (Optional.) Configuring DLDP authentication

Enabling DLDP

About this task

After a port is enabled with DLDP, the port enters Initial state and then transitions to Unidirectional state. By default, DLDP blocks a port immediately when the port transitions to Unidirectional state. This behavior causes a traffic disruption that lasts until the port enters Bidirectional state when establishing a Confirmed neighbor.

You can set the delay time for DLDP to block a port upon an Initial-to-Unidirectional state transition. DLDP does not block the port until the delay time expires.

Procedure

1. Enter system view.

   system-view

2. Enable DLDP globally.

   dldp global enable

   By default, DLDP is globally disabled.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Enable DLDP and set the delay time for DLDP to block the port upon an Initial-to-Unidirectional state transition.

   dldp enable [**initial-unidirectional-delay** *time*]

   By default, DLDP is disabled on a port, and when DLDP is enabled, a port is blocked immediately upon an Initial-to-Unidirectional state transition.

Setting the interval to send advertisement packets

About this task

To make sure DLDP can detect unidirectional links before network performance deteriorates, set the advertisement interval appropriate for your network environment. As a best practice, use the default interval.

Procedure

1. Enter system view.

   system-view

2. Set the interval to send Advertisement packets.

   dldp interval *interval*

   By default, the interval is 5 seconds.

Setting the DelayDown timer

About this task

When the Tx line fails, some ports might go down and then come up again, causing optical signal jitters on the Rx line. To prevent the device from removing neighbor entries in such cases, set the DelayDown timer for the device. The device starts the DelayDown timer when a port goes down due to a Tx line failure. If the port remains down when the timer expires, the device removes the DLDP neighbor information. If the port comes up, the device takes no action.

Procedure

1. Enter system view.

   system-view

2. Set the DelayDown timer.

   dldp delaydown-timer *time*

   The default is 1 second.

   The DelayDown timer setting applies to all DLDP-enabled ports.

Setting the port shutdown mode

About this task

On detecting a unidirectional link, DLDP shuts down the ports in one of the following modes:

- **Auto mode**—When DLDP detects a unidirectional link, it shuts down the unidirectional port. When the link becomes bidirectional, DLDP brings up the port that was shut down.
- **Manual mode**—When DLDP detects a unidirectional link, it does not shut down the port. You need to manually shut it down. To verify the link status, use the **undo shutdown** command to bring up the port. If the link becomes bidirectional, the port becomes bidirectional. Use this mode to prevent normal links from being shut down because of false unidirectional link reports in the following cases:
  - The network performance is low.
  - The device is busy.
  - The CPU usage is high.
- **Hybrid mode**—When DLDP detects a unidirectional link, it shuts down the unidirectional port and stops link detection. To verify the link status, use the **undo shutdown** command to bring up the port. If the link becomes bidirectional, the port becomes bidirectional.

Restrictions and guidelines

You can set the port shutdown mode for all interfaces in system view or for a single interface in interface view. The setting in interface view takes precedence over the setting in system view.

Setting the global port shutdown mode

1. Enter system view.

   system-view

2. Set the global port shutdown mode.

   dldp unidirectional-shutdown { **auto** | **hybrid** | **manual** }

The default mode is **auto**.

Setting the port shutdown mode for an interface

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Set the the port shutdown mode for the interface.
   dldp port unidirectional-shutdown { **auto** | **hybrid** | **manual** }
   By default, the global setting is used.

Configuring DLDP authentication

About this task

You can guard your network against attacks and malicious probes by configuring an appropriate DLDP authentication mode, which can be plain text authentication or MD5 authentication. If your network is safe, you can choose not to authenticate.

Procedure

1. Enter system view.
   system-view
2. Configure a DLDP authentication mode.
   dldp authentication-mode { **md5** | **none** | **simple** }
   The default authentication mode is **none**.
3. Configure the password for DLDP authentication.
   dldp authentication-password { **cipher** | **simple** } *string*
   By default, no password is configured for DLDP authentication.
   If you do not configure the authentication password after you configure the authentication mode, the authentication mode is **none** no matter which authentication mode you configure.

Display and maintenance commands for DLDP

Execute **display** commands in any view and the **reset** command in user view.

Task	Command
Display the DLDP configuration globally and of a port.	**display dldp** [**interface** *interface-type interface-number*]
Display the statistics on DLDP packets passing through a port.	**display dldp statistics** [**interface** *interface-type interface-number*]
Clear the statistics on DLDP packets passing through a port.	**reset dldp statistics** [**interface** *interface-type interface-number*]

DLDP configuration examples

Example: Configuring the auto port shutdown mode

Network configuration

As shown in Figure 5, Device A and Device B are connected through two fiber pairs.

Configure DLDP to automatically shut down the faulty port upon detecting a unidirectional link, and automatically bring up the port after you clear the fault.

Figure 5 Network diagram

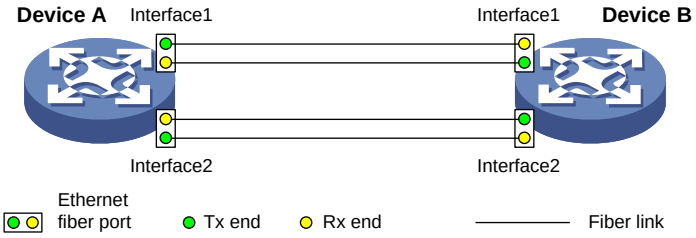


Table 5 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure Device A:

   # Enable DLDP globally.

   ```
   <DeviceA> system-view
   [DeviceA] dldp global enable
   ```

   # Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] duplex full
   [DeviceA-GigabitEthernet1/0/1] speed 1000
   [DeviceA-GigabitEthernet1/0/1] dldp enable
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

   ```
   [DeviceA] interface gigabitethernet 1/0/2
   [DeviceA-GigabitEthernet1/0/2] duplex full
   [DeviceA-GigabitEthernet1/0/2] speed 1000
   [DeviceA-GigabitEthernet1/0/2] dldp enable
   [DeviceA-GigabitEthernet1/0/2] quit
   ```

   # Set the global port shutdown mode to auto.

   ```
   [DeviceA] dldp unidirectional-shutdown auto
   ```

2. Configure Device B:

   # Enable DLDP globally.

```
<DeviceB> system-view
[DeviceB] dldp global enable
```

Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] duplex full
[DeviceB-GigabitEthernet1/0/1] speed 1000
[DeviceB-GigabitEthernet1/0/1] dldp enable
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] duplex full
[DeviceB-GigabitEthernet1/0/2] speed 1000
[DeviceB-GigabitEthernet1/0/2] dldp enable
[DeviceB-GigabitEthernet1/0/2] quit
```

Set the global port shutdown mode to auto.

```
[DeviceB] dldp unidirectional-shutdown auto
```

Verifying the configuration

Display the DLDP configuration globally and on all the DLDP-enabled ports of Device A.

```
[DeviceA] display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Auto
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2

Interface GigabitEthernet1/0/1
 DLDP port state: Bidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 1
  Neighbor state: Confirmed
  Neighbor aged time: 11s
  Neighbor echo time: -

Interface GigabitEthernet1/0/2
 DLDP port state: Bidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 2
  Neighbor state: Confirmed
  Neighbor aged time: 12s
```

```
  Neighbor echo time: -
```

The output shows that both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are bidirectional.

Enable the monitoring of logs on the current terminal on Device A. Set the lowest level of the logs that can be output to the current terminal to 6.

```
[DeviceA] quit
<DeviceA> terminal monitor
The current terminal is enabled to display logs.
<DeviceA> terminal logging level 6
```

The following log information is displayed on Device A:

```
<DeviceA>%Jul 11 17:40:31:089 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface Physical state on the interface GigabitEthernet1/0/1 changed to down.
%Jul 11 17:40:31:091 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface GigabitEthernet1/0/1 changed to down.
%Jul 11 17:40:31:677 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface Physical state on the interface GigabitEthernet1/0/2 changed to down.
%Jul 11 17:40:31:678 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface GigabitEthernet1/0/2 changed to down.
%Jul 11 17:40:38:544 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface Physical state on the interface GigabitEthernet1/0/1 l changed to up.
%Jul 11 17:40:38:836 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface Physical state on the interface GigabitEthernet1/0/2 changed to up.
```

The output shows the following:

- The port status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 is down and then up.
- The link status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 is always down.

Display the DLDP configuration globally and of all the DLDP-enabled ports.

```
<DeviceA> display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Auto
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2

Interface GigabitEthernet1/0/1
 DLDP port state: Unidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 0 (Maximum number ever detected: 1)

Interface GigabitEthernet1/0/2
 DLDP port state: Unidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 0 (Maximum number ever detected: 1)
```

The output shows that the DLDP port status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 is unidirectional. DLDP detects unidirectional links on them and automatically shuts down the two ports.

The unidirectional links are caused by cross-connected fibers. Correct the fiber connections. As a result, the ports shut down by DLDP automatically recover, and Device A displays the following log information:

```
<DeviceA>%Jul 11 17:42:57:709 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the
interface GigabitEthernet1/0/1 changed to down.
%Jul 11 17:42:58:603 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/2 changed to down.
%Jul 11 17:43:02:342 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/1 changed to up.
%Jul 11 17:43:02:343 2012 DeviceA DLDP/6/DLDP_NEIGHBOR_CONFIRMED: A neighbor was confirmed
on interface GigabitEthernet1/0/1. The neighbor's system MAC is 0023-8956-3600, and the
port index is 1.
%Jul 11 17:43:02:344 2012 DeviceA DLDP/6/DLDP_LINK_BIDIRECTIONAL: DLDP detected a
bidirectional link on interface GigabitEthernet1/0/1.
%Jul 11 17:43:02:353 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/1 changed to up.
%Jul 11 17:43:02:357 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/2 changed to up.
%Jul 11 17:43:02:362 2012 DeviceA DLDP/6/DLDP_NEIGHBOR_CONFIRMED: A neighbor was confirmed
on interface GigabitEthernet1/0/2. The neighbor's system MAC is 0023-8956-3600, and the
port index is 2.
%Jul 11 17:43:02:362 2012 DeviceA DLDP/6/DLDP_LINK_BIDIRECTIONAL: DLDP detected a
bidirectional link on interface GigabitEthernet1/0/2.
%Jul 11 17:43:02:368 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/2 changed to up.
```

The output shows that the port status and link status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are now up and their DLDP neighbors are determined.

Example: Configuring the manual port shutdown mode

Network configuration

As shown in Figure 6, Device A and Device B are connected through two fiber pairs.

Configure DLDP to detect unidirectional links. When a unidirectional link is detected, the administrator must manually shut down the port.

Figure 6 Network diagram

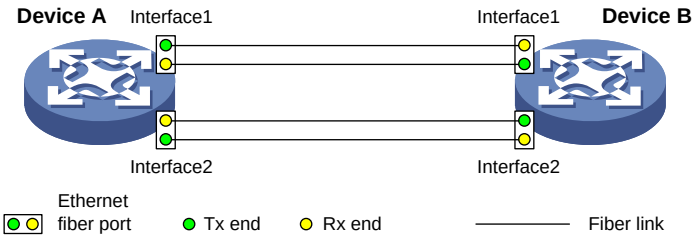

Table 6 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure Device A:

   # Enable DLDP globally.

   ```
   <DeviceA> system-view
   [DeviceA] dldp enable
   ```

   # Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] duplex full
   [DeviceA-GigabitEthernet1/0/1] speed 1000
   [DeviceA-GigabitEthernet1/0/1] dldp enable
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

   ```
   [DeviceA] interface gigabitethernet 1/0/2
   [DeviceA-GigabitEthernet1/0/2] duplex full
   [DeviceA-GigabitEthernet1/0/2] speed 1000
   [DeviceA-GigabitEthernet1/0/2] dldp enable
   [DeviceA-GigabitEthernet1/0/2] quit
   ```

   # Set the global port shutdown mode to manual.

   ```
   [DeviceA] dldp unidirectional-shutdown manual
   ```

2. Configure Device B:

   # Enable DLDP globally.

   ```
   <DeviceB> system-view
   [DeviceB] dldp global enable
   ```

   # Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

   ```
   [DeviceB] interface gigabitethernet 1/0/1
   [DeviceB-GigabitEthernet1/0/1] duplex full
   [DeviceB-GigabitEthernet1/0/1] speed 1000
   [DeviceB-GigabitEthernet1/0/1] dldp enable
   [DeviceB-GigabitEthernet1/0/1] quit
   ```

   # Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

   ```
   [DeviceB] interface gigabitethernet 1/0/2
   [DeviceB-GigabitEthernet1/0/2] duplex full
   [DeviceB-GigabitEthernet1/0/2] speed 1000
   [DeviceB-GigabitEthernet1/0/2] dldp enable
   [DeviceB-GigabitEthernet1/0/2] quit
   ```

   # Set the global port shutdown mode to manual.

   ```
   [DeviceB] dldp unidirectional-shutdown manual
   ```

Verifying the configuration

Display the DLDP configuration globally and on all the DLDP-enabled ports of Device A.

```
[DeviceA] display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
```

```
 DLDP unidirectional-shutdown mode: Manual
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2

Interface GigabitEthernet1/0/1
 DLDP port state: Bidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 1
  Neighbor state: Confirmed
  Neighbor aged time: 11s
  Neighbor echo time: -

Interface GigabitEthernet1/0/2
 DLDP port state: Bidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 2
  Neighbor state: Confirmed
  Neighbor aged time: 12s
  Neighbor echo time: -
```

The output shows that both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are in bidirectional state, which means both links are bidirectional.

Enable the monitoring of logs on the current terminal on Device A. Set the lowest level of the logs that can be output to the current terminal to 6.

```
[DeviceA] quit
<DeviceA> terminal monitor
The current terminal is enabled to display logs.
<DeviceA> terminal logging level 6
```

The following log information is displayed on Device A:

```
<DeviceA>%Jul 12 08:29:17:786 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the
interface GigabitEthernet1/0/1 changed to down.
%Jul 12 08:29:17:787 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/1 changed to down.
%Jul 12 08:29:17:800 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/2 changed to down.
%Jul 12 08:29:17:800 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/2 changed to down.
%Jul 12 08:29:25:004 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/1 changed to up.
%Jul 12 08:29:25:005 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/1 changed to up.
%Jul 12 08:29:25:893 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/2 changed to up.
```

```
%Jul 12 08:29:25:894 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/2 changed to up.
```

The output shows that the port status and link status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are down and then up.

Display the DLDP configuration globally and of all the DLDP-enabled ports.

```
<DeviceA> display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Manual
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2

Interface GigabitEthernet1/0/1
 DLDP port state: Unidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 0 (Maximum number ever detected: 1)

Interface GigabitEthernet1/0/2
 DLDP port state: Unidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 0 (Maximum number ever detected: 1)
```

The output shows that the DLDP port status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 is unidirectional. DLDP detects unidirectional links on the two ports but does not shut them down.

The unidirectional links are caused by cross-connected fibers. Manually shut down the two ports:

Shut down GigabitEthernet 1/0/1.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] shutdown
```

The following log information is displayed on Device A:

```
[DeviceA-GigabitEthernet1/0/1]%Jul 12 08:34:23:717 2012 DeviceA IFNET/3/PHY_UPDOWN:
Physical state on the interface GigabitEthernet1/0/1 changed to down.

port index is 1.

%Jul 12 08:48:25:953 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/1 changed to up.

%Jul 12 08:48:25:953 2012 DeviceA DLDP/6/DLDP_LINK_BIDIRECTIONAL: DLDP detected a
bidirectional link on interface GigabitEthernet1/0/1.
```

The output shows that the port status and link status of GigabitEthernet 1/0/1 are now up and its DLDP neighbors are determined.

Example: Configuring the hybrid port shutdown mode

Network configuration

As shown in Figure 7Figure 6, Device A and Device B are connected through two fiber pairs.

Configure DLDP to detect unidirectional links. When a unidirectional link is detected, DLDP automatically shuts down the unidirectional port. The administrator needs to bring up the port after clearing the fault.

Figure 7 Network diagram

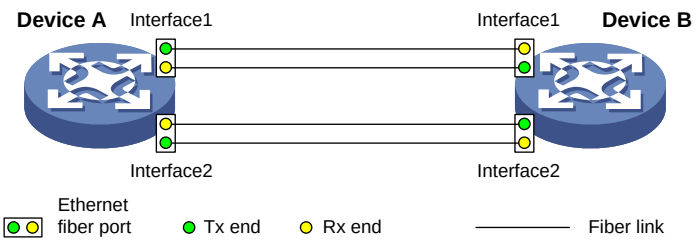

Table 7 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure Device A:

   # Enable DLDP globally.

   ```
   <DeviceA> system-view
   [DeviceA] dldp enable
   ```

   # Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] duplex full
   [DeviceA-GigabitEthernet1/0/1] speed 1000
   [DeviceA-GigabitEthernet1/0/1] dldp enable
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

   ```
   [DeviceA] interface gigabitethernet 1/0/2
   [DeviceA-GigabitEthernet1/0/2] duplex full
   [DeviceA-GigabitEthernet1/0/2] speed 1000
   [DeviceA-GigabitEthernet1/0/2] dldp enable
   [DeviceA-GigabitEthernet1/0/2] quit
   ```

   # Set the global port shutdown mode to hybrid.

   ```
   [DeviceA] dldp unidirectional-shutdown hybrid
   ```

2. Configure Device B:

   # Enable DLDP globally.

   ```
   <DeviceB> system-view
   [DeviceB] dldp global enable
   ```

   # Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

   ```
   [DeviceB] interface gigabitethernet 1/0/1
   [DeviceB-GigabitEthernet1/0/1] duplex full
   [DeviceB-GigabitEthernet1/0/1] speed 1000
   [DeviceB-GigabitEthernet1/0/1] dldp enable
   [DeviceB-GigabitEthernet1/0/1] quit
   ```

   # Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

   ```
   [DeviceB] interface gigabitethernet 1/0/2
   [DeviceB-GigabitEthernet1/0/2] duplex full
   [DeviceB-GigabitEthernet1/0/2] speed 1000
   [DeviceB-GigabitEthernet1/0/2] dldp enable
   [DeviceB-GigabitEthernet1/0/2] quit
   ```

   # Set the global port shutdown mode to hybrid.

   ```
   [DeviceB] dldp unidirectional-shutdown hybrid
   ```

Verifying the configuration

Display the DLDP configuration globally and on all the DLDP-enabled ports of Device A.

```
[DeviceA] display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Hybrid
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2

Interface GigabitEthernet1/0/1
 DLDP port state: Bidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 1
  Neighbor state: Confirmed
  Neighbor aged time: 11s
  Neighbor echo time: -

Interface GigabitEthernet1/0/2
 DLDP port state: Bidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 2
  Neighbor state: Confirmed
  Neighbor aged time: 12s
  Neighbor echo time: -
```

The output shows that both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are in bidirectional state, which means both links are bidirectional.

Enable the monitoring of logs on the current terminal on Device A. Set the lowest level of the logs that can be output to the current terminal to 6.

```
[DeviceA] quit
<DeviceA> terminal monitor
The current terminal is enabled to display logs.
<DeviceA> terminal logging level 6
```

The following log information is displayed on Device A:

```
<DeviceA>%Jan  4 07:16:06:556 2011 DeviceA DLDP/5/DLDP_NEIGHBOR_AGED: A neighbor on
interface
GigabitEthernet1/0/1 was deleted because the neighbor was aged. The neighbor's system MAC
is 0023-8956-3600, and the port index is 162.
%Jan  4 07:16:06:560 2011 DeviceA DLDP/5/DLDP_NEIGHBOR_AGED: A neighbor on interface
GigabitEthernet1/0/2 was deleted because the neighbor was aged. The neighbor's system MAC
is 0023-8956-3600, and the port index is 165.

unidirectional link on interface GigabitEthernet1/0/1. DLDP automatically shut down the
interface. Please manually bring up the interface.
%Jan  4 07:16:07:156 2011 DeviceA DLDP/3/DLDP_LINK_UNIDIRECTIONAL: DLDP detected a
unidirectional link on interface GigabitEthernet1/0/2. DLDP automatically shut down the
interface. Please manually bring up the interface.
```

The output shows that the port status and link status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are down.

Display the DLDP configuration globally and of all the DLDP-enabled ports.

```
<DeviceA> display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Hybrid
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2

Interface GigabitEthernet1/0/1
 DLDP port state: Inactive
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port's neighbors: 0 (Maximum number ever detected: 1)
Interface GigabitEthernet1/0/2
 DLDP port state: Inactive
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port's neighbors: 0 (Maximum number ever detected: 1)
```

The output shows that DLDP detects a unidirectional link and shuts down GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

The unidirectional links are caused by cross-connected fibers. Bring up the two ports after correcting the fiber connection:

Bring up GigabitEthernet 1/0/1.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] undo shutdown
```

The following log information is displayed on Device A:

```
[DeviceA-GigabitEthernet1/0/1]%Jan  4 07:33:26:574 2011 DeviceA IFNET/3/PHY_UPDOWN:
Physical state on the interface GigabitEthernet1/0/1 changed to up.
%Jan 4 07:33:57:562 2011 DeviceA DLDP/6/DLDP_NEIGHBOR_CONFIRMED: A neighbor was confirmed
on interface GigabitEthernet1/0/1. The neighbor's system MAC is 0023-8956-3600, and the
port index is 162.
```

```
%Jan  4 07:33:57:563 2011 DeviceA DLDP/6/DLDP_LINK_BIDIRECTIONAL: DLDP detected a

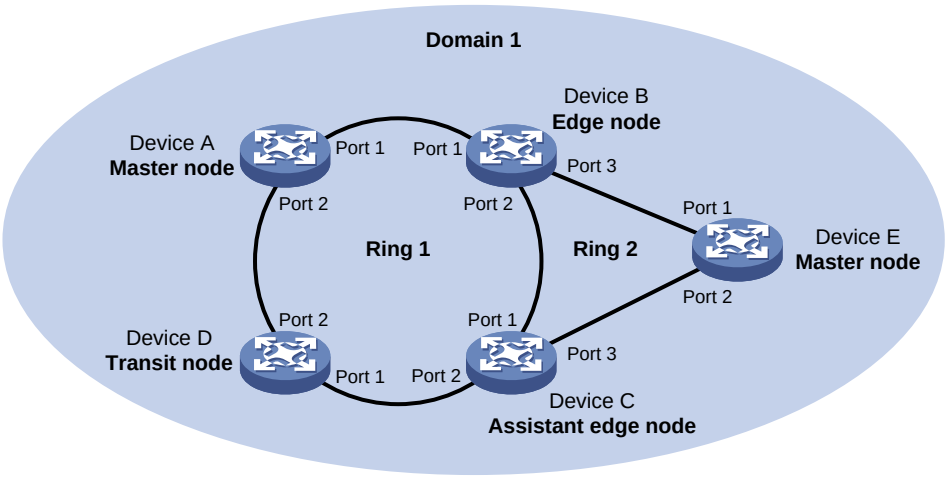
Configuring RRPP



About RRPP

The Rapid Ring Protection Protocol (RRPP) is an H3C-proprietary link layer protocol designed for Ethernet rings. RRPP can prevent broadcast storms caused by data loops when an Ethernet ring is healthy. RRPP can also rapidly restore the communication paths between the nodes when a link is disconnected on the ring. Compared with the spanning tree protocol, the convergence time of RRPP is fast and independent of the number of nodes in the Ethernet ring. RRPP is applicable to large-diameter networks.

RRPP networking

Figure 1 shows a typical RRPP network with two Ethernet rings and multiple nodes. RRPP detects ring status and sends topology change information by exchanging Rapid Ring Protection Protocol Data Units (RRPPDUs) among the nodes.

Figure 1 `RRPP networking diagram`

RRPP domain

An RRPP domain is uniquely identified by a domain ID. The interconnected devices with the same domain ID and control VLANs constitute an RRPP domain. An RRPP domain contains the following elements:

- Primary ring and subring.
- Control VLAN.
- Master node, transit node, edge node, and assistant edge node.
- Primary port, secondary port, common port, and edge port.

As shown in Figure 1, Domain 1 is an RRPP domain, containing two RRPP rings: Ring 1 and Ring 2. All the nodes on the two RRPP rings belong to the RRPP domain.

RRPP ring

A ring-shaped Ethernet topology is called an RRPP ring. RRPP rings include primary rings and subrings. You can configure a ring as either the primary ring or a subring by specifying its ring level. The primary ring is of level 0, and a subring is of level 1. An RRPP domain contains one or multiple RRPP rings, one serving as the primary ring and the others serving as subrings. A ring can be in one of the following states:

- **`Health state`**—All physical links on the Ethernet ring are connected.
- **`Disconnect state`**—Some physical links on the Ethernet ring are not connected.

As shown in Figure 1, Domain 1 contains two RRPP rings: Ring 1 and Ring 2. The level is set to 0 for Ring 1 and 1 for Ring 2. Ring 1 is configured as the primary ring, and Ring 2 is configured as a subring.

Control VLAN and protected VLAN

1. Control VLAN

   In an RRPP domain, a control VLAN is dedicated to transferring RRPPDUs. On a device, the ports accessing an RRPP ring belong to the control VLANs of the ring, and only these ports can join the control VLANs.

   An RRPP domain is configured with the following control VLANs:

   - One primary control VLAN, which is the control VLAN for the primary ring.
   - One secondary control VLAN, which is the control VLAN for subrings.

   After you specify a VLAN as the primary control VLAN, the system automatically configures the secondary control VLAN. The VLAN ID is the primary control VLAN ID plus one. All subrings in the same RRPP domain share the same secondary control VLAN. IP address configuration is prohibited on the control VLAN interfaces.

2. Protected VLAN

   A protected VLAN is dedicated to transferring data packets. Both RRPP ports and non-RRPP ports can be assigned to a protected VLAN.

Node role

Each device on an RRPP ring is a node. The role of a node is configurable. RRPP has the following node roles:

- **Master node**—Each ring has only one master node. The master node initiates the polling mechanism and determines the operations to be performed after a topology change.
- **Transit node**—On the primary ring, transit nodes refer to all nodes except the master node. On the subring, transit nodes refer to all nodes except the master node and the nodes where the primary ring intersects with the subring. A transit node monitors the state of its directly connected RRPP links and notifies the master node of the link state changes, if any. Based on the link state changes, the master node determines the operations to be performed.
- **Edge node**—A special node residing on both the primary ring and a subring at the same time. An edge node acts as a master node or transit node on the primary ring and as an edge node on the subring.
- **Assistant edge node**—A special node residing on both the primary ring and a subring at the same time. An assistant edge node acts as a master node or transit node on the primary ring and as an assistant edge node on the subring. This node works in conjunction with the edge node to detect the integrity of the primary ring and to perform loop guard.

As shown in Figure 1, Ring 1 is the primary ring and Ring 2 is a subring. Device A is the master node of Ring 1. Device B, Device C, and Device D are the transit nodes of Ring 1. Device E is the master node of Ring 2, Device B is the edge node of Ring 2, and Device C is the assistant edge node of Ring 2.

Port role

1. Primary port and secondary port

   Each master node or transit node has two ports connected to an RRPP ring, a primary port and a secondary port. You can determine the role of a port.

   In terms of functionality, the primary port and the secondary port of a master node have the following differences:

   - The primary port and the secondary port are designed to play the role of sending and receiving Hello packets, respectively.

- When an RRPP ring is in Health state, the secondary port logically denies protected VLANs and permits only the packets from the control VLANs.
- When an RRPP ring is in Disconnect state, the secondary port forwards packets from protected VLANs.

In terms of functionality, the primary port and the secondary port of a transit node are the same. Both are designed for transferring protocol packets and data packets over an RRPP ring.

As shown in Figure 1, Device A is the master node of Ring 1. Port 1 and Port 2 are the primary port and the secondary port of the master node on Ring 1, respectively. Device B, Device C, and Device D are the transit nodes of Ring 1. Their Port 1 and Port 2 are the primary port and the secondary port on Ring 1, respectively.

2. Common port and edge port

   The ports connecting the edge node and assistant edge node to the primary ring are common ports. The ports connecting the edge node and assistant edge node only to the subrings are edge ports. You can determine the role of a port.

   As shown in Figure 1, Device B and Device C reside on Ring 1 and Ring 2. Device B's Port 1 and Port 2 and Device C's Port 1 and Port 2 access the primary ring, so they are common ports. Device B's Port 3 and Device C's Port 3 access only the subring, so they are edge ports.

RRPP ring group

To reduce Edge-Hello traffic, you can configure a group of subrings on the edge node or assistant edge node. You must configure a device as the edge node of these subrings, and another device as the assistant edge node of these subrings. Additionally, the subrings of the edge node and assistant edge node must connect to the same subring packet tunnels in major ring (SRPTs). Edge-Hello packets of the edge node of these subrings travel to the assistant edge node of these subrings over the same link.

An RRPP ring group configured on the edge node is an edge node RRPP ring group. An RRPP ring group configured on an assistant edge node is an assistant edge node RRPP ring group. Only one subring in an edge node RRPP ring group is allowed to send Edge-Hello packets.

RRPPDUs

RRPPDUs of subrings are transmitted as data packets in the primary ring, and RRPPDUs of the primary ring can only be transmitted within the primary ring. In the primary ring, Common-Flush-FDB packets and Complete-Flush-FDB packets of subrings are sent to the CPU on each node for processing.

Table 1 RRPPDU types and their functions

Type	Description
Hello	The master node sends Hello packets (also known as Health packets) to detect the integrity of a ring in a network.
Link-Down	When a port on the transit node, edge node, or assistant edge node fails, the node initiates Link-Down packets to notify the master node of the disconnection of the ring.
Common-Flush-FDB	When an RRPP ring transits to Disconnect state, the master node initiates Common-Flush-FDB (FDB stands for Forwarding Database) packets. It uses the packets to instruct the transit nodes, edge nodes, and assistant edge nodes to update their own MAC address entries and ARP/ND entries.
Complete-Flush-FDB	When an RRPP ring transits to Health state, the master node sends Complete-Flush-FDB packets for the following purposes: • Instruct the transit nodes, edge nodes, and assistant edge nodes to update their MAC address entries and ARP/ND entries. • Instruct the transit nodes to unblock temporarily blocked ports.

Edge-Hello	The edge node sends Edge-Hello packets to examine the SRPTs between the edge node and the assistant edge node.
Major-Fault	The assistant edge node sends Major-Fault packets to notify the edge node of SRPT failure when an SRPT between assistant edge node and edge node is disconnected.

RRPP timers

When RRPP determines the link state of an Ethernet ring, it uses the following timers:

Hello timer

The Hello timer specifies the interval at which the master node sends Hello packets out of the primary port.

Fail timer

The Fail timer specifies the maximum delay of Hello packets sent from the primary port to the secondary port of the master node. If the secondary port receives the Hello packets sent by the local master node before the Fail timer expires, the ring is in Health state. If the secondary port does not receive the Hello packets before the Fail timer expires, the ring transits to Disconnect state.

In an RRPP domain, a transit node learns the Fail timer value on the master node through the received Hello packets. This ensures that all nodes in the ring network have consistent Fail timer settings.

Link-up delay timer

This feature prevents frequent switchover of RRPP traffic forwarding paths caused by unstable RRPP port states. This feature behaves differently depending on whether you specify the **`distribute`** keyword in the **`linkup-delay-timer`** command.

- If you do not specify the **`distribute`** keyword, the master node starts the link-up delay timer when a faulty port comes up and the master node receives Hello packets from the secondary port.
  - If the master node can still receive Hello packets from the secondary port after the link-up delay timer expires, the master node performs the following operations:
    - Changes the RRPP ring state from Disconnect to Health.
    - Switches the traffic from the secondary port to the primary port.
  - If the master node cannot receive Hello packets from the secondary port after the Fail timer expires and before the link-up delay timer expires, the master node performs the following operations:
    - Stops the link-up delay timer.
    - Keeps the RRPP ring in Disconnect state.
- If you specify the **`distribute`** keyword, all nodes in the RRPP domain can learn the value of the link-up delay timer through Hello packets. When the faulty port comes up, the master node performs the following operations:
  - The hosting RRPP node blocks the faulty port (the faulty port cannot send or receive any packets).
  - Starts the link-up delay timer.

  If the port does not become faulty after the link-up delay timer expires, the hosting RRPP node sets the port state to up. The master node can receive Hello packets from its secondary port again. Then, the master node changes the RRPP ring state from Disconnect to Health and switches the traffic from the secondary port to the primary port.

  If the port becomes faulty again before the link-up delay timer expires, the hosting RRPP node blocks the port and stops the link-up delay timer.

How RRPP works

Polling mechanism

The polling mechanism is used by the master node of an RRPP ring to examine the Health state of the ring network.

The master node sends Hello packets out of its primary port at the Hello interval. These Hello packets travel through each transit node on the ring in turn.

- If the ring is complete, the secondary port of the master node receives Hello packets before the Fail timer expires. The master node keeps the secondary port blocked.
- If the ring is disconnected, the secondary port of the master node fails to receive Hello packets before the Fail timer expires. The master node releases the secondary port from blocking protected VLANs. It sends Common-Flush-FDB packets to instruct all transit nodes to update their own MAC address entries and ARP/ND entries.

Load balancing

In a ring network, traffic from multiple VLANs might be transmitted at the same time. RRPP can implement load balancing by transmitting traffic from different VLANs along different paths.

You can configure multiple RRPP domains for a ring network. Each RRPP domain transmits the traffic from the specified VLANs (protected VLANs). Traffic from different VLANs can be transmitted according to different topologies in the ring network for load balancing.

As shown in the schematic diagram for a single-ring load balancing network, Ring 1 is configured as the primary ring of Domain 1 and Domain 2, which are configured with different protected VLANs. Device A is the master node of Ring 1 in Domain 1. Device B is the master node of Ring 1 in Domain 2. With such configurations, traffic from different VLANs can be transmitted on different links for load balancing in the single-ring network.

Link down alarm mechanism

In an RRPP domain, when the transit node, edge node, or assistant edge node finds that any of its ports is down, it immediately sends Link-Down packets to the master node. When the master node receives a Link-Down packet, it takes the following actions:

- Releases the secondary port from blocking protected VLANs.
- Sends Common-Flush-FDB packets to instruct all the transit nodes, edge nodes, and assistant edge nodes to update their MAC address entries and ARP/ND entries.

After each node updates its own entries, traffic is switched to the normal link.

Ring recovery

When the ports in an RRPP domain on the transit nodes, edge nodes, or assistant edge nodes come up again, the ring is recovered. However, the master node might detect the ring recovery after a period of time. A temporary loop might arise in the protected VLAN during this period. As a result, a broadcast storm occurs.

To prevent such cases, non-master nodes block the ports immediately when they find the ports accessing the ring are brought up again. The nodes block only the packets from the protected VLAN, and they permit only the packets from the control VLAN to pass through. The blocked ports are activated only when the nodes determine that no loop will be generated by these ports.

Broadcast storm suppression mechanism in case of SRPT failure in a multi-homed subring

As shown in the schematic diagram for a dual-homed-ring network, Ring 1 is the primary ring, and Ring 2 and Ring 3 are subrings. When the two SRPTs between the edge node and the assistant edge node are down, the master nodes of Ring 2 and Ring 3 will open their secondary ports. A loop is generated among Device B, Device C, Device E, and Device F, causing a broadcast storm.

To avoid generating a loop, the edge node will temporarily block the edge port. The blocked edge port is activated only when the edge node determines that no loop will be generated when the edge port is activated.

RRPP ring group

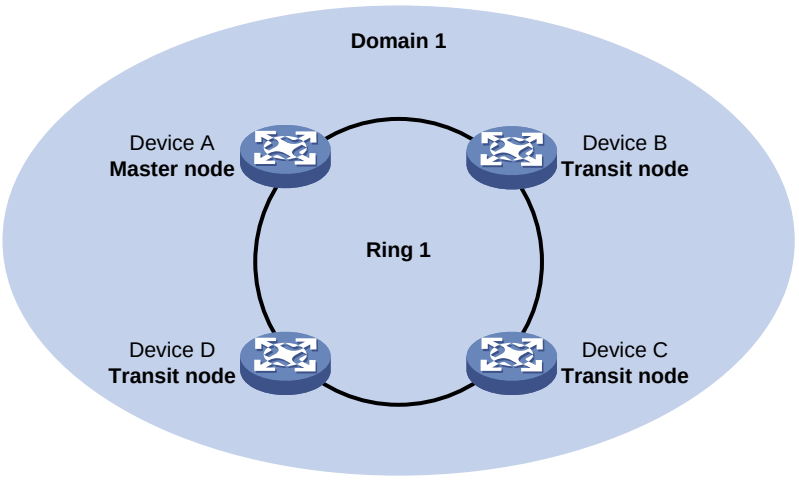
In an edge node RRPP ring group, only the activated subring with the smallest domain ID and ring ID can send Edge-Hello packets. In an assistant edge node RRPP ring group, any activated subring that has received Edge-Hello packets will forward these packets to the other activated subrings. When an edge node RRPP ring group and an assistant edge node RRPP ring group are configured, the CPU workload is reduced because of the following reasons:

- Only one subring sends Edge-Hello packets on the edge node.
- Only one subring receives Edge-Hello packets on the assistant edge node.

As shown in the schematic diagram for a dual-homed-ring network, Device B is the edge node of Ring 2 and Ring 3. Device C is the assistant edge node of Ring 2 and Ring 3. Device B and Device C need to send or receive Edge-Hello packets frequently. If more subrings are configured or more domains are configured for load balancing, Device B and Device C will send or receive a large number of Edge-Hello packets.

To reduce Edge-Hello traffic, perform the following tasks:

- Assign Ring 2 and Ring 3 to an RRPP ring group configured on the edge node Device B.
- Assign Ring 2 and Ring 3 to an RRPP ring group configured on the assistant edge node Device C.



If all rings are activated, only Ring 2 on Device B sends Edge-Hello packets.

Typical RRPP networking

Single ring

As shown in Figure 2, only a single ring exists in the network topology. You need only define an RRPP domain.

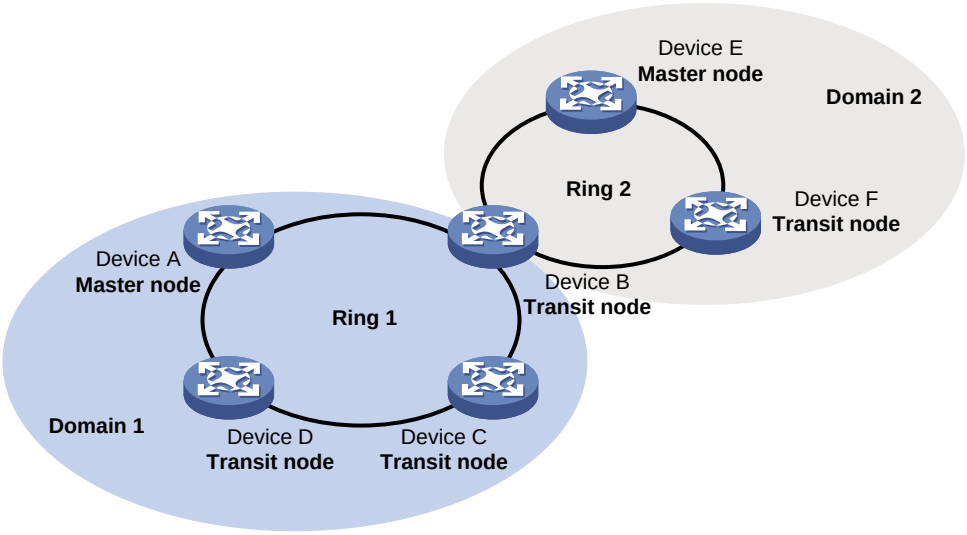


Figure 2 Schematic diagram for a single-ring network

Tangent rings

As shown in Figure 3, two or more rings exist in the network topology and only one common node exists between rings. You must define an RRPP domain for each ring.

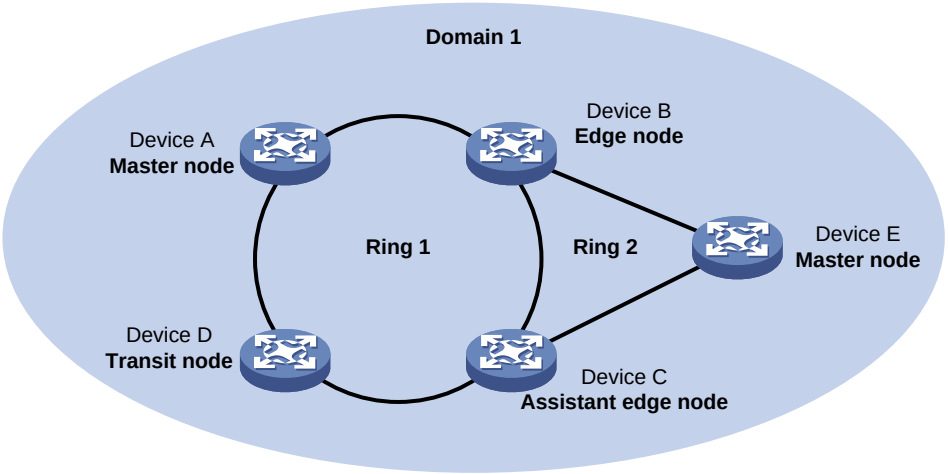

Figure 3 Schematic diagram for a tangent-ring network

Intersecting rings

As shown in Figure 4, two or more rings exist in the network topology and two common nodes exist between rings. You need only define an RRPP domain and configure one ring as the primary ring and the other rings as subrings.

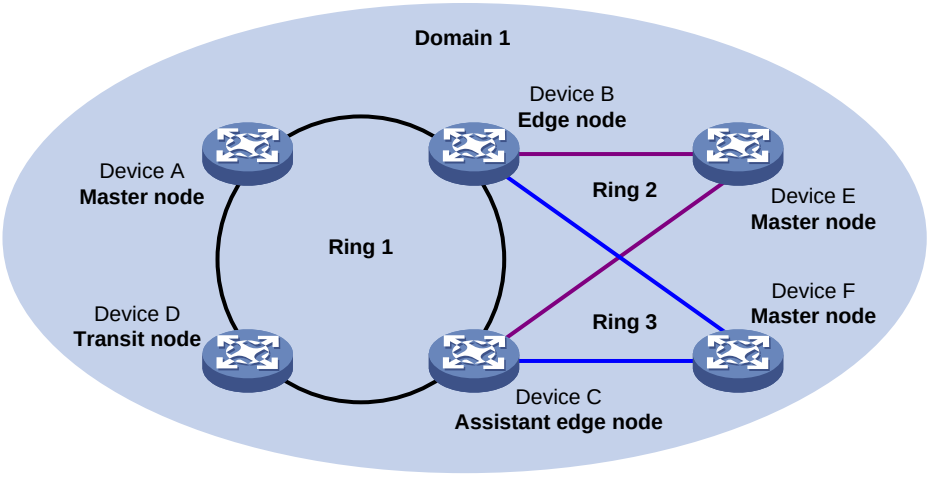

Figure 4 Schematic diagram for an intersecting-ring network

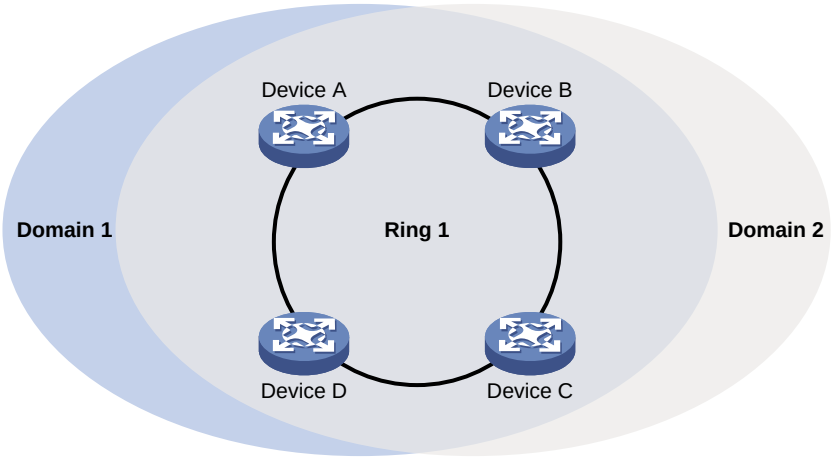
Dual-homed rings

As shown in Figure 5, two or more rings exist in the network topology and two similar common nodes exist between rings. You need only define an RRPP domain and configure one ring as the primary ring and the other rings as subrings.

Figure 5 Schematic diagram for a dual-homed-ring network

Single-ring load balancing



In a single-ring network, you can achieve load balancing by configuring multiple domains.

As shown in Figure 6:

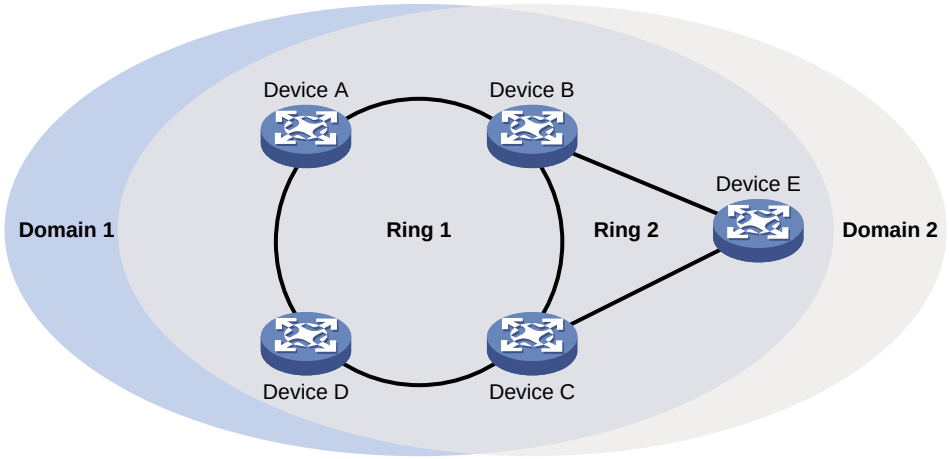
- Ring 1 is configured as the primary ring of both Domain 1 and Domain 2.
- Domain 1 and Domain 2 are configured with different protected VLANs.
- In Domain 1, Device A is configured as the master node of Ring 1.
- In Domain 2, Device B is configured as the master node of Ring 1.

Such configurations enable the ring to block different links based on VLANs and achieve single-ring load balancing.

Figure 6 Schematic diagram for a single-ring load balancing network

Intersecting-ring load balancing

In an intersecting-ring network, you can also achieve load balancing by configuring multiple domains.



As shown in Figure 7:

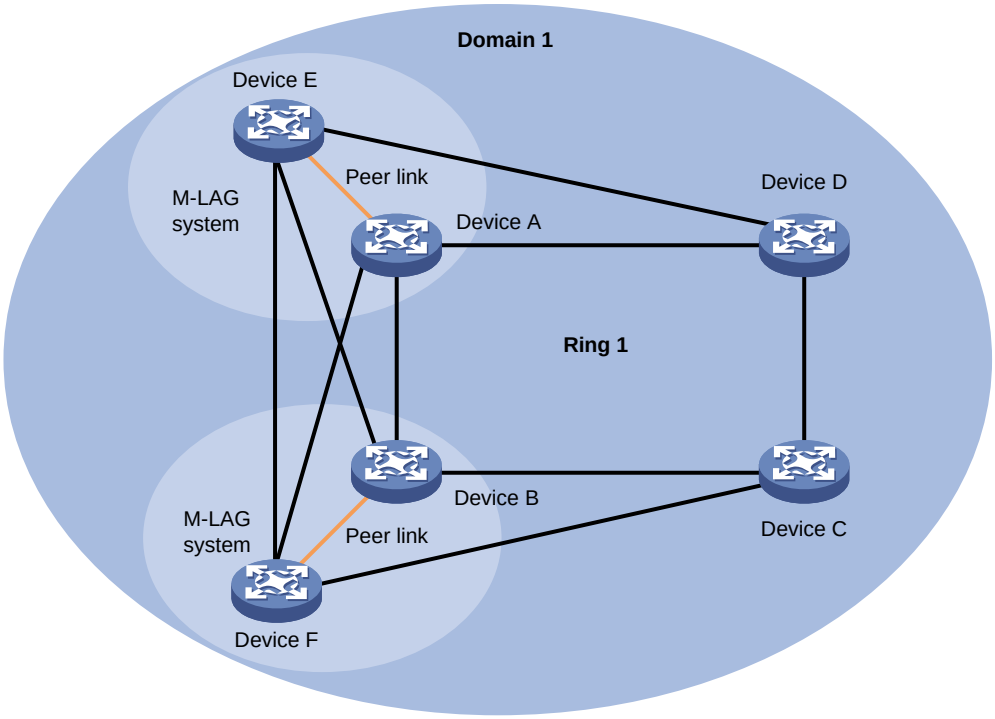
- Ring 1 is the primary ring and Ring 2 is the subring in both Domain 1 and Domain 2.
- Domain 1 and Domain 2 are configured with different protected VLANs.
- Device A is configured as the master node of Ring 1 in Domain 1.

- Device D is configured as the master node of Ring 1 in Domain 2.
- Device E is configured as the master node of Ring 2 in both Domain 1 and Domain 2. However, different ports on Device E are blocked in Domain 1 and Domain 2.

Traffic from different VLANs can travel over different paths in the subring and primary ring.

Figure 7 Schematic diagram for an intersecting-ring load balancing network

RRPP with M-LAG



NOTE:

The S5200-EI-G switch series does not support the M-LAG feature.

M-LAG allows you to virtualize the devices in an RRPP ring into one system through multichassis link, thereby achieving device-level redundancy and load balancing.

As shown in Figure 8, the M-LAG system composed of Device A and Device E is the master node of Ring 1, and the M-LAG system composed of Device B and Device F is the transit node of Ring 1. For more information about M-LAG, see *Layer 2—LAN Switching Configuration Guide*.

Figure 8 RRPP with M-LAG

Protocols and standards

RFC 3619, *Extreme Networks' Ethernet Automatic Protection Switching (EAPS) Version 1*

Restrictions and guidelines: RRPP configuration

- RRPP does not have an auto election mechanism. You must configure each node in the ring network correctly for RRPP to monitor and protect the ring network.
- You can configure RRPP in the following order:
  - Create RRPP domains based on service planning.
  - Specify control VLANs and protected VLANs for each RRPP domain.
  - Determine the ring roles and node roles based on the traffic paths in each RRPP domain.
- To ensure correct operation of the RRPP feature, do not configure user authentication settings (such as AAA, 802.1X, MAC address authentication, and portal) on RRPP ports.

RRPP tasks at a glance

To configure RRPP, perform the following tasks:

1. Creating an RRPP domain

   Perform this task on devices you want to configure as nodes in the RRPP domain.
2. Configuring control VLANs

   Perform this task on all nodes in the RRPP domain.
3. Configuring protected VLANs

   Perform this task on all nodes in the RRPP domain.

4. Configuring RRPP rings
   a. Configuring RRPP ports

      Perform this task on each node's ports intended for accessing RRPP rings.
   b. Configuring RRPP nodes

      Perform this task on all nodes in the RRPP domain.
5. Activating an RRPP domain

   Perform this task on all nodes in the RRPP domain.
6. (Optional.) Configuring RRPP timers

   Perform this task on the master node in the RRPP domain.
   - Configuring the Hello timer and Fail timer
   - Configuring the link-up delay timer
7. (Optional.) Configuring an RRPP ring group

   Perform this task on the edge node and assistant edge node in the RRPP domain.
8. (Optional.) Enabling SNMP notifications for RRPP

Prerequisites for RRPP

Before you configure RRPP, you must physically construct a ring-shaped Ethernet topology.

Creating an RRPP domain

About this task

When you create an RRPP domain, specify a domain ID to uniquely identify the RRPP domain. All devices in the same RRPP domain must be configured with the same domain ID.

Restrictions and guidelines

Perform this task on devices you want to configure as nodes in the RRPP domain.

Procedure

1. Enter system view.

   `system-view`
2. Create an RRPP domain and enter RRPP domain view.

   `rrpp domain` *`domain-id`*

Configuring control VLANs

Restrictions and guidelines

- Perform this task on all nodes in the RRPP domain.
- Before you configure RRPP rings in an RRPP domain, configure the same control VLANs for all nodes in the RRPP domain first. You need only configure the primary control VLAN for an RRPP domain. The system automatically configures the secondary control VLAN. It uses the primary control VLAN ID plus 1 as the secondary control VLAN ID. For the control VLAN configuration to succeed, make sure the IDs of the two control VLANs are consecutive and have not been previously assigned.
- Do not configure the default VLAN of a port accessing an RRPP ring as the control VLAN.

- A VLAN with VLAN interface resource reservation cannot be configured as the control VLAN. For more information about VLAN interface resource reservation, see *Layer 2—LAN Switching Configuration Guide*.
- The primary and secondary control VLAN IDs must be different from the Layer 3 Ethernet subinterface IDs of the master ring and subrings.
- For RRPPDUs to be correctly forwarded, do not enable QinQ or VLAN mapping on control VLANs.
- After you configure RRPP rings for an RRPP domain, you cannot delete or modify the primary control VLAN of the domain. You can only use the **undo control-vlan** command to delete a primary control VLAN.
- To transparently transmit RRPPDUs on a device not configured with RRPP, make sure only the two ports accessing the RRPP ring permit packets from the control VLANs. Otherwise, the packets from other VLANs might enter the control VLANs in transparent transmission mode and strike the RRPP ring.
- When configuring RRPP with M-LAG, make sure the peer-link interface is a trunk port. The peer-link interface will automatically join or leave a control VLAN as the control VLAN is created or deleted.

Procedure

1. Enter system view.
   system-view
2. Enter RRPP domain view.
   rrpp domain *domain-id*
3. Configure the primary control VLAN for the RRPP domain.
   control-vlan *vlan-id*

Configuring protected VLANs

Restrictions and guidelines

- Perform this task on all nodes in the RRPP domain.
- Before you configure RRPP rings in an RRPP domain, configure the same protected VLANs for all nodes in the RRPP domain. All VLANs to which the RRPP ports are assigned must be protected by the RRPP domains.
- When you configure load balancing, you must configure different protected VLANs for different RRPP domains.

Prerequisites

Before you configure protected VLANs, you must configure an MST region and the VLAN-to-instance mapping table. For more information about MST regions, see spanning tree configuration in *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter RRPP domain view.
   rrpp domain *domain-id*
3. Configure protected VLANs for the RRPP domain.
   protected-vlan reference-instance *instance-id-list*

Configuring RRPP rings

When you configure an RRPP ring, you must configure the ports connecting each node to the RRPP ring before configuring the nodes.

Prerequisites

Before you configure an RRPP ring, you must configure control VLANs and protected VLANs.

Configuring RRPP ports

Restrictions and guidelines

- Perform this task on each node's ports intended for accessing RRPP rings.
- To accelerate topology convergence, use the **link-delay** command to enable link status rapid report function on an RRPP port. Use this command to set the physical state change suppression interval to 0 seconds. For more information about the **link-delay** command, see *Layer 2—LAN Switching Command Reference*.
- Do not assign a port to both an aggregation group and an RRPP ring. If you do so, the port does not take effect on the RRPP ring.
- Do not assign a peer-link interface to an RRPP ring. A peer-link interface does not work for an RRPP ring.
- Do not assign both an M-LAG interface and a non-M-LAG interface to an RRPP ring. If you do so, the M-LAG interface does not take effect on the RRPP ring.

Procedure

1. Enter system view.

   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.

   interface *interface-type interface-number*
3. Configure the link type of the interface as trunk.

   port link-type trunk

   By default, the link type of an interface is access.

   For more information about the command, see *Layer 2—LAN Switching Command Reference*.
4. Assign the trunk port to the protected VLANs of the RRPP domain.

   port trunk permit vlan { *vlan-id-list* | **all** }

   By default, a trunk port allows only packets from VLAN 1 to pass through.

   RRPP ports always allow packets from the control VLANs to pass through.

   For more information about the command, see *Layer 2—LAN Switching Command Reference*.
5. Disable the spanning tree feature.

   undo stp enable

   By default, the spanning tree feature is enabled.

   For more information about the command, see *Layer 2—LAN Switching Command Reference*.

Configuring RRPP nodes

Restrictions and guidelines

- Perform this task on all nodes in the RRPP domain.
- If a device carries multiple RRPP rings in an RRPP domain, it can only be an edge node or an assistant edge node on a subring.
- When you configure an edge node or an assistant edge node, you must configure the primary ring before configuring the subrings.

Specifying a master node

1. Enter system view.

   system-view
2. Enter RRPP domain view.

   rrpp domain *domain-id*
3. Specify the current device as the master node of the ring, and specify the primary port and the secondary port.

   ring *ring-id* **node-mode master** [**primary-port** *interface-type interface-number*] [**secondary-port** *interface-type interface-number*] **level** *level-value*

Specifying a transit node

1. Enter system view.

   system-view
2. Enter RRPP domain view.

   rrpp domain *domain-id*
3. Specify the current device as a transit node of the ring, and specify the primary port and the secondary port.

   ring *ring-id* **node-mode transit** [**primary-port** *interface-type interface-number*] [**secondary-port** *interface-type interface-number*] **level** *level-value*

Specifying an edge node

1. Enter system view.

   system-view
2. Enter RRPP domain view.

   rrpp domain *domain-id*
3. Specify the current device as a master node or transit node of the primary ring, and specify the primary port and the secondary port.

   ring *ring-id* **node-mode** { **master** | **transit** } [**primary-port** *interface-type interface-number*] [**secondary-port** *interface-type interface-number*] **level** *level-value*
4. Specify the current device as the edge node of a subring, and specify the edge port.

   ring *ring-id* **node-mode edge** [**edge-port** *interface-type interface-number*]

Specifying an assistant edge node

1. Enter system view.

   system-view
2. Enter RRPP domain view.

rrpp domain *domain-id*

3. Specify the current device as a master node or transit node of the primary ring, and specify the primary port and the secondary port.

   ring *ring-id* **node-mode** { **master** | **transit** } [**primary-port** *interface-type interface-number*] [**secondary-port** *interface-type interface-number*] **level** *level-value*

   By default, a device is not a node of the RRPP ring.

4. Specify the current device as the assistant edge node of the subring, and specify an edge port.

   ring *ring-id* **node-mode assistant-edge** [**edge-port** *interface-type interface-number*]

Activating an RRPP domain

Restrictions and guidelines

- Perform this task on all nodes in the RRPP domain.
- Before you activate an RRPP domain on the current device, enable the RRPP protocol and RRPP rings for the RRPP domain on the current device.
- Before you enable subrings on a device, you must enable the primary ring. Before you disable the primary ring on the device, you must disable all subrings. Otherwise, the system displays error prompts.
- To prevent Hello packets of subrings from being looped on the primary ring, enable the primary ring on its master node first. Then enable the subrings on their respective master nodes.

Procedure

1. Enter system view.

   system-view

2. Enable RRPP.

   rrpp enable

   By default, RRPP is disabled.

3. Enter RRPP domain view.

   rrpp domain *domain-id*

4. Enable the specified RRPP ring.

   ring *ring-id* **enable**

   By default, an RRPP ring is disabled.

Configuring RRPP timers

Restrictions and guidelines for RRPP timer configuration

Perform this task on the master node of an RRPP domain.

Configuring the Hello timer and Fail timer

Restrictions and guidelines

- The Fail timer must be greater than or equal to three times the Hello timer.

- In a dual-homed-ring network, to avoid temporary loops when the primary ring fails, make sure the value of *A* is greater than the value of *B*, where:
  - *A* is the difference between the Fail timer values on the master node of the subring and the master node of the primary ring.
  - *B* is twice the Hello timer value on the master node of the subring.

Procedure

1. Enter system view.
   system-view
2. Enter RRPP domain view.
   rrpp domain *domain-id*
3. Set the Hello timer and Fail timer for the RRPP domain.
   timer hello-timer *hello-value* **fail-timer** *fail-value*
   By default, the Hello timer value is 1 second and the Fail timer value is 3 seconds.

Configuring the link-up delay timer

Restrictions and guidelines

If the **distribute** keyword is not specified, the link-up delay timer value cannot be greater than the Fail timer value minus twice the Hello timer value.

If you specify the **distribute** keyword in an RRPP network implementing load balancing, you must configure the link-up delay timer for each RRPP domain for the timer to take effect. If you set different timer values for different RRPP domains, the smallest timer value takes effect.

Procedure

1. Enter system view.
   system-view
2. Enter RRPP domain view.
   rrpp domain *domain-id*
3. Set the link-up delay timer for the RRPP domain.
   linkup-delay-timer *delay-time* [**distribute**]
   By default, the link-up delay timer value is 0 seconds, and the **distribute** keyword is not specified.

Configuring an RRPP ring group

About this task

To reduce Edge-Hello traffic, assign subrings with the same edge node and assistant edge node to an RRPP ring group. An RRPP ring group must be configured on both the edge node and the assistant edge node. It can only be configured on these two types of nodes.

Restrictions and guidelines

- Perform this task on the edge node and assistant edge node in the RRPP domain.
- You can assign a subring to only one RRPP ring group. The RRPP ring groups configured on the edge node and the assistant edge node must contain the same subrings. Otherwise, the RRPP ring group cannot operate correctly.
- The subrings in an RRPP ring group must share the same edge node and assistant edge node. The edge node and the assistant edge node must have the same SRPTs.

- Make sure a device is either the edge node or the assistant edge node on the subrings in an RRPP ring group.
- Make sure the RRPP ring groups on the edge node and the assistant edge node have the same configurations and activation status.
- Make sure all subrings in an RRPP ring group have the same SRPTs. If the SRPTs of these subrings are different, the RRPP ring group cannot operate correctly.

Procedure

1. Enter system view.
   system-view
2. Create an RRPP ring group and enter RRPP ring group view.
   rrpp ring-group *ring-group-id*
   By default, no RRPP ring groups exist.
3. Assign the specified subrings to the RRPP ring group.
   domain *domain-id* **ring** *ring-id-list*
   By default, no subrings are assigned to an RRPP ring group.

Enabling SNMP notifications for RRPP

About this task

To report critical RRPP events to an NMS, enable SNMP notifications for RRPP. For RRPP event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

Procedure

1. Enter system view.
   system-view
2. Enable SNMP notifications for RRPP.
   snmp-agent trap enable rrpp [**major-fault** | **multi-master** | **ring-fail** | **ring-recover**] *
   By default, SNMP notifications for RRPP are disabled.

Display and maintenance commands for RRPP

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display brief RRPP information.	**display rrpp brief**
Display RRPP group configuration information.	**display rrpp ring-group** [*ring-group-id*]
Display RRPPDU statistics.	**display rrpp statistics domain** *domain-id* [**ring** *ring-id*]
Display detailed RRPP information.	**display rrpp verbose domain** *domain-id* [**ring** *ring-id*]
Clear RRPPDU statistics.	**reset rrpp statistics domain**

	domain-id [**ring** *ring-id*]

RRPP configuration examples

Example: Configuring a single ring

Network configuration

As shown in Figure 9:

- Device A, Device B, Device C, and Device D form RRPP domain 1. Specify the primary control VLAN of RRPP domain 1 as VLAN 4092. Specify the protected VLANs of RRPP domain 1 as VLANs 1 through 30.
- Device A, Device B, Device C, and Device D form primary ring 1.
- Specify Device A as the master node of primary ring 1, GigabitEthernet 1/0/1 as the primary port, and GigabitEthernet 1/0/2 as the secondary port.
- Specify Device B, Device C, and Device D as the transit nodes of primary ring 1. Specify GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port on Device B, Device C, and Device D.

Figure 9 `Network diagram`

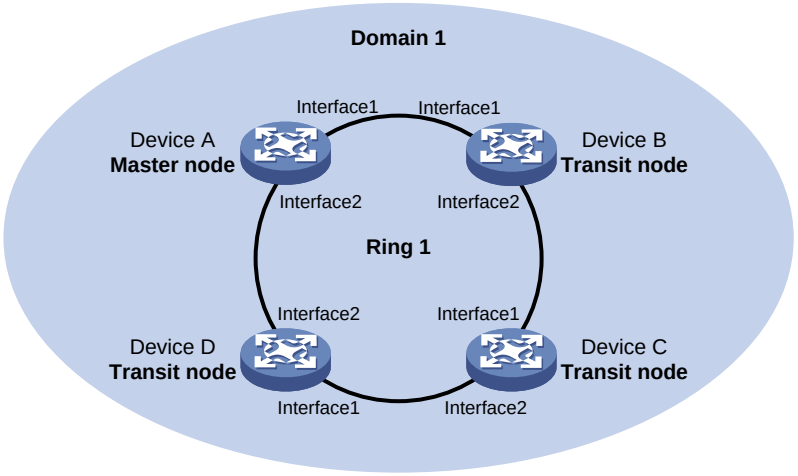


Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure Device A:

   # Create VLANs 1 through 30.

   ```
   <DeviceA> system-view
   [DeviceA] vlan 1 to 30
   ```

   # Map these VLANs to MSTI 1.

   ```
   [DeviceA] stp region-configuration
   [DeviceA-mst-region] instance 1 vlan 1 to 30
   ```

Activate the MST region configuration.

```
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] link-delay up 0
[DeviceA-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceA-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] link-delay up 0
[DeviceA-GigabitEthernet1/0/2] link-delay down 0
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceA] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceA-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceA-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device A as the master node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceA-rrpp-domain1] ring 1 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceA-rrpp-domain1] ring 1 enable
[DeviceA-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceA] rrpp enable
```

2. Configure Device B:

Create VLANs 1 through 30.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] link-delay up 0
[DeviceB-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] link-delay up 0
[DeviceB-GigabitEthernet1/0/2] link-delay down 0
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceB] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceB-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceB-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device B as the transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceB-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceB-rrpp-domain1] ring 1 enable
[DeviceB-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceB] rrpp enable
```

3. Configure Device C:

Create VLANs 1 through 30.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] link-delay up 0
[DeviceC-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] link-delay up 0
[DeviceC-GigabitEthernet1/0/2] link-delay down 0
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceC] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceC-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceC-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device C as the transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceC-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceC-rrpp-domain1] ring 1 enable
[DeviceC-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceC] rrpp enable
```

4. Configure Device D:

Create VLANs 1 through 30.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceD] stp region-configuration
[DeviceD-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] link-delay up 0
[DeviceD-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] link-delay up 0
[DeviceD-GigabitEthernet1/0/2] link-delay down 0
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceD] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceD-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceD-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device D as the transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceD-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceD-rrpp-domain1] ring 1 enable
[DeviceD-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceD] rrpp enable
```

Verifying the configuration

Use the **`display rrpp verbose`** command to display detailed RRPP information on the device, such as ring state and port state.

```
[DeviceA] display rrpp verbose domain 1
 Domain ID     : 1
 Control VLAN  : Primary 4092, Secondary 4093
 Protected VLAN: Reference instance 1
 Hello timer   : 1 sec, Fail timer: 3 sec
 Linkup-Delay timer: 0 sec

 Ring ID       : 1
 Ring level    : 0
 Node mode     : Master
 Ring state    : Complete
 Enable status : Yes, Active status: Yes
 Primary port  : GE1/0/1                   Port status: UP
 Secondary port: GE1/0/2                   Port status: BLOCKED
```

Example: Configuring intersecting rings

Network configuration

As shown in Figure 10:

- Device A, Device B, Device C, Device D, and Device E form RRPP domain 1. VLAN 4092 is the primary control VLAN of RRPP domain 1. RRPP domain 1 protects VLANs 1 through 30.
- Device A, Device B, Device C, and Device D form primary ring 1. Device B, Device C, and Device E form subring 2.
- Device A is the master node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 the secondary port.
- Device E is the master node of subring 2, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 the secondary port.
- Device B is the transit node of primary ring 1 and the edge node of subring 2, with GigabitEthernet 1/0/3 as the edge port.
- Device C is the transit node of primary ring 1 and the assistant edge node of subring 1, with GigabitEthernet 1/0/3 as the edge port.
- Device D is the transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 the secondary port.

Figure 10 `Network diagram`

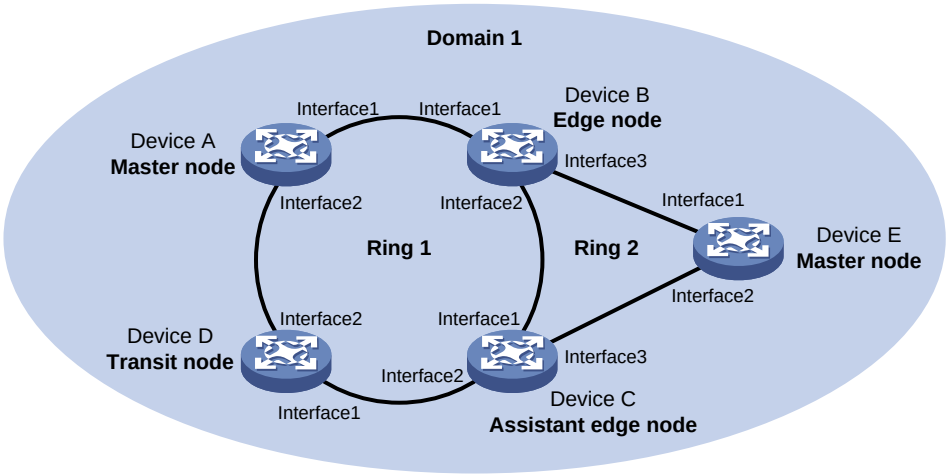

Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure Device A:

Create VLANs 1 through 30.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceA] stp region-configuration
[DeviceA-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] link-delay up 0
[DeviceA-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceA-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] link-delay up 0
[DeviceA-GigabitEthernet1/0/2] link-delay down 0
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceA] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceA-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceA-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device A as the master node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceA-rrpp-domain1] ring 1 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceA-rrpp-domain1] ring 1 enable
[DeviceA-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceA] rrpp enable
```

2. Configure Device B:

Create VLANs 1 through 30.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] link-delay up 0
[DeviceB-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] link-delay up 0
[DeviceB-GigabitEthernet1/0/2] link-delay down 0
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] link-delay up 0
[DeviceB-GigabitEthernet1/0/3] undo stp enable
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/3] quit
```

Create RRPP domain 1.

```
[DeviceB] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceB-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceB-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device B as a transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceB-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceB-rrpp-domain1] ring 1 enable
```

Configure Device B as the edge node of subring 2, with GigabitEthernet 1/0/3 as the edge port. Enable ring 2.

```
[DeviceB-rrpp-domain1] ring 2 node-mode edge edge-port gigabitethernet 1/0/3
[DeviceB-rrpp-domain1] ring 2 enable
[DeviceB-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceB] rrpp enable
```

3. Configure Device C:

Create VLANs 1 through 30.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] link-delay up 0
[DeviceC-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] link-delay up 0
[DeviceC-GigabitEthernet1/0/2] link-delay down 0
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/3
[DeviceC-GigabitEthernet1/0/3] link-delay up 0
[DeviceC-GigabitEthernet1/0/3] link-delay down 0
[DeviceC-GigabitEthernet1/0/3] undo stp enable
[DeviceC-GigabitEthernet1/0/3] port link-type trunk
[DeviceC-GigabitEthernet1/0/3] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/3] quit
```

Create RRPP domain 1.

```
[DeviceC] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceC-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceC-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device C as a transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceC-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceC-rrpp-domain1] ring 1 enable
```

Configure Device C as the assistant edge node of subring 2, with GigabitEthernet 1/0/3 as the edge port. Enable ring 2.

```
[DeviceC-rrpp-domain1] ring 2 node-mode assistant-edge edge-port gigabitethernet
1/0/3
[DeviceC-rrpp-domain1] ring 2 enable
[DeviceC-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceC] rrpp enable
```

4. Configure Device D:

Create VLANs 1 through 30.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceD] stp region-configuration
[DeviceD-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] link-delay up 0
[DeviceD-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] link-delay up 0
[DeviceD-GigabitEthernet1/0/2] link-delay down 0
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceD] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceD-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceD-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device D as the transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceD-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceD-rrpp-domain1] ring 1 enable
[DeviceD-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceD] rrpp enable
```

5. Configure Device E:

Create VLANs 1 through 30.

```
<DeviceE> system-view
```

```
[DeviceE] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceE] stp region-configuration
[DeviceE-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceE-mst-region] active region-configuration
[DeviceE-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceE] interface gigabitethernet 1/0/1
[DeviceE-GigabitEthernet1/0/1] link-delay up 0
[DeviceE-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceE-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceE-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceE-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceE-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceE] interface gigabitethernet 1/0/2
[DeviceE-GigabitEthernet1/0/2] link-delay up 0
[DeviceE-GigabitEthernet1/0/2] link-delay down 0
[DeviceE-GigabitEthernet1/0/2] undo stp enable
[DeviceE-GigabitEthernet1/0/2] port link-type trunk
[DeviceE-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceE-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceE] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceE-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceE-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device E as the master node of subring 2, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 2.

```
[DeviceE-rrpp-domain1] ring 2 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 1
[DeviceE-rrpp-domain1] ring 2 enable
[DeviceE-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceE] rrpp enable
```

Verifying the configuration

Use the **`display rrpp verbose`** command to display detailed RRPP information on the device, such as ring state and port state.

Example: Configuring load-balanced intersecting rings

Network configuration

As shown in Figure 11:

- Device A, Device B, Device C, Device D, and Device F form RRPP domain 1. VLAN 100 is the primary control VLAN of the RRPP domain. Device A is the master node of the primary ring, Ring 1. Device D is the transit node of Ring 1. Device F is the master node of the subring Ring 3. Device C is the edge node of the subring Ring 3. Device B is the assistant edge node of the subring Ring 3.
- Device A, Device B, Device C, Device D, and Device E form RRPP domain 2. VLAN 105 is the primary control VLAN of the RRPP domain. Device A is the master node of the primary ring, Ring 1. Device D is the transit node of Ring 1. Device E is the master node of the subring Ring 2. Device C is the edge node of the subring Ring 2. Device B is the assistant edge node of the subring Ring 2.
- Specify VLAN 11 as the protected VLAN of domain 1, and VLAN 12 the protected VLAN of domain 2. You can implement VLAN-based load balancing on Ring 1.
- Ring 2 and Ring 3 have the same edge node and assistant edge node, and the two subrings have the same SRPTs. You can add Ring 2 and Ring 3 to an RRPP ring group to reduce Edge-Hello traffic.

Figure 11 `Network diagram`

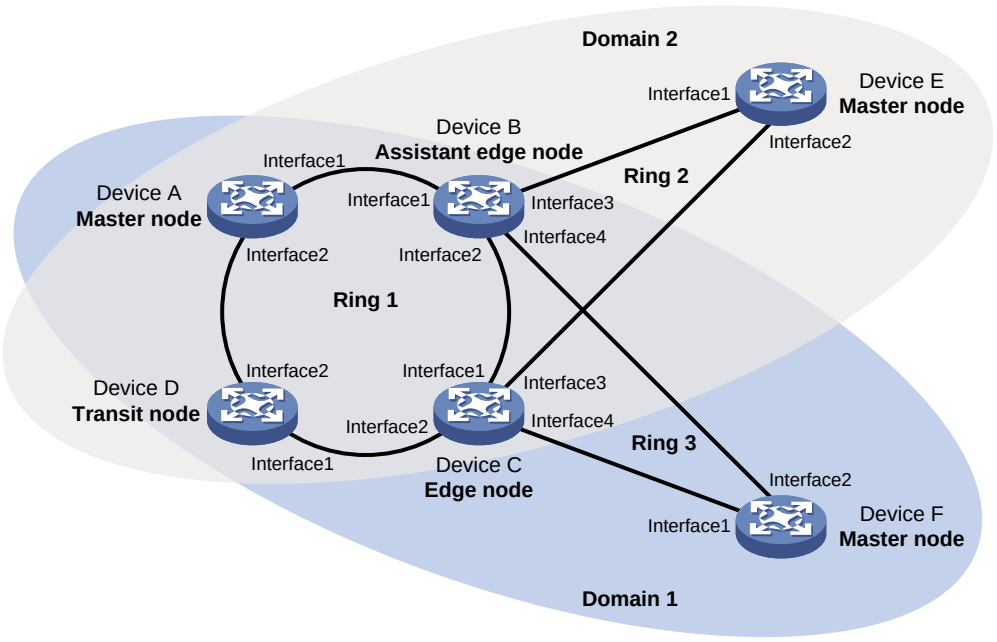

Table 4 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4

Procedure

1. Configure Device A:

Create VLANs 11 and 12.

```
<DeviceA> system-view
[DeviceA] vlan 11 to 12
```

Map VLAN 11 to MSTI 1 and VLAN 12 to MSTI 2.

```
[DeviceA] stp region-configuration
[DeviceA-mst-region] instance 1 vlan 11
[DeviceA-mst-region] instance 2 vlan 12
```

Activate the MST region configuration.

```
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] link-delay up 0
[DeviceA-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceA-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Remove the port from VLAN 1, and assign it to VLANs 11 and 12.

```
[DeviceA-GigabitEthernet1/0/1] undo port trunk permit vlan 1
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 11 12
```

Configure VLAN 11 as the default VLAN.

```
[DeviceA-GigabitEthernet1/0/1] port trunk pvid vlan 11
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] link-delay up 0
[DeviceA-GigabitEthernet1/0/2] link-delay down 0
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] undo port trunk permit vlan 1
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 11 12
[DeviceA-GigabitEthernet1/0/2] port trunk pvid vlan 11
[DeviceA-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceA] rrpp domain 1
```

Configure VLAN 100 as the primary control VLAN of RRPP domain 1.

```
[DeviceA-rrpp-domain1] control-vlan 100
```

Configure the VLAN mapped to MSTI 1 as the protected VLAN of RRPP domain 1.

```
[DeviceA-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device A as the master node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceA-rrpp-domain1] ring 1 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceA-rrpp-domain1] ring 1 enable
```

```
[DeviceA-rrpp-domain1] quit
```

Create RRPP domain 2.

```
[DeviceA] rrpp domain 2
```

Configure VLAN 105 as the primary control VLAN of RRPP domain 2.

```
[DeviceA-rrpp-domain2] control-vlan 105
```

Configure the VLAN mapped to MSTI 2 as the protected VLAN of RRPP domain 2.

```
[DeviceA-rrpp-domain2] protected-vlan reference-instance 2
```

Configure Device A as the master node of primary ring 1, with GigabitEthernet 1/0/2 as the master port and GigabitEthernet 1/0/1 as the secondary port. Enable ring 1.

```
[DeviceA-rrpp-domain2] ring 1 node-mode master primary-port gigabitethernet 1/0/2
secondary-port gigabitethernet 1/0/1 level 0
[DeviceA-rrpp-domain2] ring 1 enable
[DeviceA-rrpp-domain2] quit
```

Enable RRPP.

```
[DeviceA] rrpp enable
```

2. Configure Device B:

Create VLANs 11 and 12.

```
<DeviceB> system-view
[DeviceB] vlan 11 to 12
```

Map VLAN 11 to MSTI 1 and VLAN 12 to MSTI 2.

```
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 11
[DeviceB-mst-region] instance 2 vlan 12
```

Activate the MST region configuration.

```
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] link-delay up 0
[DeviceB-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Remove the port from VLAN 1, and assign it to VLANs 11 and 12.

```
[DeviceB-GigabitEthernet1/0/1] undo port trunk permit vlan 1
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 11 12
```

Configure VLAN 11 as the default VLAN.

```
[DeviceB-GigabitEthernet1/0/1] port trunk pvid vlan 11
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] link-delay up 0
[DeviceB-GigabitEthernet1/0/2] link-delay down 0
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] undo port trunk permit vlan 1
```

```
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 11 12
[DeviceB-GigabitEthernet1/0/2] port trunk pvid vlan 11
[DeviceB-GigabitEthernet1/0/2] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/3.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] link-delay up 0
[DeviceB-GigabitEthernet1/0/3] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/3] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
```

Remove the port from VLAN 1, and assign it to VLAN 12.

```
[DeviceB-GigabitEthernet1/0/3] undo port trunk permit vlan 1
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan 12
```

Configure VLAN 12 as the default VLAN.

```
[DeviceB-GigabitEthernet1/0/3] port trunk pvid vlan 12
[DeviceB-GigabitEthernet1/0/3] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/4.

```
[DeviceB] interface gigabitethernet 1/0/4
[DeviceB-GigabitEthernet1/0/4] link-delay up 0
[DeviceB-GigabitEthernet1/0/4] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/4] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceB-GigabitEthernet1/0/4] port link-type trunk
```

Remove the port from VLAN 1, and assign it to VLAN 11.

```
[DeviceB-GigabitEthernet1/0/4] undo port trunk permit vlan 1
[DeviceB-GigabitEthernet1/0/4] port trunk permit vlan 11
```

Configure VLAN 11 as the default VLAN.

```
[DeviceB-GigabitEthernet1/0/4] port trunk pvid vlan 11
[DeviceB-GigabitEthernet1/0/4] quit
```

Create RRPP domain 1.

```
[DeviceB] rrpp domain 1
```

Configure VLAN 100 as the primary control VLAN of RRPP domain 1.

```
[DeviceB-rrpp-domain1] control-vlan 100
```

Configure the VLAN mapped to MSTI 1 as the protected VLAN of RRPP domain 1.

```
[DeviceB-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device B as a transit node of primary ring 1 in RRPP domain 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceB-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceB-rrpp-domain1] ring 1 enable
```

Configure Device B as the assistant edge node of subring 3 in RRPP domain 1, with GigabitEthernet 1/0/4 as the edge port. Enable subring 3.

```
[DeviceB-rrpp-domain1] ring 3 node-mode assistant-edge edge-port gigabitethernet
1/0/4
[DeviceB-rrpp-domain1] ring 3 enable
```

```
[DeviceB-rrpp-domain1] quit
```

Create RRPP domain 2.

```
[DeviceB] rrpp domain 2
```

Configure VLAN 105 as the primary control VLAN of RRPP domain 2.

```
[DeviceB-rrpp-domain2] control-vlan 105
```

Configure the VLAN mapped to MSTI 2 as the protected VLAN of RRPP domain 2.

```
[DeviceB-rrpp-domain2] protected-vlan reference-instance 2
```

Configure Device B as the transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceB-rrpp-domain2] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceB-rrpp-domain2] ring 1 enable
```

Configure Device B as the assistant edge node of subring 2 in RRPP domain 2, with GigabitEthernet 1/0/3 as the edge port. Enable subring 2.

```
[DeviceB-rrpp-domain2] ring 2 node-mode assistant-edge edge-port gigabitethernet
1/0/3
[DeviceB-rrpp-domain2] ring 2 enable
[DeviceC-rrpp-domain2] quit
```

Enable RRPP.

```
[DeviceB] rrpp enable
```

3. Configure Device C:

Create VLANs 11 and 12.

```
<DeviceC> system-view
[DeviceC] vlan 11 to 12
```

Map VLAN 11 to MSTI 1 and VLAN 12 to MSTI 2.

```
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 11
[DeviceC-mst-region] instance 2 vlan 12
```

Activate the MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] link-delay up 0
[DeviceC-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Remove the port from VLAN 1, and assign it to VLANs 11 and 12.

```
[DeviceC-GigabitEthernet1/0/1] undo port trunk permit vlan 1
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 11 12
```

Configure VLAN 11 as the default VLAN.

```
[DeviceC-GigabitEthernet1/0/1] port trunk pvid vlan 11
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
```

```
[DeviceC-GigabitEthernet1/0/2] link-delay up 0
[DeviceC-GigabitEthernet1/0/2] link-delay down 0
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] undo port trunk permit vlan 1
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 11 12
[DeviceC-GigabitEthernet1/0/2] port trunk pvid vlan 11
[DeviceC-GigabitEthernet1/0/2] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/3.

```
[DeviceC] interface gigabitethernet 1/0/3
[DeviceC-GigabitEthernet1/0/3] link-delay up 0
[DeviceC-GigabitEthernet1/0/3] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/3] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/3] port link-type trunk
```

Remove the port from VLAN 1, and assign it to VLAN 12.

```
[DeviceC-GigabitEthernet1/0/3] undo port trunk permit vlan 1
[DeviceC-GigabitEthernet1/0/3] port trunk permit vlan 12
```

Configure VLAN 12 as the default VLAN.

```
[DeviceC-GigabitEthernet1/0/3] port trunk pvid vlan 12
[DeviceC-GigabitEthernet1/0/3] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/4.

```
[DeviceC] interface gigabitethernet 1/0/4
[DeviceC-GigabitEthernet1/0/4] link-delay up 0
[DeviceC-GigabitEthernet1/0/4] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/4] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/4] port link-type trunk
```

Remove the port from VLAN 1, and assign it to VLAN 11.

```
[DeviceC-GigabitEthernet1/0/4] undo port trunk permit vlan 1
[DeviceC-GigabitEthernet1/0/4] port trunk permit vlan 11
```

Configure VLAN 11 as the default VLAN.

```
[DeviceC-GigabitEthernet1/0/4] port trunk pvid vlan 11
[DeviceC-GigabitEthernet1/0/4] quit
```

Create RRPP domain 1.

```
[DeviceC] rrpp domain 1
```

Configure VLAN 100 as the primary control VLAN of RRPP domain 1.

```
[DeviceC-rrpp-domain1] control-vlan 100
```

Configure the VLAN mapped to MSTI 1 as the protected VLAN of RRPP domain 1.

```
[DeviceC-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device C as the transit node of primary ring 1 in RRPP domain 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceC-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
```

```
[DeviceC-rrpp-domain1] ring 1 enable
```

Configure Device C as the edge node of subring 3 in RRPP domain 1, with GigabitEthernet 1/0/4 as the edge port. Enable subring 3.

```
[DeviceC-rrpp-domain1] ring 3 node-mode edge edge-port gigabitethernet 1/0/4
[DeviceC-rrpp-domain1] ring 3 enable
[DeviceC-rrpp-domain1] quit
```

Create RRPP domain 2.

```

Configure VLAN 11 as the default VLAN.

```
[DeviceD-GigabitEthernet1/0/1] port trunk pvid vlan 11
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] link-delay up 0
[DeviceD-GigabitEthernet1/0/2] link-delay down 0
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] undo port trunk permit vlan 1
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 11 12
[DeviceD-GigabitEthernet1/0/2] port trunk pvid vlan 11
[DeviceD-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceD] rrpp domain 1
```

Configure VLAN 100 as the primary control VLAN of RRPP domain 1.

```
[DeviceD-rrpp-domain1] control-vlan 100
```

Configure the VLAN mapped to MSTI 1 as the protected VLAN of RRPP domain 1.

```
[DeviceD-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device D as the transit node of primary ring 1 in RRPP domain 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceD-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceD-rrpp-domain1] ring 1 enable
[DeviceD-rrpp-domain1] quit
```

Create RRPP domain 2.

```
[DeviceD] rrpp domain 2
```

Configure VLAN 105 as the primary control VLAN of RRPP domain 2.

```
[DeviceD-rrpp-domain2] control-vlan 105
```

Configure the VLAN mapped to MSTI 2 as the protected VLAN of RRPP domain 2.

```
[DeviceD-rrpp-domain2] protected-vlan reference-instance 2
```

Configure Device D as the transit node of primary ring 1 in RRPP domain 2, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceD-rrpp-domain2] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceD-rrpp-domain2] ring 1 enable
[DeviceD-rrpp-domain2] quit
```

Enable RRPP.

```
[DeviceD] rrpp enable
```

5. Configure Device E:

Create VLAN 12.

```
<DeviceE> system-view
[DeviceE] vlan 12
```

Map VLAN 12 to MSTI 2.

```
[DeviceE-vlan12] quit
[DeviceE] stp region-configuration
[DeviceE-mst-region] instance 2 vlan 12
```

Activate the MST region configuration.

```
[DeviceE-mst-region] active region-configuration
[DeviceE-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceE] interface gigabitethernet 1/0/1
[DeviceE-GigabitEthernet1/0/1] link-delay up 0
[DeviceE-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceE-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceE-GigabitEthernet1/0/1] port link-type trunk
```

Remove the port from VLAN 1, and assign it to VLAN 12.

```
[DeviceE-GigabitEthernet1/0/1] undo port trunk permit vlan 1
[DeviceE-GigabitEthernet1/0/1] port trunk permit vlan 12
```

Configure VLAN 12 as the default VLAN.

```
[DeviceE-GigabitEthernet1/0/1] port trunk pvid vlan 12
[DeviceE-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceE] interface gigabitethernet 1/0/2
[DeviceE-GigabitEthernet1/0/2] link-delay up 0
[DeviceE-GigabitEthernet1/0/2] link-delay down 0
[DeviceE-GigabitEthernet1/0/2] undo stp enable
[DeviceE-GigabitEthernet1/0/2] port link-type trunk
[DeviceE-GigabitEthernet1/0/2] undo port trunk permit vlan 1
[DeviceE-GigabitEthernet1/0/2] port trunk permit vlan 12
[DeviceE-GigabitEthernet1/0/2] port trunk pvid vlan 12
[DeviceE-GigabitEthernet1/0/2] quit
```

Create RRPP domain 2.

```
[DeviceE] rrpp domain 2
```

Configure VLAN 105 as the primary control VLAN of RRPP domain 2.

```
[DeviceE-rrpp-domain2] control-vlan 105
```

Configure the VLAN mapped to MSTI 2 as the protected VLAN of RRPP domain 2.

```
[DeviceE-rrpp-domain2] protected-vlan reference-instance 2
```

Configure Device E as the master mode of subring 2 in RRPP domain 2, with GigabitEthernet 1/0/2 as the primary port and GigabitEthernet 1/0/1 as the secondary port. Enable ring 2.

```
[DeviceE-rrpp-domain2] ring 2 node-mode master primary-port gigabitethernet 1/0/2
secondary-port gigabitethernet 1/0/1 level 1
[DeviceE-rrpp-domain2] ring 2 enable
[DeviceE-rrpp-domain2] quit
```

Enable RRPP.

```
[DeviceE] rrpp enable
```

6. Configure Device F:

Create VLAN 11.

```
<DeviceF> system-view
[DeviceF] vlan 11
[DeviceF-vlan11] quit
```

Map VLAN 11 to MSTI 1.

```
[DeviceF] stp region-configuration
[DeviceF-mst-region] instance 1 vlan 11
```

Activate the MST region configuration.

```
[DeviceF-mst-region] active region-configuration
[DeviceF-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceF] interface gigabitethernet 1/0/1
[DeviceF-GigabitEthernet1/0/1] link-delay up 0
[DeviceF-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceF-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceF-GigabitEthernet1/0/1] port link-type trunk
```

Remove the port from VLAN 1, and assign it to VLAN 11.

```
[DeviceF-GigabitEthernet1/0/1] undo port trunk permit vlan 1
[DeviceF-GigabitEthernet1/0/1] port trunk permit vlan 11
```

Configure VLAN 11 as the default VLAN.

```
[DeviceF-GigabitEthernet1/0/1] port trunk pvid vlan 11
[DeviceF-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceF] interface gigabitethernet 1/0/2
[DeviceF-GigabitEthernet1/0/2] link-delay up 0
[DeviceF-GigabitEthernet1/0/2] link-delay down 0
[DeviceF-GigabitEthernet1/0/2] undo stp enable
[DeviceF-GigabitEthernet1/0/2] port link-type trunk
[DeviceF-GigabitEthernet1/0/2] undo port trunk permit vlan 1
[DeviceF-GigabitEthernet1/0/2] port trunk permit vlan 11
[DeviceF-GigabitEthernet1/0/2] port trunk pvid vlan 11
[DeviceF-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceF] rrpp domain 1
```

Configure VLAN 100 as the primary control VLAN of RRPP domain 1.

```
[DeviceF-rrpp-domain1] control-vlan 100
```

Configure the VLAN mapped to MSTI 1 as the protected VLAN of RRPP domain 1.

```
[DeviceF-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device F as the master node of subring 3 in RRPP domain 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable subring 3.

```
[DeviceF-rrpp-domain1] ring 3 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 1
[DeviceF-rrpp-domain1] ring 3 enable
[DeviceF-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceF] rrpp enable
```

7. Configure RRPP ring group settings on Device B and Device C:

Create RRPP ring group 1 on Device B, and add subrings 2 and 3 to the RRPP ring group.

```
[DeviceB] rrpp ring-group 1
[DeviceB-rrpp-ring-group1] domain 2 ring 2
```

```
[DeviceB-rrpp-ring-group1] domain 1 ring 3
```

Create RRPP ring group 1 on Device C, and add subrings 2 and 3 to the RRPP ring group.

```
[DeviceC] rrpp ring-group 1
[DeviceC-rrpp-ring-group1] domain 2 ring 2
[DeviceC-rrpp-ring-group1] domain 1 ring 3
```

Verifying the configuration

Use the **display rrpp verbose** command to display detailed RRPP information on the device, such as ring state and port state.

Troubleshooting RRPP

The primary node cannot receive Hello packets when the link state is normal

Symptom

When the link state is normal, the master node cannot receive Hello packets, and it unblocks the secondary port.

Analysis

The following are possible causes:

- One or more nodes on the RRPP ring are not enabled with RRPP.
- The domain IDs or control VLANs are not the same for all nodes on the RRPP ring.
- The port on the RRPP ring does not work correctly.

Solution

To resolve the problem:

1. Use the **display rrpp brief** command to determine whether RRPP is enabled for all nodes. If it is not, use the **rrpp enable** command and the **ring enable** command to enable RRPP and RRPP rings for all nodes.
2. Use the **display rrpp brief** command to determine whether the domain ID and primary control VLAN ID are the same for all nodes. If they are not, set the same domain ID and primary control VLAN ID for the nodes.
3. Use the **display rrpp verbose** command to examine the link state of each port in each ring.
4. Use the **debugging rrpp** command on each node to determine whether a port receives or transmits Hello packets. If it does not, Hello packets are lost.
5. If the problem persists, contact H3C Support.

Configuring ERPS

About ERPS

Ethernet Ring Protection Switching (ERPS) is a robust link layer protocol that ensures a loop-free topology and implements quick link recovery.

ERPS structure

Figure 1 ERPS ring structure

Rings

ERPS rings can be divided into major rings and subrings. An ERPS network consists of one major ring or multiple major rings, and multiple subrings. By default, a ring is a major ring. You can configure a ring as a subring manually.

As shown in the ERPS ring structure diagram, a major ring is a closed ring formed by Device A, Device B, Device C, and Device D. A subring is an open ring formed by the link Device C<—>Device E<—>Device F<—>Device D.

RPL

An ERPS ring is composed of many nodes. Some nodes use ring protection links (RPLs) to prevent loops on the ERPS ring. As shown in the ERPS ring structure diagram, the link between Device A and Device B or the link between Device E and Device F is an RPL.

Nodes

ERPS nodes include owner nodes, neighbor nodes, interconnection nodes, and normal nodes.

- The owner node and neighbor node block and unblock ports on the RPL to prevent loops and switch traffic. An RPL connects an owner node and a neighbor node.
- Interconnection nodes connect different rings. Interconnection nodes reside on subrings and forward service packets but not protocol packets.
- Normal nodes forward both service packets and protocol packets.

As shown in the ERPS ring structure diagram, on the major ring, Device A is the owner node and Device B is the neighbor node. On the subring, Device E is the owner node and Device F is the neighbor node. Devices C and D are interconnection nodes.

Ports

Each node consists of two ERPS ring member ports: Port 0 and port 1. ERPS ring member ports have the following types:

- **RPL port**—Port on an RPL link.
- **Interconnection port**—Port that connects a subring to a major ring.
- **Normal port**—Default type of a port that forwards both service packets and protocol packets.

As shown in the ERPS ring structure diagram, ports A1, B1, E1, and F1 are RPL ports. Ports C3 and D3 are interconnection ports. Other ports are normal ports.

Instances

An ERPS ring supports multiple ERPS instances. An ERPS instance is a logical ring to process service and protocol packets. Each ERPS instance has its own owner node and maintains its own state and data. An ERPS instance is uniquely identified by the ring ID and VLAN ID of ERPS packets. The ring ID indicates the ring of ERPS packets. It can be represented by the last byte in the destination MAC address of the packets. The VLAN ID indicates the ERPS instance of the packets.

ERPS protocol packets

ERPS protocol packets are Ring Automatic Protection Switching (R-APS) packets. You can configure the R-APS packet level. A node does not process R-APS packets whose levels are greater than the level of the packets sent by the node. On a ring, the levels of R-APS packets must be the same for all nodes in an ERPS instance.

Table 1 R-APS packet types and functions

Packet type	Function
No request, RPL block (NR-RB)	When the link is stable, an owner node in idle state periodically sends NR-RB packets to inform other nodes that the RPL ports are blocked. The nodes that receive the NR-RB packets unblock available ports and update MAC address entries.
No request (NR)	After the link fault is cleared, the node that detects the recovery periodically sends NR packets. When the owner node receives the NR packets, it starts the WTR timer. The node stops sending NR packets after receiving NR-RB packets from the owner node.
Signal fail (SF)	When a link fails to send or receive signals, the node that detects the fault periodically sends SF packets. When the owner node and neighbor node receive the FS packets, they unblock the RPL ports. The node stops sending SF packets after the fault is cleared.
Manual switch (MS)	A port configured with the MS mode is blocked and periodically sends MS packets. When other nodes receive the MS packets, they unblock available ports and update MAC address entries.
Forced switch (FS)	A port configured with the FS mode is blocked and periodically sends FS packets. When other nodes receive the FS packets, they unblock all ports and update MAC address entries.
Flush	If the topology of a subring changes, the interconnection ports on the subring broadcasts flush packets. All nodes that receive the flush packets update MAC address entries.

NOTE:

- Typically R-APS packets are transmitted within a ring. The flush packets sourced from the subring can be forwarded to the major ring.
- Service packets can be transmitted between different rings.

ERPS node states

Table 2 ERPS states

State	Description
Init	State for a non-interconnection node that has less than two ERPS ring member ports or for an interconnection node that does not have ERPS ring member ports.
Idle	Stable state when all non-RPL links are available. In this state, the owner node blocks the RPL port and periodically sends NR-RB packets. The neighbor node blocks the RPL port. All nodes enter the idle state after the owner node enters the idle state.
Protection	State when a non-RPL link is faulty. In this state, the RPL link is unblocked to forward traffic. All nodes enter the protection state after a node enters the protection state.
MS	State when traffic paths are manually switched. All nodes enter the MS state after a node is configured with the MS mode.
FS	State when traffic paths are forcibly switched. All nodes enter the FS state after a node is configured with the FS mode.
Pending	Transient state between the previous states.

ERPS timers

Hold-off timer

The hold-off timer starts when the port detects a link fault. The port reports the link fault if the fault persists when the timer expires.

This timer delays the fault report time and affects the link switching performance.

Guard timer

The guard timer starts when the port detects a link recovery. The port does not process R-APS packets before the timer expires.

This timer prevents R-APS packets from impacting the network and affects the link switching performance when multiple points of failures exist.

WTR timer

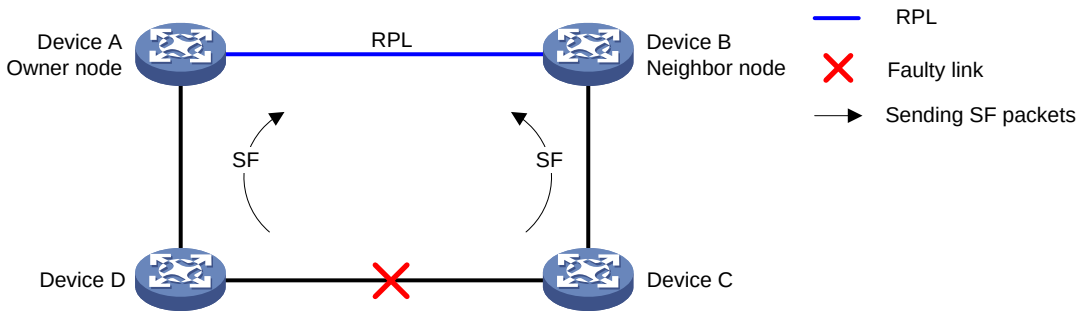
In revertive mode, the WTR timer starts when the owner node in protection state receives NR packets. The RPL is unblocked and the recovered node is blocked before the timer expires. The owner node blocks the RPL and sends NR-RB packets when the timer expires. If the port receives SF packets before the timer expires, the timer stops and the RPL remains unblocked.

This timer prevents intermittent link failures from impacting the network.

WTB timer

In revertive mode, the WTB timer starts when the owner node in MS or FS state receives NR packets. The RPL is unblocked and the recovered node sends NR packets before the timer expires. The owner node blocks the RPL and sends NR-RB packets when the timer expires. If the port receives SF packets before the timer expires, the timer stops and the RPL remains unblocked.

This timer prevents the RPL ports from being blocked and unblocked frequently.



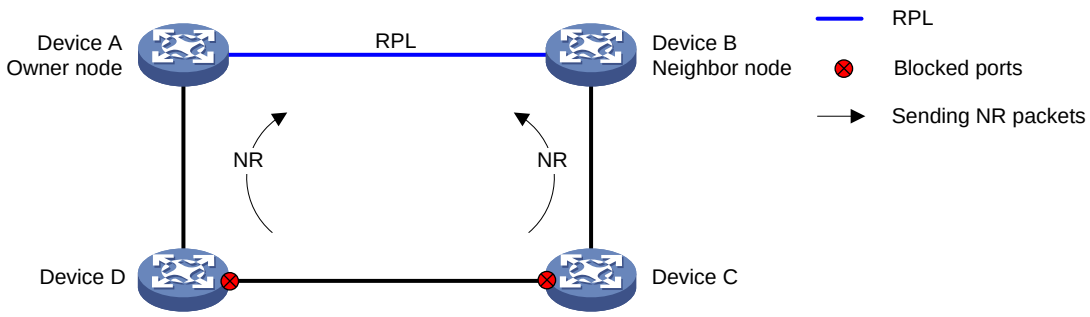
ERPS operation mechanism

ERPS uses the detection mechanism defined in ITU-T G.8032/Y.1344 to locate the point of failure and identify unidirectional or bidirectional faults.

ERPS uses the SF packets to report signal failures on a link and the NR packets to report link recovery. When a node detects a link status change, the node sends three packets first and then sends subsequent packets every five seconds.

Link-down report mechanism

Figure 2 Link-down report mechanism



As shown in Figure 2, the link-down report mechanism uses the following process:

1. Device C and Device D detect the link failure and perform the following operations:
   a. Block the ports on both side of the faulty link.
   b. Periodically send SF packets to other nodes.
2. Device A and Device B receive the SF packets and perform the following operations:
   a. Unblock RPL ports.
   b. Update the MAC address entries.

Service packets are switched to the RPL link.

Link recovery mechanism

Figure 3 Link recovery mechanism

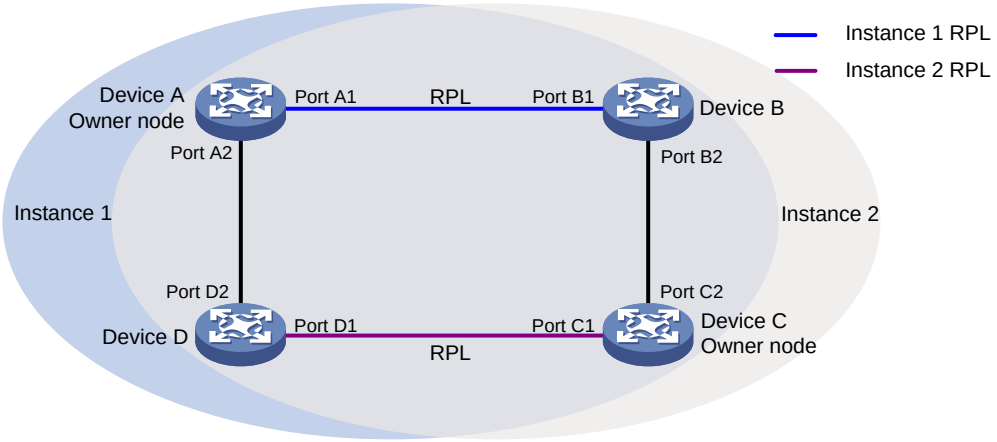
As shown in Figure 3, the link recovery mechanism uses the following process:

1. Device C and Device D detect the link recovery and perform the following operations:
   a. Block the recovered ports.
   b. Start the guard timer.
   c. Send NR packets.
2. When Device A (owner node) receives the NR packets, it does not perform any operations if it is in non-revertive mode. If Device A is in revertive mode, it performs the following operations:

a. Starts the WTR timer.

b. Blocks the RPL port and periodically sends NR-RB packets when the WTR timer expires.

3. When other nodes receive the NR-RB packets, they perform the following operations:



a. Device B (neighbor port) blocks the RPL port.

b. Device C and Device D unblock the recovered ports.

Service packets are switched to the recovered link.

Multi-instance load balancing mechanism

Figure 4 Multi-instance load balancing mechanism

An ERPS ring topology might carry traffic from multiple VLANs. Traffic from different VLANs can be load balanced among different ERPS instances.

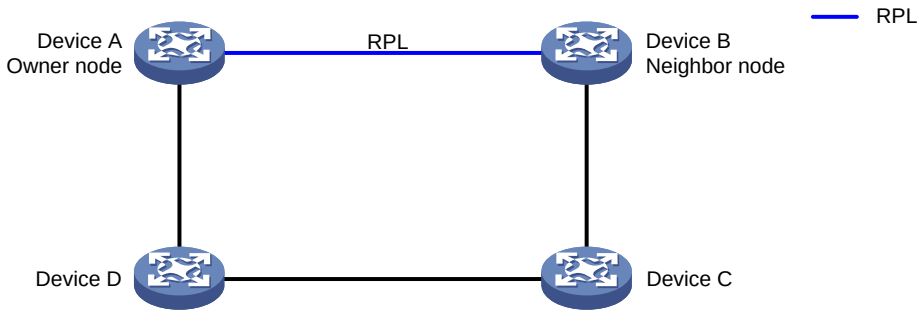
ERPS uses the following types of VLANs:

- **Control VLAN**—Carries ERPS protocol packets. Each ERPS instance has its own control VLAN.
- **Protected VLAN**—Carries data packets. Each ERPS instance has its own protected VLAN. Protected VLANs are configured by using the mappings between VLANs and MSTIs.

As shown in Figure 4, the ERPS ring is configured with instance 1 and instance 2. For instance 1, the owner node is Device A, and the RPL is the link between Device A and Device B. For instance 2, the owner node is Device C, and the RPL is the link between Device C and Device D. Traffic from different VLANs can be load balanced among different links.

Manual configuration mechanism

ERPS supports the following manual configuration modes:



- **MS**—Use the **`erps switch manual`** command to block an ERPS ring member port. A port in MS mode is blocked and sends MS packets. The nodes that receive the MS packets unblock available ports. If the nodes in MS mode receive an SF packet, they unblock the blocked ports.
- **FS**—Use the **`erps switch force ring`** command to block an ERPS ring member port. A port in FS mode is blocked and sends FS packets. The nodes that receive the FS packets unblock available ports. If the nodes in FS mode receive an SF packet, they do not unblock the blocked ports.

ERPS network diagrams

One major ring

The network has one major ring.

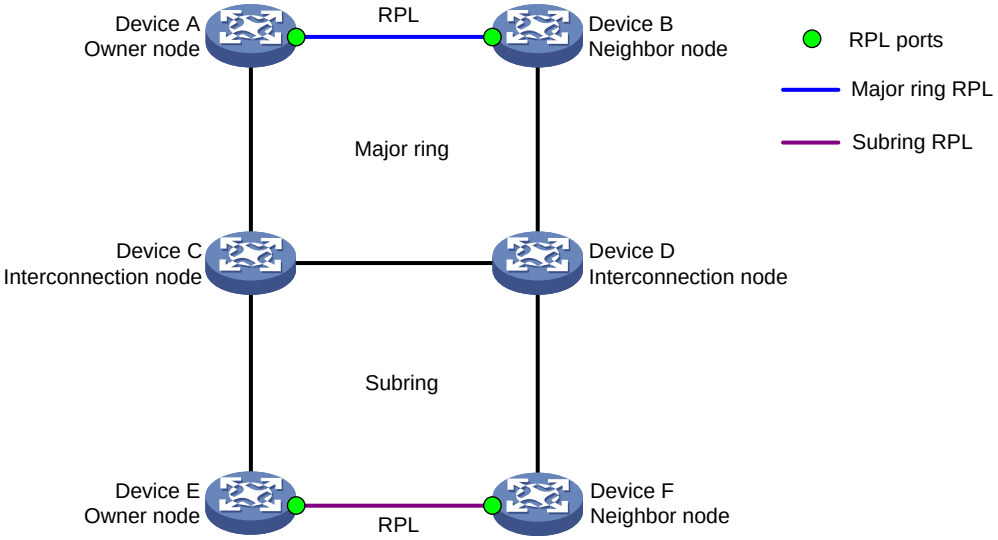


Figure 5 Network diagram

One major ring connecting one subring

The network has one major ring and one subring.

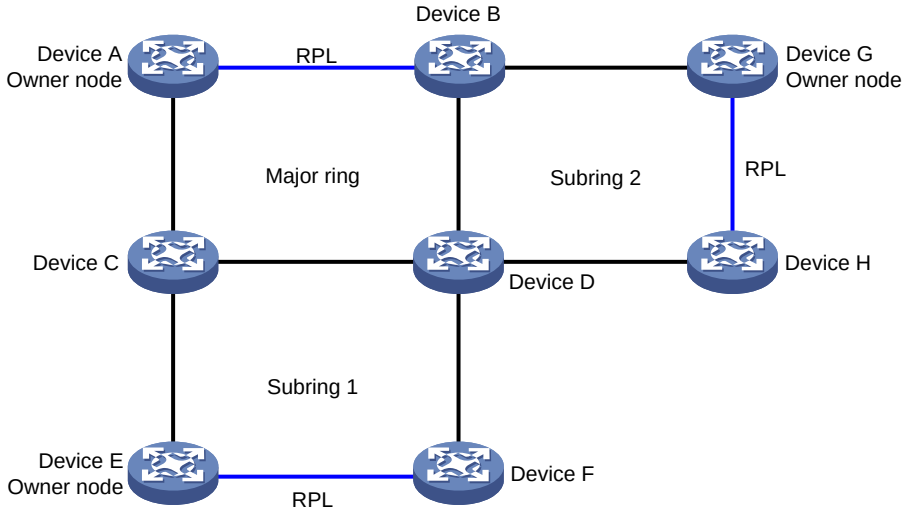

Figure 6 Network diagram

One major ring connecting multiple subrings

The network has three or more rings. Each subring is connected to the major ring by two interconnection nodes.

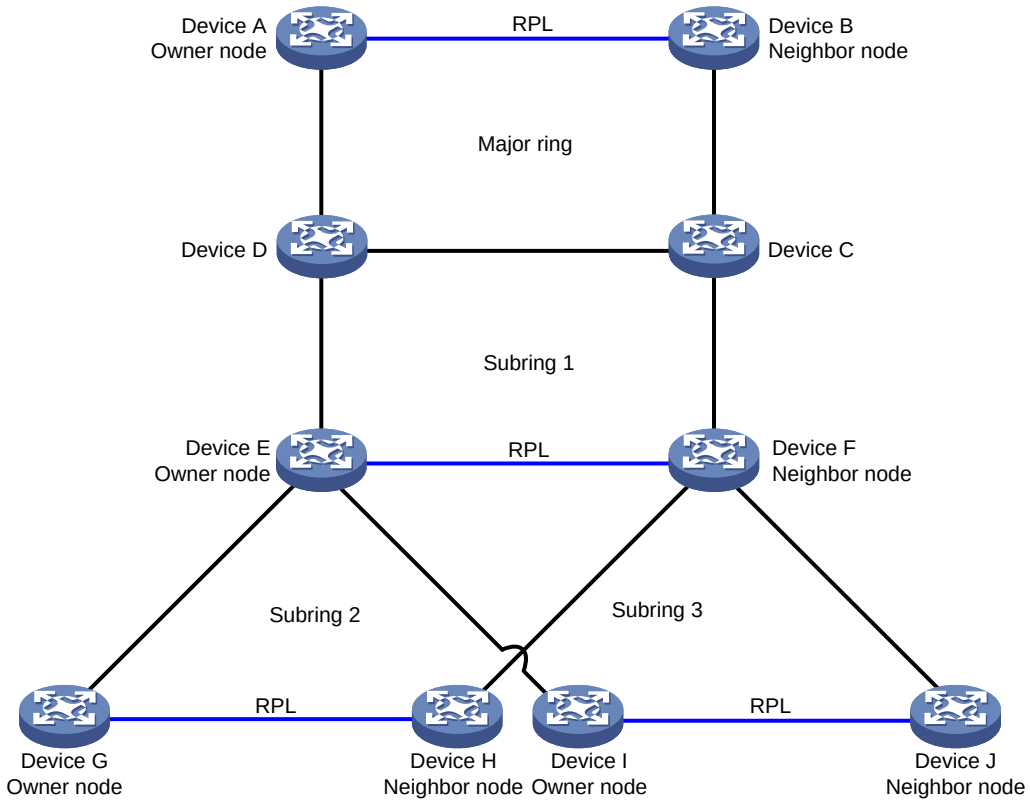

Figure 7 Network diagram

One subring connecting multiple subrings

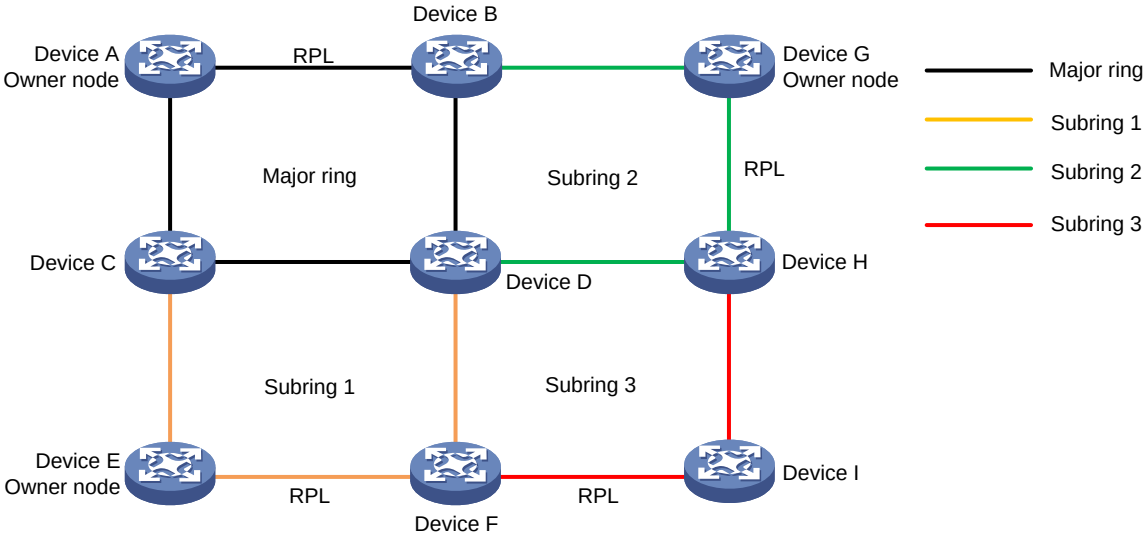
The network has three or more rings. As shown in Figure 8, subring 1 is connected to the major ring. Other subrings are connected to subring 1 by two interconnection nodes.

Figure 8 Network diagram

One subring connecting multiple rings

The network has three or more rings. A minimum of one subring is connected to two rings. As shown in Figure 9, one interconnection node on subring 2 is connected to the major ring; and another interconnection node is connected to subring 1. As shown in Figure 10, subring 3 is connected to subring 1 and subring 2.

Figure 9 Network diagram 1



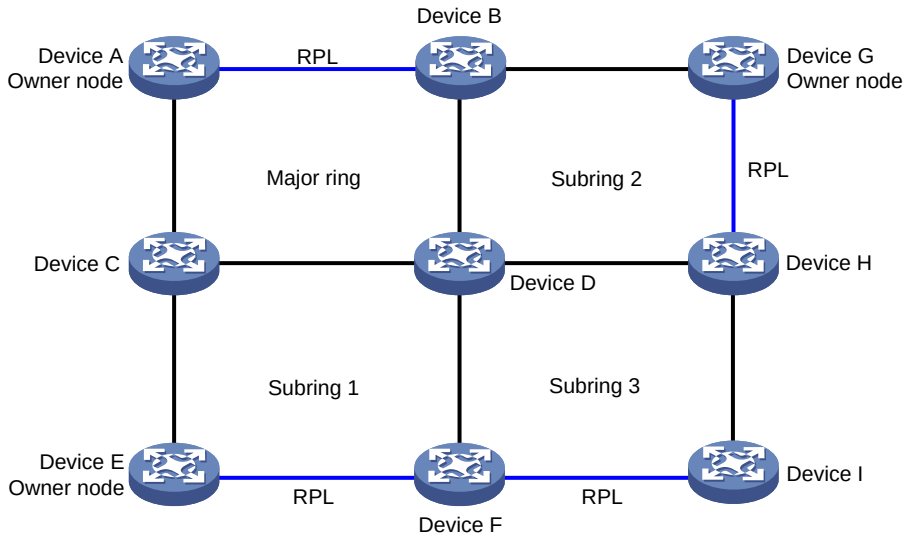


Figure 10 Network diagram 2

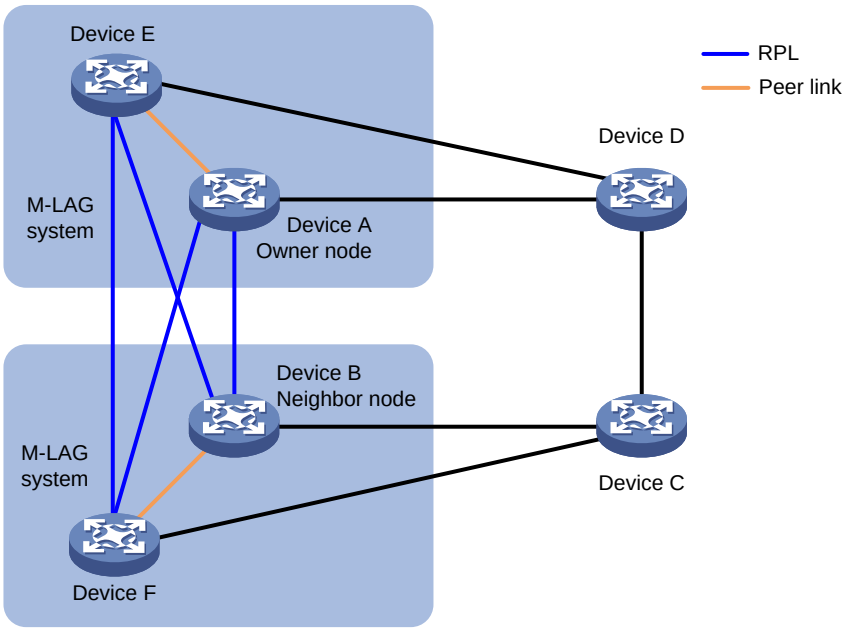
ERPS with M-LAG



NOTE:

The S5200-EI-G switch series does not support the M-LAG feature.

M-LAG allows you to virtualize the devices in an ERPS ring into one system through multichassis link, thereby achieving device-level redundancy and load balancing.

You can use the **`display erps detail ring`** command to determine whether ERPS works correctly in an M-LAG network. For more information about M-LAG, see *Layer 2—LAN Switching Configuration Guide*.

Figure 11 ERPS with M-LAG

Protocols and standards

- ITU-T G.8032, *Recommendation ITU-T G.8032/Y.1344, Ethernet ring protection switching*
- IEEE 802.1D, *IEEE Std 802.1D™-2004, IEEE Standard for Local and Metropolitan Area Networks—Media Access Control (MAC) Bridges*
- IEEE 802.3, *IEEE Std 802.3-2008, IEEE Standard for Information technology*

Restrictions and guidelines: ERPS configuration

ERPS does not provide an election mechanism. To implement ring detection and protection, configure all nodes correctly.

ERPS tasks at a glance

To configure ERPS, perform the following tasks:

1. Enabling ERPS globally

   Perform this task on devices you want to configure as ERPS nodes.
2. Configuring an ERPS ring

   Perform this task on all nodes on an ERPS ring.

   a. Creating an ERPS ring

   b. Configuring ERPS ring member ports

   c. Configuring control VLANs

   d. Configuring protected VLANs

   e. Configuring the node role
3. Enabling ERPS for an instance

   Perform this task on all nodes on an ERPS ring.

4. (Optional.) Enabling R-APS packets to carry the ring ID in the destination MAC address
   Perform this task on all nodes on an ERPS ring.
5. (Optional.) Configuring R-APS packet levels
6. (Optional.) Setting ERPS timers
   Perform this task on the owner node on an ERPS ring.
7. (Optional.) Setting the non-revertive mode
   Perform this task on the owner node on an ERPS ring.
8. (Optional.) Setting a switchover mode
   Perform this task on the nodes that you want to block their ports.
9. (Optional.) Enabling flush packet transparent transmission
   Perform this task on the interconnection node on an ERPS ring.
10. (Optional.) Removing the MS mode and FS mode settings for an ERPS ring

Prerequisites

Before you configure ERPS, complete the following tasks:

- Establish the Ethernet ring topology.
- Determine the ERPS rings, ERPS instances, control VLANs, protected VLANs, and node roles.

Enabling ERPS globally

Restrictions and guidelines

- Perform this task on devices you want to configure as ERPS nodes.
- For ERPS to take effect for an instance, enable it globally first.

Procedure

1. Enter system view.
   `system-view`
2. Enable ERPS globally.
   `erps enable`
   By default, ERPS is disabled globally.

Configuring an ERPS ring

Creating an ERPS ring

Restrictions and guidelines

- Perform this task on all nodes on an ERPS ring.
- A ring ID uniquely identifies an ERPS ring. All nodes on an ERPS ring must be configured with the same ring ID.

Procedure

1. Enter system view.
   `system-view`
2. Create an ERPS ring.

erps ring *ring-id*

3. (Optional.) Configure the ring type.

   ring-type sub-ring

   By default, an ERPS ring is a major ring.

Configuring ERPS ring member ports

Restrictions and guidelines

- Perform this task on each node's ports intended for accessing ERPS rings.
- ERPS ring member ports automatically allow packets from the control VLAN to pass through.
- For faster topology convergence, use the **link-delay** command on ERPS ring member ports to set the physical state change suppression interval to 0 seconds. For more information about the **link-delay** command, see *Layer 2—LAN Switching Command Reference*.
- You must configure ERPS ring member ports as trunk ports.
- Do not assign an interface to both an aggregation group and an ERPS ring. If you do so, the interface does not take effect on the ERPS ring and cannot be displayed by using the **display erps detail** command.
- Do not assign a peer-link interface to an ERPS ring. A peer-link interface does not work for an ERPS ring and cannot be displayed by using the **display erps detail** command.
- Do not assign both an M-LAG interface and a non-M-LAG interface on a non-interconnection node to an ERPS ring. If you do so, the M-LAG interface does not take effect on the ERPS ring.

Configuring ERPS ring member port attributes

1. Enter system view.

   system-view

2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.

   interface *interface-type interface-number*

3. Configure the port as a trunk port.

   port link-type trunk

   By default, a port is an access port.

   For more information about this command, see *Layer 2—LAN Switching Command Reference*.

4. Assign the trunk port to protected VLANs.

   port trunk permit vlan { *vlan-id-list* | **all** }

   By default, a trunk port is assigned only to VLAN 1.

   For more information about this command, see *Layer 2—LAN Switching Command Reference*.

5. Disable the spanning tree feature.

   undo stp enable

   By default, the spanning tree feature is enabled.

   For more information about this command, see *Layer 2—LAN Switching Command Reference*.

Configuring an ERPS ring member port

1. Enter system view.

   system-view

2. Enter ERPS ring view.

   erps ring *ring-id*

3. Configure an ERPS ring member port.

{ **port0** | **port1** } **interface** *interface-type interface-number*

By default, an ERPS ring does not have ERPS ring member ports.

Configuring control VLANs

Restrictions and guidelines

- Perform this task on all nodes on an ERPS ring.
- The control VLAN must be a VLAN that has not been created on the device.
- Configure the same control VLAN for all nodes in an ERPS instance.
- Do not configure the default VLAN of an ERPS ring member port as the control VLAN.
- Do not enable QinQ or VLAN mapping on control VLANs. If you do, ERPS packets cannot be correctly forwarded and received.
- Make sure the ERPS instance has been configured. After the ERPS instance is enabled, the control VLAN cannot be changed.
- For a device not configured with ERPS to transparently transmit ERPS packets, make sure only the two ports accessing the ERPS ring permit packets from the control VLAN. If other ports on the device permit packets from the control VLAN, the packets from other VLANs might enter the control VLAN and strike the ERPS ring.
- When configuring ERPS with M-LAG, make sure the peer-link interface is a trunk port. The peer-link interface will automatically join or leave a control VLAN as the control VLAN is created or deleted.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enable ERPS instance view.
   instance *instance-id*
4. Configure a control VLAN.
   control-vlan *vlan-id*

Configuring protected VLANs

Restrictions and guidelines

- Perform this task on all nodes on an ERPS ring.
- Configure the same protected VLAN for all nodes of an ERPS instance. To implement load balancing, configure different protected VLANs for different ERPS instances.

Prerequisites

Before you configure protected VLANs, you must configure an MST region and the VLAN-to-instance mapping table. For more information about MST regions, see spanning tree configuration in *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.

erps ring *ring-id*

3. Enable ERPS instance view.
   instance *instance-id*
4. Configure the protected VLANs.
   protected-vlan reference-instance *instance-id-list*

Configuring the node role

Restrictions and guidelines

- Perform this task on all nodes on an ERPS ring.
- For the owner node to work correctly, you must configure only one owner node for an ERPS ring.
- You can only configure the interconnection node for subrings.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enter ERPS instance view.
   instance *instance-id*
4. Configure the node role.
   node-role { { **owner** | **neighbor** } **rpl** | **interconnection** } { **port0** | **port1** }
   By default, a node is a normal node.

Enabling ERPS for an instance

Restrictions and guidelines

- Perform this task on all nodes on an ERPS ring.
- You can enable ERPS for an instance only when it is configured with a control VLAN and a protected VLAN.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enter ERPS instance view.
   instance *instance-id*
4. Enable ERPS for the instance.
   instance enable
   By default, ERPS is disabled for an instance.

Enabling R-APS packets to carry the ring ID in the destination MAC address

About this task

Perform this task to configure the ring ID as the last byte of the destination MAC address for R-APS packets. The ring of R-APS packets can be identified by their destination MAC addresses.

Restrictions and guidelines

Perform this task on all nodes on an ERPS ring.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enable R-APS packets to carry the ring ID in the destination MAC address.
   r-aps ring-mac
   By default, R-APS packets do not carry ring IDs in their destination MAC addresses. The last byte of the destination MAC address is 1.

Configuring R-APS packet levels

Restrictions and guidelines

Perform this task on all nodes on an ERPS ring.

On a ring, the levels of R-APS packets must be the same for all nodes in an ERPS instance.

A node does not process R-APS packets whose levels are greater than the level of R-APS packets sent by the node.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enter ERPS instance view.
   instance *instance-id*
4. Configure the R-APS packet level.
   r-aps level *level-value*
   By default, the level for R-APS packets is 7.

Setting ERPS timers

Restrictions and guidelines

Perform this task on the owner node on an ERPS ring.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enter ERPS instance view.
   instance *instance-id*
4. Set the guard timer.
   timer guard *guard-value*
   By default, the guard timer is 500 milliseconds.
5. Set the hold-off timer.
   timer hold-off *hold-off-value*
   By default, the hold-off timer is 0 milliseconds.
6. Set the WTR timer.
   timer wtr *wtr-value*
   By default, the WTR timer is 5 minutes.

Setting the non-revertive mode

About this task

Perform this task if you do not want to switch back to the recovered link after the link fault is cleared.

Restrictions and guidelines

Perform this task on the owner node on an ERPS ring.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enter ERPS instance view.
   instance *instance-id*
4. Set the non-revertive mode.
   revertive-operation non-revertive
   By default, revertive mode is used.

Setting a switchover mode

Restrictions and guidelines

Perform this task on the nodes that you want to block their ports.

Procedure

1. Enter system view.
   system-view
2. Set a switchover mode.

erps switch { **force** | **manual** } **ring** *ring-id* **instance** *instance-id* { **port0** | **port1** }

By default, no switchover mode is not set.

Enabling flush packet transparent transmission

About this task

This feature enables the interconnection nodes to forward flush packets for topology changes in the subring to the ring associated with the subring. The associated ring can flush the MAC address table quickly to speed up convergence.

Restrictions and guidelines

Perform this task on the interconnection node on an ERPS ring.

To use this feature, you must also associate a subring on the interconnection node with the ring.

Procedure

1. Enter system view.
   system-view
2. Enable flush packet transparent transmission.
   erps tcn-propagation
   By default, flush packet transparent transmission is disabled.

Removing the MS mode and FS mode settings for an ERPS ring

About this task

After you configure this task, the owner node can ignore the WTR timer and immediately switch traffic to the recovered link upon link recovery.

This task also switches an ERPS ring in non-revertive mode to revertive mode.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   erps clear ring *ring-id* **instance** *instance-id*

Displaying and maintaining ERPS

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display brief ERPS information.	**display erps**
Display detailed ERPS information.	**display erps detail ring** *ring-id* [**instance** *instance-id*]
Display ERPS packet statistics.	**display erps statistics** [**ring** *ring-id*

Task	Command
	[**instance** *instance-id*]]
Clear ERPS packet statistics.	**reset erps statistics ring** *ring-id* [**instance** *instance-id*]

Troubleshooting ERPS

The owner node cannot receive SF packets from a faulty node when the link state is normal

Symptom

The link between the owner node and the faulty node is available, but the owner node cannot receive SF packets sent by the faulty node. The RPL port is blocked.

Analysis

Possible reasons include:

- ERPS is not enabled for some nodes on the ERPS ring.
- The ring IDs are different for the nodes on the same ERPS ring.
- The control VLAN IDs are different for the nodes in the same ERPS instance.
- A port on the ERPS ring is faulty.

Solutions

To resolve the problem:

- Use the **display erps** command to examine whether ERPS is enabled for all nodes on the ERPS ring. If ERPS is disabled for some nodes, use the **erps enable** command to enable ERPS for the nodes.
- Set the same ring ID for all nodes on a ERPS ring and configure the same control VLAN for all nodes in an ERPS instance.
- Use the **display erps detail** command to examine the port status for all nodes. Bring up the ports in down state.
- Use the **debugging erps** command on all nodes to view debugging information about packets and node status.

Configuring Smart Link

About Smart Link

Application scenario

Smart Link is an H3C-proprietary protocol that provides link redundancy and subsecond convergence time in a dual uplink network. As shown in Figure 1, Smart Link is configured on Device C and Device D. The secondary link takes over quickly when the primary link fails.

Figure 1 Smart link application scenario diagram

A Smart Link network has the following devices:

- **Smart Link devices**—A Smart Link device has two uplinks. A Smart Link device must be configured with a smart link group and a transmit control VLAN to transmit flush messages. Device C and Device D in Figure 1 are Smart Link devices.
- **Associated devices**—An associated device is an uplink device to which Smart Link devices are connected. An associated device supports Smart Link, and receives flush messages sent from the specified control VLAN. When a primary/secondary link switchover occurs, the associated device updates the MAC address entries and ARP/ND entries according to received flush messages. Device A, Device B, and Device E in Figure 1 are associated devices.

Terminology

Smart link group

A smart link group consists of only two member ports: the primary and the secondary ports. Only one port is active for forwarding at a time, and the other port is blocked and in standby state. When link failure occurs on the active port due to port shutdown or the presence of unidirectional link, the standby port becomes active and takes over. The original active port transits to the blocked state.

As shown in the Smart link application scenario diagram, Port C1 and Port C2 of Device C form a smart link group. Port C1 is active, and Port C2 is standby. Port D1 and Port D2 of Device D form another smart link group. Port D1 is active, and Port D2 is standby.

Primary/secondary port

Primary port and secondary port are two port types in a smart link group. When both ports in a smart link group are up, the primary port preferentially transits to the forwarding state. The secondary port stays in standby state. When the primary port fails, the secondary port takes over to forward traffic.

As shown in the Smart link application scenario diagram, Port C1 of Device C and Port D1 of Device D are primary ports. Port C2 of Device C and Port D2 of Device D are secondary ports.

Primary/secondary link

The link that connects the primary port in a smart link group is the primary link. The link that connects the secondary port is the secondary link.

Flush message

When link switchover occurs, the smart link group uses flush messages to notify other devices to refresh their MAC address entries and ARP/ND entries. Flush messages are common multicast data packets, and will be dropped by a blocked receiving port.

Protected VLAN

A smart link group controls the forwarding state of protected VLANs. Each smart link group on a port controls a different protected VLAN. The state of the port in a protected VLAN is determined by the state of the port in the smart link group.

Transmit control VLAN

The transmit control VLAN is used for transmitting flush messages. When link switchover occurs, the devices (such as Device C and Device D in the Smart link application scenario diagram) send flush messages within the transmit control VLAN.

Receive control VLAN

The receive control VLAN is used for receiving and processing flush messages. When link switchover occurs, the devices (such as Device A, Device B, and Device E in the Smart link application scenario diagram) receive and process flush messages in the receive control VLAN. In addition, they refresh their MAC address entries and ARP/ND entries.

How Smart Link works

Link backup

As shown in the Smart link application scenario diagram, the link on Port C1 of Device C is the primary link. The link on Port C2 of Device C is the secondary link. Port C1 is in forwarding state, and Port C2 is in standby state. When the primary link fails, Port C2 takes over to forward traffic and Port C1 is blocked and placed in standby state.

When a port switches to the forwarding state, the system outputs log information to notify the user of the port state change.

Topology change

Link switchover might outdate the MAC address entries and ARP/ND entries on all devices. A flush update mechanism is provided to ensure correct packet transmission. With this mechanism, a Smart Link-enabled device updates its information by transmitting flush messages over the backup link to its upstream devices. This mechanism requires the upstream devices to be capable of recognizing Smart Link flush messages to update their MAC address forwarding entries and ARP/ND entries.

Preemption mode

As shown in the Smart link application scenario diagram, the link on Port C1 of Device C is the primary link. The link on Port C2 of Device C is the secondary link. When the primary link fails, Port C1 is automatically blocked and placed in standby state, and Port C2 takes over to forward traffic. When the primary link recovers, one of the following actions occurs:

- If the smart link group is not configured with a preemption mode, Port C1 stays blocked to keep traffic forwarding stable. Port C1 does not take over to forward traffic until the next link switchover.
- If the smart link group is configured with a preemption mode and the preemption conditions are met, Port C1 takes over to forward traffic as soon as its link recovers. Port C2 is automatically blocked and placed in standby state.

Load sharing

A ring network might carry traffic of multiple VLANs. Smart Link can forward traffic from different VLANs in different smart link groups for load sharing.

To implement load sharing, you can assign a port to multiple smart link groups. Configure each group with a different protected VLAN. Make sure the state of the port is different in these smart link groups, so traffic from different VLANs can be forwarded along different paths.

You can configure protected VLANs for a smart link group by referencing Multiple Spanning Tree Instances (MSTIs). For more information about MSTIs, see *Layer 2—LAN Switching Configuration Guide*.

Collaboration between Smart Link and Monitor Link for port status detection

Smart Link cannot detect when faults occur on the uplink of the upstream devices or when faults are cleared. You can configure the Monitor Link function to monitor the status of the uplink ports of the upstream devices. Monitor Link adapts the up/down state of downlink ports to uplink ports, and triggers Smart Link to perform link switchover on the downstream device. For more information about Monitor Link, see "Configuring Monitor Link."

Restrictions and guidelines: Smart Link configuration

When you configure Smart Link, follow these restrictions and guidelines:

- If you configure a port as both an aggregation group member and a smart link group member, only the aggregation group configuration takes effect. The port is not shown in the output from the **`display smart-link group`** command. The smart link group configuration takes effect after the port leaves the aggregation group.
- The S5200-EI-G switch series does not support the M-LAG feature.
- In an M-LAG network:
  - The two M-LAG member devices must have the same Smart Link settings.

- For a smart link group to work with an M-LAG system, assign only M-LAG interfaces to the smart link group.
- Do not assign a peer-link interface to a smart link group.

Smart Link tasks at a glance

To configure Smart Link, perform the following tasks:

1. Configuring a Smart Link device
   a. Configuring protected VLANs for a smart link group
   b. Configuring member ports for a smart link group
   c. (Optional.) Configuring a preemption mode for a smart link group
   d. (Optional.) Enabling the sending of flush messages
2. Enabling an associated device to receive flush messages

Configuring a Smart Link device

Prerequisites for Smart Link device configuration

Before configuring a Smart Link device, complete the following tasks:

- To prevent loops, shut down a port before configuring it as a smart link group member. You can bring up the port only after completing the smart link group configuration.
- Disable the spanning tree feature, RRPP, and ERPS on the ports you want to add to the smart link group.

Configuring protected VLANs for a smart link group

Prerequisites

Before you configure protected VLANs, you must configure an MST region and the VLAN-to-instance mapping table. For more information about MST regions, see spanning tree configuration in *Layer 2—LAN Switching Configration Guide*.

Procedure

1. Enter system view.
   `system-view`
2. Create a smart link group and enter smart link group view.
   `smart-link group` *`group-id`*
3. Configure protected VLANs for the smart link group.
   `protected-vlan reference-instance` *`instance-id-list`*

Configuring member ports for a smart link group

Restrictions and guidelines

You can configure member ports for a smart link group either in smart link group view or in interface view. The configurations made in these two views have the same effect.

In smart link group view

1. Enter system view.

system-view

2. Create a smart link group and enter smart link group view.
   smart-link group *group-id*
3. Configure member ports for a smart link group.
   port *interface-type interface-number* { **primary** | **secondary** }
   By default, no member port is configured for a smart link group.

In interface view

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. Configure member ports for a smart link group.
   port smart-link group *group-id* { **primary** | **secondary** }
   By default, an interface is not a smart link group member.

Configuring a preemption mode for a smart link group

1. Enter system view.
   system-view
2. Enter smart link group view.
   smart-link group *group-id*
3. Configure a preemption mode for the smart link group.
   preemption mode { **role** | **speed** [**threshold** *threshold-value*] }
   By default, preemption is disabled.
4. Configure the preemption delay.
   preemption delay *delay*
   By default, the preemption delay is 1 second.
   The preemption delay configuration takes effect only after a preemption mode is configured.

Enabling the sending of flush messages

Restrictions and guidelines

- The control VLAN configured for a smart link group must be different from the control VLAN configured for any other smart link group.
- Make sure the configured control VLAN already exists, and assign the smart link group member ports to the control VLAN.
- The control VLAN of a smart link group must also be one of its protected VLANs. Do not remove the control VLAN. Otherwise, flush messages cannot be sent correctly.

Procedure

1. Enter system view.
   system-view
2. Enter smart link group view.
   smart-link group *group-id*
3. Enable flush update.

flush enable [**control-vlan** *vlan-id*]

By default, flush update is enabled, and VLAN 1 is the control VLAN.

Enabling the sending of dummy messages

Restrictions and guidelines

After you enable this feature, the device can send the MAC addresses learned from downlink ports to the peer through dummy messages. The device performs such actions when the state of ports in the smart link group changes from standby to active.

Restrictions and guidelines

Sending of flush messages and sending of dummy messages are mutually exclusive.

After you enable sending of dummy messages, configure the **undo stp enable** command on the connected device to prevent packet loss.

Procedure

1. Enter system view.
   system-view
2. Enter smart link group view.
   smart-link group *group-id*
3. Enable sending of dummy messages.
   dummy enable [**max-number** *number*] [**times** *times*]
   By default, sending of dummy messages is enabled.

Enabling an associated device to receive flush messages

Restrictions and guidelines

- You do not need to enable all ports on the associated devices to receive flush messages. Enable the feature only on all control VLANs of ports on the primary and secondary links between the Smart Link device and the destination device.
- If no control VLAN is specified for processing flush messages, the device forwards the received flush messages without any processing.
- Make sure the receive control VLAN is the same as the transmit control VLAN configured on the Smart Link device. If they are not the same, the associated device will forward the received flush messages directly without any processing.
- Do not remove the control VLANs. Otherwise, flush messages cannot be sent correctly.
- Make sure the control VLANs are existing VLANs, and assign the ports capable of receiving flush messages to the control VLANs.

Prerequisites

Disable the spanning tree feature on the associated device's ports that connect to the member ports of the smart link group. Otherwise, the ports will discard flush messages when they are not in forwarding state if a topology change occurs.

Procedure

1. Enter system view.
   system-view

2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. Configure the control VLANs for receiving flush messages.
   smart-link flush enable [**control-vlan** *vlan-id-list*]
   By default, no control VLAN receives flush messages.

Display and maintenance commands for Smart Link

Execute **display** commands in any view and the **reset** command in user view:

Task	Command
Display information about the received flush messages.	**display smart-link flush**
Display smart link group information.	**display smart-link group** { *group-id* | **all** }
Clear the statistics about flush messages.	**reset smart-link statistics**

Smart Link configuration examples

Example: Configuring a single smart link group

Network configuration

As shown in Figure 2:

- Device C and Device D are Smart Link devices. Device A, Device B, and Device E are associated devices. Traffic of VLANs 1 through 30 on Device C and Device D is dually uplinked to Device A.
- Configure Smart Link on Device C and Device D for dual uplink backup.

Figure 2 Network diagram

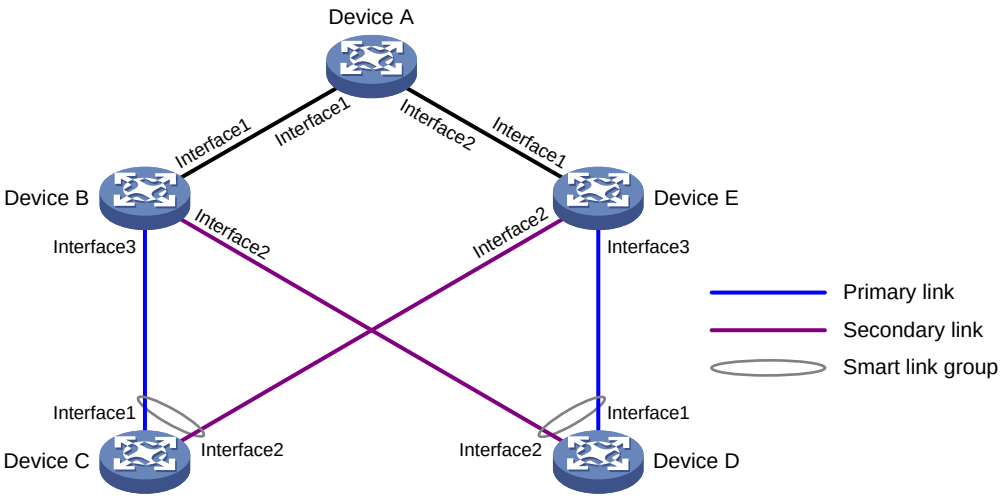

Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure Device C:

Create VLANs 1 through 30.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Shut down GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] shutdown
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] shutdown
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/2] quit
```

Create smart link group 1, and configure all VLANs mapped to MSTI 1 as the protected VLANs.

```
[DeviceC] smart-link group 1
[DeviceC-smlk-group1] protected-vlan reference-instance 1
```

Configure GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port for smart link group 1.

```
[DeviceC-smlk-group1] port gigabitethernet 1/0/1 primary
[DeviceC-smlk-group1] port gigabitethernet 1/0/2 secondary
```

Enable flush message sending in smart link group 1, and configure VLAN 10 as the transmit control VLAN.

```
[DeviceC-smlk-group1] flush enable control-vlan 10
[DeviceC-smlk-group1] quit
```

Bring up GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 again.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] undo shutdown
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] undo shutdown
[DeviceC-GigabitEthernet1/0/2] quit
```

2. Configure Device D:

Create VLANs 1 through 30.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceD] stp region-configuration
[DeviceD-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

Shut down GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] shutdown
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] shutdown
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/2] quit
```

Create smart link group 1, and configure all VLANs mapped to MSTI 1 as the protected VLANs.

```
[DeviceD] smart-link group 1
[DeviceD-smlk-group1] protected-vlan reference-instance 1
```

Configure GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port for smart link group 1.

```
[DeviceD-smlk-group1] port gigabitethernet 1/0/1 primary
[DeviceD-smlk-group1] port gigabitethernet 1/0/2 secondary
```

Enable flush message sending in smart link group 1, and configure VLAN 20 as the transmit control VLAN.

```
[DeviceD-smlk-group1] flush enable control-vlan 20
[DeviceD-smlk-group1] quit
```

Bring up GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 again.

```
[DeviceD] interface gigabitethernet 1/0/1
```

```
[DeviceD-GigabitEthernet1/0/1] undo shutdown
[DeviceD-GigabitEthernet1/0/1] quit
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] undo shutdown
[DeviceD-GigabitEthernet1/0/2] quit
```

3. Configure Device B:

Create VLANs 1 through 30.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving and configure VLAN 10 and VLAN 20 as the receive control VLANs on the port.

```
[DeviceB-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 20
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/2] undo stp enable
```

Enable flush message receiving and configure VLAN 20 as the receive control VLAN on the port.

```
[DeviceB-GigabitEthernet1/0/2] smart-link flush enable control-vlan 20
[DeviceB-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan 1 to 30
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/3] undo stp enable
```

Enable flush message receiving and configure VLAN 10 as the receive control VLAN on the port.

```
[DeviceB-GigabitEthernet1/0/3] smart-link flush enable control-vlan 10
[DeviceB-GigabitEthernet1/0/3] quit
```

4. Configure Device E:

Create VLANs 1 through 30.

```
<DeviceE> system-view
[DeviceE] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceE] interface gigabitethernet 1/0/1
[DeviceE-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceE-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving and configure VLAN 10 and VLAN 20 as the receive control VLANs on the port.

```
[DeviceE-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 20
[DeviceE-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[DeviceE] interface gigabitethernet 1/0/2
[DeviceE-GigabitEthernet1/0/2] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceE-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
```

Disable the spanning tree feature on the port.

```
[DeviceE-GigabitEthernet1/0/2] undo stp enable
```

Enable flush message receiving and configure VLAN 10 as the receive control VLAN on the port.

```
[DeviceE-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10
[DeviceE-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 as a trunk port.

```
[DeviceE] interface gigabitethernet 1/0/3
[DeviceE-GigabitEthernet1/0/3] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceE-GigabitEthernet1/0/3] port trunk permit vlan 1 to 30
```

Disable the spanning tree feature on the port.

```
[DeviceE-GigabitEthernet1/0/3] undo stp enable
```

Enable flush message receiving and configure VLAN 20 as the receive control VLAN on the port.

```
[DeviceE-GigabitEthernet1/0/3] smart-link flush enable control-vlan 20
[DeviceE-GigabitEthernet1/0/3] quit
```

5. Configure Device A:

Create VLANs 1 through 30.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving and configure VLAN 10 and VLAN 20 as the receive control VLANs on the port.

```
[DeviceA-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 20
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 20
[DeviceA-GigabitEthernet1/0/2] quit
```

Verifying the configuration

Display the smart link group configuration on Device C.

```
[DeviceC] display smart-link group 1
Smart link group 1 information:
  Device ID       : 000f-e23d-5af0
  Preemption mode : None
  Preemption delay: 1(s)
  Control VLAN    : 10
  Protected VLAN  : Reference Instance 1

  Member                  Role      State   Flush-count     Last-flush-time
  ------------------------------------------------------------------------------
  GE1/0/1                 PRIMARY   ACTIVE  5               16:45:20 2012/04/21
  GE1/0/2                 SECONDARY STANDBY 1               16:37:20 2012/04/21
```

Display the flush messages received on Device B.

```
[DeviceB] display smart-link flush
 Received flush packets                              : 5
 Receiving interface of the last flush packet        : GigabitEthernet1/0/3
 Receiving time of the last flush packet             : 16:50:21 2012/04/21
 Device ID of the last flush packet                  : 000f-e23d-5af0
 Control VLAN of the last flush packet               : 10
```

Example: Configuring multiple smart link groups load sharing

Network configuration

As shown in Figure 3:

- Device C is a Smart Link device. Device A, Device B, and Device D are associated devices. Traffic of VLANs 1 through 200 on Device C is dually uplinked to Device A by Device B and Device D.
- Implement dual uplink backup and load sharing on Device C. Traffic of VLANs 1 through 100 is uplinked to Device A by Device B. Traffic of VLANs 101 through 200 is uplinked to Device A by Device D.

Figure 3 Network diagram

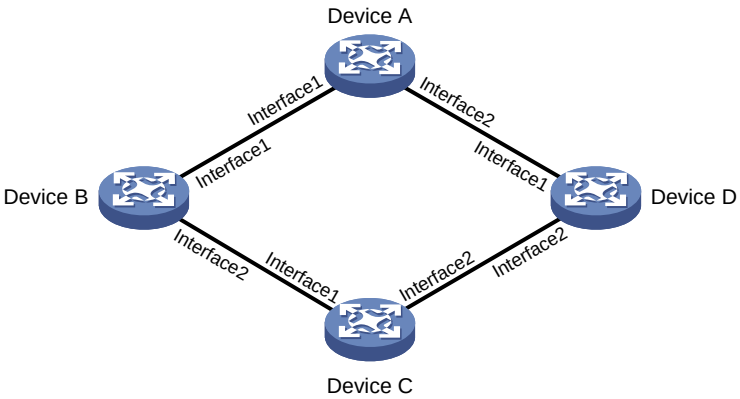

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure Device C:

Create VLAN 1 through VLAN 200.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 200
```

Map VLANs 1 through 100 to MSTI 1, and VLANs 101 through 200 to MSTI 2.

```
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 100
[DeviceC-mst-region] instance 2 vlan 101 to 200
```

Activate the MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Shut down GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] shutdown
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLAN 1 through VLAN 200.

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] shutdown
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
[DeviceC-GigabitEthernet1/0/2] quit
```

Create smart link group 1, and configure all VLANs mapped to MSTI 1 as the protected VLANs for smart link group 1.

```
[DeviceC] smart-link group 1
[DeviceC-smlk-group1] protected-vlan reference-instance 1
```

Configure GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port for smart link group 1.

```
[DeviceC-smlk-group1] port gigabitethernet 1/0/1 primary
[DeviceC-smlk-group1] port gigabitethernet 1/0/2 secondary
```

Enable role preemption in smart link group 1, enable flush message sending, and configure VLAN 10 as the transmit control VLAN.

```
[DeviceC-smlk-group1] preemption mode role
[DeviceC-smlk-group1] flush enable control-vlan 10
```

```
[DeviceC-smlk-group1] quit
```

Create smart link group 2, and configure all VLANs mapped to MSTI 2 as the protected VLANs for smart link group 2.

```
[DeviceC] smart-link group 2
[DeviceC-smlk-group2] protected-vlan reference-instance 2
```

Configure GigabitEthernet 1/0/1 as the secondary port and GigabitEthernet 1/0/2 as the primary port for smart link group 2.

```
[DeviceC-smlk-group2] port gigabitethernet 1/0/2 primary
[DeviceC-smlk-group2] port gigabitethernet 1/0/1 secondary
```

Enable role preemption in smart link group 2, enable flush message sending, and configure VLAN 110 as the transmit control VLAN.

```
[DeviceC-smlk-group2] preemption mode role
[DeviceC-smlk-group2] flush enable control-vlan 110
[DeviceC-smlk-group2] quit
```

Bring up GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] undo shutdown
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] undo shutdown
[DeviceC-GigabitEthernet1/0/2] quit
```

2. Configure Device B:

Create VLAN 1 through VLAN 200.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 200
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceB-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/2] undo stp enable
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceB-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
[DeviceB-GigabitEthernet1/0/2] quit
```

3. Configure Device D:

Create VLAN 1 through VLAN 200.

```
<DeviceD> system-view
```

```
[DeviceD] vlan 1 to 200
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceD-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/2] undo stp enable
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceD-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
[DeviceD-GigabitEthernet1/0/2] quit
```

4. Configure Device A:

Create VLAN 1 through VLAN 200.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 200
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceA-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
[DeviceA-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
[DeviceA-GigabitEthernet1/0/2] quit
```

Verifying the configuration

Display the smart link group configuration on Device C.

```
[DeviceC] display smart-link group all
Smart link group 1 information:
  Device ID       : 000f-e23d-5af0
  Preemption mode : Role
  Preemption delay: 1(s)
```

```
  Control VLAN    : 10
  Protected VLAN  : Reference Instance 1

  Member                  Role      State   Flush-count     Last-flush-time
  ------------------------------------------------------------------------------
  GE1/0/1                 PRIMARY   ACTIVE  5               16:45:20 2012/04/21

Configuring Monitor Link

For the S5200-EI-G switch series, only Release 8307P60 and later support Monitor Link.

About Monitor Link

Monitor Link is an H3C-proprietary protocol that associates the state of downlink interfaces with the state of uplink interfaces in a monitor link group. When Monitor Link shuts down the downlink interfaces because of an uplink failure, the downstream device changes connectivity to another link.

Figure 1 Monitor Link application scenarios

A monitor link group contains uplink and downlink interfaces. An interface can belong to only one monitor link group.

- Uplink interfaces are the monitored interfaces.
- Downlink interfaces are the monitoring interfaces.

As shown in Figure 1:

- Port B1 and Port B2 of Device B form a monitor link group. Port B1 is an uplink interface, and Port B2 is a downlink interface.
- Port D1 and Port D2 of Device D form another monitor link group. Port D1 is an uplink interface, and Port D2 is a downlink interface.

A monitor link group works independently of other monitor link groups. When a monitor link group does not contain any uplink interface or all its uplink interfaces are down, the monitor link group goes down. It forces all downlink interfaces down at the same time. When any uplink interface comes up, the monitor link group comes up and brings up all the downlink interfaces.

Restrictions and guidelines: Monitor Link configuration

Follow these restrictions and guidelines when you configure Monitor Link:

- Do not manually shut down or bring up the downlink interfaces in a monitor link group.
- To avoid frequent state changes of downlink interfaces in the event that uplink interfaces in the monitor link group flap, you can configure a switchover delay. The switchover delay is the time that the downlink interfaces wait before they come up following an uplink interface.

Monitor Link tasks at a glance

To configure Monitor Link, perform the following tasks:

- Enabling Monitor Link globally
- Creating a monitor link group
- Configuring monitor link group member interfaces
- Enabling Monitor Link to monitor BGP instance process state
- (Optional.) Configuring the uplink interface threshold for triggering monitor link group state switchover
- (Optional.) Configuring the switchover delay for the downlink interfaces in a monitor link group

Enabling Monitor Link globally

About this task

All monitor link groups can operate only after you enable Monitor Link globally. When you disable Monitor Link globally, all monitor link groups cannot operate and the downlink interfaces brought down by the monitor link groups resume their original states.

Procedure

1. Enter system view.
   system-view
2. Enable Monitor Link globally.
   undo monitor-link disable
   By default, Monitor Link is enabled globally.

Creating a monitor link group

1. Enter system view.
   system-view
2. Create a monitor link group and enter monitor link group view.
   monitor-link group *group-id*

Configuring monitor link group member interfaces

Restrictions and guidelines

- An interface can be assigned to only one monitor link group.
- To avoid undesired down/up state changes on the downlink interfaces, configure uplink interfaces before you configure downlink interfaces.
- If you have configured an interface as the downlink interface of a monitor link group, do not configure its subinterfaces as the uplink interfaces of any monitor link group. Otherwise, the Monitor Link operation might be interrupted.
- The state of subinterfaces is associated with the state of the interface. Do not add the interface and its subinterfaces to the same monitor link group. Otherwise, the monitor link group performance might be affected.
- If you have configured a Selected port of an aggregation group as the downlink interface of a monitor link group, do not configure an Unselected port of the aggregation group as the uplink interface of the monitor link group.
- Do not add an aggregate interface and its member ports to the same monitor link group.
- You can configure member interfaces for a monitor link group in monitor link group view or interface view. Configurations made in these views have the same effect. The configuration is supported by the following interfaces:
  - Layer 2 Ethernet interfaces and Layer 2 aggregate interfaces.
  - Layer 3 Ethernet interfaces/subinterfaces and Layer 3 aggregate interfaces/subinterfaces.
  - Loopback interfaces.
  - VLAN interfaces.

Configuring monitor link group member interfaces in monitor link group view

1. Enter system view.

   system-view
2. Enter monitor link group view.

   monitor-link group *group-id*
3. Configure member interfaces for the monitor link group.

   port *interface-type* { *interface-number* | *interface-number*.*subnumber* } { **downlink** | **uplink** }

   By default, no member interfaces exist in a monitor link group.

Configuring monitor link group member interfaces in interface view

1. Enter system view.

   system-view
2. Enter interface view or subinterface view.

   interface *interface-type* { *interface-number* | *interface-number.subnumber* }
3. Configure the interface as a member of a monitor link group.

port monitor-link group *group-id* { **downlink** | **uplink** }

By default, the interface is not a monitor link group member.

Enabling Monitor Link to monitor BGP instance process state

About this task

The Monitor Link group can monitor not only uplink interfaces but also BGP process and session state information:

- BGP process state changes are counted as uplink interface state changes. When a BGP process goes down (the BGP process exists), Monitor Link takes it as an uplink interface down event. When the BGP process comes up, Monitor Link takes it as an uplink interface up event.
- BGP session state changes are counted as uplink interface state changes. When a BGP session goes down, Monitor Link takes it as an uplink interface down event. When the BGP session comes up, Monitor Link takes it as an uplink interface up event. For more information about monitoring BGP session state, see advanced BGP configuration in *Layer 3—IP Routing Configuration Guide*.

The monitor link group goes down and forces all downlink interfaces down when the number of monitored uplink interfaces in up state is below the uplink interface threshold. When the number of uplink interfaces in up state is greater than or equal to the uplink interface threshold, the monitor link group comes up and restores all downlink interfaces to up state.

Restrictions and guidelines

When the BGP processes and sessions monitored by the monitor link group belong to the same BGP instance, the following situations exist:

- When BGP sessions in up state exist in the BGP instance, Monitor link counts only the number of BGP sessions in up state when counting the number of uplink interfaces in up state. In this case, Monitor link does not count the number of BGP processes in up state.
- When no BGP sessions in up state exist in the BGP instance, Monitor link only checks whether the BGP instance process is up when counting the number of uplink interfaces in up state.

Procedure

1. Enter system view.

   system-view
2. Enter monitor link group view.

   monitor-link group *group-id*
3. Enable Monitor Link to monitor the process state of the specified BGP instance.

   monitor bgp *instance-name*

Configuring the uplink interface threshold for triggering monitor link group state switchover

1. Enter system view.

   system-view
2. Enter monitor link group view.

   monitor-link group *group-id*
3. Configure the uplink interface threshold for triggering monitor link group state switchover.

uplink up-port-threshold *number-of-port*

By default, the uplink interface threshold for triggering monitor link group state switchover is 1.

Configuring the switchover delay for the downlink interfaces in a monitor link group

1. Enter system view.
   system-view
2. Enter monitor link group view.
   monitor-link group *group-id*
3. Configure the switchover delay for the downlink interfaces in the monitor link group.
   downlink up-delay *delay*
   By default, the switchover delay is 0 seconds. The downlink interfaces come up as soon as an uplink interface comes up.

Display and maintenance commands for Monitor Link

Execute the **display** command in any view:

Task	Command
Display monitor link group information.	**display monitor-link** [**bgp**] **group** { *group-id* | **all** }

Monitor Link configuration examples

Example: Configuring Monitor Link

Network configuration

As shown in Figure 2:

- Device C is a Smart Link device, and Device A, Device B, and Device D are associated devices. Traffic of VLANs 1 through 30 on Device C is dual-uplinked to Device A through a smart link group.
- Implement dual uplink backup on Device C. When the link between Device A and Device B (or Device D) fails, Device C can detect the link fault. It then performs uplink switchover in the smart link group.

For more information about Smart Link, see "Configuring Smart Link."

Figure 2 Network diagram

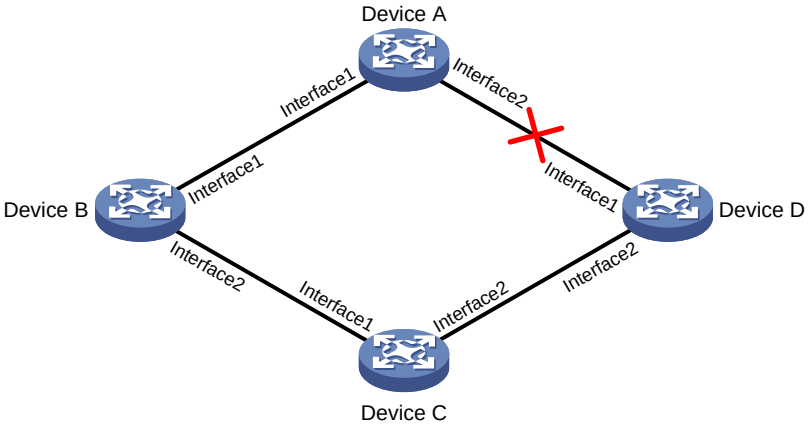

Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure Device C:

   # Create VLANs 1 through 30.

   ```
   <DeviceC> system-view
   [DeviceC] vlan 1 to 30
   ```

   # Map these VLANs to MSTI 1.

   ```
   [DeviceC] stp region-configuration
   [DeviceC-mst-region] instance 1 vlan 1 to 30
   ```

   # Activate MST region configuration.

   ```
   [DeviceC-mst-region] active region-configuration
   [DeviceC-mst-region] quit
   ```

   # Shut down GigabitEthernet 1/0/1.

   ```

   [DeviceC-GigabitEthernet1/0/1] shutdown
   ```

   # Disable the spanning tree feature on the interface.

   ```
   [DeviceC-GigabitEthernet1/0/1] undo stp enable
   ```

   # Configure the interface as a trunk port.

   ```
   [DeviceC-GigabitEthernet1/0/1] port link-type trunk
   ```

   # Assign the interface to VLANs 1 through 30.

   ```
   [DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
   [DeviceC-GigabitEthernet1/0/1] quit
   ```

   # Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

   ```
   [DeviceC] interface gigabitethernet 1/0/2
   [DeviceC-GigabitEthernet1/0/2] shutdown
   [DeviceC-GigabitEthernet1/0/2] undo stp enable
   [DeviceC-GigabitEthernet1/0/2] port link-type trunk
   [DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
   ```

```
[DeviceC-GigabitEthernet1/0/2] quit
```

Create smart link group 1, and configure all the VLANs mapped to MSTI 1 as the protected VLANs for smart link group 1.

```
[DeviceC] smart-link group 1
[DeviceC-smlk-group1] protected-vlan reference-instance 1
```

Configure GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port for smart link group 1.

```
[DeviceC-smlk-group1] port gigabitethernet 1/0/1 primary
[DeviceC-smlk-group1] port gigabitethernet 1/0/2 secondary
```

Enable the smart link group to transmit flush messages.

```
[DeviceC-smlk-group1] flush enable
[DeviceC-smlk-group1] quit
```

Bring up GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] undo shutdown
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] undo shutdown
[DeviceC-GigabitEthernet1/0/2] quit
```

2. Configure Device A:

Create VLANs 1 through 30.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving on the interface.

```
[DeviceA-GigabitEthernet1/0/1] smart-link flush enable
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] smart-link flush enable
[DeviceA-GigabitEthernet1/0/2] quit
```

3. Configure Device B:

Create VLANs 1 through 30.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving on the interface.

```
[DeviceB-GigabitEthernet1/0/1] smart-link flush enable
[DeviceB-GigabitEthernet1/0/1] quit
```

Disable the spanning tree feature on GigabitEthernet 1/0/2.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] undo stp enable
```

Configure the interface as a trunk port.

```
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
```

Enable flush message receiving on the interface.

```
[DeviceB-GigabitEthernet1/0/2] smart-link flush enable
[DeviceB-GigabitEthernet1/0/2] quit
```

Create monitor link group 1.

```
[DeviceB] monitor-link group 1
```

Configure GigabitEthernet 1/0/1 as an uplink interface for monitor link group 1.

```
[DeviceB-mtlk-group1] port gigabitethernet 1/0/1 uplink
```

Configure GigabitEthernet 1/0/2 as a downlink interface for monitor link group 1.

```
[DeviceB-mtlk-group1] port gigabitethernet 1/0/2 downlink
[DeviceB-mtlk-group1] quit
```

4. Configure Device D:

Create VLANs 1 through 30.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving on the interface.

```
[DeviceD-GigabitEthernet1/0/1] smart-link flush enable
[DeviceD-GigabitEthernet1/0/1] quit
```

Disable the spanning tree feature on GigabitEthernet 1/0/2.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] undo stp enable
```

Configure the interface as a trunk port.

```
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
```

Enable flush message receiving on the interface.

```
[DeviceD-GigabitEthernet1/0/2] smart-link flush enable
[DeviceD-GigabitEthernet1/0/2] quit
```

Create monitor link group 1.

```
[DeviceD] monitor-link group 1
```

Configure GigabitEthernet 1/0/1 as an uplink interface for monitor link group 1.

```
[DeviceD-mtlk-group1] port gigabitethernet 1/0/1 uplink
```

Configure GigabitEthernet 1/0/2 as a downlink interface for monitor link group 1.

```
[DeviceD-mtlk-group1] port gigabitethernet 1/0/2 downlink
[DeviceD-mtlk-group1] quit
```

Verifying the configuration

When GigabitEthernet 1/0/2 on Device A goes down because of a link fault, verify information about monitor link group 1 on Device B.

```
[DeviceB] display monitor-link group 1
Monitor link group 1 information:
  Group status     : UP
  Downlink up delay: 0(s)
  Last up time     : 16:38:26 2012/4/21
  Last down time   : 16:37:20 2012/4/21
  Up port threshold: 1

  Member                    Role       Status
  ----------------------------------------------
  GE1/0/1                   UPLINK     UP
  GE1/0/2                   DOWNLINK   UP
```

Verify information about monitor link group 1 on Device D.

```
[DeviceD] display monitor-link group 1
Monitor link group 1 information:
  Group status     : DOWN
  Downlink up delay: 0(s)
  Last up time     : 16:37:20 2012/4/21
  Last down time   : 16:38:26 2012/4/21
  Up port threshold: 1

  Member                    Role       Status
  ----------------------------------------------
  GE1/0/1                   UPLINK     DOWN
  GE1/0/2                   DOWNLINK   DOWN (Monitor Link)
```

Configuring VRRP

About VRRP

Typically, you can configure a default gateway for every host on a LAN. All packets destined for other networks are sent through the default gateway. As shown in Figure 1, when the default gateway fails, no hosts can communicate with external networks.

Figure 1 LAN networking

Using a default gateway facilitates your configuration but requires high availability. Using more egress gateways improves link availability but introduces the problem of routing among the egresses.

Virtual Router Redundancy Protocol (VRRP) is designed to address this issue. VRRP adds a group of network gateways to a VRRP group called a virtual router. The VRRP group has one master and multiple backups, and provides a virtual IP address. The hosts on the subnet use the virtual IP address as their default network gateway to communicate with external networks.

VRRP avoids single points of failure and simplifies the configuration on hosts. When the master in the VRRP group on a multicast or broadcast LAN (for example, an Ethernet network) fails, another router in the VRRP group takes over. The switchover is complete without causing dynamic route recalculation, route re-discovery, gateway reconfiguration on the hosts, or traffic interruption.

VRRP has two versions: VRRPv2 and VRRPv3. VRRPv2 supports IPv4 VRRP. VRRPv3 supports IPv4 VRRP and IPv6 VRRP.

VRRP group

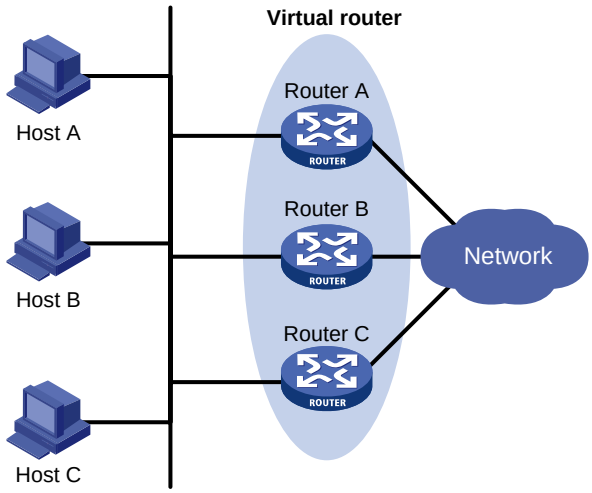
VRRP adds a group of network gateways to a VRRP group called a virtual router. The VRRP group has one master and multiple backups, and provides a virtual IP address. The hosts on the subnet use the virtual IP address as their default network gateway to communicate with external networks.

The administrator can add a router to a VRRP group by creating the VRRP group on a Layer 3 interface on the router.

NOTE:

On a device, the interfaces added to VRRP groups having the same VRRP group number belong to

different VRRP groups.



VRRP standard mode

VRRP networking

As shown in Figure 2, Router A, Router B, and Router C form a virtual router, which has a manually configured virtual IP address. Hosts on the subnet use the virtual router as the default gateway.

The router with the highest priority among the three routers is elected as the master, and the other two are backups. Only the master in the VRRP group can provide gateway service. When the master fails, the backup routers elect a new master to take over for nonstop gateway service.

Figure 2 VRRP networking

Virtual IP address and IP address owner

The virtual IP address of the virtual router can be either of the following IP addresses:

- Unused IP address on the subnet where the VRRP group resides.
- IP address of an interface on a router in the VRRP group.

In the latter case, the router is called the IP address owner. A VRRP group can have only one IP address owner.

Router priority in a VRRP group

VRRP determines the role (master or backup) of each router in a VRRP group by priority. A router with higher priority is more likely to become the master.

A VRRP priority can be in the range of 0 to 255, and a greater number represents a higher priority. Priorities 1 to 254 are configurable. Priority 0 is reserved for special uses, and priority 255 is for the IP address owner. The IP address owner in a VRRP group always has a running priority of 255 and acts as the master as long as it operates correctly.

Preemption

A router in a VRRP group operates in either non-preemptive mode or preemptive mode.

- **Non-preemptive mode**—The master router acts as the master as long as it operates correctly, even if a backup router is later assigned a higher priority. Non-preemptive mode helps avoid frequent switchover between the master and backup routers.
- **Preemptive mode**—A backup starts a new master election and takes over as master when it detects that it has a higher priority than the current master. Preemptive mode ensures that the router with the highest priority in a VRRP group always acts as the master.

Authentication method

To avoid attacks from unauthorized users, VRRP member routers add authentication keys in VRRP packets to authenticate one another. VRRP provides the following authentication methods:

- Simple authentication

  The sender fills an authentication key into the VRRP packet, and the receiver compares the received authentication key with its local authentication key. If the two authentication keys match, the received VRRP packet is legitimate. Otherwise, the received packet is illegitimate and gets discarded.
- MD5 authentication

  The sender computes a digest for the VRRP packet by using the authentication key and MD5 algorithm, and saves the result to the packet. The receiver performs the same operation with the authentication key and MD5 algorithm, and compares the result with the content in the authentication header. If the results match, the received VRRP packet is legitimate. Otherwise, the received packet is illegitimate and gets discarded.

On a secure network, you can choose to not authenticate VRRP packets.

NOTE:

IPv4 VRRPv3 and IPv6 VRRPv3 do not support VRRP packet authentication.

VRRP timers

Skew_Time

Skew_Time helps avoid the situation that multiple backups in a VRRP group become the master when the master in the VRRP group fails.

Skew_Time is not configurable; its value depends on the VRRP version.

- In VRRPv2 (described in RFC 3768), Skew_Time is (256 – Router priority)/256.
- In VRRPv3 (described in RFC 5798), Skew_Time is ((256 – Router priority) × VRRP advertisement interval)/256.

VRRP advertisement interval

The master in a VRRP group periodically sends VRRP advertisements to declare its presence.

You can configure the interval at which the master sends VRRP advertisements. If a backup does not receive any VRRP advertisement when the timer (3 × VRRP advertisement interval + Skew_Time) expires, it takes over as the master.

VRRP preemption delay timer

You can configure the VRRP preemption delay timer for the following purposes:

- Avoid frequent state changes among members in a VRRP group.
- Provide the backups with enough time to collect information (such as routing information).

In preempt mode, a backup does not immediately become the master after it receives an advertisement with lower priority than the local priority. Instead, it waits for a period of time (preemption delay time + Skew_Time) before taking over as the master.

Master election

Routers in a VRRP group determine their roles by priority. When a router joins a VRRP group, it has a backup role. The router role changes according to the following situations:

- If the backup does not receive any VRRP advertisement when the timer (3 × advertisement interval + Skew_Time) expires, it becomes the master.
- If the backup receives a VRRP advertisement with the same or greater priority within the timer (3 × advertisement interval + Skew_Time), it remains a backup.
- If the backup receives a VRRP advertisement with a smaller priority within the timer (3 × advertisement interval + Skew_Time), the following results apply:
  - It remains a backup when operating in non-preemptive mode.
  - It becomes the master when operating in preemptive mode.

The elected master starts a VRRP advertisement interval to periodically send VRRP advertisements to notify the backups that it is operating correctly. Each of the backups starts a timer to wait for advertisements from the master.

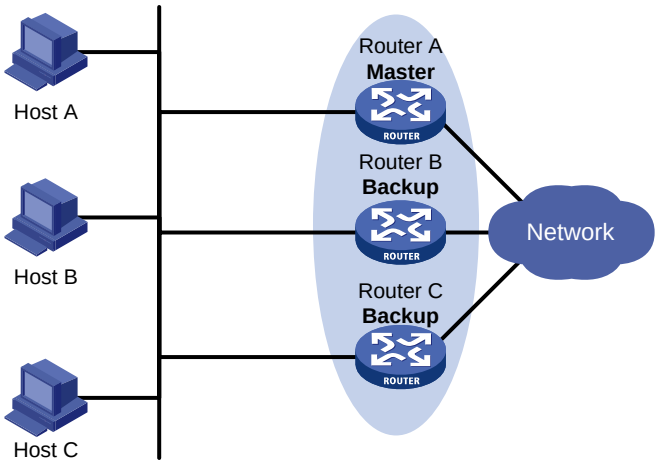
When multiple routers in a VRRP group declare that they are the master because of network problems, the one with the highest priority becomes the master. If two routers have the same priority, the one with the highest IP address becomes the master.

VRRP tracking

The VRRP tracking function uses network quality analyzer (NQA) or bidirectional forwarding detection (BFD) to monitor the state of the master or the upstream link. The collaboration between VRRP and NQA or BFD through a track entry implements the following functions:

- Monitors the upstream link and changes the priority of the router according to the state of the link. If the upstream link fails, the hosts on the subnet cannot access external networks through the router and the state of the track entry becomes Negative. The priority of the master decreases by a specified value, and a router with a higher priority in the VRRP group becomes the master. The switchover ensures uninterrupted communication between the hosts on the subnet and external networks.
- Monitors the state of the master on the backups. When the master fails, a backup immediately takes over to ensure uninterrupted communication.

When the track entry changes from Negative to Positive or Notready, the router automatically restores its priority. For more information about track entries, see "Configuring Track."



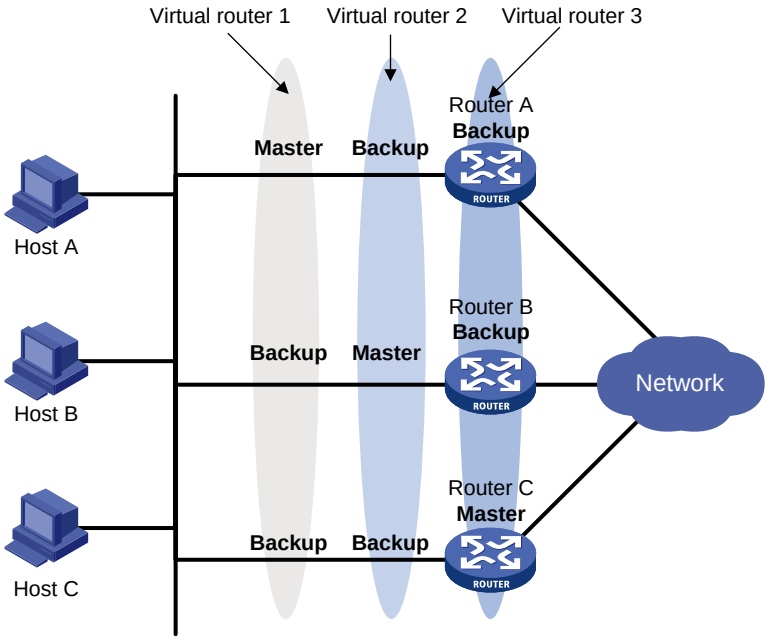
To enable VRRP tracking, configure the routers in the VRRP group to operate in preemptive mode first. This configuration ensures that only the router with the highest priority operates as the master.

VRRP application

Master/backup

In master/backup mode, only the master forwards packets, as shown in Figure 3. When the master fails, a new master is elected from among the backups. This mode requires only one VRRP group, and each router in the group has a different priority. The one with the highest priority becomes the master.

Figure 3 VRRP in master/backup mode



Assume that Router A is acting as the master to forward packets to external networks, and Router B and Router C are backups in listening state. When Router A fails, Router B and Router C elect a new master to forward packets for hosts on the subnet.

Load sharing

A router can join multiple VRRP groups. With different priorities in different VRRP groups, the router can act as the master in one VRRP group and a backup in another.

In load sharing mode, multiple VRRP groups provide gateway services. This mode requires a minimum of two VRRP groups, and each group has one master and multiple backups. The master roles in the VRRP groups are assumed by different routers, as shown in Figure 4.

Figure 4 Load sharing of VRRP

A router can be in multiple VRRP groups and have a different priority in each group.

As shown in Figure 4, the following VRRP groups exist:

- **VRRP group 1**—Router A is the master. Router B and Router C are the backups.
- **VRRP group 2**—Router B is the master. Router A and Router C are the backups.

- **VRRP group 3**—Router C is the master. Router A and Router B are the backups.

To implement load sharing among Router A, Router B, and Router C, perform the following tasks:

- Configure the virtual IP addresses of VRRP group 1, 2, and 3 as default gateway IP addresses for hosts on the subnet.
- Assign the highest priority to Router A, B, and C in VRRP group 1, 2, and 3, respectively.

VRRP load balancing mode

In a standard-mode VRRP group, only the master can forward packets and backups are in listening state. You can create multiple VRRP groups to share traffic, but you must configure different gateways for hosts on the subnet.

In load balancing mode, a VRRP group maps its virtual IP address to multiple virtual MAC addresses, assigning one virtual MAC address to each member router. Every router in this VRRP group can forward traffic and respond to IPv4 ARP requests or IPv6 ND requests from hosts. Because their virtual MAC addresses are different, traffic from hosts is distributed across the VRRP group members. Load balancing mode simplifies configuration and improves forwarding efficiency.

VRRP load balancing mode uses the same master election, preemption, and tracking mechanisms as the standard mode. New mechanisms have been introduced to VRRP load balancing mode, as described in the following sections.

Virtual forwarder

Virtual forwarder creation

Virtual MAC addresses enable traffic distribution across routers in a VRRP group. To enable routers in the VRRP group to forward packets, VFs must be created on them. Each VF is associated with a virtual MAC address in the VRRP group and forwards packets that are sent to this virtual MAC address.

VFs are created on routers in a VRRP group, as follows:

1. The master assigns virtual MAC addresses to all routers in the VRRP group. Each member router creates a VF for this MAC address and becomes the owner of this VF.
2. Each VF owner advertises its VF information to the other member routers.
3. After receiving the VF advertisement, each of the other routers creates the advertised VF.

Eventually, every member router maintains one VF for each virtual MAC address in the VRRP group.

VF weight and priority

The weight of a VF indicates the forwarding capability of a VF. A higher weight means higher forwarding capability. When the weight is lower than the lower limit of failure, the VF cannot forward packets.

The priority of a VF determines the VF state. Among the VFs created on different member routers for the same virtual MAC address, the VF with the highest priority is in active state. This VF, known as the active virtual forwarder (AVF), forwards packets. All other VFs listen to the state of the AVF and are known as the listening virtual forwarders (LVFs). VF priority is in the range of 0 to 255, where 255 is reserved for the VF owner. When the weight of a VF owner is higher than or equal to the lower limit of failure, the priority of the VF owner is 255.

The priority of a VF is calculated based on its weight.

- If the VF weight is higher than or equal to the lower limit of failure, the following VF priorities apply:
  - On a VF owner, the VF priority is 255.
  - On a non-VF owner, the VF priority is calculated as weight/(number of local AVFs + 1).

- If the VF weight is lower than the lower limit of failure, the VF priority is 0.

VF backup

The VFs corresponding to a virtual MAC address on different routers in the VRRP group back up one another.

Figure 5 VF information

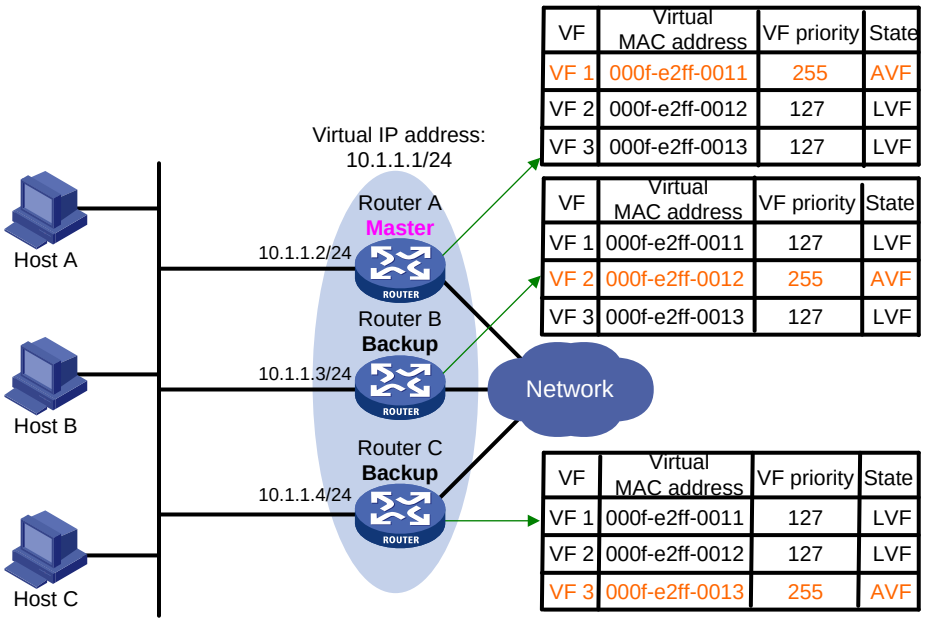


Figure 5 shows the VF table on each router in the VRRP group and how the VFs back up one another. The master, Router A, assigns virtual MAC addresses 000f-e2ff-0011, 000f-e2ff-0012, and 000f-e2ff-0013 to itself, Router B, and Router C, respectively. Each router creates VF 1, VF 2, and VF 3 for virtual MAC addresses 000f-e2ff-0011, 000f-e2ff-0012, and 000f-e2ff-0013, respectively. The VFs for the same virtual MAC address on different routers back up one another. For example, the VF 1 instances on Router A, Router B, and Router C back up one another.

- The VF 1 instance on Router A (the VF 1 owner) has priority 255. It acts as the AVF to forward packets sent to virtual MAC address 000f-e2ff-0011.
- The VF 1 instances on Router B and Router C have a priority of 255/(1 + 1), or 127. Because their priorities are lower than the priority of the VF 1 instance on Router A, they act as LVFs. These LVFs listen to the state of the VF 1 instance on Router A.
- When the VF 1 instance on Router A fails, the VF 1 instances on Router B and Router C elect the one with higher priority as the new AVF. This AVF forwards packets destined for virtual MAC address 000f-e2ff-0011. If the two LVFs' priorities are the same, the LVF with a greater device MAC address becomes the new AVF.

A VF always operates in preemptive mode. When an LVF finds its priority value higher than the one advertised by the AVF, the LVF declares itself as the AVF.

VF timers

When the AVF on a router fails, the new AVF on another router creates the following timers for the failed AVF:

- **Redirect timer**—Before this timer expires, the master still uses the virtual MAC address corresponding to the failed AVF to respond to ARP/ND requests from hosts. The VF owner can share traffic load if the VF owner resumes normal operation within this time. When this timer expires, the master stops using the virtual MAC address corresponding to the failed AVF to respond to ARP/ND requests from hosts.

- **Timeout timer**—The duration after which the new AVF takes over responsibilities of the failed VF owner. Before this timer expires, all routers in the VRRP group keep the VFs that correspond to the failed AVF. The new AVF forwards packets destined for the virtual MAC address of the failed AVF. When this timer expires, all routers in the VRRP group remove the VFs that correspond to the failed AVF, including the new AVF. Packets destined for the virtual MAC address of the failed AVF are not forwarded any longer.

VF tracking

An AVF forwards packets destined for the MAC address of the AVF. If the AVF's upstream link fails but no LVF takes over, the hosts that use the AVF's MAC address as their gateway MAC address cannot access the external network.

The VF tracking function can solve this problem. You can use NQA or BFD to monitor the upstream link state of the VF owner, and associate the VFs with NQA or BFD through the tracking function. This enables the collaboration between VRRP and NQA or BFD through the Track module. When the upstream link fails, the state of the track entry changes to Negative. The weights of the VFs (including the AVF) on the router decrease by a specific value. The corresponding LVF with a higher priority on another router becomes the AVF and forwards packets.

Protocols and standards

- RFC 3768, *Virtual Router Redundancy Protocol (VRRP)*
- RFC 5798, *Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6*

Configuring IPv4 VRRP

Restrictions and guidelines: IPv4 VRRP configuration

IPv4 VRRP does not take effect on member ports of aggregation groups.

Configuration on the routers in an IPv4 VRRP group must be consistent.

Each IPv4 VRRP group corresponds to a virtual MAC address. The maximum number of IPv4 VRRP groups supported on an interface depends on the maximum number of virtual MAC addresses supported on the interface.

IPv4 VRRP tasks at a glance

To configure IPv4 VRRP, perform the following tasks:

1. (Optional.) Specifying the IPv4 VRRP version
2. Configuring an IPv4 VRRP group
3. (Optional.) Configuring the virtual MAC address for an IPv4 VRRP group
4. (Optional.) Configuring IPv4 VRRP packet attributes
5. (Optional.) Setting the packet sending mode for IPv4 VRRPv3
6. (Optional.) Enabling periodic sending of gratuitous ARP packets for IPv4 VRRP
7. (Optional.) Configuring a subordinate IPv4 VRRP group to follow a master IPv4 VRRP group
8. (Optional.) Setting the state transition delay timer for an IPv4 VRRP group
9. (Optional.) Enabling SNMP notifications for VRRP
10. (Optional.) Enabling the isolation mode for IPv4 VRRP

Specifying the IPv4 VRRP version

About this task

IPv4 VRRP can use VRRPv2 and VRRPv3.

Restrictions and guidelines

For an IPv4 VRRP group to operate correctly, make sure the same VRRP version is used on all routers in the IPv4 VRRP group.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify the version of VRRP.
   vrrp version *version-number*
   By default, VRRPv3 is used.

Configuring an IPv4 VRRP group

About this task

A VRRP group can operate correctly after you create it and assign a minimum of one virtual IP address to it. You can configure multiple virtual IP addresses for the VRRP group on an interface that connects to multiple subnets for router backup on different subnets.

If you disable an IPv4 VRRP group, the VRRP group enters **Initialize** state, and the existing configuration on the VRRP group remains unchanged. You can modify the configuration of the VRRP group. The modification takes effect when you enable the VRRP group again.

Restrictions and guidelines

Item	Remarks
Maximum number of VRRP groups and virtual IP addresses	
Virtual IP address	When VRRP is operating in standard mode, the virtual IP address of a VRRP group can be either of the following addresses: • Unused IP address on the subnet where the VRRP group resides. • IP address of an interface on a router in the VRRP group. An IPv4 VRRP group without virtual IP addresses configured can exist on a device provided that other settings (for example, priority and preemption mode) are available. Such a VRRP group stays in inactive state and does not function. For hosts in the subnet to access external networks, as a best practice, configure the following addresses in the same subnet: • Virtual IP address of an IPv4 VRRP group. • Downlink interface IP addresses of the VRRP group members.
IP address owner	On an IP address owner, as a best practice, do not use the **network** command to enable OSPF on the interface owning the virtual IP address of the VRRP group. For more information about the **network** command, see *Layer 3—IP Routing Command Reference*. After you remove the VRRP group on an IP address owner, a backup in the VRRP group takes over as the master. The actual IP address of the

Item	Remarks
	interface on the IP address owner will conflict with the virtual IP address of the new master. To avoid the conflict, change the IP address of the interface on the IP address owner before you remove the VRRP group from the interface. The running priority of an IP address owner is always 255, and you do not need to configure it. An IP address owner always operates in preemptive mode. If you configure the **vrrp vrid track priority reduced** or **vrrp vrid track switchover** command on an IP address owner, the configuration does not take effect until the router becomes a non-IP address owner.
VRRP association with a track entry	When the track entry changes from Negative to Positive or Notready, the router automatically restores its priority or the failed master router becomes the master again.

Creating a VRRP group and assigning a virtual IP address

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Create a VRRP group and assign a virtual IP address.
   vrrp vrid *virtual-router-id* **virtual-ip** *virtual-address*

Configuring an IPv4 VRRP group

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the priority of the router in the VRRP group.
   vrrp vrid *virtual-router-id* **priority** *priority-value*
   The default setting is 100.
4. Enable the preemptive mode for the router in a VRRP group and set the preemption delay time.
   vrrp vrid *virtual-router-id* **preempt-mode** [**delay** *delay-value*]
   By default, the router in a VRRP group operates in preemptive mode and the preemption delay time is 0 centiseconds, which means an immediate preemption.
5. Associate a VRRP group with a track entry.
   vrrp vrid *virtual-router-id* **track** *track-entry-number* { **forwarder-switchover member-ip** *ip-address* | **priority reduced** [*priority-reduced*] | **switchover** | **weight reduced** [*weight-reduced*] }
   By default, a VRRP group is not associated with any track entries.

Disabling an IPv4 VRRP group

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Disable a VRRP group.

vrrp vrid *virtual-router-id* **shutdown**

By default, an IPv4 VRRP group is enabled.

CAUTION:

You can use this command to temporarily disable an IPv4 VRRP group. After you execute this command, packets sent to the IPv4 VRRP group might be discarded.

Configuring the virtual MAC address for an IPv4 VRRP group

About this task

By default, after the network administrator creates an IPv4 VRRP group, the device automatically generates a virtual MAC address for the IPv4 VRRP group based on the VRRP protocol requirements for communication purposes. After you configure this feature, the device will set the virtual MAC address of the IPv4 VRRP group to the specified value. This can meet the requirements in specific scenarios (such as in a static ARP network).

Restrictions and guidelines

This feature takes effect only when the local device acts as the master in the IPv4 VRRP group.

The virtual MAC addresses of the IPv4 VRRP group and IPv6 VRRP group deployed on an interface cannot be the same.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the virtual MAC address for the IPv4 VRRP group.

   vrrp vrid *virtual-router-id* **virtual-mac** *virtual-mac*

   By default, no virtual MAC address is configured for the IPv4 VRRP group. The device will automatically generate a virtual MAC address for the IPv4 VRRP group.

Configuring IPv4 VRRP packet attributes

Restrictions and guidelines

- You can configure different authentication modes and authentication keys for VRRP groups on an interface. However, members of the same VRRP group must use the same authentication mode and authentication key.
- In VRRPv2, all routers in a VRRP group must have the same VRRP advertisement interval.
- In VRRPv3, authentication mode and authentication key settings do not take effect.
- In VRRPv3, routers in an IPv4 VRRP group can have different intervals for sending VRRP advertisements. The master in the VRRP group sends VRRP advertisements at specified intervals, and carries the interval in the advertisements. After a backup receives the advertisement, it records the interval in the advertisement. If the backup does not receive a VRRP advertisement before the timer (3 x recorded interval + Skew_Time) expires, it regards the master as failed and takes over.
- If you use M-LAG and VRRP together, make sure the keepalive hold timer is shorter than the VRRP advertisement interval. Violation of this restriction might cause a VRRP master/backup switchover to occur before peer link failure is confirmed. To set the keepalive hold timer, use the

m-lag keepalive hold-time command. For more information about this command, see *Layer 2—LAN Switching Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the authentication mode and authentication key for an IPv4 VRRP group to send and receive VRRP packets.

   vrrp vrid *virtual-router-id* **authentication-mode** { **md5** | **simple** } { **cipher** | **plain** } *string*

   By default, authentication is disabled.

4. Set the interval at which the master in an IPv4 VRRP group sends VRRP advertisements.

   vrrp vrid *virtual-router-id* **timer advertise** *adver-interval*

   The default setting is 100 centiseconds.

   As a best practice to maintain system stability, set the VRRP advertisement interval to be greater than 100 centiseconds.

5. Specify the source interface for receiving and sending VRRP packets.

   vrrp vrid *virtual-router-id* **source-interface** *interface-type interface-number*

   By default, the source interface for receiving and sending VRRP packets is not specified. The interface where the VRRP group resides sends and receives VRRP packets.

6. Enable TTL check for IPv4 VRRP packets.

   vrrp check-ttl enable

   By default, TTL check for IPv4 VRRP packets is enabled.

7. Use the standard algorithm to calculate the checksum of IPv4 VRRP packets.

   vrrp vrid *virtual-router-id* **checksum-standard**

   By default, the device uses the private algorithm to calculate the checksum of IPv4 VRRP packets.

   Configure this command when the device forms a VRRP group with a device from another vendor. This can avoid checksum check failure and IPv4 VRRP group setup failure when the two ends use different methods to calculate the checksum in IPv4 VRRP packets.

8. Return to system view.

   quit

9. Set a DSCP value for VRRP packets.

   vrrp dscp *dscp-value*

   By default, the DSCP value for VRRP packets is 48.

   The DSCP value identifies the packet priority during transmission.

Setting the packet sending mode for IPv4 VRRPv3

About this task

A router configured with VRRPv3 can process incoming VRRPv2 packets, but a router configured with VRRPv2 cannot process incoming VRRPv3 packets. When the VRRP version of the routers in a VRRP group is changed from VRRPv2 to VRRPv3, multiple masters might be elected in the VRRP group. To resolve the problem, you can set the packet sending mode for IPv4 VRRPv3. This task

enables a router configured with VRRPv3 to send VRRPv2 packets and communicate with routers configured with VRRPv2.

Restrictions and guidelines

- The packet sending mode for IPv4 VRRPv3 takes effect only on outgoing VRRP packets. A router configured with VRRPv3 can process incoming VRRPv2 and VRRPv3 packets.
- If you set the packet sending mode for IPv4 VRRPv3 and configure VRRP packet authentication, authentication information will be carried in outgoing VRRPv2 packets but not in outgoing VRRPv3 packets.
- The VRRP advertisement interval is set in centiseconds by using the **vrrp vrid timer advertise** command. The VRRP advertisement interval carried in VRRPv2 packets sent from routers configured with VRRPv3 might be different from the configured value. For information about the VRRP advertisement interval, see the **vrrp vrid timer advertise** command in *High Availability Command Reference*.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the packet sending mode for IPv4 VRRPv3.
   vrrp vrid *virtual-router-id* **vrrpv3-send-packet** { **v2-only** | **v2v3-both** }
   By default, a router configured with VRRPv3 sends only VRRPv3 packets.

Enabling periodic sending of gratuitous ARP packets for IPv4 VRRP

About this task

This feature enables the master router in a VRRP group to periodically send gratuitous ARP packets. Then the downstream devices can update the MAC address entry for the virtual MAC address of the VRRP group in a timely manner.

Restrictions and guidelines

- This feature takes effect only in VRRP standard mode.
- If you change the sending interval for gratuitous ARP packets, the configuration takes effect at the next sending interval.
- The master sends the first gratuitous ARP packet at a random time in the second half of the set interval after you execute the **vrrp send-gratuitous-arp** command. This prevents too many gratuitous ARP packets from being sent at the same time.
- The sending interval for gratuitous ARP packets might be much longer than the set interval when the following conditions are met:
  - Multiple VRRP groups exist on the device.
  - A short sending interval is set.

Procedure

1. Enter system view.
   system-view
2. Enable periodic sending of gratuitous ARP packets for IPv4 VRRP.
   vrrp send-gratuitous-arp [**interval** *interval*]

By default, periodic sending of gratuitous ARP packets is disabled for IPv4 VRRP.

Configuring a subordinate IPv4 VRRP group to follow a master IPv4 VRRP group

About this task

Each VRRP group determines the device role (master or backup) by exchanging VRRP packets among member devices, which might consume excessive bandwidth and CPU resources. To reduce the number of VRRP packets in the network, you can configure a subordinate VRRP group to follow a master VRRP group.

A master VRRP group determines the device role through exchanging VRRP packets among member devices. A VRRP group that follows a master group, called a subordinate VRRP group, does not exchange VRRP packets among its member devices. The state of the subordinate VRRP group follows the state of the master group.

Restrictions and guidelines

- To ensure the master router election, configure the settings such as the router priority, preemptive mode, and tracking function for the master IPv4 VRRP group. The settings are not required for subordinate IPv4 VRRP groups.
- An IPv4 VRRP group cannot be both a master group and a subordinate group.
- An IPv4 VRRP group stays in **Inactive** state if it is configured to follow a nonexistent master group.
- If an IPv4 VRRP group in **Inactive** or **Initialize** state follows a master group that is not in **Inactive** state, the state of the VRRP group does not change.
- A subordinate IPv4 VRRP group does not exchange VRRP packets, which might cause the MAC address entry for its virtual MAC address not to be updated on downstream devices. As a best practice, enable periodic sending of gratuitous ARP packets for IPv4 VRRP by using the **vrrp send-gratuitous-arp** command.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Configure an IPv4 VRRP group as a master group and assign a name to it.

   vrrp vrid *virtual-router-id* **name** *name*

   By default, an IPv4 VRRP group does not act as a master group.
4. Return to system view.

   quit
5. Enter interface view.

   interface *interface-type interface-number*
6. Configure an IPv4 VRRP group to follow a master group.

   vrrp vrid *virtual-router-id* **follow** *name*

   By default, an IPv4 VRRP group does not follow a master VRRP group.

Setting the state transition delay timer for an IPv4 VRRP group

About this task

Typically, an IPv4 VRRP group immediately transitions from **Initialize** to **Master** or **Backup** state when the interface where the IPv4 VRRP group resides comes up. If the device restarts or the interface state changes frequently, the IPv4 VRRP group state might be unstable, and the VRRP group operation might be affected.This task allows you to solve this issue.

Restrictions and guidelines

The delay time for an IPv4 VRRP group to transition from **Initialize** to **Master** or **Backup** state is in the range of 0 to 60 seconds.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Set the state transition delay timer for the IPv4 VRRP group.

   vrrp state-transition-delay *delay-value*

   By default, the delay time is 0 seconds for the IPv4 VRRP group to transition from **Initialize** to **Master** or **Backup** state.

Enabling SNMP notifications for VRRP

About this task

To report critical VRRP events to an NMS, enable SNMP notifications for VRRP. For VRRP event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

Procedure

1. Enter system view.

   system-view
2. Enable SNMP notifications for VRRP.

   snmp-agent trap enable vrrp [**auth-failure** | **new-master**]

   By default, SNMP notifications for VRRP are enabled.

Enabling the isolation mode for IPv4 VRRP

About this task

To maintain the master in an IPv4 VRRP group, use this feature to perform a master/backup switchover. In isolation mode, the maintenance operation on the device is performed after a master/backup switchover and does not affect services.

Enabling the isolation mode sets the priority of the device to 0 in the IPv4 VRRP group.

Restrictions and guidelines

If you set the priority with the **vrrp vrid priority** command for a device in isolation mode, the setting does not take effect until the isolation mode is disabled.

Procedure

1. Enter system view.
   system-view
2. Enable the isolation mode for IPv4 VRRP.
   vrrp isolate enable
   By default, the isolation mode is disabled for IPv4 VRRP.

Display and maintenance commands for IPv4 VRRP

Execute **display** commands in any view and the **reset** command in user view.

Task	Command
Display states of IPv4 VRRP groups.	**display vrrp** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*]] [**verbose**]
Display IPv4 VRRP packet anomaly information.	**display vrrp abnormal-info** [**interface** *interface-type interface-number* [**vrid** *vrid-id*]]
Display master-to-subordinate IPv4 VRRP group bindings.	**display vrrp binding** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*] | **name** *name*]
Display statistics for IPv4 VRRP groups.	**display vrrp statistics** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*]]
Clear statistics for IPv4 VRRP groups.	**reset vrrp statistics** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*]]

Configuring IPv6 VRRP

Restrictions and guidelines: IPv6 VRRP configuration

IPv6 VRRP does not take effect on member ports of aggregation groups.

Configuration on the routers in an IPv6 VRRP group must be consistent.

Each IPv6 VRRP group corresponds to a virtual MAC address. The maximum number of IPv6 VRRP groups supported on an interface depends on the maximum number of virtual MAC addresses supported on the interface.

IPv6 VRRP tasks at a glance

To configure IPv6 VRRP, perform the following tasks:

1. Configuring an IPv6 VRRP group
2. (Optional.) Configuring the virtual MAC address for an IPv6 VRRP group
3. (Optional.) Configuring IPv6 VRRP packet attributes
4. (Optional.) Enabling periodic sending of ND packets for IPv6 VRRP

5. (Optional.) Configuring a subordinate IPv6 VRRP group to follow a master IPv6 VRRP group
6. (Optional.) Setting the state transition delay timer for an IPv6 VRRP group
7. (Optional.) Enabling the isolation mode for IPv6 VRRP

Configuring an IPv6 VRRP group

About this task

A VRRP group can work correctly after you create it and assign a minimum of one virtual IPv6 address for it. You can configure multiple virtual IPv6 addresses for the VRRP group on an interface that connects to multiple subnets for router backup.

If you disable an IPv6 VRRP group, the VRRP group enters **Initialize** state, and the existing configuration on the VRRP group remains unchanged. You can modify the configuration of the VRRP group. The modification takes effect when you enable the VRRP group again.

Restrictions and guidelines

Item	Remarks
Maximum number of VRRP groups and virtual IPv6 addresses	
Virtual IPv6 address	An IPv6 VRRP group without virtual IPv6 addresses configured can exist on a device provided that other settings (for example, priority and preemption mode) are available. Such a VRRP group stays in inactive state and does not function. For hosts in the subnet to access external networks, as a best practice, configure the following addresses in the same subnet: • Virtual IPv6 address of an IPv6 VRRP group. • Downlink interface IPv6 addresses of the VRRP group members.
IP address owner	On an IP address owner, as a best practice, do not use the **ospfv3 area** command to enable OSPF on the interface owning the virtual IPv6 address of the VRRP group. For more information about the **ospfv3 area** command, see *Layer 3—IP Routing Command Reference*. After you remove the IPv6 VRRP group on an IP address owner, a backup in the IPv6 VRRP group takes over as the master. The actual IPv6 address of the interface on the IP address owner will conflict with the virtual IPv6 address of the new master. To avoid the conflict, change the IPv6 address of the interface on the IP address owner before you remove the IPv6 VRRP group from the interface. The running priority of an IP address owner is always 255, and you do not need to configure it. An IP address owner always operates in preemptive mode. If you configure the **vrrp ipv6 vrid track priority reduced** or **vrrp ipv6 vrid track switchover** command on an IP address owner, the configuration does not take effect until the router becomes a non-IP address owner. On an IP address owner, disable Duplicate Address Detection (DAD) on the interface configured with VRRP. To disable DAD, set the *interval* argument to 0 for the **ipv6 nd dad attempts** command. For more information about the command, see IPv6 basics commands in *Layer 3—IP Services Command Reference*.
VRRP association with a track entry	When the track entry changes from Negative to Positive or Notready, the router automatically restores its priority or the failed master router becomes the master again.

Creating a VRRP group and assign a virtual IPv6 address

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Create a VRRP group and assign a virtual IPv6 address, which is a link-local address.

   vrrp ipv6 vrid *virtual-router-id* **virtual-ip** *virtual-address* **link-local**

   The first virtual IPv6 address that you assign to an IPv6 VRRP group must be a link-local address. It must be the last address you remove. Only one link-local address is allowed in a VRRP group.

Configuring an IPv6 VRRP group

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Assign a virtual IPv6 address, which is a global unicast address.

   vrrp ipv6 vrid *virtual-router-id* **virtual-ip** *virtual-address*

   By default, no global unicast address is assigned to an IPv6 VRRP group.

4. Set the priority of the router in the VRRP group.

   vrrp ipv6 vrid *virtual-router-id* **priority** *priority-value*

   The default setting is 100.

5. Enable the preemptive mode for the router in a VRRP group and set the preemption delay time.

   vrrp ipv6 vrid *virtual-router-id* **preempt-mode** [**delay** *delay-value*]

   By default, the router in a VRRP group operates in preemptive mode and the preemption delay time is 0 centiseconds, which means an immediate preemption.

6. Associate a VRRP group with a track entry.

   vrrp ipv6 vrid *virtual-router-id* **track** *track-entry-number* { **forwarder-switchover member-ip** *ipv6-address* | **priority reduced** [*priority-reduced*] | **switchover** | **weight reduced** [*weight-reduced*] }

   By default, a VRRP group is not associated with any track entries.

Disabling an IPv6 VRRP group

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Disable an IPv6 VRRP group.

   vrrp ipv6 vrid *virtual-router-id* **shutdown**

   By default, an IPv6 VRRP group is enabled.

CAUTION:

You can use this command to temporarily disable an IPv6 VRRP group. After you execute this command, packets sent to the IPv6 VRRP group might be discarded.

Configuring the virtual MAC address for an IPv6 VRRP group

About this task

By default, after the network administrator creates an IPv6 VRRP group, the device automatically generates a virtual MAC address for the IPv6 VRRP group based on the VRRP protocol requirements for communication purposes. After you configure this feature, the device will set the virtual MAC address of the IPv6 VRRP group to the specified value. This can meet the requirements in specific scenarios (such as in a static ARP network).

Restrictions and guidelines

This feature takes effect only when the local device acts as the master in the IPv6 VRRP group.

The virtual MAC addresses of the IPv4 VRRP group and IPv6 VRRP group deployed on an interface cannot be the same.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the virtual MAC address for the IPv6 VRRP group.
   vrrp ipv6 vrid *virtual-router-id* **virtual-mac** *virtual-mac*

   By default, no virtual MAC address is configured for the IPv6 VRRP group. The device will automatically generate a virtual MAC address for the IPv6 VRRP group.

Configuring IPv6 VRRP packet attributes

Restrictions and guidelines

- The routers in an IPv6 VRRP group can have different intervals for sending VRRP advertisements. The master in the VRRP group sends VRRP advertisements at the specified interval and carries the interval attribute in the advertisements. After a backup receives the advertisement, it records the interval in the advertisement. If the backup does not receive a VRRP advertisement before the timer (3 x recorded interval + Skew_Time) expires, it regards the master as failed and takes over.
- A high volume of network traffic might cause a backup to fail to receive VRRP advertisements from the master within the specified time. As a result, an unexpected master switchover occurs. To solve this problem, configure a larger interval.
- If you use M-LAG and VRRP together, make sure the keepalive hold timer is shorter than the IPv6 VRRP advertisement interval. Violation of this restriction might cause a VRRP master/backup switchover to occur before peer link failure is confirmed. To set the keepalive hold timer, use the **m-lag keepalive hold-time** command. For more information about this command, see *Layer 2—LAN Switching Command Reference*.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the IPv6 VRRP advertisement interval.
   vrrp ipv6 vrid *virtual-router-id* **timer advertise** *adver-interval*

   The default setting is 100 centiseconds.

As a best practice to maintain system stability, set the VRRP advertisement interval to be greater than 100 centiseconds.

4. Return to system view.

   quit

5. Set a DSCP value for IPv6 VRRP packets.

   vrrp ipv6 dscp *dscp-value*

   By default, the DSCP value for IPv6 VRRP packets is 56.

   The DSCP value identifies the packet priority during transmission.

Enabling periodic sending of ND packets for IPv6 VRRP

About this task

This feature enables the master router in an IPv6 VRRP group to periodically send ND packets. Then the downstream devices can update the MAC address entry for the virtual MAC address of the IPv6 VRRP group in a timely manner.

Restrictions and guidelines

- This feature takes effect only in VRRP standard mode.
- If you change the sending interval for ND packets, the configuration takes effect at the next sending interval.
- The master sends the first ND packet at a random time in the second half of the set interval after you execute the **vrrp ipv6 send-nd** command. This prevents too many ND packets from being sent at the same time.
- The sending interval for ND packets might be much longer than the set interval when the following conditions are met:
  - Multiple IPv6 VRRP groups exist on the device.
  - A short sending interval is set.

Procedure

1. Enter system view.

   system-view

2. Enable periodic sending of ND packets for IPv6 VRRP.

   vrrp ipv6 send-nd [**interval** *interval*]

   By default, periodic sending of ND packets is disabled for IPv6 VRRP.

Configuring a subordinate IPv6 VRRP group to follow a master IPv6 VRRP group

About this task

Each IPv6 VRRP group determines the device role (master or backup) by exchanging VRRP packets among member devices, which might consume excessive bandwidth and CPU resources. To reduce the number of VRRP packets in the network, you can configure a subordinate IPv6 VRRP group to follow a master IPv6 VRRP group.

A master IPv6 VRRP group determines the device role through exchanging VRRP packets among member devices. An IPv6 VRRP group that follows a master group, called a subordinate VRRP group, does not exchange VRRP packets among its member devices. The state of the subordinate VRRP group follows the state of the master group.

Restrictions and guidelines

- To ensure the master router election, configure the settings such as the router priority, preemptive mode, and tracking function for the master IPv6 VRRP group. The settings are not required for subordinate IPv6 VRRP groups.
- An IPv6 VRRP group cannot be both a master group and a subordinate group.
- An IPv6 VRRP group stays in **Inactive** state if it is configured to follow a nonexistent master IPv6 VRRP group.
- If an IPv6 VRRP group in **Inactive** or **Initialize** state follows a master group that is not in **Inactive** state, the state of the VRRP group does not change.
- A subordinate IPv6 VRRP group does not exchange VRRP packets, which might cause the MAC address entry for its virtual MAC address not to be updated on downstream devices. As a best practice, enable periodic sending of ND packets for IPv6 VRRP by using the **vrrp ipv6 send-nd** command.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure an IPv6 VRRP group as a master group and assign a name to it.
   vrrp ipv6 vrid *virtual-router-id* **name** *name*
   By default, an IPv6 VRRP group does not act as a master group.
4. Return to system view.
   quit
5. Enter interface view.
   interface *interface-type interface-number*
6. Configure an IPv6 VRRP group to follow a master group.
   vrrp ipv6 vrid *virtual-router-id* **follow** *name*
   By default, an IPv6 VRRP group does not follow a master VRRP group.

Setting the state transition delay timer for an IPv6 VRRP group

About this task

Typically, an IPv6 VRRP group immediately transitions from **Initialize** to **Master** or **Backup** state when the interface where the IPv6 VRRP group resides comes up. If the device restarts or the interface state changes frequently, the IPv6 VRRP group state might be unstable, and the VRRP group operation might be affected.This task allows you to solve this issue.

Restrictions and guidelines

The delay time for an IPv6 VRRP group to transition from **Initialize** to **Master** or **Backup** state is in the range of 0 to 60 seconds.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*

3. Set the state transition delay timer for the IPv6 VRRP group.

   vrrp ipv6 state-transition-delay *delay-value*

   By default, the delay time is 0 seconds for the IPv6 VRRP group to transition from **Initialize** to **Master** or **Backup** state.

Enabling the isolation mode for IPv6 VRRP

About this task

To maintain the master in an IPv6 VRRP group, use this feature to perform a master/backup switchover. In isolation mode, the maintenance operation on the device is performed after a master/backup switchover and does not affect services.

Enabling the isolation mode sets the priority of the device to 0 in the IPv6 VRRP group.

Restrictions and guidelines

If you set the priority with the **vrrp ipv6 vrid priority** command for a device in isolation mode, the setting does not take effect until the isolation mode is disabled.

Procedure

1. Enter system view.

   system-view

2. Enable the isolation mode for IPv6 VRRP.

   vrrp ipv6 isolate enable

   By default, the isolation mode is disabled for IPv6 VRRP.

Display and maintenance commands for IPv6 VRRP

Execute **display** commands in any view and the **reset** command in user view.

Task	Command
Display the states of IPv6 VRRP groups.	**display vrrp ipv6** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*]] [**verbose**]
Display IPv6 VRRP packet anomaly information.	**display vrrp ipv6 abnormal-info** [**interface** *interface-type interface-number* [**vrid** *vrid-id*]]
Display master-to-subordinate IPv6 VRRP group bindings.	**display vrrp ipv6 binding** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*] | **name** *name*]

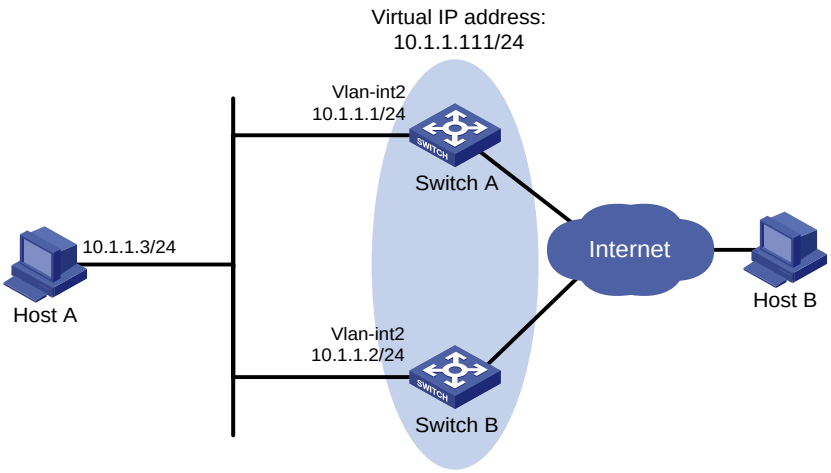
IPv4 VRRP configuration examples



Example: Configuring a single VRRP group

Network configuration

As shown in Figure 6, Switch A and Switch B form a VRRP group. They use the virtual IP address 10.1.1.111/24 to provide gateway service for the subnet where Host A resides.

Switch A operates as the master to forward packets from Host A to Host B. When Switch A fails, Switch B takes over to forward packets for Host A.

Figure 6 Network diagram

Procedure

1. Configure Switch A:

   # Configure VLAN 2.

   ```
   <SwitchA> system-view
   [SwitchA] vlan 2
   [SwitchA-vlan2] port gigabitethernet 1/0/5
   [SwitchA-vlan2] quit
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ip address 10.1.1.1 255.255.255.0
   ```

   # Create VRRP group 1 on VLAN-interface 2, and set its virtual IP address to 10.1.1.111.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.111
   ```

   # Assign Switch A a higher priority than Switch B in VRRP group 1, so Switch A can become the master.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   ```

   # Configure Switch A to operate in preemptive mode, so it can become the master whenever it operates correctly. Set the preemption delay to 5000 centiseconds to avoid frequent status switchover.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 preempt-mode delay 5000
   ```

2. Configure Switch B:

   # Configure VLAN 2.

   ```
   <SwitchB> system-view
   [SwitchB] vlan 2
   ```

```
[SwitchB-Vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 10.1.1.2 255.255.255.0
```

Create VRRP group 1 on VLAN-interface 2, and set its virtual IP address to 10.1.1.111.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.111
```

Set the priority of Router B to 100 in VRRP group 1.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 priority 100
```

Configure Switch B to operate in preemptive mode, and set the preemption delay to 5000 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 preempt-mode delay 5000
```

Verifying the configuration

Ping Host B from Host A. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp verbose

     First connection : 2023/03/11 16:29:42:111
     Last status change : 2023/03/11 16:30:42:111
```

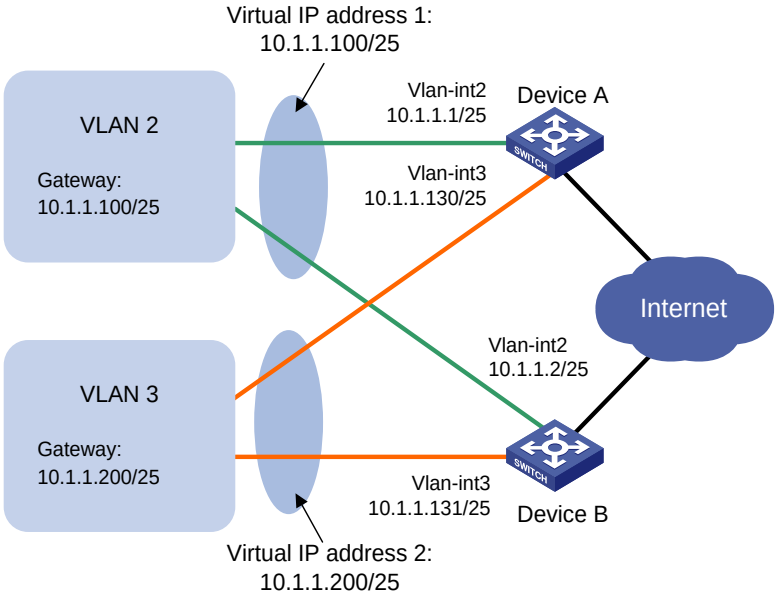
The output shows that after Switch A resumes normal operation, it becomes the master to forward packets from Host A to Host B.



Example: Configuring multiple VRRP groups

Network configuration

As shown in Figure 7, Switch A and Switch B form two VRRP groups. VRRP group 1 uses the virtual IP address 10.1.1.100/25 to provide gateway service for hosts in VLAN 2, and VRRP group 2 uses the virtual IP address 10.1.1.200/25 to provide gateway service for hosts in VLAN 3.

Assign a higher priority to Switch A than Switch B in VRRP group 1, but a lower priority in VRRP group 2. Traffic from VLAN 2 and VLAN 3 can then be distributed between the two switches. When one of the switches fails, the healthy switch provides gateway service for both VLANs.

Figure 7 Network diagram

Procedure

1. Configure Switch A:

   # Configure VLAN 2.

   ```
   <SwitchA> system-view
   [SwitchA] vlan 2
   [SwitchA-vlan2] port gigabitethernet 1/0/5
   [SwitchA-vlan2] quit
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ip address 10.1.1.1 255.255.255.128
   ```

   # Create VRRP group 1, and set its virtual IP address to 10.1.1.100.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.100
   ```

   # Assign Switch A a higher priority than Switch B in VRRP group 1, so Switch A can become the master in the group.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   [SwitchA-Vlan-interface2] quit
   ```

   # Configure VLAN 3.

   ```
   [SwitchA] vlan 3
   [SwitchA-vlan3] port gigabitethernet 1/0/6
   [SwitchA-vlan3] quit
   [SwitchA] interface vlan-interface 3
   ```

```
[SwitchA-Vlan-interface3] ip address 10.1.1.130 255.255.255.128
```

Create VRRP group 2, and set its virtual IP address to 10.1.1.200.

```
[SwitchA-Vlan-interface3] vrrp vrid 2 virtual-ip 10.1.1.200
```

2. Configure Switch B:

Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 10.1.1.2 255.255.255.128
```

Create VRRP group 1, and set its virtual IP address to 10.1.1.100.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.100
[SwitchB-Vlan-interface2] quit
```

Configure VLAN 3.

```
[SwitchB] vlan 3
[SwitchB-vlan3] port gigabitethernet 1/0/6
[SwitchB-vlan3] quit
[SwitchB] interface vlan-interface 3
[SwitchB-Vlan-interface3] ip address 10.1.1.131 255.255.255.128
```

Create VRRP group 2, and set its virtual IP address to 10.1.1.200.

```
[SwitchB-Vlan-interface3] vrrp vrid 2 virtual-ip 10.1.1.200
```

Assign Switch B a higher priority than Switch A in VRRP group 2, so Switch B can become the master in the group.

```
[SwitchB-Vlan-interface3] vrrp vrid 2 priority 110
```

Verifying the configuration

Display detailed information about the VRRP groups on Switch A.

     Last status change : 2023/03/11 16:30:42:111
```

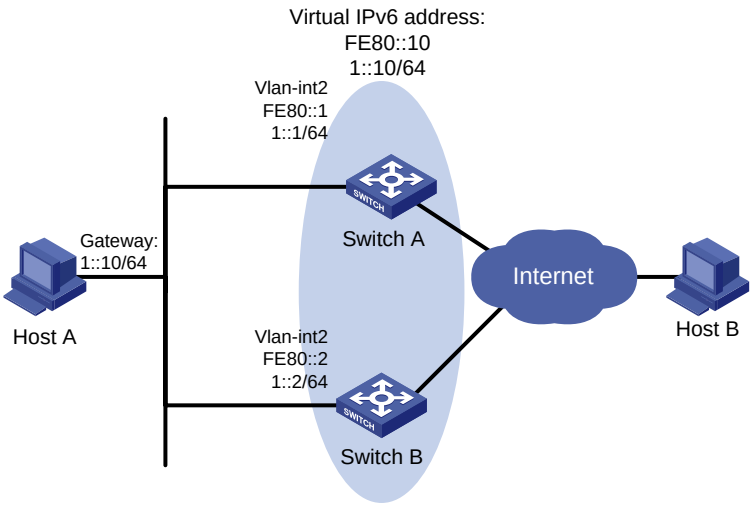
The output shows the following information:

- Switch A is operating as the master in VRRP group 1 to forward Internet traffic for hosts that use the default gateway 10.1.1.100/25.
- Switch B is operating as the master in VRRP group 2 to forward Internet traffic for hosts that use the default gateway 10.1.1.200/25.

IPv6 VRRP configuration examples

Example: Configuring a single VRRP group



Network configuration

As shown in Figure 8, Switch A and Switch B form a VRRP group. They use the virtual IP addresses 1::10/64 and FE80::10 to provide gateway service for the subnet where Host A resides.

Host A learns 1::10/64 as its default gateway from RA messages sent by the switches.

Switch A operates as the master to forward packets from Host A to Host B. When Switch A fails, Switch B takes over to forward packets for Host A.

Figure 8 Network diagram

Procedure

1. Configure Switch A:

   # Configure VLAN 2.

   ```
   <SwitchA> system-view
   [SwitchA] vlan 2
   [SwitchA-vlan2] port gigabitethernet 1/0/5
   [SwitchA-vlan2] quit
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ipv6 address fe80::1 link-local
   [SwitchA-Vlan-interface2] ipv6 address 1::1 64
   ```

   # Create VRRP group 1, and set its virtual IPv6 addresses to FE80::10 and 1::10.

   ```
   [SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
   [SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
   ```

   # Assign Switch A a higher priority than Switch B in VRRP group 1, so Switch A can become the master.

   ```
   [SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 priority 110
   ```

   # Configure Switch A to operate in preemptive mode, so it can become the master whenever it operates correctly. Set the preemption delay to 5000 centiseconds to avoid frequent status switchover.

   ```
   [SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode delay 5000
   ```

Enable Switch A to send RA messages, so Host A can learn the default gateway address.

```
[SwitchA-Vlan-interface2] undo ipv6 nd ra halt
```

2. Configure Switch B:

Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ipv6 address fe80::2 link-local
[SwitchB-Vlan-interface2] ipv6 address 1::2 64
```

Create VRRP group 1 and set its virtual IPv6 addresses to FE80::10 and 1::10.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

Configure Switch B to operate in preemptive mode, and set the preemption delay to 5000 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode delay 5000
```

Enable Switch B to send RA messages, so Host A can learn the default gateway address.

```
[SwitchB-Vlan-interface2] undo ipv6 nd ra halt
```

Verifying the configuration

Ping Host B from Host A. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

Last status change : 2023/03/11 16:30:42:111
```

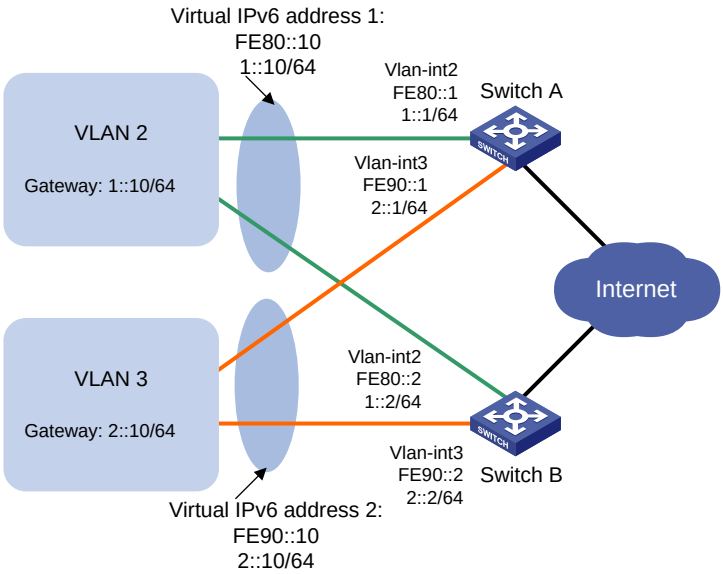
The output shows that after Switch A resumes normal operation, it becomes the master to forward packets from Host A to Host B.

Example: Configuring multiple VRRP groups



Network configuration

As shown in Figure 9, Switch A and Switch B form two VRRP groups. VRRP group 1 uses the virtual IPv6 addresses 1::10/64 and FE80::10 to provide gateway service for hosts in VLAN 2. VRRP group 2 uses the virtual IPv6 addresses 2::10/64 and FE90::10 to provide gateway service for hosts in VLAN 3.

From RA messages sent by the switches, hosts in VLAN 2 learn 1::10/64 as their default gateway. Hosts in VLAN 3 learn 2::10/64 as their default gateway.

Assign Switch A a higher priority than Switch B in VRRP group 1 but a lower priority in VRRP group 2. Traffic from VLAN 2 and VLAN 3 can then be distributed between the two switches. When one of the switches fails, the healthy switch provides gateway service for both VLANs.

Figure 9 Network diagram

Procedure

1. Configure Switch A:

   # Configure VLAN 2.

```
<SwitchA> system-view
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/5
[SwitchA-vlan2] quit
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ipv6 address fe80::1 link-local
[SwitchA-Vlan-interface2] ipv6 address 1::1 64
```

Create VRRP group 1, and set its virtual IPv6 addresses to FE80::10 to 1::10.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

Assign Switch A a higher priority than Switch B in VRRP group 1, so Switch A can become the master in the group.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 priority 110
```

Enable Switch A to send RA messages, so hosts in VLAN 2 can learn the default gateway address.

```
[SwitchA-Vlan-interface2] undo ipv6 nd ra halt
[SwitchA-Vlan-interface2] quit
```

Configure VLAN 3.

```
[SwitchA] vlan 3
[SwitchA-vlan3] port gigabitethernet 1/0/6
[SwitchA-vlan3] quit
[SwitchA] interface vlan-interface 3
[SwitchA-Vlan-interface3] ipv6 address fe90::1 link-local
[SwitchA-Vlan-interface3] ipv6 address 2::1 64
```

Create VRRP group 2, and set its virtual IPv6 addresses to FE90::10 and 2::10.

```
[SwitchA-Vlan-interface3] vrrp ipv6 vrid 2 virtual-ip fe90::10 link-local
[SwitchA-Vlan-interface3] vrrp ipv6 vrid 2 virtual-ip 2::10
```

Enable Switch A to send RA messages, so hosts in VLAN 3 can learn the default gateway address.

```
[SwitchA-Vlan-interface3] undo ipv6 nd ra halt
```

2. Configure Switch B:

Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ipv6 address fe80::2 link-local
[SwitchB-Vlan-interface2] ipv6 address 1::2 64
```

Create VRRP group 1, and set its virtual IPv6 addresses to FE80::10 and 1::10.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

Enable Switch B to send RA messages, so hosts in VLAN 2 can learn the default gateway address.

```
[SwitchB-Vlan-interface2] undo ipv6 nd ra halt
[SwitchB-Vlan-interface2] quit
```

Configure VLAN 3.

```
[SwitchB] vlan 3
[SwitchB-vlan3] port gigabitethernet 1/0/6
[SwitchB-vlan3] quit
[SwitchB] interface vlan-interface 3
[SwitchB-Vlan-interface3] ipv6 address fe90::2 link-local
[SwitchB-Vlan-interface3] ipv6 address 2::2 64
```

Create VRRP group 2, and set its virtual IPv6 addresses to FE90::10 and 2::10.

```
[SwitchB-Vlan-interface3] vrrp ipv6 vrid 2 virtual-ip fe90::10 link-local
[SwitchB-Vlan-interface3] vrrp ipv6 vrid 2 virtual-ip 2::10
```

Assign Switch B a higher priority than Switch A in VRRP group 2, so Switch B can become the master in the group.

```
[SwitchB-Vlan-interface3] vrrp ipv6 vrid 2 priority 110
```

Enable Switch B to send RA messages, so hosts in VLAN 3 can learn the default gateway address.

```
[SwitchB-Vlan-interface3] undo ipv6 nd ra halt
```

Verifying the configuration

Display detailed information about the VRRP groups on Switch A.

```
[SwitchA-Vlan-interface3] display vrrp ipv6 verbose

The output shows the following information:

- Switch A is operating as the master in VRRP group 1 to forward Internet traffic for hosts that use the default gateway 1::10/64.
- Switch B is operating as the master in VRRP group 2 to forward Internet traffic for hosts that use the default gateway 2::10/64.

Troubleshooting VRRP

An error prompt is displayed

Symptom

An error prompt "The virtual router detected a VRRP configuration error." is displayed during configuration.

Analysis

This symptom is probably caused by the following reasons:

- The VRRP advertisement interval in the packet is not the same as that for the current VRRP group (in VRRPv2 only).
- The number of virtual IP addresses in the packet is not the same as that for the current VRRP group.
- The virtual IP address list is not the same as that for the current VRRP group.
- A device in the VRRP group receives illegitimate VRRP packets. For example, the IP address owner receives a VRRP packet with the priority 255.

Solution

To resolve the problem:

1. Modify the configuration on routers in VRRP groups to ensure consistent configuration.

2. Take fault location and anti-attack measures to eliminate potential threats.
3. If the problem persists, contact H3C Support.

Multiple masters appear in a VRRP group

Symptom

Multiple masters appear in a VRRP group.

Analysis

It is normal for a VRRP group to have multiple masters for a short time, and this situation requires no manual intervention.

If multiple masters coexist for a longer period, check for the following conditions:

- The masters cannot receive advertisements from each other.
- The received advertisements are illegitimate.

Solution

To resolve the problem:

1. Ping between these masters:
   - If the ping operation fails, examine network connectivity.
   - If the ping operation succeeds, check for configuration inconsistencies in the number of virtual IP addresses, virtual IP addresses, and authentication. For IPv4 VRRP, also make sure the same version of VRRP is configured on all routers in the VRRP group. For VRRPv2, make sure the same VRRP advertisement interval is configured on the routers in the VRRP group.
2. If the problem persists, contact H3C Support.

Fast VRRP state flapping

Symptom

Fast VRRP state flapping occurs.

Analysis

The VRRP advertisement interval is set too short.

Solution

To resolve the problem:

1. Increase the interval for sending VRRP advertisements or introduce a preemption delay.
2. If the problem persists, contact H3C Support.

Configuring BFD

About BFD

Bidirectional forwarding detection (BFD) provides a general-purpose, standard, medium- and protocol-independent fast failure detection mechanism. It can detect and monitor the connectivity of forwarding paths to detect communication failures quickly so that measures can be taken to ensure service continuity and enhance network availability.

BFD can uniformly and quickly detect the failures of the bidirectional forwarding paths between two devices for upper-layer protocols such as routing protocols. The hello mechanism used by upper-layer protocols needs seconds to detect a link failure, while BFD can provide detection measured in milliseconds.

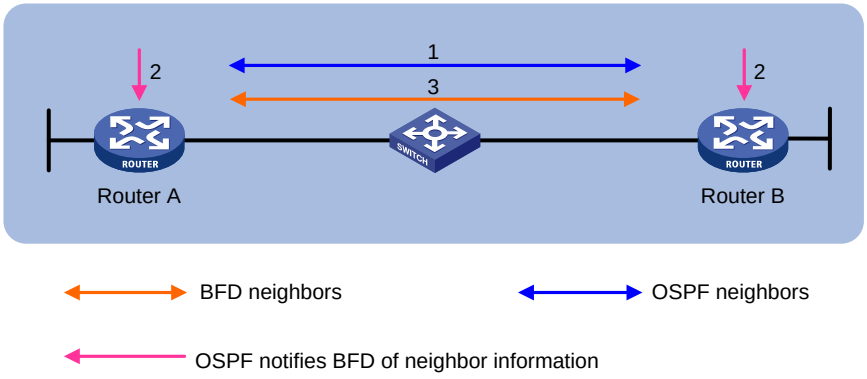
Mechanism

BFD establishes a session between two network devices to detect failures on the bidirectional forwarding paths between the devices and provide services for upper-layer protocols. BFD provides no neighbor discovery mechanism. Protocols that BFD services notify BFD of devices to which it needs to establish sessions. After a session is established, if no BFD control packet is received from the peer within the negotiated BFD interval, BFD notifies a failure to the protocol, which then takes appropriate measures.

Figure 1 describes the operation of BFD for OSPF.

1. OSPF discovers neighbors by sending Hello packets and establishes neighbor relationships.
2. After establishing neighbor relationships, OSPF notifies BFD of the neighbor information, including destination and source addresses.
3. BFD uses the information to establish BFD sessions.
4. After session establishment, BFD starts periodic link detection.

Figure 1 BFD session establishment



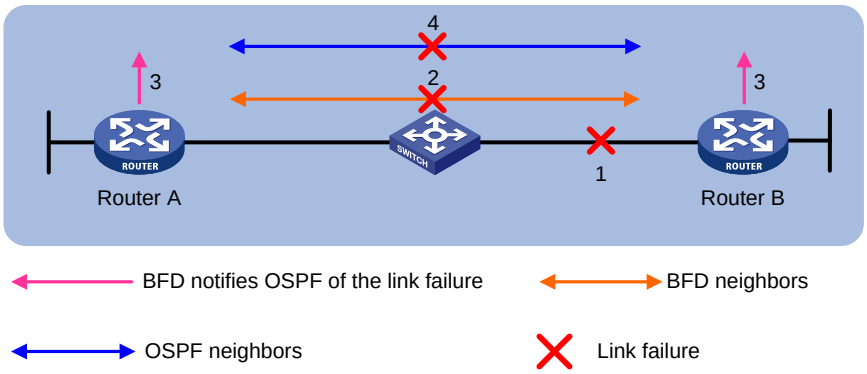


Figure 2 describes the BFD fault detection process.

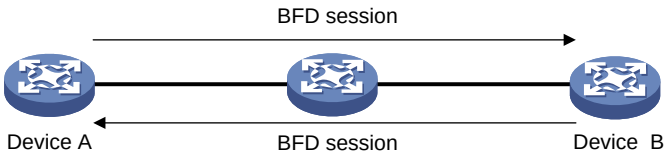
5. The detected link fails.
6. BFD detects the link failure and tears down the session.
7. BFD notifies the neighbor unreachability to OSPF.
8. OSPF terminates the neighbor relationship on the link.

Figure 2 BFD fault detection

BFD establishes sessions in echo packet mode or control packet mode depending on the BFD packets used.

Single-hop detection and multihop detection

BFD can be used for single-hop and multihop detections.



- **Single-hop detection**—Detects the IP connectivity between two directly connected systems, for example, Device A and Device B as shown in Figure 3.

  Figure 3 Single-hop detection

- **Multihop detection**—Detects any of the paths between two systems, for example, Device A and Device B as shown in Figure 4. These paths have multiple hops, and might overlap.

  Figure 4 Multihop detection

BFD session states

A BFD session can be in DOWN, ADMIN DOWN, INIT or UP state. The meanings of the states are as follows:

- **DOWN**—The local BFD session has been shut down or is newly created. This state indicates that the forwarding path is unavailable and that the upper-layer application must take an appropriate action, such as primary/backup path switchover.
- **ADMIN DOWN**—The BFD session of the local system is administratively shut down. This state does not indicate that the forwarding path is unavailable. The upper-layer application is not required to take an action.
- **INIT**—The local end can communicate with the remote end and requires the BFD session to transition to UP state.

- **UP**—The BFD session has been established on the local end. This state indicates that the forwarding path is available.

BFD session modes

BFD sessions use echo packets and control packets.

Echo packet mode

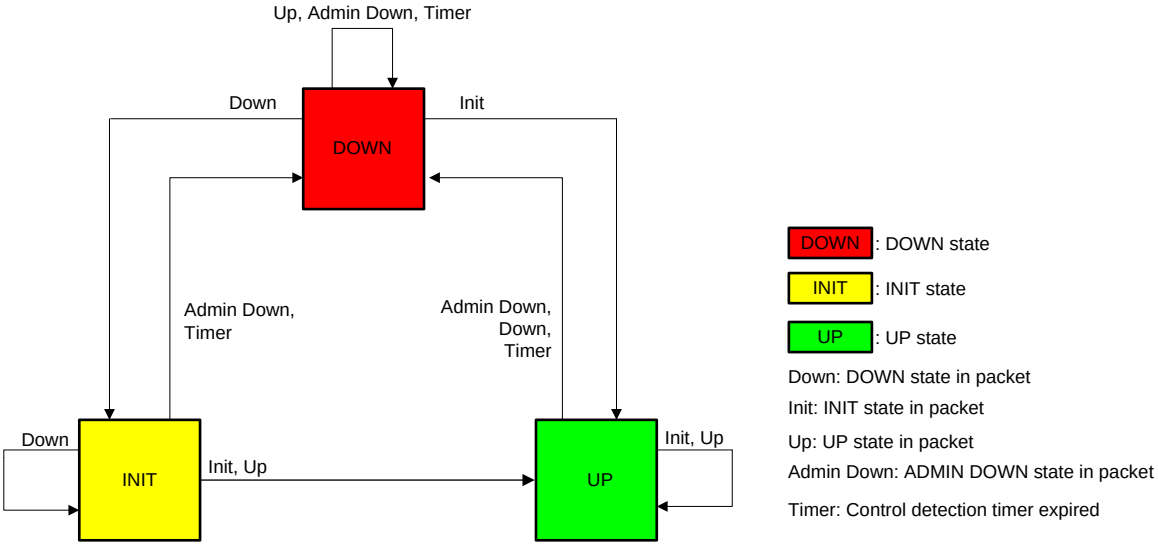
Echo packets are encapsulated into UDP packets. The packet contains destination port 3785, a destination IP address (transmitting interface's IP address), and a source IP address (transmitting interface's IP address).

The local end of the link sends echo packets to establish BFD sessions and monitor link status. The peer end does not establish BFD sessions and only forwards the packets back to the originating end. If the local end does not receive echo packets from the peer end within the detection time, it considers the session down.

BFD sessions in echo packet mode do not require both ends to support BFD. Upon receiving BFD echo packets, the peer end loops back the packets for detection purposes.

In echo packet mode, BFD supports only single-hop detection and the BFD sessions are independent of the operating mode.

Control packet mode



Control packets are encapsulated into UDP packets with port number 3784 for single-hop detection or port number 4784 for multihop detection.

The two ends of the link negotiate the establishment of BFD sessions by using the session parameters carried in control packets. Session parameters include session discriminators, desired minimum packet sending and receiving intervals, and local BFD session state.

State machine transition mechanism for a BFD session in control packet mode

Figure 5 shows the state machine transition mechanism for a BFD session in control packet mode. The ADMIN DOWN state in the state machine is also the DOWN state.

Figure 5 State machine transition mechanism for a BFD session

BFD control packet format

Figure 6 shows the format of a BFD control packet. The BFD control packet contains the required portion and optional authentication portion.

Figure 6 BFD control packet format

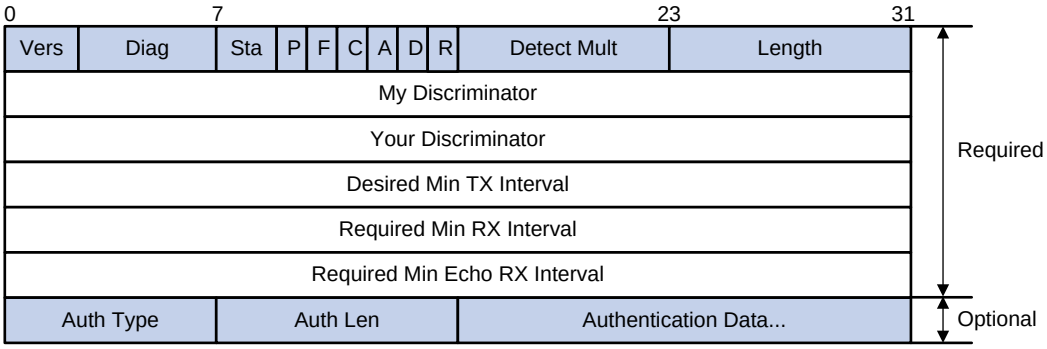


Table 1 shows the description of the fields in a BFD control packet.

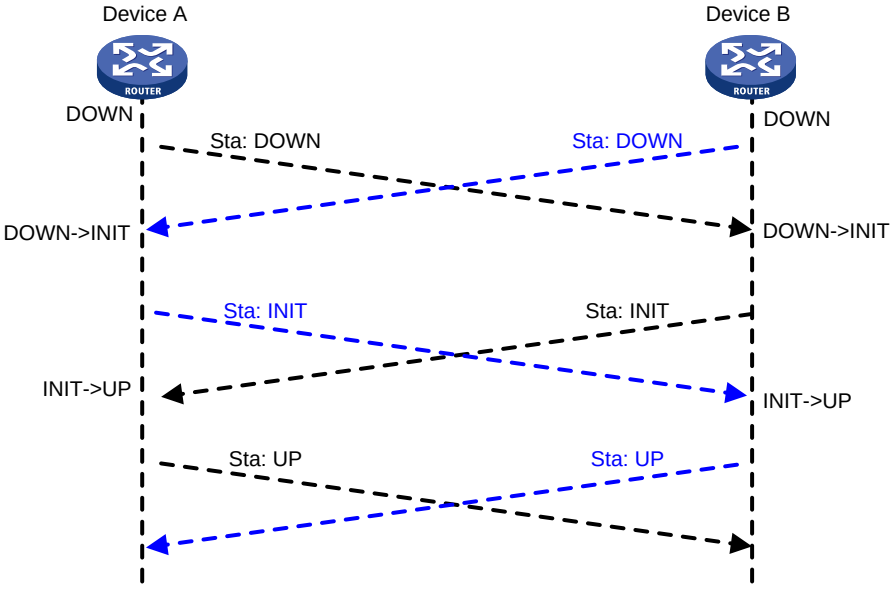
Table 1 BFD control packet field description

Field	Length	Description
Vers (Version)	3 bits	BFD version number. The current version number is 1.
Diag (Diagnostic)	5 bits	Diagnostic code, which indicates the reason for the most recent session down of the sender. Options include: • **0**—No diagnostic information. • **1**—A control-mode BFD session goes down because local detection times out. • **2**—An echo-mode BFD session goes down, because local detection times out or the source IP address of echo packets is deleted. • **3**—The remote end notifies the local end of BFD session down upon detection timeout. • **7**—The local system prevents a BFD session from being established. • **31**—A packet in AdminDown state is received from the remote end.
Sta (State)	2 bits	BFD session state of the sender: • **0**—AdminDown. • **1**—Down. • **2**—Init. • **3**—Up.
P (Poll)	1 bit	Upon session parameter changes, the sender sends a BFD packet with the P bit set. The receiver must immediately respond this packet. • **0**—The sender does not request verification. • **1**—The sender requests verification of the connectivity or parameter changes.
F (Final)	1 bit	The F bit determines whether BFD sends a response packet upon receiving a packet with the P bit set. • **0**—The sending system does not respond to packets with the P bit set. • **1**—The sending system responds to received packets with the P bit set.
C (Control Plane Independent)	1 bit	Forwarding- and control-plane separation bit. If this bit is set, the BFD implementation is independent of its control plane. That is, changes in the control plane do not affect BFD detection. For example, when IS-IS on the control

Field	Length	Description
		plane performs GR, BFD can continue to detect link state. • **1**—The BFD implementation on the sending system is independent of the control plane. That is, BFD packets are transmitted on the forwarding plane. BFD can still perform link detection even if the control plane becomes invalid. • **0**—Indicates that BFD packets are transmitted on the control plane.
A (Authentication Present)	1 bit	If this bit is set, the control packet contains the authentication field and the session requires authentication.
D (Demand)	1 bit	If this bit is set, the sender wants to operate in Demand mode. If this bit is not set, the sender does not want to operate in Demand mode or does not support the Demand mode.
M (Multipoint)	1 bit	Reserved bit. It is set to 0 during transmission and ignored during reception.
Detect Mult	8 bits	Detect time multiplier used by the detecting party to calculate the detection interval.
Length	8 bits	BFD control packet length, in bytes.
My Discriminator	32 bits	Local discriminator of the BFD session. It is a unique, non-zero value generated by the sender to identify a BFD session.
Your Discriminator	32 bits	Remote discriminator of the BFD session. If a BFD control packet is received from the session-associated neighbor, the value is My Discriminator in the received packet. If no BFD control packet is received from the neighbor, this value is 0.
Desired Min TX Interval	32 bits	Minimum interval for sending BFD control packets desired by the local system, in microseconds.
Required Min RX Interval	32 bits	Minimum interval for receiving BFD control packets supported by the local system, in milliseconds.
Required Min Echo RX Interval	32 bits	Minimum interval for receiving BFD echo packets supported by the local system, in milliseconds. Value 0 indicates that the echo function is not supported.
Auth Type	8 bits	Authentication type.
Auth Len	8 bits	Authentication field length in bytes, including Auth Type field and Auth Len fields.
Authentication Data	Variable	Authentication data field.

Establishing a BFD session in control packet mode

BFD can use the following operating modes to establish a session:



- **Active mode**—BFD actively sends BFD control packets regardless of whether any BFD control packet is received from the peer.
- **Passive mode**—BFD does not send control packets until a BFD control packet is received from the peer.

At least one end must operate in active mode for a BFD session to be established.

BFD uses a three-way handshake mechanism to establish sessions. The sender fills the Sta field with the current session state in the transmitted BFD control packets. The receiver transits the state

machine states based on the Sta field value in the received BFD control packets and local session status to establish a session.

Figure 7 BFD session establishment process

Detection mechanism of the BFD session in control packet mode

After a BFD session in control packet mode is established, the two ends can operate in the following modes:

- **Asynchronous mode**—The device periodically sends BFD control packets. The device considers that the session is down if it does not receive any BFD control packets within the detection interval. By default, a BFD session is in Asynchronous mode.
- **Demand mode**—If a large number of BFD sessions exist in the system, you can specify the Demand mode to prevent periodic sending of BFD control packets from affecting system operations. As a best practice, enable the BFD echo function when the detection mode is Demand mode.
  - If the local end operates in Demand mode, the local device periodically sends BFD control packets with the D bit set to 1. Upon receiving such packets, if the peer end operates in Asynchronous mode (default setting), it stops sending BFD control packets.
  - If the peer end is operating in Demand mode, both ends stop sending BFD control packets. When the connectivity to another system needs to be verified explicitly, a system sends several BFD control packets with the P bit set at the negotiated transmit interval. If no packets with the F bit set to 1 are received from the peer end within the detection interval, the session is considered down. If a packet with the F bit set to 1 is received from the peer end, the connectivity is found to be up, and no more BFD control packets are sent until the next command is issued.

Echo function of a BFD session in control packet mode

When you use Asynchronous mode BFD to detect the connectivity between directly connected devices, you can enable the echo function. This function enables the local system to periodically send echo packets to the remote system and reduces the control packet receiving rate to save bandwidth usage. The remote system loops back the echo packets to the local system without processing them. If the local system does not receive echo packets looped back from the remote system in a consecutive number of times, the local system declares the BFD session down.

The echo function is supported only for single-hop detection.

BFD session creation methods

BFD sessions in control packet mode can be created statically or established dynamically.

BFD sessions are distinguished by the local discriminator and remote discriminator in control packets. The main difference between a statically created session and a dynamically established session is that they obtain the local discriminator and remote discriminator in different ways.

- The local discriminator and remote discriminator of a static BFD session are manually configured.
- The local discriminator of a dynamic BFD session is automatically assigned by the device, and the remote discriminator is obtained during BFD session negotiation. Typically, BFD assigns a fixed range of local discriminators. In an M-LAG network, when M-LAG devices use dynamic BFD sessions to detect downlink connectivity, BFD assigns local discriminator ranges based on the M-LAG system ID, which means that M-LAG devices with different system IDs are assigned different local discriminator ranges.

BFD session flapping suppression

When BFD detects a link failure, it tears down the BFD session and notifies the upper-layer protocol of the failure. When the upper-layer protocol re-establishes a neighbor relationship, the BFD session comes up again. BFD session flaps occur when a link fails and recovers repeatedly, which consumes significant system resources and causes network instability. You can use BFD session flapping suppression to solve the previous problems.

This feature allows you to suppress BFD session flapping by setting different suppression intervals based on the BFD session down times. Within the suppression intervals, BFD sessions cannot be re-established. The more the BFD session down times, the longer the suppression time to avoid BFD flapping.

Hardware BFD

Software BFD uses the CPU to receive and send BFD packets and to maintain the BFD state machine. Software BFD greatly consumes CPU resources and cannot support a large number of BFD sessions.

Hardware BFD uses hardware chips to process CPU-intensive tasks, such as receiving and sending BFD packets and fault detection. Hardware BFD improves CPU utilization and can support a large number of BFD sessions.

The **Hardware mode** field in the output from the **`display bfd session verbose`** command indicates whether BFD packets are processed in hardware:

- **Enabled**—BFD packets are processed in hardware.
- **Disabled**—BFD packets are processed in software.

You can take the following actions to disable hardware BFD:

- Execute commands that are not supported by hardware BFD.
- Remove cards that support hardware BFD.

When you disable hardware BFD, the BFD session might flap. Before performing this operation, make sure you understand its potential impact on the network.

Supported features

Table 2 shows the features supported by BFD.

Table 2 Features supported by BFD

Feature	Reference
Link aggregation	Ethernet link aggregation in *Layer 2—LAN Switching Configuration Guide*

Link types supported by BFD

BFD can detect connectivity for various types of links, as shown in Table 3.

Table 3 Link types supported by BFD

Link category	Link types	Description
IP link	• Layer 3 Ethernet interface • Layer 3 Ethernet subinterface (including aggregate subinterface)	You can establish BFD sessions separately for an Ethernet interface and each of its subinterfaces. As a best practice, do not perform that operation.
Ethernet aggregate link	• Layer 2 Ethernet aggregate link • Member links of the Layer 2 Ethernet aggregate link • Layer 3 Ethernet aggregate link • Member links of the Layer 3 Ethernet aggregate link	You can establish BFD sessions separately for trunk member ports and the trunk port. As a best practice, do not perform that operation.
PW	Single segment of PW	Supports using both statically and dynamically established BFD sessions to detect PWs.

Technical benefits of BFD

BFD has the following technical benefits:

- BFD can detect the failures of the bidirectional forwarding paths of any type (including logical links, such as tunnels) between two network devices.
- BFD can provide services for upper-layer protocols and unified detection mechanisms.

- BFD provides millisecond-level detection speed to accelerate network convergence, reduce application interruption time, and enhance network reliability.

Protocols and standards

- RFC 5880, *Bidirectional Forwarding Detection (BFD)*
- RFC 5881, *Bidirectional Forwarding Detection (BFD) for IPv4 and IPv6 (Single Hop)*
- RFC 5882, *Generic Application of Bidirectional Forwarding Detection (BFD)*
- RFC 5883, *Bidirectional Forwarding Detection (BFD) for Multihop Paths*
- RFC 7130, *Bidirectional Forwarding Detection (BFD) on Link Aggregation Group (LAG) Interfaces*

Restrictions and guidelines: BFD configuration

- By default, the device runs BFD version 1 and is compatible with BFD version 0. You cannot change the BFD version to 0 through commands. When the peer device runs BFD version 0, the local device automatically switches to BFD version 0.
- After a BFD session is established, the two ends negotiate BFD parameters, including minimum sending interval, minimum receiving interval, initialization mode, and packet authentication, by exchanging negotiation packets. They use the negotiated parameters without affecting the session status.
- As a best practice, use control-packet-mode BFD session on a downstream device to detect connectivity with an M-LAG device. Echo-packet-mode BFD sessions might fail to detect link failures.
- BFD session flapping might occur on an aggregate interface with member ports on different IRF member devices. When the master device, which receives and sends BFD packets, is removed or restarted, a subordinate device might not immediately take over. For example, a subordinate device will not take over when the subordinate device has a short detection time or a large number of BFD sessions.
- In a scenario where centralized devices form an IRF fabric and establish a BGP neighbor relationship with another device, using a multihop BFD session to detect link state might lead to BFD session flapping during IRF master/subordinate switchover when BFD packets cannot be sent or received in a timely manner. This can further result in BGP neighbor flapping. Before you use BFD in such a situation, make sure you understand the protection impact.

BFD tasks at a glance

All the BFD tasks are optional.

9. Configuring BFD sessions in echo packet mode

10. Configuring BFD sessions in control packet mode

- Configuring the session establishment mode
- Configuring the detection mode
- Creating a static BFD session
- Configuring detection time settings
- Configuring the authentication mode
- Configuring the notification delay timer for session establishment failures
- Enabling the echo function
- Creating a static BFD session for detecting the aggregate link of a Layer 3 aggregate interface

- Configuring the TTL value for BFD packets

11. Delaying BFD session negotiation
12. Configuring a BFD template
13. Configuring event logging and SNMP notifications for BFD
    - Enabling BFD event logging
    - Enabling SNMP notifications for BFD

Configuring BFD sessions in echo packet mode

About BFD session creation methods

A BFD session can be created manually by using the **bfd static** command or created dynamically through collaboration between an application module and BFD.

Creating a static BFD session

About this task

A static BFD session in echo packet mode can be used to perform single-hop detection or multihop detection.

Restrictions and guidelines

You need to create a static BFD session in echo packet mode on only the local device to perform detection.

When creating a static BFD session, you must specify a peer IPv4 or IPv6 address. The system checks only the format of the IP address but not its correctness. If the peer IPv4 or IPv6 address is incorrect, the static BFD session cannot be established.

Different static BFD sessions cannot have the same local discriminator.

As a best practice, specify the source IP address for echo packets when creating a static BFD session. If you do not specify the source IP address, the device uses the IP address specified in the **bfd echo-source-ip** or **bfd echo-source-ipv6** command as the source IP address of echo packets.

Creating a static BFD session for single-hop detection

14. Enter system view.

    system-view

15. Configure the source IP address of echo packets.
    - Configure the source IP address of echo packets.

      bfd echo-source-ip *ip-address*

      By default, no source IPv4 address is configured for echo packets.

      As a best practice, do not configure the source IPv4 address to be on the same network segment as any local interfaces. This can avoid network congestion caused a large number of ICMP redirect packets sent from the peer.
    - Configure the source IPv6 address of echo packets.

      bfd echo-source-ipv6 *ipv6-address*

      By default, no source IPv6 address is configured for echo packets.

      The source IPv6 address of echo packets can only be a global unicast address.
16. Create a static BFD session and enter static BFD session view.

IPv4:

bfd static *session-name* [**peer-ip** *ipv4-address* **interface** *interface-type interface-number* **destination-ip** *ipv4-address* [**source-ip** *ipv4-address*] **one-arm-echo** [**discriminator** { **auto** | **local** *local-value* }]]

IPv6:

bfd static *session-name* [**peer-ipv6** *ipv6-address* **interface** *interface-type interface-number* **destination-ipv6** *ipv6-address* [**source-ipv6** *ipv6-address*] **one-arm-echo** [**discriminator** { **auto** | **local** *local-value* }]]

17. (Optional.) Specify a local discriminator for the static BFD session.

    discriminator local *local-value*

    By default, no local discriminator is specified.

    You can use this command only if you do not specify a local discriminator when creating a static BFD session.

Creating a static BFD session for multihop detection

18. Enter system view.

    system-view

19. (Optional.) Configure the source IP address of echo packets.
    - Configure the source IPv4 address of echo packets.

      bfd echo-source-ip *ip-address*

      By default, no source IPv4 address is configured for echo packets.

      As a best practice, do not configure the source IPv4 address to be on the same network segment as any local interfaces. If you configure such a source IPv4 address, a large number of ICMP redirect packets might be sent from the peer, resulting in link congestion.
    - Configure the source IPv6 address of echo packets.

      bfd echo-source-ipv6 *ipv6-address*

      By default, no source IPv6 address is configured for echo packets.

      The source IPv6 address of echo packets can only be a global unicast address.

20. Create a static BFD session and enter static BFD session view.

    IPv4:

    bfd static *session-name* [**peer-ip** *ipv4-address* [**vpn-instance** *vpn-instance-name*] **destination-ip** *ipv4-address* [**source-ip** *ipv4-address*] **one-arm-echo**[**discriminator** { **auto** | **local** *local-value* }]]

    IPv6:

    bfd static *session-name* [**peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*] **destination-ipv6** *ipv6-address* [**source-ipv6** *ipv6-address*] **one-arm-echo** [**discriminator** { **auto** | **local** *local-value* }]]

21. (Optional.) Specify a local discriminator for the static BFD session.

    discriminator local *local-value*

    By default, no local discriminator is specified.

    You can use this command only if you do not specify a local discriminator when creating a static BFD session.

Configuring detection time settings

About this task

When creating a BFD session in echo packet mode, you can configure the minimum interval for receiving BFD echo packets and the detection time multiplier for the device.

Restrictions and guidelines

When the same BFD session (with the same source IP address, destination IP address, interface, VPN, and destination port number) is associated with multiple upper layer applications, BFD selects the detection time settings for the BFD session as follows:

22. Minimum values of the following settings:
    - Settings configured in static BFD session view.
    - Settings configured in the BFD template specified by the upper layer application.
    - Settings configured by the upper layer application.
23. Settings configured in interface view or system view.
24. Default settings.

When a BFD session is associated with only one upper layer application, BFD selects the detection time settings for the BFD session as follows:

25. BFD selects the detection time settings for the BFD session based on whether the upper layer application supports using a BFD template and configuring detection time settings:
    - If a BFD template is specified and detection time settings are also configured for the upper layer application, BFD selects the settings configured in the specified BFD template.
    - If a BFD template is specified for the upper layer application that does not support configuring detection time settings, BFD selects the settings configured in the specified BFD template.
    - If detection time settings are configured for the upper layer application that does not support using a BFD template, BFD selects the configured settings.
26. Settings configured in interface view or system view.
27. Default settings.

Configure detection time settings for single-hop BFD detection

28. Enter system view.

    system-view
29. Enter interface view or static BFD session view.
    - Enter interface view.

      interface *interface-type interface-number*
    - Enter static BFD session view.

      bfd static *session-name*

      The static BFD session must already exist.

      To configure parameters for a static BFD session, you must enter its view.
30. Set the minimum interval for receiving BFD echo packets.

    bfd min-echo-receive-interval *interval*

    The default setting is 400 milliseconds.
31. Set the detection time multiplier.

    bfd detect-multiplier *value*

    The default setting is 5.

Configure detection time settings for multihop BFD detection

32. Enter system view.
    system-view
33. (Optional.) Enter static BFD session view.
    bfd static *session-name*
    The static BFD session must already exist.
    To configure parameters for a static BFD session, you must enter its view.
34. Set the minimum interval for receiving BFD echo packets.
    bfd multi-hop min-echo-receive-interval *interval*
    The default setting is 400 milliseconds.
35. Set the detection time multiplier.
    bfd multi-hop detect-multiplier *value*
    The default setting is 5.

Configuring BFD sessions in control packet mode

About BFD session creation methods

BFD sessions in control packet mode can be created statically or established dynamically.

BFD sessions are distinguished by the local discriminator and remote discriminator in control packets. The main difference between a statically created session and a dynamically established session is that they obtain the local discriminator and remote discriminator in different ways.

- The local discriminator and remote discriminator of a static BFD session are specified manually in the **bfd static** command or in the commands that associate specific applications with BFD.
- The local discriminator of a dynamic BFD session is assigned by the device, and the remote discriminator is obtained during BFD session negotiation. The device can automatically assign the local discriminator to the BFD session in the following conditions:
  - The **auto** keyword is specified for the **bfd static** command.
  - The local and remote discriminators are not specified for the BFD session associated with a specific application.

Restrictions and guidelines

After an upper-layer protocol is configured to support BFD, the device automatically creates BFD sessions in c**ontrol packet mode. You do not need to perform this task.**

Configuring the session establishment mode

About this task

BFD can use the following operating modes to establish a session:

- **Active mode**—BFD actively sends BFD control packets regardless of whether any BFD control packet is received from the peer.
- **Passive mode**—BFD does not send control packets until a BFD control packet is received from the peer.

At least one end must operate in active mode for a BFD session to be established.

Procedure

36. Enter system view.
    system-view
37. Configure the BFD session establishment mode.
    bfd session init-mode { **active** | **passive** }
    By default, BFD uses the active mode to establish a session.

Configuring the detection mode

About this task

After a BFD session is established, the two ends can operate in the following modes:

- **Asynchronous mode**—The device periodically sends BFD control packets. The device considers that the session is down if it does not receive any BFD control packets within the detection interval.
- **Demand mode**—The Demand mode can be used to reduce the overhead when a large number of BFD sessions exist.
  - If the peer end is operating in Asynchronous mode (default), the peer end stops sending BFD control packets after receiving control packets with the D bit set. In this scenario, BFD detects only the link between the local end and the peer end. The device considers that the session is down if it does not receive any BFD control packets within the detection interval.
  - If the peer end is operating in Demand mode, both ends stop sending BFD control packets. In this scenario, the system uses features other than BFD, such as Hello packets and hardware CC, to verify the connectivity to another system.

Restrictions and guidelines

The **bfd demand enable** command cannot take effect when any of the following conditions exist:

- Echo-packet-mode BFD sessions exist on the device.
- BFD sessions for detecting aggregate links exist on the device.
- After the **bfd detect-interface source-ip** command is configured, the **bfd detect-interface first-fail-timer** and **bfd detect-interface special-processing** commands are configured.

Procedure

38. Enter system view.
    system-view
39. Enter interface view.
    interface *interface-type interface-number*
40. Specify the Demand mode for the BFD session.
    bfd demand enable
    By default, a BFD session is in Asynchronous mode.

Creating a static BFD session

About this task

A static BFD session can be used for single-hop detection and multihop detection. By working with Track, a static BFD session can provide fast failure detection. For more information about Track association with BFD, see "Configuring Track."

Restrictions and guidelines for static BFD session configuration

If a static BFD session is created on the remote end, the static BFD session must be created on the local end.

When creating a static BFD session, you must specify a peer IPv4 or IPv6 address. The system checks only the format of the IP address but not its correctness. If the peer IPv4 or IPv6 address is incorrect, the static BFD session cannot be established.

Different static BFD sessions cannot have the same local discriminator.

Creating a static BFD session for single-hop detection

41. Enter system view.

system-view

42. Create a static BFD session and enter static BFD session view.

IPv4:

bfd static *session-name* **peer-ip** *ipv4-address* **interface** *interface-type interface-number* **source-ip** *ipv4-address* [**discriminator** { **auto** | **local** *local-value* **remote** *remote-value* }]

For a static BFD session to be established, specify the IPv4 address of the peer interface where the static BFD session resides for the **peer-ip** *ipv4-address* option. Specify the IPv4 address of the local interface where the static BFD session resides for the **source-ip** *ipv4-address* option.

IPv6:

bfd static *session-name* **peer-ipv6** *ipv6-address* **interface** *interface-type interface-number* **source-ipv6** *ipv6-address* [**discriminator** { **auto** | **local** *local-value* **remote** *remote-value* }]

For a static BFD session to be established, specify the IPv6 address of the peer interface where the static BFD session resides for the **peer-ipv6** *ipv6-address* option. Specify the IPv6 address of the local interface where the static BFD session resides for the **source-ipv6** *ipv6-address* option.

43. (Optional.) Specify the local and remote discriminators for the static BFD session.

discriminator { **local** *local-value* | **remote** *remote-value* }

By default, no local discriminator or remote discriminator is specified for a static BFD session.

Use this command only if you do not specify the local or remote discriminator when creating a static BFD session.

Create a static BFD session for multihop detection

44. Enter system view.

system-view

45. Create a static BFD session and enter static BFD session view.

IPv4:

bfd static *session-name* **peer-ip** *ipv4-address* [**vpn-instance** *vpn-instance-name*] **source-ip** *ipv4-address* [**discriminator** { **auto** |**local** *local-value* **remote** *remote-value* }] [**track-interface** *interface-type interface-number*]

IPv6:

bfd static *session-name* **peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*] **source-ipv6** *ipv6-address* [**discriminator** { **auto** | **local** *local-value* **remote** *remote-value* }] [**track-interface** *interface-type interface-number*]

46. (Optional.) Specify the local and remote discriminators for the static BFD session.

discriminator { **local** *local-value* | **remote** *remote-value* }

By default, no local discriminator or remote discriminator is specified for a static BFD session.

Use this command only if you do not specify the local or remote discriminator when creating a static BFD session.

Configuring detection time settings

About this task

When creating a BFD session in control packet mode, you can configure the minimum interval for receiving and transmitting BFD control packets and the detection time multiplier for the device.

Restrictions and guidelines

When the same BFD session (with the same source IP address, destination IP address, interface, VPN, and destination port number) is associated with multiple upper layer applications, BFD selects the detection time settings for the BFD session as follows:

1. Minimum values of the following settings:
   - Settings configured in static BFD session view.
   - Settings configured in the BFD template specified by the upper layer application.
   - Settings configured by the upper layer application.
2. Settings configured in interface view or system view.
3. Default settings.

When a BFD session is associated with only one upper layer application, BFD selects the detection time settings for the BFD session as follows:

1. BFD selects the detection time settings for the BFD session based on whether the upper layer application supports using a BFD template and configuring detection time settings:
   - If a BFD template is specified and detection time settings are also configured for the upper layer application, BFD selects the settings configured in the specified BFD template.
   - If a BFD template is specified for the upper layer application that does not support configuring detection time settings, BFD selects the settings configured in the specified BFD template.
   - If detection time settings are configured for the upper layer application that does not support using a BFD template, BFD selects the configured settings.
2. Settings configured in interface view or system view.
3. Default settings.

You can use the **bfd min-receive-interval** and **bfd min-control-interval** commands to adjust the minimum interval for receiving single-hop BFD control packets. Follow these guidelines when you configure the commands:

- If you configure both the **bfd min-receive-interval** and **bfd min-control-interval** commands, the time interval configured by the **bfd min-receive-interval** command takes precedence.
- If you do not configure the **bfd min-receive-interval** or **bfd min-control-interval** command, the device uses the default value for the **bfd min-receive-interval** command as the minimum interval for receiving single-hop BFD control packets.
- If you configure either the **bfd min-receive-interval** or **bfd min-control-interval** command, the device uses the value configured for that command as the minimum interval for receiving single-hop BFD control packets.

You can use the **bfd min-transmit-interval** and **bfd min-control-interval** commands to adjust the minimum interval for transmitting single-hop BFD control packets. Follow these guidelines when you configure the commands:

- If you configure both the **bfd min-transmit-interval** and **bfd min-control-interval** commands, the time interval configured by the **bfd min-transmit-interval** command takes precedence.
- If you do not configure the **bfd min-transmit-interval** or **bfd min-control-interval** command, the device uses the default value for the **bfd min-transmit-interval** command as the minimum interval for transmitting single-hop BFD control packets.
- If you configure either the **bfd min-transmit-interval** or **bfd min-control-interval** command, the device uses the value configured for that command as the minimum interval for transmitting single-hop BFD control packets.

You can use the **bfd multi-hop min-receive-interval** and **bfd multi-hop min-control-interval** commands to adjust the minimum interval for receiving multihop BFD control packets. Follow these guidelines when you configure the commands:

- If you configure both the **bfd multi-hop min-receive-interval** and **bfd multi-hop min-control-interval** commands, the time interval configured by the **bfd multi-hop min-receive-interval** command takes precedence.
- If you do not configure the **bfd multi-hop min-receive-interval** or **bfd multi-hop min-control-interval** command, the device uses the default value for the **bfd multi-hop min-receive-interval** command as the minimum interval for receiving multihop BFD control packets.
- If you configure either the **bfd multi-hop min-receive-interval** or **bfd multi-hop min-control-interval** command, the device uses the value configured for that command as the minimum interval for receiving multihop BFD control packets.

You can use the **bfd multi-hop min-transmit-interval** and **bfd multi-hop min-control-interval** commands to adjust the minimum interval for transmitting multihop BFD control packets. Follow these guidelines when you configure the commands:

- If you configure both the **bfd multi-hop min-transmit-interval** and **bfd multi-hop min-control-interval** commands, the time interval configured by the **bfd multi-hop min-transmit-interval** command takes precedence.
- If you do not configure the **bfd multi-hop min-transmit-interval** or **bfd multi-hop min-control-interval** command, the device uses the default value for the **bfd multi-hop min-transmit-interval** command as the minimum interval for transmitting multihop BFD control packets.
- If you configure either the **bfd multi-hop min-transmit-interval** or **bfd multi-hop min-control-interval** command, the device uses the value configured for that command as the minimum interval for transmitting multihop BFD control packets.

Configure detection time settings for single-hop BFD detection

1. Enter system view.

   system-view
2. Enter interface view or static BFD session view.
   - Enter interface view.

     interface *interface-type interface-number*
   - Enter static BFD session view.

     bfd static *session-name*

     To configure parameters for a static BFD session, you must enter its view.

3. Set the minimum interval for receiving echo packets.
   bfd min-echo-receive-interval *interval*
   The default setting is 400 milliseconds.
4. Set the minimum interval for transmitting and receiving single-hop BFD control packets.
   - Set the minimum interval for transmitting single-hop BFD control packets.
     bfd min-transmit-interval *interval*
     The default setting is 400 milliseconds.
   - Set the minimum interval for receiving single-hop BFD control packets.
     bfd min-receive-interval *interval*
     The default setting is 400 milliseconds.
5. Set the minimum interval for transmitting and receiving single-hop BFD control packets.
   bfd min-control-interval *interval*
   The default setting is 400 milliseconds.
6. Set the single-hop detection time multiplier.
   bfd detect-multiplier *value*
   The default setting is 5.

Configure detection time settings for multihop BFD detection

7. Enter system view.
   system-view
8. (Optional.) Enter static BFD session view.
   bfd static *session-name*
   To configure parameters for a static BFD session, you must enter its view.
9. Set the multihop detection time multiplier.
   bfd multi-hop detect-multiplier *value*
   The default setting is 5.
10. Set the minimum interval for transmitting and receiving multihop BFD control packets.
    - Set the minimum interval for transmitting multihop BFD control packets.
      bfd multi-hop min-transmit-interval *interval*
      The default setting is 400 milliseconds.
    - Set the minimum interval for receiving multihop BFD control packets.
      bfd multi-hop min-receive-interval *interval*
      The default setting is 400 milliseconds.
11. Set the minimum interval for transmitting and receiving multihop BFD control packets.
    bfd multi-hop min-control-interval *interval*
    By default, the minimum interval for transmitting and receiving multihop BFD control packets is 400 milliseconds.

Configuring the authentication mode

About this task

You can configure authentication settings, including algorithm and key, to enhance BFD session security.

Configure the authentication mode for a single-hop BFD session

12. Enter system view.

system-view

13. Enter interface view or static BFD session view.
    - Enter interface view.

      interface *interface-type interface-number*
    - Enter static BFD session view.

      bfd static *session-name*

      The static BFD session must already exist.

      To configure parameters for a static BFD session, you must enter its view.
14. Configure the authentication mode for single-hop control packets.

    bfd authentication-mode { **hmac-md5** | **hmac-mmd5** | **hmac-msha1** | **hmac-sha1** | **m-md5** | **m-sha1** | **md5** | **sha1** | **simple** } *key-id* { **cipher** *cipher-string* | **plain** *plain-string* }

    By default, no authentication mode is configured for single-hop control packets.

Configure the authentication mode for a multihop BFD session

15. Enter system view.

    system-view
16. (Optional.) Enter static BFD session view.

    bfd static *session-name*

    The static BFD session must already exist.

    To configure parameters for a static BFD session, you must enter its view.
17. Configure the authentication mode for multihop BFD control packets.

    bfd multi-hop authentication-mode { **hmac-md5** | **hmac-mmd5** | **hmac-msha1** | **hmac-sha1** | **m-md5** | **m-sha1** | **md5** | **sha1** | **simple** } *key-id* { **cipher** *cipher-string* | **plain** *plain-string* }

    By default, no authentication mode is configured for multihop BFD control packets.

Configuring the notification delay timer for session establishment failures

About this task

By default, BFD does not notify upper-layer protocols of session establishment failures. The notification is required in some scenarios. For example, upon a session establishment failure in an aggregate link, the aggregate link can place the associated member port in Unselected state based on the failure notification. You can configure the delay timer for BFD to notify upper-layer protocols of session establishment failures.

Restrictions and guidelines

This feature does not apply to BFD sessions in echo packet mode.

Procedure

1. Enter system view.

   system-view
2. Set the delay timer for BFD to notify upper-layer protocols of session establishment failures.

   bfd init-fail-timer *seconds*

   By default, BFD does not notify upper-layer protocols of session establishment failures.

CAUTION:

For session establishment failures caused by configuration mismatches at the two ends, this command can cause the upper-layer protocol to act incorrectly. Therefore, use this command with caution. BFD status mismatch and BFD authentication configuration mismatch are examples of configuration mismatches.

Enabling the echo function

About this task

When you use Asynchronous mode BFD to detect the connectivity between directly connected devices, you can enable the echo function. This function enables the local system to periodically send echo packets to the remote system and reduces the control packet receiving rate to save bandwidth usage. The remote system loops back the echo packets to the local system without processing them. If the local system does not receive echo packets looped back from the remote system in a consecutive number of times, the local system declares the BFD session down.

This function is supported only for single-hop detection.

Restrictions and guidelines

This function does not take effect on BFD sessions associated with interface states.

Procedure

3. Enter system view.

   system-view

4. Enter interface view or static BFD session view.
   - Enter interface view.

     interface *interface-type interface-number*
   - Enter static BFD session view.

     bfd static *session-name*

     The static BFD session must already exist.
5. Enable the echo function.

   bfd echo [**receive** | **send**] **enable**

   By default, the echo function is disabled.

Creating a static BFD session for detecting the aggregate link of a Layer 3 aggregate interface

About this task

To use BFD to detect an aggregate link, choose one as needed:

- Method 1: Execute the **link-aggregation bfd** command to enable BFD for an aggregation group.
- Method 2: Execute the **bfd static** command with the **bind-route-aggregation** keyword specified to create static BFD sessions for detecting an aggregate link and its member links.

If you use Method 1, the Ethernet link aggregation module will mistakenly consider the aggregation link unavailable when the BFD session goes down due to the failure of a single member link. To avoid this issue, use Method 2. To perform multihop detection, use Method 1, because Method 2 only supports single-hop detection.

The operating mechanisms and restrictions and guidelines of the two methods are as shown in Table 4. You can choose only one of the methods.

Table 4 Methods of using BFD to detect an aggregate link

Method	Operating mechanism	Single-hop/multihop detection	Restrictions and guidelines
Method 1	Create a BFD session for detecting the aggregate link. Each member interface of the aggregate link takes turns to send BFD packets.	Both single-hop detection and multihop detection are supported.	• Make sure the source and destination IP addresses are reversed between the two ends of the aggregate link. For example, if you execute **link-aggregation bfd ipv4 source** *1.1.1.1* **destination** *2.2.2.2* at the local end, execute **link-aggregation bfd ipv4 source** *2.2.2.2* **destination** *1.1.1.1* at the peer end. The source and destination IP addresses must be different unicast addresses other than 0.0.0.0. • You can configure only one static BFD session to detect the aggregate link of an aggregate interface. • You cannot execute the **bfd static bind-route-aggregation** command for aggregate sub-interfaces.

Method	Operating mechanism	Single-hop/multihop detection	Restrictions and guidelines
Method 2	1. Create a static BFD session to associate with the aggregated link. 2. Create a static BFD sub-session for detecting each member interface of the aggregated link. 3. The BFD session is in up state as long as a sub-session is in up state, indicating the aggregated link is available. The BFD session goes down only when all sub-sessions are in down state, indicating the aggregated link is unavailable.	Only single-hop detection is supported.	• Make sure the source and destination IP addresses are reversed between the two ends. For example, if you execute **bfd static** *abc* **bind-route-aggregation peer-ipv4** *1.1.1.1* **interface** *route-aggregation 1* **source-ipv4** *1.1.1.2* **discriminator auto** at the local end, execute **bfd static** *abc* **bind-route-aggregation peer-ipv4** *1.1.1.2* **interface** *route-aggregation 1* **source-ipv4** *1.1.1.1* **discriminator auto** at the peer end. The source and destination IP addresses must be different unicast addresses other than 0.0.0.0. • You can configure only one static BFD session to detect the aggregate link of an aggregate interface. • You cannot execute the **bfd static bind-route-aggregation** command for aggregate sub-interfaces.

Procedure

6. Enter system view.

   system-view

7. Create a static BFD session and enter static BFD session view.

   IPv4:

   bfd static *session-name* [**bind-route-aggregation peer-ip** *ipv4-address* **interface** *interface-type interface-number* **source-ip** *ipv4-address* **discriminator auto**]

   Make sure the source and destination IP addresses are reversed between the two ends of the aggregate link. The source and destination IP addresses must be different unicast addresses other than 0.0.0.0.

   IPv6:

   bfd static *session-name* [**bind-route-aggregation peer-ipv6** *ipv6-address* **interface** *interface-type interface-number* **source-ipv6** *ipv6-address* **discriminator auto**]

   Make sure the source and destination IP addresses are reversed between the two ends of the aggregate link. The source and destination IP addresses must be different unicast addresses other than 0::0.

Configuring the TTL value for BFD packets

About this task

When you connect an H3C device to a third-party device, for successful BFD session negotiation, make sure the TTL value settings for BFD packets on both ends of the BFD session are the same. When the device receives a BFD packet in DOWN or INIT state from its peer, it verifies the TTL value of the packet and performs one of the following actions:

- For a single-hop BFD session, if the device receives a packet that carries a TTL value that is different from the TTL value specified with the **bfd ttl** command, the device drops the packet.
- For a multihop BFD session, if the device receives a packet that carries a TTL value that is greater than the TTL value specified with the **bfd ttl** command, the device drops the packet.
- If the BFD session is already up, the device sets the BFD session state to AdminDown, which triggers a BFD session renegotiation.

Restrictions and guidelines

- The **bfd ttl** command does not take effect on BFD sessions in echo packet mode.
- For an IPv4 or IPv6 address with different mask lengths or prefix lengths, the device uses the TTL value specified with the longest mask or prefix length.
- For an IPv4 or IPv6 subnet, the TTL value of single-hop BFD packets must be greater than the TTL value of multihop BFD packets.

Procedure

8. Enter system view.

system-view

9. Specify the TTL value for BFD packets.

bfd { **peer-ip** *ipv4-address mask-length* | **peer-ipv6** *ipv6-address prefix-length* } **ttl** { **single-hop** | **multi-hop** } *ttl-value*

By default, the TTL value of single-hop BFD packets is 255 and the TTL value of multihop BFD packets is 64.

Configuring BFD session flapping suppression

About this task

When BFD detects a link failure, it tears down the BFD session and notifies the upper-layer protocol of the failure. When the upper-layer protocol re-establishes a neighbor relationship, the BFD session comes up again. BFD session flaps occur when a link fails and recovers repeatedly, which consumes significant system resources and causes network instability.

This feature allows you to suppress BFD session flapping by using the *initial-interval*, *secondary-interval*, and *maximum-interval* arguments.

- A BFD session is suppressed within the specified interval. The suppression time does not exceed the *maximum-interval*.
- After a BFD session goes down for the second time, it cannot be re-established within the *initial-interval*.
- After a BFD session goes down for the third time, it cannot be re-established within the *secondary-interval*.
- After a BFD session goes down for the fourth time and at any later time, the following rules apply:

- If *secondary-interval* × 2^{n-3} is smaller than or equal to the *maximum-interval*, the BFD session cannot be re-established within the *secondary-interval* × 2^{n-3}.
- If *secondary-interval* × 2^{n-3} is greater than the *maximum-interval*, the BFD session cannot be re-established within the *maximum-interval*.

The letter n, starting from 4, is the number of times the BFD session flaps.

Procedure

10. Enter system view.
    system-view
11. Configure BFD session flapping suppression.
    bfd dampening [**maximum** *maximum-interval* **initial** *initial-interval* **secondary** *secondary-interval*]
    By default, BFD sessions are not suppressed.
    The values for the *initial-interval* and *secondary-interval* arguments cannot be greater than or equal to the value for the *maximum-interval* argument.

Delaying BFD session negotiation

About this task

If an upper-layer protocol uses BFD to detect the active path, packet loss might occur in the following situations:

- An active/standby path switchover is triggered upon a device reboot. If the BFD session comes up after a device reboot, the traffic on the standby path will be switched over to the active path. In this case, traffic loss will occur if the active path of the upper-layer protocol has not recovered completely.
- An active/standby path switchover is triggered after the active path goes down. If the BFD session comes up before the active path recovers, the traffic on the standby path will be switched over to the active path. In this case, traffic loss will occur.

To solve the traffic loss problem, you can delay BFD session negotiation.

Delaying BFD session negotiation upon a device reboot

About this task

This function starts a delay timer when the device reboots successfully. Before this timer expires, the device does not perform session negotiation on BFD sessions in down state and newly created sessions.

Procedure

12. Enter system view.
    system-view
13. Enable BFD session negotiation delay upon a device reboot and set a delay timer.
    bfd session-negotiation delay-upon-reboot *interval*
    By default, BFD session negotiation delay is disabled for a device reboot.

Delaying BFD session negotiation for down BFD sessions

About this task

This function starts a delay timer for each BFD session from up to down state and each newly created session. Before the timer expires, the device does not perform session negotiation on each BFD session.

Procedure

14. Enter system view.
    system-view
15. Enable session negotiation delay for down BFD sessions and set a delay timer.
    bfd session-negotiation delay-upon-down *interval*
    By default, session negotiation delay is disabled for down BFD sessions.

Configuring a BFD template

About this task

Perform this task to specify BFD parameters in a template for sessions without next hops. You can configure BFD parameters for LSPs and PWs through a BFD template.

This task can also be used to specify BFD parameters for BFD sessions that detect interface states.

Restrictions and guidelines

The S5200-EI-G switch series does not support this feature.

Procedure

16. Enter system view.
    system-view
17. Create a BFD template and enter BFD template view.
    bfd template *template-name*
18. Set the detection time multiplier.
    bfd detect-multiplier *value*
    The default setting is 5.
19. Set the minimum interval for transmitting and receiving BFD control packets.
    bfd min-control-interval *interval*
    The default setting is 400 milliseconds.

Configuring event logging and SNMP notifications for BFD

Enabling BFD event logging

About this task

Use this feature to enable the device to record the following types of BFD event logs to help you locate the reason for BFD session state anomalies:

- BFD session down events.

- Driver packet-sending events.

Procedure

20. Enter system view.

```
system-view
```

21. Enable BFD event logging.

```
bfd event-log enable { down [ log-size ] | driver-packet
[ detection-abnormal-autostop ] }
```

By default, BFD event logging is disabled.

You can repeat this command to modify the maximum number of logs allowed for BFD session down events. After modification, the device clears recorded logs.

The device can record a maximum number of 8192 logs for driver packet-sending events.

Enabling SNMP notifications for BFD

About this task

To report critical BFD events to an NMS, enable SNMP notifications for BFD. For BFD event notifications to be sent correctly, you must also configure SNMP as described in *Network Management and Monitoring Configuration Guide*.

Procedure

22. Enter system view.

```
system-view
```

23. Enable SNMP notifications for BFD.

```
snmp-agent trap enable bfd
```

By default, SNMP notifications are enabled for BFD.

Display and maintenance commands for BFD

Execute the **display** command in any view and the **reset** command in user view.

Task	Command
Display BFD session information.	**display bfd session** [**discriminator local** *local-value* | **static** *session-name* | **verbose**] **display bfd session** [[**dynamic**] [**control** | **echo**] [**ip**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [**peer-ip** *ipv4-address* [**vpn-instance** *vpn-instance-name*]] [**verbose**]] **display bfd session** [[**dynamic**] [**control** | **echo**] [**ipv6**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [**peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*]] [**verbose**]] **display bfd session** [[**static**] [**ip**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [**peer-ip** *ipv4-address* [**vpn-instance** *vpn-instance-name*]] [**verbose**] **display bfd session** [[**static**] [**ipv6**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [**peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*]] [**verbose**]
Display information about static BFD sessions created to detect the aggregate links and member links of Layer 3 aggregate interfaces.	**display bfd session route-aggregation** [**interface** *interface-type interface-number*]
Display the TTL values for BFD packets.	**display bfd ttl**
Clear BFD session statistics.	**reset bfd session statistics**

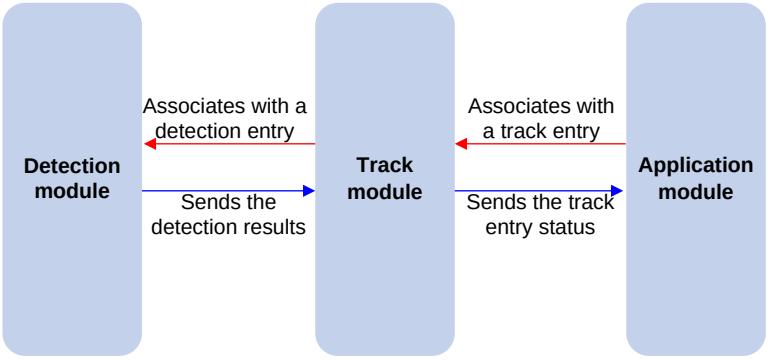
Configuring Track

About Track

The Track module works between application modules and detection modules. It shields the differences between various detection modules from application modules.



Collaboration mechanism

The Track module collaborates with detection modules and application modules.

As shown in Figure 1, collaboration is enabled when you associate the Track module with a detection module and an application module, and it operates as follows:

1. The detection module probes specific objects such as interface status, link status, network reachability, and network performance, and informs the Track module of detection results.
2. The Track module sends the detection results to the application module.
3. When notified of changes for the tracked object, the application modules can react to avoid communication interruption and network performance degradation.

Figure 1 Collaboration through the Track module

Collaboration between the Track module and a detection module

The detection module sends the detection result of the tracked object to the Track module. The Track module changes the status of the track entry as follows:

- If the tracked object operates correctly, the state of the track entry is Positive. For example, the track entry state is Positive in one of the following conditions:
  - The target interface is up.
  - The target network is reachable.
- If the tracked object does not operate correctly, the state of the track entry is Negative. For example, the track entry state is Negative in one of the following conditions:
  - The target interface is down.
  - The target network is unreachable.
- If the detection result is invalid, the state of the track entry is NotReady. For example, the track entry state is NotReady if its associated NQA operation does not exist.

Collaboration between the Track module and an application module

The track module reports the track entry status changes to the application module. The application module can then take correct actions to avoid communication interruption and network performance degradation.

Supported detection modules

The following detection modules can be associated with the Track module:

- NQA.
- BFD.
- Interface management.
- Route management.
- LLDP.
- M-LAG (not supported by the S5200-EI-G switch series)

You can also associate a track entry with a list of objects called a tracked list. The state of a tracked list is determined by the states of all objects in the list. The following types of tracked lists are supported:

- **Boolean AND list**—The state of a Boolean AND list is determined by the states of the tracked objects using the Boolean AND operation.
- **Boolean OR list**—The state of a Boolean OR list is determined by the states of the tracked objects using the Boolean OR operation.
- **Percentage threshold list**—The state of a percentage threshold list is determined by comparing the percentage of positive objects in the list with the percentage thresholds configured for the list.
- **Weight threshold list**—The state of a weight threshold list is determined by comparing the weight of positive objects in the list with the weight thresholds configured for the list.

Supported application modules

The following application modules can be associated with the Track module:

- VRRP.
- Static routing.
- PBR.
- Traffic redirection.
- Embedded Automation Architecture (EAA).

Restrictions and guidelines: Track configuration

When configuring a track entry for an application module, you can set a notification delay to avoid immediate notification of status changes.

When the delay is not configured and the route convergence is slower than the link state change notification, communication failures occur. For example, when the master in a VRRP group detects an uplink interface failure through Track, Track immediately notifies the master to decrease its priority. A backup with a higher priority then preempts as the new master. When the failed uplink interface recovers, the Track module immediately notifies the original master to restore its priority. If the uplink route has not recovered, forwarding failure will occur.

Collaboration application example

The following is an example of collaboration between NQA, Track, and static routing.

Configure a static route with next hop 192.168.0.88 on the device. If the next hop is reachable, the static route is valid. If the next hop becomes unreachable, the static route is invalid. For this purpose, configure NQA-Track-static routing collaboration as follows:

1. Create an NQA operation to monitor the accessibility of IP address 192.168.0.88.
2. Create a track entry and associate it with the NQA operation.
   - When next hop 192.168.0.88 is reachable, NQA sends the result to the Track module. The Track module sets the track entry to Positive state.
   - When the next hop becomes unreachable, NQA sends the result to the Track module. The Track module sets the track entry to Negative state.
3. Associate the track entry with the static route.
   - When the track entry is in Positive state, the static routing module considers the static route to be valid.
   - When the track entry is in Negative state, the static routing module considers the static route to be invalid.

Track tasks at a glance

To implement the collaboration function, establish associations between the Track module and detection modules, and between the Track module and application modules.

To configure the Track module, perform the following tasks:

1. Associating the Track module with a detection module
   - Associating Track with NQA
   - Associating Track with BFD
   - Associating Track with interface management
   - Associating Track with route management
   - Associating Track with LLDP
   - Associating Track with M-LAG MAD state
2. Associating Track with a tracked list
   - Associating Track with a Boolean list
   - Associating Track with a percentage threshold list
   - Associating Track with a weight threshold list
3. Associating the Track module with an application module
   - Associating Track with VRRP
   - Associating Track with static routing
   - Associating Track with PBR
   - Associating Track with traffic redirection
   - Associating Track with EAA

Associating the Track module with a detection module

Associating Track with NQA

About this task

NQA supports multiple operation types to analyze network performance and service quality. For example, an NQA operation can periodically detect whether a destination is reachable, or whether a TCP connection can be established.

An NQA operation operates as follows when it is associated with a track entry:

- If the consecutive probe failures reach the specified threshold, the NQA module notifies the Track module that the tracked object has malfunctioned. The Track module then sets the track entry to Negative state.
- If the specified threshold is not reached, the NQA module notifies the Track module that the tracked object is operating correctly. The Track module then sets the track entry to Positive state.

For more information about NQA, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

If you associate a track entry with a nonexistent NQA operation or reaction entry, the state of the track entry is NotReady.

Procedure

1. Enter system view.

   system-view

2. Create a track entry, associate it with an NQA reaction entry, and enter its view.

   track *track-entry-number* **nqa entry** *admin-name operation-tag* **reaction** *item-number*

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with BFD

About this task

You can associate a track entry with an echo-mode BFD session, a control-mode BFD session, or a static BFD session. For more information about BFD, see "Configuring BFD."

The associated Track and BFD operate as follows:

- If the BFD detects that the link fails, it informs the Track module of the link failure. The Track module sets the track entry to Negative state.
- If the BFD detects that the link is operating correctly, the Track module sets the track entry to Positive state.

After associating a track entry with an echo-packet-mode BFD session, by default, the device checks the echo response receiving interface. If it is different from the echo packet output interface, the device takes the echo response packet as an invalid packet, and discards it. The BFD session then goes down. When multiple paths are available for the BFD session, as a best practice, enable

checking for the echo response receiving interface. This can avoid BFD session failure when the echo response receiving interface is different from the echo packet output interface.

Restrictions and guidelines

When you associate a track entry with BFD, do not configure the virtual IP address of a VRRP group as the local or remote address of the BFD session.

For correct establishment of a control-mode BFD session, follow these guidelines when you execute the **track bfd ctrl** command:

- Execute the **track bfd ctrl** command on both the local and peer ends.
- Specify the BFD session parameters (outgoing interface, source IP address, and destination IP address of BFD control packets) correctly for the command.

Prerequisites

Before you associate Track with an echo-mode BFD session, configure the source IP address of BFD echo packets. For more information, see "Configuring BFD."

Procedure

1. Enter system view.

   system-view

2. Create a track entry, associate it with a BFD session, and enter its view. Choose the options to configure as needed:
   - Create a track entry, and associate it with an echo-mode BFD session.

     track *track-entry-number* **bfd echo interface** *interface-type interface-number* **remote** { **ip** *remote-ipv4-address* | **ipv6** *remote-ipv6-address* } **local** { **ip** *local-ipv4-address* | **ipv6** *local-ipv6-address* } [**ignore-rx-interface**]
   - Create a track entry, and associate it with a control-mode BFD session.

     track *track-entry-number* **bfd ctrl** [**interface** *interface-type interface-number* | **vpn-instance** *vpn-instance-name*] **remote** { **ip** *remote-ipv4-address* | **ipv6** *remote-ipv6-address* } **local** { **ip** *local-ipv4-address* | **ipv6** *local-ipv6-address* }
   - Create a track entry, and associate it with a static BFD session.

     track *track-entry-number* **bfd static** *bfd-session-name*

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with interface management

About this task

The interface management module monitors the link status or network-layer protocol status of interfaces. The associated Track and interface management operate as follows:

- When the link or network-layer protocol status of the interface changes to up, the interface management module informs the Track module of the change. The Track module sets the track entry to Positive state.
- When the link or network-layer protocol status of the interface changes to down, the interface management module informs the Track module of the change. The Track module sets the track entry to Negative state.

Procedure

1. Enter system view.

   system-view

2. Create a track entry, associate it with interface management, and enter its view.
   - Create a track entry to monitor the link status of an interface.

     track *track-entry-number* **interface** *interface-type interface-number*
   - Create a track entry to monitor the physical status of an interface.

     track *track-entry-number* **interface** *interface-type interface-number* **physical**
   - Create a track entry to monitor the network layer protocol status of an interface.

     track *track-entry-number* **interface** *interface-type interface-number* **protocol** { **ipv4** | **ipv6** }

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with route management

About this task

The route management module monitors route entry changes in the routing table. The associated Track and route management operate as follows:

- Monitor the specified route entry:
  - If the route entry exists in the routing table, the route management module informs the Track module. The Track module then sets the track entry to Positive state.
  - When the route entry is removed from the routing table, the route management module informs the Track module of the change. The Track module then sets the track entry to Negative state.
- Monitor the number of ECMP routes associated with the specified route entry:
  - When the number of ECMP routes is within the specified range, the route management module informs the Track module. The Track module then sets the track entry to Positive state.
  - When the number of ECMP routes is out of the specified range, the route management module informs the Track module. The Track module then sets the track entry to Negative state.

Associating a track entry with an IPv4 route entry

1. Enter system view.

   system-view

2. Create a track entry, associate it with a route entry, and enter its view.

   track *track-entry-number* **ip route** [**vpn-instance** *vpn-instance-name*] *ipv4-address* { *mask-length* | *mask* } { **ecmp-number** { **greater-equal** *min-ecmp-number* | **less-equal** *max-ecmp-number* } * | **reachability** }

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with LLDP

About this task

The LLDP module detects neighbor availability and informs the detection result to the Track module. The associated Track and LLDP operate as follows:

- When the neighbor is available, the Track module sets the track entry to Positive state.
- When the neighbor is unavailable, the Track module sets the track entry to Negative state.

For more information about LLDP, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Create a track entry, associate it with an LLDP interface, and enter its view.

   track *track-entry-number* **lldp neighbor interface** *interface-type interface-number*

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with M-LAG MAD state

About this task

M-LAG provides the MAD mechanism to set associated device interfaces to M-LAG MAD DOWN state when the peer link between M-LAG member devices goes down. This can avoid traffic forwarding failure on the interfaces and avoid impacts on services. When the peer link comes up and the delay timer expires, M-LAG brings up the interfaces placed in M-LAG MAD DOWN state.

The associated Track and M-LAG MAD state operate as follows:

- If specific interfaces on the device are set to M-LAG MAD DOWN state, the Track module sets the track entry to Negative state.
- If the interfaces in M-LAG MAD DOWN state come up, the Track module sets the track entry to Positive state.
- If no M-LAG MAD state change events are triggered or received, the Track module sets the track entry to NotReady state.

For more information about M-LAG MAD, see M-LAG configuration in *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Create a track entry, associate it with M-LAG MAD state, and enter its view.

   track *track-entry-number* **mlag-mad-status**

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with a tracked list

Associating Track with a Boolean list

About this task

A Boolean list is a list of tracked objects based on a Boolean logic. It can be further divided into the following types:

- **Boolean AND list**—A Boolean AND list is set to the Positive state only when all objects are in Positive state. If one or more objects are in Negative state, the tracked list is set to the Negative state.
- **Boolean OR list**—A Boolean OR list is set to the Positive state if any object is in Positive state. If all objects are in Negative state, the tracked list is set to the Negative state.

Procedure

1. Enter system view.

   system-view
2. Create a Boolean tracked list and enter its view.

   track *track-entry-number* **list boolean** { **and** | **or** }
3. (Optional.) Set the delay for notifying the application module of tracked list state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the tracked list state changes.
4. Add the track entry as an object to the tracked list.

   object *track-entry-number* [**not**]

   By default, a tracked list does not contain any objects.

   Repeat this step to add all interested objects to the tracked list.

Associating Track with a percentage threshold list

About this task

The state of a percentage threshold list is determined by comparing the percentage of positive objects in the list with the percentage thresholds configured for the list.

- If the percentage of positive objects is equal to or above the positive state threshold, the list is set to the Positive state.
- If the percentage of positive objects is equal to or below the negative state threshold, the list is set to the Negative state.
- The state of a percentage threshold list remains unchanged if the percentage of positive objects is below the positive state threshold and above the negative state threshold.

Procedure

1. Enter system view.

   system-view
2. Create a percentage threshold list and enter its view.

   track *track-entry-number* **list threshold percentage**
3. (Optional.) Set the delay for notifying the application module of tracked list state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

By default, the Track module notifies the application module immediately when the tracked list state changes.

4. Add the track entry as an object to the tracked list.

   object *track-entry-number*

   By default, a tracked list does not contain any objects.

   Repeat this step to add all interested objects to the tracked list.

5. Configure the threshold values used to determine the state of the percentage threshold list.

   threshold percentage { **negative** *negative-threshold* | **positive** *positive-threshold* } *

   By default, the negative state threshold is 0% and the positive state threshold is 1%.

Associating Track with a weight threshold list

About this task

The state of a weight threshold list is determined by comparing the weight of positive objects in the list with the weight thresholds configured for the list.

- If the total weight of positive objects is equal to or above the positive state threshold, the list is set to the Positive state.
- If the total weight of positive objects is equal to or below the negative state threshold, the list is set to the Negative state.
- The state of a weight threshold list remains unchanged if the total weight of positive objects is below the positive state threshold and above the negative state threshold.

Procedure

1. Enter system view.

   system-view

2. Create a weight threshold list and enter its view.

   track *track-entry-number* **list threshold weight**

3. (Optional.) Set the delay for notifying the application module of tracked list state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the tracked list state changes.

4. Add the track entry as an object to the tracked list.

   object *track-entry-number* [**weight** *weight*]

   By default, a tracked list does not contain any objects.

   Repeat this step to add all interested objects to the tracked list.

5. Configure the threshold values used to determine the state of the weight threshold list.

   threshold weight { **negative** *negative-threshold* | **positive** *positive-threshold* } *

   By default, the negative state threshold is 0 and the positive state threshold is 1.

Associating the Track module with an application module

Before you associate the Track module with an application module, make sure the associated track entry has been created.

Prerequisites for associating the Track module with an application module

Create a track entry first before you associate it with an application module.

An application module might obtain incorrect track entry status information if the associated track entry does not exist.

For more information about the Track and application module collaboration commands, see the command reference of the associated application module.

Associating Track with VRRP

About this task

When VRRP is operating in standard mode or load balancing mode, associate the Track module with the VRRP group to implement the following actions:

- Change the priority of a router according to the status of the uplink. If a fault occurs on the uplink of the router, the VRRP group is not aware of the uplink failure. If the router is the master, hosts in the LAN cannot access the external network. To resolve this problem, configure a detection module-Track-VRRP collaboration. The detection module monitors the status of the uplink of the router and notifies the Track module of the detection result.

  When the uplink fails, the detection module notifies the Track module to change the status of the monitored track entry to Negative. The priority of the master decreases by a user-specified value. A router with a higher priority in the VRRP group becomes the master.
- Monitor the master on a backup. If a fault occurs on the master, the backup operating in switchover mode will switch to the master immediately to maintain normal communication.

When VRRP is operating in load balancing mode, associate the Track module with the VRRP VF to implement the following functions:

- Change the priority of the AVF according to its uplink state. When the uplink of the AVF fails, the track entry changes to Negative state. The weight of the AVF decreases by a user-specified value. The VF with a higher priority becomes the new AVF to forward packets.
- Monitor the AVF status from the LVF. When the AVF fails, the LVF that is operating in switchover mode becomes the new AVF to ensure continuous forwarding.

For more information about configuring VRRP, see "Configuring VRRP."

Restrictions and guidelines for Track association with VRRP

- VRRP tracking does not take effect on an IP address owner. The configuration takes effect when the router does not act as the IP address owner.

  An IP address owner is the router with its interface IP address used as the virtual IP address of the VRRP group.
- When the status of the track entry changes from Negative to Positive or NotReady, the associated router or VF restores its priority automatically.

Associating Track with a VRRP group

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Associate a track entry with a VRRP group.

vrrp [**ipv6**] **vrid** *virtual-router-id* **track** *track-entry-number* { **forwarder-switchover member-ip** *ip-address* | **priority reduced** [*priority-reduced*] **switchover** | **weight reduced** [*weight-reduced*] }

By default, no track entry is associated with a VRRP group.

This command is supported when VRRP is operating in both standard mode and load balancing mode.

Associating Track with a VRRP VF

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Associate Track with a VRRP VF.

   vrrp [**ipv6**] **vrid** *virtual-router-id* **track** *track-entry-number* { **forwarder-switchover member-ip** *ip-address* | **priority reduced** [*priority-reduced*] **switchover** | **weight reduced** [*weight-reduced*] }

   By default, no track entry is associated with a VRRP VF.

   This command is configurable when VRRP is operating in standard mode or load balancing mode. However, the configuration takes effect only when VRRP is operating in load balancing mode.

Associating Track with static routing

About this task

A static route is a manually configured route to route packets. For more information about static route configuration, see *Layer 3—IP Routing Configuration Guide*.

Static routes cannot adapt to network topology changes. Link failures or network topological changes can make the routes unreachable and cause communication interruption.

To resolve this problem, configure another route to back up the static route. When the static route is reachable, packets are forwarded through the static route. When the static route is unreachable, packets are forwarded through the backup route.

To check the accessibility of a static route in real time, associate the Track module with the static route.

If you specify the next hop but not the output interface when configuring a static route, you can configure the static routing-Track-detection module collaboration. This collaboration enables you to verify the accessibility of the static route based on the track entry state.

- If the track entry is in Positive state, the following conditions exist:
  - The next hop of the static route is reachable.
  - The configured static route is valid.
- If the track entry is in Negative state, the following conditions exist:
  - The next hop of the static route is not reachable.
  - The configured static route is invalid.
- If the track entry is in NotReady state, the following conditions exist:
  - The accessibility of the next hop of the static route is unknown.
  - The static route is valid.

Restrictions and guidelines

In static routing-Track-NQA collaboration, you must configure the same VPN instance name for the NQA operation and the next hop of the static route. Otherwise, the accessibility detection cannot operate correctly.

If a static route needs route recursion, the associated track entry must monitor the next hop of the recursive route. The next hop of the static route cannot be monitored. Otherwise, a valid route might be considered invalid.

Associating Track with an IPv4 static route

1. Enter system view.

   system-view

2. Associate an IPv4 static route with a track entry to check the accessibility of the next hop.

   Public network:

   ip route-static { *dest-address* { *mask-length* | *mask* } | **group** *group-name* } { *interface-type interface-number* [*next-hop-address*] **track** *track-entry-number* | *next-hop-address* [**recursive-lookup host-route**] **track** *track-entry-number* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   VPN:

   ip route-static vpn-instance *s-vpn-instance-name* { *dest-address* { *mask-length* | *mask* } | **group** *group-name* } { *interface-type interface-number* [*next-hop-address*] **track** *track-entry-number* | *next-hop-address* [**recursive-lookup host-route**] [**public**] **track** *track-entry-number* | **vpn-instance** *d-vpn-instance-name next-hop-address* [**recursive-lookup host-route**] **track** *track-entry-number* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, an IPv4 static route is not associated with any track entries.

Associating Track with an IPv6 static route

1. Enter system view.

   system-view

2. Associate an IPv6 static route with a track entry to check the accessibility of the next hop.

   Public network:

   ipv6 route-static *ipv6-address prefix-length* { *interface-type interface-number* [*next-hop-address*] **track** *track-entry-number* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   VPN:

   ipv6 route-static vpn-instance *s-vpn-instance-name ipv6-address prefix-length* { *interface-type interface-number* [*next-hop-address*] **track** *track-entry-number* | *next-hop-address* [**public**] **track** *track-entry-number* | **vpn-instance** *d-vpn-instance-name next-hop-address* [**recursive-lookup host-route**] **track** *track-entry-number* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, an IPv6 static route is not associated with any track entries.

Associating Track with PBR

About this task

PBR uses user-defined policies to route packets. You can specify parameters in a PBR policy to guide the forwarding of the packets that match specific criteria. For more information about PBR, see *Layer 3—IP Routing Configuration Guide*.

PBR cannot detect the availability of any action taken on packets. When an action is not available, packets processed by the action might be discarded. For example, if the output interface specified for PBR fails, PBR cannot detect the failure, and continues to forward matching packets out of the interface.

To enable PBR to detect topology changes and improve the flexibility of the PBR application, configure Track-PBR-detection module collaboration.

After you associate a track entry with an apply clause, the detection module associated with the track entry sends Track the detection result of the availability of the tracked object.

- The Positive state of the track entry indicates that the object is available, and the apply clause is valid.
- The Negative state of the track entry indicates that the object is not available, and the apply clause is invalid.
- The NotReady state of the track entry indicates that the apply clause is valid.

Prerequisites for Track association with PBR

Before you associate Track with PBR, create a policy node, and set the match criteria.

Associating Track with PBR

1. Enter system view.

   system-view
2. Create a policy node and enter its view.

   policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*
3. Set match criteria. Choose the options to configure as needed:
   - Set an ACL match criterion.

     if-match acl { *acl-number* | **name** *acl-name* }

     By default, no ACL match criterion is set.

     The ACL match criterion cannot match Layer 2 information.

     When using the ACL to match packets, PBR ignores the time range settings in the ACL. If the specified ACL does not exist, no packets will be matched.

     When using the ACL to match packets, interface PBR ignores the action (**permit** or **deny**) setting in the ACL.

     When using the ACL to match packets, local PBR uses only the **permit** action in the ACL.
4. Set actions and associate the policy node with a track entry. Choose the options to configure as needed:
   - Set the next hop.

     apply next-hop [**vpn-instance** *vpn-instance-name* | **inbound-vpn**] { *ip-address* [**direct**] [**track** *track-entry-number*]}&<1-4>

     By default, no next hop is set.

Associating Track with IPv6 PBR

1. Enter system view.

system-view

2. Create an IPv6 policy node and enter its view.

   ipv6 policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

3. Set match criteria. Choose the options to configure as needed:

   - Set an ACL match criterion.

     if-match acl { *ipv6-acl-number* | **name** *ipv6-acl-name* }

     By default, no ACL match criterion is set.

     The ACL match criterion cannot match Layer 2 information.

     When using the ACL to match packets, IPv6 PBR ignores the action (**permit** or **deny**) and time range settings in the ACL.

4. Set actions and associate the policy node with a track entry. Choose the options to configure as needed:

   - Set the next hop.

     apply next-hop [**vpn-instance** *vpn-instance-name* | **inbound-vpn**] { *ipv6-address* [**direct**] [**track** *track-entry-number*] } &<1-4>

     By default, no next hop is set.

Associating Track with traffic redirection

About this task

Traffic redirection redirects the packets matching specific criteria to a certain location, such as to an interface, a CPU, or a next hop. When the location (for example, next hop) is not reachable, packets redirected to it are lost. To check the accessibility of the next hop in real time, associate Track with traffic redirection. For more information about traffic redirection, see QoS configuration in *ACL and QoS Configuration Guide*.

- If the track entry is in Positive state, the following conditions exist:
  - The next hop is reachable.
  - Traffic redirection redirects packets to the next hop.
- If the track entry is in Negative state, the following conditions exist:
  - The next hop is not reachable.
  - Traffic redirection does not redirect packets.

  The packets are forwarded based on the routing table lookup result.
- If the track entry is in NotReady state, the following conditions exist:
  - The accessibility of the next hop is unknown.
  - Traffic redirection redirects packets to the next hop of the unknown state.

Procedure

1. Enter system view.

   system-view

2. Create a behavior and enter behavior view.

   traffic behavior *behavior-name*

3. Associate Track with traffic redirection.

   redirect next-hop { *ipv4-add* [**track** *track-entry-number*] [*ipv4-add* [**track** *track-entry-number*]] | *ipv6-add* [*interface-type interface-number*] [**track** *track-entry-number*] [*ipv6-add* [*interface-type interface-number*] [**track** *track-entry-number*]] }

By default, no track entry is associated with traffic redirection.

Associating Track with EAA

About this task

You can configure EAA track event monitor policies to monitor the positive-to-negative or negative-to-positive state changes of track entries.

- If you specify only one track entry for a policy, EAA triggers the policy when it detects the specified state change on the track entry.
- If you specify multiple track entries for a policy, EAA triggers the policy when it detects the specified state change on the last monitored track entry. For example, if you configure a policy to monitor the positive-to-negative state change of multiple track entries, EAA triggers the policy when the last positive track entry monitored by the policy is changed to the Negative state.

You can set a suppression time for a track event monitor policy. The timer starts when the policy is triggered. The system does not process messages that report the monitored track event until the timer times out.

For more information about EAA, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Create a CLI-defined monitor policy and enter its view, or enter the view of an existing CLI-defined monitor policy.

   rtm cli-policy *policy-name*
3. Configure a track event.

   event track *track-entry-number-list* **state** { **negative** | **positive** } [**suppress-time** *suppress-time*]

   By default, a monitor policy does not monitor any track event.

Display and maintenance commands for Track

Execute **display** commands in any view.

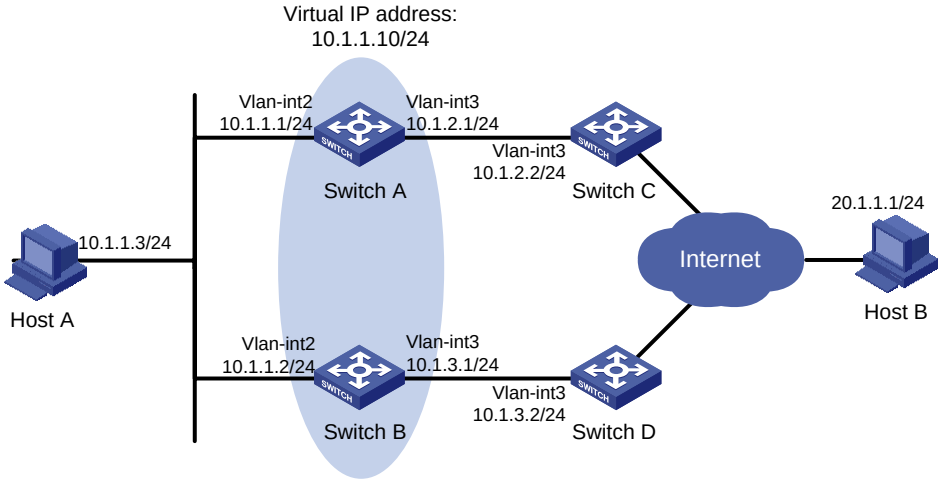
Task	Command
Display information about track entries.	**display track** { *track-entry-number* | **all** [**negative** | **positive**] } [**brief**]

The output shows that when the control-mode BFD session detects that Router A fails, the Track module notifies VRRP to change the status of Router B to master. The backup can quickly preempt as the master without waiting for a period three times the advertisement interval plus the Skew_Time.

Track configuration examples

Example: Configuring VRRP-Track-NQA collaboration

Network configuration



As shown in Figure 2:

- Host A requires access to Host B. The default gateway of Host A is 10.1.1.10/24.
- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 10.1.1.10.

Configure VRRP-Track-NQA collaboration to monitor the uplink on the master and meet the following requirements:

- When Switch A operates correctly, Switch A forwards packets from Host A to Host B.
- When NQA detects a fault on the uplink of Switch A, Switch B forwards packets from Host A to Host B.

Figure 2 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 2. (Details not shown.)
2. Configure an NQA operation on Switch A:

   # Create an NQA operation with administrator name **admin** and operation tag **test**.

   ```
   <SwitchA> system-view
   [SwitchA] nqa entry admin test
   ```

   # Specify the **ICMP echo** operation type.

   ```
   [SwitchA-nqa-admin-test] type icmp-echo
   ```

   # Specify 10.1.2.2 as the destination address of ICMP echo requests.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] destination ip 10.1.2.2
   ```

   # Configure the ICMP echo operation to repeat every 100 milliseconds.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] frequency 100
   ```

   # Configure reaction entry 1, specifying that five consecutive probe failures trigger the Track module.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] reaction 1 checked-element probe-fail
   threshold-type consecutive 5 action-type trigger-only
   [SwitchA-nqa-admin-test-icmp-echo] quit
   ```

   # Start the NQA operation.

   ```
   [SwitchA] nqa schedule admin test start-time now lifetime forever
   ```

3. On Switch A, configure track entry 1, and associate it with reaction entry 1 of the NQA operation.

   ```
   [SwitchA] track 1 nqa entry admin test reaction 1
   [SwitchA-track-1] quit
   ```

4. Configure VRRP on Switch A:

   # Specify VRRPv2 to run on VLAN-interface 2.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] vrrp version 2
```

   # Create VRRP group 1, and configure virtual IP address 10.1.1.10 for the group.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
```

   # Set the priority of Switch A to 110 in VRRP group 1.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
```

   # Set the authentication mode of VRRP group 1 to **simple**, and the authentication key to **hello**.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 authentication-mode simple hello
```

   # Configure the master to send VRRP packets every 500 centiseconds.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 timer advertise 500
```

   # Configure Switch A to operate in preemptive mode and set the preemption delay to 5000 centiseconds.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 preempt-mode timer delay 5000
```

   # Associate VRRP group 1 with track entry 1 and decrease the router priority by 30 when the state of track entry 1 changes to Negative.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 track 1 priority reduced 30
```

5. Configure VRRP on Switch B:

   # Specify VRRPv2 to run on VLAN-interface 2.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp version 2
```

   # Create VRRP group 1, and configure virtual IP address 10.1.1.10 for the group.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
```

   # Set the authentication mode of VRRP group 1 to **simple**, and the authentication key to **hello**.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 authentication-mode simple hello
```

   # Configure the master to send VRRP packets every 500 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 timer advertise 500
```

   # Configure Switch B to operate in preemptive mode and set the preemption delay to 5000 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 preempt-mode timer delay 5000
```

Verifying the configuration

Ping Host B from Host A to verify that Host B is reachable. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp verbose
IPv4 Virtual Router Information:

```

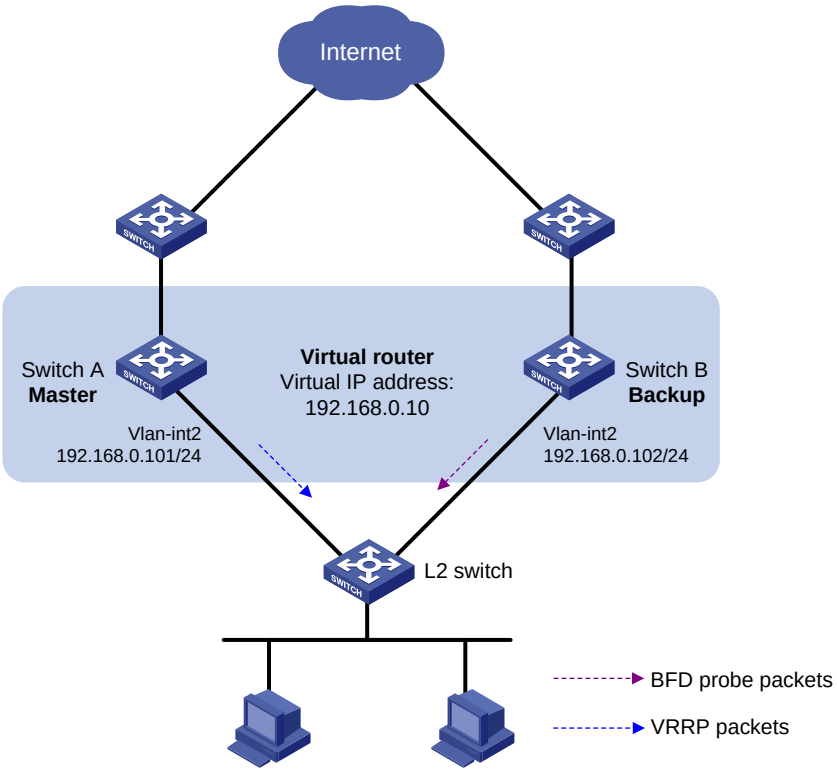
The output shows that Switch A becomes the backup, and Switch B becomes the master. Switch B forwards packets from Host A to Host B.

Example: Configuring an echo-mode BFD session for a VRRP backup to monitor the master

Network configuration



As shown in Figure 3:

- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 192.168.0.10.
- The default gateway of the hosts in the LAN is 192.168.0.10.

Configure VRRP-Track-BFD (echo mode) collaboration to monitor the master on the backup and meet the following requirements:

- When Switch A operates correctly, the hosts in the LAN access the Internet through Switch A.
- When Switch A fails, the backup (Switch B) can detect the state change of the master through the echo-mode BFD session and become the new master. The hosts in the LAN access the Internet through Switch B.

Figure 3 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 3. (Details not shown.)
2. Configure Switch A:

   # Create VRRP group 1, and configure virtual IP address 192.168.0.10 for the group.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   ```

   # Set the priority of Switch A to 110 in VRRP group 1.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   [SwitchA-Vlan-interface2] return
   ```

3. Configure Switch B:

   # Specify 10.10.10.10 as the source address of BFD echo packets.

   ```
   <SwitchB> system-view

    Master IP        : 192.168.0.102
  VRRP Track Information:
    Track Object   : 1             State : Negative          Switchover
```

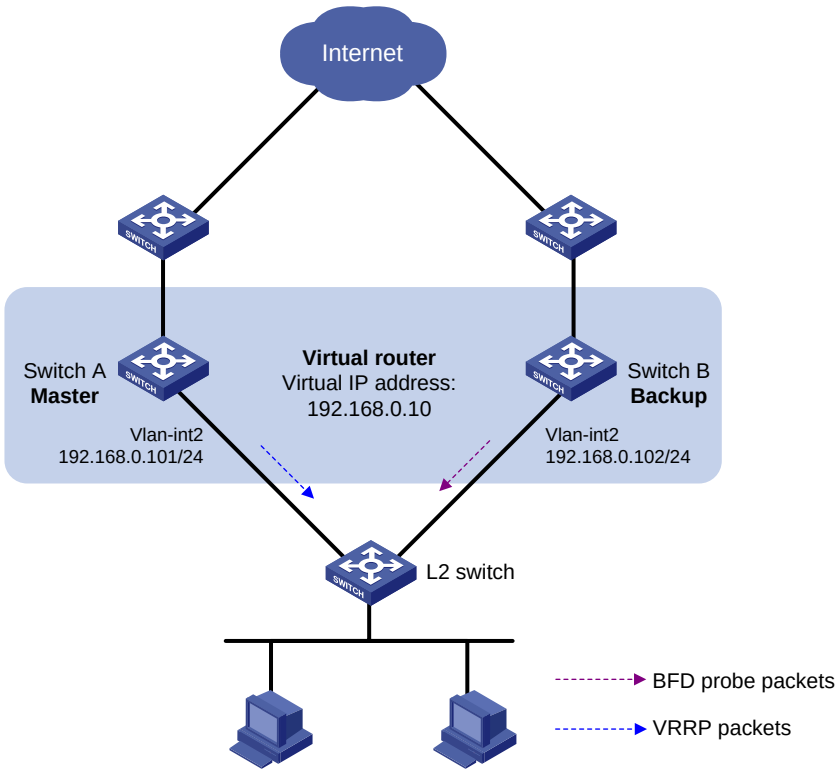
The output shows that when the echo-mode BFD session detects that Switch A fails, the Track module notifies VRRP to change the status of Switch B to master. The backup can quickly preempt as the master without waiting for a period three times the advertisement interval plus the Skew_Time.

Example: Configuring a control-mode BFD session for a VRRP backup to monitor the master

Network configuration



As shown in Figure 4:

- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 192.168.0.10.
- The default gateway of the hosts in the LAN is 192.168.0.10.

Configure VRRP-Track-BFD (control mode) collaboration to monitor the master on the backup and meet the following requirements:

- When Switch A operates correctly, the hosts in the LAN access the Internet through Switch A.
- When Switch A fails, the backup (Switch B) can detect the state change of the master through the control-mode BFD session and become the new master. The hosts in the LAN access the Internet through Switch B.

Figure 4 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 4. (Details not shown.)
2. Configure Switch A:

   # Create VRRP group 1, and configure virtual IP address 192.168.0.10 for the group.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   ```

   # Set the priority of Switch A to 110 in VRRP group 1.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   [SwitchA-Vlan-interface2] return
   ```

   # Create track entry 1, and associate it with the control-mode BFD session to verify the reachability of Switch B.

   ```
   [SwitchA] track 1 bfd ctrl interface vlan-interface 2 remote ip 192.168.0.102 local
   ip 192.168.0.101
   [SwitchA-track-1] quit
   ```

3. Configure Switch B:

   # Create VRRP group 1, and configure virtual IP address 192.168.0.10 for the group.

   ```
   <SwitchB> system-view
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   ```

   # Configure VRRP group 1 to monitor track entry 1 so Switch B can take over as the master once the track entry changes to the Negative state.

   ```
   [SwitchB-Vlan-interface2] vrrp vrid 1 track 1 switchover
   [SwitchB-Vlan-interface2] return
   ```

   # Create track entry 1, and associate it with the control-mode BFD session to verify the reachability of Switch A.

   ```
   [SwitchB] track 1 bfd ctrl interface vlan-interface 2 remote ip 192.168.0.101 local
   ip 192.168.0.102
   [SwitchB-track-1] quit
   ```

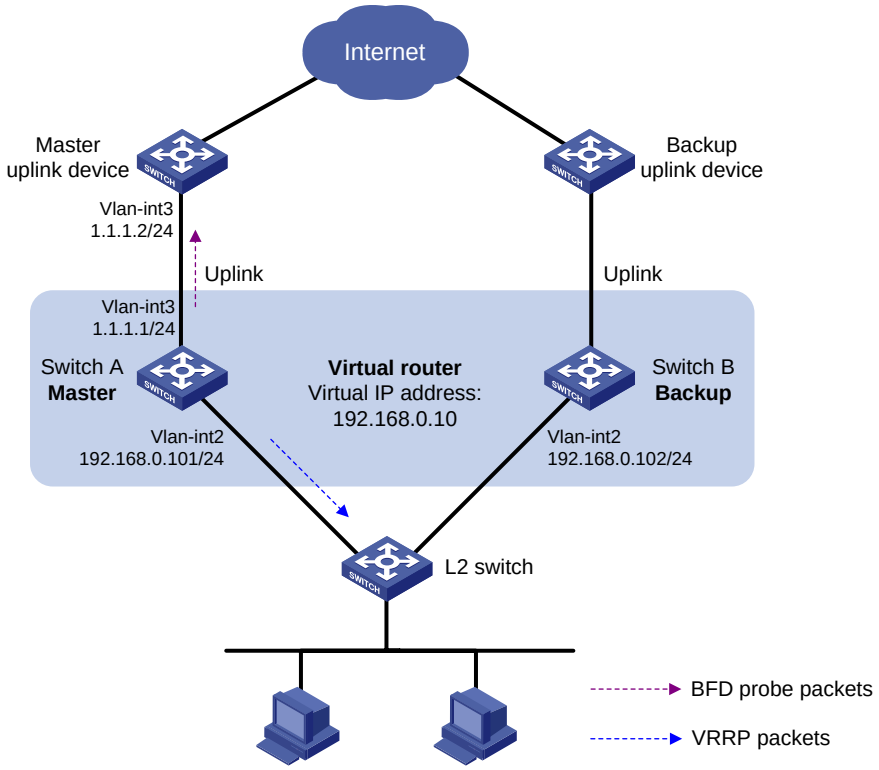
Example: Configuring an echo-mode BFD session for the VRRP master to monitor the uplink

Network configuration



As shown in Figure 5:

- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 192.168.0.10.
- The default gateway of the hosts in the LAN is 192.168.0.10.

Configure VRRP-Track-BFD (echo mode) collaboration to monitor the uplink on the master and meet the following requirements:

- When Switch A operates correctly, the hosts in the LAN access the Internet through Switch A.
- When Switch A detects that the uplink is down through the echo-mode BFD session, Switch B can preempt as the master. The hosts in the LAN can access the Internet through Switch B.

Figure 5 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 5. (Details not shown.)
2. Configure Switch A:

   # Specify 10.10.10.10 as the source address of BFD echo packets.

   ```
   <SwitchA> system-view
   [SwitchA] bfd echo-source-ip 10.10.10.10
   ```

   # Create track entry 1 for the echo-mode BFD session to verify the reachability of the uplink device (1.1.1.2).

   ```
   [SwitchA] track 1 bfd echo interface vlan-interface 3 remote ip 1.1.1.2 local ip
   1.1.1.1
   [SwitchA-track-1] quit
   ```

   # Create VRRP group 1, and specify 192.168.0.10 as the virtual IP address of the group.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   ```

   # Set the priority of Switch A to 110 in VRRP group 1.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   ```

   # Associate VRRP group 1 with track entry 1 and decrease the router priority by 20 when the state of track entry 1 changes to Negative.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 track 1 priority reduced 20
   [SwitchA-Vlan-interface2] return
   ```

3. On Switch B, create VRRP group 1, and specify 192.168.0.10 as the virtual IP address of the group.

   ```
   <SwitchB> system-view
   [SwitchB] interface vlan-interface 2
   ```

```

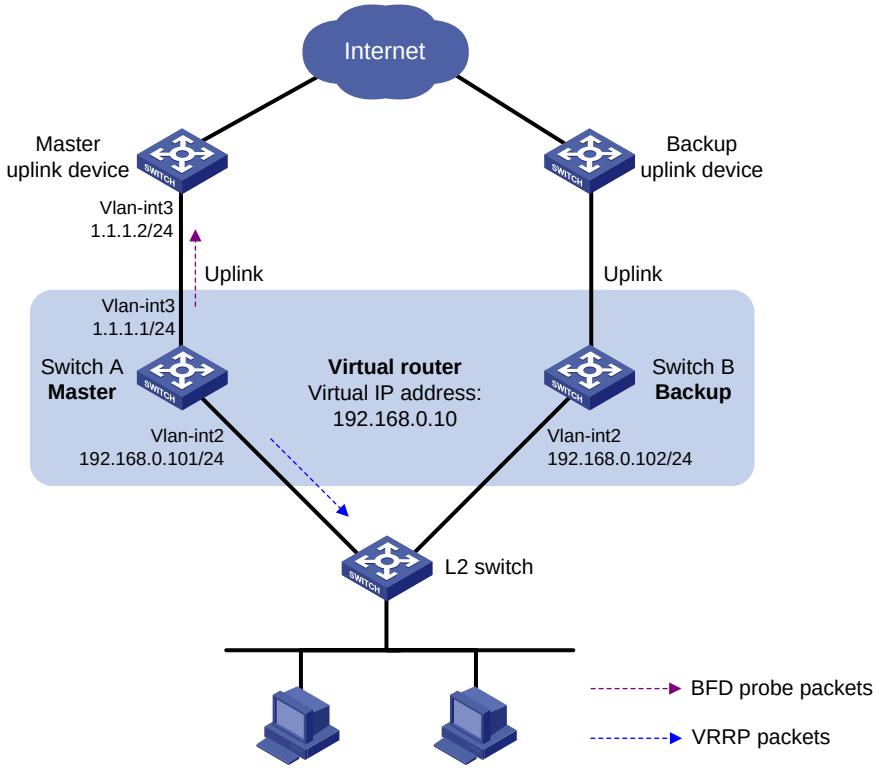
The output shows that when Switch A detects that the uplink fails through the echo-mode BFD session, it decreases its priority by 20. Switch B then preempts as the master.

Example: Configuring a control-mode BFD session for the VRRP master to monitor the uplink

Network configuration



As shown in Figure 6:

- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 192.168.0.10.
- The default gateway of the hosts in the LAN is 192.168.0.10.

Configure VRRP-Track-BFD (control mode) collaboration to monitor the uplink on the master and meet the following requirements:

- When Switch A operates correctly, the hosts in the LAN access the Internet through Switch A.
- When Switch A detects that the uplink is down through the control-mode BFD session, Switch B can preempt as the master. The hosts in the LAN can access the Internet through Switch B.

Figure 6 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 6. (Details not shown.)
2. Configure Switch A:

   # Create VRRP group 1, and specify 192.168.0.10 as the virtual IP address of the group.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   ```

Set the priority of Switch A to 110 in VRRP group 1.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
```

Associate VRRP group 1 with track entry 1 and decrease the router priority by 20 when the state of track entry 1 changes to Negative.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 track 1 priority reduced 20
[SwitchA-Vlan-interface2] quit
```

Create track entry 1 for the control-mode BFD session to monitor the reachability of the uplink device (1.1.1.2).

```
[SwitchA] track 1 bfd ctrl interface vlan-interface 3 remote ip 1.1.1.2 local ip
1.1.1.1
[SwitchA-track-1] quit
```

3. On the uplink device of Switch A, create track entry 1 and associate it with the control-mode BFD session to verify the reachability of the Switch A.

```
<Master> system-view
[Master] track 1 bfd ctrl interface vlan-interface 3 remote ip 1.1.1.1 local ip 1.1.1.2
```

4. On Switch B, create VRRP group 1, and specify 192.168.0.10 as the virtual IP address of the group.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
[SwitchB-Vlan-interface2] return
```

     Master IP        : 192.168.0.102
```

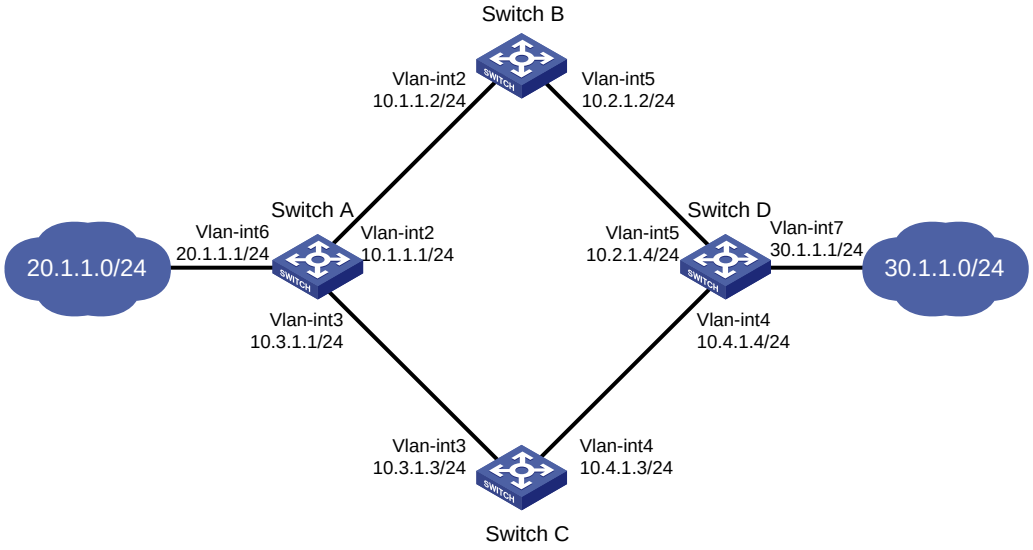
The output shows that when Switch A detects that the uplink fails through the control-mode BFD session, it decreases its priority by 20. Switch B then preempts as the master.

Example: Configuring static routing-Track-NQA collaboration

Network configuration



As shown in Figure 7:

- Switch A is the default gateway of the hosts in network 20.1.1.0/24.
- Switch D is the default gateway of the hosts in network 30.1.1.0/24.
- Hosts in the two networks communicate with each other through static routes.

To ensure network availability, configure route backup and static routing-Track-NQA collaboration on Switch A and Switch D as follows:

- On Switch A, assign a higher priority to the static route to 30.1.1.0/24 with next hop Switch B. This route is the master route. The static route to 30.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the backup route takes effect. Switch A forwards packets to 30.1.1.0/24 through Switch C.
- On Switch D, assign a higher priority to the static route to 20.1.1.0/24 with next hop Switch B. This route is the master route. The static route to 20.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the backup route takes effect. Switch D forwards packets to 20.1.1.0/24 through Switch C.

Figure 7 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 7. (Details not shown.)
2. Configure Switch A:

   # Configure a static route to 30.1.1.0/24 with next hop 10.1.1.2 and the default priority (60). Associate this static route with track entry 1.

   ```
   <SwitchA> system-view
   [SwitchA] ip route-static 30.1.1.0 24 10.1.1.2 track 1
   ```

   # Configure a static route to 30.1.1.0/24 with next hop 10.3.1.3 and priority 80.

   ```
   [SwitchA] ip route-static 30.1.1.0 24 10.3.1.3 preference 80
   ```

   # Configure a static route to 10.2.1.4 with next hop 10.1.1.2.

   ```
   [SwitchA] ip route-static 10.2.1.4 24 10.1.1.2
   ```

   # Create an NQA operation with administrator name **admin** and operation tag **test**.

   ```
   [SwitchA] nqa entry admin test
   ```

   # Specify the **ICMP echo** operation type.

   ```
   [SwitchA-nqa-admin-test] type icmp-echo
   ```

   # Specify 10.2.1.4 as the destination address of the operation.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] destination ip 10.2.1.4
   ```

   # Specify 10.1.1.2 as the next hop of the operation.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] next-hop ip 10.1.1.2
   ```

   # Configure the ICMP echo operation to repeat every 100 milliseconds.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] frequency 100
   ```

   # Configure reaction entry 1, specifying that five consecutive probe failures trigger the Track module.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] reaction 1 checked-element probe-fail
   threshold-type consecutive 5 action-type trigger-only
   [SwitchA-nqa-admin-test-icmp-echo] quit
   ```

   # Start the NQA operation.

   ```
   [SwitchA] nqa schedule admin test start-time now lifetime forever
   ```

   # Configure track entry 1, and associate it with reaction entry 1 of the NQA operation.

```
[SwitchA] track 1 nqa entry admin test reaction 1
[SwitchA-track-1] quit
```

3. Configure Switch B:

Configure a static route to 30.1.1.0/24 with next hop 10.2.1.4.

```
<SwitchB> system-view
[SwitchB] ip route-static 30.1.1.0 24 10.2.1.4
```

Configure a static route to 20.1.1.0/24 with next hop 10.1.1.1.

```
[SwitchB] ip route-static 20.1.1.0 24 10.1.1.1
```

4. Configure Switch C:

Configure a static route to 30.1.1.0/24 with next hop 10.4.1.4.

```
<SwitchC> system-view
[SwitchC] ip route-static 30.1.1.0 24 10.4.1.4
```

Configure a static route to 20.1.1.0/24 with next hop 10.3.1.1.

```
[SwitchC] ip route-static 20.1.1.0 24 10.3.1.1
```

5. Configure Switch D:

Configure a static route to 20.1.1.0/24 with next hop 10.2.1.2 and the default priority (60). Associate this static route with track entry 1.

```
<SwitchD> system-view
[SwitchD] ip route-static 20.1.1.0 24 10.2.1.2 track 1
```

Configure a static route to 20.1.1.0/24 with next hop 10.4.1.3 and priority 80.

```
[SwitchD] ip route-static 20.1.1.0 24 10.4.1.3 preference 80
```

Configure a static route to 10.1.1.1 with next hop 10.2.1.2.

```
[SwitchD] ip route-static 10.1.1.1 24 10.2.1.2
```

Create an NQA operation with administrator name **admin** and operation tag **test**.

```
[SwitchD] nqa entry admin test
```

Specify the **ICMP echo** operation type.

```
[SwitchD-nqa-admin-test] type icmp-echo
```

Specify 10.1.1.1 as the destination address of the operation.

```
[SwitchD-nqa-admin-test-icmp-echo] destination ip 10.1.1.1
```

Specify 10.2.1.2 as the next hop of the operation.

```
[SwitchD-nqa-admin-test-icmp-echo] next-hop ip 10.2.1.2
```

Configure the ICMP echo operation to repeat every 100 milliseconds.

```
[SwitchD-nqa-admin-test-icmp-echo] frequency 100
```

Configure reaction entry 1, specifying that five consecutive probe failures trigger the Track module.

```
[SwitchD-nqa-admin-test-icmp-echo] reaction 1 checked-element probe-fail
threshold-type consecutive 5 action-type trigger-only
[SwitchD-nqa-admin-test-icmp-echo] quit
```

Start the NQA operation.

```
[SwitchD] nqa schedule admin test start-time now lifetime forever
```

Configure track entry 1, and associate it with reaction entry 1 of the NQA operation.

```
[SwitchD] track 1 nqa entry admin test reaction 1
[SwitchD-track-1] quit
```

Verifying the configuration

Display information about the track entry on Switch A.

```
[SwitchA] display track all
```

```
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: NQA
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    NQA entry: admin test
    Reaction: 1
    Remote IP/URL: 10.2.1.4
    Local IP:--
    Interface:--
```

The output shows that the status of the track entry is Positive, indicating that the NQA operation has succeeded and the master route is available.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 10       Routes : 10

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.1.1.0/24         Direct 0    0            10.1.1.1        Vlan2
10.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0

10.3.1.1/32         Direct 0    0            127.0.0.1       InLoop0
20.1.1.0/24         Direct 0    0            20.1.1.1        Vlan6
20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
30.1.1.0/24         Static 60   0            10.1.1.2        Vlan2
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Switch A forwards packets to 30.1.1.0/24 through Switch B.

Remove the IP address of interface VLAN-interface 2 on Switch B.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] undo ip address
```

Display information about the track entry on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Negative
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: NQA
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    NQA entry: admin test
    Reaction: 1
    Remote IP/URL: 10.2.1.4
    Local IP:--
    Interface:--
```

The output shows that the status of the track entry is Negative, indicating that the NQA operation has failed and the master route is unavailable.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 10       Routes : 10

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.1.1.0/24         Direct 0    0            10.1.1.1        Vlan2

5 packet(s) transmitted, 5 packet(s) received, 0.00% packet loss
round-trip min/avg/max/std-dev = 1/1/2/1 ms
```

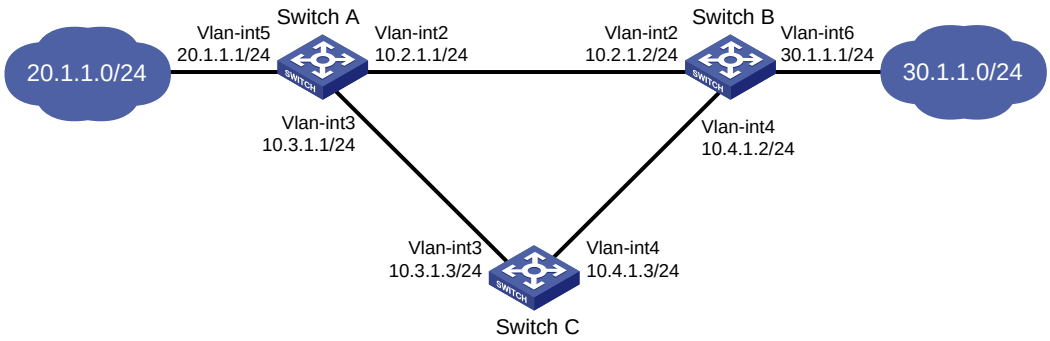
Example: Configuring static routing-Track-BFD (echo mode) collaboration

Network configuration



As shown in Figure 8:

- Switch A is the default gateway of the hosts in network 20.1.1.0/24.
- Switch B is the default gateway of the hosts in network 30.1.1.0/24.
- Hosts in the two networks communicate with each other through static routes.

To ensure network availability, configure route backup and static routing-Track-BFD (echo mode) collaboration on Switch A and Switch B as follows:

- On Switch A, assign a higher priority to the static route to 30.1.1.0/24 with next hop Switch B. This route is the master route. The static route to 30.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the echo-mode BFD session can quickly detect the route failure to make the backup route take effect.
- On Switch B, assign a higher priority to the static route to 20.1.1.0/24 with next hop Switch A. This route is the master route. The static route to 20.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the echo-mode BFD session can quickly detect the route failure to make the backup route take effect.

Figure 8 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 8. (Details not shown.)
2. Configure Switch A:

   # Configure a static route to 30.1.1.0/24 with next hop 10.2.1.2 and the default priority (60). Associate this static route with track entry 1.

   ```
   <SwitchA> system-view
   [SwitchA] ip route-static 30.1.1.0 24 10.2.1.2 track 1
   ```

   # Configure a static route to 30.1.1.0/24 with next hop 10.3.1.3 and priority 80.

   ```
   [SwitchA] ip route-static 30.1.1.0 24 10.3.1.3 preference 80
   ```

   # Specify 10.10.10.10 as the source address of BFD echo packets.

   ```
   [SwitchA] bfd echo-source-ip 10.10.10.10
   ```

   # Configure track entry 1, and associate it with the echo-mode BFD session to verify the connectivity between Switch A and Switch B.

   ```
   [SwitchA] track 1 bfd echo interface vlan-interface 2 remote ip 10.2.1.2 local ip
   10.2.1.1
   [SwitchA-track-1] quit
   ```

3. Configure Switch B:

   # Configure a static route to 20.1.1.0/24 with next hop 10.2.1.1 and the default priority (60). Associate this static route with track entry 1.

```
<SwitchB> system-view
[SwitchB] ip route-static 20.1.1.0 24 10.2.1.1 track 1
```

   # Configure a static route to 20.1.1.0/24 with next hop 10.4.1.3 and priority 80.

```
[SwitchB] ip route-static 20.1.1.0 24 10.4.1.3 preference 80
```

   # Specify 1.1.1.1 as the source address of BFD echo packets.

```
[SwitchB] bfd echo-source-ip 1.1.1.1
```

   # Configure track entry 1, and associate it with the echo-mode BFD session to verify the connectivity between Switch B and Switch A.

```
[SwitchB] track 1 bfd echo interface vlan-interface 2 remote ip 10.2.1.1 local ip
10.2.1.2
[SwitchB-track-1] quit
```

4. Configure Switch C:

   # Configure a static route to 30.1.1.0/24 with next hop 10.4.1.2.

```
<SwitchC> system-view
[SwitchC] ip route-static 30.1.1.0 24 10.4.1.2
```

   # Configure a static route to 20.1.1.0/24 with next hop 10.3.1.1.

```
[SwitchC] ip route-static 20.1.1.0 24 10.3.1.1
```

Verifying the configuration

Display information about the track entry on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: BFD echo
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    BFD session mode: Echo
    Outgoing interface: Vlan-interface2
    Remote IP: 10.2.1.2
    Local IP: 10.2.1.1
```

The output shows that the status of the track entry is Positive, indicating that next hop 10.2.1.2 is reachable.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 9        Routes : 9

Destination/Mask    Proto  Pre  Cost         NextHop         Interface

30.1.1.0/24         Static 60   0            10.2.1.2        Vlan2
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Switch A forwards packets to 30.1.1.0/24 through Switch B. The master static route has taken effect.

Remove the IP address of VLAN-interface 2 on Switch B.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] undo ip address
```

Display information about the track entry on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Negative
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: BFD echo
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    BFD session mode: Echo
    Outgoing interface: Vlan-interface2
    VPN instance name: --
    Remote IP: 10.2.1.2
    Local IP: 10.2.1.1
```

The output shows that the status of the track entry is Negative, indicating that next hop 10.2.1.2 is unreachable.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 9        Routes : 9

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.2.1.0/24         Direct 0    0            10.2.1.1        Vlan2
10.2.1.1/32         Direct 0    0            127.0.0.1       InLoop0
10.3.1.0/24         Direct 0    0            10.3.1.1        Vlan3
10.3.1.1/32         Direct 0    0            127.0.0.1       InLoop0
20.1.1.0/24         Direct 0    0            20.1.1.1        Vlan5
20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
30.1.1.0/24         Static 80   0            10.3.1.3        Vlan3
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Switch A forwards packets to 30.1.1.0/24 through Switch C. The backup static route has taken effect.

Verify that the hosts in 20.1.1.0/24 can communicate with the hosts in 30.1.1.0/24 when the master route fails.

```
[SwitchA] ping -a 20.1.1.1 30.1.1.1
Ping 30.1.1.1: 56  data bytes, press CTRL_C to break
Reply from 30.1.1.1: bytes=56 Sequence=1 ttl=254 time=2 ms
Reply from 30.1.1.1: bytes=56 Sequence=2 ttl=254 time=1 ms
```

```
Reply from 30.1.1.1: bytes=56 Sequence=3 ttl=254 time=1 ms
Reply from 30.1.1.1: bytes=56 Sequence=4 ttl=254 time=2 ms
Reply from 30.1.1.1: bytes=56 Sequence=5 ttl=254 time=1 ms

--- Ping statistics for 30.1.1.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.00% packet loss
round-trip min/avg/max/std-dev = 1/1/2/1 ms
```

Verify that the hosts in 30.1.1.0/24 can still communicate with the hosts in 20.1.1.0/24 when the master route fails.

```
[SwitchB] ping -a 30.1.1.1 20.1.1.1
Ping 20.1.1.1: 56  data bytes, press CTRL_C to break
Reply from 20.1.1.1: bytes=56 Sequence=1 ttl=254 time=2 ms

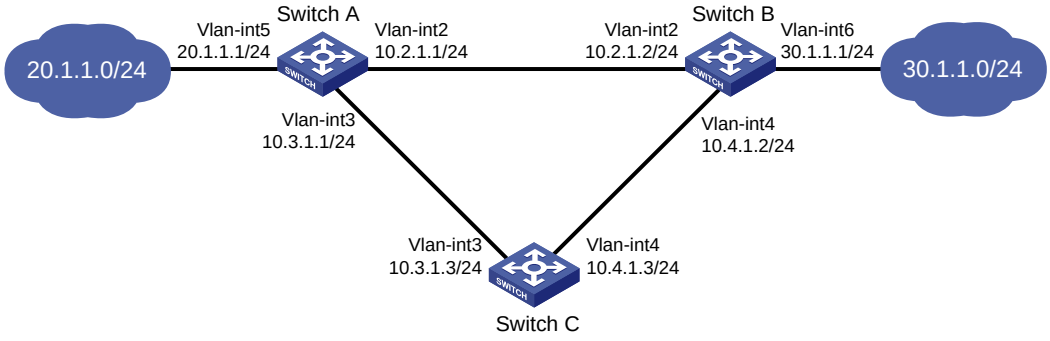
--- Ping statistics for 20.1.1.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.00% packet loss
round-trip min/avg/max/std-dev = 1/1/2/1 ms
```

Example: Configuring static routing-Track-BFD (control mode) collaboration

Network configuration



As shown in Figure 9:

- Switch A is the default gateway of the hosts in network 20.1.1.0/24.
- Switch B is the default gateway of the hosts in network 30.1.1.0/24.
- Hosts in the two networks communicate with each other through static routes.

To ensure network availability, configure route backup and static routing-Track-BFD (control mode) collaboration on Switch A and Switch B as follows:

- On Switch A, assign a higher priority to the static route to 30.1.1.0/24 with next hop Switch B. This route is the master route. The static route to 30.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the control-mode BFD session can quickly detect the route failure to make the backup route take effect.
- On Switch B, assign a higher priority to the static route to 20.1.1.0/24 with next hop Switch A. This route is the master route. The static route to 20.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the control-mode BFD session can quickly detect the route failure to make the backup route take effect.

Figure 9 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 9. (Details not shown.)
2. Configure Switch A:

   # Configure a static route to 30.1.1.0/24 with next hop 10.2.1.2 and the default priority (60). Associate this static route with track entry 1.

   ```
   <SwitchA> system-view
   [SwitchA] ip route-static 30.1.1.0 24 10.2.1.2 track 1
   ```

   # Configure a static route to 30.1.1.0/24 with next hop 10.3.1.3 and priority 80.

   ```
   [SwitchA] ip route-static 30.1.1.0 24 10.3.1.3 preference 80
   ```

   # Configure track entry 1, and associate it with the control-mode BFD session to verify the connectivity between Switch A and Switch B.

   ```
   [SwitchA] track 1 bfd ctrl interface vlan-interface 2 remote ip 10.2.1.2 local ip 10.2.1.1
   [SwitchA-track-1] quit
   ```

3. Configure Switch B:

   # Configure a static route to 20.1.1.0/24 with next hop 10.2.1.1 and the default priority (60). Associate this static route with track entry 1.

   ```
   <SwitchB> system-view
   [SwitchB] ip route-static 20.1.1.0 24 10.2.1.1 track 1
   ```

   # Configure a static route to 20.1.1.0/24 with next hop 10.4.1.3 and priority 80.

   ```
   [SwitchB] ip route-static 20.1.1.0 24 10.4.1.3 preference 80
   ```

   # Configure track entry 1, and associate it with the control-mode BFD session to verify the connectivity between Switch B and Switch A.

   ```
   [SwitchB] track 1 bfd ctrl interface vlan-interface 2 remote ip 10.2.1.1 local ip 10.2.1.2
   [SwitchB-track-1] quit
   ```

4. Configure Switch C:

   # Configure a static route to 30.1.1.0/24 with next hop 10.4.1.2.

   ```
   <SwitchC> system-view
   [SwitchC] ip route-static 30.1.1.0 24 10.4.1.2
   ```

   # Configure a static route to 20.1.1.0/24 with next hop 10.3.1.1.

   ```
   [SwitchC] ip route-static 20.1.1.0 24 10.3.1.1
   ```

Verifying the configuration

Display information about the track entry on Switch A.

```
[SwitchA] display track all
```

```
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: BFD ctrl
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    BFD session mode: Ctrl
    Outgoing interface: Vlan-interface2
    VPN instance name: --
    Remote IP: 10.2.1.2
    Local IP: 10.2.1.1
```

The output shows that the status of the track entry is Positive, indicating that next hop 10.2.1.2 is reachable.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 9        Routes : 9

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.2.1.0/24         Direct 0    0            10.2.1.1        Vlan2
10.2.1.1/32         Direct 0    0            127.0.0.1       InLoop0

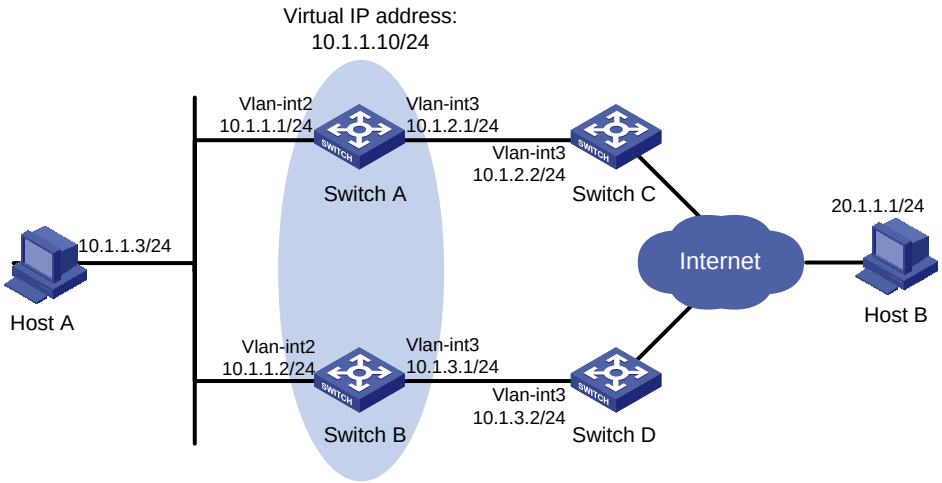
Reply from 20.1.1.1: bytes=56 Sequence=5 ttl=254 time=1 ms

--- Ping statistics for 20.1.1.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.00% packet loss
round-trip min/avg/max/std-dev = 1/1/2/1 ms
```

Example: Configuring VRRP-Track-interface management collaboration

Network configuration



As shown in Figure 10:

- Host A requires access to Host B. The default gateway of Host A is 10.1.1.10/24.
- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 10.1.1.10.

Configure VRRP-Track-interface management collaboration to monitor the uplink interface on the master and meet the following requirements:

- When Switch A operates correctly, Switch A forwards packets from Host A to Host B.
- When VRRP detects a fault on the uplink interface of Switch A through the interface management module, Switch B forwards packets from Host A to Host B.

Figure 10 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 10. (Details not shown.)
2. Configure Switch A:

   # Configure track entry 1 and associate it with the link status of the uplink interface VLAN-interface 3.

   ```
   [SwitchA] track 1 interface vlan-interface 3
   [SwitchA-track-1] quit
   ```

   # Create VRRP group 1 and configure virtual IP address 10.1.1.10 for the group.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
   ```

   # Set the priority of Switch A to 110 in VRRP group 1.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   ```

   # Associate VRRP group 1 with track entry 1 and decrease the router priority by 30 when the state of track entry 1 changes to Negative.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 track 1 priority reduced 30
   ```

3. On Switch B, create VRRP group 1, and configure virtual IP address 10.1.1.10 for the group.

   ```
   <SwitchB> system-view
   ```

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
```

Verifying the configuration

Ping Host B from Host A to verify that Host B is reachable. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp verbose
IPv4 Virtual Router Information:

    Master IP         : 10.1.1.2
  VRRP Track Information:
    Track Object   : 1              State : Negative          Pri Reduced : 30
```

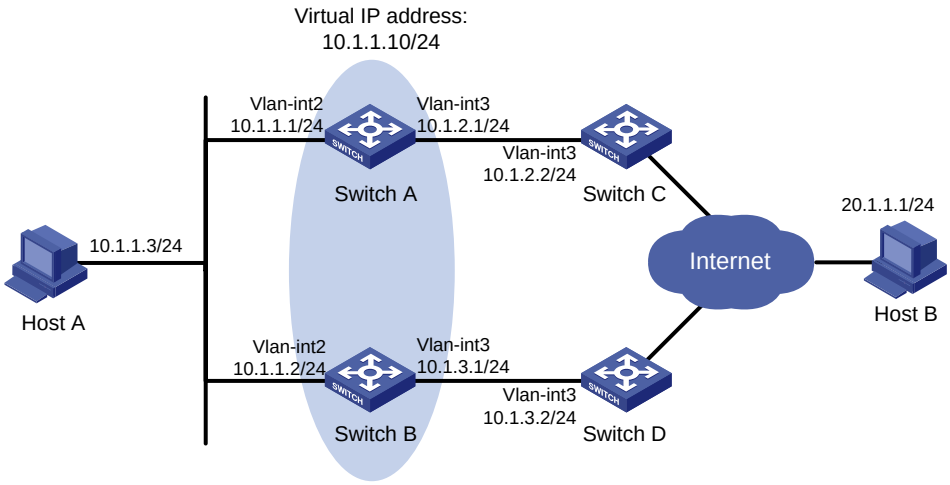
Display detailed information about VRRP group 1 on Switch B.

```
[SwitchB-Vlan-interface2] display vrrp verbose
IPv4 Virtual Router Information:
 Running Mode      : Standard
 Total number of virtual routers : 1
   Interface Vlan-interface2
     VRID              : 1                Adver Timer   : 100
     Admin Status      : Up               State         : Master
     Config Pri        : 100              Running Pri   : 100
     Preempt Mode      : Yes              Delay Time    : 0
     Auth Type         : Not supported
     Version           : 3
     Virtual IP        : 10.1.1.10
     Virtual MAC       : 0000-5e00-0101
     Master IP         : 10.1.1.2
```

The output shows that Switch A becomes the backup, and Switch B becomes the master. Switch B forwards packets from Host A to Host B.

Example: Configuring VRRP-Track-route management collaboration

Network configuration



As shown in Figure 11:

- Host A requires access to Host B. The default gateway of Host A is 10.1.1.10/24.
- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 10.1.1.10.
- BGP peer relationships are established between Switch A and Switch C and between Switch B and Switch D. Switch C and Switch D advertise the default route 0.0.0.0/0 to Switch A and Switch B.

Configure VRRP-Track-route management collaboration to meet the following requirements:

- When Switch A operates correctly, Switch A forwards packets from Host A to Host B.
- When VRRP detects the removal of the default route from the routing table of Switch A through route management, Switch B forwards packets from Host A to Host B.

Figure 11 Network diagram

Procedure

1. Configure the IP address of each interface, as shown in Figure 11. (Details not shown.)
2. Establish an IBGP peer relationship between Switch A and Switch C, and configure Switch C to advertise the default route 0.0.0.0/0 to Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA-bgp-default] peer 10.1.2.2 as-number 100
[SwitchA-bgp-default] address-family ipv4
[SwitchA-bgp-default-ipv4] peer 10.1.2.2 enable
<SwitchC> system-view
[SwitchC] bgp 100
[SwitchC-bgp-default] peer 10.1.2.1 as-number 100
[SwitchC-bgp-default] address-family ipv4
[SwitchC-bgp-default-ipv4] peer 10.1.2.1 enable
[SwitchC-bgp-default-ipv4] peer 10.1.2.1 default-route-advertise
[SwitchC-bgp-default-ipv4] quit
```

3. Configure Switch B and Switch D in the same way Switch A and Switch C are configured. (Details not shown.)
4. Configure Track and VRRP on Switch A:

   # Configure track entry 1, and associate it with the default route 0.0.0.0/0.

```
[SwitchA] track 1 ip route 0.0.0.0 0.0.0.0 reachability
[SwitchA-track-1] quit
```

   # Create VRRP group 1, and configure virtual IP address 10.1.1.10 for the group.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
```

   # Set the priority of Switch A to 110 in VRRP group 1.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
```

   # Associate VRRP group 1 with track entry 1 and decrease the Switch priority by 30 when the state of track entry 1 changes to Negative.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 track 1 priority reduced 30
[SwitchA-Vlan-interface2] quit
```

5. On Switch B, create VRRP group 1, and configure virtual IP address 10.1.1.10 for the group.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
[SwitchB-Vlan-interface2] quit
```

Verifying the configuration

Ping Host B from Host A to verify that Host B is reachable. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA] display vrrp verbose
IPv4 Virtual Router Information:
 Running Mode       : Standard
 Total number of virtual routers : 1
   Interface Vlan-interface2
     VRID             : 1              Adver Timer  : 100
     Admin Status     : Up             State        : Master

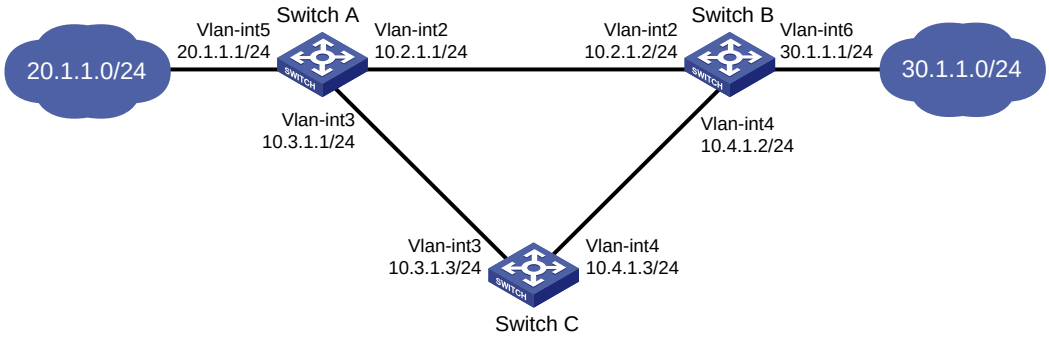
    Virtual MAC       : 0000-5e00-0101
    Master IP         : 10.1.1.2
```

The output shows that Switch A becomes the backup, and Switch B becomes the master. Switch B forwards packets from Host A to Host B.

Example: Configuring static routing-Track-LLDP collaboration

Network requirements

As shown in Figure 12:



- Switch A is the default gateway of the hosts in network 20.1.1.0/24.
- Switch B is the default gateway of the hosts in network 30.1.1.0/24.
- Hosts in the two networks communicate with each other through static routes.

To ensure network availability, configure route backup and static routing-Track-LLDP collaboration on Switch A and Switch B as follows:

- On Switch A, assign a higher priority to the static route to 30.1.1.0/24 with next hop Switch B. This route is the master route. The static route to 30.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the backup route takes effect. Switch A forwards packets destined for 30.1.1.0/24 to Switch C.

- On Switch B, assign a higher priority to the static route to 20.1.1.0/24 with next hop Switch A. This route is the master route. The static route to 20.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the backup route takes effect. Switch B forwards packets destined for 20.1.1.0/24 to Switch C.

Figure 12 Network diagram

Procedure

1. Configure the IP address of each interface, as shown in Figure 12. (Details not shown.)
2. Configure Switch A:

   # Configure a static route to 30.1.1.0/24 with next hop 10.1.1.2 and the default priority (60). Associate this static route with track entry 1.

   ```
   <SwitchA> system-view
   [SwitchA] ip route-static 30.1.1.0 24 10.2.1.2 track 1
   ```

   # Configure a static route to 30.1.1.0/24 with next hop 10.3.1.3 and priority 80.

   ```
   [SwitchA] ip route-static 30.1.1.0 24 10.3.1.3 preference 80
   ```

   # Enable LLDP globally.

   ```
   [SwitchA] lldp global enable
   ```

   # Enable LLDP on GigabitEthernet 1/0/1. (This step is optional because LLDP is enabled on the port by default.)

   ```
   [SwitchA] interface gigabitethernet 1/0/1
   [SwitchA-GigabitEthernet1/0/1] lldp enable
   ```

   # Configure track entry 1 and associate it with the availability of the neighbor for LLDP interface Gigabitethernet 1/0/1.

   ```
   [SwitchA] track 1 lldp neighbor interface gigabitethernet 1/0/1
   [SwitchA-track-1] quit
   ```

3. Configure Switch B:

   # Configure a static route to 20.1.1.0/24 with next hop 10.2.1.1 and the default priority (60). Associate this static route with track entry 1.

   ```
   <SwitchB> system-view
   [SwitchB] ip route-static 20.1.1.0 24 10.2.1.1 track 1
   ```

   # Configure a static route to 20.1.1.0/24 with next hop 10.4.1.3 and priority 80.

   ```
   [SwitchB] ip route-static 20.1.1.0 24 10.4.1.3 preference 80
   ```

   # Enable LLDP globally.

   ```
   [SwitchB] lldp global enable
   ```

   # Enable LLDP on GigabitEthernet 1/0/1. (This step is optional because LLDP is enabled on the port by default.)

   ```
   [SwitchB] interface gigabitethernet 1/0/1
   [SwitchB-GigabitEthernet1/0/1] lldp enable
   ```

Configure track entry 1 and associate it with the availability of the neighbor for LLDP interface GigabitEthernet 1/0/1.

```
[SwitchB] track 1 lldp neighbor interface gigabitethernet 1/0/1
[SwitchB-track-1] quit
```

4. Configure Switch C:

Configure a static route to 30.1.1.0/24 with next hop 10.4.1.2.

```
<SwitchC> system-view
[SwitchC] ip route-static 30.1.1.0 24 10.4.1.2
```

Configure a static route to 20.1.1.0/24 with next hop 10.3.1.1.

```
[SwitchC] ip route-static 20.1.1.0 24 10.3.1.1
```

Verifying the configuration

Display track entry information on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: LLDP
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    LLDP interface: GigabitEthernet1/0/1
```

The output shows that the status of track entry 1 is Positive, indicating that the neighbor of LLDP interface GigabitEthernet 1/0/1 is available. The master route takes effect.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 9        Routes : 9

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.2.1.0/24         Direct 0    0            10.2.1.1        GE1/0/1
10.2.1.1/32         Direct 0    0            127.0.0.1       InLoop0
10.3.1.0/24         Direct 0    0            10.3.1.1        GE1/0/2
10.3.1.1/32         Direct 0    0            127.0.0.1       InLoop0
20.1.1.0/24         Direct 0    0            20.1.1.1        GE1/0/3
20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
30.1.1.0/24         Static 60   0            10.2.1.2        GE1/0/1
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Switch A forwards packets to 30.1.1.0/24 through Switch B.

On Switch B, disable LLDP on GigabitEthernet 1/0/1.

```
<SwitchB> system-view
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] undo lldp enable
```

Display track entry information on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Negative
  Duration: 0 days 0 hours 0 minutes 32 seconds
```

```
  Tracked object type: LLDP
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    LLDP interface: GigabitEthernet1/0/1
```

The output shows that the status of track entry 1 is Negative, indicating that the neighbor of LLDP interface GigabitEthernet 1/0/1 is unavailable. The master route fails.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 9        Routes : 9

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.2.1.0/24         Direct 0    0            10.2.1.1        GE1/0/1
10.2.1.1/32         Direct 0    0            127.0.0.1       InLoop0
10.3.1.0/24         Direct 0    0            10.3.1.1        GE1/0/2
10.3.1.1/32         Direct 0    0            127.0.0.1       InLoop0
20.1.1.0/24         Direct 0    0            20.1.1.1        GE1/0/3
20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
30.1.1.0/24         Static 80   0            10.3.1.3        GE1/0/2
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Switch A forwards packets destined for 30.1.1.0/24 to Switch C. The backup static route has taken effect.

Verify that hosts in 20.1.1.0/24 can communicate with the hosts in 30.1.1.0/24 when the master route fails.

```
[SwitchA] ping -a 20.1.1.1 30.1.1.1
Ping 30.1.1.1: 56  data bytes, press CTRL_C to break
Reply from 30.1.1.1: bytes=56 Sequence=1 ttl=254 time=2 ms
Reply from 30.1.1.1: bytes=56 Sequence=2 ttl=254 time=1 ms
Reply from 30.1.1.1: bytes=56 Sequence=3 ttl=254 time=1 ms
Reply from 30.1.1.1: bytes=56 Sequence=4 ttl=254 time=2 ms
Reply from 30.1.1.1: bytes=56 Sequence=5 ttl=254 time=1 ms

--- Ping statistics for 30.1.1.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.00% packet loss
round-trip min/avg/max/std-dev = 1/1/2/1 ms
```

Verify that the hosts in 30.1.1.0/24 can communicate with the hosts in 20.1.1.0/24 when the master route fails.

```
[SwitchB] ping -a 30.1.1.1 20.1.1.1
Ping 20.1.1.1: 56  data bytes, press CTRL_C to break
Reply from 20.1.1.1: bytes=56 Sequence=1 ttl=254 time=2 ms
Reply from 20.1.1.1: bytes=56 Sequence=2 ttl=254 time=1 ms
Reply from 20.1.1.1: bytes=56 Sequence=3 ttl=254 time=1 ms
Reply from 20.1.1.1: bytes=56 Sequence=4 ttl=254 time=1 ms
Reply from 20.1.1.1: bytes=56 Sequence=5 ttl=254 time=1 ms

--- Ping statistics for 20.1.1.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.00% packet loss
```

```

Configuring process placement

About process placement

Process

A process contains a set of codes and provides specific functionality. For example, an AAA process provides AAA functions.

Each process runs in a protected memory space to prevent problems with one process from impacting the entire system.

Node

The term "node" in this document refers to CPUs that run the Comware system. If the IRF fabric has multiple member devices, each member device has a node.

Process redundancy

The system backs up each active process running on one node to all the other nodes. When an active process fails, one of its standby processes promptly takes over without impacting any other service.

Process redundancy provides the following benefits:

- Improves service availability.
- Enables the system to quickly regain reliability after device status changes in such conditions as removal of an IRF member.

Process placement

The execution of process placement policies varies by the location of active processes.

- An active process running only on the master device does not support placement optimization. If you configure a process placement policy for the process, the system displays a configuration failure message. When such an active process fails, the system automatically restarts the process. The standby processes are used for active/standby switchover and ISSU.
- Some active processes can run on either the master or subordinate device. When such an active process fails, the system uses a placement policy to select a new active process among standby processes.

Default process placement policy

The system provides a default process placement policy that takes effect for all processes. By default, the default process placement policy defines the following rules:

- The active process runs on the CPU of the master, and the standby processes run on the CPU of the subordinate device.
- A process runs at the location where it ran the last time and does not move to any other location during startup or operation.

- The addition of a new node does not impact current active processes. A new active process selects one node with sufficient CPU and memory resources. (You can use the **display cpu-usage** and **display memory** commands to view CPU and memory usage information.)

You can modify the default placement policy in the view you enter by using the **placement program default** command. You can also configure a placement policy for a specific process in the view you enter by using the **placement program** *program-name* [**instance** *instance-name*] command. A placement policy for a process takes precedence over the default process placement policy.

Process placement affinities

You can configure the following settings for a process placement policy to optimize process placement:

- **affinity location-set**—Location affinity, the preference for the process to run on a specific node.
- **affinity location-type**—Location type affinity, the preference for the process to run on a particular type of node. For more information about node types, see "Configuring a location type affinity."
- **affinity program**—Process affinity, the preference for the process to run on the same node as a particular process.
- **affinity self**—Self affinity, the preference for one instance of the process to run on the same node as any other instance of the process.

Affinities include positive affinities (**attract**) and negative affinities (**repulse**), all represented by integers in the range of 1 to 100000.

- The higher the attract value, the stronger the preference.
- The higher the repulse value, the weaker the preference.

Process placement optimization

After you apply new placement policies, the system makes placement decisions based on the new policies, node resources, and topology status. If the new location for an active process is different from the current node, the system changes the state of the process to standby, and uses the standby process on the preferred location as the new active process.

Restrictions and guidelines: process placement configuration

- Configuring process placement on an IRF fabric with only one member device does not change the location of processes. All processes run on the CPU of the IRF member device.
- Configuring process placement on an IRF fabric with multiple member devices places specific active processes to specific CPUs. In case of multiple CPUs, the system performs process redundancy. The number of standby processes and their CPU locations vary by function module. The system by default automatically determines the location for each active process, and process placement optimization is not required. If optimization is required, contact H3C Support to avoid service interruption.
- For an instance of a process, the settings in placement policy view of the instance, in placement policy view of the process, and in default placement policy view are in descending order of priority. For a process, the settings in placement policy view of the process take precedence over the settings in default placement policy view.

- To view the current location of an active process and its predicted new location after optimization, use the **display placement reoptimize** command.

Process placement tasks at a glance

To configure process placement, perform the following tasks:

1. Configuring process placement policy

   Choose the following tasks as needed:

   - Configuring a location affinity
   - Configuring a location type affinity
   - Configuring a process affinity
   - Configuring a self affinity
2. Optimizing process placement

Configuring process placement policy

Configuring a location affinity

1. Enter system view.

   system-view
2. Enter placement process view.
   - Enter default placement process view.
   - **placement program default**
   - Enter specified placement process view.
   - **placement program** { *program-name* [**instance** *instance-name*]

   Settings in default placement process view take effect for all processes. Settings in placement process view take effect only for the specified process.
3. Set the location affinity.

   affinity location-set { **slot** *slot-number* }&<1-5> { **attract** *strength* | **default** | **none** | **repulse** *strength* }

   By default, no location affinity is set.

Configuring a location type affinity

About this task

The following location types are available:

- **current**—Current location of the active process, which can be displayed with the **display placement program** command.
- **paired**—Locations of standby processes.
- **primary**—Master device.

Procedure

1. Enter system view.

   system-view
2. Enter placement process view.

- Enter default placement process view.
- **placement program default**
- Enter specified placement process view.
- **placement program** { *program-name* [**instance** *instance-name*]

Settings in default placement process view take effect for all processes. Settings in placement process view take effect only for the specified process.

3. Set the location type affinity.

   affinity location-type { **current** | **paired** | **primary** } { **attract** *strength* | **repulse** *strength* | **default** | **none** }

   By default, no location type affinity is set.

Configuring a process affinity

1. Enter system view.

   system-view

2. Enter placement process view.
   - Enter default placement process view.
   - **placement program default**
   - Enter specified placement process view.
   - **placement program** { *program-name* [**instance** *instance-name*]

   Settings in default placement process view take effect for all processes. Settings in placement process view take effect only for the specified process.

3. Configure the affinity for the process to run on the same location as another process.

   affinity program *program-name* { **attract** *strength* | **default** | **none** | **repulse** *strength* }

   By default, no process affinity is set.

Configuring a self affinity

About this task

A self affinity determines the preference for one instance of a process to run on the same node as any other instance of the process. The self affinity setting does not take effect for a process that has only one instance.

Procedure

1. Enter system view.

   system-view

2. Enter placement process view.
   - Enter default placement process view.
   - **placement program default**
   - Enter specified placement process view.
   - **placement program** { *program-name* [**instance** *instance-name*]

   Settings in default placement process view take effect for all processes. Settings in placement process view take effect only for the specified process.

3. Configure a self affinity.

   affinity self { **attract** *strength* | **repulse** *strength* | **default** | **none** }

   By default, no self affinity is set.

Optimizing process placement

Restrictions and guidelines

CAUTION:
To avoid neighbor flapping of related protocols, make sure HA features such as NSR or GR are configured for the processes and are stable before optimizing process placement.

To keep the system stable, do not perform any tasks that require process restart when you optimize process placement.

Procedure

1. Enter system view.
   system-view
2. Optimize process placement.
   placement reoptimize

Display and maintenance commands for process placement

Execute **display** commands in any view.

Task	Command
Display service group information.	**display ha service-group** { *program-name* [**instance** *instance-name*] | **all** }
Display the running processes on a specific location.	**display placement location** { **all** | **slot** *slot-number* }
Display process placement policy information.	**display placement policy program** { program-name | **all** | **default** }
Display the location of a process.	**display placement program** { *program-name* | **all** }

Configuring Ethernet OAM

The S5200-EI-G switch series does not support Ethernet OAM.

About Ethernet OAM

Ethernet Operation, Administration, and Maintenance (OAM) is a tool that monitors Layer 2 link status and addresses common link-related issues on the "last mile." Ethernet OAM improves Ethernet management and maintainability. You can use it to monitor the status of the point-to-point link between two directly connected devices.

Major functions of Ethernet OAM

Ethernet OAM provides the following functions:

- **Link performance monitoring**—Monitors the performance indices of a link, including packet loss, delay, and jitter, and collects traffic statistics of various types.
- **Fault detection and alarm**—Checks the connectivity of a link by sending OAM protocol data units (OAMPDUs) and reports to the network administrators when a link error occurs.
- **Remote loopback**—Checks link quality and locates link errors by looping back OAMPDUs.

Ethernet OAMPDUs

Ethernet OAM operates on the data link layer. Ethernet OAM reports the link status by periodically exchanging OAMPDUs between devices, so that the administrator can effectively manage the network.

Ethernet OAMPDUs include the following types shown in Table 1.

Table 1 Functions of different types of OAMPDUs

OAMPDU type	Function
Information OAMPDU	Used for transmitting state information of an Ethernet OAM entity, including the information about the local device and remote devices, and customized information, to the remote Ethernet OAM entity, and maintaining OAM connections.
Event Notification OAMPDU	Used by link monitoring to notify the remote OAM entity when it detects problems on the link in between.
Loopback Control OAMPDU	Used for remote loopback control. By inserting the information used to enable/disable loopback to a loopback control OAMPDU, you can enable/disable loopback on a remote OAM entity.

NOTE:

Throughout this document, an Ethernet OAM-enabled port is called an Ethernet OAM entity or an OAM entity.

How Ethernet OAM works

This section describes the working procedures of Ethernet OAM.

Ethernet OAM connection establishment

OAM connection establishment is also known as the Discovery phase, where an Ethernet OAM entity discovers the remote OAM entity to establish a session.

In this phase, two connected OAM entities exchange Information OAMPDUs to advertise their OAM configuration and capabilities to each other for a comparison. If their Loopback, link detection, and link event settings match, the OAM entities establish an OAM connection.

An OAM entity operates in active mode or passive mode. OAM entities in active mode initiate OAM connections, and OAM entities in passive mode wait and respond to the OAM connection requests. To set up an OAM connection between two OAM entities, you must set at least one entity to operate in active mode.

Table 2 shows the actions that a device can perform in different modes.

Table 2 Active Ethernet OAM mode and passive Ethernet OAM mode

Item	Active Ethernet OAM mode	Passive Ethernet OAM mode
Initiating OAM Discovery	Available	Unavailable
Responding to OAM Discovery	Available	Available
Transmitting Information OAMPDUs	Available	Available
Transmitting Event Notification OAMPDUs	Available	Available
Transmitting Information OAMPDUs without any TLV	Available	Available
Transmitting Loopback Control OAMPDUs	Available	Unavailable
Responding to Loopback Control OAMPDUs	Available	Available

After an Ethernet OAM connection is established, the Ethernet OAM entities exchange Information OAMPDUs at the handshake packet transmission interval to detect the availability of the Ethernet OAM connection. If an Ethernet OAM entity receives no Information OAMPDU within the Ethernet OAM connection timeout time, the Ethernet OAM connection is considered disconnected.

Link monitoring

Error detection in an Ethernet is difficult, especially when the physical connection in the network is not disconnected, but network performance is degrading gradually.

Link monitoring detects link faults in various environments. Ethernet OAM entities monitor link status by exchanging Event Notification OAMPDUs. When detecting one of the link error events listed in Table 3, an OAM entity sends an Event Notification OAMPDU to its peer OAM entity. The network administrator can keep track of network status changes by retrieving the log.

Table 3 Ethernet OAM link error events

Ethernet OAM link events	Description
Errored symbol event	An errored symbol event occurs when the number of detected symbol errors in the detection window (specified number of received symbols) exceeds the predefined threshold.
Errored frame event	An errored frame event occurs when the number of detected error frames in the detection window (specified detection interval) exceeds the predefined threshold.
Errored frame period event	An errored frame period event occurs when the number of frame errors in

Ethernet OAM link events	Description
	the detection window (specified number of received frames) exceeds the predefined threshold.
Errored frame seconds event	An errored frame seconds event occurs when the number of errored frame seconds (the second in which an errored frame appears is called an errored frame second) detected on a port in the detection window (specified detection interval) reaches the predefined threshold.

Remote fault detection

Information OAMPDUs are exchanged periodically among Ethernet OAM entities across established OAM connections. When traffic is interrupted due to device failure or unavailability, the Ethernet OAM entity at the faulty end sends error information to its peer. The Ethernet OAM entity uses the flag field in Information OAMPDUs to indicate the error information (any critical link event type as shown in Table 4). You can use the log information to track ongoing link status and troubleshoot problems promptly.

Table 4 Critical link events

Type	Description	OAMPDU transmission frequencies
Link Fault	Peer link signal is lost.	Once per second.
Dying Gasp	An unexpected fault, such as power failure, occurred.	Non-stop.
Critical Event	An undetermined critical event happened.	Non-stop.

Protocols and standards

IEEE 802.3ah, *Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications*

Restrictions and guidelines: Ethernet OAM configuration

The device's support for sending and receiving Information OAMPDUs carrying critical link events is as follows:

- Can receive Information OAMPDUs carrying the critical link events listed in Table 4.
- Can send Information OAMPDUs carrying Link Fault events.
- Can send Information OAMPDUs carrying Dying Gasp events when the device is rebooted or relevant ports are manually shut down. Physical IRF ports, however, are unable to send this type of OAMPDUs.
- Cannot send Information OAMPDUs carrying Critical Events.

Ethernet OAM tasks at a glance

To configure Ethernet OAM, perform the following tasks:

1. Configuring basic Ethernet OAM functions
2. (Optional.) Configuring the Ethernet OAM connection detection timers
3. (Optional.) Configuring link event detection

- Configuring errored symbol event detection
- Configuring errored frame event detection
- Configuring errored frame period event detection
- Configuring errored frame seconds event detection

4. (Optional.) Configuring the action a port takes after it receives an Ethernet OAM event from the remote end

Configuring basic Ethernet OAM functions

About this task

To set up an Ethernet OAM connection between two Ethernet OAM entities, you must set at least one entity to operate in active mode. An Ethernet OAM entity can initiate OAM connection only in active mode.

Restrictions and guidelines

To change the Ethernet OAM mode on an Ethernet OAM-enabled port, first disable Ethernet OAM on the port.

Procedure

1. Enter system view.
   `System-view`
2. Enter Layer 2/Layer 3 Ethernet port view.
   `interface` *`interface-type interface-number`*
3. Set the Ethernet OAM mode.
   `oam mode` { **`active`** | **`passive`** }
   The default is active Ethernet OAM mode.
4. Enable Ethernet OAM.
   `oam enable`
   Ethernet OAM is disabled by default.

Configuring the Ethernet OAM connection detection timers

About the Ethernet OAM connection detection timers

After an Ethernet OAM connection is established, the Ethernet OAM entities exchange Information OAMPDUs at the handshake packet transmission interval to detect the availability of the Ethernet OAM connection. If an Ethernet OAM entity receives no Information OAMPDU within the Ethernet OAM connection timeout time, the Ethernet OAM connection is considered disconnected.

By adjusting the handshake packet transmission interval and the connection timeout timer, you can change the detection time resolution for Ethernet OAM connections.

Restrictions and guidelines for configuring Ethernet OAM connection detection timers

When you configure Ethernet OAM, follow these restrictions and guidelines:

- You can configure this command in system view or port view. The configuration in system view takes effect on all ports, and the configuration in port view takes effect on the specified port. For a port, the configuration in port view takes precedence.
- After the timeout timer of an Ethernet OAM connection expires, the local OAM entity ages out and terminates its connection with the peer OAM entity. To keep the Ethernet OAM connections stable, set the connection timeout timer to be at least five times the handshake packet transmission interval.

Configuring the Ethernet OAM connection detection timers globally

1. Enter system view.
   System-view
2. Configure the Ethernet OAM handshake packet transmission interval.
   oam global timer hello *interval*
   The default is 1000 milliseconds.
3. Configure the Ethernet OAM connection timeout timer.
   oam global timer keepalive *interval*
   The default is 5000 milliseconds.

Configuring the Ethernet OAM connection detection timers on a port

1. Enter system view.
   System-view
2. Enter Layer 2/Layer 3 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the Ethernet OAM handshake packet transmission interval.
   oam timer hello *interval*
   By default, an interface uses the value configured globally.
4. Configure the Ethernet OAM connection timeout timer.
   oam timer keepalive *interval*
   By default, an interface uses the value configured globally.

Configuring errored symbol event detection

Restrictions and guidelines for configuring errored symbol event detection

You can configure this function in system view or port view. The configuration in system view takes effect on all ports, and the configuration in port view takes effect on the specified port. For a port, the configuration in port view takes precedence.

Configuring errored symbol event detection globally

1. Enter system view.
   system-view
2. Configure the errored symbol event detection window.
   oam global errored-symbol-period window *window-value*
   By default, the errored symbol event detection window is 100000000.
3. Configure the errored symbol event triggering threshold.
   oam global errored-symbol-period threshold *threshold-value*
   By default, the errored symbol event triggering threshold is 1.

Configuring errored symbol event detection on a port

1. Enter system view.
   system-view
2. Enter Layer 2/Layer 3 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the errored symbol event detection window.
   oam errored-symbol-period window *window-value*
   By default, an interface uses the value configured globally.
4. Configure the errored symbol event triggering threshold.
   oam errored-symbol-period threshold *threshold-value*
   By default, an interface uses the value configured globally.

Configuring errored frame event detection

Restrictions and guidelines for configuring errored frame event detection

You can configure this function in system view or port view. The configuration in system view takes effect on all ports, and the configuration in port view takes effect on the specified port. For a port, the configuration in port view takes precedence.

Configuring errored frame event detection globally

1. Enter system view.
   system-view
2. Configure the errored frame event detection window.
   oam global errored-frame window *window-value*
   By default, the errored frame event detection window is 1000 milliseconds.
3. Configure the errored frame event triggering threshold.
   oam global errored-frame threshold *threshold-value*
   By default, the errored frame event triggering threshold is 1.

Configuring errored frame event detection on a port

1. Enter system view.
   system-view
2. Enter Layer 2/Layer 3 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the errored frame event detection window.
   oam errored-frame window *window-value*
   By default, an interface uses the value configured globally.
4. Configure the errored frame event triggering threshold.
   oam errored-frame threshold *threshold-value*
   By default, an interface uses the value configured globally.

Configuring errored frame period event detection

Restrictions and guidelines for configuring errored frame period event detection

You can configure this function in system view or port view. The configuration in system view takes effect on all ports, and the configuration in port view takes effect on the specified port. For a port, the configuration in port view takes precedence.

Configuring errored frame period event detection globally

1. Enter system view.
   system-view
2. Configure the errored frame period event detection window.
   oam global errored-frame-period window *window-value*
   By default, the errored frame period event detection window is 10000000.
3. Configure the errored frame period event triggering threshold.
   oam global errored-frame-period threshold *threshold-value*
   By default, the errored frame period event triggering threshold is 1.

Configuring errored frame period event detection on a port

1. Enter system view.
   system-view
2. Enter Layer 2/Layer 3 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the errored frame period event detection window.
   oam errored-frame-period window *window-value*
   By default, an interface uses the value configured globally.
4. Configure the errored frame period event triggering threshold.
   oam errored-frame-period threshold *threshold-value*

By default, an interface uses the value configured globally.

Configuring errored frame seconds event detection

Restrictions and guidelines for configuring errored frame seconds event detection

- You can configure this function in system view or port view. The configuration in system view takes effect on all ports, and the configuration in port view takes effect on the specified port. For a port, the configuration in port view takes precedence.
- Make sure the errored frame seconds triggering threshold is less than the errored frame seconds detection window. Otherwise, no errored frame seconds event can be generated.

Configuring errored frame seconds event detection globally

1. Enter system view.
   system-view
2. Configure the errored frame seconds event detection window.
   oam global errored-frame-seconds window *window-value*
   By default, the errored frame seconds event detection window is 60000 milliseconds.
3. Configure the errored frame seconds event triggering threshold.
   oam global errored-frame-seconds threshold *threshold-value*
   By default, the errored frame seconds event triggering threshold is 1.

Configuring errored frame seconds event detection on a port

1. Enter system view.
   system-view
2. Enter Layer 2/Layer 3 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the errored frame seconds event detection window.
   oam errored-frame-seconds window *window-value*
   By default, an interface uses the value configured globally.
4. Configure the errored frame seconds event triggering threshold.
   oam errored-frame-seconds threshold *threshold-value*
   By default, an interface uses the value configured globally.

Configuring the action a port takes after it receives an Ethernet OAM event from the remote end

About this task

This feature enables a port to log events and automatically terminate the OAM connection and set the link state to down.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2/Layer 3 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the action the port takes after it receives an Ethernet OAM event from the remote end.
   oam remote-failure { **connection-expired** | **critical-event** | **dying-gasp** | **link-fault** } **action error-link-down**
   By default, the port only logs the Ethernet OAM event it receives from the remote end.

Display and maintenance commands for Ethernet OAM

Execute **display** commands in any view and **reset** commands in user view:

Task	Command
Display information about an Ethernet OAM connection.	**display oam** { **local** | **remote** } [**interface** *interface-type interface-number*]
Display Ethernet OAM configuration.	**display oam configuration** [**interface** *interface-type interface-number*]
Display the statistics on critical events after an Ethernet OAM connection is established.	**display oam critical-event** [**interface** *interface-type interface-number*]
Display the statistics on Ethernet OAM link error events after an Ethernet OAM connection is established.	**display oam link-event** { **local** | **remote** } [**interface** *interface-type interface-number*]
Clear statistics on Ethernet OAM packets and Ethernet OAM link error events.	**reset oam** [**interface** *interface-type interface-number*]

Ethernet OAM configuration examples

Example: Configuring Ethernet OAM

Network configuration

On the network shown in Figure 1, perform the following operations:

- Enable Ethernet OAM on Device A and Device B to auto-detect link errors between the two devices
- Determine the performance of the link between Device A and Device B by collecting statistics about the error frames received by Device A

Figure 1 Network diagram

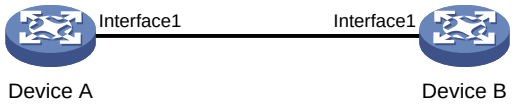

Table 5 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

1. Configure Device A:

   # Configure GigabitEthernet 1/0/1 to operate in active Ethernet OAM mode, and enable Ethernet OAM for it.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] oam mode active
[DeviceA-GigabitEthernet1/0/1] oam enable
```

   # Set the errored frame event detection window to 20000 milliseconds, and set the errored frame event triggering threshold to 10.

```
[DeviceA-GigabitEthernet1/0/1] oam errored-frame window 200
[DeviceA-GigabitEthernet1/0/1] oam errored-frame threshold 10
[DeviceA-GigabitEthernet1/0/1] quit
```

2. Configure Device B:

   # Configure GigabitEthernet 1/0/1 to operate in passive Ethernet OAM mode (the default), and enable Ethernet OAM for it.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] oam mode passive
[DeviceB-GigabitEthernet1/0/1] oam enable
[DeviceB-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Use the **display oam critical-event** command to display the statistics of Ethernet OAM critical link events. For example:

Display the statistics of Ethernet OAM critical link events on all the ports of Device A.

```
[DeviceA] display oam critical-event
-----------[GigabitEthernet1/0/1] -----------
 Local link status   : UP
 Event statistics
   Link fault        : Not occurred
   Dying gasp        : Not occurred
   Critical event    : Not occurred
```

The output shows that no critical link event occurred on the link between Device A and Device B.

Use the **display oam link-event** command to display the statistics of Ethernet OAM link events. For example:

Display Ethernet OAM link event statistics of the local end of Device A.

```
[DeviceA] display oam link-event local
------------ [GigabitEthernet1/0/1] -----------
 Link status: UP
 OAM local errored frame event
   Event time stamp        : 5789 x 100 milliseconds
   Errored frame window    : 200 x 100 milliseconds
   Errored frame threshold : 10 error frames
   Errored frame           : 13 error frames
   Error running total     : 350 error frames
   Event running total     : 17 events
```

The output shows the following:

- 350 errors occurred after Ethernet OAM is enabled on Device A.
- 17 errors were caused by error frames.
- The link is unstable.

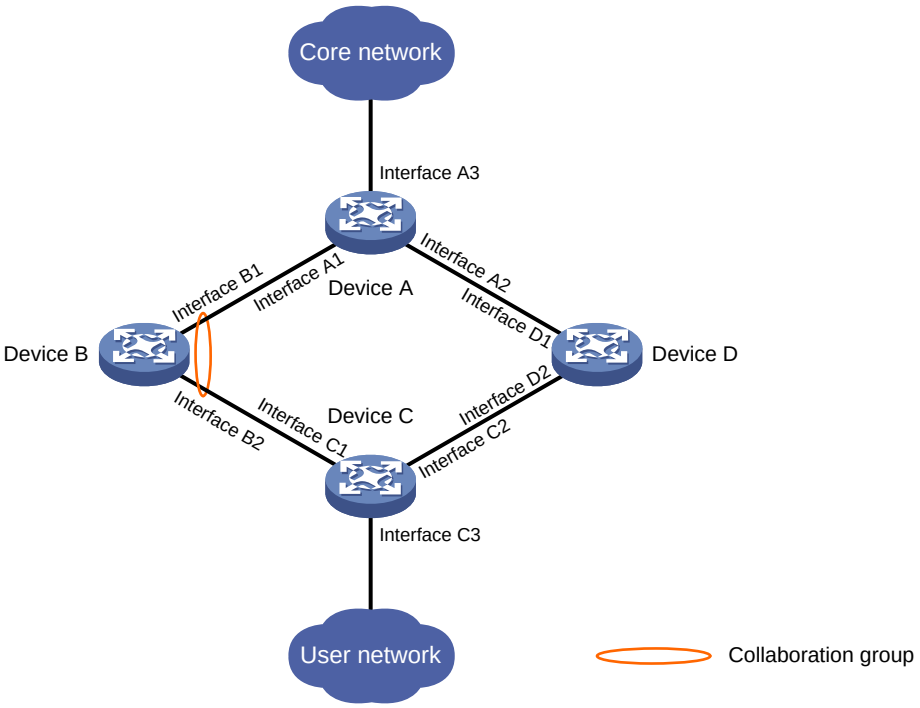
Configuring interface collaboration

About interface collaboration



The interface collaboration feature assigns different interfaces on a device to a collaboration group and associates the states of these interfaces. All member interfaces in a collaboration group can or cannot transmit packets at the same time. This feature is typically used to associate the states of downlink and uplink interfaces.

Typical application

As shown in Figure 1, Device C accesses the core network through Device B. When Interface B1 goes down, the switchover of traffic from Device C to Device D is slow because Interface B2 is still up.

If Interface B1 and Interface B2 belong to one collaboration group, Device B brings down Interface B2 when Interface B1 goes down to achieve fast traffic switchover. Similarly, the device brings down Interface B1 when Interface B2 goes down.

Figure 1 Interface collaboration application scenario

How interface collaboration works

The interface collaboration feature works as follows:

- When any member interface in a collaboration group goes down, the device sets all other member interfaces in the collaboration group to the **Collaboration-down** state. The state of the collaboration group is down, and no member interfaces in the collaboration group can transmit packets.

- When any member interface in **DOWN** or **Collaboration-down** state comes up, the device attempts to bring up all other member interfaces in the collaboration group.
  - If all other member interfaces come up in 10 seconds, the collaboration group comes up. All member interfaces in the collaboration group can transmit packets.
  - If any member interface cannot come up in 10 seconds, the device sets that member interface to **DOWN** state and sets all other member interfaces to the **Collaboration-down** state. The collaboration group goes down, and no member interfaces in the collaboration group can transmit packets.

Restrictions and guidelines: Interface collaboration configuration

This feature cannot be used together with the external security service bypass feature. For more information about external security service bypass, see Layer 2 forwarding configuration in *Layer 2—LAN Switching Configuration Guide*.

Interface collaboration tasks at a glance

To configure interface collaboration, perform the following tasks:

1. Creating a collaboration group
2. Configuring collaboration group member interfaces
3. (Optional.) Configuring the delay for the member interfaces in a collaboration group
4. (Optional.) Removing ineffective member interfaces from all collaboration groups

Prerequisites for interface collaboration

Before configuring interface collaboration, you must enable Monitor Link globally (see "Configuring Monitor Link").

Creating a collaboration group

1. Enter system view.
   `system-view`
2. Create a collaboration group and enter collaboration group view.
   `collaboration-group` *`group-id`*
   By default, no collaboration groups exist.

Configuring collaboration group member interfaces

Restrictions and guidelines

An interface can belong to only one collaboration group.

For a collaboration group to work correctly, do not assign its member interfaces to a redundancy group.

Do not add both an aggregate interface and its member ports to the same collaboration group.

Do not add both Selected ports and Unselected ports in a dynamic aggregation group to the same collaboration group.

If you have configured a member interface as the uplink/downlink interface of a monitor link group, do not configure any other member interface in the same collaboration group as the downlink/uplink interface of any monitor link group.

You can assign only one interface of a link to a collaboration group.

You can configure member interfaces for a collaboration group in collaboration group view or interface view. Configurations made in these views have the same effect.

Configuring a collaboration group member interface in collaboration group view

1. Enter system view.
   system-view
2. Enter collaboration group view.
   collaboration-group *group-id*
3. Configure an interface as a member of the collaboration group.
   port *interface-type interface-number*
   By default, no member interfaces exist in a collaboration group.

Configuring a collaboration group member interface in interface view

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the interface as a member of a collaboration group.
   port collaboration-group *group-id*
   By default, an interface is not a collaboration group member.

Configuring the delay for the member interfaces in a collaboration group to come up

About this task

By default, member interfaces in a collaboration group come up and forward service traffic immediately after the device restarts. Traffic loss occurs if the service modules have not returned to normal state.

Perform this task to enable the member interfaces to come up after a configurable delay time upon a device restart.

Procedure

1. Enter system view.
   system-view

2. Enter collaboration group view.
   collaboration-group *group-id*
3. Configure the delay for the member interfaces in a collaboration group to come up.
   up-delay *delay*
   By default, the delay time is 0 seconds. The member interfaces come up as soon as the device restarts.

Removing ineffective member interfaces from all collaboration groups

About this task

A member interface in a collaboration group becomes ineffective when the card that hosts the interface is removed or changed to another slot or the ID of the IRF member device that hosts the interface changes. This task prevents an ineffective interface from causing all other member interfaces in the same collaboration group to go down.

An ineffective interface cannot be automatically assigned to the original collaboration group when its hosting card is reinstalled or changed back to the original slot or the IRF member ID is changed back to the original ID. You must assign it to the original collaboration group manually.

Procedure

1. Enter system view.
   system-view
2. Enter collaboration group view.
   collaboration-group clean

Display and maintenance commands for interface collaboration

Execute the **display** command in any view:

Task	Command
Display collaboration group information.	**display collaboration-group** { *group-id* | **all** } [**verbose**]

Interface collaboration configuration examples

Example: Configuring interface collaboration for Layer 3 interfaces

Network configuration

As shown in Figure 2, configure interface collaboration on Device B. When GigabitEthernet 1/0/1 on Device B goes down, Device B brings down GigabitEthernet 1/0/2. When GigabitEthernet 1/0/2 on Device B goes down, Device B brings down GigabitEthernet 1/0/1.

Figure 2 Network diagram

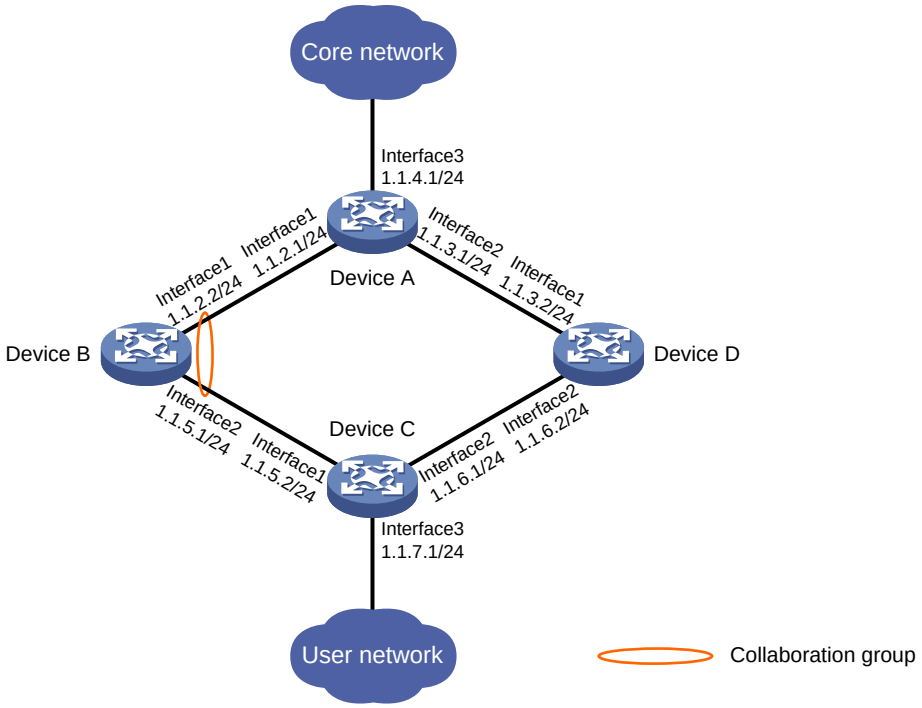


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure routes to enable Device A and Device C to prefer the route through Device B for forwarding traffic to each other. (This example uses static routes):

   # Configure IP addresses for interfaces. (Details not shown.)

   # Configure four static routes on Device A.

   ```
   <DeviceA> system-view
   [DeviceA] ip route-static 1.1.5.0 255.255.255.0 1.1.2.2
   [DeviceA] ip route-static 1.1.7.0 255.255.255.0 1.1.2.2 preference 50
   [DeviceA] ip route-static 1.1.6.0 255.255.255.0 1.1.3.2
   [DeviceA] ip route-static 1.1.7.0 255.255.255.0 1.1.3.2 preference 70
   ```

   # Configure two static routes on Device B.

   ```
   <DeviceB> system-view
   [DeviceB] ip route-static 1.1.4.0 255.255.255.0 1.1.2.1
   [DeviceB] ip route-static 1.1.7.0 255.255.255.0 1.1.5.2
   ```

   # Configure four static routes on Device C.

   ```
   <DeviceC> system-view
   [DeviceC] ip route-static 1.1.2.0 255.255.255.0 1.1.5.1
   [DeviceC] ip route-static 1.1.4.0 255.255.255.0 1.1.5.1 preference 50
   [DeviceC] ip route-static 1.1.3.0 255.255.255.0 1.1.6.2
   ```

```
[DeviceC] ip route-static 1.1.4.0 255.255.255.0 1.1.6.2 preference 70
```

Configure two static routes on Device D.

```
<DeviceD> system-view
[DeviceD] ip route-static 1.1.4.0 255.255.255.0 1.1.3.1
[DeviceD] ip route-static 1.1.7.0 255.255.255.0 1.1.6.1
```

2. Configure interface collaboration on Device B:

Enter system view.

```
<DeviceB> system-view
```

Enable Monitor Link globally. By default, Monitor Link is enabled globally.

```
[DeviceB] undo monitor-link disable
```

Create collaboration group 1.

```
[DeviceB] collaboration-group 1
```

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to collaboration group 1.

```
[DeviceB-collaboration-group1] port gigabitethernet 1/0/1
[DeviceB-collaboration-group1] port gigabitethernet 1/0/2
```

Verifying the configuration

1. Verify that the state of the uplink interface affects the state of the downlink interface.

Display the static routing information on Device C.

```
[DeviceC] display ip routing-table protocol static

Summary count : 3

Static Routing table status : <Active>
Summary count : 3

Destination/Mask   Proto   Pre Cost        NextHop         Interface
1.1.2.0/24         Static  60  0           1.1.5.1         GE1/0/1
1.1.3.0/24         Static  60  0           1.1.6.2         GE1/0/2
1.1.4.0/24         Static  50  0           1.1.5.1         GE1/0/1

Static Routing table status : <Inactive>
Summary count : 0
```

The output shows that the effective route from Device C to Device A goes through Device B.

Shut down GigabitEthernet 1/0/1 on Device B, and display information about collaboration group 1.

```
[DeviceB] display collaboration-group 1 verbose
Collaboration group protocol status: Enabled
Collaboration group 1 information:
  Group status     : DOWN
  Member up delay  : 0 seconds
  Last up time     : 16:55:34 2017/04/05
  Last down time   : 16:57:22 2017/04/05
  Member                    Status
  GE1/0/1                   DOWN
  GE1/0/2                   Collaboration-down
```

The output shows that collaboration group 1 is in DOWN state, GigabitEthernet 1/0/1 is in DOWN state, and GigabitEthernet 1/0/2 is in Collaboration-down state.

Display the static routing information on Device C.

```
[DeviceC] display ip routing-table protocol static

Summary count : 2

Static Routing table status : <Active>
Summary count : 2

Destination/Mask   Proto   Pre Cost        NextHop         Interface
1.1.3.0/24         Static  60  0           1.1.6.2         GE1/0/2
1.1.4.0/24         Static  70  0           1.1.6.2         GE1/0/2

Static Routing table status : <Inactive>
Summary count : 0
```

The output shows that the effective route from Device C to Device A goes through Device D.

2. Verify that the state of the downlink interface affects the state of the uplink interface.

Display the static routing information on Device A.

```
[DeviceA] display ip routing-table protocol static

Summary count : 3

Static Routing table status : <Active>
Summary count : 3

Destination/Mask   Proto   Pre Cost        NextHop         Interface
1.1.5.0/24         Static  60  0           1.1.2.2         GE1/0/1
1.1.6.0/24         Static  60  0           1.1.3.2         GE1/0/2
1.1.7.0/24         Static  50  0           1.1.2.2         GE1/0/1

Static Routing table status : <Inactive>
Summary count : 0
```

The output shows that the effective route from Device A to Device C goes through Device B.

Shut down GigabitEthernet 1/0/2 on Device B, and display information about collaboration group 1.

```
[DeviceB] display collaboration-group 1 verbose
Collaboration group protocol status: Enabled
Collaboration group 1 information:
  Group status     : DOWN
  Member up delay  : 0 seconds
  Last up time     : 17:11:47 2017/04/05

Summary count : 0
```

The output shows that the effective route from Device A to Device C goes through Device D.

Example: Configuring interface collaboration for Layer 2 interfaces

Network configuration

As shown in Figure 3, Device C is a Smart Link device, and Device A cannot receive flush messages.

Configure interface collaboration on Device B. When GigabitEthernet 1/0/1 on Device B goes down, Device B brings down GigabitEthernet 1/0/2. When GigabitEthernet 1/0/2 on Device B goes down, Device B brings down GigabitEthernet 1/0/1.

Figure 3 Network diagram

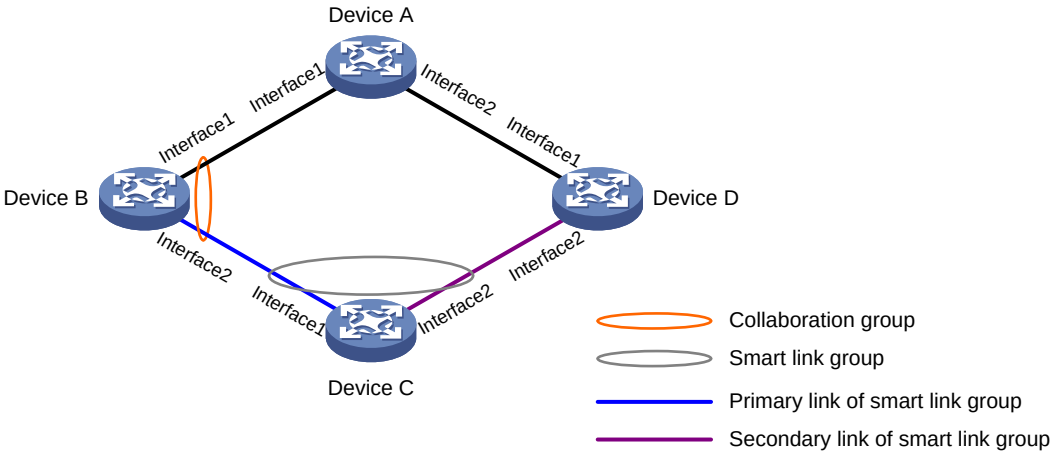

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure Smart Link on Device C:

Create a smart link group, and configure GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port for the smart link group. (Details not shown.)

For more information about configuring Smart Link, see "Configuring Smart Link."

2. Configure Device B:

Enable Monitor Link globally. By default, Monitor Link is enabled globally.

```
<DeviceB> system-view
[DeviceB] undo monitor-link disable
```

Create collaboration group 1.

```
[DeviceB] collaboration-group 1
```

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to collaboration group 1.

```
[DeviceB-collaboration-group1] port gigabitethernet 1/0/1
[DeviceB-collaboration-group1] port gigabitethernet 1/0/2
```

Verifying the configuration

1. Verify that the state of the uplink interface affects the state of the downlink interface.

Display information about smart link group 1 on Device C.

```
[DeviceC] display smart-link group 1
Smart link group 1 information:
  Device ID       : 2007-6f03-0700
  Preemption mode : None
  Preemption delay: 1(s)
  Control VLAN    : 1
  Protected VLAN  : Reference Instance 1

  Member                  Role      State   Flush-count     Last-flush-time
  ------------------------------------------------------------------------------
  GE1/0/1                 PRIMARY   ACTIVE  2               20:19:28 2017/04/05
  GE1/0/2                 SECONDARY STANDBY 0               NA
```

The output shows that the primary port of smart link group 1 is GigabitEthernet 1/0/1, and the traffic is sent out of GigabitEthernet 1/0/1.

Shut down GigabitEthernet 1/0/1 on Device B, and display information about collaboration group 1.

```
[DeviceB] display collaboration-group 1 verbose
Collaboration group protocol status: Enabled
Collaboration group 1 information:
  Group status     : DOWN
  Member up delay  : 0 seconds
  Last up time     : 20:19:58 2017/04/05
  Last down time   : 20:27:02 2017/04/05
  Member                    Status
  GE1/0/1                   DOWN
  GE1/0/2                   Collaboration-down
```

The output shows that collaboration group 1 is in DOWN state, GigabitEthernet 1/0/1 is in DOWN state, and GigabitEthernet 1/0/2 is in Collaboration-down state.

Display information about smart link group 1 on Device C.

```
[DeviceC] display smart-link group 1
Smart link group 1 information:
  Device ID       : 2007-6f03-0700
  Preemption mode : None
```

```
  Preemption delay: 1(s)
  Control VLAN    : 1
  Protected VLAN  : Reference Instance 1

  Member                  Role      State   Flush-count     Last-flush-time
  ------------------------------------------------------------------------------
  GE1/0/1                 PRIMARY   DOWN    2               20:19:28 2017/04/05
  GE1/0/2                 SECONDARY ACTIVE  1               20:26:35 2017/04/05
```

The output shows that GigabitEthernet 1/0/2 becomes the primary port of smart link group 1, and the traffic is sent out of GigabitEthernet 1/0/2.

2. Verify that the state of the downlink interface affects the state of the uplink interface.

Display information about GigabitEthernet 1/0/1 on Device A.

```
[DeviceA] display interface gigabitethernet 1/0/1 brief
Brief information on interfaces in bridge mode:
Link: ADM - administratively down; Stby - standby
Speed: (a) - auto
Duplex: (a)/A - auto; H - half; F - full
Type: A - access; T - trunk; H - hybrid
Interface            Link Speed     Duplex Type PVID Description
GE1/0/1              UP   1G(a)     F(a)   A    1
```

The output shows that GigabitEthernet 1/0/1 is in UP state.

Shut down GigabitEthernet 1/0/2 on Device B, and display information about collaboration group 1.

```
[DeviceB] display collaboration-group 1 verbose
Collaboration group protocol status: Enabled
Collaboration group 1 information:
  Group status     : DOWN
  Member up delay  : 0 seconds
  Last up time     : 20:19:58 2017/04/05
  Last down time   : 20:27:02 2017/04/05
  Member                    Status
  GE1/0/1                   Collaboration-down
  GE1/0/2                   DOWN
```

The output shows that collaboration group 1 is in DOWN state, GigabitEthernet 1/0/1 is in Collaboration-down state, and GigabitEthernet 1/0/2 is in DOWN state.

Display information about GigabitEthernet 1/0/1 on Device A.

```
[DeviceA] display interface gigabitethernet 1/0/1 brief
Brief information on interfaces in bridge mode:
Link: ADM - administratively down; Stby - standby
Speed: (a) - auto
Duplex: (a)/A - auto; H - half; F - full
Type: A - access; T - trunk; H - hybrid
Interface            Link Speed     Duplex Type PVID Description
GE1/0/1              DOWN auto      A      A    1
```

The output shows that GigabitEthernet 1/0/1 is in DOWN state.

The information in this document is subject to change without notice. All contents in this document, including statements, information, and recommendations, are believed to be accurate, but they are presented without warranty of any kind, express or implied. H3C shall not be liable for technical or editorial errors or omissions contained herein.

Preface

This configuration guide describes the fundamentals and configuration procedures for network management and monitoring features. It describes how to view system information, collect network traffic statistics, assess the network performance, synchronize time for all devices with clocks in your network, and use the ping, tracert, and debug commands to check and debug the current network connectivity.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.

Convention	Description
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

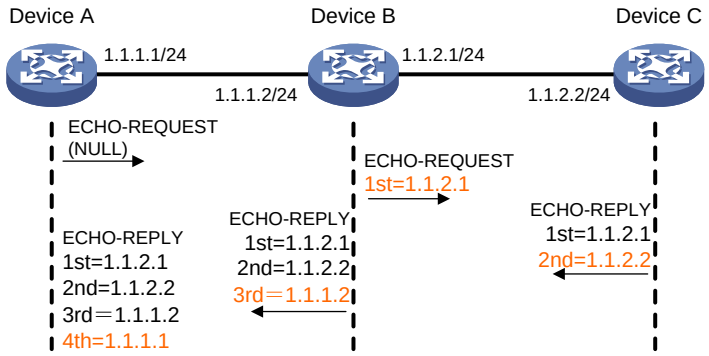
Using ping, tracert, and system debugging

This chapter covers ping, tracert, and information about debugging the system.

Ping

About ping



Use the ping utility to determine if an address is reachable.

Ping sends ICMP echo requests (ECHO-REQUEST) to the destination device. Upon receiving the requests, the destination device responds with ICMP echo replies (ECHO-REPLY) to the source device. The source device outputs statistics about the ping operation, including the number of packets sent, number of echo replies received, and the round-trip time. You can measure the network performance by analyzing these statistics.

You can use the **`ping -r`** command to display the routers through which ICMP echo requests have passed. The test procedure of **`ping -r`** is as shown in Figure 1:

1. The source device (Device A) sends an ICMP echo request to the destination device (Device C) with the RR option empty.
2. The intermediate device (Device B) adds the IP address of its outbound interface (1.1.2.1) to the RR option of the ICMP echo request, and forwards the packet.
3. Upon receiving the request, the destination device copies the RR option in the request and adds the IP address of its outbound interface (1.1.2.2) to the RR option. Then the destination device sends an ICMP echo reply.
4. The intermediate device adds the IP address of its outbound interface (1.1.1.2) to the RR option in the ICMP echo reply, and then forwards the reply.
5. Upon receiving the reply, the source device adds the IP address of its inbound interface (1.1.1.1) to the RR option. The detailed information of routes from Device A to Device C is formatted as: 1.1.1.1 <-> {1.1.1.2; 1.1.2.1} <-> 1.1.2.2.

Figure 1 Ping operation

Using a ping command to test network connectivity

Perform the following tasks in any view:

- Determine if an IPv4 address is reachable.

ping [**ip**] [**-a** *source-ip* | **-c** *count* | **-f** | **-h** *ttl* | **-i** *interface-type interface-number* | **-m** *interval* | **-n** | **-no-log** | **-p** *pad* | **-q** | **-r** | **-s** *packet-size* | **-t** *timeout* | **-tos** *tos* | **-v** | { **-topology** *topo-name* | **-vpn-instance** *vpn-instance-name* }] * *host*

Increase the timeout time (indicated by the **-t** keyword) on a low-speed network.

- Determine if an IPv6 address is reachable.

  ping ipv6 [**-a** *source-ipv6* | **-c** *count* | **-i** *interface-type interface-number* | **-m** *interval* | **-no-log** | **-q** | **-s** *packet-size* | **-t** *timeout* | **-tc** *traffic-class* | **-v** | **-vpn-instance** *vpn-instance-name*] * *host*

  Increase the timeout time (indicated by the **-t** keyword) on a low-speed network.

Example: Using the ping utility

Network configuration

As shown in Figure 2, determine if Device A and Device C can reach each other.

Figure 2 Network diagram

Procedure

Test the connectivity between Device A and Device C.

```
<DeviceA> ping 1.1.2.2
Ping 1.1.2.2 (1.1.2.2): 56 data bytes, press CTRL+C to break
56 bytes from 1.1.2.2: icmp_seq=0 ttl=254 time=2.137 ms
56 bytes from 1.1.2.2: icmp_seq=1 ttl=254 time=2.051 ms
56 bytes from 1.1.2.2: icmp_seq=2 ttl=254 time=1.996 ms
56 bytes from 1.1.2.2: icmp_seq=3 ttl=254 time=1.963 ms
56 bytes from 1.1.2.2: icmp_seq=4 ttl=254 time=1.991 ms

--- Ping statistics for 1.1.2.2 ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 1.963/2.028/2.137/0.062 ms
```

The output shows the following information:

- Device A sends five ICMP packets to Device C and Device A receives five ICMP packets.
- No ICMP packet is lost.
- The route is reachable.

Configuring proxy probe

About this task

Proxy probe is a network reachability diagnostic tool. It test reachability from the local device to a directly connected peer interface through a proxy node. It is applicable to scenarios where the local device cannot communicate directly with the target interface, for example, in cross-protocol scenarios such as probing from an IPv4 device to an IPv6 device. The ping command can test

connectivity between two nodes and requires the source to have a route to the destination for the probe to succeed.

As per RFC 8335, this feature allows indirect probe by using ICMP extension messages and a local protocol table as follows:

1. With the **probe** command configured, the probe node sends an ICMP Extended Echo Request to a proxy node.
2. Upon receiving the probe packet, the proxy node does not forward it directly to the probed node. Instead, it checks local ARP or ND entries to determine reachability of the probed node and then replies with an ICMP Extended Echo Reply.
3. Upon receiving the reply from the proxy node, the probe node obtains the status of the probed interface.

Restrictions and guidelines

- If you specify a proxy node by its host name, you must first configure domain name system (DNS) on the device.
- For the proxy node to retrieve target node status through local ARP or ND entries, make sure the probe device, proxy device, and target device have Layer 3 connectivity.
- You can press Ctrl+C to terminate the probe. Use this key combination to terminate long-running or large-scale probing tasks.

Prerequisites

- Verify that the the proxy node and the target node has Layer 3 connectivity.
- If you specify a proxy node by its host name, configure the DNS server address in advance.

Procedure

Perform the following tasks in any view.

- Use an IPv4 proxy node to probe an IPv4 or IPv6 node.

  probe *proxy-host* **by-remote-address** [**ipv6**] *remote-ip* [**count** *count*]
- Use an IPv6 proxy node to probe an IPv4 or IPv6 node.

  probe ipv6 *proxy-host* **by-remote-address** [**ipv6**] *remote-ip* [**count** *count*]

Tracert

About tracert

Tracert (also called Traceroute) enables retrieval of the IP addresses of Layer 3 devices in the path to a destination. In the event of network failure, use tracert to test network connectivity and identify failed nodes.

Figure 3 Tracert operation

Tracert uses received ICMP error messages to get the IP addresses of devices. Tracert works as shown in Figure 3:

1. The source device sends a UDP packet with a TTL value of 1 to the destination device. The destination UDP port is not used by any application on the destination device.
2. The first hop (Device B, the first Layer 3 device that receives the packet) responds by sending a TTL-expired ICMP error message to the source, with its IP address (1.1.1.2) encapsulated. This way, the source device can get the address of the first Layer 3 device (1.1.1.2).
3. The source device sends a packet with a TTL value of 2 to the destination device.
4. The second hop (Device C) responds with a TTL-expired ICMP error message, which gives the source device the address of the second Layer 3 device (1.1.2.2).
5. This process continues until a packet sent by the source device reaches the ultimate destination device. Because no application uses the destination port specified in the packet, the destination device responds with a port-unreachable ICMP message to the source device, with its IP address encapsulated. This way, the source device gets the IP address of the destination device (1.1.3.2).
6. The source device determines that:
   - The packet has reached the destination device after receiving the port-unreachable ICMP message.
   - The path to the destination device is 1.1.1.2 to 1.1.2.2 to 1.1.3.2.

Prerequisites

Before you use a tracert command, perform the tasks in this section.

For an IPv4 network:

- Enable sending of ICMP timeout packets on the intermediate devices (devices between the source and destination devices). If the intermediate devices are H3C devices, execute the **ip ttl-expires enable** command on the devices. For more information about this command, see *Layer 3—IP Services Command Reference*.
- Enable sending of ICMP destination unreachable packets on the destination device. If the destination device is an H3C device, execute the **ip unreachables enable** command. For more information about this command, see *Layer 3—IP Services Command Reference*.

For an IPv6 network:

- Enable sending of ICMPv6 timeout packets on the intermediate devices (devices between the source and destination devices). If the intermediate devices are H3C devices, execute the

ipv6 hoplimit-expires enable command on the devices. For more information about this command, see *Layer 3—IP Services Command Reference*.

- Enable sending of ICMPv6 destination unreachable packets on the destination device. If the destination device is an H3C device, execute the **ipv6 unreachables enable** command. For more information about this command, see *Layer 3—IP Services Command Reference*.

Using a tracert command to identify failed or all nodes in a path

Perform the following tasks in any view:

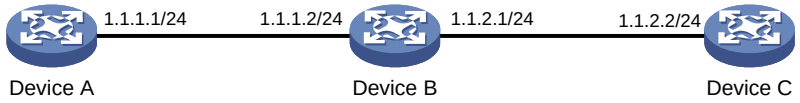
- Trace the route to an IPv4 destination.

  tracert [**-a** *source-ip* | **-e** | **-f** *first-ttl* | **-m** *max-ttl* | **-p** *port* | **-q** *packet-number* | **-t** *tos* | { **-topology** *topo-name* | **-vpn-instance** *vpn-instance-name* [**-resolve-as** { **global** | **none** | **vpn** }] } | **-w** *timeout*] * *host*

- Trace the route to an IPv6 destination.

  tracert ipv6 [**-a** *source-ipv6* | **-e** | **-f** *first-hop* | **-m** *max-hops* | **-p** *port* | **-q** *packet-number* | **-t** *traffic-class* | **-vpn-instance** *vpn-instance-name* [**-resolve-as** { **global** | **none** | **vpn** }] | **-w** *timeout*] * *host*

  Only the S5200-HI-G switch series supports this command.



Example: Using the tracert utility

Network configuration

As shown in Figure 4, Device A failed to Telnet to Device C.

Test the network connectivity between Device A and Device C. If they cannot reach each other, locate the failed nodes in the network.

Figure 4 Network diagram

Procedure

1. Configure IP addresses for the devices as shown in Figure 4.
2. Configure a static route on Device A.

```
<DeviceA> system-view
[DeviceA] ip route-static 0.0.0.0 0.0.0.0 1.1.1.2
```

3. Test connectivity between Device A and Device C.

```
[DeviceA] ping 1.1.2.2
Ping 1.1.2.2(1.1.2.2): 56 -data bytes, press CTRL+C to break
Request time out
Request time out
Request time out
Request time out
Request time out

--- Ping statistics for 1.1.2.2 ---
```

```
5 packet(s) transmitted,0 packet(s) received,100.0% packet loss
```

The output shows that Device A and Device C cannot reach each other.

4. Identify failed nodes:

   # Enable sending of ICMP timeout packets on Device B.

```
<DeviceB> system-view
[DeviceB] ip ttl-expires enable
```

   # Enable sending of ICMP destination unreachable packets on Device C.

```
<DeviceC> system-view
[DeviceC] ip unreachables enable
```

   # Identify failed nodes.

```
[DeviceA] tracert 1.1.2.2
traceroute to 1.1.2.2 (1.1.2.2) 30 hops at most,40 bytes each packet, press CTRL+C
to break
 1  1.1.1.2 (1.1.1.2) 1 ms 2 ms 1 ms
 2  * * *
 3  * * *
 4  * * *
 5
[DeviceA]
```

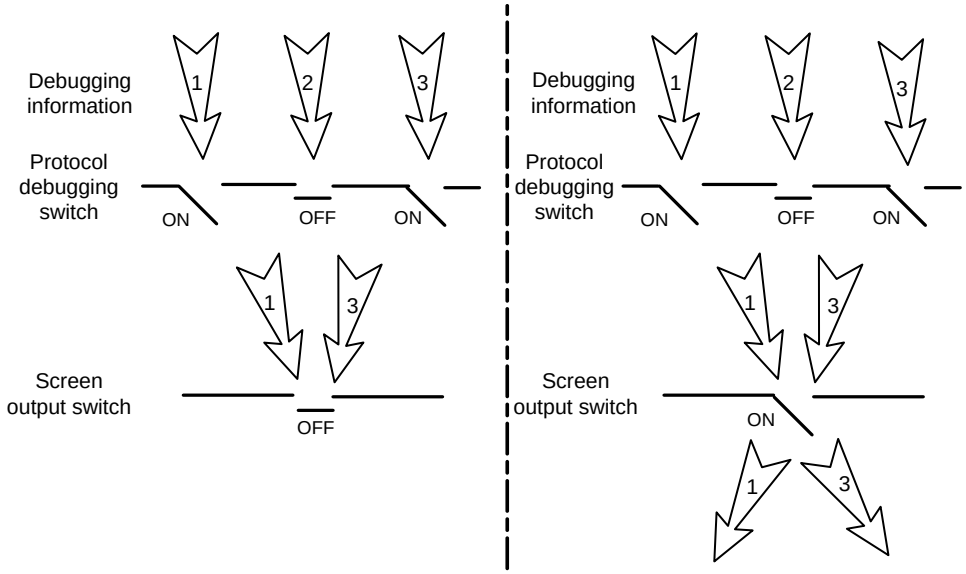
   The output shows that Device A can reach Device B but cannot reach Device C. An error has occurred on the connection between Device B and Device C.

5. To identify the cause of the issue, execute the following commands on Device A and Device C:
   - Execute the **`debugging ip icmp`** command and verify that Device A and Device C can send and receive the correct ICMP packets.
   - Execute the **`display ip routing-table`** command to verify that Device A and Device C have a route to each other.

System debugging

About system debugging

The device supports debugging for the majority of protocols and features, and provides debugging information to help users diagnose errors.



The following switches control the display of debugging information:

- **Module debugging switch**—Controls whether to generate the module-specific debugging information.
- **Screen output switch**—Controls whether to display the debugging information on a certain screen. Use **`terminal monitor`** and **`terminal logging level`** commands to turn on the screen output switch. For more information about these two commands, see *Network Management and Monitoring Command Reference*.

As shown in Figure 5, the device can provide debugging for the three modules 1, 2, and 3. The debugging information can be output on a terminal only when both the module debugging switch and the screen output switch are turned on.

Debugging information is typically displayed on a console. You can also send debugging information to other destinations. For more information, see "Configuring the information center."

Figure 5 Relationship between the module and screen output switch

Configuring debugging

Restrictions and guidelines

CAUTION:

Output of excessive debugging messages increases the CPU usage and downgrades the system performance. To guarantee system performance, enable debugging only for modules that are in an exceptional condition.

Enable debugging for modules for troubleshooting purposes. When debugging is complete, use the **undo debugging all** command to disable all the debugging functions.

Procedure

1. Enable debugging for a module.

   debugging *module-name* [*option*]

   By default, debugging is disabled for all modules.

   This command is available in user view.

Display and maintenance commands for debugging

Execute **display** commands in any view.

Task	Command
Display the enabled debugging features.	**display debugging** [*module-name*]

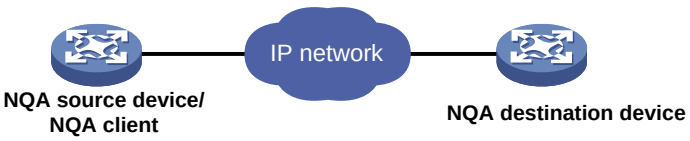
Configuring NQA

About NQA

Network quality analyzer (NQA) allows you to measure network performance, verify the service levels for IP services and applications, and troubleshoot network problems.



NQA architecture

An NQA operation contains a set of parameters such as the operation type, destination IP address, and port number to define how the operation is performed. Each NQA operation is identified by the combination of the administrator name and the operation tag. You can configure the NQA client to run the operations at scheduled time periods.

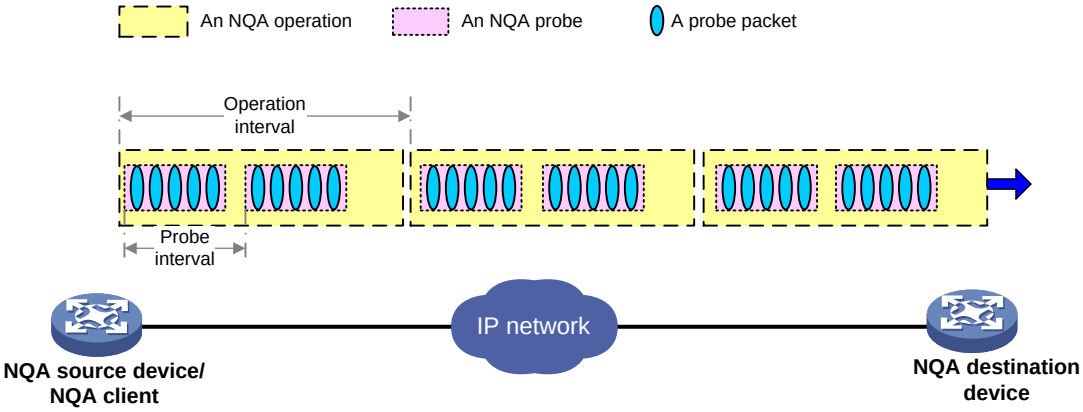
As shown in Figure 1, the NQA source device (NQA client) sends data to the NQA destination device by simulating IP services and applications to measure network performance.

All types of NQA operations require the NQA client, but only the TCP, UDP echo, UDP jitter, and voice operations require the NQA server. The NQA operations for services that are already provided by the destination device such as FTP do not need the NQA server. You can configure the NQA server to listen and respond to specific IP addresses and ports to meet various test needs.

Figure 1 Network diagram

NQA operating mechanism

The NQA client and NQA server interact as follows:



1. The NQA client constructs probe packets of the operation type, and sends them to the NQA server.
2. The NQA server processes the probe packets and sends back reply packets.
3. Upon receiving the replies, the NQA client calculates the packet loss ratio and round-trip time to determine the network performance and service quality.

After an NQA operation starts, the NQA client repeats the operation at the specified interval.

An NQA operation can contain multiple probes. You can set the number of probes the NQA client performs in an operation.

For the voice and path jitter operations, the NQA client performs only one probe per operation.

Figure 2 NQA operation diagram

Collaboration with Track

NQA can collaborate with the Track module to notify application modules of state or performance changes so that the application modules can take predefined actions.

The NQA + Track collaboration is available for the following application modules:

- VRRP
- Static routing.
- Policy-based routing.
- Traffic redirecting.

The following describes how a static route destined for 192.168.0.100 is monitored through collaboration:

1. NQA monitors the reachability to 192.168.0.100.
2. When 192.168.0.100 becomes unreachable, NQA notifies the Track module of the change.
3. The Track module notifies the static routing module of the state change.
4. The static routing module sets the static route to invalid according to a predefined action.

For more information about collaboration, see *High Availability Configuration Guide*.

Threshold monitoring

Threshold monitoring enables the NQA client to take a predefined action when the NQA operation performance metrics violate the specified thresholds.

Table 1 describes the relationships between performance metrics and NQA operation types.

Table 1 Performance metrics and NQA operation types

Performance metric	NQA operation types that can gather the metric
Probe duration	All NQA operation types except UDP jitter, UDP tracert, path jitter, and voice
Number of probe failures	All NQA operation types except UDP jitter, UDP tracert, path jitter, and voice
Round-trip time	ICMP jitter, UDP jitter, and voice
Number of discarded packets	ICMP jitter, UDP jitter, and voice

Performance metric	NQA operation types that can gather the metric
One-way jitter (source-to-destination or destination-to-source)	ICMP jitter, UDP jitter, and voice
One-way delay (source-to-destination or destination-to-source)	ICMP jitter, UDP jitter, and voice
Calculated Planning Impairment Factor (ICPIF) (see "Configuring the voice operation")	Voice
Mean Opinion Scores (MOS) (see "Configuring the voice operation")	Voice

NQA templates

An NQA template is a set of parameters (such as destination address and port number) that defines how an NQA operation is performed. Features can use the NQA template to collect statistics.

You can create multiple NQA templates on the NQA client. Each template must be identified by a unique template name.

Restrictions and guidelines: NQA configuration

An NQA operation depends on a series of conditions such as routing table, FIB table, ARP table, and probe packet output interface state. During the initial startup of the device, the NQA operation might fail when it does not meet the previous conditions. If the NQA operation is associated with a track entry, the track entry state might also change, resulting in collaboration with the service function associated with the track entry.

To avoid probe failures, follow these restrictions and guidelines when configuring the listening ports on the NQA client and NQA server:

- Do not specify a well-known port.
- Make sure the specified port number is not used by any services on the device.
  - To obtain the IPv4 addresses and the port numbers in use on this device, see the **Local Addr:port** field in the output from the **`display tcp`** and **`display udp`** commands.
  - To obtain the IPv6 addresses and the port numbers in use on this device, see the **LAddr->port** field in the output from the **`display ipv6 tcp`** and **`display ipv6 udp`** commands.

If the source IP address of NQA probe packets has been NATed through the Easy IP feature, the local device might fail to receive NQA response packets, resulting in NQA operation failure. As a best practice, use the **`source interface`**, **`source ip`**, or **`source ipv6`** command to specify the source IP address of NQA probe packets to prevent the source IP address from being translated by NAT. In the output from the **`display nat all`** command, if the **NAT address group information** field contains the output interface IP address of NQA probe packets, or the **NAT outbound information** field contains the output interface of NQA probe packets, the source IP address of NQA probe packets will be NATed by the Easy IP feature. Avoid specifying the IP address and interface when configuring the source IP address. For more information about Easy IP, see NAT configuration in *Layer 3—IP Services Configuration Guide*.

The destination port configured for the operation (with the **`destination port`** command) on the NQA client must be the same as the listening port configured on the server.

An NQA operation depends on a series of conditions such as routing table, FIB table, ARP table, and probe packet output interface state. During the initial startup of the device, the NQA operation might fail when it does not meet the previous conditions.

For latency operation results to be accurate, synchronize time between the source and the destination with an accuracy higher than or equal to the operation result calculation accuracy.

NQA tasks at a glance

To configure NQA, perform the following tasks:

1. Configuring the NQA server

   Perform this task on the destination device before you configure the TCP, UDP echo, UDP jitter, and voice operations.
2. Enabling the NQA client
3. Configuring NQA operations or NQA templates

   Choose the following tasks as needed:

   - Configuring NQA operations on the NQA client
   - Configuring NQA templates on the NQA client

   After you configure an NQA operation, you can schedule the NQA client to run the NQA operation.

   An NQA template does not run immediately after it is configured. The template creates and run the NQA operation only when it is required by the feature (such as load balancing) to which the template is applied.

Configuring the NQA server

Restrictions and guidelines

To perform TCP, UDP echo, UDP jitter, and voice operations, you must configure the NQA server on the destination device. The NQA server listens and responds to requests on the specified IP addresses and ports.

You can configure multiple TCP or UDP listening services on an NQA server, where each corresponds to a specific IP address and port number.

The IP address, port number, and VPN instance for a listening service must be unique on the NQA server and match the configuration on the NQA client.

Procedure

1. Enter system view.

   system-view
2. Enable the NQA server.

   nqa server enable

   By default, the NQA server is disabled.
3. Configure a TCP listening service.

   nqa server tcp-connect *ip-address port-number* [**vpn-instance** *vpn-instance-name*] [**tos** *tos*]

   This task is required for only TCP and DLSw operations. For the DLSw operation, the port number for the TCP listening service must be 2065.
4. Configure a UDP listening service.

   nqa server udp-echo *ip-address port-number* [**vpn-instance** *vpn-instance-name*] [**tos** *tos*]

   This task is required for only UDP echo, UDP jitter, and voice operations.

Enabling the NQA client

1. Enter system view.
   `system-view`
2. Enable the NQA client.
   `nqa agent enable`
   By default, the NQA client is enabled.
   The NQA client configuration takes effect after you enable the NQA client.

Configuring NQA operations on the NQA client

NQA operations tasks at a glance

To configure NQA operations, perform the following tasks:

1. Configuring an NQA operation
   - Configuring the ICMP echo operation
   - Configuring the ICMP jitter operation
   - Configuring the DHCP operation
   - Configuring the DNS operation
   - Configuring the FTP operation
   - Configuring the HTTP operation
   - Configuring the UDP jitter operation
   - Configuring the SNMP operation
   - Configuring the TCP operation
   - Configuring the UDP echo operation
   - Configuring the UDP tracert operation
   - Configuring the voice operation
   - Configuring the DLSw operation
   - Configuring the path jitter operation
2. (Optional.) Configuring optional parameters for the NQA operation
3. (Optional.) Configuring the collaboration feature
4. (Optional.) Configuring threshold monitoring
5. (Optional.) Configuring the NQA statistics collection feature
6. (Optional.) Configuring the saving of NQA history records
7. Scheduling the NQA operation on the NQA client

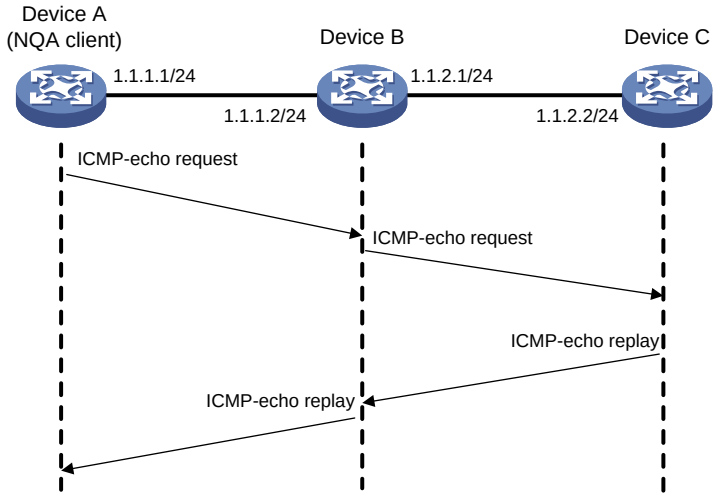
Configuring the ICMP echo operation

About this task

ICMP echo is the most basic feature of NQA, and it is implemented based on RFC 2925. An ICMP echo operation is used to test the reachability of the destination, and calculate the response time and packet loss rate by sending ICMP packets.

An ICMP echo operation is similar to ping in terms of functionality. They have the following differences:

- The TTL value of ICMP packets sent in an ICMP echo operation is 20 by default. In a complex network with multiple hops, you can change the TTL value based on the actual network requirements.
- An ICMP echo operation supports various operation parameters. For example, you can specify a next hop address for the operation. When multiple paths exist between the source and destination devices, you can configure a next hop address to specify a path to be tested.



For an ICMP echo operation, a single probe operation refers to sending one probe packet to the destination.

As shown in Figure 3, an ICMP echo operation is performed as follows:

1. An NQA client sends an ICMP echo request to the destination IP address according to the configured probe time and frequency.
2. Upon receiving the ICMP echo request, the destination IP address sends an ICMP echo reply.
3. The NQA client calculates the response time of the destination IP address and the packet loss rate based on the receiving time packet count of the ICMP-echo reply, which reflects the network performance and status.

An ICMP echo operation can succeed only if the destination device can correctly respond to ICMP echo requests.

Figure 3 ICMP echo operation diagram

Procedure

1. Enter system view.
   system-view
2. Create an NQA operation and enter NQA operation view.
   nqa entry *admin-name operation-tag*
3. Specify the ICMP echo type and enter its view.
   type icmp-echo
4. Specify the destination IP address for ICMP echo requests.
   IPv4:
   destination ip *ip-address*
   IPv6:
   destination ipv6 *ipv6-address*
   By default, no destination IP address is specified.
5. Specify the source IP address for ICMP echo requests. Choose one option as needed:

- Use the IP address of the specified interface as the source IP address.

  source interface *interface-type interface-number*

  By default, the source IP address of ICMP echo requests is the primary IP address of their output interface.

  The specified source interface must be up.
- Specify the source IPv4 address.

  source ip *ip-address*

  By default, the source IPv4 address of ICMP echo requests is the primary IPv4 address of their output interface.

  The specified source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.
- Specify the source IPv6 address.

  source ipv6 *ipv6-address*

  By default, the source IPv6 address of ICMP echo requests is the primary IPv6 address of their output interface.

  The specified source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. Specify the output interface or the next hop IP address for ICMP echo requests. Choose one option as needed: (If you configure both the output interface and next hop IP address, only the next hop IP address takes effect. To avoid probe failure, make sure the IP address belongs to a directly connected next hop.)
   - Specify the output interface for ICMP echo requests.

     out interface *interface-type interface-number*

     By default, the output interface for ICMP echo requests is not specified. The NQA client determines the output interface based on the routing table lookup.
   - Specify the next hop IPv4 address.

     next-hop ip *ip-address*

     By default, no next hop IPv4 address is specified.
   - Specify the next hop IPv6 address.

     next-hop ipv6 *ipv6-address*

     By default, no next hop IPv6 address is specified.
7. (Optional.) Set the payload size for each ICMP echo request.

   data-size *size*

   The default payload size is 100 bytes.
8. (Optional.) Specify the payload fill string for ICMP echo requests.

   data-fill *string*

   The default payload fill string is 00010203040506070809.

Configuring the ICMP jitter operation

About this task

The ICMP jitter operation measures unidirectional and bidirectional jitters. The operation result helps you to determine whether the network can carry jitter-sensitive services such as real-time voice and video services.

The ICMP jitter operation works as follows:

1. The NQA client sends ICMP packets to the destination device.

2. The destination device time stamps each packet it receives, and then sends the packet back to the NQA client.
3. Upon receiving the responses, the NQA client calculates the jitter according to the timestamps.

The ICMP jitter operation sends a number of ICMP packets to the destination device per probe. The number of packets to send is determined by using the **probe packet-number** command.

Restrictions and guidelines

The **display nqa history** command does not display the results or statistics of the ICMP jitter operation. To view the results or statistics of the operation, use the **display nqa result** or **display nqa statistics** command.

Before starting the operation, make sure the network devices are time synchronized by using NTP. For more information about NTP, see "Configuring NTP."

Procedure

1. Enter system view.
   system-view
2. Create an NQA operation and enter NQA operation view.
   nqa entry *admin-name operation-tag*
3. Specify the ICMP jitter type and enter its view.
   type icmp-jitter
4. Specify the destination IP address for ICMP packets.
   destination ip *ip-address*
   By default, no destination IP address is specified.
5. Set the number of ICMP packets sent per probe.
   probe packet-number *number*
   The default setting is 10.
6. Set the interval for sending ICMP packets.
   probe packet-interval *interval*
   The default setting is 20 milliseconds.
7. Specify how long the NQA client waits for a response from the server before it regards the response times out.
   probe packet-timeout *timeout*
   The default setting is 3000 milliseconds.
8. Specify the source IP address for ICMP packets.
   source ip *ip-address*
   By default, the source IP address of ICMP packets is the primary IP address of their output interface.
   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no ICMP packets can be sent out.

Configuring the DHCP operation

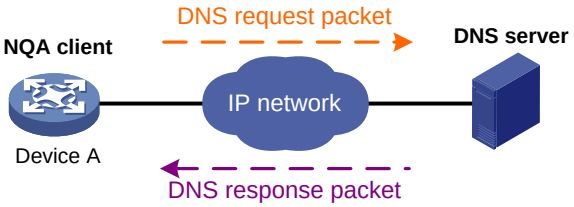
About this task

The DHCP operation measures whether or not the DHCP server can respond to client requests. DHCP also measures the amount of time it takes the NQA client to obtain an IP address from a DHCP server.

The NQA client simulates the DHCP relay agent to forward DHCP requests for IP address acquisition from the DHCP server. The interface that performs the DHCP operation does not change its IP address. When the DHCP operation completes, the NQA client sends a packet to release the obtained IP address.

The DHCP operation acquires an IP address from the DHCP server per probe.

Procedure



1. Enter system view.
   system-view
2. Create an NQA operation and enter NQA operation view.
   nqa entry *admin-name operation-tag*
3. Specify the DHCP type and enter its view.
   type dhcp
4. Specify the IP address of the DHCP server as the destination IP address of DHCP packets.
   destination ip *ip-address*
   By default, no destination IP address is specified.
5. Specify the output interface for DHCP request packets.
   out interface *interface-type interface-number*
   By default, the NQA client determines the output interface based on the routing table lookup.
6. Specify the source IP address of DHCP request packets.
   source ip *ip-address*
   By default, the source IP address of DHCP request packets is the primary IP address of their output interface.
   The specified source IP address must be the IP address of a local interface, and the local interface must be up. Otherwise, no probe packets can be sent out.

Configuring the DNS operation

About this task

The DNS operation measures the time for the NQA client to resolve a domain name into an IP address through a DNS server.

Figure 4 DNS operation diagram

The DNS operation simulates domain name resolution, and the obtained DNS entry is not saved.

The DNS operation resolves a domain name into an IP address per probe.

Procedure

1. Enter system view.
   system-view
2. Create an NQA operation and enter NQA operation view.
   nqa entry *admin-name operation-tag*

3. Specify the DNS type and enter its view.
   type dns
4. Specify the IP address of the DNS server as the destination IP address of DNS packets.
   destination ip *ip-address*
   By default, no destination IP address is specified.
5. Specify the domain name to be translated.
   resolve-target *domain-name*
   By default, no domain name is specified.

Configuring the FTP operation

About this task

The FTP operation measures the time for the NQA client to transfer a file to or download a file from an FTP server.

The FTP operation uploads or downloads a file from an FTP server per probe.

An FTP operation supports the GET and PUT operations:

- A GET operation temporarily downloads a file to the local file system, calculates the time required to download the file, and immediately deletes the file after obtaining the data to automatically releasing the occupied memory. If the name of the downloaded file is the same as an existing file on the NQA client, the original file on the NQA client will be overwritten.
- A PUT operation uploads a file with a fixed size and content to the FTP server. You can configure the name of the uploaded file, and the file content is fixed data specified internally by the system. If the configured file name is the same as the name of an existing file on the FTP server, the original file on the FTP server will be overwritten.

Restrictions and guidelines

To upload (**put**) a file to the FTP server, use the **filename** command to specify the name of the file you want to upload. The file must exist on the NQA client.

To download (**get**) a file from the FTP server, include the name of the file you want to download in the **url** command. The file must exist on the FTP server. The NQA client does not save the file obtained from the FTP server.

Use a small file for the FTP operation. A big file might result in transfer failure because of timeout, or might affect other services because of the amount of network bandwidth it occupies.

Procedure

1. Enter system view.
   system-view
2. Create an NQA operation and enter NQA operation view.
   nqa entry *admin-name operation-tag*
3. Specify the FTP type and enter its view.
   type ftp
4. Specify an FTP login username.
   username *username*
   By default, no FTP login username is specified.
5. Specify an FTP login password.
   password { **cipher** | **simple** } *string*
   By default, no FTP login password is specified.

6. Specify the source IP address for FTP request packets.

   source ip *ip-address*

   By default, the source IP address of FTP request packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no FTP requests can be sent out.

7. Set the data transmission mode.

   mode { **active** | **passive** }

   The default mode is **active**.

8. Specify the FTP operation type.

   operation { **get** | **put** }

   The default FTP operation type is **get**.

9. Specify the destination URL for the FTP operation.

   url *url*

   By default, no destination URL is specified for an FTP operation.

   Enter the URL in one of the following formats:

   - ftp://*host*/*filename*.
   - ftp://*host:port*/*filename*.

   If the value for the *host* parameter is an IPv6 address, you must use a pair of square brackets ([]) to include the IPv6 address, for example, ftp://[2001::1]/test. The *filename* argument is required only for the **get** operation.

10. Specify the name of the file to be uploaded.

    filename *file-name*

    By default, no file is specified.

    This task is required only for the **put** operation.

    The configuration does not take effect for the **get** operation.

Configuring the HTTP operation

About this task

The HTTP operation measures the time for the NQA client to obtain responses from an HTTP server.

The HTTP operation supports the following operation types:

- **Get**—Retrieves data such as a Web page from the HTTP server.
- **Post**—Sends data to the HTTP server for processing.
- **Raw**—Sends a user-defined HTTP request to the HTTP server. You must manually configure the content of the HTTP request to be sent.

In an HTTP operation, the NQA client sends a GET or POST request to the HTTP server at the specified address, and then calculates the operation time after receiving a reply. This process is to establish a connection with the HTTP server. If the connection is successfully established, the operation succeeds.

The HTTP operation completes the operation of the specified type per probe.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

nqa entry *admin-name operation-tag*

3. Specify the HTTP type and enter its view.

   type http

4. Specify the destination URL for the HTTP operation.

   url *url*

   By default, no destination URL is specified for an HTTP operation.

   Enter the URL in one of the following formats:

   - http://*host*/*resource*
   - http://*host:port/resource*

   If the value for the *host* parameter is an IPv6 address, you must use a pair of square brackets ([]) to include the IPv6 address, for example, http://[2001::1]/test.

5. Specify an HTTP login username.

   username *username*

   By default, no HTTP login username is specified.

6. Specify an HTTP login password.

   password { **cipher** | **simple** } *string*

   By default, no HTTP login password is specified.

7. Specify the HTTP version.

   version { **v1.0** | **v1.1** }

   By default, HTTP 1.0 is used.

8. Specify the HTTP operation type.

   operation { **get** | **post** | **raw** }

   The default HTTP operation type is **get**.

   If you set the operation type to **raw**, the client pads the content configured in raw request view to the HTTP request to send to the HTTP server.

9. Configure the HTTP raw request.

   a. Enter raw request view.

      raw-request

      Every time you enter raw request view, the previously configured raw request content is cleared.

   b. Enter or paste the request content.

      By default, no request content is configured.

      To ensure successful operations, make sure the request content does not contain command aliases configured by using the **alias** command. For more information about the **alias** command, see CLI commands in *Fundamentals Command Reference*.

   c. Save the input and return to HTTP operation view:

      quit

   This step is required only when the operation type is set to **raw**.

10. Specify the source IP address for the HTTP packets.

    source ip *ip-address*

    By default, the source IP address of HTTP packets is the primary IP address of their output interface.

    The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no request packets can be sent out.

Configuring the UDP jitter operation

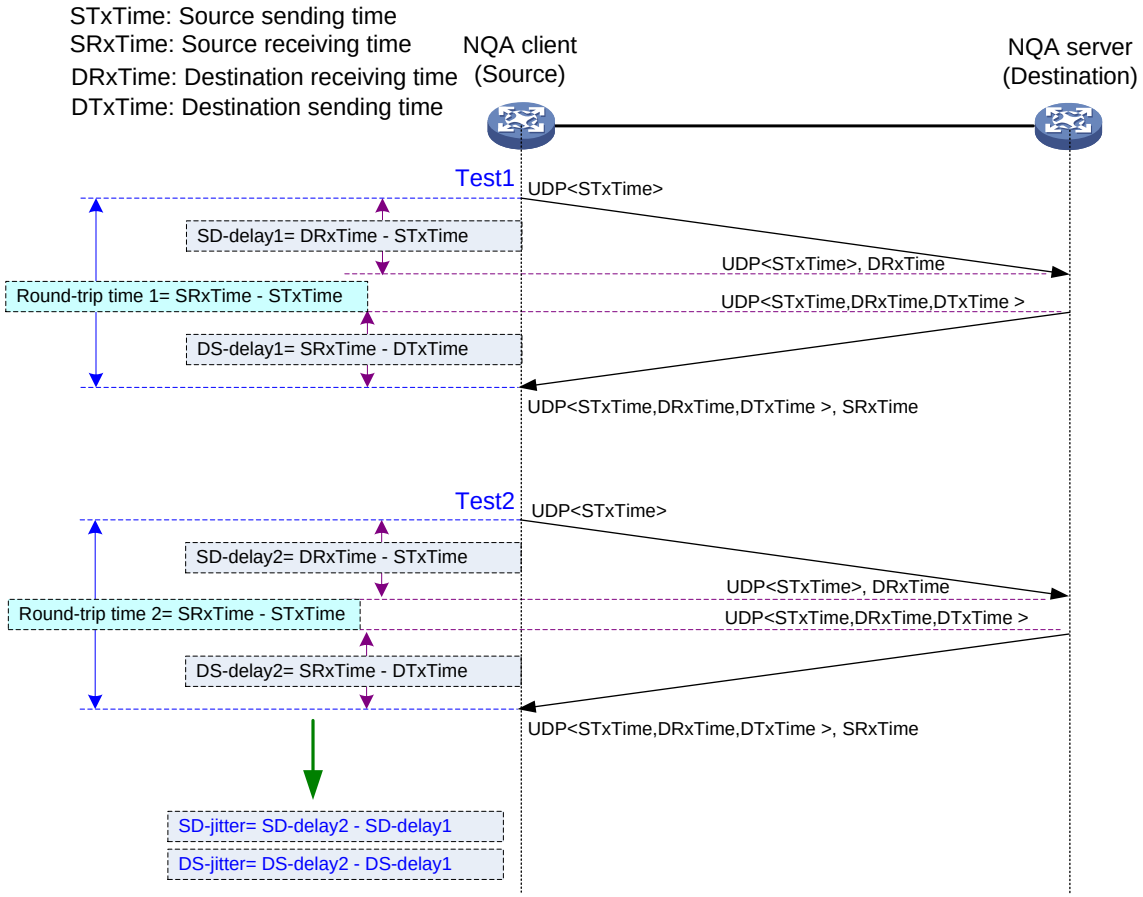
About this task

UDP jitter overview

UDP jitter is an important tool to detect network status and monitor real-time service quality. Real-time services (such as voice and video services) have high delay and jitter requirements. You can use a UDP jitter operation to determine whether a network can guarantee service quality for real-time services.

UDP jitter probe packets are proprietary packets, requiring the peer device to be an H3C device with the NQA server feature enabled and associated NQA server parameters configured.

In a UDP jitter operation, a group of packets are sent in one probe, and this group of packets corresponds to one history record only. As a best practice to obtain the UDP jitter operation results, view the probe results, rather than the history records.



The UDP jitter operation results include one-way delay information. If this information is critical, make sure the time on both devices is synchronized to the millisecond level by using a time synchronization feature (such as PTP). If the information is not critical, time synchronization is not required.

UDP jitter operations

As shown in Figure 5, a UDP jitter operation is performed as follows:

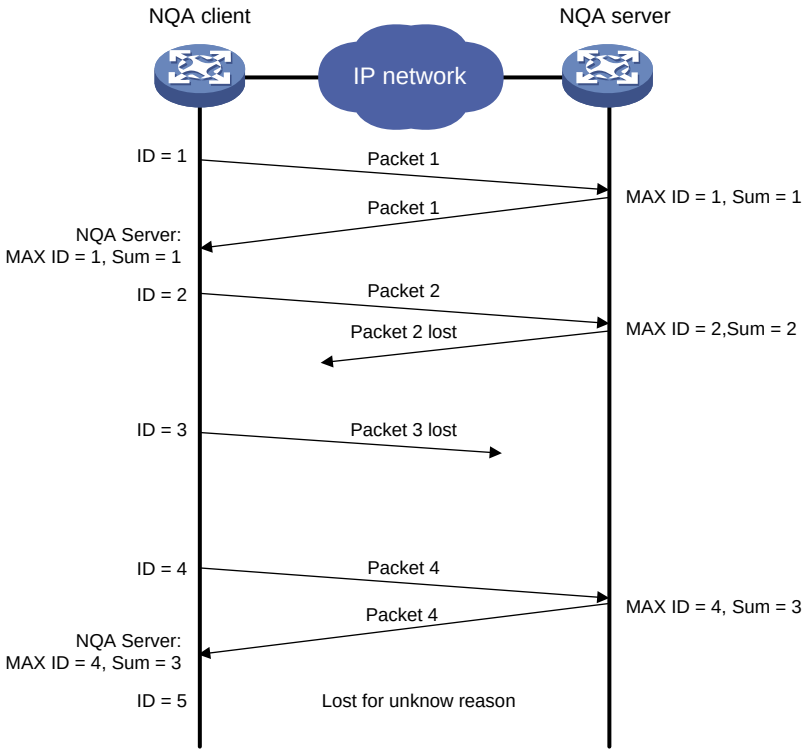
1. The NQA client sends a UDP jitter packet to the NQA server, and records the packet leaving time STxTime.
2. When the UDP jitter packet arrives at the NQA server, the NQA server adds the packet receiving time DRxTime to the packet.
3. When the UDP jitter packet leaves the NQA server, the NQA server adds the packet leaving time DTxTime.
4. When NQA client receives the reply, it records the packet receiving time SRxTime.
5. The NQA client sends multiple probe packets at a fixed interval, and the above process repeats. By recording the timestamps, the device can calculate the delay jitter from the source to the destination, as well as the delay jitter from the destination back to the source.

Figure 5 UDP jitter operation diagram

UDP-jitter one-way packet loss statistics

As shown in Figure 6, the UDP jitter client and server can collaborate to collect the one-way packet loss statistics.

Each packet sent by the NQA client includes a packet ID, which increments by 1 each time a packet is sent. The NQA server updates the greatest packet ID and the number of received packets every time it receives a packet, and sends them back to the NQA client in the reply. The NQA client then records the number of replies, and obtains the information of the NQA sever from these replies.



The NQA client can obtain the following information:

- Number of packets sent by the NQA client.
- The greatest packet ID and the number of packets received by the NQA server.
- Number of packets received by the NQA client.

It can calculate the following based on the obtained information:

- Number of packets lost from source to destination = Greatest packet ID received by the NQA server – Number of packets received by the NQA server
- Number of packets lost from destination to source = Number of packets received by the NQA server – Number of packets received by the NQA client
- Number of packets lost on the unknown directions = Number of packets sent by the NQA client – Number of packets received by the NQA client – Number of packets lost from source to destination – Number of packets lost from destination to source

Figure 6 UDP-jitter one-way packet loss statistics diagram

Restrictions and guidelines

The UDP jitter operation requires both the NQA server and the NQA client. Before you perform the UDP jitter operation, configure the UDP listening service on the NQA server. For more information about UDP listening service configuration, see "Configuring the NQA server."

To ensure successful UDP jitter operations and avoid affecting existing services, do not perform the operations on well-known ports from 1 to 1023.

The **display nqa history** command does not display the results or statistics of the UDP jitter operation. To view the results or statistics of the UDP jitter operation, use the **display nqa result** or **display nqa statistics** command.

Before starting the operation, make sure the network devices are time synchronized by using NTP. For more information about NTP, see "Configuring NTP."

Procedure

1. Enter system view.

   system-view
2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*
3. Specify the UDP jitter type and enter its view.

   type udp-jitter
4. Specify the destination IP address for UDP packets.

   destination ip *ip-address*

   By default, no destination IP address is specified.

   The destination IP address must be the same as the IP address of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

5. Specify the destination port number for UDP packets.

   destination port *port-number*

   By default, no destination port number is specified.

   The destination port number must be the same as the port number of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

6. Specify the source IP address for UDP packets.

   source ip *ip-address*

   By default, the source IP address of UDP packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no UDP packets can be sent out.

7. Specify the source port number for UDP packets.

   source port *port-number*

   By default, the system automatically selects an unused port as the source port for UDP packets.

   For successful probing, make sure the source port number specified in the command is not used by any service on the device. As a best practice, use the default port number.

8. Set the number of UDP packets sent per probe.

   probe packet-number *number*

   The default setting is 10.

9. Set the interval for sending UDP packets.

   probe packet-interval *interval*

   The default setting is 20 milliseconds.

10. Specify how long the NQA client waits for a response from the server before it regards the response times out.

    probe packet-timeout *timeout*

    The default setting is 3000 milliseconds.

11. (Optional.) Set the payload size for each UDP packet.

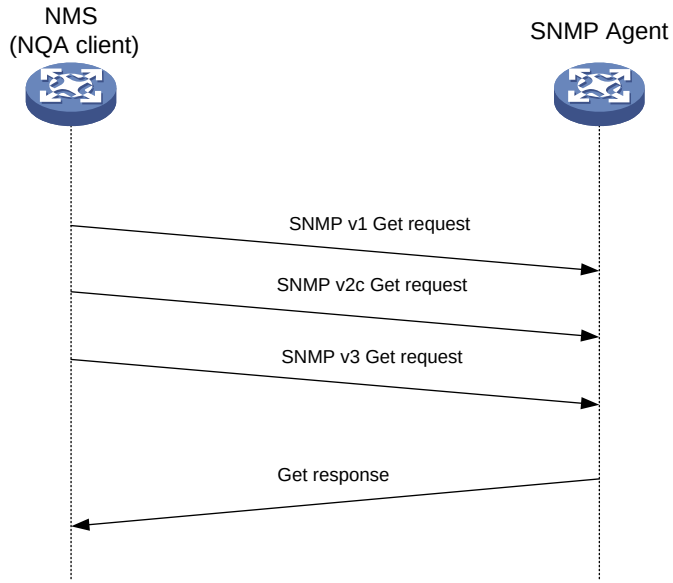
    data-size *size*

    The default payload size is 100 bytes.

12. (Optional.) Specify the payload fill string for UDP packets.

    data-fill *string*

    The default payload fill string is 00010203040506070809.



Configuring the SNMP operation

About this task

In an SNMP operation, the NQA client sends an SNMP Get request to the SNMP agent, and determines SNMP service availability on the SNMP agent based on whether it can receive a reply.

Currently, the widely used mainstream versions of SNMP on network devices are v1, v2c, and v3. During each operation, the NQA client will test all three versions of SNMP (v1, v2c, and v3). The operation is successful if a reply is received from any of these versions, as shown in Figure 7.

Figure 7 SNMP operation diagram

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the SNMP type and enter its view.

   type snmp

4. Specify the destination address for SNMP packets.

   destination ip *ip-address*

   By default, no destination IP address is specified.

5. Specify the source IP address for SNMP packets.

   source ip *ip-address*

   By default, the source IP address of SNMP packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no SNMP packets can be sent out.

6. Specify the source port number for SNMP packets.

   source port *port-number*

   By default, the system automatically selects an unused port as the source port for SNMP packets.

   For successful probing, make sure the source port number specified in the command is not used by any service on the device. As a best practice, use the default port number.

7. Specify the community name carried in the SNMPv1 and SNMPv2c packets.

   community read { **cipher** | **simple** } *community-name*

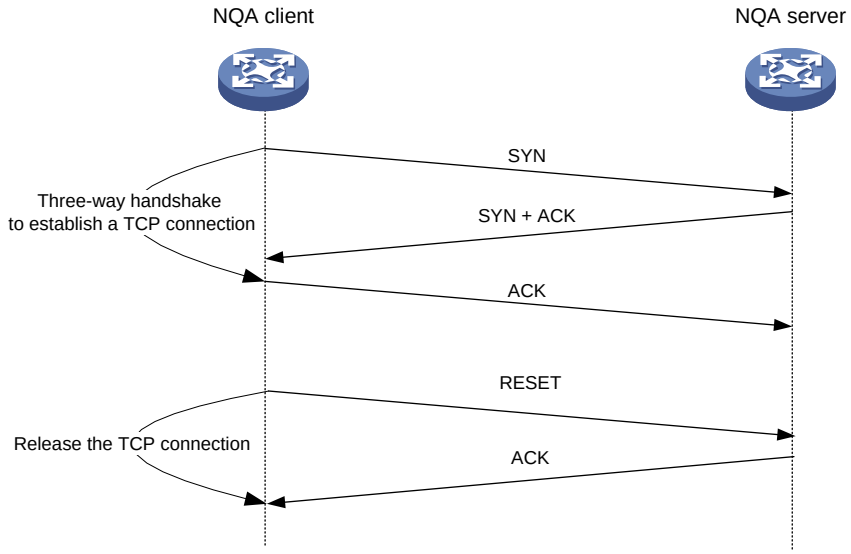
   By default, the SNMPv1 and SNMPv2c packets carry community name **public**.

   Make sure the specified community name is the same as the community name configured on the SNMP agent.

Configuring the TCP operation

About this task

The TCP operation measures the time for the NQA client to establish a TCP connection to a port on the NQA server.



Do not initiate TCP operations too frequently. Doing so might occupy too many resources and affect normal services on the destination device.

As shown in Figure 8, a TCP operation involves the following steps:

- Establish a TCP connection via the three-way handshake mechanism.
- Release the TCP connection through RESET packets.

If a TCP connection can be successfully established and then released, the operation is successful. For TCP operation, a single probe refers to the establishment of one TCP connection.

Figure 8 TCP operation diagram

Restrictions and guidelines

The TCP operation requires both the NQA server and the NQA client. Before you perform a TCP operation, configure a TCP listening service on the NQA server. For more information about the TCP listening service configuration, see "Configuring the NQA server."

The TCP operation sets up a TCP connection per probe.

Procedure

1. Enter system view.
   `system-view`
2. Create an NQA operation and enter NQA operation view.
   `nqa entry` *`admin-name operation-tag`*
3. Specify the TCP type and enter its view.
   `type tcp`
4. Specify the destination address for TCP packets.
   `destination ip` *`ip-address`*
   By default, no destination IP address is specified.

The destination address must be the same as the IP address of the TCP listening service configured on the NQA server. To configure a TCP listening service on the server, use the **nqa server tcp-connect** command.

5. Specify the destination port for TCP packets.

   destination port *port-number*

   By default, no destination port number is configured.

   The destination port number must be the same as the port number of the TCP listening service configured on the NQA server. To configure a TCP listening service on the server, use the **nqa server tcp-connect** command.

6. Specify the source IP address for TCP packets.

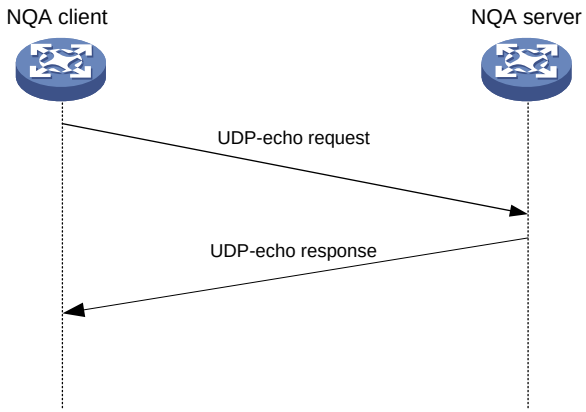
   source ip *ip-address*

   By default, the source IP address of TCP packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no TCP packets can be sent out.

Configuring the UDP echo operation

About this task



A UDP echo operation is typically used to test the connectivity and delay of a network. When you test the network connectivity and delay with UDP packets, you must enable NQA server on the peer end, and enable up the associated UDP port on the NQA server.

For a UDP echo operation, a probe refers to sending a probe packet.

As shown in Figure 9, a UDP echo operation is performed as follows:

1. The NQA client sends a UDP packet to the destination according to the configured probe time and frequency.
2. Upon receiving the UDP packet, the destination end sends a reply based on the packet.
3. Upon receiving the UDP packet, the NQA client calculates the time for the packet to reach the destination IP address and the packet loss rate, which reflects the network performance and status.

Figure 9 UDP echo operation diagram

Restrictions and guidelines

The UDP echo operation requires both the NQA server and the NQA client. Before you perform a UDP echo operation, configure a UDP listening service on the NQA server. For more information about the UDP listening service configuration, see "Configuring the NQA server."

The UDP echo operation sends a UDP packet to the destination device per probe.

Procedure

1. Enter system view.
   system-view
2. Create an NQA operation and enter NQA operation view.
   nqa entry *admin-name operation-tag*
3. Specify the UDP echo type and enter its view.
   type udp-echo
4. Specify the destination address for UDP packets.
   destination ip *ip-address*

   By default, no destination IP address is specified.

   The destination address must be the same as the IP address of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.
5. Specify the destination port number for UDP packets.
   destination port *port-number*

   By default, no destination port number is specified.

   The destination port number must be the same as the port number of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.
6. Specify the source IP address for UDP packets.
   source ip *ip-address*

   By default, the source IP address of UDP packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no UDP packets can be sent out.
7. Specify the source port number for UDP packets.
   source port *port-number*

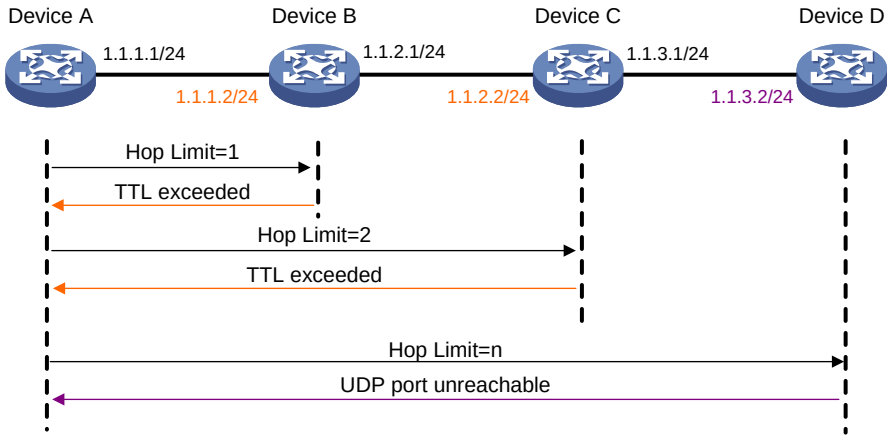
   By default, the system automatically selects an unused port as the source port for UDP packets.

   For successful probing, make sure the source port number specified in the command is not used by any service on the device. As a best practice, use the default port number.
8. (Optional.) Set the payload size for each UDP packet.
   data-size *size*

   The default setting is 100 bytes.
9. (Optional.) Specify the payload fill string for UDP packets.
   data-fill *string*

   The default payload fill string is 00010203040506070809.

Configuring the UDP tracert operation



About this task

The UDP tracert operation determines the routing path from the source device to the destination device. A UDP tracert operation sends a probe packet to a hop along the path per probe.

As shown in Figure 10, the UDP tracert operation is implemented based on the ICMP protocol. The operation process is similar to that of a regular tracert as follows:

1. The source device (Device A) sends an IP packet to the destination device (Device D) with a TTL value of 1 and a UDP port number that no application on the destination can use.
2. The first hop (Device B, the Layer 3 device that first receives the packet) responds by sending a TTL-expired ICMP message (containing IP address 1.1.1.2 of the first hop) to the source. In this way, the source device obtains the IP address of the first Layer 3 device (1.1.1.2).
3. The source device sends a packet with a TTL value of 2 to the destination device.
4. The second hop (Device C) responds with a TTL-expired ICMP message. In this way, the source device obtains the IP address of the second Layer 3 device (1.1.2.2).
5. This process continues until the packet reaches the destination device. Because no application on the destination device uses the specified UDP port, the destination device returns a port-unreachable ICMP error message (containing IP address 1.1.3.2 of the destination device).
6. Upon receiving the port-unreachable ICMP error message, the source device determines that the packet has reached the destination, and obtains the path from the source to the destination (1.1.1.2; 1.1.2.2; 1.1.3.2).

Figure 10 UDP tracert operation diagram

Restrictions and guidelines

The UDP tracert operation is not supported on IPv6 networks. To determine the routing path that the IPv6 packets traverse from the source to the destination, use the **tracert ipv6** command. For more information about the command, see *Network Management and Monitoring Command Reference.*

Prerequisites

Before you configure the UDP tracert operation, you must perform the following tasks:

- Enable sending ICMP time exceeded messages on the intermediate devices between the source and destination devices. If the intermediate devices are H3C devices, use the **ip ttl-expires enable** command.
- Enable sending ICMP destination unreachable messages on the destination device. If the destination device is an H3C device, use the **ip unreachables enable** command.

  For more information about the **ip ttl-expires enable** and **ip unreachables enable** commands, see *Layer 3—IP Services Command Reference*.

Procedure

1. Enter system view.

   system-view
2. Create an NQA operation and enter NQA operation view.

nqa entry *admin-name operation-tag*

3. Specify the UDP tracert operation type and enter its view.

   type udp-tracert

4. Specify the destination device for the operation. Choose one option as needed:
   - Specify the destination device by its host name.

     destination host *host-name*

     By default, no destination host name is specified.
   - Specify the destination device by its IP address.

     destination ip *ip-address*

     By default, no destination IP address is specified.

5. Specify the destination port number for UDP packets.

   destination port *port-number*

   By default, the destination port number is 33434.

   This port number must be an unused number on the destination device, so that the destination device can reply with ICMP port unreachable messages.

6. Specify an output interface for UDP packets.

   out interface *interface-type interface-number*

   By default, the NQA client determines the output interface based on the routing table lookup.

7. Specify the source IP address for UDP packets.
   - Specify the IP address of the specified interface as the source IP address.

     source interface *interface-type interface-number*

     By default, the source IP address of UDP packets is the primary IP address of their output interface.
   - Specify the source IP address.

     source ip *ip-address*

     The specified source interface must be up. The source IP address must be the IP address of a local interface, and the local interface must be up. Otherwise, no probe packets can be sent out.

8. Specify the source port number for UDP packets.

   source port *port-number*

   By default, the system automatically selects an unused port as the source port for UDP packets.

   For successful probing, make sure the source port number specified in the command is not used by any service on the device. As a best practice, use the default port number.

9. Set the maximum number of consecutive probe failures.

   max-failure *times*

   The default setting is 5.

10. Set the initial TTL value for UDP packets.

    init-ttl *value*

    The default setting is 1.

11. (Optional.) Set the payload size for each UDP packet.

    data-size *size*

    The default setting is 100 bytes.

12. (Optional.) Enable the no-fragmentation feature.

    no-fragment enable

    By default, the no-fragmentation feature is disabled.

Configuring the voice operation

About this task

The voice operation measures VoIP network performance.

The voice operation works as follows:

1. The NQA client sends voice packets at sending intervals to the destination device (NQA server).

   The voice packets are of one of the following codec types:

   - G.711 A-law.
   - G.711 μ-law.
   - G.729 A-law.

2. The destination device time stamps each voice packet it receives and sends it back to the source.
3. Upon receiving the packet, the source device calculates the jitter and one-way delay based on the timestamp.

The voice operation sends a number of voice packets to the destination device per probe. The number of packets to send per probe is determined by using the **probe packet-number** command.

The following parameters that reflect VoIP network performance can be calculated by using the metrics gathered by the voice operation:

- **Calculated Planning Impairment Factor (ICPIF)**—Measures impairment to voice quality on a VoIP network. It is decided by packet loss and delay. A higher value represents a lower service quality.
- **Mean Opinion Scores (MOS)**—A MOS value can be evaluated by using the ICPIF value, in the range of 1 to 5. A higher value represents a higher service quality.

The evaluation of voice quality depends on users' tolerance for voice quality. For users with higher tolerance for voice quality, use the **advantage-factor** command to set an advantage factor. When the system calculates the ICPIF value, it subtracts the advantage factor to modify ICPIF and MOS values for voice quality evaluation.

The voice operation requires both the NQA server and the NQA client. Before you perform a voice operation, configure a UDP listening service on the NQA server. For more information about UDP listening service configuration, see "Configuring the NQA server."

Restrictions and guidelines

To ensure successful voice operations and avoid affecting existing services, do not perform the operations on well-known ports from 1 to 1023.

The **display nqa history** command does not display the results or statistics of the voice operation. To view the results or statistics of the voice operation, use the **display nqa result** or **display nqa statistics** command.

Before starting the operation, make sure the network devices are time synchronized by using NTP. For more information about NTP, see "Configuring NTP."

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the voice type and enter its view.

type voice

4. Specify the destination IP address for voice packets.

   destination ip *ip-address*

   By default, no destination IP address is configured.

   The destination IP address must be the same as the IP address of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

5. Specify the destination port number for voice packets.

   destination port *port-number*

   By default, no destination port number is configured.

   The destination port number must be the same as the port number of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

6. Specify the source IP address for voice packets.

   source ip *ip-address*

   By default, the source IP address of voice packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no voice packets can be sent out.

7. Specify the source port number for voice packets.

   source port *port-number*

   By default, the system automatically selects an unused port as the source port for voice packets.

   For successful probing, make sure the source port number specified in the command is not used by any service on the device. As a best practice, use the default port number.

8. Configure the basic voice operation parameters.
   - Specify the codec type.

     codec-type { **g711a** | **g711u** | **g729a** }

     By default, the codec type is G.711 A-law.
   - Set the advantage factor for calculating MOS and ICPIF values.

     advantage-factor *factor*

     By default, the advantage factor is 0.

9. Configure the probe parameters for the voice operation.
   - Set the number of voice packets to be sent per probe.

     probe packet-number *number*

     The default setting is 1000.
   - Set the interval for sending voice packets.

     probe packet-interval *interval*

     The default setting is 20 milliseconds.
   - Specify how long the NQA client waits for a response from the server before it regards the response times out.

     probe packet-timeout *timeout*

     The default setting is 5000 milliseconds.

10. Configure the payload parameters.

    a. Set the payload size for voice packets.

    data-size *size*

By default, the voice packet size varies by codec type. The default packet size is 172 bytes for G.711A-law and G.711 μ-law codec type, and 32 bytes for G.729 A-law codec type.

b. (Optional.) Specify the payload fill string for voice packets.

data-fill *string*

The default payload fill string is 00010203040506070809.

Configuring the DLSw operation

About this task

The DLSw operation measures the response time of a DLSw device.

An NQA DLSw operation initiates a TCP connection to the DLSw port of the peer device, and then determines the DLSw status (enabled or not) on the peer device based on whether the connection can be established. Similar to a TCP operation in implementation, an NQA DLSw operation can be considered as a TCP operation with a fixed destination port number.

The DLSw operation sets up a DLSw connection to the DLSw device per probe.

Restrictions and guidelines

For the DLSw operation to succeed, configure the **nqa server tcp-connect** command on the NQA server and make sure the port number for the TCP listening service is 2065.

Procedure

1. Enter system view.

system-view

2. Create an NQA operation and enter NQA operation view.

nqa entry *admin-name operation-tag*

3. Specify the DLSw type and enter its view.

type dlsw

4. Specify the destination IP address for the probe packets.

destination ip *ip-address*

By default, no destination IP address is specified.

5. Specify the source IP address for the probe packets.

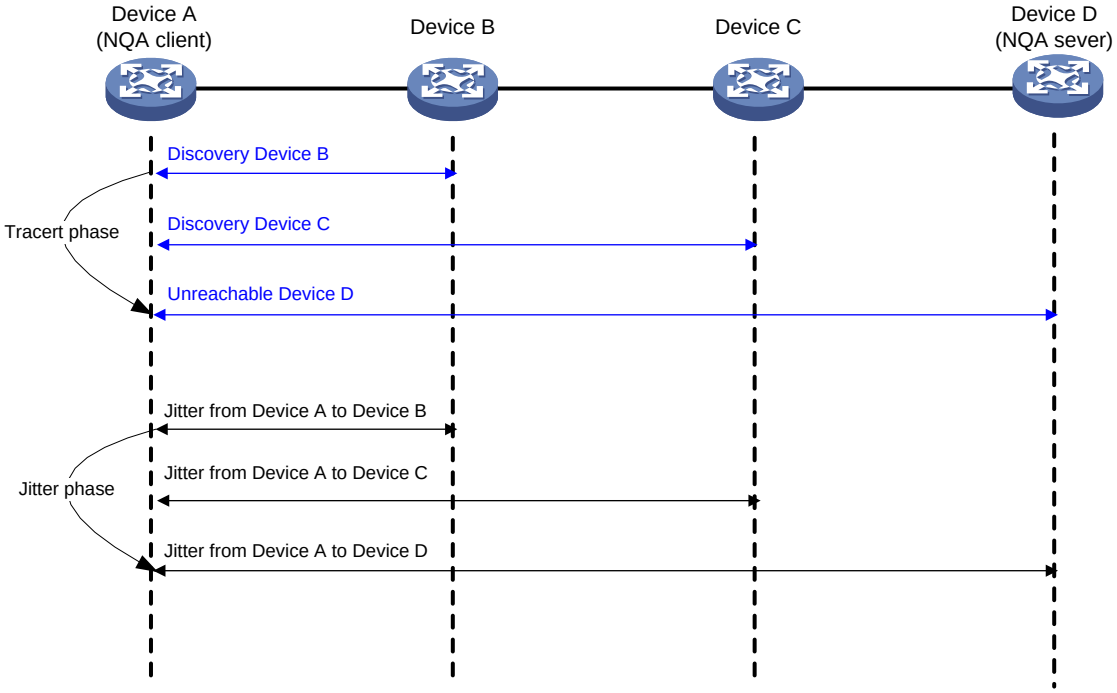
source ip *ip-address*

By default, the source IP address of the probe packets is the primary IP address of their output interface.

The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

Configuring the path jitter operation

About this task



As a supplement to the UDP jitter operation, the path jitter operation is used in scenarios with significant jitter to further detect the quality of the network along the intermediate path. This can help you identify specific path segments with poor network performance.

As shown in Figure 11, a path jitter operation involves the following steps per probe:

1. The NQA client obtains the path to the destination through tracert. A maximum of 64 hops can be detected.

2. The NQA client sends a number of ICMP echo requests to each hop along the path to check for packet loss and calculate the delay and jitter time of the path. The path jitter operation records the average jitter, positive jitter, and negative jitter values for each path.

Figure 11 Path jitter operation diagram

Prerequisites

Before you configure the path jitter operation, you must perform the following tasks:

- Enable sending ICMP time exceeded messages on the intermediate devices between the source and destination devices. If the intermediate devices are H3C devices, use the **ip ttl-expires enable** command.
- Enable sending ICMP destination unreachable messages on the destination device. If the destination device is an H3C device, use the **ip unreachables enable** command.

  For more information about the **ip ttl-expires enable** and **ip unreachables enable** commands, see *Layer 3—IP Services Command Reference*.

Procedure

1. Enter system view.

   system-view
2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*
3. Specify the path jitter type and enter its view.

   type path-jitter
4. Specify the destination IP address for ICMP echo requests.

   destination ip *ip-address*

   By default, no destination IP address is specified.
5. Specify the source IP address for ICMP echo requests.

   source ip *ip-address*

   By default, the source IP address of ICMP echo requests is the primary IP address of their output interface.

The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no ICMP echo requests can be sent out.

6. Configure the probe parameters for the path jitter operation.
   a. Set the number of ICMP echo requests to be sent per probe.
      probe packet-number *number*
      The default setting is 10.
   b. Set the interval for sending ICMP echo requests.
      probe packet-interval *interval*
      The default setting is 20 milliseconds.
   c. Specify how long the NQA client waits for a response from the server before it regards the response times out.
      probe packet-timeout *timeout*
      The default setting is 3000 milliseconds.
7. (Optional.) Specify an LSR path.
   lsr-path *ip-address*&<1-8>
   By default, no LSR path is specified.
   The path jitter operation uses tracert to detect the LSR path to the destination, and sends ICMP echo requests to each hop on the LSR path.
8. Perform the path jitter operation only on the destination address.
   target-only
   By default, the path jitter operation is performed on each hop on the path to the destination.
9. (Optional.) Set the payload size for each ICMP echo request.
   data-size *size*
   The default setting is 100 bytes.
10. (Optional.) Specify the payload fill string for ICMP echo requests.
    data-fill *string*
    The default payload fill string is 00010203040506070809.

Configuring optional parameters for the NQA operation

Restrictions and guidelines

The parameter settings take effect only on the current operation.

The supported parameters vary by NQA operation type. For information about supported parameters, see NQA commands in *Network Management and Monitoring Command Reference*.

Procedure

1. Enter system view.
   system-view
2. Enter the view of an existing NQA operation.
   nqa entry *admin-name operation-tag*
3. Specify an NQA operation type and enter its view.
   type { **dhcp** | **dlsw** | **dns** | | **ftp** | **http** | **icmp-echo** | **icmp-jitter** | **path-jitter** | **snmp** | **tcp** | **udp-echo** | **udp-jitter** | **udp-tracert** | **voice** }
4. Configure a description for the operation.
   description *text*
   By default, no description is configured.

5. Set the interval at which the NQA operation repeats.

   frequency *interval*

   For a voice or path jitter operation, the default setting is 60000 milliseconds.

   For other types of operations, the default setting is 0 milliseconds, and only one operation is performed.

   When the interval expires, but the operation is not completed or is not timed out, the next operation does not start.

6. Specify the probe times.

   probe count *times*

   In an UDP tracert operation, the NQA client performs three probes to each hop to the destination by default.

   In other types of operations, the NQA client performs one probe to the destination per operation by default.

   This command is not available for the voice and path jitter operations. Each of these operations performs only one probe.

7. Set the probe timeout time.

   probe timeout *timeout*

   The default setting is 3000 milliseconds.

8. Set the maximum number of hops that the probe packets can traverse.

   ttl *value*

   The default setting is 30 for probe packets of the UDP tracert operation, and is 20 for probe packets of other types of operations.

9. Set the ToS value in the IP header of the probe packets.

   tos *value*

   The default setting is 0.

10. Enable the routing table bypass feature.

    route-option bypass-route

    By default, the routing table bypass feature is disabled.

    This command does not take effect if the destination address of the NQA operation is an IPv6 address.

11. Specify the VPN instance where the operation is performed.

    vpn-instance *vpn-instance-name*

    By default, the operation is performed on the public network.

Configuring the collaboration feature

About this task

The collaboration feature associates a detection module, the Track module, and an application module. You can use NQA as a detection module in the collaboration feature to monitor the NQA operation. If the number of consecutive NQA operation failures reaches the specified threshold, the Track-associated application module is triggered to take relevant actions.

Restrictions and guidelines

The collaboration feature is not available for the following types of operations:

- ICMP jitter operation.
- UDP jitter operation.
- UDP tracert operation.

- Voice operation.
- Path jitter operation.

Procedure

1. Enter system view.

   system-view
2. Enter the view of an existing NQA operation.

   nqa entry *admin-name operation-tag*
3. Configure a reaction entry.

   reaction *item-number* **checked-element probe-fail threshold-type consecutive** *consecutive-occurrences* **action-type trigger-only**

   You cannot modify the content of an existing reaction entry.
4. Return to system view.

   quit
5. Associate Track with NQA.

   For information about the configuration, see *High Availability Configuration Guide*.
6. Associate Track with an application module.

   For information about the configuration, see *High Availability Configuration Guide*.

Configuring threshold monitoring

About this task

This feature allows you to monitor the NQA operation running status.

An NQA operation supports the following threshold types:

- **average**—If the average value for the monitored performance metric either exceeds the upper threshold or goes below the lower threshold, a threshold violation occurs.
- **accumulate**—If the total number of times that the monitored performance metric is out of the specified value range reaches or exceeds the specified threshold, a threshold violation occurs.
- **consecutive**—If the number of consecutive times that the monitored performance metric is out of the specified value range reaches or exceeds the specified threshold, a threshold violation occurs.

Threshold violations for the average or accumulate threshold type are determined on a per NQA operation basis. The threshold violations for the consecutive type are determined from the time the NQA operation starts.

The following actions might be triggered:

- **none**—NQA displays results only on the terminal screen. It does not send traps to the NMS.
- **trap-only**—NQA displays results on the terminal screen, and meanwhile it sends traps to the NMS.

  To send traps to the NMS, the NMS address must be specified by using the **snmp-agent target-host** command. For more information about the command, see *Network Management and Monitoring Command Reference*.
- **trigger-only**—NQA displays results on the terminal screen, and meanwhile triggers other modules for collaboration.

In a reaction entry, configure a monitored element, a threshold type, and an action to be triggered to implement threshold monitoring.

The state of a reaction entry can be invalid, over-threshold, or below-threshold.

- Before an NQA operation starts, the reaction entry is in invalid state.
- If the threshold is violated, the state of the entry is set to over-threshold. Otherwise, the state of the entry is set to below-threshold.

Restrictions and guidelines

The threshold monitoring feature is not available for the path jitter operations.

Procedure

1. Enter system view.

   system-view

2. Enter the view of an existing NQA operation.

   nqa entry *admin-name operation-tag*

3. Enable sending traps to the NMS when specific conditions are met.

   reaction trap { **path-change** | **probe-failure** *consecutive-probe-failures* | **test-complete** | **test-failure** [*accumulate-probe-failures*] }

   By default, no traps are sent to the NMS.

   The ICMP jitter, UDP jitter, and voice operations support only the **test-complete** keyword.

   The following parameters are not available for the UDP tracert operation:

   - The **probe-failure** *consecutive-probe-failures* option.
   - The *accumulate-probe-failures* argument.

4. Configure threshold monitoring. Choose the options to configure as needed:

   - Monitor the operation duration.

     reaction *item-number* **checked-element probe-duration threshold-type** { **accumulate** *accumulate-occurrences* | **average** | **consecutive** *consecutive-occurrences* } **threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

     This reaction entry is not supported in the ICMP jitter, UDP jitter, UDP tracert, or voice operations

   - Monitor failure times.

     reaction *item-number* **checked-element probe-fail threshold-type** { **accumulate** *accumulate-occurrences* | **consecutive** *consecutive-occurrences* } [**action-type** { **none** | **trap-only** }]

     This reaction entry is not supported in the ICMP jitter, UDP jitter, UDP tracert, or voice operations.

   - Monitor the number of consecutive operation failures.

     reaction *item-number* **checked-element test-fail threshold-type consecutive** *consecutive-occurrences* **threshold-value** *upper-threshold* **action-type** { **none** | **trap-only** }

     Only the ICMP echo, TCP/UDP echo, DHCP, DLSw, DNS, FTP, HTTP, and SNMP operations support this reaction entry.

   - Monitor the operation result change.

     reaction *item-number* **checked-element test-result-change threshold-value** *upper-threshold* **action-type** { **none** | **trap-only** }

     Only the ICMP echo operation supports this reaction entry.

   - Monitor the round-trip time.

     reaction *item-number* **checked-element rtt threshold-type** { **accumulate** *accumulate-occurrences* | **average** } **threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

Only the ICMP jitter, UDP jitter, and voice operations support this reaction entry.

- Monitor packet loss.

  reaction *item-number* **checked-element packet-loss threshold-type accumulate** *accumulate-occurrences* [**action-type** { **none** | **trap-only** }]

  Only the ICMP jitter, UDP jitter, and voice operations support this reaction entry.

- Monitor the one-way jitter.

  reaction *item-number* **checked-element** { **jitter-ds** | **jitter-sd** } **threshold-type** { **accumulate** *accumulate-occurrences* | **average** } **threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

  Only the ICMP jitter, UDP jitter, and voice operations support this reaction entry.

- Monitor the one-way delay.

  reaction *item-number* **checked-element** { **owd-ds** | **owd-sd** } **threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

  Only the ICMP jitter, UDP jitter, and voice operations support this reaction entry.

- Monitor the ICPIF value.

  reaction *item-number* **checked-element icpif threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

  Only the voice operation supports this reaction entry.

- Monitor the MOS value.

  reaction *item-number* **checked-element mos threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

  Only the voice operation supports this reaction entry.

The DNS operation does not support the action of sending trap messages. For the DNS operation, the action type can only be **none**.

Configuring the NQA statistics collection feature

About this task

NQA forms statistics within the same collection interval as a statistics group. To display information about the statistics groups, use the **display nqa statistics** command.

When the maximum number of statistics groups is reached, the NQA client deletes the oldest statistics group to save a new one.

A statistics group is automatically deleted when its hold time expires.

Restrictions and guidelines

The NQA statistics collection feature is not available for the UDP tracert operations.

If you use the **frequency** command to set the interval to 0 milliseconds for an NQA operation, NQA does not generate any statistics group for the operation.

Procedure

1. Enter system view.

   system-view

2. Enter the view of an existing NQA operation.

   nqa entry *admin-name operation-tag*

3. Set the statistics collection interval.

statistics interval *interval*

The default setting is 60 minutes.

4. Set the maximum number of statistics groups that can be saved.

   statistics max-group *number*

   By default, the NQA client can save a maximum of two statistics groups for an operation.

   To disable the NQA statistics collection feature, set the *number* argument to 0.

5. Set the hold time of statistics groups.

   statistics hold-time *hold-time*

   The default setting is 120 minutes.

Configuring the saving of NQA history records

About this task

This task enables the NQA client to save NQA history records. You can use the **display nqa history** command to display the NQA history records.

Restrictions and guidelines

The NQA history record saving feature is not available for the following types of operations:

- ICMP jitter operation.
- UDP jitter operation.
- Voice operation.
- Path jitter operation.

Procedure

1. Enter system view.

   system-view

2. Enter the view of an existing NQA operation.

   nqa entry *admin-name operation-tag*

3. Enable the saving of history records for the NQA operation.

   history-record enable

   By default, this feature is enabled only for the UDP tracert operation.

4. Set the lifetime of history records.

   history-record keep-time *keep-time*

   The default setting is 120 minutes.

   A record is deleted when its lifetime is reached.

5. Set the maximum number of history records that can be saved.

   history-record number *number*

   The default setting is 50.

   When the maximum number of history records is reached, the system will delete the oldest record to save a new one.

Scheduling the NQA operation on the NQA client

About this task

The NQA operation runs between the specified start time and end time (the start time plus operation duration). If the specified start time is ahead of the system time, the operation starts immediately. If

both the specified start and end time are ahead of the system time, the operation does not start. To display the current system time, use the **display clock** command.

Restrictions and guidelines

You cannot enter the operation type view or the operation view of a scheduled NQA operation.

A system time adjustment does not affect started or completed NQA operations. It affects only the NQA operations that have not started.

Procedure

1. Enter system view.

   system-view

2. Specify the scheduling parameters for an NQA operation.

   nqa schedule *admin-name operation-tag* **start-time** { *hh:mm:ss* [*yyyy/mm/dd* | *mm/dd/yyyy*] | **now** } **lifetime** { *lifetime* | **forever** } [**recurring**]

Configuring NQA templates on the NQA client

Restrictions and guidelines

Some operation parameters for an NQA template can be specified by the template configuration or the feature (such as load balancing) that uses the template. When both are specified, the parameters in the template configuration take effect.

NQA template tasks at a glance

To configure NQA templates, perform the following tasks:

1. Perform at least one of the following tasks:
   - Configuring the ICMP template
   - Configuring the DNS template
   - Configuring the TCP template
   - Configuring the TCP half open template
   - Configuring the UDP template
   - Configuring the HTTP template
   - Configuring the HTTPS template
   - Configuring the FTP template
   - Configuring the RADIUS template
   - Configuring the SSL template
2. (Optional.) Configuring optional parameters for the NQA template

Configuring the ICMP template

About this task

A feature that uses the ICMP template performs the ICMP operation to measure the reachability of a destination device. The ICMP template is supported on both IPv4 and IPv6 networks.

Procedure

1. Enter system view.

system-view

2. Create an ICMP template and enter its view.

   nqa template icmp *name*

3. Specify the destination IP address for the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is configured.

4. Specify the source IP address for ICMP echo requests. Choose one option as needed:

   - Use the IP address of the specified interface as the source IP address.

     source interface *interface-type interface-number*

     By default, the primary IP address of the output interface is used as the source IP address of ICMP echo requests.

     The specified source interface must be up.

   - Specify the source IPv4 address.

     source ip *ip-address*

     By default, the primary IPv4 address of the output interface is used as the source IPv4 address of ICMP echo requests.

     The specified source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   - Specify the source IPv6 address.

     source ipv6 *ipv6-address*

     By default, the primary IPv6 address of the output interface is used as the source IPv6 address of ICMP echo requests.

     The specified source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

5. Specify the next hop IP address for ICMP echo requests.

   IPv4:

   next-hop ip *ip-address*

   IPv6:

   next-hop ipv6 *ipv6-address*

   By default, no IP address of the next hop is configured.

   To avoid probe failure, make sure the IP address belongs to a directly connected next hop.

6. Configure the probe result sending on a per-probe basis.

   reaction trigger per-probe

   By default, the probe result is sent to the feature that uses the template after three consecutive failed or successful probes.

   If you execute the **reaction trigger per-probe** and **reaction trigger probe-pass** commands multiple times, the most recent configuration takes effect.

   If you execute the **reaction trigger per-probe** and **reaction trigger probe-fail** commands multiple times, the most recent configuration takes effect.

7. (Optional.) Set the payload size for each ICMP request.

   data-size *size*

   The default setting is 100 bytes.

8. (Optional.) Specify the payload fill string for ICMP echo requests.

   data-fill *string*

   The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring the DNS template

About this task

A feature that uses the DNS template performs the DNS operation to determine the status of the server. The DNS template is supported on both IPv4 and IPv6 networks.

In DNS template view, you can specify the address expected to be returned. If the returned IP addresses include the expected address, the DNS server is valid and the operation succeeds. Otherwise, the operation fails.

Prerequisites

Create a mapping between the domain name and an address before you perform the DNS operation. For information about configuring the DNS server, see documents about the DNS server configuration.

Procedure

1. Enter system view.

   system-view

2. Create a DNS template and enter DNS template view.

   nqa template dns *name*

3. Specify the destination IP address for the probe packets.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination address is specified.

4. Specify the destination port number for the probe packets.

   destination port *port-number*

   By default, the destination port number is 53.

5. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the source IPv4 address of the probe packets is the primary IPv4 address of their output interface.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the source IPv6 address of the probe packets is the primary IPv6 address of their output interface.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. Specify the source port number for the probe packets.

   source port *port-number*

By default, the system automatically selects an unused port as the source port for probe packets.

For successful probing, make sure the source port number specified in the command is not used by any service on the device. As a best practice, use the default port number.

7. Specify the domain name to be translated.

   resolve-target *domain-name*

   By default, no domain name is specified.

8. Specify the domain name resolution type.

   resolve-type { **A** | **AAAA** }

   By default, the type is type A.

   A type A query resolves a domain name to a mapped IPv4 address, and a type AAAA query to a mapped IPv6 address.

9. (Optional.) Specify the IP address that is expected to be returned.

   IPv4:

   expect ip *ip-address*

   IPv6:

   expect ipv6 *ipv6-address*

   By default, no expected IP address is specified.

Configuring the TCP template

About this task

A feature that uses the TCP template performs the TCP operation to test whether the NQA client can establish a TCP connection to a specific port on the server.

In TCP template view, you can specify the expected data to be returned. If you do not specify the expected data, the TCP operation tests only whether the client can establish a TCP connection to the server.

The TCP operation requires both the NQA server and the NQA client. Before you perform a TCP operation, configure a TCP listening service on the NQA server. For more information about the TCP listening service configuration, see "Configuring the NQA server."

Procedure

1. Enter system view.

   system-view

2. Create a TCP template and enter its view.

   nqa template tcp *name*

3. Specify the destination IP address for the probe packets.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

   The destination address must be the same as the IP address of the TCP listening service configured on the NQA server. To configure a TCP listening service on the server, use the **nqa server tcp-connect** command.

4. Specify the destination port number for the operation.

   destination port *port-number*

By default, no destination port number is specified.

The destination port number must be the same as the port number of the TCP listening service configured on the NQA server. To configure a TCP listening service on the server, use the **nqa server tcp-connect** command.

5. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. (Optional.) Specify the payload fill string for the probe packets.

   data-fill *string*

   By default, no payload fill string is configured for probe packets.

7. (Optional.) Configure the expected data.

   expect data *expression* [**offset** *number*]

   By default, no expected data is configured.

   The NQA client performs expect data check only when you configure both the **data-fill** and **expect-data** commands.

Configuring the TCP half open template

About this task

A feature that uses the TCP half open template performs the TCP half open operation to test whether the TCP service is available on the server. The TCP half open operation is used when the feature cannot get a response from the TCP server through an existing TCP connection.

In the TCP half open operation, the NQA client sends a TCP ACK packet to the server. If the client receives an RST packet, it considers that the TCP service is available on the server.

Procedure

1. Enter system view.

   system-view

2. Create a TCP half open template and enter its view.

   nqa template tcphalfopen *name*

3. Specify the destination IP address of the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

The destination address must be the same as the IP address of the TCP listening service configured on the NQA server. To configure a TCP listening service on the server, use the **nqa server tcp-connect** command.

4. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

5. Specify the next hop IP address for the probe packets.

   IPv4:

   next-hop ip *ip-address*

   IPv6:

   next-hop ipv6 *ipv6-address*

   By default, the IP address of the next hop is configured.

   To avoid probe failure, make sure the IP address belongs to a directly connected next hop.

6. Configure the probe result sending on a per-probe basis.

   reaction trigger per-probe

   By default, the probe result is sent to the feature that uses the template after three consecutive failed or successful probes.

   If you execute the **reaction trigger per-probe** and **reaction trigger probe-pass** commands multiple times, the most recent configuration takes effect.

   If you execute the **reaction trigger per-probe** and **reaction trigger probe-fail** commands multiple times, the most recent configuration takes effect.

Configuring the UDP template

About this task

A feature that uses the UDP template performs the UDP operation to test the following items:

- Reachability of a specific port on the NQA server.
- Availability of the requested service on the NQA server.

In UDP template view, you can specify the expected data to be returned. If you do not specify the expected data, the UDP operation tests only whether the client can receive the response packet from the server.

The UDP operation requires both the NQA server and the NQA client. Before you perform a UDP operation, configure a UDP listening service on the NQA server. For more information about the UDP listening service configuration, see "Configuring the NQA server."

Procedure

1. Enter system view.

system-view

2. Create a UDP template and enter its view.

   nqa template udp *name*

3. Specify the destination IP address of the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

   The destination address must be the same as the IP address of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

4. Specify the destination port number for the operation.

   destination port *port-number*

   By default, no destination port number is specified.

   The destination port number must be the same as the port number of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

5. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. Specify the payload fill string for the probe packets.

   data-fill *string*

   The default payload fill string is the hexadecimal string 00010203040506070809.

7. (Optional.) Set the payload size for the probe packets.

   data-size *size*

   The default setting is 100 bytes.

8. (Optional.) Configure the expected data.

   expect data *expression* [**offset** *number*]

   By default, no expected data is configured.

   Expected data check is performed only when both the **data-fill** command and the **expect data** command are configured.

Configuring the HTTP template

About this task

A feature that uses the HTTP template performs the HTTP operation to measure the time it takes the NQA client to obtain data from an HTTP server.

The expected data is checked only when the data is configured and the HTTP response contains the Content-Length field in the HTTP header.

The status code of the HTTP packet is a three-digit field in decimal notation, and it includes the status information for the HTTP server. The first digit defines the class of response.

Prerequisites

Before you perform the HTTP operation, you must configure the HTTP server.

Procedure

1. Enter system view.

   system-view

2. Create an HTTP template and enter its view.

   nqa template http *name*

3. Specify the destination URL for the HTTP template.

   url *url*

   By default, no destination URL is specified for an HTTP template.

   Enter the URL in one of the following formats:

   - http://*host*/*resource*
   - http://*host*:*port*/*resource*

   If the value for the *host* parameter is an IPv6 address, you must use a pair of square brackets ([]) to include the IPv6 address, for example, http://[2001::1]/test.

4. Specify an HTTP login username.

   username *username*

   By default, no HTTP login username is specified.

5. Specify an HTTP login password.

   password { **cipher** | **simple** } *string*

   By default, no HTTP login password is specified.

6. Specify the HTTP version.

   version { **v1.0** | **v1.1** }

   By default, HTTP 1.0 is used.

7. Specify the HTTP operation type.

   operation { **get** | **post** | **raw** }

   By default, the HTTP operation type is **get**.

   If you set the operation type to raw, the client pads the content configured in raw request view to the HTTP request to send to the HTTP server.

8. Configure the content of the HTTP raw request.

   a. Enter raw request view.

      raw-request

      Every time you enter raw request view, the previously configured raw request content is cleared.

   b. Enter or paste the request content.

By default, no request content is configured.

To ensure successful operations, make sure the request content does not contain command aliases configured by using the **alias** command. For more information about the **alias** command, see CLI commands in *Fundamentals Command Reference*.

c. Return to HTTP template view.

quit

The system automatically saves the configuration in raw request view before it returns to HTTP template view.

This step is required only when the operation type is set to **raw**.

9. Specify the source IP address for the probe packets.

IPv4:

source ip *ip-address*

By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

IPv6:

source ipv6 *ipv6-address*

By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

10. (Optional.) Configure the expected status codes.

expect status *status-list*

By default, no expected status code is configured.

11. (Optional.) Configure the expected data.

expect data *expression* [**offset** *number*]

By default, no expected data is configured.

Configuring the HTTPS template

About this task

A feature that uses the HTTPS template performs the HTTPS operation to measure the time it takes for the NQA client to obtain data from an HTTPS server.

The expected data is checked only when the expected data is configured and the HTTPS response contains the Content-Length field in the HTTPS header.

The status code of the HTTPS packet is a three-digit field in decimal notation, and it includes the status information for the HTTPS server. The first digit defines the class of response.

Prerequisites

Before you perform the HTTPS operation, configure the HTTPS server and the SSL client policy for the SSL client. For information about configuring SSL client policies, see *Security Configuration Guide*.

Procedure

1. Enter system view.

system-view

2. Create an HTTPS template and enter its view.

nqa template https *name*

3. Specify the destination URL for the HTTPS template.

   url *url*

   By default, no destination URL is specified for an HTTPS template.

   Enter the URL in one of the following formats:

   - https://*host*/*resource*
   - https://*host*:*port*/*resource*

   If the value for the *host* parameter is an IPv6 address, you must use a pair of square brackets ([]) to include the IPv6 address, for example, https://[2001::1]/test.

4. Specify an HTTPS login username.

   username *username*

   By default, no HTTPS login username is specified.

5. Specify an HTTPS login password.

   password { **cipher** | **simple** } *string*

   By default, no HTTPS login password is specified.

6. Specify an SSL client policy.

   ssl-client-policy *policy-name*

   By default, no SSL client policy is specified.

7. Specify the HTTPS version.

   version { **v1.0** | **v1.1** }

   By default, HTTPS 1.0 is used.

8. Specify the HTTPS operation type.

   operation { **get** | **post** | **raw** }

   By default, the HTTPS operation type is **get**.

   If you set the operation type to raw, the client pads the content configured in raw request view to the HTTPS request to send to the HTTPS server.

9. Configure the content of the HTTPS raw request.

   a. Enter raw request view.

      raw-request

      Every time you enter raw request view, the previously configured raw request content is cleared.

   b. Enter or paste the request content.

      By default, no request content is configured.

      To ensure successful operations, make sure the request content does not contain command aliases configured by using the **alias** command. For more information about the **alias** command, see CLI commands in *Fundamentals Command Reference*.

   c. Return to HTTPS template view.

      quit

      The system automatically saves the configuration in raw request view before it returns to HTTPS template view.

   This step is required only when the operation type is set to **raw**.

10. Specify the source IP address for the probe packets.

    IPv4:

    source ip *ip-address*

By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

IPv6:

source ipv6 *ipv6-address*

By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

11. (Optional.) Configure the expected data.

expect data *expression* [**offset** *number*]

By default, no expected data is configured.

12. (Optional.) Configure the expected status codes.

expect status *status-list*

By default, no expected status code is configured.

Configuring the FTP template

About this task

A feature that uses the FTP template performs the FTP operation. The operation measures the time it takes the NQA client to transfer a file to or download a file from an FTP server.

Configure the username and password for the FTP client to log in to the FTP server before you perform an FTP operation. For information about configuring the FTP server, see *Fundamentals Configuration Guide*.

Procedure

1. Enter system view.

system-view

2. Create an FTP template and enter its view.

nqa template ftp *name*

3. Specify an FTP login username.

username *username*

By default, no FTP login username is specified.

4. Specify an FTP login password.

password { **cipher** | **simple** } *sting*

By default, no FTP login password is specified.

5. Specify the source IP address for the probe packets.

IPv4:

source ip *ip-address*

By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

IPv6:

source ipv6 *ipv6-address*

By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. Set the data transmission mode.

   mode { **active** | **passive** }

   The default mode is **active**.

7. Specify the FTP operation type.

   operation { **get** | **put** }

   By default, the FTP operation type is **get**, which means obtaining files from the FTP server.

8. Specify the destination URL for the FTP template.

   url *url*

   By default, no destination URL is specified for an FTP template.

   Enter the URL in one of the following formats:

   - ftp://*host*/*filename*.
   - ftp://*host*:*port*/*filename*.

   If the value for the *host* parameter is an IPv6 address, you must use a pair of square brackets ([]) to include the IPv6 address, for example, ftp://[2001::1]/test. When you perform the **get** operation, the file name is required.

   When you perform the **put** operation, the *filename* argument does not take effect, even if it is specified. The file name for the **put** operation is determined by using the **filename** command.

9. Specify the name of a file to be transferred.

   filename *filename*

   By default, no file is specified.

   This task is required only for the **put** operation.

   The configuration does not take effect for the **get** operation.

Configuring the RADIUS template

About this task

A feature that uses the RADIUS template performs the RADIUS authentication operation to check the availability of the authentication service on the RADIUS server.

The RADIUS authentication operation workflow is as follows:

1. The NQA client sends an authentication request (Access-Request) to the RADIUS server. The request includes the username and the password. The password is encrypted by using the MD5 algorithm and the shared key.
2. The RADIUS server authenticates the username and password.
   - If the authentication succeeds, the server sends an Access-Accept packet to the NQA client.
   - If the authentication fails, the server sends an Access-Reject packet to the NQA client.
3. The NQA client determines the availability of the authentication service on the RADIUS server based on the response packet it received:
   - If an Access-Accept packet is received, the authentication service is available on the RADIUS server.
   - If an Access-Reject packet is received, the authentication service is not available on the RADIUS server.

Prerequisites

Before you configure the RADIUS template, specify a username, password, and shared key on the RADIUS server. For more information about configuring the RADIUS server, see AAA in *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Create a RADIUS template and enter its view.

   nqa template radius *name*

3. Specify the destination IP address of the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

4. Specify the destination port number for the operation.

   destination port *port-number*

   By default, the destination port number is 1812.

5. Specify a username.

   username *username*

   By default, no username is specified.

6. Specify a password.

   password { **cipher** | **simple** } *string*

   By default, no password is specified.

7. Specify a shared key for secure RADIUS authentication.

   key { **cipher** | **simple** } *string*

   By default, no shared key is specified for RADIUS authentication.

8. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

Configuring the SSL template

About this task

A feature that uses the SSL template performs the SSL operation to measure the time required to establish an SSL connection to an SSL server.

Prerequisites

Before you configure the SSL template, you must configure the SSL client policy. For information about configuring SSL client policies, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Create an SSL template and enter its view.

   nqa template ssl *name*
3. Specify the destination IP address of the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.
4. Specify the destination port number for the operation.

   destination port *port-number*

   By default, the destination port number is not specified.
5. Specify an SSL client policy.

   ssl-client-policy *policy-name*

   By default, no SSL client policy is specified.
6. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

Configuring optional parameters for the NQA template

Restrictions and guidelines

Unless otherwise specified, the following optional parameters apply to all types of NQA templates.

The parameter settings take effect only on the current NQA template.

Procedure

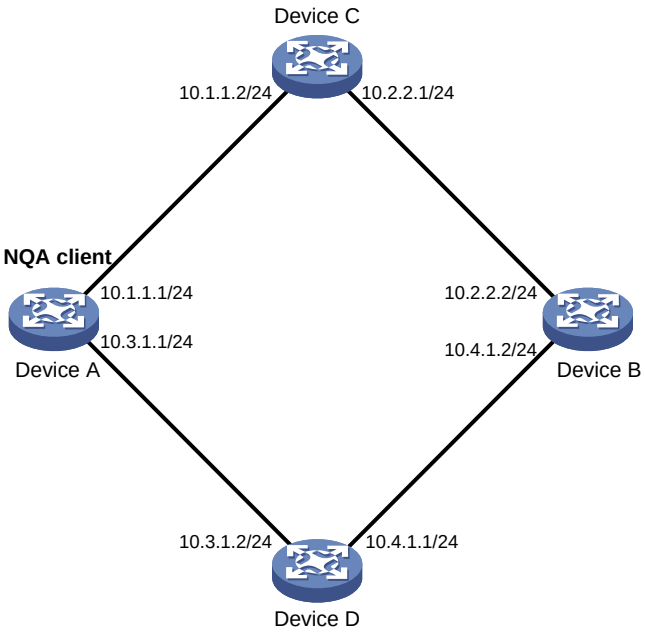
1. Enter system view.
   system-view
2. Enter the view of an existing NQA template.
   nqa template { **dns** | **ftp** | **http** | **https** | **icmp** | **radius** | **ssl** | **tcp** | **tcphalfopen** | **udp** } *name*
3. Configure a description.
   description *text*
   By default, no description is configured.
4. Set the interval at which the NQA operation repeats.
   frequency *interval*
   The default setting is 5000 milliseconds.
   If the operation is not completed when the interval expires, the next operation does not start.
5. Set the probe timeout time.
   probe timeout *timeout*
   The default setting is 3000 milliseconds.
6. Set the TTL for the probe packets.
   ttl *value*
   The default setting is 20.
   This command is not available for the ARP template.
7. Set the ToS value in the IP header of the probe packets.
   tos *value*
   The default setting is 0.
   This command is not available for the ARP template.
8. Specify the VPN instance where the operation is performed.
   vpn-instance *vpn-instance-name*
   By default, the operation is performed on the public network.
9. Set the number of consecutive successful probes to determine a successful operation event.
   reaction trigger probe-pass *count*
   The default setting is 3.
   If the number of consecutive successful probes for an NQA operation is reached, the NQA client notifies the feature that uses the template of the successful operation event.
10. Set the number of consecutive probe failures to determine an operation failure.
    reaction trigger probe-fail *count*
    The default setting is 3.
    If the number of consecutive probe failures for an NQA operation is reached, the NQA client notifies the feature that uses the NQA template of the operation failure.

Display and maintenance commands for NQA

Execute **display** commands in any view.

Task	Command
Display history records of NQA	**display nqa history** [*admin-name*

Task	Command
operations.	*operation-tag*]
Display the current monitoring results of reaction entries.	**display nqa reaction counters** [*admin-name operation-tag* [*item-number*]]
Display the most recent result of the NQA operation.	**display nqa result** [*admin-name operation-tag*]
Display NQA server status.	**display nqa server status**
Display NQA statistics.	**display nqa statistics** [*admin-name operation-tag*]



NQA configuration examples

Example: Configuring the ICMP echo operation

Network configuration

As shown in Figure 12, configure an ICMP echo operation on the NQA client (Device A) to test the round-trip time to Device B. The next hop of Device A is Device C.

Figure 12 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 12. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create an ICMP echo operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type icmp-echo
```

Specify 10.2.2.2 as the destination IP address of ICMP echo requests.

```
[DeviceA-nqa-admin-test1-icmp-echo] destination ip 10.2.2.2
```

Specify 10.1.1.2 as the next hop. The ICMP echo requests are sent through Device C to Device B.

```
[DeviceA-nqa-admin-test1-icmp-echo] next-hop ip 10.1.1.2
```

Configure the ICMP echo operation to perform 10 probes.

```
[DeviceA-nqa-admin-test1-icmp-echo] probe count 10
```

Set the probe timeout time to 500 milliseconds for the ICMP echo operation.

```
[DeviceA-nqa-admin-test1-icmp-echo] probe timeout 500
```

Configure the ICMP echo operation to repeat every 5000 milliseconds.

```
[DeviceA-nqa-admin-test1-icmp-echo] frequency 5000
```

Enable saving history records.

```
[DeviceA-nqa-admin-test1-icmp-echo] history-record enable
```

Set the maximum number of history records to 10.

```
[DeviceA-nqa-admin-test1-icmp-echo] history-record number 10
[DeviceA-nqa-admin-test1-icmp-echo] quit
```

Start the ICMP echo operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the ICMP echo operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the ICMP echo operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 10             Receive response times: 10
    Min/Max/Average round trip time: 2/5/3
    Square-Sum of round trip time: 96
    Last succeeded probe time: 2019-08-23 15:00:01.2
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the ICMP echo operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test) history records:
  Index      Response     Status           Time
  370        3            Succeeded        2019-08-23 15:00:01.2
  369        3            Succeeded        2019-08-23 15:00:01.2
  368        3            Succeeded        2019-08-23 15:00:01.2
  367        5            Succeeded        2019-08-23 15:00:01.2
  366        3            Succeeded        2019-08-23 15:00:01.2
  365        3            Succeeded        2019-08-23 15:00:01.2
  364        3            Succeeded        2019-08-23 15:00:01.1
  363        2            Succeeded        2019-08-23 15:00:01.1
  362        3            Succeeded        2019-08-23 15:00:01.1
  361        2            Succeeded        2019-08-23 15:00:01.1
```

The output shows that the packets sent by Device A can reach Device B through Device C. No packet loss occurs during the operation. The minimum, maximum, and average round-trip times are 2, 5, and 3 milliseconds, respectively.

Example: Configuring the ICMP jitter operation

Network configuration

As shown in Figure 13, configure an ICMP jitter operation to test the jitter between Device A and Device B.

Figure 13 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 13. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device A:

   # Create an ICMP jitter operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type icmp-jitter
   ```

   # Specify 10.2.2.2 as the destination address for the operation.

   ```
   [DeviceA-nqa-admin-test1-icmp-jitter] destination ip 10.2.2.2
   ```

   # Configure the operation to repeat every 1000 milliseconds.

   ```
   [DeviceA-nqa-admin-test1-icmp-jitter] frequency 1000
   [DeviceA-nqa-admin-test1-icmp-jitter] quit
   ```

   # Start the ICMP jitter operation.

   ```
   [DeviceA] nqa schedule admin test1 start-time now lifetime forever
   ```

   # After the ICMP jitter operation runs for a period of time, stop the operation.

   ```
   [DeviceA] undo nqa schedule admin test1
   ```

Verifying the configuration

Display the most recent result of the ICMP jitter operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 10              Receive response times: 10
    Min/Max/Average round trip time: 1/2/1
    Square-Sum of round trip time: 13
    Last packet received time: 2019-03-09 17:40:29.8
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
    Packets out of sequence: 0
```

```
    Packets arrived late: 0
  ICMP-jitter results:
   RTT number: 10
    Min positive SD: 0                    Min positive DS: 0

```

Example: Configuring the DHCP operation

Network configuration

As shown in Figure 14, configure a DHCP operation to test the time required for Switch A to obtain an IP address from the DHCP server (Switch B).

Figure 14 Network diagram

Procedure

Create a DHCP operation.

```
<SwitchA> system-view
[SwitchA] nqa entry admin test1
[SwitchA-nqa-admin-test1] type dhcp
```

Specify the DHCP server address (10.1.1.2) as the destination address.

```
[SwitchA-nqa-admin-test1-dhcp] destination ip 10.1.1.2
```

Enable the saving of history records.

```
[SwitchA-nqa-admin-test1-dhcp] history-record enable
[SwitchA-nqa-admin-test1-dhcp] quit
```

Start the DHCP operation.

```
[SwitchA] nqa schedule admin test1 start-time now lifetime forever
```

After the DHCP operation runs for a period of time, stop the operation.

```
[SwitchA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the DHCP operation.

```
[SwitchA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 512/512/512
    Square-Sum of round trip time: 262144
```

```
    Last succeeded probe time: 2019-11-22 09:56:03.2
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the DHCP operation.

```
[SwitchA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          512          Succeeded        2019-11-22 09:56:03.2
```

The output shows that it took Switch A 512 milliseconds to obtain an IP address from the DHCP server.

Example: Configuring the DNS operation

Network configuration

As shown in Figure 15, configure a DNS operation to test whether Device A can perform address resolution through the DNS server and test the resolution time.

Figure 15 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 15. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create a DNS operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type dns
```

Specify the IP address of the DNS server (10.2.2.2) as the destination address.

```
[DeviceA-nqa-admin-test1-dns] destination ip 10.2.2.2
```

Specify **host.com** as the domain name to be translated.

```
[DeviceA-nqa-admin-test1-dns] resolve-target host.com
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test1-dns] history-record enable
[DeviceA-nqa-admin-test1-dns] quit
```

Start the DNS operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the DNS operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the DNS operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 62/62/62
    Square-Sum of round trip time: 3844
    Last succeeded probe time: 2019-11-10 10:49:37.3
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the DNS operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test) history records:
  Index      Response     Status           Time
  1          62           Succeeded        2019-11-10 10:49:37.3
```

The output shows that it took Device A 62 milliseconds to translate domain name **host.com** into an IP address.

Example: Configuring the FTP operation

Network configuration

As shown in Figure 16, configure an FTP operation to test the time required for Device A to upload a file to the FTP server. The login username and password are **admin** and **systemtest**, respectively. The file to be transferred to the FTP server is **config.txt**.

Figure 16 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 16. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create an FTP operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type ftp
```

Specify the URL of the FTP server.

```
[DeviceA-nqa-admin-test-ftp] url ftp://10.2.2.2
```

Specify 10.1.1.1 as the source IP address.

```
[DeviceA-nqa-admin-test1-ftp] source ip 10.1.1.1
```

Configure the device to upload file **config.txt** to the FTP server.

```
[DeviceA-nqa-admin-test1-ftp] operation put
[DeviceA-nqa-admin-test1-ftp] filename config.txt
```

Set the username to **admin** for the FTP operation.

```
[DeviceA-nqa-admin-test1-ftp] username admin
```

Set the password to **systemtest** for the FTP operation.

```
[DeviceA-nqa-admin-test1-ftp] password simple systemtest
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test1-ftp] history-record enable
[DeviceA-nqa-admin-test1-ftp] quit
```

Start the FTP operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the FTP operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the FTP operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 173/173/173
    Square-Sum of round trip time: 29929
    Last succeeded probe time: 2019-11-22 10:07:28.6
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to disconnect: 0
    Failures due to no connection: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the FTP operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          173          Succeeded        2019-11-22 10:07:28.6
```

The output shows that it took Device A 173 milliseconds to upload a file to the FTP server.

Example: Configuring the HTTP operation

Network configuration

As shown in Figure 17, configure an HTTP operation on the NQA client to test the time required to obtain data from the HTTP server.

Figure 17 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 17. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create an HTTP operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type http
```

Specify the URL of the HTTP server.

```
[DeviceA-nqa-admin-test1-http] url http://10.2.2.2/index.htm
```

Configure the HTTP operation to get data from the HTTP server.

```
[DeviceA-nqa-admin-test1-http] operation get
```

Configure the operation to use HTTP version 1.0.

```
[DeviceA-nqa-admin-test1-http] version v1.0
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test1-http] history-record enable
[DeviceA-nqa-admin-test1-http] quit
```

Start the HTTP operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the HTTP operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the HTTP operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 64/64/64
    Square-Sum of round trip time: 4096
    Last succeeded probe time: 2019-11-22 10:12:47.9
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to disconnect: 0
    Failures due to no connection: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the HTTP operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          64           Succeeded        2019-11-22 10:12:47.9
```

The output shows that it took Device A 64 milliseconds to obtain data from the HTTP server.

Example: Configuring the UDP jitter operation

Network configuration

As shown in Figure 18, configure a UDP jitter operation to test the jitter, delay, and round-trip time between Device A and Device B.

Figure 18 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 18. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

   ```
   <DeviceB> system-view
   [DeviceB] nqa server enable
   ```

   # Configure a listening service to listen to UDP port 9000 on IP address 10.2.2.2.

   ```
   [DeviceB] nqa server udp-echo 10.2.2.2 9000
   ```

4. Configure Device A:

   # Create a UDP jitter operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type udp-jitter
   ```

   # Specify 10.2.2.2 as the destination address of the operation.

   ```
   [DeviceA-nqa-admin-test1-udp-jitter] destination ip 10.2.2.2
   ```

   # Set the destination port number to 9000.

   ```
   [DeviceA-nqa-admin-test1-udp-jitter] destination port 9000
   ```

   # Configure the operation to repeat every 1000 milliseconds.

   ```
   [DeviceA-nqa-admin-test1-udp-jitter] frequency 1000
   [DeviceA-nqa-admin-test1-udp-jitter] quit
   ```

   # Start the UDP jitter operation.

   ```
   [DeviceA] nqa schedule admin test1 start-time now lifetime forever
   ```

   # After the UDP jitter operation runs for a period of time, stop the operation.

   ```
   [DeviceA] undo nqa schedule admin test1
   ```

Verifying the configuration

Display the most recent result of the UDP jitter operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 10              Receive response times: 10
    Min/Max/Average round trip time: 15/32/17
    Square-Sum of round trip time: 3235
    Last packet received time: 2019-05-29 13:56:17.6
```

```
  Extended results:

```

Example: Configuring the SNMP operation

Network configuration

As shown in Figure 19, configure an SNMP operation to test the time the NQA client uses to get a response from the SNMP agent.

Figure 19 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 19. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure the SNMP agent (Device B):

   # Set the SNMP version to **all**.

   ```
   <DeviceB> system-view
   [DeviceB] snmp-agent sys-info version all
   ```

   # Set the read community to **public**.

   ```
   [DeviceB] snmp-agent community read public
   ```

   # Set the write community to **private**.

   ```
   [DeviceB] snmp-agent community write private
   ```

4. Configure Device A:

   # Create an SNMP operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type snmp
```

Specify 10.2.2.2 as the destination IP address of the SNMP operation.

```
[DeviceA-nqa-admin-test1-snmp] destination ip 10.2.2.2
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test1-snmp] history-record enable
[DeviceA-nqa-admin-test1-snmp] quit
```

Start the SNMP operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the SNMP operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the SNMP operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 50/50/50
    Square-Sum of round trip time: 2500
    Last succeeded probe time: 2019-11-22 10:24:41.1
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the SNMP operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          50           Succeeded        2019-11-22 10:24:41.1
```

The output shows that it took Device A 50 milliseconds to receive a response from the SNMP agent.

Example: Configuring the TCP operation

Network configuration

As shown in Figure 20, configure a TCP operation to test the time required for Device A to establish a TCP connection with Device B.

Figure 20 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 20. (Details not shown.)

2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

   ```
   <DeviceB> system-view
   [DeviceB] nqa server enable
   ```

   # Configure a listening service to listen to TCP port 9000 on IP address 10.2.2.2.

   ```
   [DeviceB] nqa server tcp-connect 10.2.2.2 9000
   ```

4. Configure Device A:

   # Create a TCP operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type tcp
   ```

   # Specify 10.2.2.2 as the destination IP address.

   ```
   [DeviceA-nqa-admin-test1-tcp] destination ip 10.2.2.2
   ```

   # Set the destination port number to 9000.

   ```
   [DeviceA-nqa-admin-test1-tcp] destination port 9000
   ```

   # Enable the saving of history records.

   ```
   [DeviceA-nqa-admin-test1-tcp] history-record enable
   [DeviceA-nqa-admin-test1-tcp] quit
   ```

   # Start the TCP operation.

   ```
   [DeviceA] nqa schedule admin test1 start-time now lifetime forever
   ```

   # After the TCP operation runs for a period of time, stop the operation.

   ```
   [DeviceA] undo nqa schedule admin test1
   ```

Verifying the configuration

Display the most recent result of the TCP operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 13/13/13
    Square-Sum of round trip time: 169
    Last succeeded probe time: 2019-11-22 10:27:25.1
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to disconnect: 0
    Failures due to no connection: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the TCP operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          13           Succeeded        2019-11-22 10:27:25.1
```

The output shows that it took Device A 13 milliseconds to establish a TCP connection to port 9000 on the NQA server.

Example: Configuring the UDP echo operation

Network configuration

As shown in Figure 21, configure a UDP echo operation on the NQA client to test the round-trip time to Device B. The destination port number is 8000.

Figure 21 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 21. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

   ```
   <DeviceB> system-view
   [DeviceB] nqa server enable
   ```

   # Configure a listening service to listen to UDP port 8000 on IP address 10.2.2.2.

   ```
   [DeviceB] nqa server udp-echo 10.2.2.2 8000
   ```

4. Configure Device A:

   # Create a UDP echo operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type udp-echo
   ```

   # Specify 10.2.2.2 as the destination IP address.

   ```
   [DeviceA-nqa-admin-test1-udp-echo] destination ip 10.2.2.2
   ```

   # Set the destination port number to 8000.

   ```
   [DeviceA-nqa-admin-test1-udp-echo] destination port 8000
   ```

   # Enable the saving of history records.

   ```
   [DeviceA-nqa-admin-test1-udp-echo] history-record enable
   [DeviceA-nqa-admin-test1-udp-echo] quit
   ```

   # Start the UDP echo operation.

   ```
   [DeviceA] nqa schedule admin test1 start-time now lifetime forever
   ```

   # After the UDP echo operation runs for a period of time, stop the operation.

   ```
   [DeviceA] undo nqa schedule admin test1
   ```

Verifying the configuration

Display the most recent result of the UDP echo operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 25/25/25
    Square-Sum of round trip time: 625
    Last succeeded probe time: 2019-11-22 10:36:17.9
```

```
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the UDP echo operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          25           Succeeded        2019-11-22 10:36:17.9
```

The output shows that the round-trip time between Device A and port 8000 on Device B is 25 milliseconds.

Example: Configuring the UDP tracert operation

Network configuration

As shown in Figure 22, configure a UDP tracert operation to determine the routing path from Device A to Device B.

Figure 22 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 22. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Execute the **ip ttl-expires enable** command on the intermediate devices and execute the **ip unreachables enable** command on Device B.
4. Configure Device A:

   # Create a UDP tracert operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type udp-tracert
   ```

   # Specify 10.2.2.2 as the destination IP address.

   ```
   [DeviceA-nqa-admin-test1-udp-tracert] destination ip 10.2.2.2
   ```

   # Set the destination port number to 33434.

   ```
   [DeviceA-nqa-admin-test1-udp-tracert] destination port 33434
   ```

   # Configure Device A to perform three probes to each hop.

   ```
   [DeviceA-nqa-admin-test1-udp-tracert] probe count 3
   ```

   # Set the probe timeout time to 500 milliseconds.

   ```
   [DeviceA-nqa-admin-test1-udp-tracert] probe timeout 500
   ```

   # Configure the UDP tracert operation to repeat every 5000 milliseconds.

   ```
   [DeviceA-nqa-admin-test1-udp-tracert] frequency 5000
   ```

   # Specify GigabitEthernet 1/0/1 as the output interface for UDP packets.

```
[DeviceA-nqa-admin-test1-udp-tracert] out interface gigabitethernet 1/0/1
```

Enable the no-fragmentation feature.

```
[DeviceA-nqa-admin-test1-udp-tracert] no-fragment enable
```

Set the maximum number of consecutive probe failures to 6.

```
[DeviceA-nqa-admin-test1-udp-tracert] max-failure 6
```

Set the TTL value to 1 for UDP packets in the start round of the UDP tracert operation.

```
[DeviceA-nqa-admin-test1-udp-tracert] init-ttl 1
```

Start the UDP tracert operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the UDP tracert operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the UDP tracert operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 6              Receive response times: 6
    Min/Max/Average round trip time: 1/1/1
    Square-Sum of round trip time: 1
    Last succeeded probe time: 2019-09-09 14:46:06.2
  Extended results:
    Packet loss in test: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
Failures due to other errors: 0

Example: Configuring the voice operation

Network configuration

As shown in Figure 23, configure a voice operation to test jitters, delay, MOS, and ICPIF between Device A and Device B.

Figure 23 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 23. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

   ```
   <DeviceB> system-view
   [DeviceB] nqa server enable
   ```

   # Configure a listening service to listen to UDP port 9000 on IP address 10.2.2.2.

   ```
   [DeviceB] nqa server udp-echo 10.2.2.2 9000
   ```

4. Configure Device A:

   # Create a voice operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type voice
   ```

   # Specify 10.2.2.2 as the destination IP address.

   ```
   [DeviceA-nqa-admin-test1-voice] destination ip 10.2.2.2
   ```

   # Set the destination port number to 9000.

   ```
   [DeviceA-nqa-admin-test1-voice] destination port 9000
   [DeviceA-nqa-admin-test1-voice] quit
   ```

   # Start the voice operation.

   ```
   [DeviceA] nqa schedule admin test1 start-time now lifetime forever
   ```

   # After the voice operation runs for a period of time, stop the operation.

   ```
   [DeviceA] undo nqa schedule admin test1
   ```

Verifying the configuration

Display the most recent result of the voice operation.

Example: Configuring the DLSw operation

Network configuration

As shown in Figure 24, configure a DLSw operation to test the response time of the DLSw device.

Figure 24 Network diagram

Procedure

1. Configure Device A:

Assign IP addresses to interfaces, as shown in Figure 24. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create a DLSw operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type dlsw
```

Specify 10.2.2.2 as the destination IP address.

```
[DeviceA-nqa-admin-test1-dlsw] destination ip 10.2.2.2
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test1-dlsw] history-record enable
[DeviceA-nqa-admin-test1-dlsw] quit
```

Start the DLSw operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the DLSw operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

2. Configure Device B:

Assign IP addresses to interfaces. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Enable the NQA server.

```
<DeviceB> system-view
[DeviceB] nqa server enable
```

Configure a listening service to listen to TCP port 2065 on IP address 10.2.2.2. (For the DLSw operation, the port number for the TCP listening service must be 2065.)

```
[DeviceB] nqa server tcp-connect 10.2.2.2 2065
```

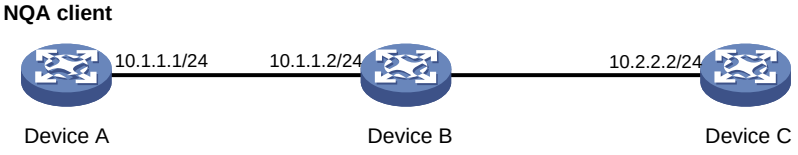
Verifying the configuration

Display the most recent result of the DLSw operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 19/19/19
    Square-Sum of round trip time: 361
    Last succeeded probe time: 2019-11-22 10:40:27.7
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to disconnect: 0
    Failures due to no connection: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the DLSw operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          19           Succeeded        2019-11-22 10:40:27.7
```



The output shows that the response time of the DLSw device is 19 milliseconds.

Example: Configuring the path jitter operation

Network configuration

As shown in Figure 25, configure a path jitter operation to test the round trip time and jitters from Device A to Device B and Device C.

Figure 25 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 25. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Execute the **ip ttl-expires enable** command on Device B and execute the **ip unreachables enable** command on Device C.

Create a path jitter operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type path-jitter
```

Specify 10.2.2.2 as the destination IP address of ICMP echo requests.

```
[DeviceA-nqa-admin-test1-path-jitter] destination ip 10.2.2.2
```

Configure the path jitter operation to repeat every 10000 milliseconds.

```
[DeviceA-nqa-admin-test1-path-jitter] frequency 10000
[DeviceA-nqa-admin-test1-path-jitter] quit
```

Start the path jitter operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the path jitter operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the path jitter operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
  Hop IP 10.1.1.2
    Basic Results
      Send operation times: 10              Receive response times: 10

```

Example: Configuring NQA collaboration

Network configuration

As shown in Figure 26, configure a static route to Switch C with Switch B as the next hop on Switch A. Associate the static route, a track entry, and an ICMP echo operation to monitor the state of the static route.

Figure 26 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 26. (Details not shown.)
2. On Switch A, configure a static route, and associate the static route with track entry 1.

   ```
   <SwitchA> system-view
   [SwitchA] ip route-static 10.1.1.2 24 10.2.1.1 track 1
   ```
3. On Switch A, configure an ICMP echo operation:

   # Create an NQA operation with administrator name **admin** and operation tag **test1**.

   ```
   [SwitchA] nqa entry admin test1
   ```

   # Configure the NQA operation type as ICMP echo.

   ```
   [SwitchA-nqa-admin-test1] type icmp-echo
   ```

   # Specify 10.2.1.1 as the destination IP address.

```
[SwitchA-nqa-admin-test1-icmp-echo] destination ip 10.2.1.1
```

Configure the operation to repeat every 100 milliseconds.

```
[SwitchA-nqa-admin-test1-icmp-echo] frequency 100
```

Create reaction entry 1. If the number of consecutive probe failures reaches 5, collaboration is triggered.

```
[SwitchA-nqa-admin-test1-icmp-echo] reaction 1 checked-element probe-fail
threshold-type consecutive 5 action-type trigger-only
[SwitchA-nqa-admin-test1-icmp-echo] quit
```

Start the ICMP operation.

```
[SwitchA] nqa schedule admin test1 start-time now lifetime forever
```

4. On Switch A, create track entry 1, and associate it with reaction entry 1 of the NQA operation.

```
[SwitchA] track 1 nqa entry admin test1 reaction 1
```

Verifying the configuration

Display information about all the track entries on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 0 seconds
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    NQA entry: admin test1
    Reaction: 1
```

Display brief information about active routes in the routing table on Switch A.

```
[SwitchA] display ip routing-table

Destinations : 13        Routes : 13

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
0.0.0.0/32          Direct 0    0            127.0.0.1       InLoop0
10.1.1.0/24         Static 60   0            10.2.1.1        Vlan3

10.2.1.0/32         Direct 0    0            10.2.1.2        Vlan3
10.2.1.2/32         Direct 0    0            127.0.0.1       InLoop0
10.2.1.255/32       Direct 0    0            10.2.1.2        Vlan3
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.0/32        Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
127.255.255.255/32  Direct 0    0            127.0.0.1       InLoop0
224.0.0.0/4         Direct 0    0            0.0.0.0         NULL0
224.0.0.0/24        Direct 0    0            0.0.0.0         NULL0
255.255.255.255/32  Direct 0    0            127.0.0.1       InLoop0
```

The output shows that the static route with the next hop 10.2.1.1 is active, and the status of the track entry is positive.

Remove the IP address of VLAN-interface 3 on Switch B.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 3
[SwitchB-Vlan-interface3] undo ip address
```

Display information about all the track entries on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Negative
  Duration: 0 days 0 hours 0 minutes 0 seconds
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    NQA entry: admin test1
    Reaction: 1
```

Display brief information about active routes in the routing table on Switch A.

```
[SwitchA] display ip routing-table

Destinations : 12        Routes : 12

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
0.0.0.0/32          Direct 0    0            127.0.0.1       InLoop0
10.2.1.0/24         Direct 0    0            10.2.1.2        Vlan3

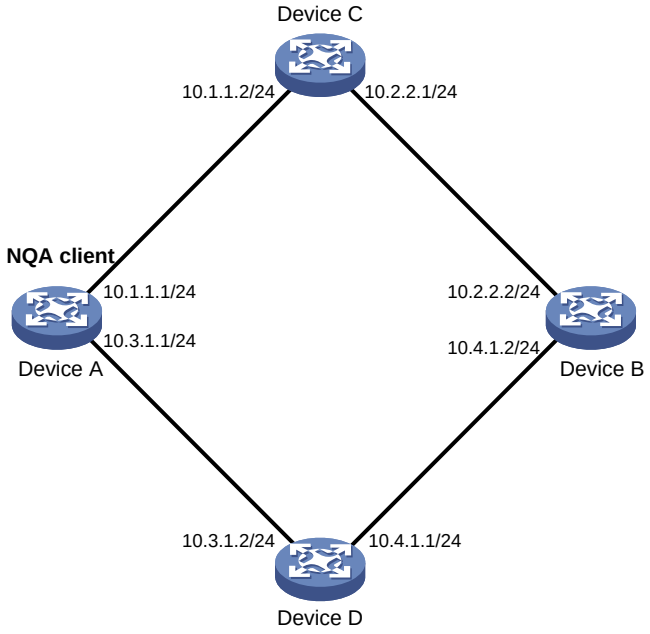
255.255.255.255/32  Direct 0    0            127.0.0.1       InLoop0
```



The output shows that the static route does not exist, and the status of the track entry is negative.

Example: Configuring the ICMP template

Network configuration

As shown in Figure 27, configure an ICMP template for a feature to perform the ICMP echo operation from Device A to Device B.

Figure 27 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 27. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create ICMP template **icmp**.

```
<DeviceA> system-view
[DeviceA] nqa template icmp icmp
```

Specify 10.2.2.2 as the destination IP address of ICMP echo requests.

```
[DeviceA-nqatplt-icmp-icmp] destination ip 10.2.2.2
```

Set the probe timeout time to 500 milliseconds for the ICMP echo operation.

```
[DeviceA-nqatplt-icmp-icmp] probe timeout 500
```

Configure the ICMP echo operation to repeat every 3000 milliseconds.

```
[DeviceA-nqatplt-icmp-icmp] frequency 3000
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-icmp-icmp] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-icmp-icmp] reaction trigger probe-fail 2
```

Example: Configuring the DNS template

Network configuration

As shown in Figure 28, configure a DNS template for a feature to perform the DNS operation. The operation tests whether Device A can perform the address resolution through the DNS server.

Figure 28 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 28. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create DNS template **dns**.

```
<DeviceA> system-view
[DeviceA] nqa template dns dns
```

Specify the IP address of the DNS server (10.2.2.2) as the destination IP address.

```
[DeviceA-nqatplt-dns-dns] destination ip 10.2.2.2
```

Specify **host.com** as the domain name to be translated.

```
[DeviceA-nqatplt-dns-dns] resolve-target host.com
```

Set the domain name resolution type to type A.

```
[DeviceA-nqatplt-dns-dns] resolve-type A
```

Specify 3.3.3.3 as the expected IP address.

```
[DeviceA-nqatplt-dns-dns] expect ip 3.3.3.3
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-dns-dns] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-dns-dns] reaction trigger probe-fail 2
```

Example: Configuring the TCP template

Network configuration

As shown in Figure 29, configure a TCP template for a feature to perform the TCP operation. The operation tests whether Device A can establish a TCP connection to Device B.

Figure 29 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 29. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

```
<DeviceB> system-view
[DeviceB] nqa server enable
```

Configure a listening service to listen to TCP port 9000 on IP address 10.2.2.2.

```
[DeviceB] nqa server tcp-connect 10.2.2.2 9000
```

4. Configure Device A:

Create TCP template **tcp**.

```
<DeviceA> system-view
[DeviceA] nqa template tcp tcp
```

Specify 10.2.2.2 as the destination IP address.

```
[DeviceA-nqatplt-tcp-tcp] destination ip 10.2.2.2
```

Set the destination port number to 9000.

```
[DeviceA-nqatplt-tcp-tcp] destination port 9000
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-tcp-tcp] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-tcp-tcp] reaction trigger probe-fail 2
```

Example: Configuring the TCP half open template

Network configuration

As shown in Figure 30, configure a TCP half open template for a feature to test whether Device B can provide the TCP service for Device A.

Figure 30 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 30. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device A:

Create TCP half open template **test**.

```
<DeviceA> system-view
[DeviceA] nqa template tcphalfopen test
```

Specify 10.2.2.2 as the destination IP address.

```
[DeviceA-nqatplt-tcphalfopen-test] destination ip 10.2.2.2
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-tcphalfopen-test] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-tcphalfopen-test] reaction trigger probe-fail 2
```

Example: Configuring the UDP template

Network configuration

As shown in Figure 31, configure a UDP template for a feature to perform the UDP operation. The operation tests whether Device A can receive a response from Device B.

Figure 31 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 31. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

   ```
   <DeviceB> system-view
   [DeviceB] nqa server enable
   ```

   # Configure a listening service to listen to UDP port 9000 on IP address 10.2.2.2.

   ```
   [DeviceB] nqa server udp-echo 10.2.2.2 9000
   ```

4. Configure Device A:

   # Create UDP template **udp**.

   ```
   <DeviceA> system-view
   [DeviceA] nqa template udp udp
   ```

   # Specify 10.2.2.2 as the destination IP address.

   ```
   [DeviceA-nqatplt-udp-udp] destination ip 10.2.2.2
   ```

   # Set the destination port number to 9000.

   ```
   [DeviceA-nqatplt-udp-udp] destination port 9000
   ```

   # Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

   ```
   [DeviceA-nqatplt-udp-udp] reaction trigger probe-pass 2
   ```

   # Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

   ```
   [DeviceA-nqatplt-udp-udp] reaction trigger probe-fail 2
   ```

Example: Configuring the HTTP template

Network configuration

As shown in Figure 32, configure an HTTP template for a feature to perform the HTTP operation. The operation tests whether the NQA client can get data from the HTTP server.

Figure 32 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 32. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create HTTP template **http**.

```
<DeviceA> system-view
[DeviceA] nqa template http http
```

Specify **http://10.2.2.2/index.htm** as the URL of the HTTP server.

```
[DeviceA-nqatplt-http-http] url http://10.2.2.2/index.htm
```

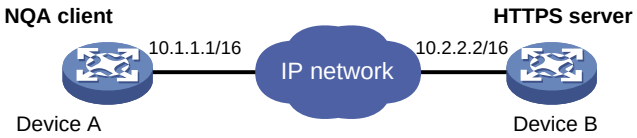
Set the HTTP operation type to **get**.

```
[DeviceA-nqatplt-http-http] operation get
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-http-http] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.



```
[DeviceA-nqatplt-http-http] reaction trigger probe-fail 2
```

Example: Configuring the HTTPS template

Network configuration

As shown in Figure 33, configure an HTTPS template for a feature to test whether the NQA client can get data from the HTTPS server (Device B).

Figure 33 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 33. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Configure an SSL client policy named **abc** on Device A, and make sure Device A can use the policy to connect to the HTTPS server. (Details not shown.)

Create HTTPS template **test**.

```
<DeviceA> system-view
[DeviceA] nqa template https https
```

Specify **http://10.2.2.2/index.htm** as the URL of the HTTPS server.

```
[DeviceA-nqatplt-https-https] url https://10.2.2.2/index.htm
```

Specify SSL client policy **abc** for the HTTPS template.

```
[DeviceA-nqatplt-https- https] ssl-client-policy abc
```

Set the HTTPS operation type to **get** (the default HTTPS operation type).

```
[DeviceA-nqatplt-https-https] operation get
```

Set the HTTPS version to 1.0 (the default HTTPS version).

```
 [DeviceA-nqatplt-https-https] version v1.0
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-https-https] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-https-https] reaction trigger probe-fail 2
```

Example: Configuring the FTP template

Network configuration

As shown in Figure 34, configure an FTP template for a feature to perform the FTP operation. The operation tests whether Device A can upload a file to the FTP server. The login username and password are **admin** and **systemtest**, respectively. The file to be transferred to the FTP server is **config.txt**.

Figure 34 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 34. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create FTP template **ftp**.

```
<DeviceA> system-view
[DeviceA] nqa template ftp ftp
```

Specify the URL of the FTP server.

```
[DeviceA-nqatplt-ftp-ftp] url ftp://10.2.2.2
```

Specify 10.1.1.1 as the source IP address.

```
[DeviceA-nqatplt-ftp-ftp] source ip 10.1.1.1
```

Configure the device to upload file **config.txt** to the FTP server.

```
[DeviceA-nqatplt-ftp-ftp] operation put
[DeviceA-nqatplt-ftp-ftp] filename config.txt
```

Set the username to **admin** for the FTP server login.

```
[DeviceA-nqatplt-ftp-ftp] username admin
```

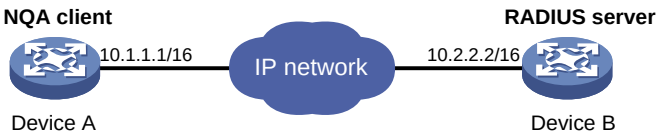
Set the password to **systemtest** for the FTP server login.

```
[DeviceA-nqatplt-ftp-ftp] password simple systemtest
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-ftp-ftp] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.



```
[DeviceA-nqatplt-ftp-ftp] reaction trigger probe-fail 2
```

Example: Configuring the RADIUS template

Network configuration

As shown in Figure 35, configure a RADIUS template for a feature to test whether the RADIUS server (Device B) can provide authentication service for Device A. The username and password are **admin** and **systemtest**, respectively. The shared key is **123456** for secure RADIUS authentication.

Figure 35 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 35. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Configure the RADIUS server. (Details not shown.)

Create RADIUS template **radius**.

```
<DeviceA> system-view
[DeviceA] nqa template radius radius
```

Specify 10.2.2.2 as the destination IP address of the operation.

```
[DeviceA-nqatplt-radius-radius] destination ip 10.2.2.2
```

Set the username to **admin**.

```
[DeviceA-nqatplt-radius-radius] username admin
```

Set the password to **systemtest**.

```
[DeviceA-nqatplt-radius-radius] password simple systemtest
```

Set the shared key to **123456** in plain text for secure RADIUS authentication.

```
[DeviceA-nqatplt-radius-radius] key simple 123456
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-radius-radius] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-radius-radius] reaction trigger probe-fail 2
```

Example: Configuring the SSL template

Network configuration

As shown in Figure 36, configure an SSL template for a feature to test whether Device A can establish an SSL connection to the SSL server on Device B.

Figure 36 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 36. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Configure an SSL client policy named **abc** on Device A, and make sure Device A can use the policy to connect to the SSL server on Device B. (Details not shown.)

Create SSL template **ssl**.

```
<DeviceA> system-view
[DeviceA] nqa template ssl ssl
```

Set the destination IP address and port number to **10.2.2.2** and **9000**, respectively.

```
[DeviceA-nqatplt-ssl-ssl] destination ip 10.2.2.2
[DeviceA-nqatplt-ssl-ssl] destination port 9000
```

Specify SSL client policy **abc** for the SSL template.

```
[DeviceA-nqatplt-ssl-ssl] ssl-client-policy abc
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-ssl-ssl] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-ssl-ssl] reaction trigger probe-fail 2
```

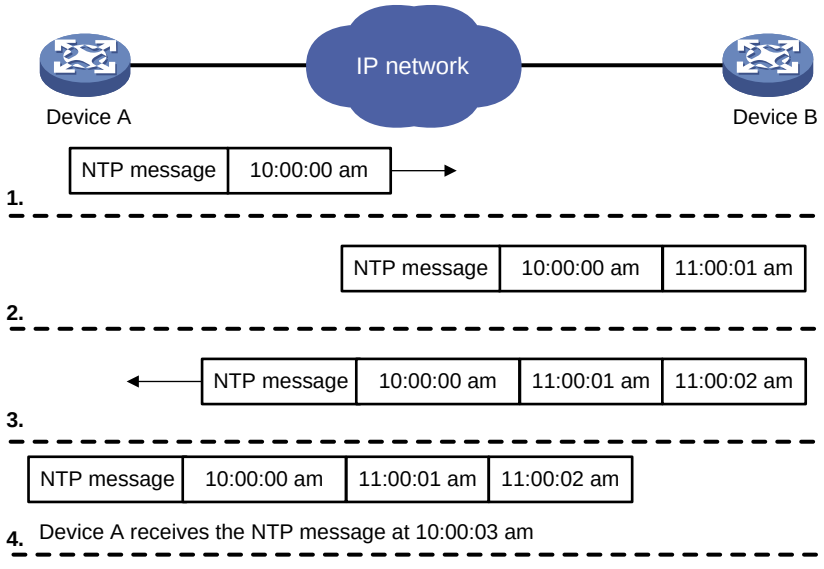
Configuring NTP

About NTP

NTP is used to synchronize system clocks among distributed time servers and clients on a network. NTP runs over UDP and uses UDP port 123.

NTP application scenarios

Various tasks, including network management, charging, auditing, and distributed computing depend on accurate and synchronized system time setting on the network devices. NTP is typically used in large networks to dynamically synchronize time among network devices.



NTP guarantees higher clock accuracy than manual system clock setting. In a small network that does not require high clock accuracy, you can keep time synchronized among devices by changing their system clocks one by one.

NTP working mechanism

Figure 1 shows how NTP synchronizes the system time between two devices (Device A and Device B, in this example). Assume that:

- Prior to the time synchronization, the time is set to 10:00:00 am for Device A and 11:00:00 am for Device B.
- Device B is used as the NTP server. Device A is to be synchronized to Device B.
- It takes 1 second for an NTP message to travel from Device A to Device B, and from Device B to Device A.
- It takes 1 second for Device B to process the NTP message.

Figure 1 Basic work flow

The synchronization process is as follows:

2. Device A sends Device B an NTP message, which is timestamped when it leaves Device A. The time stamp is 10:00:00 am (T1).

3. When this NTP message arrives at Device B, Device B adds a timestamp showing the time when the message arrived at Device B. The timestamp is 11:00:01 am (T2).
4. When the NTP message leaves Device B, Device B adds a timestamp showing the time when the message left Device B. The timestamp is 11:00:02 am (T3).
5. When Device A receives the NTP message, the local time of Device A is 10:00:03 am (T4).

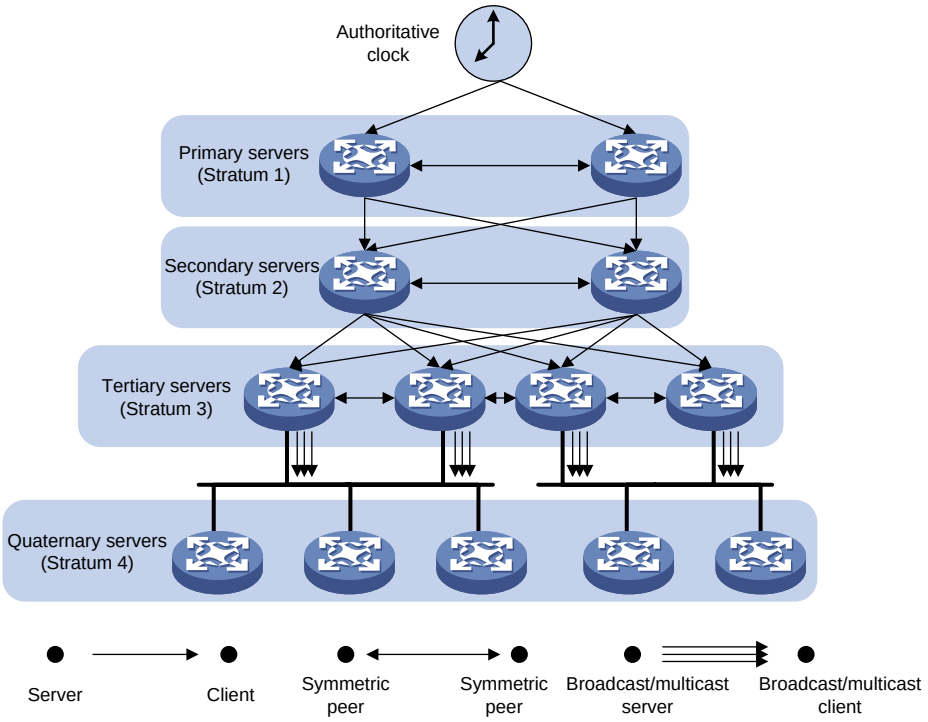
Up to now, Device A can calculate the following parameters based on the timestamps:

- The roundtrip delay of the NTP message: Delay = (T4 – T1) – (T3 – T2) = 2 seconds.
- Time difference between Device A and Device B: Offset = [(T2 – T1) + (T3 – T4)] /2 = 1 hour.

Based on these parameters, Device A can be synchronized to Device B.

This is only a rough description of the work mechanism of NTP. For more information, see the related protocols and standards.

NTP architecture



CAUTION:

When the device acts as an NTP client, the NTP server's clock stratum must be not smaller than 0 and not larger than 14. If the NTP server's clock stratum is larger than 14, the device will not synchronize with that server's clock. You can log in to the NTP server to change its clock stratum by executing the **`ntp-service refclock-master`** command.

- To check the stratum for an IPv4 NTP server, execute the **`display ntp-service sessions`** command on the device and check the **stra** field in the output.
- To check the stratum for an IPv6 NTP server, execute the **`display ntp-service ipv6 sessions`** command on the device and check the **Clock stratum** field in the output.

NTP network architecture

Figure 2 NTP network architecture

As shown in Figure 2, the NTP network is a hierarchical distributed system that contains multiple tiers of clocks to provide time synchronization services. This architecture helps reduce dependency on a single time source while providing redundancy and load balancing. The following are the key components of the NTP network:

- **Stratum 0**—The highest precision devices, such as atomic clocks, GPS, or radio clocks. They do not directly connect to the network but provide time to stratum 1 servers through wired or wireless connections.
- **Stratum 1**—Servers directly connected to stratum 0 devices. They act as primary time servers or reference clocks. Stratum 1 servers are typically used to provide precise time for public or private networks.
- **Stratum 2**—Servers connected to stratum 1 servers, receiving time from one or more stratum 1 servers and then providing time to lower-stratum servers or clients.
- **Stratum 3 through stratum 15**—Servers that receive time from servers of a higher stratum and that distribute this time down. Each stratum introduces some delay and jitter, but time synchronization accuracy can be achieved through complex algorithms and the use of multiple time sources.

If the devices in a network cannot synchronize to an authoritative time source, you can perform the following tasks:

- Select a device that has a relatively accurate clock from the network.
- Use the local clock of the device as the reference clock to synchronize other devices in the network.

NTP stratum

The NTP clock stratum represents the hierarchical level of an NTP server within the time synchronization structure. The stratum value is in the range of 1 to 15, with a larger value indicating a greater distance from the reference time source, which might result in reduced synchronization accuracy.

The clock stratum is typically determined automatically based on the upstream time source to which the server is connected. An NTP client only synchronizes with an NTP server whose clock stratum is less than or equal to its own, and the server’s stratum must be in the range of 0 to 14. Therefore, if you configure the device as an NTP server, you must set its clock stratum according to the network hierarchy.

NTP association modes

About NTP association modes

NTP supports the following association modes:

- Client/server mode
- Symmetric active/passive mode
- Broadcast mode
- Multicast mode

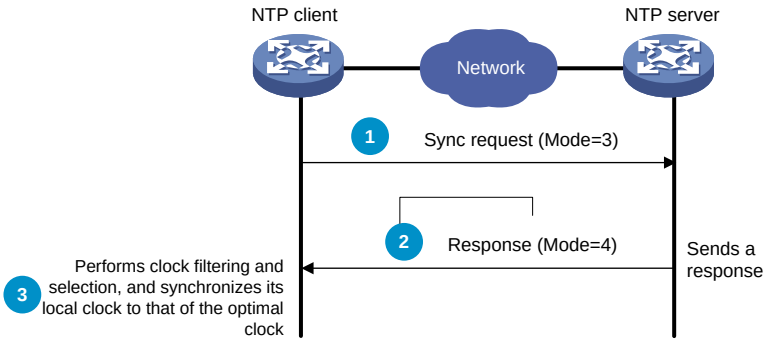
You can select one or more association modes for time synchronization. Table 1 provides detailed description for the four association modes. If the device acts as an NTP client and receives multiple NTP clock signals, it selects the optimal NTP clock for time synchronization.

In this document, an "NTP server" or a "server" refers to a device that operates as an NTP server in client/server mode. Time servers refer to all the devices that can provide time synchronization, including NTP servers, NTP symmetric peers, broadcast servers, and multicast servers.

Table 1 NTP association modes

Mode	Working process	Principle	Application scenario
Client/server	On the client, specify the IP address of the NTP server. A client sends a clock synchronization message to the NTP servers. Upon receiving the message, the servers automatically operate in server mode and send a reply. If the client can be synchronized to multiple time servers, it selects an optimal clock and synchronizes its local clock to the optimal reference source after receiving the replies from the servers.	A client can synchronize to a server, but a server cannot synchronize to a client.	As the NTP architecture diagram in "NTP architecture" shows, this mode is intended for scenarios where devices with a higher stratum value obtain time from a device with a lower stratum value.
Symmetric active/passive	On the symmetric active peer, specify the IP address of the symmetric passive peer. A symmetric active peer periodically sends clock synchronization messages to a symmetric passive peer. The symmetric passive peer automatically operates in symmetric passive mode and sends a reply. If the symmetric active peer can be synchronized to multiple time servers, it selects an optimal clock and synchronizes its local clock to the optimal reference source after receiving the replies from the servers.	A symmetric active peer and a symmetric passive peer can be synchronized to each other. If both of them are synchronized, the peer with a higher stratum is synchronized to the peer with a lower stratum.	As the NTP architecture diagram in "NTP architecture" shows, this mode is most often used between servers with the same stratum to operate as a backup for one another. If a server fails to communicate with all the servers of a lower stratum, the server can still synchronize to the servers of the same stratum.
Broadcast	A server periodically sends clock synchronization messages to the broadcast address 255.255.255.255. Clients listen to the broadcast messages from the servers to synchronize to the server according to the broadcast messages. When a client receives the first broadcast message, the client and the server start to exchange messages to calculate the network delay between them. Then, only the broadcast server sends clock synchronization messages.	A broadcast client can synchronize to a broadcast server, but a broadcast server cannot synchronize to a broadcast client.	A broadcast server sends clock synchronization messages to synchronize clients in the same subnet. As the NTP architecture diagram in "NTP architecture" shows, broadcast mode is intended for configurations involving one or a few servers and a potentially large client population. The broadcast mode has lower time accuracy than the client/server and symmetric active/passive modes because only the broadcast servers send clock synchronization messages.
Multicast	A multicast server periodically sends clock synchronization messages to the user-configured	A multicast client can synchronize to a multicast server, but a	A multicast server can provide time synchronization for clients

Mode	Working process	Principle	Application scenario
	multicast address. Clients listen to the multicast messages from servers and synchronize to the server according to the received messages.	multicast server cannot synchronize to a multicast client.	in the same subnet or in different subnets. The multicast mode has lower time accuracy than the client/server and symmetric active/passive modes.



Operating mechanism for client/server association mode

NTP client/server mode allows an NTP server to maintain time information and allow NTP clients to communicate with the server to calibrate their clocks. In this mode, clients can accurately synchronize time with the server, ensuring time consistency across the network.

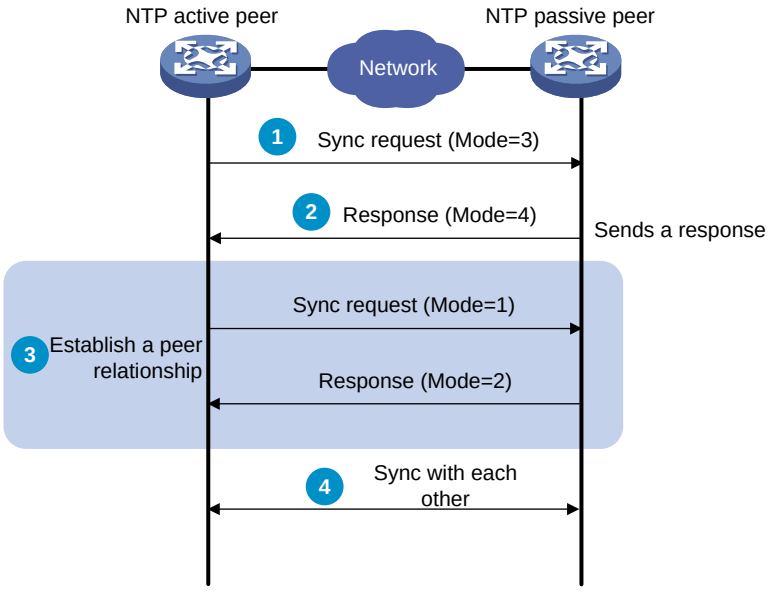
The time synchronization process in NTP client/server mode is as follows:

1. The client periodically sends time synchronization request messages to the server, with the mode field set to 3, indicating client mode. The client does not concern about the server's reachability or stratum.
2. Upon receiving the synchronization request from the client, the server fills the current time information in the response message and sets the mode field to 4, indicating server mode. Then, it sends the message back to the client. During this process, the server does not need to retain any state information about the client.
3. Upon receiving the response from the server, the client performs clock filtering and selection, and synchronizes its local clock to that of the optimal clock.

Figure 3 Operating mechanism for client/server association mode

Operating mechanism for symmetric active/passive mode

In symmetric active/passive mode, time synchronization is implemented through communication and negotiation between two nodes (peers). Both peers can act as the time source, with the more reliable and accurate time from both nodes as the optimal time.



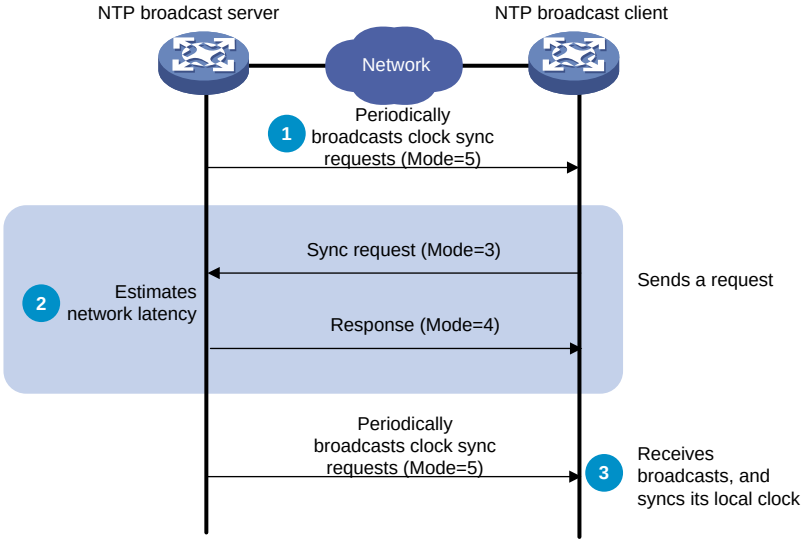
The time synchronization process in symmetric active/passive mode is as follows:

1. The symmetric active peer first sends a message with the mode field set to 1 (indicating an active peer), and the passive peer responds with a message with the mode field set to 2 (indicating a passive peer) to establish a peer relationship.
2. The peers send and receive time information for each other and use it to adjust their clocks. During this process, the two peers calculate the round-trip time delay and offset, and adjust their local clocks accordingly.

The peer with a smaller clock stratum will synchronize the clock of the peer with a greater clock stratum. The stratum indicates the distance from the standard time source. Nodes with a lower stratum are determined as closer to the standard time source, and therefore more reliable.

If the active peer can synchronize time with multiple time servers, it performs clock filtering and selection after receiving a response message. NTP uses a series of complex algorithms, such as clock filtering, offset prediction, and jitter estimation to select the best time sample and adjust the local time accordingly. Through these algorithms, the peers select the most stable and reliable time sample over a period as the basis for time synchronization.

Figure 4 Operating mechanism for symmetric active/passive mode



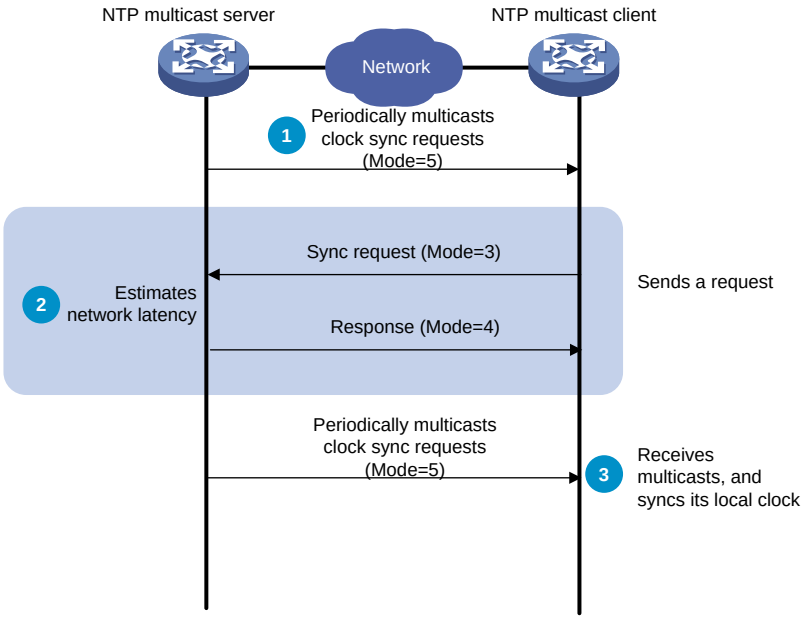
Operating mechanism for broadcast mode

NTP broadcast mode allows an NTP server to broadcast time information to the entire network. In this mode, any NTP clients listening to the broadcast can receive the time information and synchronize their system clocks accordingly.

The time synchronization process in NTP broadcast mode is as follows:

1. The broadcast server periodically sends clock synchronization request messages to broadcast address 255.255.255.255, with the mode field set to 5, indicating broadcast mode.
2. The broadcast client listens to the broadcast messages from the server. When the client receives the first broadcast message, the client and the server start to exchange messages to calculate the network delay between them.
3. The client enters broadcast mode, continues to listen for subsequent broadcast messages, and synchronizes its local clock based on the time information in these messages. Then, only the broadcast server sends clock synchronization messages.

Figure 5 Operating mechanism for broadcast mode



Operating mechanism for multicast mode

NTP multicast mode allows an NTP server to send time synchronization messages to user-configured IPv4 or IPv6 multicast addresses. A multicast server can provide time synchronization for clients in the same subnet or in different subnets. Only clients that have joined a multicast group can receive and process these messages.

The time synchronization process in NTP multicast mode is as follows:

1. The multicast server periodically sends clock synchronization request messages to the user-configured IPv4 or IPv6 multicast address, with the mode field set to 5, indicating multicast mode.
2. The broadcast client listens to the broadcast messages from the server. When the client receives the first broadcast message, the client and the server start to exchange messages to calculate the network delay between them.
3. The client enters multicast mode, continues to listen for subsequent multicast messages, and synchronizes its local clock based on the time information in these messages.

Figure 6 Operating mechanism for multicast mode

NTP security

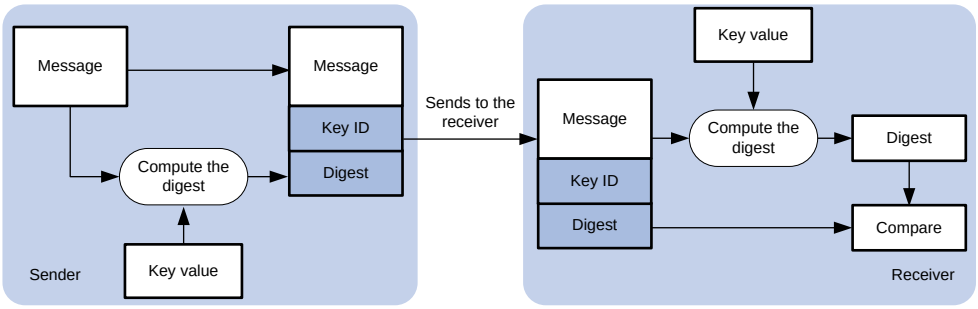
To improve time synchronization security, NTP provides the access control and authentication functions.

NTP access control

You can control NTP access by using an ACL. The access rights are in the following order, from the least restrictive to the most restrictive:

- **Peer**—Allows time requests and NTP control queries (such as alarms, authentication status, and time server information) and allows the local device to synchronize itself to a peer device.
- **Server**—Allows time requests and NTP control queries, but does not allow the local device to synchronize itself to a peer device.
- **Synchronization**—Allows only time requests from a system whose address passes the access list criteria.
- **Query**—Allows only NTP control queries from a peer device to the local device.

When the device receives an NTP request, it matches the request against the access rights in order from the least restrictive to the most restrictive: **peer**, **server**, **synchronization**, and **query**.



- If no NTP access control is configured, the **peer** access right applies.
- If the IP address of the peer device matches a **permit** statement in an ACL, the access right is granted to the peer device. If a **deny** statement or no ACL is matched, no access right is granted.
- If no ACL is specified for an access right or the ACL specified for the access right is not created, the access right is not granted.
- If none of the ACLs specified for the access rights is created, the **peer** access right applies.
- If none of the ACLs specified for the access rights contains rules, no access right is granted.

This feature provides minimal security for a system running NTP. A more secure method is NTP authentication.

NTP authentication

Use this feature to authenticate the NTP messages for security purposes. If an NTP message passes authentication, the device can receive it and get time synchronization information. If not, the device discards the message. This function makes sure the device does not synchronize to an unauthorized time server.

Figure 7 NTP authentication

As shown in Figure 7, NTP authentication is performed as follows:

2. The sender uses the key identified by the key ID to calculate a digest for the NTP message through the MD5/HMAC authentication algorithm. Then it sends the calculated digest together with the NTP message and key ID to the receiver.
3. Upon receiving the message, the receiver performs the following actions:
   a. Finds the key according to the key ID in the message.
   b. Uses the key and the MD5/HMAC authentication algorithm to calculate the digest for the message.
   c. Compares the digest with the digest contained in the NTP message.
      - If they are different, the receiver discards the message.
      - If they are the same and an NTP association is not required to be established, the receiver provides a response packet. For information about NTP associations, see "Configuring the maximum number of dynamic associations."
      - If they are the same and an NTP association is required to be established or has existed, the local device determines whether the sender is allowed to use the authentication ID. If the sender is allowed to use the authentication ID, the receiver accepts the message. If the sender is not allowed to use the authentication ID, the receiver discards the message.

Protocols and standards

- RFC 1305, *Network Time Protocol (Version 3) Specification, Implementation and Analysis*
- RFC 5905, *Network Time Protocol Version 4: Protocol and Algorithms Specification*

FIPS compliance

Higher security is required in FIPS mode. When the device operates in FIPS mode, the following restrictions apply for NTP:

- NTP can operate only in client/server mode and symmetric active/passive peer mode, and cannot operate in multicast or broadcast mode.
- Only NTPv3 and NTPv4 are supported. NTPv1 and NTPv2 are not supported.
- NTP supports the HMAC-SHA-1, HMAC-SHA-256, HMAC-SHA-384, and HMAC-SHA-512 authentication algorithms and does not support the MD5 authentication algorithm.

For more information about FIPS mode, see *Security Configuration Guide*.

Restrictions and guidelines: NTP configuration

- You cannot configure both NTP and SNTP on the same device. NTP and SNTP communicate using UDP port 123 by default. If another service module uses this port, the device will fail to enable NTP and SNTP. If you enable NTP or SNTP, other service modules cannot use port 123.
- NTP is supported only on the following Layer 3 interfaces:
  - Layer 3 Ethernet interfaces.
  - Layer 3 Ethernet subinterfaces.
  - Layer 3 aggregate interfaces.
  - Layer 3 aggregate subinterfaces.
  - VLAN interfaces.
  - Tunnel interfaces.
- Do not configure NTP settings on an aggregate member port.
- The NTP service and SNTP service are mutually exclusive. You can only enable either NTP service or SNTP service at a time.
- To avoid frequent time changes or even synchronization failures, do not specify more than one reference source on a network.
- For correct time synchronization, make sure the time offset between the system time and the NTP clock source is less than 68 years.
- To use NTP for time synchronization, you must use the **`clock protocol`** command to specify NTP for obtaining the time. For more information about the **`clock protocol`** command, see device management commands in *Fundamentals Command Reference*.

△ **CAUTION:**

When the device acts as an NTP client, the NTP server's clock stratum must be not smaller than 0 and not larger than 14. If the NTP server's clock stratum is larger than 14, the device will not synchronize with that server's clock. You can log in to the NTP server to change its clock stratum by executing the **`ntp-service refclock-master`** command.

- To check the stratum for an IPv4 NTP server, execute the **`display ntp-service sessions`** command on the device and check the **stra** field in the output.
- To check the stratum for an IPv6 NTP server, execute the **`display ntp-service ipv6 sessions`** command on the device and check the **Clock stratum** field in the output.

Client/server mode tasks at a glance

Tasks on the client

1. Enabling the NTP service

   By default, the NTP service is enabled. You do not need to perform this step.
2. Configuring NTP in client/server mode
3. (Optional.) Configuring access control rights
4. (Optional.) Configuring NTP authentication in client/server mode
5. (Optional.) Controlling NTP message sending and receiving
   - Specifying a source address for NTP messages
   - Disabling an interface from receiving NTP messages

- Configuring the maximum number of dynamic associations
- Setting a DSCP value for NTP packets

6. (Optional.) Controlling NTP time synchronization
   - Ignoring clock stratum level restrictions on NTP clients
   - Setting the maximum offset allowed for time synchronization through NTP
7. (Optional.) Specifying the NTP time-offset thresholds for log and trap outputs

Tasks on the server

1. Enabling the NTP service

   By default, the NTP service is enabled. You do not need to perform this step.
2. Configuring NTP in client/server mode

   You must enable the NTP server. By default, the NTP server is enabled. You do not need to perform this step.
3. (Optional.) Configuring the local clock as the reference source
4. (Optional.) Configuring access control rights
5. (Optional.) Configuring NTP authentication in client/server mode
6. (Optional.) Controlling NTP message sending and receiving
   - Specifying a source address for NTP messages
   - Disabling an interface from receiving NTP messages
   - Configuring the maximum number of dynamic associations
   - Setting a DSCP value for NTP packets

Symmetric active/passive mode tasks at a glance

Tasks on the active peer

1. Enabling the NTP service

   By default, the NTP service is enabled. You do not need to perform this step.
2. Configuring NTP in symmetric active/passive mode
3. (Optional.) Configuring the local clock as the reference source
4. (Optional.) Configuring access control rights
5. (Optional.) Configuring NTP authentication in symmetric active/passive mode
6. (Optional.) Controlling NTP message sending and receiving
   - Specifying a source address for NTP messages
   - Disabling an interface from receiving NTP messages
   - Configuring the maximum number of dynamic associations
   - Setting a DSCP value for NTP packets
7. (Optional.) Controlling NTP time synchronization
   - Ignoring clock stratum level restrictions on NTP clients
   - Setting the maximum offset allowed for time synchronization through NTP
8. (Optional.) Specifying the NTP time-offset thresholds for log and trap outputs

Tasks on the passive peer

1. Enabling the NTP service

   By default, the NTP service is enabled. You do not need to perform this step.
2. (Optional.) Configuring the local clock as the reference source

3. (Optional.) Configuring access control rights
4. (Optional.) Configuring NTP authentication in symmetric active/passive mode
5. (Optional.) Controlling NTP message sending and receiving
   - Specifying a source address for NTP messages
   - Disabling an interface from receiving NTP messages
   - Configuring the maximum number of dynamic associations
   - Setting a DSCP value for NTP packets
6. (Optional.) Controlling NTP time synchronization
   - Ignoring clock stratum level restrictions on NTP clients
   - Setting the maximum offset allowed for time synchronization through NTP
7. (Optional.) Specifying the NTP time-offset thresholds for log and trap outputs

Broadcast mode tasks at a glance

Tasks on the broadcast client

1. Enabling the NTP service

   By default, the NTP service is enabled. You do not need to perform this step.
2. Configuring NTP authentication in broadcast mode
3. (Optional.) Configuring access control rights
4. Configuring NTP authentication in broadcast mode
5. (Optional.) Controlling NTP message sending and receiving
   - Specifying a source address for NTP messages
   - Disabling an interface from receiving NTP messages
   - Configuring the maximum number of dynamic associations
   - Setting a DSCP value for NTP packets
6. (Optional.) Controlling NTP time synchronization
   - Ignoring clock stratum level restrictions on NTP clients
   - Setting the maximum offset allowed for time synchronization through NTP
7. (Optional.) Specifying the NTP time-offset thresholds for log and trap outputs

Tasks on the broadcast server

1. Enabling the NTP service

   By default, the NTP service is enabled. You do not need to perform this step.
2. Configuring NTP in broadcast mode
3. (Optional.) Configuring the local clock as the reference source
4. (Optional.) Configuring access control rights
5. Configuring NTP authentication in broadcast mode
6. (Optional.) Controlling NTP message sending and receiving
   - Specifying a source address for NTP messages
   - Disabling an interface from receiving NTP messages
   - Configuring the maximum number of dynamic associations
   - Setting a DSCP value for NTP packets

Multicast mode tasks at a glance

Tasks on the multicast client

1. Enabling the NTP service

   By default, the NTP service is enabled. You do not need to perform this step.
2. Configuring NTP in multicast mode
3. (Optional.) Configuring access control rights
   - Configuring NTP authentication in multicast mode
4. (Optional.) Controlling NTP message sending and receiving
   - Specifying a source address for NTP messages
   - Disabling an interface from receiving NTP messages
   - Configuring the maximum number of dynamic associations
   - Setting a DSCP value for NTP packets
5. (Optional.) Controlling NTP time synchronization
   - Ignoring clock stratum level restrictions on NTP clients
   - Setting the maximum offset allowed for time synchronization through NTP
6. (Optional.) Specifying the NTP time-offset thresholds for log and trap outputs

Tasks on the multicast server

1. Enabling the NTP service

   By default, the NTP service is enabled. You do not need to perform this step.
2. Configuring NTP in multicast mode
3. (Optional.) Configuring the local clock as the reference source
4. (Optional.) Configuring access control rights
5. (Optional.) Configuring NTP authentication in multicast mode
6. (Optional.) Controlling NTP message sending and receiving
   - Specifying a source address for NTP messages
   - Disabling an interface from receiving NTP messages
   - Configuring the maximum number of dynamic associations
   - Setting a DSCP value for NTP packets

Enabling the NTP service

Restrictions and guidelines

NTP and SNTP are mutually exclusive. Before you enable NTP, make sure SNTP is disabled.

Procedure

1. Enter system view.

   `system-view`
2. Enable the NTP service.

   `ntp-service enable`

   By default, the NTP service is disabled.

Configuring NTP association mode

Configuring NTP in client/server mode

About this task

By default, NTP uses UDP port 123 for communication. If another service module uses this port, the device will fail to enable NTP.

- When NTP service is enabled, the device will act as the NTP server or client and use UDP port 123 to provide NTP service. If another service module uses this port, the device will fail to enable NTP.
- For security purposes, the device will disable UDP port 123 and assign a currently free UDP port number to NTP if you disable IPv4 NTP server during operation of the NTP feature by executing the **undo ntp-service time-server enable** command. If IPv4 NTP server is enabled, the device will switch the NTP listening port back to 123.
- For security purposes, the device will disable UDP port 123 and assign a currently free UDP port number to NTP if you disable IPv6 NTP server during operation of the NTP feature by executing the **undo ntp-service ipv6 time-server enable** command. If IPv6 NTP server is enabled, the device will switch the IPv6 NTP listening port back to 123.

Restrictions and guidelines

To configure NTP in client/server mode, specify an NTP server for the client.

For a client to synchronize to an NTP server, make sure the server is synchronized by other devices or uses its local clock as the reference source.

If the stratum level of a server is higher than or equal to a client, the client will not synchronize to that server.

You can specify multiple servers for a client by executing the **ntp-service unicast-server** or **ntp-service ipv6 unicast-server** command multiple times.

Configuring the NTP client

1. Enter system view.

   system-view

2. Specify an NTP server for the device.

   IPv4:

   ntp-service unicast-server { *server-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **maxpoll** *maxpoll-interval* | **minpoll** *minpoll-interval* | **priority** | **source** *interface-type interface-number* | **version** *number*] *

   IPv6:

   ntp-service ipv6 unicast-server { *server-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **maxpoll** *maxpoll-interval* | **minpoll** *minpoll-interval* | **priority** | **source** *interface-type interface-number*] *

   By default, no NTP server is specified.

Configuring the NTP server

1. Enter system view.

   system-view

2. Enable NTP server.

   IPv4 network:

ntp-service time-server enable

By default, NTP server is enabled.

IPv6 network:

ntp-service ipv6 time-server enable

By default, IPv6 NTP server is enabled.

A device can synchronize the time of other devices through NTP only when it meets the following conditions:

- NTP server is enabled on the device by using the **ntp-service time-server enable** command.
- The device is permitted by the ACLs configured in the **ntp-service acl** or **ntp-service ipv6 acl** command on the other devices.

If you disable NTP server on the device, the device cannot synchronize the time of other devices through NTP.

Configuring NTP in symmetric active/passive mode

Restrictions and guidelines

To configure NTP in symmetric active/passive mode, specify a symmetric passive peer for the active peer.

For a symmetric passive peer to process NTP messages from a symmetric active peer, execute the **ntp-service enable** command on the symmetric passive peer to enable NTP.

For time synchronization between the symmetric active peer and the symmetric passive peer, make sure either or both of them are in synchronized state.

You can specify multiple symmetric passive peers by executing the **ntp-service unicast-peer** or **ntp-service ipv6 unicast-peer** command multiple times.

In IPv4 NTP symmetric peers mode, broadcast mode, or multicast mode, do not execute the **undo ntp-service time-server enable** command, no matter whether the device acts as an NTP client or server. If you fail to do so, UDP port 123 in the IPv4 protocol stack will be disabled, affecting NTP clock synchronization.

In IPv6 NTP symmetric peers mode, broadcast mode, or multicast mode, do not execute the **undo ntp-service ipv6 time-server enable** command, no matter whether the device acts as an IPv6 NTP client or server. If you fail to do so, UDP port 123 in the IPv6 protocol stack will be disabled, affecting IPv6 NTP clock synchronization.

Configuring an active peer

1. Enter system view.

   system-view

2. Specify a symmetric passive peer for the device.

   IPv4:

   ntp-service unicast-peer { *peer-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **maxpoll** *maxpoll-interval* | **minpoll** *minpoll-interval* | **priority** | **source** *interface-type interface-number* | **version** *number*] *

   IPv6:

   ntp-service ipv6 unicast-peer { *peer-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **maxpoll** *maxpoll-interval* | **minpoll** *minpoll-interval* | **priority** | **source** *interface-type interface-number*] *

By default, no symmetric passive peer is specified.

3. Enable NTP server.

   IPv4 network:

   ntp-service time-server enable

   By default, NTP server is enabled.

   IPv6 network:

   ntp-service ipv6 time-server enable

   By default, IPv6 NTP server is enabled.

   A device can synchronize the time of other devices through NTP only when it meets the following conditions:

   - NTP server is enabled on the device by using the **ntp-service time-server enable** command.
   - The device is permitted by the ACLs configured in the **ntp-service acl** or **ntp-service ipv6 acl** command on the other devices.

   If you disable NTP server on the device, the device cannot synchronize the time of other devices through NTP.

Configuring a passive peer

1. Enter system view.

   system-view

2. Enable NTP server.

   IPv4:

   ntp-service time-server enable

   By default, IPv4 NTP server is enabled.

   IPv6:

   ntp-service ipv6 time-server enable

   By default, IPv6 NTP server is enabled.

   A device can provide NTP synchronization to other devices only when it meets the following conditions:

   - NTP server is enabled on the device.
   - The device is permitted by the ACLs configured in the **ntp-service acl** or **ntp-service ipv6 acl** command on the other devices.

   If you disable NTP server on the device, the device cannot synchronize the time of other devices through NTP or synchronize time to the NTP server in symmetric peers, broadcast, or multicast mode.

Configuring NTP in broadcast mode

Restrictions and guidelines

To configure NTP in broadcast mode, you must configure an NTP broadcast client and an NTP broadcast server.

For a broadcast client to synchronize to a broadcast server, make sure the broadcast server is synchronized by other devices or uses its local clock as the reference source.

Configuring the broadcast client

1. Enter system view.

   system-view

2. Enable NTP server.

   IPv4:

   ntp-service time-server enable

   By default, IPv4 NTP server is enabled.

   IPv6:

   ntp-service ipv6 time-server enable

   By default, IPv6 NTP server is enabled.

   A device can provide NTP synchronization to other devices only when it meets the following conditions:

   - NTP server is enabled on the device.
   - The device is permitted by the ACLs configured in the **ntp-service acl** or **ntp-service ipv6 acl** command on the other devices.

   If you disable NTP server on the device, the device cannot synchronize the time of other devices through NTP or synchronize time to the NTP server in symmetric peers, broadcast, or multicast mode.

3. Enter interface view.

   interface *interface-type interface-number*

4. Configure the device to operate in broadcast client mode.

   ntp-service broadcast-client

   By default, the device does not operate in any NTP association mode.

   After you execute the command, the device receives NTP broadcast messages from the specified interface.

Configuring the broadcast server

1. Enter system view.

   system-view

2. Enable NTP server.

   IPv4 network:

   ntp-service time-server enable

   By default, NTP server is enabled.

   IPv6 network:

   ntp-service ipv6 time-server enable

   By default, IPv6 NTP server is enabled.

   A device can synchronize the time of other devices through NTP only when it meets the following conditions:

   - NTP server is enabled on the device by using the **ntp-service time-server enable** command.
   - The device is permitted by the ACLs configured in the **ntp-service acl** or **ntp-service ipv6 acl** command on the other devices.

   If you disable NTP server on the device, the device cannot synchronize the time of other devices through NTP or synchronize time to the NTP server in symmetric peers, broadcast, or multicast mode..

3. Enter interface view.

   interface *interface-type interface-number*

4. Configure the device to operate in NTP broadcast server mode.

   ntp-service broadcast-server [**authentication-keyid** *keyid* | **version** *number*] *

By default, the device does not operate in any NTP association mode.

After you execute the command, the device sends NTP broadcast messages from the specified interface.

Configuring NTP in multicast mode

Restrictions and guidelines

To configure NTP in multicast mode, you must configure an NTP multicast client and an NTP multicast server.

For a multicast client to synchronize to a multicast server, make sure the multicast server is synchronized by other devices or uses its local clock as the reference source.

Configuring a multicast client

1. Enter system view.

   system-view

2. Enable NTP server.

   IPv4:

   ntp-service time-server enable

   By default, IPv4 NTP server is enabled.

   IPv6:

   ntp-service ipv6 time-server enable

   By default, IPv6 NTP server is enabled.

   A device can provide NTP synchronization to other devices only when it meets the following conditions:

   - NTP server is enabled on the device.
   - The device is permitted by the ACLs configured in the **ntp-service acl** or **ntp-service ipv6 acl** command on the other devices.

   If you disable NTP server on the device, the device cannot synchronize the time of other devices through NTP or synchronize time to the NTP server in symmetric peers, broadcast, or multicast mode.

3. Enter interface view.

   interface *interface-type interface-number*

4. Configure the device to operate in multicast client mode.

   IPv4:

   ntp-service multicast-client [*ip-address*]

   IPv6:

   ntp-service ipv6 multicast-client *ipv6-address*

   By default, the device does not operate in any NTP association mode.

   After you execute the command, the device receives NTP multicast messages from the specified interface.

Configuring the multicast server

1. Enter system view.

   system-view

2. Enable NTP server.

   IPv4 network:

   ntp-service time-server enable

By default, NTP server is enabled.

IPv6 network:

ntp-service ipv6 time-server enable

By default, IPv6 NTP server is enabled.

A device can synchronize the time of other devices through NTP only when it meets the following conditions:

- NTP server is enabled on the device by using the **ntp-service time-server enable** command.
- The device is permitted by the ACLs configured in the **ntp-service acl** or **ntp-service ipv6 acl** command on the other devices.

If you disable NTP server on the device, the device cannot synchronize the time of other devices through NTP.

3. Enter interface view.

   interface *interface-type interface-number*

4. Configure the device to operate in multicast server mode.

   IPv4:

   ntp-service multicast-server [*ip-address*][**authentication-keyid** *keyid* | **ttl** *ttl-number* | **version** *number*]*

   IPv6:

   ntp-service ipv6 multicast-server *ipv6-address* [**authentication-keyid** *keyid* | **ttl** *ttl-number*] *

   By default, the device does not operate in any NTP association mode.

   After you execute the command, the device sends NTP multicast messages from the specified interface.

Configuring the local clock as the reference source

About this task

The clock stratum of an NTP server that obtains time synchronization from an authoritative clock (such as an atomic clock) is typically set to 1 and used as the primary time server to synchronize the clocks of other devices in the network. The NTP distance between devices and the primary time server in the network, which is the number of servers in the NTP synchronization chain, determines the stratum of the device clocks.

If the devices in a network cannot synchronize to an authoritative time source, you can perform the following tasks:

- Select a device that has a relatively accurate clock from the network.
- Use the local clock of the device as the reference clock to synchronize other devices in the network.

Restrictions and guidelines

Make sure the local clock can provide the time accuracy required for the network. After you configure the local clock as the reference source, the local clock is synchronized, and can operate as a time server to synchronize other devices in the network. If the local clock is incorrect, timing errors occur.

The system time reverts to the initial BIOS default after a cold reboot. The system clock stops and does not record the passing of time during a warm reboot. As a best practice, do not configure the local clock as the reference source or configure the device as a time server.

Devices differ in clock precision. As a best practice to avoid network flapping and clock synchronization failure, configure only one reference clock on the same network segment and make sure the clock has high precision.

Prerequisites

Before you configure this feature, adjust the local system time to ensure that it is accurate.

Procedure

1. Enter system view.
   system-view
2. Configure the local clock as the reference source.
   ntp-service refclock-master [*ip-address*] [*stratum*]
   By default, the device does not use the local clock as the reference source.

Configuring access control rights

Prerequisites

Before you configure the right for peer devices to access the NTP services on the local device, create and configure ACLs associated with the access right. For information about configuring an ACL, see *ACL and QoS Configuration Guide*.

Restrictions and guidelines

Table 2 Restrictions and guidelines for configuring NTP access control rights

Access control right	Whether the time can be synchronized (whether configurable on a client)	Whether can synchronize the time of other devices (whether configurable on a time server)	Whether allows control queries
Peer	Yes	Yes	Yes
Server	No	Yes	Yes
Synchronization	No	Yes	No
Query	No	No	Yes

The **ntp-service noquery enable** command and its undo form are used only to configure the device to disallow or allow control queries and do not disable or enable clock synchronization. If the **ntp-service noquery enable** command or its undo form and the **ntp-service acl** or **ntp-service ipv6 acl** command are both configured, the **ntp-service noquery enable** command or its undo form determines whether control queries are allowed.

Procedure

1. Enter system view.
   system-view
2. Configure the right for peer devices to access the NTP services on the local device.
   IPv4:
   ntp-service access { **peer** | **query** | **server** | **synchronization** } **acl** *ipv4-acl-number*
   IPv6:

ntp-service ipv6 { **peer** |**query** | **server** | **synchronization** } **acl** *ipv6-acl-number*

By default, the right for peer devices to access the NTP services on the local device is **peer**.

3. Disallow control queries for the local device.

ntp-service noquery enable

By default, control queries for the local device are allowed.

Configuring NTP authentication

Configuring NTP authentication in client/server mode

Restrictions and guidelines

To ensure a successful NTP authentication in client/server mode, configure the same authentication key ID, algorithm, and key on the server and client. Make sure the peer device is allowed to use the key ID for authentication on the local device.

NTP authentication results differ when different configurations are performed on client and server. For more information, see Table 3. (N/A in the table means that whether the configuration is performed or not does not make any difference.)

Table 3 NTP authentication results

Client			Server	
Enable NTP authentication	**Specify the server and key**	**Trusted key**	**Enable NTP authentication**	**Trusted key**
Successful authentication				
Yes	Yes	Yes	Yes	Yes
Failed authentication				
Yes	Yes	Yes	Yes	No
Yes	Yes	Yes	No	N/A
Yes	Yes	No	N/A	N/A
Authentication not performed				
Yes	No	N/A	N/A	N/A
No	N/A	N/A	N/A	N/A

Configuring NTP authentication for a client

1. Enter system view.

system-view

2. Enable NTP authentication.

ntp-service authentication enable

By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

5. Associate the specified key with an NTP server.

   IPv4:

   ntp-service unicast-server { *server-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

   IPv6:

   ntp-service ipv6 unicast-server { *server-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

Configuring NTP authentication for a server

1. Enter system view.

   system-view

2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

Configuring NTP authentication in symmetric active/passive mode

Restrictions and guidelines

To ensure a successful NTP authentication in symmetric active/passive mode, configure the same authentication key ID, algorithm, and key on the active peer and passive peer. Make sure the peer device is allowed to use the key ID for authentication on the local device.

NTP authentication results differ when different configurations are performed on active peer and passive peer. For more information, see Table 4. (N/A in the table means that whether the configuration is performed or not does not make any difference.)

Table 4 NTP authentication results

Active peer				Passive peer	
Enable NTP authentication	**Specify the peer and key**	**Trusted key**	**Stratum level**	**Enable NTP authentication**	**Trusted key**
Successful authentication					
Yes	Yes	Yes	N/A	Yes	Yes

Active peer				Passive peer	
Enable NTP authentication	**Specify the peer and key**	**Trusted key**	**Stratum level**	**Enable NTP authentication**	**Trusted key**
Failed authentication					
Yes	Yes	Yes	N/A	Yes	No
Yes	Yes	Yes	N/A	No	N/A
Yes	No	N/A	N/A	Yes	N/A
No	N/A	N/A	N/A	Yes	N/A
Yes	Yes	No	Larger than the passive peer	N/A	N/A
Yes	Yes	No	Smaller than the passive peer	Yes	N/A
Authentication not performed					
Yes	No	N/A	N/A	No	N/A
No	N/A	N/A	N/A	No	N/A
Yes	Yes	No	Smaller than the passive peer	No	N/A

Configuring NTP authentication for an active peer

1. Enter system view.

   system-view
2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.
3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.
4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.
5. Associate the specified key with a passive peer.

   IPv4:

   ntp-service unicast-peer { *ip-address* | *peer-name* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

   IPv6:

   ntp-service ipv6 unicast-peer { *ipv6-address* | *peer-name* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

Configuring NTP authentication for a passive peer

1. Enter system view.

   system-view
2. Enable NTP authentication.

ntp-service authentication enable

By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

ntp-service reliable authentication-keyid *keyid*

By default, no authentication key is configured as a trusted key.

Configuring NTP authentication in broadcast mode

Restrictions and guidelines

To ensure a successful NTP authentication in broadcast mode, configure the same authentication key ID, algorithm, and key on the broadcast server and client. Make sure the peer device is allowed to use the key ID for authentication on the local device.

NTP authentication results differ when different configurations are performed on broadcast client and server. For more information, see Table 5. (N/A in the table means that whether the configuration is performed or not does not make any difference.)

Table 5 NTP authentication results

Broadcast server			Broadcast client	
Enable NTP authentication	**Specify the server and key**	**Trusted key**	**Enable NTP authentication**	**Trusted key**
Successful authentication				
Yes	Yes	Yes	Yes	Yes
Failed authentication				
Yes	Yes	Yes	Yes	No
Yes	Yes	Yes	No	N/A
Yes	Yes	No	Yes	N/A
Yes	No	N/A	Yes	N/A
No	N/A	N/A	Yes	N/A
Authentication not performed				
Yes	Yes	No	No	N/A
Yes	No	N/A	No	N/A
No	N/A	N/A	No	N/A

Configuring NTP authentication for a broadcast client

1. Enter system view.

system-view

2. Enable NTP authentication.

ntp-service authentication enable

By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

Configuring NTP authentication for a broadcast server

1. Enter system view.

   system-view

2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

5. Enter interface view.

   interface *interface-type interface-number*

6. Associate the specified key with the broadcast server.

   ntp-service broadcast-server authentication-keyid *keyid*

   By default, the broadcast server is not associated with a key.

Configuring NTP authentication in multicast mode

Restrictions and guidelines

To ensure a successful NTP authentication in multicast mode, configure the same authentication key ID, algorithm, and key on the multicast server and client. Make sure the peer device is allowed to use the key ID for authentication on the local device.

NTP authentication results differ when different configurations are performed on broadcast client and server. For more information, see Table 6. (N/A in the table means that whether the configuration is performed or not does not make any difference.)

Table 6 NTP authentication results

Multicast server			Multicast client	
Enable NTP authentication	**Specify the server and key**	**Trusted key**	**Enable NTP authentication**	**Trusted key**
Successful authentication				
Yes	Yes	Yes	Yes	Yes
Failed authentication				
Yes	Yes	Yes	Yes	No
Yes	Yes	Yes	No	N/A
Yes	Yes	No	Yes	N/A
Yes	No	N/A	Yes	N/A
No	N/A	N/A	Yes	N/A
Authentication not performed				
Yes	Yes	No	No	N/A
Yes	No	N/A	No	N/A
No	N/A	N/A	No	N/A

Configuring NTP authentication for a multicast client

1. Enter system view.

   system-view
2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.
3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.
4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

Configuring NTP authentication for a multicast server

1. Enter system view.

   system-view
2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.
3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

5. Enter interface view.

   interface *interface-type interface-number*

6. Associate the specified key with a multicast server.

   IPv4:

   ntp-service multicast-server [*ip-address*] **authentication-keyid** *keyid*

   IPv6:

   ntp-service ipv6 multicast-server *ipv6-multicast-address* **authentication-keyid** *keyid*

   By default, no multicast server is associated with the specified key.

Controlling NTP message sending and receiving

Specifying a source address for NTP messages

About this task

You can specify a source address for NTP messages directly or by specifying a source interface. If you specify a source interface for NTP messages, the device uses the IP address of the specified interface as the source address to send NTP messages.

Restrictions and guidelines

To prevent interface status changes from causing NTP communication failures, specify an interface that is always up as the source interface, a loopback interface for example.

When the device responds to an NTP request, the source IP address of the NTP response is always the IP address of the interface that has received the NTP request.

If you have specified the source interface for NTP messages in the **ntp-service unicast-server/ntp-service ipv6 unicast-server** or **ntp-service unicast-peer/ntp-service ipv6 unicast-peer** command, the IP address of the specified interface is used as the source IP address for NTP messages.

If you have configured the **ntp-service broadcast-server** or **ntp-service multicast-server/ntp-service ipv6 multicast-server** command in an interface view, the IP address of the interface is used as the source IP address for broadcast or multicast NTP messages.

Procedure

1. Enter system view.

   system-view

2. Specify the source address for NTP messages.

   IPv4:

   ntp-service source { *interface-type interface-number* | *ipv4-address* }

   IPv6:

   ntp-service ipv6 source *interface-type interface-number*

   By default, no source address is specified for NTP messages.

Disabling an interface from receiving NTP messages

About this task

When NTP is enabled, all interfaces by default can receive NTP messages. For security purposes, you can disable some of the interfaces from receiving NTP messages.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Disable the interface from receiving NTP packets.
   IPv4:
   undo ntp-service inbound enable
   IPv6:
   undo ntp-service ipv6 inbound enable
   By default, an interface receives NTP messages.

Configuring the maximum number of dynamic associations

About this task

Perform this task to restrict the number of dynamic associations to prevent dynamic associations from occupying too many system resources.

NTP has the following types of associations:

- **Static association**—A manually created association.
- **Dynamic association**—Temporary association created by the system during NTP operation. A dynamic association is removed if no messages are exchanged within about 12 minutes.

The following describes how an association is established in different association modes:

- **Client/server mode**—After you specify an NTP server, the system creates a static association on the client. The server simply responds passively upon the receipt of a message, rather than creating an association (static or dynamic).
- **Symmetric active/passive mode**—After you specify a symmetric passive peer on a symmetric active peer, static associations are created on the symmetric active peer, and dynamic associations are created on the symmetric passive peer.
- **Broadcast or multicast mode**—Static associations are created on the server, and dynamic associations are created on the client.

Restrictions and guidelines

A single device can have a maximum of 128 concurrent associations, including static associations and dynamic associations. After this command is configured, new associations will not be established if the maximum number of associations has been reached or exceeded.

Procedure

1. Enter system view.
   system-view
2. Configure the maximum number of dynamic sessions.
   ntp-service max-dynamic-sessions *number*
   By default, the maximum number of dynamic sessions is 100.

Setting a DSCP value for NTP packets

About this task

Configure this task to specify the sending precedence for NTP packets. This feature allows you to set a DSCP value for NTP packets when the device acts as an NTP or IPv6 NTP server or client.

Procedure

1. Enter system view.
   system-view
2. Set a DSCP value for NTP packets.
   IPv4:
   ntp-service dscp *dscp-value*
   IPv6:
   ntp-service ipv6 dscp *dscp-value*
   The default DSCP value is 48 for IPv4 packets and 56 for IPv6 packets.

Controlling NTP time synchronization

Ignoring clock stratum level restrictions on NTP clients

About this task

Application scenarios

Perform this task to control whether the device responds to time synchronization requests from NTP clients when it acts as an NTP server.

Operating mechanism

By default, when an NTP server receives a clock synchronization request from an NTP client, it checks the stratum level of the client. The server responds to the request and synchronizes the clock only if the client has a higher stratum level than the server. In some network environments, if a client has a stratum level lower than or equal to the server and changing the stratum level is not supported, you can perform this task to ignore the stratum level restrictions on NTP clients.

Procedure

1. Enter system view.
   system-view
2. Configure the device to not restrict the stratum level of NTP clients.
   ntp-service ignore clock-stratum
   By default, an NTP server restricts the stratum level of NTP clients when it synchronizes the clock with the NTP clients.

Setting the maximum offset allowed for time synchronization through NTP

About this task

Application scenarios

This feature controls whether the device synchronizes the time with an NTP server when it acts as an NTP client.

Operating mechanism

When the device acts as an NTP client, it subtracts the local time from the time provided by the NTP server to calculate the time offset. The device will adjust the local NTP time based on this offset. If this offset exceeds the configured maximum offset, the device will determine that the time from the NTP server is unreliable and will not synchronize the time from the NTP server.

Procedure

1. Enter system view.
   system-view
2. Set the maximum offset allowed for time synchronization through NTP.
   ntp-service time-offset-limit *limit-threshold*
   By default, no maximum offset is set for time synchronization through NTP.

Specifying the NTP time-offset thresholds for log and trap outputs

About this task

By default, the system synchronizes the NTP client's time to the server and outputs a log and a trap when the time offset exceeds 128 ms for multiple times.

After you set the NTP time-offset thresholds for log and trap outputs, the system synchronizes the client's time to the server when the time offset exceeds 128 ms for multiple times, but outputs logs and traps only when the time offset exceeds the specified thresholds, respectively.

Procedure

1. Enter system view.
   system-view
2. Specify the NTP time-offset thresholds for log and trap outputs.
   ntp-service time-offset-threshold { **log** *log-threshold* | **trap** *trap-threshold* } *
   By default, no NTP time-offset thresholds are set for log and trap outputs.

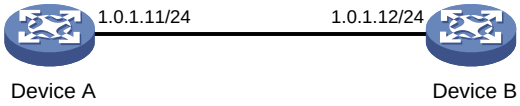
Display and maintenance commands for NTP

The **ntp-service noquery enable** command is mutually exclusive with the **display ntp-service trace** command. To use the **display ntp-service trace** command, you must configure the device to allow control queries.

Execute **display** commands in any view.

Task	Command
Display information about IPv6 NTP associations.	**display ntp-service ipv6 sessions** [**verbose**]
Display information about IPv4 NTP associations.	**display ntp-service sessions** [**verbose**]
Display information about NTP service status.	**display ntp-service status**
Display brief information about the NTP servers from the local device back to the primary NTP server.	**display ntp-service trace** [**source** *interface-type interface-number*]

NTP configuration examples



Example: Configuring NTP client/server association mode

Network configuration

As shown in Figure 8, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device B to operate in client mode and specify Device A as the NTP server of Device B.

Figure 8 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 8. (Details not shown.)
2. Configure Device A:

   # Enable the NTP service.

   ```
   <DeviceA> system-view
   [DeviceA] ntp-service enable
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [DeviceA] ntp-service refclock-master 2
   ```
3. Configure Device B:

   # Enable the NTP service.

   ```
   <DeviceB> system-view
   [DeviceB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceB] clock protocol ntp
   ```

   # Specify Device A as the NTP server of Device B.

   ```
   [DeviceB] ntp-service unicast-server 1.0.1.11
   ```

Verifying the configuration

Verify that Device B has synchronized its time with Device A, and the clock stratum level of Device B is 3.

```
[DeviceB] display ntp-service status
 Clock status: synchronized
 Clock stratum: 3
 System peer: 1.0.1.11
 Local mode: client
 Reference clock ID: 1.0.1.11
 Leap indicator: 00
 Clock jitter: 0.000977 s

```

Example: Configuring IPv6 NTP client/server association mode

Network configuration

As shown in Figure 9, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device B to operate in client mode and specify Device A as the IPv6 NTP server of Device B.

Figure 9 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 9. (Details not shown.)
2. Configure Device A:

   # Enable the NTP service.

   ```
   <DeviceA> system-view
   [DeviceA] ntp-service enable
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [DeviceA] ntp-service refclock-master 2
   ```

3. Configure Device B:

   # Enable the NTP service.

   ```
   <DeviceB> system-view
   [DeviceB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceB] clock protocol ntp
   ```

   # Specify Device A as the IPv6 NTP server of Device B.

   ```
   [DeviceB] ntp-service ipv6 unicast-server 3000::34
   ```

Verifying the configuration

Verify that Device B has synchronized its time with Device A, and the clock stratum level of Device B is 3.

```
[DeviceB] display ntp-service status
 Clock status: synchronized
 Clock stratum: 3
 System peer: 3000::34
 Local mode: client
 Reference clock ID: 163.29.247.19
 Leap indicator: 00

```

Example: Configuring NTP symmetric active/passive association mode

Network configuration

As shown in Figure 10, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device A to operate in symmetric active mode and specify Device B as the passive peer of Device A.

Figure 10 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 10. (Details not shown.)
2. Configure Device B:

   # Enable the NTP service.

```
<DeviceB> system-view
[DeviceB] ntp-service enable
```

Specify NTP for obtaining the time.

```
[DeviceB] clock protocol ntp
```

3. Configure Device A:

Enable the NTP service.

```
<DeviceA> system-view
[DeviceA] ntp-service enable
```

Specify NTP for obtaining the time.

```
[DeviceA] clock protocol ntp
```

Specify the local clock as the reference source, with stratum level 2.

```
[DeviceA] ntp-service refclock-master 2
```

Configure Device B as its symmetric passive peer.

Example: Configuring IPv6 NTP symmetric active/passive association mode

Network configuration

As shown in Figure 11, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device A to operate in symmetric active mode and specify Device B as the IPv6 passive peer of Device A.

Figure 11 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 11. (Details not shown.)
2. Configure Device B:

   # Enable the NTP service.

   ```
   <DeviceB> system-view
   [DeviceB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceB] clock protocol ntp
   ```

3. Configure Device A:

   # Enable the NTP service.

   ```
   <DeviceA> system-view
   [DeviceA] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```

```

Example: Configuring NTP broadcast association mode

Network configuration

As shown in Figure 12, configure Switch C as the NTP server for multiple devices on the same network segment so that these devices synchronize the time with Switch C.

- Configure Switch C's local clock as its reference source, with stratum level 2.
- Configure Switch C to operate in broadcast server mode and send broadcast messages from VLAN-interface 2.
- Configure Switch A and Switch B to operate in broadcast client mode, and listen to broadcast messages on VLAN-interface 2.

Figure 12 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Switch A, Switch B, and Switch C can reach each other, as shown in Figure 12. (Details not shown.)
2. Configure Switch C:

   # Enable the NTP service.

   ```
   <SwitchC> system-view
   [SwitchC] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchC] clock protocol ntp
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [SwitchC] ntp-service refclock-master 2
   ```

   # Configure Switch C to operate in broadcast server mode and send broadcast messages from VLAN-interface 2.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] ntp-service broadcast-server
```

3. Configure Switch A:

   # Enable the NTP service.

```
<SwitchA> system-view
[SwitchA] ntp-service enable
```

   # Specify NTP for obtaining the time.

```
[SwitchA] clock protocol ntp
```

   # Configure Switch A to operate in broadcast client mode and receive broadcast messages on VLAN-interface 2.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ntp-service broadcast-client
```

4. Configure Switch B:

   # Enable the NTP service.

```
<SwitchB> system-view
[SwitchB] ntp-service enable
```

   # Specify NTP for obtaining the time.

```
[SwitchB] clock protocol ntp
```

   # Configure Switch B to operate in broadcast client mode and receive broadcast messages on VLAN-interface 2.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ntp-service broadcast-client
```

Verifying the configuration

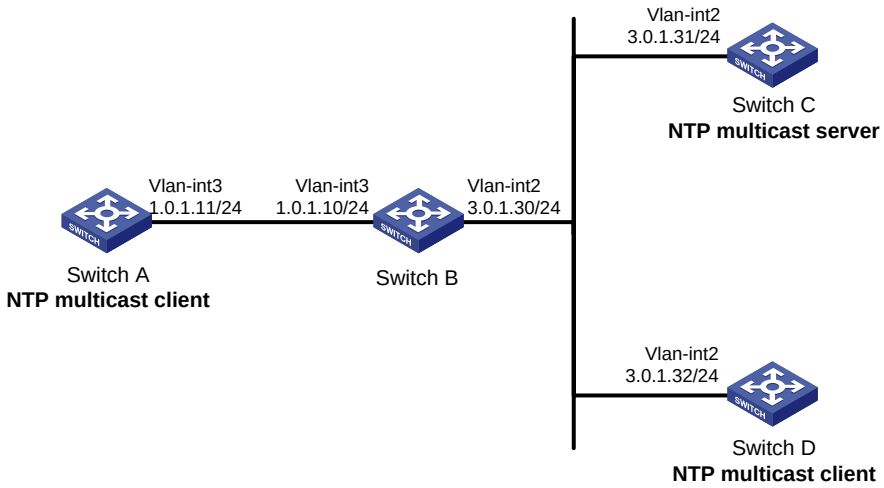
The following procedure uses Switch A as an example to verify the configuration.

Verify that Switch A has synchronized to Switch C, and the clock stratum level is 3 on Switch A and 2 on Switch C.

```
[SwitchA-Vlan-interface2] display ntp-service status
 Clock status: synchronized
 Clock stratum: 3
 System peer: 3.0.1.31
 Local mode: bclient
 Reference clock ID: 3.0.1.31
 Leap indicator: 00
 Clock jitter: 0.044281 s
 Stability: 0.000 pps
 Clock precision: 2^-23
 Root delay: 0.00229 ms
 Root dispersion: 4.12572 ms
 Reference time: d0d289fe.ec43c720  Sat, Jan  8 2019  7:00:14.922
 System poll interval: 64 s
```

Verify that an IPv4 NTP association has been established between Switch A and Switch C.

```
[SwitchA-Vlan-interface2] display ntp-service sessions
       source          reference       stra reach poll  now offset  delay disper
**************************************************************************
 [1245]3.0.1.31        127.127.1.0        2     1   64  519   -0.0 0.0022 4.1257
Notes: 1 source(master),2 source(peer),3 selected,4 candidate,5 configured.
 Total sessions: 1
```



Example: Configuring NTP multicast association mode

Network configuration

As shown in Figure 13, configure Switch C as the NTP server for multiple devices on different network segments so that these devices synchronize the time with Switch C.

- Configure Switch C's local clock as its reference source, with stratum level 2.
- Configure Switch C to operate in multicast server mode and send multicast messages from VLAN-interface 2.
- Configure Switch A and Switch D to operate in multicast client mode and receive multicast messages on VLAN-interface 3 and VLAN-interface 2, respectively.

Figure 13 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure the switches can reach each other, as shown in Figure 13. (Details not shown.)
2. Configure Switch C:

   # Enable the NTP service.

   ```
   <SwitchC> system-view
   [SwitchC] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchC] clock protocol ntp
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [SwitchC] ntp-service refclock-master 2
   ```

   # Configure Switch C to operate in multicast server mode and send multicast messages from VLAN-interface 2.

   ```
   [SwitchC] interface vlan-interface 2
   [SwitchC-Vlan-interface2] ntp-service multicast-server
   ```

3. Configure Switch D:

   # Enable the NTP service.

   ```
   <SwitchD> system-view
   [SwitchD] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchD] clock protocol ntp
   ```

Configure Switch D to operate in multicast client mode and receive multicast messages on VLAN-interface 2.

```
[SwitchD] interface vlan-interface 2
[SwitchD-Vlan-interface2] ntp-service multicast-client
```

4. Verify the configuration:

Verify that Switch D has synchronized to Switch C, and the clock stratum level is 3 on Switch D and 2 on Switch C.

Switch D and Switch C are on the same subnet, so Switch D can receive the multicast messages from Switch C without being enabled with the multicast functions.

```
[SwitchD-Vlan-interface2] display ntp-service status
 Clock status: synchronized
 Clock stratum: 3
 System peer: 3.0.1.31
 Local mode: bclient
 Reference clock ID: 3.0.1.31
 Leap indicator: 00
 Clock jitter: 0.044281 s
 Stability: 0.000 pps
 Clock precision: 2^-10
 Root delay: 0.00229 ms
 Root dispersion: 4.12572 ms
 Reference time: d0d289fe.ec43c720  Sat, Jan  8 2019  7:00:14.922
 System poll interval: 64 s
```

Verify that an IPv4 NTP association has been established between Switch D and Switch C.

```
[SwitchD-Vlan-interface2] display ntp-service sessions
      source          reference       stra reach poll  now offset  delay disper
**********************************************************************************
 [1245]3.0.1.31        127.127.1.0        2     1   64  519   -0.0 0.0022 4.1257
Notes: 1 source(master),2 source(peer),3 selected,4 candidate,5 configured.
 Total sessions: 1
```

5. Configure Switch B:

Because Switch A and Switch C are on different subnets, you must enable the multicast functions on Switch B before Switch A can receive multicast messages from Switch C.

Enable IP multicast functions.

```
<SwitchB> system-view
[SwitchB] multicast routing
[SwitchB-mrib] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] pim dm
[SwitchB-Vlan-interface2] quit
[SwitchB] vlan 3
[SwitchB-vlan3] port gigabitethernet 1/0/1
[SwitchB-vlan3] quit
[SwitchB] interface vlan-interface 3
[SwitchB-Vlan-interface3] igmp enable
[SwitchB-Vlan-interface3] igmp static-group 224.0.1.1
[SwitchB-Vlan-interface3] quit
[SwitchB] igmp-snooping
```

```
[SwitchB-igmp-snooping] quit
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] igmp-snooping static-group 224.0.1.1 vlan 3
```

6. Configure Switch A:

   # Enable the NTP service.

```
<SwitchA> system-view
[SwitchA] ntp-service enable
```

   # Specify NTP for obtaining the time.

```
[SwitchA] clock protocol ntp
```

   # Configure Switch A to operate in multicast client mode and receive multicast messages on VLAN-interface 3.

```
[SwitchA] interface vlan-interface 3
[SwitchA-Vlan-interface3] ntp-service multicast-client
```

Verifying the configuration

Verify that Switch A has synchronized its time with Switch C, and the clock stratum level of Switch A is 3.

```
[SwitchA-Vlan-interface3] display ntp-service status
 Clock status: synchronized
 Clock stratum: 3
 System peer: 3.0.1.31
 Local mode: bclient
 Reference clock ID: 3.0.1.31
 Leap indicator: 00
 Clock jitter: 0.165741 s
 Stability: 0.000 pps
 Clock precision: 2^-23
 Root delay: 0.00534 ms
 Root dispersion: 4.51282 ms
 Reference time: d0c61289.10b1193f  Wed, Dec 29 2019 20:03:21.065
 System poll interval: 64 s
```

Verify that an IPv4 NTP association has been established between Switch A and Switch C.

```

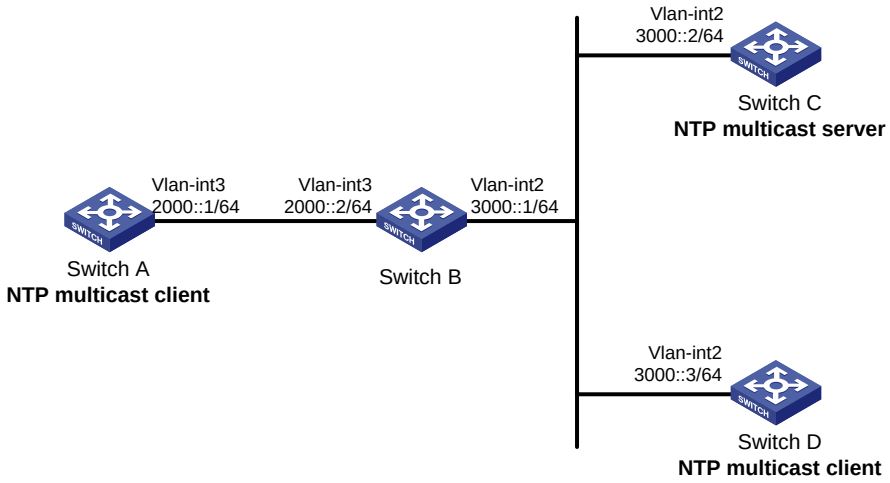
Example: Configuring IPv6 NTP multicast association mode



Network configuration

As shown in Figure 14, configure Switch C as the NTP server for multiple devices on different network segments so that these devices synchronize the time with Switch C.

- Configure Switch C's local clock as its reference source, with stratum level 2.
- Configure Switch C to operate in IPv6 multicast server mode and send IPv6 multicast messages from VLAN-interface 2.

- Configure Switch A and Switch D to operate in IPv6 multicast client mode and receive IPv6 multicast messages on VLAN-interface 3 and VLAN-interface 2, respectively.

Figure 14 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure the switches can reach each other, as shown in Figure 14. (Details not shown.)
2. Configure Switch C:

   # Enable the NTP service.

   ```
   <SwitchC> system-view
   [SwitchC] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchC] clock protocol ntp
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [SwitchC] ntp-service refclock-master 2
   ```

   # Configure Switch C to operate in IPv6 multicast server mode and send multicast messages from VLAN-interface 2.

   ```
   [SwitchC] interface vlan-interface 2
   [SwitchC-Vlan-interface2] ntp-service ipv6 multicast-server ff24::1
   ```

3. Configure Switch D:

   # Enable the NTP service.

   ```
   <SwitchD> system-view
   [SwitchD] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchD] clock protocol ntp
   ```

   # Configure Switch D to operate in IPv6 multicast client mode and receive multicast messages on VLAN-interface 2.

   ```
   [SwitchD] interface vlan-interface 2
   [SwitchD-Vlan-interface2] ntp-service ipv6 multicast-client ff24::1
   ```

4. Verify the configuration:

   # Verify that Switch D has synchronized its time with Switch C, and the clock stratum level of Switch D is 3.

   Switch D and Switch C are on the same subnet, so Switch D can Receive the IPv6 multicast messages from Switch C without being enabled with the IPv6 multicast functions.

```
[SwitchD-Vlan-interface2] display ntp-service status
 Clock status: synchronized

Example: Configuring NTP authentication in client/server association mode

Network configuration

As shown in Figure 15, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device B to operate in client mode and specify Device A as the NTP server of Device B.
- Configure NTP authentication on both Device A and Device B.

Figure 15 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 15. (Details not shown.)
2. Configure Device A:

   # Enable the NTP service.

   ```
   <DeviceA> system-view
   [DeviceA] ntp-service enable
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [DeviceA] ntp-service refclock-master 2
   ```
3. Configure Device B:

   # Enable the NTP service.

   ```
   <DeviceB> system-view
   [DeviceB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceB] clock protocol ntp
   ```

   # Enable NTP authentication on Device B.

   ```
   [DeviceB] ntp-service authentication enable
   ```

   # Create a plaintext authentication key, with key ID **42** and key value **aNiceKey**.

   ```
   [DeviceB] ntp-service authentication-keyid 42 authentication-mode md5 simple
   aNiceKey
   ```

   # Specify the key as a trusted key.

   ```
   [DeviceB] ntp-service reliable authentication-keyid 42
   ```

   # Specify Device A as the NTP server of Device B, and associate the server with key 42.

   ```
   [DeviceB] ntp-service unicast-server 1.0.1.11 authentication-keyid 42
   ```

   To enable Device B to synchronize its clock with Device A, enable NTP authentication on Device A.
4. Configure NTP authentication on Device A:

   # Enable NTP authentication.

   ```
   [DeviceA] ntp-service authentication enable
   ```

   # Create a plaintext authentication key, with key ID **42** and key value **aNiceKey**.

   ```
   [DeviceA] ntp-service authentication-keyid 42 authentication-mode md5 simple
   aNiceKey
   ```

   # Specify the key as a trusted key.

   ```
   [DeviceA] ntp-service reliable authentication-keyid 42
   ```

Verifying the configuration

Verify that Device B has synchronized its time with Device A, and the clock stratum level of Device B is 3.

```
[DeviceB] display ntp-service status

Example: Configuring NTP authentication in broadcast association mode

Network configuration

As shown in Figure 16, configure Switch C as the NTP server for multiple devices on the same network segment so that these devices synchronize the time with Switch C. Configure Switch A and Switch B to authenticate the NTP server.

- Configure Switch C's local clock as its reference source, with stratum level 3.
- Configure Switch C to operate in broadcast server mode and send broadcast messages from VLAN-interface 2.
- Configure Switch A and Switch B to operate in broadcast client mode and receive broadcast messages on VLAN-interface 2.
- Enable NTP authentication on Switch A, Switch B, and Switch C.

Figure 16 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Switch A, Switch B, and Switch C can reach each other, as shown in Figure 16. (Details not shown.)
2. Configure Switch A:

   # Enable the NTP service.

   ```
   <SwitchA> system-view
   [SwitchA] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchA] clock protocol ntp
   ```

   # Enable NTP authentication on Switch A. Create a plaintext NTP authentication key, with key ID of **88** and key value of **123456**. Specify it as a trusted key.

   ```
   [SwitchA] ntp-service authentication enable
   [SwitchA] ntp-service authentication-keyid 88 authentication-mode md5 simple 123456
   [SwitchA] ntp-service reliable authentication-keyid 88
   ```

   # Configure Switch A to operate in NTP broadcast client mode and receive NTP broadcast messages on VLAN-interface 2.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ntp-service broadcast-client
   ```

3. Configure Switch B:

   # Enable the NTP service.

   ```
   <SwitchB> system-view
   [SwitchB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchB] clock protocol ntp
   ```

   # Enable NTP authentication on Switch B. Create a plaintext NTP authentication key, with key ID of **88** and key value of **123456**. Specify it as a trusted key.

   ```
   [SwitchB] ntp-service authentication enable
   [SwitchB] ntp-service authentication-keyid 88 authentication-mode md5 simple 123456
   [SwitchB] ntp-service reliable authentication-keyid 88
   ```

   # Configure Switch B to operate in broadcast client mode and receive NTP broadcast messages on VLAN-interface 2.

   ```
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] ntp-service broadcast-client
   ```

4. Configure Switch C:

   # Enable the NTP service.

   ```
   <SwitchC> system-view
   [SwitchC] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchC] clock protocol ntp
   ```

   # Specify the local clock as the reference source, with stratum level 3.

   ```
   [SwitchC] ntp-service refclock-master 3
   ```

   # Configure Switch C to operate in NTP broadcast server mode and use VLAN-interface 2 to send NTP broadcast packets.

   ```
   [SwitchC] interface vlan-interface 2
   [SwitchC-Vlan-interface2] ntp-service broadcast-server
   [SwitchC-Vlan-interface2] quit
   ```

5. Verify the configuration:

NTP authentication is enabled on Switch A and Switch B, but not on Switch C, so Switch A and Switch B cannot synchronize their local clocks to Switch C.

```
[SwitchB-Vlan-interface2] display ntp-service status
 Clock status: unsynchronized
 Clock stratum: 16
 Reference clock ID: none
```

6. Enable NTP authentication on Switch C:

Enable NTP authentication on Switch C. Create a plaintext NTP authentication key, with key ID of **88** and key value of **123456**. Specify it as a trusted key.

```
[SwitchC] ntp-service authentication enable
[SwitchC] ntp-service authentication-keyid 88 authentication-mode md5 simple 123456
[SwitchC] ntp-service reliable authentication-keyid 88
```

Specify Switch C as an NTP broadcast server, and associate key **88** with Switch C.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] ntp-service broadcast-server authentication-keyid 88
```

Verifying the configuration

Verify that Switch B has synchronized its time with Switch C, and the clock stratum level of Switch B is 4.

```
[SwitchB-Vlan-interface2] display ntp-service status
 Clock status: synchronized
 Clock stratum: 4

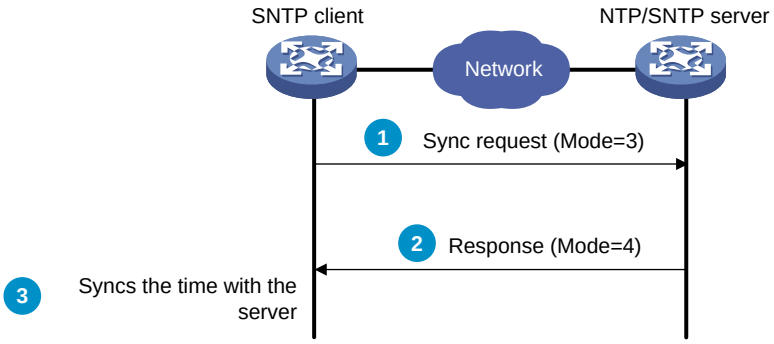
Configuring SNTP

About SNTP

SNTP is a simplified, client-only version of NTP specified in RFC 4330. It uses the same packet format and packet exchange procedure as NTP, but provides faster synchronization at the price of time accuracy.

Relationship between SNTP and NTP

The relationship between SNTP and NTP is as follows:



- **Purpose**—Both SNTP and NTP aim to synchronize the time of computer systems.
- **Protocol family**—SNTP is a subset of NTP and uses the same protocol family as NTP. SNTP uses the NTP message format.
- **Simplified version**—NTP provides additional features to enhance time synchronization accuracy, such as complex error detection and correction algorithms, dynamic server selection, load balancing, and control protocols. SNTP typically does not provide these complex features.
- **Precision**—NTP is designed to provide high-precision time synchronization on the network, typically at the millisecond level and even capable of reaching sub-millisecond levels. SNTP is suitable for scenarios where precision requirements are lower.
- **Compatibility**—In most cases, SNTP and NTP are compatible, because they use the same PDU format. This design allows interoperability between SNTP clients and NTP servers, and between NTP clients and SNTP servers.
- **Application scenarios**—SNTP, being a simplified version of NTP, is ideal for resource-constrained devices such as home routers and IP cameras, as well as applications where strict time accuracy is not critical. On the other hand, NTP is designed for use in scenarios demanding highly precise time synchronization, such as financial transaction systems, scientific research, and advanced network infrastructure.

SNTP operating mechanism

SNTP performs basic time synchronization by using some fields in NTP messages. It uses the same message exchange process as NTP but processes the received time information in a more simplified way, reducing complexity and resource requirements. The following is a typical SNTP time synchronization message exchange process:

1. The SNTP client generates an NTP message, sets the mode to client (mode 3), pads the original timestamp, and then sends it to the server.
2. Upon receiving the message, the NTP/SNTP server adds or updates the receive timestamp and transmit timestamp, sets the message mode to server (mode 4), and sends it back to the client as a response.
3. After receiving the response, the SNTP client logs the time when the response was received, extracts the transmission timestamp from the response, and adjusts the clock as needed.

Figure 17 SNTP operating mechanism

SNTP association modes

SNTP supports the following association modes:

- Client/server mode
- Broadcast mode

You can select one or more SNTP association modes for time synchronization. Table 7 provides detailed description for the association modes.

In this document, an "NTP server" or a "server" refers to a device that operates as an NTP server in client/server mode. Time servers refer to all the devices that can provide time synchronization, including NTP servers and NTP broadcast servers.

Table 7 SNTP association modes

Mode	Working process	Synchronization direction	Application scenario
Client/server	**1.** A client sends an NTP time synchronization request message to the NTP servers. **2.** After receiving the message, each NTP server automatically works in server mode and replies with a response message. **3.** The client filters and selects an optimal clock based on the received response messages and synchronizes time with that clock.	From the server to the client	As the NTP architecture diagram in "NTP architecture" shows, this mode is intended for scenarios where devices with a higher stratum value obtain time from a device with a lower stratum value.
Broadcast	**4.** A broadcast server periodically sends clock synchronization request messages to the broadcast address 255.255.255.255. **5.** Broadcast clients listen to the broadcast messages from the server and synchronize the time with the server based on the broadcast messages. When a broadcast client receives	From the broadcast server to the client.	As the NTP architecture diagram in "NTP architecture" shows, this mode is intended for scenarios where the same time server provides time synchronization for a large number of devices in the same subnet. The broadcast mode has lower time accuracy than the client/server and

Mode	Working process	Synchronization direction	Application scenario
	the first broadcast message, the client and the server start to exchange messages to calculate the network delay between them. Then, only the broadcast server sends clock synchronization messages.		symmetric active/passive modes because only the broadcast servers send clock synchronization messages.

Protocols and standards

RFC 4330, *Simple Network Time Protocol (SNTP) Version 4 for IPv4, IPv6 and OSI*

FIPS compliance

Higher security is required in FIPS mode. When the device operates in FIPS mode, the following restrictions apply for SNTP:

- SNTP can only use NTPv3 and NTPv4 packets and cannot use NTPv1 or NTPv2 packets.
- SNTP supports the HMAC-SHA-1, HMAC-SHA-256, HMAC-SHA-384, and HMAC-SHA-512 authentication algorithms and does not support the MD5 authentication algorithm.

For more information about FIPS mode, see *Security Configuration Guide*.

Restrictions and guidelines: SNTP configuration

When you configure SNTP, follow these restrictions and guidelines:

- You cannot configure both NTP and SNTP on the same device.
- To use NTP for time synchronization, you must use the **`clock protocol`** command to specify NTP for obtaining the time. For more information about the **`clock protocol`** command, see device management commands in *Fundamentals Configuration Guide*.

Client/server mode tasks at a glance

Tasks on the client

1. Enabling the SNTP service
2. Configuring SNTP authentication in client/server mode

   The device can operate in client/server mode and broadcast mode simultaneously. If the device acts as a client and receives multiple NTP clock signals at the same time, it will select the optimal NTP clock for synchronization.

   - Specifying an NTP server for the device
   - (Optional.) Configuring SNTP authentication in client/server mode
3. (Optional.) Controlling SNTP time synchronization
   - Ignoring clock stratum level restrictions on SNTP clients
   - Setting the maximum offset allowed for time synchronization through SNTP
4. (Optional.) Monitoring the time synchronization status
5. (Optional.) Specifying the SNTP time-offset thresholds for log and trap outputs

Tasks on the server

1. Enabling the SNTP service
2. (Optional.) Configuring SNTP authentication in client/server mode

Broadcast mode tasks at a glance

Tasks on the broadcast client

1. Enabling the SNTP service
2. Configuring SNTP in broadcast mode

   The device can operate in client/server mode and broadcast mode simultaneously. If the device acts as a client and receives multiple NTP clock signals at the same time, it will select the optimal NTP clock for synchronization.

   - Configuring the SNTP broadcast client
   - (Optional.) Configuring SNTP authentication in broadcast mode
3. (Optional.) Controlling SNTP time synchronization
   - Ignoring clock stratum level restrictions on SNTP clients
   - Setting the maximum offset allowed for time synchronization through SNTP
4. (Optional.) Monitoring the time synchronization status
5. (Optional.) Specifying the SNTP time-offset thresholds for log and trap outputs

NOTE:

You can deploy an NTP broadcast server in the network to act as an SNTP broadcast server. This enables SNTP time synchronization in broadcast mode.

Enabling the SNTP service

Restrictions and guidelines

The NTP service and SNTP service are mutually exclusive. Before you enable SNTP, make sure NTP is disabled.

Procedure

1. Enter system view.

   `system-view`
2. Enable the SNTP service.

   `sntp enable`

   By default, the SNTP service is disabled.

Configuring SNTP in client/server mode

Specifying an NTP server for the device

About this task

In SNTP client/server mode, the device only supports acting as a client to synchronize the clock with the NTP server.

Restrictions and guidelines

To use an NTP server as the time source, make sure its clock has been synchronized. If the stratum level of the NTP server is greater than or equal to that of the client, the client does not synchronize with the NTP server.

Procedure

1. Enter system view.

   system-view

2. Specify an NTP server for the device.

   IPv4:

   sntp unicast-server { *server-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **maxpoll** *maxpoll-interval* | **minpoll** *minpoll-interval* | **source** *interface-type interface-number* | **version** *number*] *

   IPv6:

   sntp ipv6 unicast-server { *server-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **maxpoll** *maxpoll-interval* | **minpoll** *minpoll-interval* | **source** *interface-type interface-number*] *

   By default, no NTP server is specified for the device.

   You can specify multiple NTP servers for the client by repeating this step.

   To perform authentication, you need to specify the **authentication-keyid** *keyid* option.

Configuring SNTP authentication in client/server mode

About this task

SNTP authentication ensures that an SNTP client is synchronized only to an authenticated trustworthy NTP server.

Restrictions and guidelines

Enable authentication on both the NTP server and the SNTP client.

Use the same authentication key ID, algorithm, and key on the NTP server and SNTP client. Specify the key as a trusted key on both the NTP server and the SNTP client. For information about configuring NTP authentication on an NTP server, see "Configuring NTP."

On the SNTP client, associate the specified key with the NTP server. Make sure the server is allowed to use the key ID for authentication on the client.

With authentication disabled, the SNTP client can synchronize with the NTP server regardless of whether the NTP server is enabled with authentication.

Configuring SNTP authentication on the client

1. Enter system view.

   system-view

2. Enable SNTP authentication.

   sntp authentication enable

   By default, SNTP authentication is disabled.

3. Configure an SNTP authentication key.

sntp authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

By default, no SNTP authentication key exists.

4. Specify the key as a trusted key.

sntp reliable authentication-keyid *keyid*

By default, no trusted key is specified.

5. Associate the SNTP authentication key with an NTP server.

IPv4:

sntp unicast-server { *server-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

IPv6:

sntp ipv6 unicast-server { *server-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

By default, no NTP server is specified.

Configuring SNTP authentication on the server

1. Enter system view.

system-view

2. Enable SNTP authentication.

sntp authentication enable

By default, SNTP authentication is disabled.

3. Configure an SNTP authentication key.

sntp authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

By default, no SNTP authentication key exists.

4. Specify the key as a trusted key.

sntp reliable authentication-keyid *keyid*

By default, no trusted key is specified.

Configuring SNTP in broadcast mode

Configuring the SNTP broadcast client

About this task

In SNTP broadcast mode, the device supports only operating as an SNTP broadcast client to synchronize the clock with the NTP broadcast server.

Procedure

1. Enter system view.

system-view

2. Enter interface view.

interface *interface-type interface-number*

3. Configure the device to operate in SNTP broadcast client mode.

sntp broadcast-client

By default, the device does not operate in any SNTP association mode.

After you execute the command, the device receives NTP broadcast messages from the specified interface.

Configuring SNTP authentication in broadcast mode

About this task

In some networks where time synchronization security is required, you need to enable authentication when SNTP is used. SNTP authentication ensures that the client synchronizes time only with the authenticated server, which improves network security.

Restrictions and guidelines

- You must enable authentication on both the NTP broadcast server and SNTP broadcast client.
- You must configure the same authentication key (including key ID, authentication algorithm, and key value) for the NTP broadcast server and SNTP broadcast client and set the key as a trusted key. For information about configuring authentication on an NTP broadcast server, see "Configuring NTP authentication for a broadcast server."
- If SNTP authentication is not successfully enabled on the client, the client can synchronize with the server regardless of whether authentication is enabled on the server.

Procedure

1. Enter system view.

   system-view
2. Enable SNTP authentication.

   sntp authentication enable

   By default, SNTP authentication is disabled.
3. Configure an SNTP authentication key.

   sntp authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no SNTP authentication key exists.
4. Configure the key as a trusted key.

   sntp reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

Controlling SNTP time synchronization

Ignoring clock stratum level restrictions on SNTP clients

About this task

Application scenarios

Perform this task to control whether the device responds to time synchronization requests from SNTP clients when it acts as an SNTP server.

Operating mechanism

By default, when an SNTP server receives a clock synchronization request from an SNTP client, it checks the stratum level of the client. The server responds to the request and synchronizes the clock only if the client has a higher stratum level than the server. In some network environments, if a client

has a stratum level lower than or equal to the server and changing the stratum level is not supported, you can perform this task to ignore the stratum level restrictions on SNTP clients.

Procedure

1. Enter system view.

   system-view

2. Ignore restrictions on the stratum level of SNTP clients.

   sntp ignore clock-stratum

   By default, an SNTP server restricts the stratum level of SNTP clients when it synchronizes the clock with the SNTP clients.

Setting the maximum offset allowed for time synchronization through SNTP

About this task

Application scenarios

This feature controls whether the device synchronizes the time with an SNTP server when it acts as an SNTP client.

Operating mechanism

When the device acts as an SNTP client, it subtracts the local time from the time provided by the SNTP server to calculate the time offset. The device will adjust the local SNTP time based on this offset. If this offset exceeds the configured maximum offset, the device will determine that the time from the SNTP server is unreliable and will not synchronize the time from the SNTP server.

Procedure

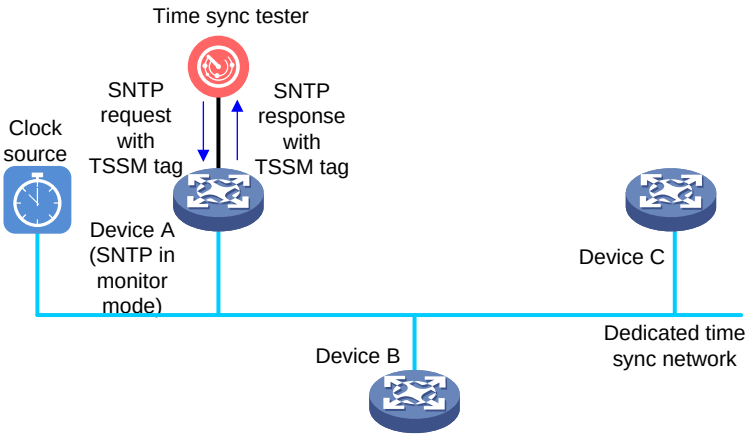
1. Enter system view.

   system-view

2. Set the maximum offset allowed for time synchronization through SNTP.

   sntp time-offset-limit *limit-threshold*

   By default, no maximum offset is set for time synchronization through SNTP.



Monitoring the time synchronization status

About this task

Application scenarios

In networks where time is synchronized through non-SNTP methods (such as dedicated time synchronization networks and PTP), you can use this feature to monitor the time synchronization status. It can identify whether the difference between the time obtained by the device and the clock source is within the allowable range and whether the device's time is affected by any sudden changes in the clock source.

Figure 18 SNTP operating in monitor mode

Operating mechanism

The Time Synchronization Status Monitoring (TSSM) tag in SNTP packets is used to enhance the security and reliability of the time synchronization process. The TSSM tag is typically used in time synchronization applications with higher security levels to ensure that responses are made only to SNTP requests from known and trusted time sources.

When the device acts as an SNTP client, the packets it send do not carry the TSSM tag, and it can synchronize time with the SNTP server.

When SNTP is enabled, the SNTP server functionality is automatically enabled on the device. When the device operates as an SNTP server:

- By default, when the device receives an SNTP request, it processes it as a clock synchronization request regardless of whether it carries the TSSM flag, and responds with a packet that does not contain the TSSM flag.
- If this command is configured, the SNTP server will identify whether the received SNTP request contains the TSSM flag. If the request does not contain the TSSM flag, the device will discard the request. The device responds to the request only if the request contains the TSSM flag.

Restrictions and guidelines

After this feature is configured, the device can synchronize its clock as an SNTP client with upstream devices, but it cannot provide SNTP time synchronization services to downstream devices.

Procedure

1. Enter system view.

   `system-view`

2. Configure the device to respond only to SNTP requests that contain the TSSM tag.

   `sntp respond-to-withtssm`

   By default, the device processes all SNTP requests regardless of whether they carry the TSSM tag when it acts as an SNTP server.

Specifying the SNTP time-offset thresholds for log and trap outputs

About this task

By default, the system synchronizes the SNTP client's time to the server and outputs a log and a trap when the time offset exceeds 128 ms for multiple times.

After you set the SNTP time-offset thresholds for log and trap outputs, the system synchronizes the client's time to the server when the time offset exceeds 128 ms for multiple times, but outputs logs and traps only when the time offset exceeds the specified thresholds, respectively.

Procedure

1. Enter system view.

   system-view

2. Specify the SNTP time-offset thresholds for log and trap outputs.

   sntp time-offset-threshold { **log** *log-threshold* | **trap** *trap-threshold* } *

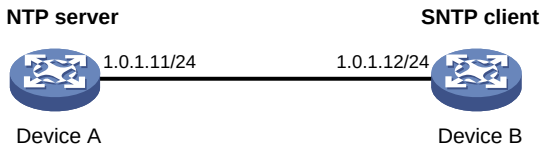
   By default, no SNTP time-offset thresholds are set for log and trap outputs.

Display and maintenance commands for SNTP

Execute **display** commands in any view.

Task	Command
Display information about all IPv6 SNTP associations.	**display sntp ipv6 sessions**
Display information about all IPv4 SNTP associations.	**display sntp sessions**

SNTP configuration examples



Example: Configuring SNTP in client/server association mode

Network configuration

As shown in Figure 19, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device B to operate in SNTP client mode, and specify Device A as the NTP server.
- Configure NTP authentication on Device A and SNTP authentication on Device B.

Figure 19 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 19. (Details not shown.)
2. Configure Device A:

   # Enable the NTP service.

   ```
   <DeviceA> system-view
   [DeviceA] ntp-service enable
   ```

Specify NTP for obtaining the time.

```
[DeviceA] clock protocol ntp
```

Configure the local clock as the reference source, with stratum level 2.

```
[DeviceA] ntp-service refclock-master 2
```

Enable NTP authentication on Device A.

```
[DeviceA] ntp-service authentication enable
```

Configure a plaintext NTP authentication key, with key ID of **10** and key value of **aNiceKey**.

```
[DeviceA] ntp-service authentication-keyid 10 authentication-mode md5 simple
aNiceKey
```

Specify the key as a trusted key.

```
[DeviceA] ntp-service reliable authentication-keyid 10
```

3. Configure Device B:

Enable the SNTP service.

```
<DeviceB> system-view
[DeviceB] sntp enable
```

Specify NTP for obtaining the time.

```
[DeviceB] clock protocol ntp
```

Enable SNTP authentication on Device B.

```
[DeviceB] sntp authentication enable
```

Configure a plaintext authentication key, with key ID of **10** and key value of **aNiceKey**.

```
[DeviceB] sntp authentication-keyid 10 authentication-mode md5 simple aNiceKey
```

Specify the key as a trusted key.

```
[DeviceB] sntp reliable authentication-keyid 10
```

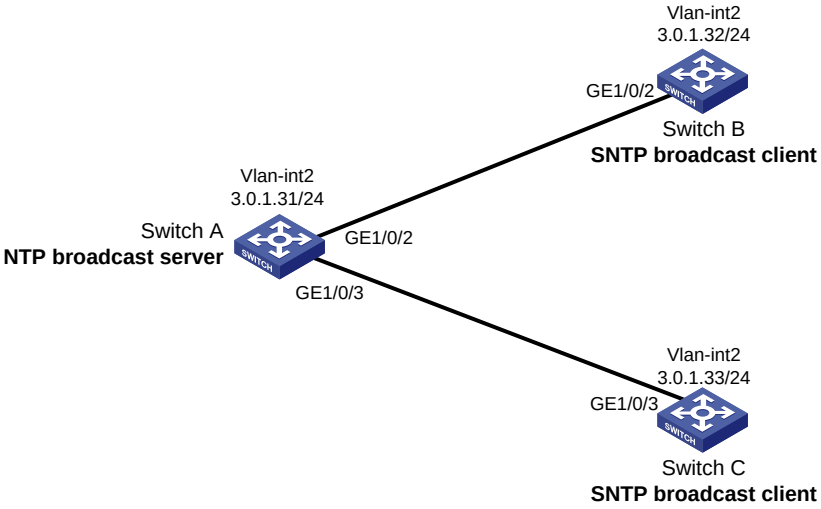
Specify Device A as the NTP server of Device B, and associate the server with key 10.

```
[DeviceB] sntp unicast-server 1.0.1.11 authentication-keyid 10
```

Verifying the configuration

Verify that an SNTP association has been established between Device B and Device A, and Device B has synchronized its time with Device A.

```
[DeviceB] display sntp sessions
SNTP server     Stratum   Version    Poll   Last receive time
1.0.1.11        2         4          64     Tue, May 17 2019  9:11:20.833 (Synced)
```



Example: Configuring SNTP in broadcast association mode

Network configuration

As shown in Figure 20, configure Switch A as the NTP broadcast server to provide NTP clock synchronization for other devices on the LAN.

- On Switch A, configure the local clock as the reference source, with stratum level 2.
- Configure Switch A to operate in broadcast server mode and send broadcast messages from VLAN-interface 2.
- Configure Switch B and Switch C to operate in broadcast client mode, and listen to broadcast messages on VLAN-interface 2.

Figure 20 Network diagram

Procedure

1. Configure Switch A:

Configure the device to use the local clock.

```
<SwitchA> system-view
[SwitchA] clock protocol none
```

Adjust the local system time to be correct.

```
[SwitchA] quit
<SwitchA> clock datetime 8:8:8 11/17/2022
```

Enable the NTP service.

```
<SwitchA> system-view
[SwitchA] ntp-service enable
```

Specify the local clock as the reference source, with stratum level 2.

```
[SwitchA] ntp-service refclock-master 2
```

Create VLAN 2 and assign GigabitEthernet1/0/2 that connects Switch B and GigabitEthernet1/0/3 that connects Switch C to VLAN 2.

```
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/2 gigabitethernet 1/0/3
[SwitchA-vlan2] quit
```

Configure Switch A to operate in broadcast server mode and send broadcast messages from VLAN-interface 2.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 3.0.1.31 24
[SwitchA-Vlan-interface2] ntp-service broadcast-server
[SwitchA-Vlan-interface2] quit
```

2. Configure Switch B:

Enable SNTP

```
<SwitchB> system-view
[SwitchB] sntp enable
```

Specify using NTP to obtain the time.

```
[SwitchB] clock protocol ntp
```

Create VLAN 2 and assign GigabitEthernet1/0/2 that connects Switch A to VLAN 2.

```
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/2
[SwitchA-vlan2] quit
```

Configure Switch B to operate in SNTP broadcast client mode and receive broadcast messages on VLAN-interface 2.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 3.0.1.32 24
[SwitchB-Vlan-interface2] sntp broadcast-client
[SwitchB-Vlan-interface2] quit
```

3. Configure Switch C:

Enable SNTP.

```
<SwitchC> system-view
[SwitchC] sntp enable
```

Specify using NTP to obtain the time.

```
[SwitchC] clock protocol ntp
```

Create VLAN 2 and assign GigabitEthernet1/0/3 that connects Switch A to VLAN 2.

```
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/3
[SwitchA-vlan2] quit
```

Configure Switch C to operate in SNTP broadcast client mode and receive broadcast messages on VLAN-interface 2.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] ip address 3.0.1.33 24
[SwitchC-Vlan-interface2] sntp broadcast-client
[SwitchC-Vlan-interface2] quit
```

Verifying the configuration

View SNTP session information on Switch B and Switch C. If information as follows is displayed, the device has established an session and synchronized the time with Switch A.

Switch B is used in this example.

```
[SwitchB] display sntp sessions
SNTP server     Stratum   Version    Poll   Last receive time
3.0.1.31        2         4          64     Thu, Nov  17 2022 08:08:40.442 (Synced)
```

View the system clock on Switch B and Switch C and verify that the time on Switch B and Switch C is consistent with that on Switch A.

Switch B is used in this example.

```
[SwitchB] display clock
08:08:45.120 UTC Thu 11/17/2022
```

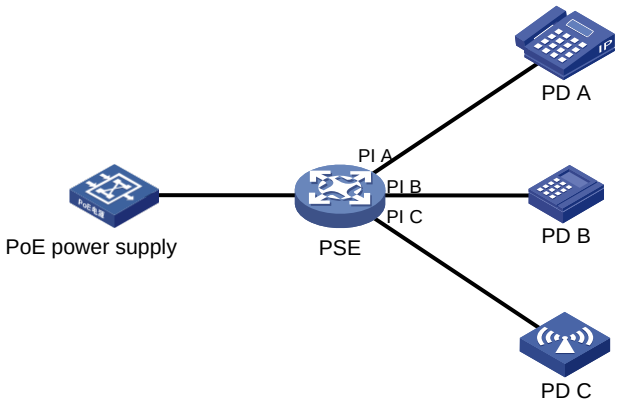
Configuring PoE

About PoE

Power over Ethernet (PoE) enables a network device to supply power to terminals over twisted pair cables.



PoE system

As shown in Figure 1, a PoE system includes the following elements:

- **PoE power supply**—A PoE power supply provides power for the entire PoE system.
- **PSE**—A power sourcing equipment (PSE) supplies power to PDs. PSE devices are classified into single-PSE devices and multiple-PSE devices.
  - A single-PSE device has only one piece of PSE firmware.
  - A multiple-PSE device has multiple PSEs. A multiple-PSE device uses PSE IDs to identify different PSEs. To view the mapping between the ID and slot number of a PSE, execute the **`display poe device`** command.

  The device is a multiple-PSE device.
- **PI**—A power interface (PI) is a PoE-capable Ethernet interface on a PSE.
- **PD**—A powered device (PD) receives power from a PSE. PDs include IP telephones, APs, portable chargers, POS terminals, and Web cameras. You can also connect a PD to a redundant power source for reliability.

Figure 1 PoE system diagram

Protocols and standards

802.3af, 802.3at, and 802.3bt are the 3rd, 4th, and 5th editions of the PoE protocol established by the IEEE. The differences between the three PoE technologies lie in their power transmission capabilities and the number of wires used for power transmission.

- 802.3af, also known as the PoE standard, was released in 2003. It provides a maximum power output of 15.4 W and uses 2 pairs of wires for power transmission.

  The name of the 802.3af standard is *802.3af-2003, IEEE Standard for Information Technology - Telecommunications and Information Exchange Between Systems - Local and Metropolitan Area Networks - Specific Requirements - Part 3: Carrier Sense Multiple Access with Collision*

Detection (CSMA/CD) Access Method and Physical Layer Specifications - Data Terminal Equipment (DTE) Power Via Media Dependent Interface (MDI).

- 802.3at, also known as the PoE+ standard, was released in 2009. It provides a maximum power output of 30 W and uses 2 or 4 pairs of wires for power transmission. It is backward compatible with the 802.3af standard.

  The name of the 802.3at standard is *802.3at-2009, IEEE Standard for Information technology-- Local and metropolitan area networks-- Specific requirements-- Part 3: CSMA/CD Access Method and Physical Layer Specifications Amendment 3: Data Terminal Equipment (DTE) Power via the Media Dependent Interface (MDI) Enhancements*.
- 802.3bt, also known as the PoE++ standard, was released in 2018. It provides a maximum power output of 90 W and is compatible with existing low-power PoE devices. This standard uses 4 pairs of wires for power transmission and supports PoE devices over long distances and with better performance. It is backward compatible with the 802.3af and 802.3at standards.

  The name of the 802.3bt standard is *802.3bt-2018 - IEEE Standard for Ethernet Amendment 2: Physical Layer and Management Parameters for Power over Ethernet over 4 pairs*.

Restrictions and guidelines: PoE configuration

CAUTION:

When a PI is IEEE 802.3at- or IEEE 802.3bt compliant, it supplies power to the PD only if the total remaining power of all PSEs is greater than or equal to the guard band. To obtain the total remaining power of all PSEs, execute the **`display poe interface`** without specifying an interface. The value of the **Remaining** field is the total remaining power of all PSEs. The guard band value depends on the PoE standard and software version.

You can configure settings for a PI through either of the following ways:

- Configure the settings directly on the PI.
- Configure a PoE profile and apply it to the PI. If you apply a PoE profile to multiple PIs, these PIs have the same PoE features. If you connect a PD to another PI, you can apply the PoE profile of the original PI to the new PI. This method relieves the task of configuring PoE on the new PI.

You can only use one way to configure a parameter for a PI. To use the other way to reconfigure a parameter, you must first remove the original configuration.

You must use the same configuration method for the **`poe max-power`** *`max-power`* and **`poe priority`** { **`critical`** | **`high`** | **`low`** } commands.

If a PI fails to supply power to a device connected to it, identify whether the device is a PD. If it is a PD, enable nonstandard PD protection for the device.

PoE configuration tasks at a glance

To configure PoE, perform the following tasks:

1. Enabling PoE
   a. Enabling PoE for a PI
2. (Optional.) Configuring PoE delay
3. (Optional.) Disabling PoE on shutdown interfaces
4. (Optional.) Allowing inrush currents drawn by PDs
5. (Optional.) Enabling PI power cycling upon a system warm reboot
6. (Optional.) Configuring PD detection

- Enabling nonstandard PD detection
- Configuring a PD disconnection detection mode

7. (Optional.) Configuring the PoE power
   - Configuring the maximum PI power
8. (Optional.) Configuring the PoE priority policy
   - Configuring the PI priority policy
9. (Optional.) Configuring PoE monitoring
   - Configuring PSE power monitoring
10. (Optional.) Configuring a PI by using a PoE profile

    To use a PoE profile to enable PoE and configure the priority and maximum power for a PI, see "Configuring a PI by using a PoE profile."
11. (Optional.) Upgrading PSE firmware in service
12. (Optional.) Enabling forced PoE power supply

Prerequisites for configuring PoE

Before you configure PoE, make sure the PoE power supply and PSEs are operating correctly.

Enabling PoE

Enabling PoE for a PI

About this task

After you enable PoE for a PI, the PI supplies power to the connected PD if the PI will not result in PSE power overload. PSE overload occurs when the sum of the power consumption of all PIs exceeds the maximum power of the PSE.

If the PI will result in PSE power overload, the following restrictions apply:

- If the PI priority policy is not enabled, the PI does not supply power to the connected PD.
- If the PI priority policy is enabled, whether the PDs can be powered depends on the priority of the PI.

For more information about the PI priority policy, see "Configuring the PI priority policy."

Restrictions and guidelines

A PI can supply power to a PD only when the PI and PD use the same power transmission mode.

Procedure

1. Enter system view.

   system-view
2. Enter PI view.

   interface *interface-type interface-number*
3. (Optional.) Configure a description for the PD connected to the PI.

   poe pd-description *text*

   By default, no description is configured for the PD connected to the PI.
4. (Optional.) Specify a PoE standard for the PI.

   poe standard { **at** | **bt** }

   By default, a PI complies with the IEEE 802.3bt PoE standard.

NOTE:

Support for this feature depends on the device model. Only some models support this feature.

5. Enable PoE for the PI.

   poe enable

   By default, when the device starts up with the initial configuration, PoE is disabled on PIs. When the device starts up with the factory defaults, PoE is enabled on PIs.

   For more information about the initial configuration and factory defaults, see configuration file management in *Fundamentals Configuration Guide*.

Enabling fast PoE for a PSE

About this task

This feature enables a PI on a PSE to supply power to PDs immediately after the PSE is powered on.

Procedure

1. Enter system view.

   system-view

2. Enable fast PoE for a PSE.

   Single-PSE device:

   poe fast-on enable

   Multiple-PSE device:

   poe fast-on enable pse *pse-id*

   By default, fast PoE is disabled on a PSE.

Configuring PoE delay

About this task

By default, the device executes the **poe enable** command and supplies power to an interface immediately when any one of the following conditions is met:

- The **poe enable** command is configured.
- The device reboots with the **poe enable** command in the configuration file.
- The interface comes up and the PoE module resumes PoE power supply to the interface.

This task creates a PoE delay timer after the **poe enable** command is executed and allows the PoE module to supply power to the PI only after the timer expires.

Restrictions and guidelines

The **undo poe enable** command is executed immediately upon configuration and is not affected by this task.

Procedure

1. Enter system view.

   system-view

2. Enable PoE delay.

   poe power-delay *time*

   By default, PoE delay is disabled.

Disabling PoE on shutdown interfaces

About this task

By default, the device continues supplying power to an interface after the interface is shut down by the **shutdown** command or by an upper layer module such as monitor link. As a result, the PD connected to the shutdown interface operates continuously but fails to access the network.

This task disables the PoE module from supplying power to an interface after the interface is shut down. After the interface comes up or you disable this task, the PoE module resumes power supply to the interface.

Restrictions and guidelines

The task does not power off an interface that has been shut down but is supplying power to a PD.

Procedure

1. Enter system view.
   system-view
2. Disable PoE on shutdown interfaces.
   poe track-shutdown
   By default, PoE is not disabled on shutdown interfaces.

Allowing inrush currents drawn by PDs

About this task

Inrush current might occur at PD startup and trigger PSE self-protection, As a result, the PSE stops supplying power to the PDs. To continue power supply to the PDs, configure this feature to allow inrush current drawn by PDs.

IEEE 802.3af and IEEE 802.3at define specifications for inrush current.

Restrictions and guidelines

CAUTION:
Inrush current might damage device components. Use this feature with caution.

Procedure

1. Enter system view.
   system-view
2. Enter PI view.
   interface *interface-type interface-number*
3. Allow inrush current drawn by PDs.
   poe high-inrush enable pse *pse-id*
   By default, inrush current drawn by PDs is not allowed.

Enabling PI power cycling upon a system warm reboot

About this task

During the system warm reboot process (upon execution of the **reboot** command), the PIs continue supplying power to the PDs but data connections between the PDs and the device are interrupted. After the system reboots, PDs might not re-initiate data connections with the device. Power cycling PIs upon a system warm reboot allows the PDs to re-establish data connections with the device after a warm reboot.

Procedure

1. Enter system view.
   system-view
2. Enter PI power cycling upon a system warm reboot.
   poe reset enable
   By default, PI power cycling upon a system warm reboot is disabled.

Configuring PD detection

Enabling nonstandard PD detection

About this task

PDs are classified into standard PDs and nonstandard PDs. Standard PDs are compliant with IEEE 802.3af and IEEE 802.3at. A PSE supplies power to a nonstandard PD only after nonstandard PD detection is enabled.

The device supports PSE-based and PI-based nonstandard PD detection. Enabling nonstandard PD detection for a PSE enables this feature for all PIs on the PSE. As a best practice for disabling nonstandard PD detection for all PIs successfully in one operation, disable this feature in both system view and interface view.

Procedure

1. Enter system view.
   system-view
2. Enable nonstandard PD detection. Choose one option as needed.
   - Enable nonstandard PD detection for the PSE.
     poe legacy enable pse *pse-id*
     By default, nonstandard PD detection is disabled for a PSE.
   - Execute the following commands in sequence to enable nonstandard PD detection for a PI:
     interface *interface-type interface-number*
     poe legacy enable
     By default, nonstandard PD detection is disabled for a PI.

Configuring a PD detection mode

About this task

The device detects PDs in one of the following modes:

- **None**—The device supplies power to PDs that are correctly connected to the device without causing short circuit.
- **Simple**—The device supplies power to PDs that comply with basic requirements of 802.3af or 802.3at.
- **Strict**—The device supplies power to PDs that comply with all requirements of 802.3af or 802.3at.
- **Loose**—The device supplies power to PDs that do not comply with basic requirements of 802.3af or 802.3at due to non-standard capacitance or high interference.

Restrictions and guidelines

CAUTION:

A non-PD device might be damaged when power is supplied to it. To avoid device damage, do not specify the **none** mode when the PI connects to a non-PD device.

For this feature to take effect on nonstandard PDs, you must enable detection for nonstandard PDs by using the **poe legacy enable** command.

Procedure

1. Enter system view.

   system-view
2. Enter PI view.

   interface *interface-type interface-number*
3. Configure the PD detection mode.

   poe detection-mode { **none** | **simple** | **strict** | **loose** }

   By default, the PD detection mode is strict.

NOTE:

Support for the **none** or **simple** detection mode depends on the device model. For some early models, the system prompts operation failure when you perform this task.

Configuring a PD disconnection detection mode

CAUTION:

If you change the PD disconnection detection mode when the device is running, the connected PDs are powered off. Be aware of the impact of this operation before you perform it.

About this task

A PSE detects PD disconnection in AC mode or DC mode. The AC mode uses less power than the DC mode.

Procedure

1. Enter system view.

   system-view
2. Configure a PD disconnection detection mode.

   poe disconnect { **ac** | **dc** }

   By default, the PD disconnection detection mode is dc.

NOTE:

Support for this feature depends on the device model. Some early models might not support this feature.

Configuring the PoE power

Configuring the maximum PI power

About this task

The maximum PI power is the maximum power that a PI can provide to the connected PD. If the PD requires more power than the maximum PI power, the PI does not supply power to the PD.

Procedure

1. Enter system view.

   system-view

2. Enter PI view.

   interface *interface-type interface-number*

3. Configure the maximum power for the PI.

   poe max-power *max-power*

   By default, the maximum power of a PI is the maximum power of the interface. The maximum interface power varies by device model. For more information, see the hardware information and specifications for the product.

Configuring the PoE priority policy

Configuring the PI priority policy

About this task

The PI priority policy enables the PSE to perform priority-based power allocation to PIs when PSE power overload occurs. The priority levels for PIs are critical, high, and low in descending order.

When PSE power overload occurs, the PSE supplies power to PDs as follows:

- If the PI priority policy is disabled, the PSE supplies power to PDs depending on whether you have configured the maximum PSE power.
  - If you have configured the maximum PSE power, the PSE does not supply power to the newly-added or existing PD that causes PSE power overload.
  - If you have not configured the maximum PSE power, the PSE works as follows:
    - If the PoE bank self-protection mechanism is triggered, power supply to newly connected PDs is prohibited. This mechanism reserves some power that is used when regular power is insufficient. If the reserved power is still insufficient, new PD connection is prohibited to avoid triggering the system power self-protection mechanism.
    - Triggering the system power self-protection mechanism causes the device to power cycle.
- If the PI priority policy is enabled, the PSE supplies power to PDs as follows:
  - If a PD being powered causes PSE power overload, the PSE stops supplying power to the PD.

- If a newly-added PD causes system power overload, the PSE supplies power to PDs in priority descending order of the PIs to which they are connected. If the newly-added PD and a PD being powered have the same priority, the PD being powered takes precedence. If multiple PIs being powered have the same priority, the PIs with smaller IDs takes precedence.

Restrictions and guidelines

Before you configure a PI with critical priority, make sure the remaining power from the maximum PSE power minus the maximum powers of the existing PIs with critical priority is greater than maximum power of the PI.

Configuration for a PI whose power is preempted remains unchanged.

Procedure

1. Enter system view.
   system-view
2. Enable the PI priority policy.
   poe pd-policy priority
   By default, the PI priority policy is disabled.
3. Enter PI view.
   interface *interface-type interface-number*
4. (Optional.) Configure a priority for the PI.
   poe priority { **critical** | **high** | **low** }
   By default, the priority for a PI is **low**.

Configuring PoE monitoring

Configuring PSE power monitoring

About this task

The system monitors PSE power utilization and sends notification messages when PSE power utilization exceeds or drops below the threshold. If PSE power utilization crosses the threshold multiple times in succession, the system sends notification messages only for the first crossing. For more information about the notification message, see "Configuring SNMP."

Procedure

1. Enter system view.
   system-view
2. Configure a power alarm threshold for a PSE.
   poe utilization-threshold *value* **pse** *pse-id*
   By default, the power alarm threshold for a PSE is 80%.

Configuring a PI by using a PoE profile

Restrictions and guidelines

To modify a PoE profile applied on a PI, first remove the PoE profile from the PI.

You can configure a PI either on the PI or by using a PoE profile. The **poe max-power** *max-power* and **poe priority** { **critical** | **high** | **low** } commands must be configured using the same method.

Configuring a PoE profile

1. Enter system view.
   system-view
2. Create a PoE profile and enter its view.
   poe-profile *profile-name* [*index*]
   By default, no PoE profiles exist.
3. Enable PoE.
   poe enable
   By default, PoE is disabled.
4. (Optional.) Configure the maximum PI power.
   poe max-power *max-power*
   By default, the maximum power of a PI is the maximum power of the interface. The maximum interface power varies by device model. For more information, see the hardware information and specifications for the product.
5. (Optional.) Configure a PI priority.
   poe priority { **critical** | **high** | **low** }
   The default priority is **low**.
   This command takes effect only after the PI priority policy is enabled.

Applying a PoE profile

Restrictions and guidelines

You can apply a PoE profile to multiple PIs in system view or a single PI in PI view. If you perform the operation in both views for the same PI, the most recent operation takes effect.

You can apply only one PoE profile to a PI.

Applying a PoE profile in system view

1. Enter system view.
   system-view
2. Apply a PoE profile to PIs.
   apply poe-profile { **index** *index* | **name** *profile-name* } **interface** *interface-range*
   By default, a PoE profile is not applied to a PI.

Applying a PoE profile in PI view

1. Enter system view.
   system-view
2. Enter PI view.
   interface *interface-type interface-number*
3. Apply the PoE profile to the interface.
   apply poe-profile { **index** *index* | **name** *profile-name* }
   By default, a PoE profile is not applied to a PI.

Upgrading PSE firmware in service

About this task

You can upgrade the PSE firmware in service in the following modes:

- **Refresh mode**—Updates the PSE firmware without deleting it. You can use the refresh mode in most cases.
- **Full mode**—Deletes the current PSE firmware and reloads a new one. Use the full mode if the PSE firmware is damaged and you cannot execute any PoE commands.

Restrictions and guidelines

If the PSE firmware upgrade fails because of interruption such as a device reboot, you can restart the device and upgrade it in full mode again. After the upgrade, restart the device manually for the new PSE firmware to take effect.

Procedure

1. Enter system view.

   system-view

2. Upgrade the PSE firmware in service.

   poe update { **full** | **refresh** } *filename* **pse** *pse-id*

Enabling forced PoE power supply

About this task

Before supplying power to a PD, the device performs a detection of the PD. It supplies power to the PD only after the PD passes the detection. If the PD fails the detection but the power provided by the device meets the PD specifications, you can configure this task to enable forced power supply to the PD.

When a PI is supplying power to PDs, the **poe force-power** command triggers the device to perform the following steps:

1. Immediately stop PoE power supply on the interface.
2. Wait for the interface to switch to forced power mode.
3. Automatically re-enable PoE power supply.

Restrictions and guidelines

This task enables the device to supply power to a PD directly without performing a detection of the PD. To avoid damaging the PD, make sure the power provided by the device meets the PD specifications before configuring this task.

If a PI is supplying PoE power, executing the **poe force-power** command forcibly re-enables PoE on that PI.

For a PoE model that supports combo interfaces, when all PIs are fully powered, power redistribution is triggered if you configure this feature on a combo interface and connect a PD to it. The system cuts power to all powered PIs, restores power to PIs enabled with forced PoE power supply, and then restores power to the remaining PIs in ascending of interface numbers.

Procedure

1. Enter system view.

   system-view

2. Enter PI view.

   interface *interface-type interface-number*

3. Enable forced PoE power supply.

   poe force-power

   By default, forced PoE power supply is disabled.

CAUTION:

This command enables the device to supply power to a PD directly without performing a detection of the PD. To avoid damaging the PD, make sure the power provided by the device meets the PD specifications before configuring this command.

Display and maintenance commands for PoE

Execute **display** commands in any view.

Task	Command
Display brief PSE information.	**display poe device** [**slot** *slot-number*]
Display the power supplying information for the specified PI.	**display poe interface** [*interface-type interface-number*]
Display power information for PIs.	**display poe interface power** [*interface-type interface-number*]
Display detailed PSE information.	**display poe pse** [*pse-id*]
Display the power supplying information for all PIs on a PSE.	**display poe pse** *pse-id* **interface**
Display power information for all PIs on a PSE.	**display poe pse** *pse-id* **interface power**
Display all information about the PoE profile.	**display poe-profile** [**index** *index* | **name** *profile-name*]
Display all information about the PoE profile applied to the specified PI.	**display poe-profile interface** *interface-type interface-number*

PoE configuration examples

Example: Configuring PoE

Network configuration

As shown in Figure 2, the device has PSE 4. Configure PoE to meet the following requirements:

- The device supplies power to IP phones and APs.
- The device preferentially guarantees power supply to IP phone B when PSE power overload occurs.
- Power supplied to AP 3 does not exceed 9000 milliwatts.

Figure 2 Network diagram

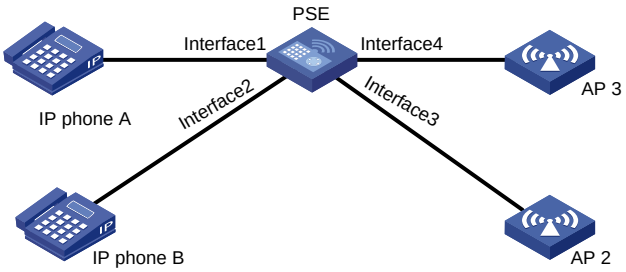


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4

Procedure

Enable the PI priority policy.

```
<PSE> system-view
[PSE] poe pd-policy priority
```

Enable PoE on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/3.

```
[PSE] interface gigabitethernet 1/0/1
[PSE-GigabitEthernet1/0/1] poe enable
[PSE-GigabitEthernet1/0/1] quit
[PSE] interface gigabitethernet 1/0/3
[PSE-GigabitEthernet1/0/3] poe enable
[PSE-GigabitEthernet1/0/3] quit
```

Enable PoE on GigabitEthernet 1/0/2, and set its power priority to **critical**.

```
[PSE] interface gigabitethernet 1/0/2
[PSE-GigabitEthernet1/0/2] poe enable
[PSE-GigabitEthernet1/0/2] poe priority critical
[PSE-GigabitEthernet1/0/2] quit
```

Enable PoE on GigabitEthernet 1/0/4, and set its maximum power to 9000 milliwatts.

```
[PSE] interface gigabitethernet 1/0/4
[PSE-GigabitEthernet1/0/4] poe enable
[PSE-GigabitEthernet1/0/4] poe max-power 9000
[PSE-GigabitEthernet1/0/4] quit
```

Verifying the configuration

Verify that the device is supplying power correctly to the IP phones and APs, and the IP phones and APs are operating correctly.

Troubleshooting PoE

Failure to set the priority of a PI to critical

Symptom

Power supply priority configuration for a PI failed.

Solution

To resolve the issue:

1. Identify whether the remaining guaranteed power of the PSE is lower than the maximum power of the PI. If it is, increase the maximum PSE power or reduce the maximum power of the PI.
2. Identify whether the priority has been configured through other methods. If the priority has been configured, remove the configuration.
3. If the issue persists, contact H3C Support.

Failure to apply a PoE profile to a PI

Symptom

PoE profile application for a PI failed.

Solution

To resolve the issue:

1. Identify whether some settings in the PoE profile have been configured. If they have been configured, remove the configuration.
2. Identify whether the settings in the PoE profile meet the requirements of the PI. If they do not, modify the settings in the PoE profile.
3. Identify whether another PoE profile is already applied to the PI. If it is, remove the application.
4. If the issue persists, contact H3C Support.

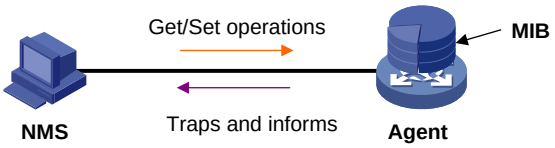
Configuring SNMP

About SNMP

Simple Network Management Protocol (SNMP) is used for a management station to access and operate the devices on a network, regardless of their vendors, physical characteristics, and interconnect technologies.



SNMP enables network administrators to read and set the variables on managed devices for state monitoring, troubleshooting, statistics collection, and other management purposes.

SNMP framework

The SNMP framework contains the following elements:

- **SNMP manager**—Works on an NMS to monitor and manage the SNMP-capable devices in the network. It can get and set values of MIB objects on an agent.
- **SNMP agent**—Works on a managed device to receive and handle requests from the NMS, and sends notifications to the NMS when events, such as an interface state change, occur.
- **Management Information Base (MIB)**—Specifies the variables (for example, interface status and CPU usage) maintained by the SNMP agent for the SNMP manager to read and set.

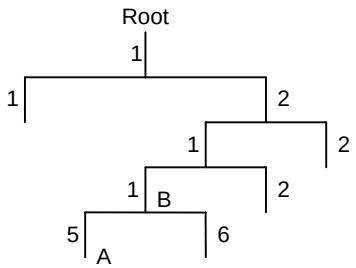


Figure 1 Relationship between NMS, agent, and MIB

MIB and view-based MIB access control

A MIB stores variables called "nodes" or "objects" in a tree hierarchy and identifies each node with a unique OID. An OID is a dotted numeric string that uniquely identifies the path from the root node to a leaf node. For example, object B in Figure 2 is uniquely identified by the OID {1.2.1.1}.

Figure 2 MIB tree

A MIB view represents a set of MIB objects (or MIB object hierarchies) with certain access privileges and is identified by a view name. The MIB objects included in the MIB view are accessible while those excluded from the MIB view are inaccessible.

A MIB view can have multiple view records each identified by a *view-name oid-tree* pair.

You control access to the MIB by assigning MIB views to SNMP groups or communities.

SNMP operations

SNMP provides the following basic operations:

- **Get**—NMS retrieves the value of an object node in an agent MIB.
- **Set**—NMS modifies the value of an object node in an agent MIB.
- **Notification**—SNMP notifications include traps and informs. The SNMP agent sends traps or informs to report events to the NMS. The difference between these two types of notification is that informs require acknowledgment but traps do not. Informs are more reliable but are also resource-consuming. Traps are available in SNMPv1, SNMPv2c, and SNMPv3. Informs are available only in SNMPv2c and SNMPv3.

Protocol versions

The device supports SNMPv1, SNMPv2c, and SNMPv3 in non-FIPS mode and supports only SNMPv3 in FIPS mode. An NMS and an SNMP agent must use the same SNMP version to communicate with each other.

- **SNMPv1**—Uses community names for authentication. To access an SNMP agent, an NMS must use the same community name as set on the SNMP agent. If the community name used by the NMS differs from the community name set on the agent, the NMS cannot establish an SNMP session to access the agent or receive traps from the agent.
- **SNMPv2c**—Uses community names for authentication. SNMPv2c is compatible with SNMPv1, but supports more operation types, data types, and error codes.
- **SNMPv3**—Uses a user-based security model (USM) to secure SNMP communication. You can configure authentication and privacy mechanisms to authenticate and encrypt SNMP packets for integrity, authenticity, and confidentiality.

Access control modes

SNMP uses the following modes to control access to MIB objects:

- **View-based Access Control Model**—VACM mode controls access to MIB objects by assigning MIB views to SNMP communities or users.
- **Role based access control**—RBAC mode controls access to MIB objects by assigning user roles to SNMP communities or users.
    - SNMP communities or users with predefined user role network-admin or level-15 have read and write access to all MIB objects.
    - SNMP communities or users with predefined user role network-operator have read-only access to all MIB objects.
    - SNMP communities or users with a user-defined user role have access rights to MIB objects as specified by the **`rule`** command.

RBAC mode controls access on a per MIB object basis, and VACM mode controls access on a MIB view basis. As a best practice to enhance MIB security, use the RBAC mode.

If you create the same SNMP community or user with both modes multiple times, the most recent configuration takes effect. For more information about RBAC, see *Fundamentals Command Reference*.

SNMP attack prevention

SNMP uses the following features to automatically detect and prevent SNMP attacks:

- **SNMP silence**—If an SNMP attack is detected, the device denies access from all NMSs during the 5-minute silence period.

- **SNMP IP address blacklist**—The device denies access from IP addresses in the blacklist during the locking period.
- **SNMP user blacklist**—The device denies access from SNMPv3 users in the blacklist during the locking period.

SNMP silence

SNMP silence enables the device to automatically detect and defend against SNMP attacks.

After you enable SNMP, the device automatically starts an SNMP silence timer and counts the number of packets that fail SNMP authentication within 1 minute.

- If the number of the packets is smaller than 100, the device restarts the timer and counting.
- If the number of the packets is equal to or greater than 100, the SNMP module enters a silence period of 4 to 5 minutes, during which the device does not respond to any SNMP packets. After the silence period expires, the SNMP module resumes normal operations and the device restarts the timer and counting.
- Whether SNMP silence must be enabled from the CLI depends on the device model.

SNMP IP blacklist

The SNMP IP blacklist feature uses the following mechanism to prevent SNMP attacks:

1. If an NMS fails to establish an SNMP connection to the device, the device adds the IP address of the NMS to the SNMP IP address blacklist, locks the IP address, and starts the observation period. The first locking period is 8 seconds and the observation period is 5 minutes. During the locking period, the IP address is not allowed to establish SNMP connections to the device.
2. After the first locking period expires, if the IP address fails to establish an SNMP connection to the device before the observation period expires, the IP address is locked for a second time and the observation period is restarted. The second locking period is 16 seconds and the observation period is 5 minutes.
3. After the second locking period expires, if the IP address fails to establish an SNMP connection to the device before the observation period expires, the IP address is locked for a third time and the observation period is restarted. The third locking period is 32 seconds and the observation period is 5 minutes.
4. After the third locking period expires, if the IP address fails to establish an SNMP connection to the device before the observation period expires, the IP address is locked for the fourth time and the observation period is restarted. The fourth locking period is 5 minutes and the observation period is 5 minutes.

If the IP address establishes an SNMP connection to the device during the observation period, the IP address will be unlocked automatically and deleted from the blacklist.

SNMP user denylist

If the number of consecutive authentication failures of an SNMPv3 user that attempts to access the device exceeds the maximum limit within the specified period of time, the system will add the user to the SNMPv3 user denylist. An SNMPv3 user in the denylist is not allowed to access the device. This feature allows you to prevent malicious attacks from unauthorized users effectively.

An SNMPv3 user added to the denylist will be removed automatically from the denylist after the locking time expires. If a user is added to the denylist mistakenly, you can manually remove it from the denylist.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

Restrictions and guidelines: SNMP configuration

For device security, follow these restrictions and guidelines when the device is operating in weak security mode:

- As a best practice, do use SNMPv1 or SNMPv2c, and do not set the community name to public or private when the device is running in weak security mode.
- As a best practice, configure an authentication algorithm and an encryption algorithm.

For device security, follow these restrictions and guidelines when the device is operating in strong security mode:

- Do not use SNMPv1 or SNMPv2c, and do not set the community name to public or private when the device is running in strong security mode.
- Configure the SHA256 authentication algorithm or an authentication algorithm with higher security, and configure the AES128 encryption algorithm or an encryption algorithm with higher security

To display security risks in the system and the corresponding recommended actions, execute the **`display system security-risk`** command. To specify the enhanced security mode for the device, execute the **`enhanced-security mode enable`** command. By default, the device runs in weak security mode. For more information about security modes, see system security configuration in *Security Configuration Guide*.

SNMP tasks at a glance

The device can act as an SNMP NMS and SNMP agent at the same time.

When the device acts as an SNMP agent, perform the following tasks:

1. Enabling the SNMP agent
2. Enabling SNMP versions
3. Configuring SNMP basic parameters
   - (Optional.) Configuring SNMP common parameters
   - Configuring an SNMPv1 or SNMPv2c community
   - Configuring an SNMPv3 group and user
4. (Optional.) Configuring SNMP attack prevention
   - Enabling SNMP silence
   - Enabling SNMP IP blacklist
   - Configuring the SNMPv3 user denylist
5. (Optional.) Enabling MIB statistics caching for interfaces
6. (Optional.) Configuring SNMP notifications
7. (Optional.) Examining the system configuration for changes
8. (Optional.) Configuring SNMP logging

Enabling the SNMP agent

Restrictions and guidelines

The SNMP agent is enabled when you use any command that begins with **`snmp-agent`** except for the **`snmp-agent calculate-password`** command.

The SNMP agent will fail to be enabled when the port that the agent will listen on is used by another service. You can use the **snmp-agent port** command to specify a listening port. To view the UDP port use information, execute the **display udp verbose** command. For more information about the **display udp verbose** command, see IP performance optimization commands in *Layer 3—IP Services Configuration Guide*.

If you disable the SNMP agent, the SNMP settings do not take effect. The **display current-configuration** command does not display the SNMP settings and the SNMP settings will not be saved in the configuration file. For the SNMP settings to take effect, enable the SNMP agent.

Procedure

1. Enter system view.
   system-view
2. Enable the SNMP agent.
   snmp-agent
   By default, the SNMP agent is disabled.

Enabling SNMP versions

About this task

Before you use the SNMP feature, execute the **display snmp-agent sys-info** command to view the current SNMP version. For the device to receive SNMP messages with a specific version, you must specify an SNMP version. To communicate with each other, an NMS and an SNMP agent must use the same SNMP version.

Restrictions and guidelines

The device supports SNMPv1, SNMPv2c, and SNMPv3 in non-FIPS mode and supports only SNMPv3 in FIPS mode.

The community name and data carried in SNMPv1 and SNMPv2c messages are in plaintext form, putting the SNMP communication at risks. As a best practice, use SNMPv3.

To use SNMP notifications in IPv6, enable SNMPv2c or SNMPv3.

Procedure

1. Enter system view.
   system-view
2. Enable SNMP versions.
   In non-FIPS mode:
   snmp-agent sys-info version { **all** | { **v1** | **v2c** | **v3** } * }
   In FIPS mode:
   snmp-agent sys-info version version v3
   By default, SNMPv3 is enabled.
   If you execute the command multiple times with different options, all the configurations take effect, but only one SNMP version is used by the agent and NMS for communication.

Configuring SNMP common parameters

Restrictions and guidelines

- SNMP engine ID

An SNMP engine ID uniquely identifies a device in an SNMP managed network. Make sure the local SNMP engine ID is unique within your SNMP managed network to avoid communication problems. By default, the device is assigned a unique SNMP engine ID.

If you have configured SNMPv3 users, change the local SNMP engine ID only when necessary. The change can void the SNMPv3 usernames and encrypted keys you have configured.

- SNMP listening port

  The SNMP agent will fail to be enabled when the port that the agent will listen on is used by another service. You can use the **snmp-agent port** command to change the SNMP listening port. As a best practice, execute the **display udp verbose** command to view the UDP port use information before specifying a new SNMP listening port. For more information about the **display udp verbose** command, see IP performance optimization commands in *Layer 3—IP Services Configuration Guide*.

- MIB view

  You can delete the default view by using the **undo snmp-agent mib-view** command. Be cautious with deleting the default MIB view. The operation blocks the access to any MIB object on the device from NMSs that use the default view. To restore the default view, restart the device.

  If you create a new MIB view, specify both permitted and excluded nodes by using the **snmp-agent mib-view** command. If the MIB view defines only excluded nodes, users bound to this view cannot access any device nodes.

  To bind MIB views, execute the **snmp-agent community** or **snmp-agent group** command.

Procedure

1. Enter system view.

   system-view

2. Specify an SNMP listening port.

   snmp-agent port *port-number*

   By default, the SNMP listening port is UDP port 161.

3. Set a local SNMP engine ID.

   snmp-agent local-engineid { *engineid* | **bridge-mac-based** }

   By default, the local SNMP engine ID is the company ID plus the device ID.

4. Set an engine ID for a remote SNMP entity.

   snmp-agent remote { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] **engineid** *engineid*

   By default, no remote entity engine IDs exist.

   This step is required for the device to send SNMPv3 notifications to a host, typically NMS.

5. Create or update a MIB view.

   snmp-agent mib-view { **excluded** | **included** } *view-name oid-tree* [**mask** *mask-value*]

   By default, the MIB view **ViewDefault** is predefined. In this view, all the MIB objects in the **iso** subtree but the **snmpUsmMIB**, **snmpVacmMIB**, and **snmpModules.18** subtrees are accessible.

   Each *view-name oid-tree* pair represents a view record. If you specify the same record with different MIB sub-tree masks multiple times, the most recent configuration takes effect.

6. Configure an SNMP global ACL.

   snmp-agent acl [**ipv6**] { *acl-number* | **name** *acl-name* }

   By default, no SNMP global ACL is configured.

7. Configure the system management information.

- Configure the system contact.

  snmp-agent sys-info contact *sys-contact*

  By default, the system contact is **New H3C Technologies Co., Ltd.**.
- Configure the system location.

  snmp-agent sys-info location *sys-location*

  By default, the system location is **Hangzhou, China**.

8. Create an SNMP context.

   snmp-agent context *context-name*

   By default, no SNMP contexts exist.
9. Configure the maximum SNMP packet size (in bytes) that the SNMP agent can handle.

   snmp-agent packet max-size *byte-count*

   By default, an SNMP agent can process SNMP packets with a maximum size of 1500 bytes.
10. Set the DSCP value for SNMP responses.

    snmp-agent packet response dscp *dscp-value*

    By default, the DSCP value for SNMP responses is 0.

Configuring an SNMPv1 or SNMPv2c community

About configuring an SNMPv1 or SNMPv2c community

You can create an SNMPv1 or SNMPv2c community by using a community name or by creating an SNMPv1 or SNMPv2c user. After you create an SNMPv1 or SNMPv2c user, the system automatically creates a community by using the username as the community name.

Restrictions and guidelines for configuring an SNMPv1 or SNMPv2c community

SNMPv1 and SNMPv2c settings are not supported in FIPS mode.

Make sure the NMS and agent use the same SNMP community name.

Only users with the network-admin or level-15 user role can create SNMPv1 or SNMPv2c communities, users, or groups. Users with other user roles cannot create SNMPv1 or SNMPv2c communities, users, or groups even if these roles are granted access to related commands or commands of the SNMPv1 or SNMPv2c feature.

Configuring an SNMPv1/v2c community by a community name

1. Enter system view.

   system-view
2. Create an SNMPv1/v2c community. Choose one option as needed.
   - In VACM mode:

     snmp-agent community { **read** | **write** } [**simple** | **cipher**] *community-name* [**mib-view** *view-name*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

- In RBAC mode:

  snmp-agent community [**simple** | **cipher**] *community-name* **user-role** *role-name* [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

3. (Optional.) Map the SNMP community name to an SNMP context.

   snmp-agent community-map *community-name* **context** *context-name*

Configuring an SNMPv1/v2c community by creating an SNMPv1/v2c user

1. Enter system view.

   system-view

2. Create an SNMPv1/v2c group.

   snmp-agent group { **v1** | **v2c** } *group-name* [**notify-view** *view-name* | **read-view** *view-name* | **write-view** *view-name*] * [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

3. Add an SNMPv1/v2c user to the group.

   snmp-agent usm-user { **v1** | **v2c** } *user-name group-name* [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   The system automatically creates an SNMP community by using the username as the community name.

4. (Optional.) Map the SNMP community name to an SNMP context.

   snmp-agent community-map *community-name* **context** *context-name*

Configuring an SNMPv3 group and user

Restrictions and guidelines for configuring an SNMPv3 group and user

Restrictions and guidelines for privilege configuration

Only users with the network-admin or level-15 user role can create SNMPv3 users or groups. Users with other user roles cannot create SNMPv3 users or groups even if these roles are granted access to related commands or commands of the SNMPv3 feature.

Restrictions and guidelines for security level configuration

All users in an SNMP group share the security level and access rights of the group.

SNMPv3 supports the following security levels, from highest to lowest:

- **Privacy**—Authentication and encryption.
- **Authentication**—Authentication but no encryption.
- **None**—No authentication or encryption.

When you create an SNMP user group or SNMPv3 user on the device, you can specify a security level. You can also specify a security level on the NMS. The following requirements must be met when you specify a security level:

- For an SNMP connection to be established successfully, make sure the security level you specify is the same or in descending order of security for the SNMP user, on the NMS, and for

the SNMP user group. If the security level is different, the security level specified on the NMS applies.

- If the security level specified on the NMS requires authentication, the security level of the SNMPv3 user must also require authentication, and the authentication password and algorithm configured on the device must match those specified on the NMS.
- If the security level specified on the NMS requires encryption, the security level of the SNMPv3 user must also require encryption, and the encryption password and algorithm configured on the device must match those specified on the NMS.

Configuring an SNMPv3 group and user in non-FIPS mode

1. Enter system view.

   system-view

2. Create an SNMPv3 group.

   snmp-agent group v3 *group-name* [**authentication** | **privacy**] [**notify-view** *view-name* | **read-view** *view-name* | **write-view** *view-name*] *[**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

3. (Optional.) Calculate the encrypted form for the key in plaintext form.

   snmp-agent calculate-password *plain-password* **mode** { **3desmd5** | **3dessha** | **3dessha224** | **3dessha256** | **3dessha384** | **3dessha512** | **aes192md5** | **aes192sha** | **aes192sha224** | **aes192sha256** | **aes192sha384** | **aes192sha512** | **aes256md5** | **aes256sha** | **aes256sha224** | **aes256sha256** | **aes256sha384** | **aes256sha512** | **md5** | **sha** | **sha224** | **sha256** | **sha384** | **sha512** } { **local-engineid** | **specified-engineid** *engineid* }

4. Create an SNMPv3 user. Choose one option as needed.

   - In VACM mode:

     snmp-agent usm-user v3 *user-name group-name* [**remote** { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] [{ **cipher** | **simple** } **authentication-mode** { **md5** | **sha** | **sha224** | **sha256** | **sha384** | **sha512** } *auth-password* [**privacy-mode** { **3des** | **aes128** | **aes192** | **aes256** | **des56** } *priv-password*]] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   - In RBAC mode:

     snmp-agent usm-user v3 *user-name* **user-role** *role-name* [**remote** { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] [{ **cipher** | **simple** } **authentication-mode** { **md5** | **sha** | **sha224** | **sha256** | **sha384** | **sha512** } *auth-password* [**privacy-mode** { **3des** | **aes128** | **aes192** | **aes256** | **des56** } *priv-password*]] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   To send notifications to an SNMPv3 NMS, you must specify the **remote** keyword.

5. (Optional.) Assign a user role to the SNMPv3 user created in RBAC mode.

   snmp-agent usm-user v3 *user-name* **user-role** *role-name*

   By default, an SNMPv3 user has the user role assigned to it at its creation.

Configuring an SNMPv3 group and user in FIPS mode

1. Enter system view.

system-view

2. Create an SNMPv3 group.

   snmp-agent group v3 *group-name* { **authentication** | **privacy** } [**notify-view** *view-name* | **read-view** *view-name* | **write-view** *view-name*] * [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

3. (Optional.) Calculate the encrypted form for the key in plaintext form.

   snmp-agent calculate-password *plain-password* **mode** { **aes192sha** | **aes192sha224** | **aes192sha256** | **aes192sha384** | **aes192sha512** | **aes256sha** | **aes256sha224** | **aes256sha256** | **aes256sha384** | **aes256sha512** | **sha** | **sha224** | **sha256** | **sha384** | **sha512** } { **local-engineid** | **specified-engineid** *engineid* }

4. Create an SNMPv3 user. Choose one option as needed.

   - In VACM mode:

     snmp-agent usm-user v3 *user-name group-name* [**remote** { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] { **cipher** | **simple** } **authentication-mode** { **sha** | **sha224** | **sha256** | **sha384** | **sha512** } *auth-password* [**privacy-mode** { **aes128** | **aes192** | **aes256** } *priv-password*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   - In RBAC mode:

     snmp-agent usm-user v3 *user-name* **user-role** *role-name* [**remote** { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] { **cipher** | **simple** } **authentication-mode** { **sha** | **sha224** | **sha256** | **sha384** | **sha512** } *auth-password* [**privacy-mode** { **aes128** | **aes192** | **aes256** } *priv-password*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   To send notifications to an SNMPv3 NMS, you must specify the **remote** keyword.

5. (Optional.) Assign a user role to the SNMPv3 user created in RBAC mode.
6. **snmp-agent usm-user v3** *user-name* **user-role** *role-name*

   By default, an SNMPv3 user has the user role assigned to it at its creation.

Configuring SNMP attack prevention

Both SNMP silence and SNMP blacklist can be used to prevent SNMP attacks. You can configure the two features simultaneously. However, during the SNMP silence period, the SNMP blacklist feature does not take effect.

Enabling SNMP silence

1. Enter system view.

   system-view

2. Enable SNMP silence.

   snmp-agent silence enable

   By default, SNMP silence is disabled.

Enabling SNMP IP blacklist

1. Enter system view.
   system-view
2. Enable SNMP IP blacklist.
   snmp-agent blacklist ip-block enable
   By default, SNMP IP blacklist is disabled.

Configuring the SNMPv3 user denylist

Adding an SNMPv3 user to the denylist

1. Enter system view.
   system-view
2. Enable SNMPv3 user denylist.
   snmp-agent denylist user enable
   By default, SNMPv3 user denylist is disabled.
3. Specify the maximum number of consecutive authentication failures within the specified period of time for adding an SNMPv3 user to the denylist.
   snmp-agent denylist user authfailure *times* **period** *period-time*
   By default, an SNMPv3 user is added to the denylist if the user has five consecutive authentication failure within 5 minutes.
4. Specify the period of time that an SNMPv3 user is kept in the denylist.
   snmp-agent denylist user timeout *time*
   By default, an SNMPv3 user is kept in the denylist for 5 minutes.

Immediately removing an SNMPv3 user from the denylist

To remove an SNMPv3 from the denylist, execute the following command in user view:

snmp-agent denylist user activate *user-name*

Enabling MIB statistics caching for interfaces

About this task

Enabling MIB statistics caching for interfaces can improve the data acquisition efficiency of network devices in a high query frequency environment and reduce their processing load. This feature enables the device to directly retrieve previously retrieved data from the cache within the cache duration, avoiding redundant calculations and enhancing performance.

With this feature enabled, the device can directly retrieve interface statistics from the cache without recalculation when the statistics are retrieved from the iftable and ifxtable through SNMP again before the end of the cache duration. This practice reduces the processing load on the device and enhances the overall data retrieval response speed.

Restrictions and guidelines

Do not set a too long cache duration. In environments with low network traffic or low query frequency, you can disable MIB statistics caching for interfaces to prevent outdated data from affecting the accuracy of network management.

Prerequisites

Before you configure this command, make sure SNMP is enabled on the device. Additionally, you must assess network traffic and query frequency to set an appropriate cache duration to ensure data accuracy.

Procedure

1. Enter system view.

   system-view

2. Enable MIB statistics caching for interfaces and set the cache duration.

   snmp-agent cache if-mib [**cache-duration** *cache-duration*]

   By default, MIB statistics caching for interfaces is enabled and the cache duration is 5 seconds.

   As a best practice to optimize read performance without sacrificing too much data timeliness, set a short cache duration, for example, 30 seconds in network environments with a high query frequency.

Configuring SNMP notifications

About SNMP notifications

The SNMP agent sends notifications (traps and informs) to inform the NMS of significant events, such as link state changes and user logins or logouts. After you enable notifications for a module, the module sends the generated notifications to the SNMP agent. The SNMP agent sends the received notifications as traps or informs based on the current configuration. Unless otherwise stated, the **trap** keyword in the command line includes both traps and informs.

Enabling SNMP notifications

Restrictions and guidelines

Enable an SNMP notification only if necessary. SNMP notifications are memory-intensive and might affect device performance.

To generate linkUp or linkDown notifications when the link state of an interface changes, you must perform the following tasks:

- Enable linkUp or linkDown notification globally by using the **snmp-agent trap enable standard** [**linkdown** | **linkup**] * command.
- Enable linkUp or linkDown notification on the interface by using the **enable snmp trap updown** command.

After you enable notifications for a module, whether the module generates notifications also depends on the configuration of the module. For more information, see the configuration guide for each module.

To use SNMP notifications in IPv6, enable SNMPv2c or SNMPv3.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications.

   snmp-agent trap enable [**configuration** | *protocol* | **sgcc** [**ucmacchangetrap** | **useropertrap** | **usertrap**] | **standard** [**authentication** | **coldstart** | **linkdown** | **linkup** | **warmstart**] * | **system**]

By default, configuration change notifications, SNMP standard notifications, SGCC private MIB notifications, and system notifications are enabled. For the SNMP notifications enabling status for other modules, see the module guide.

For the device to send SNMP notifications for a protocol, first enable the protocol.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable link state notifications.

   enable snmp trap updown

   By default, link state notifications are enabled.

Configuring parameters for sending SNMP notifications

About this task

You can configure the SNMP agent to send notifications as traps or informs to a host, typically an NMS, for analysis and management. Traps are less reliable and use fewer resources than informs, because an NMS does not send an acknowledgment when it receives a trap.

When network congestion occurs or the destination is not reachable, the SNMP agent buffers notifications in a queue. You can set the queue size and the notification lifetime (the maximum time that a notification can stay in the queue). When the queue size is reached, the system discards the new notification it receives. If modification of the queue size causes the number of notifications in the queue to exceed the queue size, the oldest notifications are dropped for new notifications. A notification is deleted when its lifetime expires.

You can extend standard linkUp/linkDown notifications to include interface description and interface type, but must make sure the NMS supports the extended SNMP messages.

Configuring the parameters for sending SNMP traps

1. Enter system view.

   system-view

2. Configure a target host.

   In non-FIPS mode:

   snmp-agent target-host trap address udp-domain { *ipv4-target-host* | **ipv6** *ipv6-target-host* } [**udp-port** *port-number*] [**dscp** *dscp-value*] [**vpn-instance** *vpn-instance-name*] **params** { **cipher-securityname** *cipher-security-string* [**v1** | **v2c**] | **securityname** *security-string* [**v1** | **v2c** | **v3** [**authentication** | **privacy**]] }

   In FIPS mode:

   snmp-agent target-host trap address udp-domain { *ipv4-target-host* | **ipv6** *ipv6-target-host* } [**udp-port** *port-number*] [**dscp** *dscp-value*] [**vpn-instance** *vpn-instance-name*] **params securityname** *security-string* **v3** { **authentication** | **privacy** }

   By default, no target host is configured.

   For the configuration to take effect, do not specify both the **v1** and **ipv6** keywords in the command, because SNNMPv1 does not support IPv6.

3. (Optional.) Configure a source address for sending traps.

   snmp-agent trap source *interface-type* { *interface-number* | *interface-number.subnumber* }

   By default, SNMP uses the IP address of the outgoing routed interface as the source IP address.

Configuring the parameters for sending SNMP informs

1. Enter system view.

   system-view

2. Configure a target host.

   In non-FIPS mode:

   snmp-agent target-host inform address udp-domain { *ipv4-target-host* | **ipv6** *ipv6-target-host* } [**udp-port** *port-number*] [**vpn-instance** *vpn-instance-name*] **params** { **cipher-securityname** *cipher-security-string* **v2c** | **securityname** *security-string* { **v2c** | **v3** [**authentication** | **privacy**] } }

   In FIPS mode:

   snmp-agent target-host inform address udp-domain { *ipv4-target-host* | **ipv6** *ipv6-target-host* } [**udp-port** *port-number*] [**vpn-instance** *vpn-instance-name*] **params securityname** *security-string* **v3** { **authentication** | **privacy** }

   By default, no target host is configured.

   Only SNMPv2c and SNMPv3 support inform packets.

3. (Optional.) Configure a source address for sending informs.

   snmp-agent inform source *interface-type* { *interface-number* | *interface-number.subnumber* }

   By default, SNMP uses the IP address of the outgoing routed interface as the source IP address.

Configuring common parameters for sending notifications

1. Enter system view.

   system-view

2. (Optional.) Enable extended linkUp/linkDown notifications.

   snmp-agent trap if-mib link extended

   By default, the SNMP agent sends standard linkUp/linkDown notifications.

   If the NMS does not support extended linkUp/linkDown notifications, do not use this command.

3. Enable the device to generate authentication failure alarm messages in extended format.

   snmp-agent trap snmpv2-mib authenticationfailure extended

   By default, the device sends authentication failure alarm messages in standard format, instead of extended format.

   This command takes effect only when authentication failure alarm is enabled in SNMP standard alarms. By default, authentication failure alarm is enabled in SNMP standard alarms.

4. (Optional.) Set the notification queue size.

   snmp-agent trap queue-size *size*

   By default, the notification queue can hold 100 notification messages.

5. (Optional.) Set the notification lifetime.

   snmp-agent trap life *seconds*

   The default notification lifetime is 120 seconds.

6. (Optional.) Specify the notification format as **CMCC**.

   snmp-agent trap format cmcc

   By default, the SNMP notifications are in general format.

7. (Optional.) Configure the device to carry its serial number in the notifications sent an NMS.

   snmp-agent trap withsn

By default, the device does not carry its serial number in the notifications sent an NMS.

8. Enable SNMP notification buffering and set the buffering interval.

   snmp-agent trapbuffer enable [**interval** *interval*]

   By default, SNMP notification buffering is enabled, and the buffering interval is 1 minute.

Examining the system configuration for changes

About this task

The SNMP module examines the system running configuration, startup configuration, and next-startup configuration file for changes periodically and generates a log if any change is found. If SNMP notifications for configuration changes has been enabled, the system generates also an SNMP notification.

Procedure

1. Enter system view.

   system-view

2. Set the interval at which the SNMP module examines the system configuration for changes.

   snmp-agent configuration-examine interval *interval*

   By default, the SNMP module examines the system configuration for changes at intervals of 600 seconds.

3. Enable SNMP notifications for system configuration changes.

   snmp-agent trap enable configuration

   By default, SNMP notifications is enabled for system configuration changes.

Configuring SNMP logging

About this task

The SNMP agent logs Get requests, Set requests, Set responses, SNMP notifications, and SNMP authentication failures, but does not log Get responses.

- **Get operation**—The agent logs the IP address of the NMS, name of the accessed node, and node OID.
- **Set operation**—The agent logs the NMS' IP address, name of accessed node, node OID, variable value, and error code and index for the Set operation.
- **Notification tracking**—The agent logs the SNMP notifications after sending them to the NMS.
- **SNMP authentication failure**—The agent logs related information when an NMS fails to be authenticated by the agent.

The SNMP module sends these logs to the information center. You can configure the information center to output these messages to certain destinations, such as the console and the log buffer. The total output size for the node field (MIB node name) and the value field (value of the MIB node) in each log entry is 1024 bytes. If this limit is exceeded, the information center truncates the data in the fields. For more information about the information center, see "Configuring the information center."

Restrictions and guidelines

Enable SNMP logging only if necessary. SNMP logging is memory-intensive and might impact device performance.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP logging.

   snmp-agent log { **all** | **authfail** | **get-operation** | **set-operation** }

   By default, SNMP logging is enabled for set operations and disabled for SNMP authentication failures and get operations.

3. Enable SNMP notification logging.

   snmp-agent trap log

   By default, SNMP notification logging is disabled.

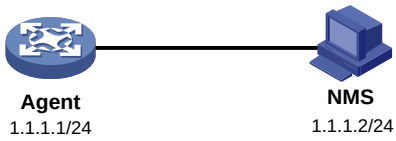
Display and maintenance commands for SNMP

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display SNMPv1 or SNMPv2c community information. (This command is not supported in FIPS mode.)	**display snmp-agent community** [**read** | **write**]
Display SNMP contexts.	**display snmp-agent context** [*context-name*]
Display SNMP group information.	**display snmp-agent group** [*group-name*]
Display the local engine ID.	**display snmp-agent local-engineid**
Display SNMP MIB node information.	**display snmp-agent mib-node** [**details** | **index-node** | **trap-node** | **verbose**]
Display MIB view information.	**display snmp-agent mib-view** [**exclude** | **include** | **viewname** *view-name*]
Display remote engine IDs.	**display snmp-agent remote** [{ *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]]
Display SNMP agent statistics.	**display snmp-agent statistics**
Display SNMP agent system information.	**display snmp-agent sys-info** [**contact** | **location** | **version**] *
Display basic information about the notification queue.	**display snmp-agent trap queue**
Display SNMP notifications drop records.	**display snmp-agent trapbuffer drop**
Display SNMP notifications sending records.	**display snmp-agent trapbuffer send**
Display the SNMP notifications enabling status for modules.	**display snmp-agent trap-list**
Display SNMPv3 user information.	**display snmp-agent usm-user** [**engineid** *engineid* | **username** *user-name* | **group** *group-name*] *
Clear all records from the SNMP trap buffer.	**reset snmp-agent trapbuffer**

SNMP configuration examples

Example: Configuring SNMPv1/SNMPv2c



The device does not support this configuration example in FIPS mode.

The configuration procedure is the same for SNMPv1 and SNMPv2c. This example uses SNMPv1.

Network configuration

As shown in Figure 3, the NMS (1.1.1.2/24) uses SNMPv1 to manage the SNMP agent (1.1.1.1/24), and the agent automatically sends notifications to report events to the NMS.

Figure 3 Network diagram

Procedure

1. Configure the SNMP agent:

   # Assign IP address **1.1.1.1/24** to the agent and make sure the agent and the NMS can reach each other. (Details not shown.)

   # Specify SNMPv1, and create read-only community **public** and read and write community **private**.

   ```
   <Agent> system-view
   [Agent] snmp-agent sys-info version v1
   [Agent] snmp-agent community read public
   [Agent] snmp-agent community write private
   ```

   # Configure contact and physical location information for the agent.

   ```
   [Agent] snmp-agent sys-info contact Mr.Wang-Tel:3306
   [Agent] snmp-agent sys-info location telephone-closet,3rd-floor
   ```

   # Enable SNMP notifications, specify the NMS at 1.1.1.2 as an SNMP trap destination, and use **public** as the community name. (To make sure the NMS can receive traps, specify the same SNMP version in the **`snmp-agent target-host`** command as is configured on the NMS.)

   ```
   [Agent] snmp-agent trap enable
   [Agent] snmp-agent target-host trap address udp-domain 1.1.1.2 params securityname
   public v1
   ```

2. Configure the SNMP NMS:
   - Specify SNMPv1.
   - Create read-only community **public**, and create read and write community **private**.
   - Set the timeout timer and maximum number of retries as needed.

   For information about configuring the NMS, see the NMS manual.

   NOTE:

   The SNMP settings on the agent and the NMS must match.

Verifying the configuration

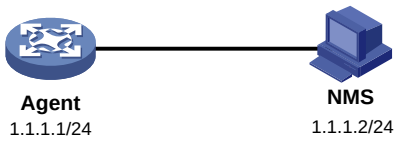
Try to get the MTU value of the NULL0 interface from the agent. The attempt succeeds.

```
Send request to 1.1.1.1/161 ...
```

```
Protocol version: SNMPv1
Operation: Get
Request binding:
1: 1.3.6.1.2.1.2.2.1.4.135471
Response binding:
1: Oid=ifMtu.135471 Syntax=INT Value=1500
Get finished
```

Use a wrong community name to get the value of a MIB node on the agent. You can see an authentication failure trap on the NMS.

```
1.1.1.1/2934 V1 Trap = authenticationFailure
SNMP Version = V1
Community = public
Command = Trap
Enterprise = 1.3.6.1.4.1.43.1.16.4.3.50
GenericID = 4
SpecificID = 0
Time Stamp = 8:35:25.68
```



Example: Configuring SNMPv3

Network configuration

As shown in Figure 4, the NMS (1.1.1.2/24) uses SNMPv3 to monitor and manage the agent (1.1.1.1/24). The agent automatically sends notifications to report events to the NMS. The default UDP port 162 is used for SNMP notifications.

The NMS and the agent perform authentication when they establish an SNMP session. The authentication algorithm is **SHA-1** and the authentication key is **123456TESTauth&!**. The NMS and the agent also encrypt the SNMP packets between them by using the **AES** algorithm and encryption key **123456TESTencr&!**.

Figure 4 Network diagram

Configuring SNMPv3 in RBAC mode

1. Configure the agent:

   # Assign IP address **1.1.1.1/24** to the agent and make sure the agent and the NMS can reach each other. (Details not shown.)

   #Create user role **test**, and assign **test** read-only access to the objects under the **snmpMIB** node (OID:1.3.6.1.6.3.1), including the **linkUp** and **linkDown** objects.

   ```
   <Agent> system-view
   [Agent] role name test
   [Agent-role-test] rule 1 permit read oid 1.3.6.1.6.3.1
   ```

   # Assign user role **test** read-only access to the **system** node (OID:1.3.6.1.2.1.1) and read-write access to the **interfaces** node(OID:1.3.6.1.2.1.2).

   ```
   [Agent-role-test] rule 2 permit read oid 1.3.6.1.2.1.1
   [Agent-role-test] rule 3 permit read write oid 1.3.6.1.2.1.2
   [Agent-role-test] quit
   ```

Create SNMPv3 user **RBACtest**. Assign user role **test** to **RBACtest.** Set the authentication algorithm to **SHA-1**, authentication key to **123456TESTauth&!**, encryption algorithm to **AES**, and encryption key to **123456TESTencr&!**.

```
[Agent] snmp-agent usm-user v3 RBACtest user-role test simple authentication-mode sha
123456TESTauth&! privacy-mode aes128 123456TESTencr&!
```

#Configure contact and physical location information for the agent.

```
[Agent] snmp-agent sys-info contact Mr.Wang-Tel:3306
[Agent] snmp-agent sys-info location telephone-closet,3rd-floor
```

#Enable notifications on the agent. Specify the NMS at 1.1.1.2 as the notification destination, and **RBACtest** as the username.

```
[Agent] snmp-agent trap enable
[Agent] snmp-agent target-host trap address udp-domain 1.1.1.2 params
securitynameRBACtest v3 privacy
```

2. Configure the NMS:

- Specify SNMPv3.
- Create SNMPv3 user **RBACtest**.
- Enable authentication and encryption. Set the authentication algorithm to **SHA-1**, authentication key to **123456TESTauth&!**, encryption algorithm to **AES**, and encryption key to **123456TESTencr&!**.
- Set the timeout timer and maximum number of retries.

For information about configuring the NMS, see the NMS manual.

NOTE:

The SNMP settings on the agent and the NMS must match.

Configuring SNMPv3 in VACM mode

1. Configure the agent:

Assign IP address 1.1.1.1/24 to the agent, and make sure the agent and the NMS can reach each other. (Details not shown.)

Create SNMPv3 group **managev3group** and assign **managev3group** read-only access to the objects under the **snmpMIB** node (OID: 1.3.6.1.2.1.2.2) in the **test** view, including the **linkUp** and **linkDown** objects.

```
<Agent> system-view
[Agent] undo snmp-agent mib-view ViewDefault
[Agent] snmp-agent mib-view included test snmpMIB
[Agent] snmp-agent group v3 managev3group privacy read-view test
```

#Assign SNMPv3 group **managev3group** read-write access to the objects under the **system** node (OID: 1.3.6.1.2.1.1) and **interfaces** node (OID:1.3.6.1.2.1.2) in the **test** view.

```
[Agent] snmp-agent mib-view included test 1.3.6.1.2.1.1
[Agent] snmp-agent mib-view included test 1.3.6.1.2.1.2
[Agent] snmp-agent group v3 managev3group privacy read-view test write-view test
```

Add user **VACMtest** to SNMPv3 group **managev3group**, and set the authentication algorithm to **SHA-1**, authentication key to **123456TESTauth&!**, encryption algorithm to **AES**, and encryption key to **123456TESTencr&!**.

```
[Agent] snmp-agent usm-user v3 VACMtest managev3group simple authentication-mode sha
123456TESTauth&! privacy-mode aes128 123456TESTencr&!
```

Configure contact and physical location information for the agent.

```
[Agent] snmp-agent sys-info contact Mr.Wang-Tel:3306
[Agent] snmp-agent sys-info location telephone-closet,3rd-floor
```

Enable notifications on the agent. Specify the NMS at 1.1.1.2 as the trap destination, and **VACMtest** as the username.

```
[Agent] snmp-agent trap enable
[Agent] snmp-agent target-host trap address udp-domain 1.1.1.2 params VACMtest v3 privacy
```

2. Configure the SNMP NMS:
   - Specify SNMPv3.
   - Create SNMPv3 user VACMtest.
   - Enable authentication and encryption. Set the authentication algorithm to **SHA-1**, authentication key to **123456TESTauth&!**, encryption algorithm to **AES**, and encryption key to **123456TESTencr&!**.
   - Set the timeout timer and maximum number of retries.

   For information about configuring the NMS, see the NMS manual.

NOTE:

The SNMP settings on the agent and the NMS must match.

Verifying the configuration

- Use username **RBACtest** to access the agent.

  # Retrieve the value of the **sysName** node. The value **Agent** is returned.

  # Set the value for the **sysName** node to **Sysname**. The operation fails because the NMS does not have write access to the node.

  # Shut down or bring up an interface on the agent. The NMS receives linkUP (OID: 1.3.6.1.6.3.1.1.5.4) or linkDown (OID: 1.3.6.1.6.3.1.1.5.3) notifications.

- Use username **VACMtest** to access the agent.

  # Retrieve the value of the **sysName** node. The value **Agent** is returned.

  # Set the value for the **sysName** node to **Sysname**. The operation succeeds.

  # Shut down or bring up an interface on the agent. The NMS receives **linkUP** (OID: 1.3.6.1.6.3.1.1.5.4) or **linkDown** (OID: 1.3.6.1.6.3.1.1.5.3) notifications.

Configuring RMON

About RMON

Remote Network Monitoring (RMON) is an SNMP-based network management protocol. It enables proactive remote monitoring and management of network devices.

RMON working mechanism

RMON can periodically or continuously collect traffic statistics for an Ethernet port and monitor the values of MIB objects on a device. When a value reaches the threshold, the device automatically logs the event or sends a notification to the NMS. The NMS does not need to constantly poll MIB variables and compare the results.

RMON uses SNMP notifications to notify NMSs of various alarm conditions. SNMP reports function and interface operating status changes such as link up, link down, and module failure to the NMS.

RMON groups

Among standard RMON groups, the device implements the statistics group, history group, event group, alarm group, probe configuration group, and user history group. The Comware system also implements a private alarm group, which enhances the standard alarm group. The probe configuration group and user history group are not configurable from the CLI. To configure these two groups, you must access the MIB.

Statistics group

The statistics group samples traffic statistics for monitored Ethernet interfaces and stores the statistics in the Ethernet statistics table (ethernetStatsTable). The statistics include:

- Number of collisions.
- CRC alignment errors.
- Number of undersize or oversize packets.
- Number of broadcasts.
- Number of multicasts.
- Number of bytes received.
- Number of packets received.

The statistics in the Ethernet statistics table are cumulative sums.

History group

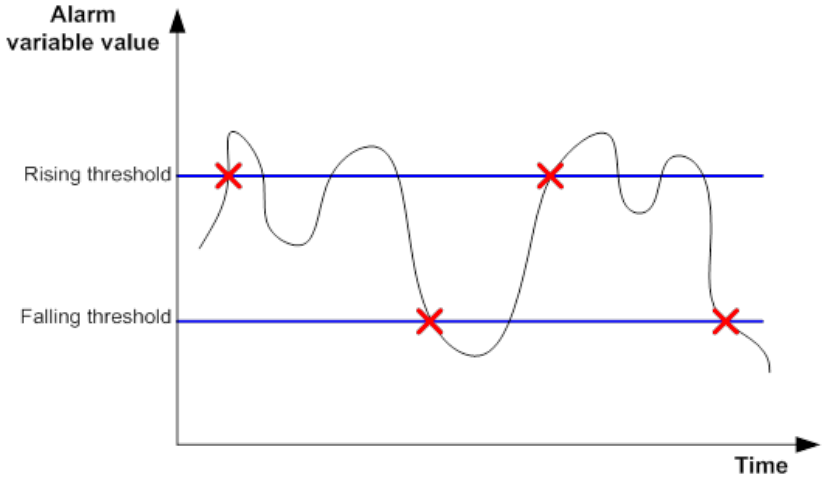
The history group periodically samples traffic statistics on interfaces and saves the history samples in the history table (etherHistoryTable). The statistics include:

- Bandwidth utilization.
- Number of error packets.
- Total number of packets.

The history table stores traffic statistics collected for each sampling interval.

Event group

The event group controls the generation and notifications of events triggered by the alarms defined in the alarm group and the private alarm group. The following are RMON alarm event handling methods:



- **Log**—Logs event information (including event time and description) in the event log table so the management device can get the logs through SNMP.
- **Trap**—Sends an SNMP notification when the event occurs.
- **Log-Trap**—Logs event information in the event log table and sends an SNMP notification when the event occurs.
- **None**—Takes no actions.

Alarm group

The RMON alarm group monitors alarm variables, such as the count of incoming packets (etherStatsPkts) on an interface. After you create an alarm entry, the RMON agent samples the value of the monitored alarm variable regularly. If the value of the monitored variable is greater than or equal to the rising threshold, a rising alarm event is triggered. If the value of the monitored variable is smaller than or equal to the falling threshold, a falling alarm event is triggered. The event group defines the action to take on the alarm event.

If an alarm entry crosses a threshold multiple times in succession, the RMON agent generates an alarm event only for the first crossing. For example, if the value of a sampled alarm variable crosses the rising threshold multiple times before it crosses the falling threshold, only the first crossing triggers a rising alarm event, as shown in Figure 1.

Figure 1 Rising and falling alarm events

Private alarm group

The private alarm group enables you to perform basic math operations on multiple variables, and compare the calculation result with the rising and falling thresholds.

The RMON agent samples variables and takes an alarm action based on a private alarm entry as follows:

1. Samples the private alarm variables in the user-defined formula.
2. Processes the sampled values with the formula.
3. Compares the calculation result with the predefined thresholds, and then takes one of the following actions:
   - Triggers the event associated with the rising alarm event if the result is equal to or greater than the rising threshold.
   - Triggers the event associated with the falling alarm event if the result is equal to or less than the falling threshold.

If a private alarm entry crosses a threshold multiple times in succession, the RMON agent generates an alarm event only for the first crossing. For example, if the value of a sampled alarm variable

crosses the rising threshold multiple times before it crosses the falling threshold, only the first crossing triggers a rising alarm event.

Sample types for the alarm group and the private alarm group

The RMON agent supports the following sample types:

- **absolute**—RMON compares the value of the monitored variable with the rising and falling thresholds at the end of the sampling interval.
- **delta**—RMON subtracts the value of the monitored variable at the previous sample from the current value, and then compares the difference with the rising and falling thresholds.

Protocols and standards

- RFC 4502, *Remote Network Monitoring Management Information Base Version 2*
- RFC 2819, *Remote Network Monitoring Management Information Base Status of this Memo*

Configuring the RMON statistics function

About the RMON statistics function

RMON implements the statistics function through the Ethernet statistics group and the history group.

The Ethernet statistics group provides the cumulative statistic for a variable from the time the statistics entry is created to the current time.

The history group provides statistics that are sampled for a variable for each sampling interval. The history group uses the history control table to control sampling, and it stores samples in the history table.

Creating an RMON Ethernet statistics entry

Restrictions and guidelines

The index of an RMON statistics entry must be globally unique. If the index has been used by another interface, the creation operation fails.

You can create only one RMON statistics entry for an Ethernet interface.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Create an RMON Ethernet statistics entry.
   rmon statistics *entry-number* [**owner** *text*]

Creating an RMON history control entry

Restrictions and guidelines

You can configure multiple history control entries for one interface, but you must make sure their entry numbers and sampling intervals are different.

You can create a history control entry successfully even if the specified bucket size exceeds the available history table size. RMON will set the bucket size as closely to the expected bucket size as possible.

Procedure

1. Enter system view.

   system-view

2. Enter Ethernet interface view.

   interface *interface-type interface-number*

3. Create an RMON history control entry.

   rmon history *entry-number* **buckets** *number* **interval** *interval* [**owner** *text*]

   By default, no RMON history control entries exist.

   You can create multiple RMON history control entries for an Ethernet interface.

Configuring the RMON alarm function

Restrictions and guidelines

When you create a new event, alarm, or private alarm entry, follow these restrictions and guidelines:

- The entry must not have the same set of parameters as an existing entry.
- The maximum number of entries is not reached.

Table 1 shows the parameters to be compared for duplication and the entry limits.

Table 1 RMON configuration restrictions

Entry	Parameters to be compared	Maximum number of entries
Event	• Event description (**description** *string*) • Event type (**log**, **trap**, **logtrap**, or **none**) • Community name (*security-string*)	60
Alarm	• Alarm variable (*alarm-variable*) • Sampling interval (*sampling-interval*) • Sample type (**absolute** or **delta**) • Rising threshold (*threshold-value1*) • Falling threshold (*threshold-value2*)	60
Private alarm	• Alarm variable formula (*prialarm-formula*) • Sampling interval (*sampling-interval*) • Sample type (**absolute** or **delta**) • Rising threshold (*threshold-value1*) • Falling threshold (*threshold-value2*)	50

Prerequisites

To send notifications to the NMS when an alarm is triggered, configure the SNMP agent as described in "Configuring SNMP" before configuring the RMON alarm function.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Create an RMON event entry.

   rmon event *entry-number* [**description** *string*] { **log** | **log-trap** *security-string* | **none** | **trap** *security-string* } [**owner** *text*]

   By default, no RMON event entries exist.

3. Create an RMON alarm entry.

   - Create an RMON alarm entry.

     rmon alarm *entry-number alarm-variable sampling-interval* { **absolute** | **delta** } [**startup-alarm** { **falling** | **rising** | **rising-falling** }] **rising-threshold** *threshold-value1 event-entry1* **falling-threshold** *threshold-value2 event-entry2* [**owner** *text*]

   - Create an RMON private alarm entry.

     rmon prialarm *entry-number prialarm-formula prialarm-des sampling-interval* { **absolute** | **delta** } [**startup-alarm** { **falling** | **rising** | **rising-falling** }] **rising-threshold** *threshold-value1 event-entry1* **falling-threshold** *threshold-value2 event-entry2* **entrytype** { **forever** | **cycle** *cycle-period* } [**owner** *text*]

   By default, no RMON alarm entries or RMON private alarm entries exist.

   You can associate an alarm with an event that has not been created yet. The alarm will trigger the event only after the event is created.

Display and maintenance commands for RMON

Execute **display** commands in any view.

Task	Command
Display RMON alarm entries.	**display rmon alarm** [*entry-number*]
Display RMON event entries.	**display rmon event** [*entry-number*]
Display log information for event entries.	**display rmon eventlog** [*entry-number*]
Display RMON history control entries and history samples.	**display rmon history** [*interface-type interface-number*]
Display RMON private alarm entries.	**display rmon prialarm** [*entry-number*]
Display RMON statistics.	**display rmon statistics** [*interface-type interface-number*]

RMON configuration examples

Example: Configuring the Ethernet statistics function

Network configuration

As shown in Figure 2, create an RMON Ethernet statistics entry on the device to gather cumulative traffic statistics for GigabitEthernet 1/0/1.

Figure 2 Network diagram

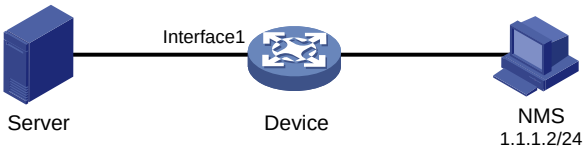


Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

Create an RMON Ethernet statistics entry for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rmon statistics 1 owner user1
```

Verifying the configuration

Display statistics collected for GigabitEthernet 1/0/1.

```
<Sysname> display rmon statistics gigabitethernet 1/0/1
EtherStatsEntry 1 owned by user1 is VALID.
  Interface : GigabitEthernet1/0/1<ifIndex.3>
  etherStatsOctets         : 21657     , etherStatsPkts          : 307
  etherStatsBroadcastPkts  : 56        , etherStatsMulticastPkts : 34
  etherStatsUndersizePkts  : 0         , etherStatsOversizePkts  : 0
  etherStatsFragments      : 0         , etherStatsJabbers       : 0
  etherStatsCRCAlignErrors : 0         , etherStatsCollisions    : 0
  etherStatsDropEvents (insufficient resources): 0
  Incoming packets by size:
  64     : 235       ,  65-127  : 67        ,  128-255  : 4
  256-511: 1         ,  512-1023: 0         ,  1024-1518: 0
```

Get the traffic statistics from the NMS through SNMP. (Details not shown.)

Example: Configuring the history statistics function

Network configuration

As shown in Figure 3, create an RMON history control entry on the device to sample traffic statistics for GigabitEthernet 1/0/1 every minute.

Figure 3 Network diagram

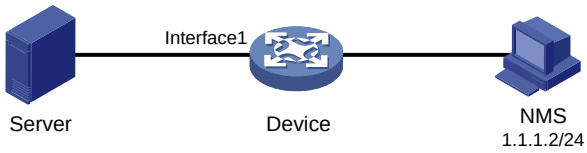

Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

Create an RMON history control entry to sample traffic statistics every minute for GigabitEthernet 1/0/1. Retain a maximum of eight samples for the interface in the history statistics table.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rmon history 1 buckets 8 interval 60 owner user1
```

Verifying the configuration

Display the history statistics collected for GigabitEthernet 1/0/1.

```
[Sysname-GigabitEthernet1/0/1] display rmon history
HistoryControlEntry 1 owned by user1 is VALID
  Sampled interface     : GigabitEthernet1/0/1<ifIndex.3>
  Sampling interval     : 60(sec) with 8 buckets max
  Sampling record 1 :
    dropevents        : 0         , octets               : 834
    packets           : 8         , broadcast packets    : 1
    multicast packets : 6         , CRC alignment errors : 0
    undersize packets : 0         , oversize packets     : 0
    fragments         : 0         , jabbers              : 0
    collisions        : 0         , utilization          : 0
  Sampling record 2 :
    dropevents        : 0         , octets               : 962
    packets           : 10        , broadcast packets    : 3
    multicast packets : 6         , CRC alignment errors : 0
    undersize packets : 0         , oversize packets     : 0
    fragments         : 0         , jabbers              : 0
    collisions        : 0         , utilization          : 0
```

Get the traffic statistics from the NMS through SNMP. (Details not shown.)

Example: Configuring the alarm function

Network configuration

As shown in Figure 4, configure the device to monitor the incoming traffic statistic on GigabitEthernet 1/0/1, and send RMON alarms when either of the following conditions is met:

- The 5-second delta sample for the traffic statistic crosses the rising threshold (100).
- The 5-second delta sample for the traffic statistic drops below the falling threshold (50).

Figure 4 Network diagram

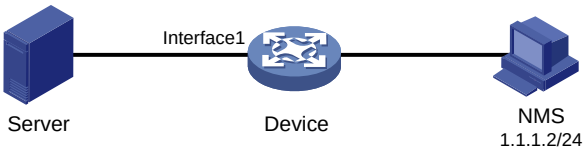

Table 4 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

Configure the SNMP agent (the device) with the same SNMP settings as the NMS at 1.1.1.2. This example uses SNMPv1, read community **public**, and write community **private**.

```
<Sysname> system-view
[Sysname] snmp-agent
[Sysname] snmp-agent community read public
[Sysname] snmp-agent community write private
[Sysname] snmp-agent sys-info version v1
[Sysname] snmp-agent trap enable
[Sysname] snmp-agent trap log
[Sysname] snmp-agent target-host trap address udp-domain 1.1.1.2 params securityname
public
```

Create an RMON Ethernet statistics entry for GigabitEthernet 1/0/1.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rmon statistics 1 owner user1
[Sysname-GigabitEthernet1/0/1] quit
```

Create an RMON event entry and an RMON alarm entry to send SNMP notifications when the delta sample for 1.3.6.1.2.1.16.1.1.1.4.1 exceeds 100 or drops below 50.

```
[Sysname] rmon event 1 trap public owner user1
[Sysname] rmon alarm 1 1.3.6.1.2.1.16.1.1.1.4.1 5 delta rising-threshold 100 1
falling-threshold 50 1 owner user1
```

NOTE:

The string 1.3.6.1.2.1.16.1.1.1.4.1 is the object instance for GigabitEthernet 1/0/1. The digits before the last digit (1.3.6.1.2.1.16.1.1.1.4) represent the object for total incoming traffic statistics. The last digit (1) is the RMON Ethernet statistics entry index for GigabitEthernet 1/0/1.

Verifying the configuration

Display the RMON alarm entry.

```
<Sysname> display rmon alarm 1
AlarmEntry 1 owned by user1 is VALID.
  Sample type                    : delta
  Sampled variable               : 1.3.6.1.2.1.16.1.1.1.4.1<etherStatsOctets.1>
  Sampling interval (in seconds) : 5
  Rising threshold               : 100(associated with event 1)
  Falling threshold              : 50(associated with event 1)
  Alarm sent upon entry startup  : risingOrFallingAlarm
```

```
  Latest value                   : 0
```

Display statistics for GigabitEthernet 1/0/1.

```
<Sysname> display rmon statistics gigabitethernet 1/0/1
EtherStatsEntry 1 owned by user1 is VALID.
  Interface : GigabitEthernet1/0/1<ifIndex.3>
  etherStatsOctets         : 57329     , etherStatsPkts          : 455
  etherStatsBroadcastPkts  : 53        , etherStatsMulticastPkts : 353
  etherStatsUndersizePkts  : 0         , etherStatsOversizePkts  : 0
  etherStatsFragments      : 0         , etherStatsJabbers       : 0
  etherStatsCRCAlignErrors : 0         , etherStatsCollisions    : 0
  etherStatsDropEvents (insufficient resources): 0
  Incoming packets by size :
  64     : 7         ,  65-127  : 413       ,  128-255  : 35
  256-511: 0         ,  512-1023: 0         ,  1024-1518: 0
```

The NMS receives the notification when the alarm is triggered.

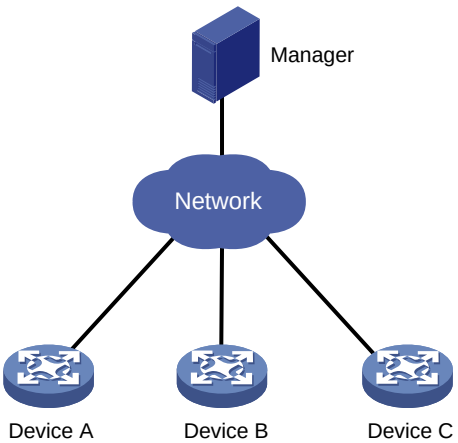
Using Ansible for automated configuration management

About Ansible

Ansible is an automation tool used for remote deployment on a large scale of devices that can be accessed through SSH. Deployed with Ansible, the system can perform large-scale and automated system O&M operations such as cluster configuration and application deployment. The flexible Ansible usage and replicable deployment parameters significantly reduce duplicated effort of O&M personnel and improve the O&M efficiency.

Ansible is programmed in Python and uses SSH to connect to network devices for centralized configuration and management.

Ansible network architecture



As shown in Figure 1, an Ansible system consists of the following elements:

- **Manager**—A host installed with Ansible. For more information about installing Ansible, see the Ansible official website.

  The manager supports remote configuration such as creating VLANs. Not all services modules are configurable through Ansible. To identify the service modules that you can configure by using Ansible, access the Comware 7 Python library.
- **Managed device**—A managed device acts as an SSH server and does not require any agent software to be installed. Once an SSH connection is established between the manager and the device, the device automatically executes the commands deployed by the manager.

  H3C devices can act as managed devices.

Figure 1 Ansible network architecture

Basic Ansible concepts

Figure 2 Basic Ansible concepts

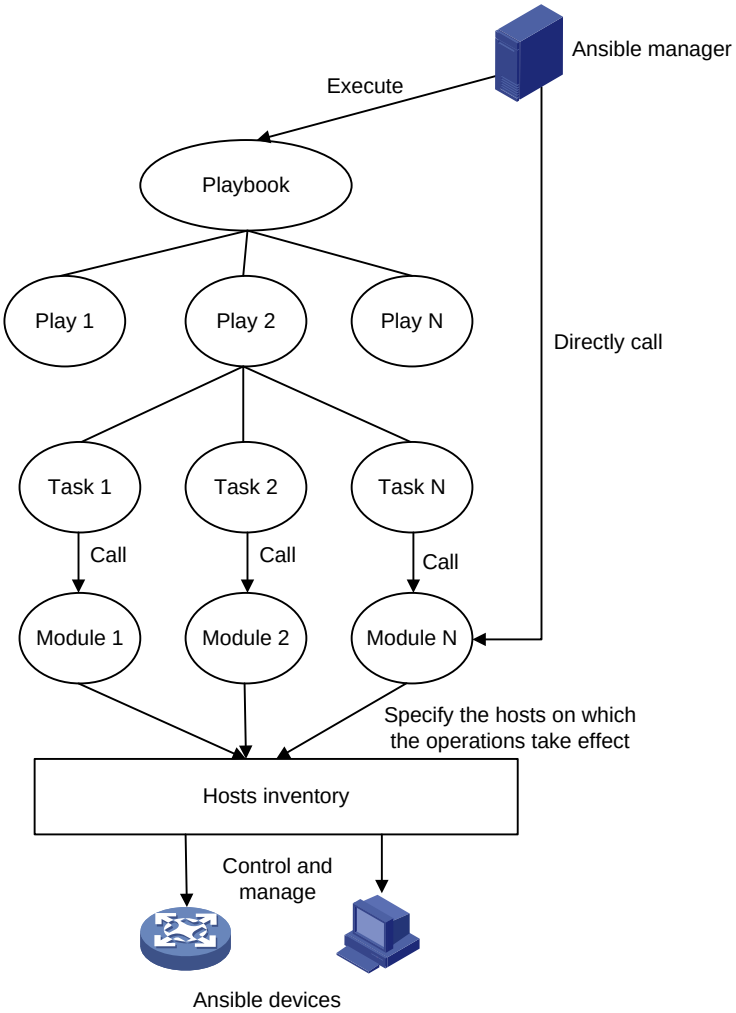


Figure 3 shows the basic Ansible concepts:

- **Playbook—**An automated script written in YAML format. A playbook contains all configuration to be deployed to the devices and is executed in the order of the content. It avoids repeated and large-scale input on the manager, which is crucial for Ansible automation.
- **Play**—A play contains all operations targeted at a group of hosts. A playbook can contain multiple plays.
- **Task**—A basic unit that describes the operation and configuration to be executed on the target hosts. Each operation corresponds to a task. For example, creating VLAN 10 and specifying an IP address for VLAN-interface 10 correspond to two separate tasks. A play can contain multiple tasks.
- **Module**—A module can be a Python or Bash script. Ansible can perform specific operations on the target hosts and return the results only after tasks call modules. Modules can be called in the playbook or directly called by command lines on the manager. As a best practice to avoid repeated execution of commands, use the playbook to call modules.
- **Hosts inventory**—An important configuration file that informs Ansible of hosts to be managed and categorizes them. Target hosts of the operations written in the playbook must be defined in the hosts inventory.

Basic Ansible concepts

Figure 3 Basic Ansible concepts

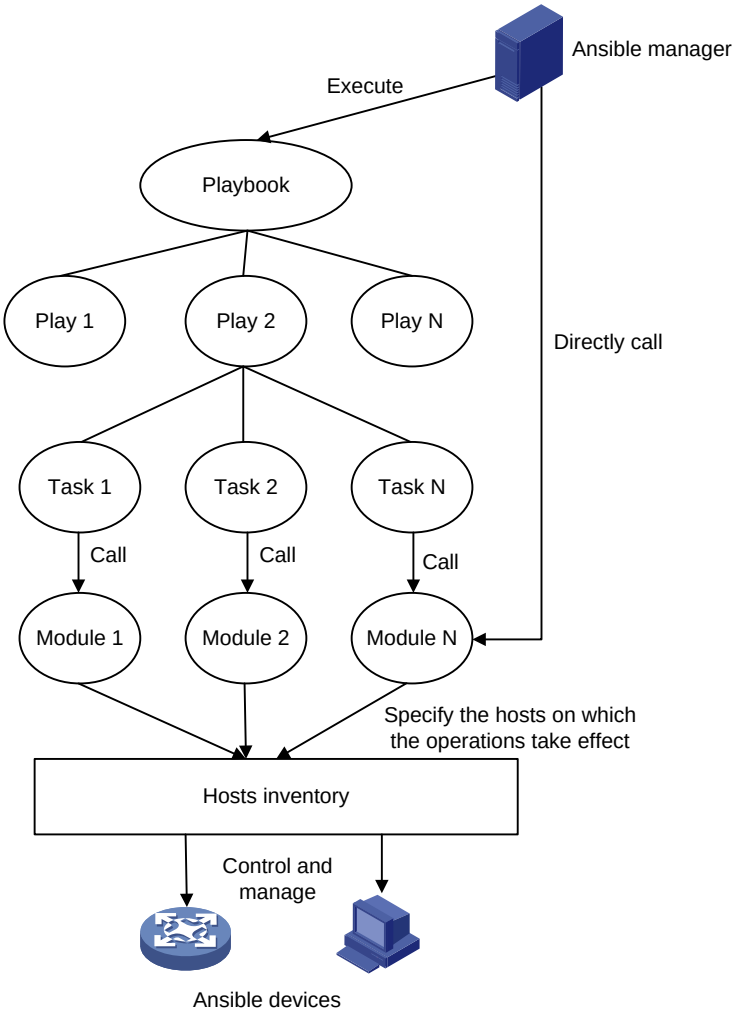

Figure 3 shows the basic Ansible concepts:

- **Playbook—**An automated script written in YAML format. A playbook contains all configuration to be deployed to the devices and is executed in the order of the content. It avoids repeated and large-scale input on the manager, which is crucial for Ansible automation.
- **Play**—A play contains all operations targeted at a group of hosts. A playbook can contain multiple plays.
- **Task**—A basic unit that describes the operation and configuration to be executed on the target hosts. Each operation corresponds to a task. For example, creating VLAN 10 and specifying an IP address for VLAN-interface 10 correspond to two separate tasks. A play can contain multiple tasks.
- **Module**—A module can be a Python or Bash script. Ansible can perform specific operations on the target hosts and return the results only after tasks call modules. Modules can be called in the playbook or directly called by command lines on the manager. As a best practice to avoid repeated execution of commands, use the playbook to call modules.
- **Hosts inventory**—An important configuration file that informs Ansible of hosts to be managed and categorizes them. Target hosts of the operations written in the playbook must be defined in the hosts inventory.

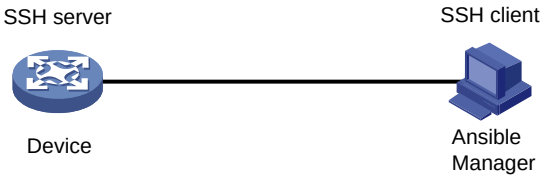
How Ansible works

1. Install Ansible on the manager and write the operations to be executed by the devices in the playbook.
2. The manager (SSH client) initiates SSH connections to the devices (SSH servers).
3. The manager executes the playbook to deploy commands to the target devices.
4. The devices automatically execute the received commands.

Prerequisites for Ansible

Before you use Ansible to configure the device, complete the following tasks:

- Configure NTP or PTP or manually configure the system time on the Ansible server and the device to synchronize their system time. For more information about time synchronization, see device management configuration in *Fundamentals Configuration guide* and NTP and PTP configuration in *Network Management and Monitoring Configuration Guide*.
- Configure the device as an SSH server. For more information about SSH configuration, see *Security Configuration Guide*.



Device setup examples for management with Ansible

Example: Setting up the device for management with Ansible

Network configuration

As shown in Figure 4, enable SSH server on the device and use the Ansible manager to manage the device over SSH.

Figure 4 Network diagram

Prerequisites

1. Assign IP addresses to the device and manager. Make sure they have connectivity to each other.
2. Configure NTP or PTP or manually configure the system time on both the device and manager so they use the same system time. (Details not shown.)

Configuring the device as an SSH server

Create local key pairs. For more information, see SSH configuration in *Security Configuration Guide*.

Create a local user named **abc** and set the password for the user.

```
<Device> system-view
[Device]local-user abc
[Device-luser-manage-abc] password simple 123456TESTplat&!
```

Assign the network-admin user role to the user and authorize the user to use SSH, HTTP, and HTTPS services.

```
[Device-luser-manage-abc] authorization-attribute user-role network-admin
[Device-luser-manage-abc] service-type ssh http https
[Device-luser-manage-abc] quit
```

Enable NETCONF over SSH.

```
[Device] netconf ssh server enable
```

Enable scheme authentication for SSH login and assign the network-admin user role to the login users.

```
[Device] line vty 0 63
[Device-line-vty0-63] authentication-mode scheme
[Device-line-vty0-63] user-role network-admin
[Device-line-vty0-63] quit
```

Enable the SSH server.

```
[Device] ssh server enable
```

Authorize SSH user abc to use all service types, including SCP, SFTP, Stelnet, and NETCONF. Set the authentication method to password.

```
[Device] ssh user abc service-type all authentication-type password
```

Enable the SFTP server or SCP server.

- If the device supports SFTP, enable the SFTP server.
  ```
  [Device] sftp server enable
  ```
- If the device does not support SFTP, enable the SCP server.
  ```
  [Device] scp server enable
  ```

Configuring the Ansible manager

In this example, the Ubuntu operating system is installed on the manager. To use a manager installed with another Linux system or Unix-like system, see the Ansible documentation official website at https://docs.ansible.com.

To configure the Ansible manager:

1. Configure the default hosts inventory:

   The default hosts inventory file path is **/etc/ansible/hosts**. The manager must write the host information of the device (such as the IP address or domain name) in this file, for example:

   ```
   192.168.1.1    Device
   ```

   For more information about the hosts inventory writing rules and editing the file path, see the Ansible documentation official website at https://docs.ansible.com.

2. Use the PiP tool to install Ansible.

   # Check the Python version.

   ```
   $ python --version
   ```

   # If Python is not installed, install it first.

   ```
   $ sudo apt-get update
   $ sudo apt-get install python3
   ```

   # Check the PiP version.

   ```
   $ pip --version
   ```

   # If PiP is not installed, install it first.

   ```
   $ sudo apt-get update
   $ sudo apt-get install python-pip
   ```

   # Install Ansible.

```
$ sudo pip install markupsafe
$ sudo pip install ansible
```

After installation, check the Ansible version.

```
$ ansible -- version
```

3. Install the Python library.

NOTE:

When Ansible executes scripts, the called modules must be implemented via Python. Install the Python library to obtain the code that enables the modules called by the playbook to operate correctly.

Download the up-to-date Comware Python library source code from GitHub.

```
$ sudo git clone https://github.com/HPENetworking/pyhpecw7
```

Install the Comware Python library.

```
$ cd pyhpecw7-master
$ sudo chmod 777 setup.py
$ sudo python setup.py install
```

NOTE:

If a message displays a missing component, use the **`$ sudo apt-get install`** *xxx* command to install the component. *xxx* represents the name of a component.

Download the Ansible module.

```
$ sudo git clone https://github.com/HPENetworking/ansible-hpe-cw7
```

Use the **`find`** command to search for the **namespaces.py** file from the root directory. If the file is found and the file path contains **pyhpecw7**, open the file and edit the content as follows:

```
HPDATA="http://www.h3c.com/netconf/data:1.0"
HPDATA_C='{'+HPDATA+'}'
NETCONFBASE="urn:ietf:params:xml:ns:netconf:base:1.0"
NETCONFBASE_C='{'+NETCONFBASE+'}'
HPCONFIG="http://www.h3c.com/netconf/data:1.0"
HPCONFIG_C='{'+HPCONFIG+'}'
HPACTION="http://www.h3c.com/netconf/data:1.0"
HPACTION_C='{'+HPACTION+'}'
```

4. Configure the SSH service.

Install an SSH server.

```
$ sudo apt-get install ssh
```

Edit the sshd configuration file. Change the value for the **PermitRootLogin** field to **Yes**.

```
$ sudo vi sshd_config
```

Restart the SSH service.

```
$ sudo service ssh restart
```

5. Define the hosts inventory variables.

In the **ansible-hpe-cw7-master/hosts** file, change the username and password that the manager use to log in to the device through SSH. The manager uses the new username and password to log in to all hosts.

```
[all:vars]
```

```
username=abc
password=123456TESTplat&!
```

In the **ansible-hpe-cw7-master/hosts** file, change the **[switches]** field to **Device**. All host names of **[switches]** belong to the same group. Ansible can execute the same task on all hosts in the group.

```
[switches]
Device
```

6. Write the playbook.

Create the **vlans.yml** file and write the following code in the file:

```
---
- name: VLAN automation with Ansible on Devices
  hosts: switches
  gather_facts: no
  connection: local

  tasks:
    - name: ensure VLAN 10 exists
      comware_vlan: vlanid=10 name=VLAN10 descr=LOCAL_SEGMENT username={{ username }}
password={{ password }} hostname={{ inventory_hostname }}

    - name: ensure VLAN 20 exists
      comware_vlan: vlanid=20 state=present username={{ username }}
password={{ password }} hostname={{ inventory_hostname }}
```

7. Execute the script.

Grant the permission to execute the **vlans.yml** file.

```
$ sudo chmod 777 vlans.yml
```

Use the **`ansible-playbook`** command to execute the **vlans.yml** file.

```
$ sudo ansible-playbook -i hosts vlans.yml

PLAY [VLAN automation with Ansible on Devices] *********************************

TASK [ensure VLAN 10 exists] ***************************************************
changed: [Device]

TASK [ensure VLAN 20 exists] ***************************************************
ok: [Device]

PLAY RECAP *********************************************************************
Device                     : ok=2    changed=1     unreachable=0    failed=0
```

The output shows that the script created VLAN 10 and detected that VLAN 20 already existed.

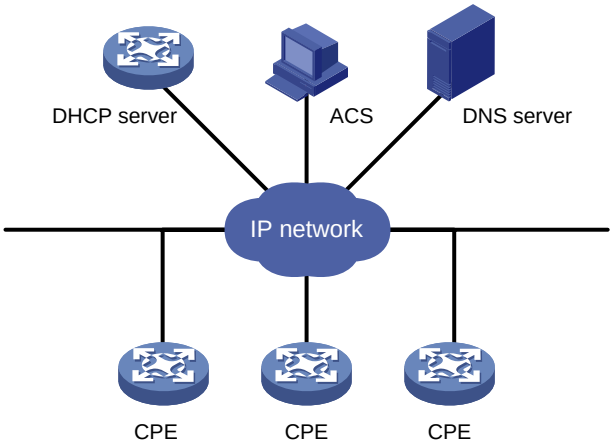
Configuring CWMP

About CWMP



CPE WAN Management Protocol (CWMP), also called "TR-069," is a DSL Forum technical specification for remote management of network devices.

The protocol was initially designed to provide remote autoconfiguration through a server for large numbers of dispersed end-user devices in a network. CWMP can be used on different types of networks, including Ethernet.

CWMP network framework

Figure 1 shows a basic CWMP network framework.

Figure 1 CWMP network framework

A basic CWMP network includes the following network elements:

- **ACS**—Autoconfiguration server, the management device in the network.
- **CPE**—Customer premises equipment, the managed device in the network.
- **DNS server**—Domain name system server. CWMP defines that the ACS and the CPE use URLs to identify and access each other. DNS is used to resolve the URLs.
- **DHCP server**—Assigns ACS attributes along with IP addresses to CPEs when the CPEs are powered on. DHCP server is optional in CWMP. With a DHCP server, you do not need to configure ACS attributes manually on each CPE. The CPEs can contact the ACS automatically when they are powered on for the first time.

The device is operating as a CPE in the CWMP framework.

Basic CWMP functions

You can autoconfigure and upgrade CPEs in bulk from the ACS.

Autoconfiguration

You can create configuration files for different categories of CPEs on the ACS. Based on the device models and serial numbers of the CPEs, the ACS verifies the categories of the CPEs and issues the associated configuration to them.

The following are methods available for the ACS to issue configuration to the CPE:

- Transfers the configuration file to the CPE, and specifies the file as the next-startup configuration file. At a reboot, the CPE starts up with the ACS-specified configuration file.
- Runs the configuration in the CPE's RAM. The configuration takes effect immediately on the CPE. For the running configuration to survive a reboot, you must save the configuration on the CPE.

CPE software management

The ACS can manage CPE software upgrade.

When the ACS finds a software version update, the ACS notifies the CPE to download the software image file from a specific location. The location can be the URL of the ACS or an independent file server.

If the CPE successfully downloads the software image file and the file is validated, the CPE notifies the ACS of a successful download. If the CPE fails to download the software image file or the file is invalidated, the CPE notifies the ACS of an unsuccessful download.

Data backup

The ACS can require the CPE to upload a configuration file or log file to a specific location. The destination location can be the ACS or a file server.

CPE status and performance monitoring

The ACS can monitor the status and performance of CPEs. Table 1 shows the available CPE status and performance objects for the ACS to monitor.

Table 1 CPE status and performance objects available for the ACS to monitor

Category	Objects	Remarks
Device information	Manufacturer ManufacturerOUI SerialNumber HardwareVersion SoftwareVersion	N/A
Operating status and information	DeviceStatus UpTime	N/A
Configuration file	ConfigFile	Local configuration file stored on CPE for upgrade. The ACS can issue configuration to the CPE by transferring a configuration file to the CPE or running the configuration in CPE's RAM.
CWMP settings	ACS URL	URL address of the ACS to which the CPE initiates a CWMP connection. This object is also used for main/backup ACS switchover.
	ACS username ACS password	When the username and password of the ACS are changed, the ACS changes the ACS username and password on the CPE to the new username and password. When a main/backup ACS switchover occurs, the main ACS also changes the ACS username and password to the backup ACS username and password.
	PeriodicInformEnable	Whether to enable or disable the periodic Inform feature.
	PeriodicInformInterval	Interval for periodic connection from the CPE

Category	Objects	Remarks
		to the ACS for configuration and software update.
	PeriodicInformTime	Scheduled time for connection from the CPE to the ACS for configuration and software update.
	ConnectionRequestURL (CPE URL)	N/A
	ConnectionRequestUsername (CPE username) ConnectionRequestPassword (CPE password)	CPE username and password for authentication from the ACS to the CPE.

How CWMP works

RPC methods

CWMP uses remote procedure call (RPC) methods for bidirectional communication between CPE and ACS. The RPC methods are encapsulated in HTTP or HTTPS.

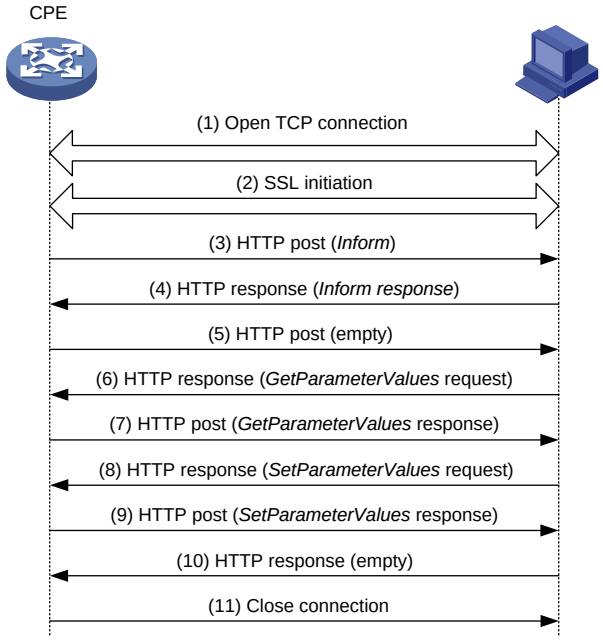
Table 2 shows the primary RPC methods used in CWMP.

Table 2 RPC methods

RPC method	Description
Get	The ACS obtains the values of parameters on the CPE.
Set	The ACS modifies the values of parameters on the CPE.
Inform	The CPE sends an Inform message to the ACS for the following purposes: • Initiates a connection to the ACS. • Reports configuration changes to the ACS. • Periodically updates CPE settings to the ACS.
Download	The ACS requires the CPE to download a configuration or software image file from a specific URL for software or configuration update.
Upload	The ACS requires the CPE to upload a file to a specific URL.
Reboot	The ACS reboots the CPE remotely for the CPE to complete an upgrade or recover from an error condition.

Autoconnect between ACS and CPE

The CPE automatically initiates a connection to the ACS when one of the following events occurs:



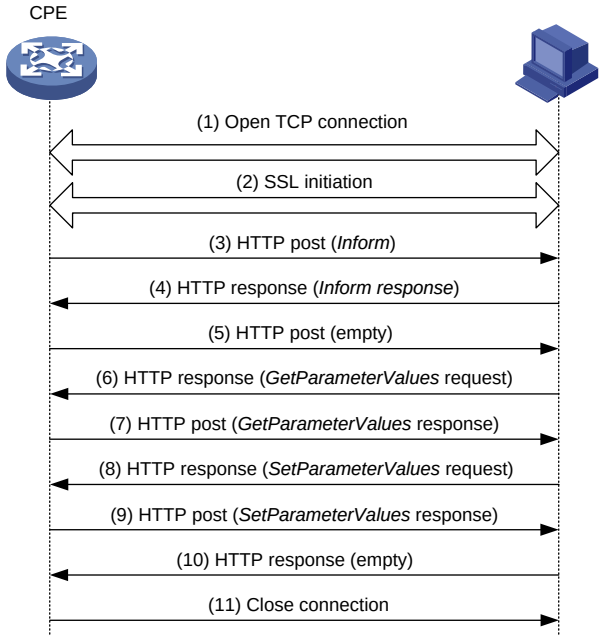
- ACS URL change. The CPE initiates a connection request to the new ACS URL.
- CPE startup. The CPE initiates a connection to the ACS after the startup.
- Timeout of the periodic Inform interval. The CPE re-initiates a connection to the ACS at the Inform interval.
- Expiration of the scheduled connection initiation time. The CPE initiates a connection to the ACS at the scheduled time.

CWMP connection establishment

Step 1 through step 5 in Figure 2 show the procedure of establishing a connection between the CPE and the ACS.

1. After obtaining the basic ACS parameters, the CPE initiates a TCP connection to the ACS.
2. If HTTPS is used, the CPE and the ACS initialize SSL for a secure HTTP connection.
3. The CPE sends an Inform message in HTTPS to initiate a CWMP session.
4. After the CPE passes authentication, the ACS returns an Inform response to establish the session.
5. After sending all requests, the CPE sends an empty HTTP post message.

Figure 2 CWMP connection establishment



Main/backup ACS switchover

Typically, two ACSs are used in a CWMP network for consecutive monitoring on CPEs. When the main ACS needs to reboot, it points the CPE to the backup ACS. Step 6 through step 11 in Figure 3 show the procedure of a main/backup ACS switchover.

1. Before the main ACS reboots, it queries the ACS URL set on the CPE.
2. The CPE replies with its ACS URL setting.
3. The main ACS sends a Set request to change the ACS URL on the CPE to the backup ACS URL.
4. After the ACS URL is modified, the CPE sends a response.
5. The main ACS sends an empty HTTP message to notify the CPE that it has no other requests.
6. The CPE closes the connection, and then initiates a new connection to the backup ACS URL.

Figure 3 Main and backup ACS switchover

Restrictions and guidelines: CWMP configuration

CWMP is available only in IPv4 networks. If you configure CWMP in an IPv6 network, the feature does not take effect.

You can configure ACS and CPE attributes from the CPE's CLI, the DHCP server, or the ACS. For an attribute, the CLI- and ACS-assigned values have higher priority than the DHCP-assigned value. The CLI- and ACS-assigned values overwrite each other, whichever is assigned later.

This document only describes configuring ACS and CPE attributes from the CLI and DHCP server. For more information about configuring and using the ACS, see ACS documentation.

CWMP tasks at a glance

To configure CWMP, perform the following tasks:

1. Enabling CWMP from the CLI

   You can also enable CWMP from a DHCP server.
2. Configuring ACS attributes
   a. Configuring the preferred ACS attributes
   b. (Optional.) Configuring the default ACS attributes from the CLI
3. Configuring CPE attributes
   a. Specifying an SSL client policy for HTTPS connection to ACS

      This task is required when the ACS uses HTTPS for secure access.
   b. (Optional.) Configuring ACS authentication parameters
   c. (Optional.) Configuring the provision code
   d. (Optional.) Configuring the CWMP connection interface
   e. (Optional.) Configuring autoconnect parameters
   f. (Optional.) Setting the close-wait timer

g. (Optional.) Enabling NAT traversal for the CPE

Enabling CWMP from the CLI

1. Enter system view.
   system-view
2. Enter CWMP view.
   cwmp
3. Enable CWMP.
   cwmp enable
   By default, CWMP is disabled.

Configuring ACS attributes

About ACS attributes

You can configure two sets of ACS attributes for the CPE: preferred and default.

- The preferred ACS attributes are configurable from the CPE's CLI, the DHCP server, and ACS.
- The default ACS attributes are configurable only from the CLI.

If the preferred ACS attributes are not configured, the CPE uses the default ACS attributes for connection establishment.

Configuring the preferred ACS attributes

Assigning ACS attributes from the DHCP server

The DHCP server in a CWMP network assigns the following information to CPEs:

- IP addresses for the CPEs.
- DNS server address.
- ACS URL and ACS login authentication information.

This section introduces how to use DHCP option 43 to assign the ACS URL and ACS login authentication username and password. For more information about DHCP and DNS, see *Layer 3—IP Services Configuration Guide*.

If the DHCP server is an H3C device, you can configure DHCP option 43 by using the **option 43 hex 01***length URL username password* command.

- *length*—A hexadecimal number that indicates the total length of the *length*, *URL*, *username*, and *password* arguments, including the spaces between these arguments. No space is allowed between the **01** keyword and the length value.
- *URL*—ACS URL.
- *username*—Username for the CPE to authenticate to the ACS.
- *password*—Password for the CPE to authenticate to the ACS.

NOTE:

The ACS URL, username and password must use the hexadecimal format and be space separated.

The following example configures the ACS address as **https://169.254.76.31:7547/acs**, username as **1234**, and password as **5678**:

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] option 43 hex
012368747470733A2F2F3136392E3235342E37362E33313A3735343720313233342035363738
```

Table 3 Hexadecimal forms of the ACS attributes

Attribute	Attribute value	Hexadecimal form
Length	39 characters	27
ACS URL	https://169.254.76.31:7547/acs	68747470733A2F2F3136392E3235342E37362E33313A3735343720 **NOTE:** The two ending digits (20) represent the space.
ACS connect username	1234	3132333420 **NOTE:** The two ending digits (20) represent the space.
ACS connect password	5678	35363738

Configuring the preferred ACS attributes from the CLI

1. Enter system view.
   system-view
2. Enter CWMP view.
   cwmp
3. Configure the preferred ACS URL.
   cwmp acs url *url*
   By default, no preferred ACS URL has been configured.
4. Configure the username for authentication to the preferred ACS URL.
   cwmp acs username *username*
   By default, no username has been configured for authentication to the preferred ACS URL.
5. (Optional.) Configure the password for authentication to the preferred ACS URL.
   cwmp acs password { **cipher** | **simple** } *string*
   By default, no password has been configured for authentication to the preferred ACS URL.

Configuring the default ACS attributes from the CLI

1. Enter system view.
   system-view
2. Enter CWMP view.
   cwmp
3. Configure the default ACS URL.
   cwmp acs default url *url*
   By default, no default ACS URL has been configured.
4. Configure the username for authentication to the default ACS URL.
   cwmp acs default username *username*
   By default, no username has been configured for authentication to the default ACS URL.

5. (Optional.) Configure the password for authentication to the default ACS URL.

   cwmp acs default password { **cipher** | **simple** } *string*

   By default, no password has been configured for authentication to the default ACS URL.

Configuring CPE attributes

About CPE attributes

You can configure the following CPE attributes only from the CPE's CLI.

- CWMP connection interface.
- NAT traversal.
- Maximum number of connection retries.
- SSL client policy for HTTPS connection to ACS.

For other CPE attribute values, you can assign them to the CPE from the CPE's CLI or the ACS. The CLI- and ACS-assigned values overwrite each other, whichever is assigned later.

Specifying an SSL client policy for HTTPS connection to ACS

About this task

This task is required when the ACS uses HTTPS for secure access. CWMP uses HTTP or HTTPS for data transmission. When HTTPS is used, the ACS URL begins with **https://**. You must specify an SSL client policy for the CPE to authenticate the ACS for HTTPS connection establishment.

Prerequisites

Before you perform this task, first create an SSL client policy. For more information about configuring SSL client policies, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter CWMP view.

   cwmp

3. Specify an SSL client policy.

   ssl client-policy *policy-name*

   By default, no SSL client policy is specified.

Configuring ACS authentication parameters

About this task

To protect the CPE against unauthorized access, configure a CPE username and password for ACS authentication. When an ACS initiates a connection to the CPE, the ACS must provide the correct username and password.

Procedure

1. Enter system view.

   system-view

2. Enter CWMP view.

cwmp

3. Configure the username for authentication to the CPE.

   cwmp cpe username *username*

   By default, no username has been configured for authentication to the CPE.

4. (Optional.) Configure the password for authentication to the CPE.

   cwmp cpe password { **cipher** | **simple** } *string*

   By default, no password has been configured for authentication to the CPE.

   The password setting is optional. You can specify only a username for authentication.

Configuring the provision code

About this task

The ACS can use the provision code to identify services assigned to each CPE. For correct configuration deployment, make sure the same provision code is configured on the CPE and the ACS. For information about the support of your ACS for provision codes, see the ACS documentation.

Procedure

1. Enter system view.

   system-view

2. Enter CWMP view.

   cwmp

3. Configure the provision code.

   cwmp cpe provision-code *provision-code*

   The default provision code is **PROVISIONINGCODE**.

Configuring the CWMP connection interface

About this task

The CWMP connection interface is the interface that the CPE uses to communicate with the ACS. To establish a CWMP connection, the CPE sends the IP address of this interface in the Inform messages, and the ACS replies to this IP address.

Typically, the CPE selects the CWMP connection interface automatically. If the CWMP connection interface is not the interface that connects the CPE to the ACS, the CPE fails to establish a CWMP connection with the ACS. In this case, you need to manually set the CWMP connection interface.

Procedure

1. Enter system view.

   system-view

2. Enter CWMP view.

   cwmp

3. Specify the interface that connects to the ACS as the CWMP connection interface.

   cwmp cpe connect interface *interface-type interface-number*

   By default, no CWMP connection interface is specified.

Configuring autoconnect parameters

About this task

You can configure the CPE to connect to the ACS periodically, or at a scheduled time for configuration or software update.

The CPE retries a connection automatically when one of the following events occurs:

- The CPE fails to connect to the ACS. The CPE considers a connection attempt as having failed when the close-wait timer expires. This timer starts when the CPE sends an Inform request. If the CPE fails to receive a response before the timer expires, the CPE resends the Inform request.
- The connection is disconnected before the session on the connection is completed.

To protect system resources, limit the number of retries that the CPE can make to connect to the ACS.

Configuring the periodic Inform feature

1. Enter system view.
   `system-view`
2. Enter CWMP view.
   `cwmp`
3. Enable the periodic Inform feature.
   `cwmp cpe inform interval enable`
   By default, this function is disabled.
4. Set the Inform interval.
   `cwmp cpe inform interval` *`interval`*
   By default, the CPE sends an Inform message to start a session every 600 seconds.

Scheduling a connection initiation

1. Enter system view.
   `system-view`
2. Enter CWMP view.
   `cwmp`
3. Schedule a connection initiation.
   `cwmp cpe inform time` *`time`*
   By default, no connection initiation has been scheduled.

Setting the maximum number of connection retries

1. Enter system view.
   `system-view`
2. Enter CWMP view.
   `cwmp`
3. Set the maximum number of connection retries.
   `cwmp cpe connect retry` *`retries`*
   By default, the CPE retries a failed connection until the connection is established.

Setting the close-wait timer

About this task

The close-wait timer specifies the following:

- The maximum amount of time the CPE waits for the response to a session request. The CPE determines that its session attempt has failed when the timer expires.
- The amount of time the connection to the ACS can be idle before it is terminated. The CPE terminates the connection to the ACS if no traffic is sent or received before the timer expires.

Procedure

1. Enter system view.
   `system-view`
2. Enter CWMP view.
   `cwmp`
3. Set the close-wait timer.
   `cwmp cpe wait timeout` *`seconds`*
   By default, the close-wait timer is 30 seconds.

Enabling NAT traversal for the CPE

About this task

For the connection request initiated from the ACS to reach the CPE, you must enable NAT traversal on the CPE when a NAT gateway resides between the CPE and the ACS.

The NAT traversal feature complies with RFC 3489 Simple Traversal of UDP Through NATs (STUN). The feature enables the CPE to discover the NAT gateway, and obtain an open NAT binding (a public IP address and port binding) through which the ACS can send unsolicited packets. The CPE sends the binding to the ACS when it initiates a connection to the ACS. For the connection requests sent by the ACS at any time to reach the CPE, the CPE maintains the open NAT binding.

Procedure

1. Enter system view.
   `system-view`
2. Enter CWMP view.
   `cwmp`
3. Enable NAT traversal.
   `cwmp cpe stun enable`
   By default, NAT traversal is disabled on the CPE.

Display and maintenance commands for CWMP

Execute **`display`** commands in any view.

Task	Command
Display CWMP configuration.	**`display cwmp configuration`**
Display the current status of CWMP.	**`display cwmp status`**

CWMP configuration examples

Example: Configuring CWMP

Network configuration

As shown in Figure 4, use H3C IMC BIMS as the ACS to bulk-configure the devices (CPEs), and assign ACS attributes to the CPEs from the DHCP server.

The configuration files for the CPEs in equipment rooms A and B are **configure1.cfg** and **configure2.cfg**, respectively.

Figure 4 Network diagram

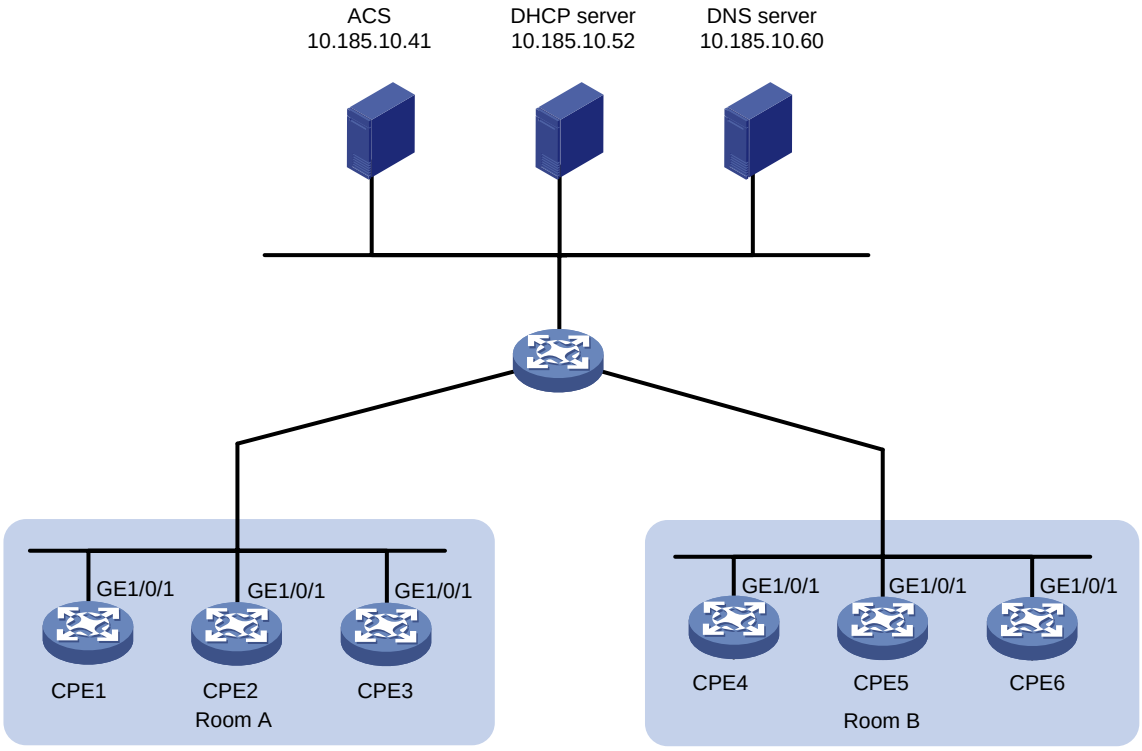


Table 4 shows the ACS attributes for the CPEs to connect to the ACS.

Table 4 ACS attributes

Item	Setting
Preferred ACS URL	https://10.185.10.41:9090
ACS username	admin
ACS password	12345

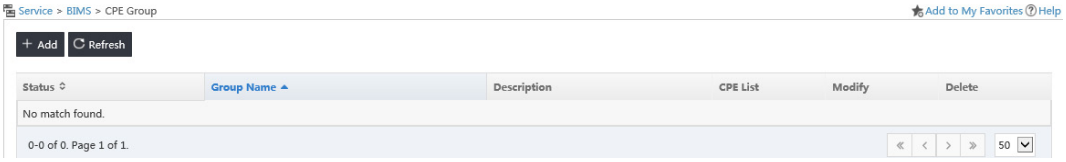
Table 5 lists serial numbers of the CPEs.

Table 5 CPE list

Room	Device	Serial number
A	CPE 1	210231A95YH10C000045
	CPE 2	210235AOLNH12000010

Room	Device	Serial number
	CPE 3	210235AOLNH12000015
B	CPE 4	210235AOLNH12000017
	CPE 5	210235AOLNH12000020
	CPE 6	210235AOLNH12000022

Configuring the ACS



Figures in this section are for illustration only.

To configure the ACS:

1. Log in to the ACS:
   a. Launch a Web browser on the ACS configuration terminal.
   b. In the address bar of the Web browser, enter the ACS URL and port number. This example uses **https://10.185.10.41:8080/imc**.
   c. On the login page, enter the ACS login username and password, and then click **Login**.
2. Create a CPE group for each equipment room:
   a. Select **Service** > **BIMS** > **CPE Group** from the top navigation bar.

      The **CPE Group** page appears.

      Figure 5 CPE Group page

   b. Click **Add**.
   c. Enter a username, and then click **OK**.

      Figure 6 Adding a CPE group

   d. Repeat the previous two steps to create a CPE group for CPEs in Room B.
3. Add CPEs to the CPE group for each equipment room:
   a. Select **Service** > **BIMS** > **Resource Management** > **Add CPE** from the top navigation bar.
   b. On the **Add CPE** page, configure the following parameters:
      - **Authentication Type**—Select **ACS UserName**.
      - **CPE Name**—Enter a CPE name.
      - **ACS Username**—Enter **admin**.
      - **ACS Password Generated**—Select **Manual Input**.

- **ACS Password**—Enter a password for ACS authentication.
- **ACS Confirm Password**—Re-enter the password.
- **CPE Model**—Select the CPE model.
- **CPE Group**—Select the CPE group.

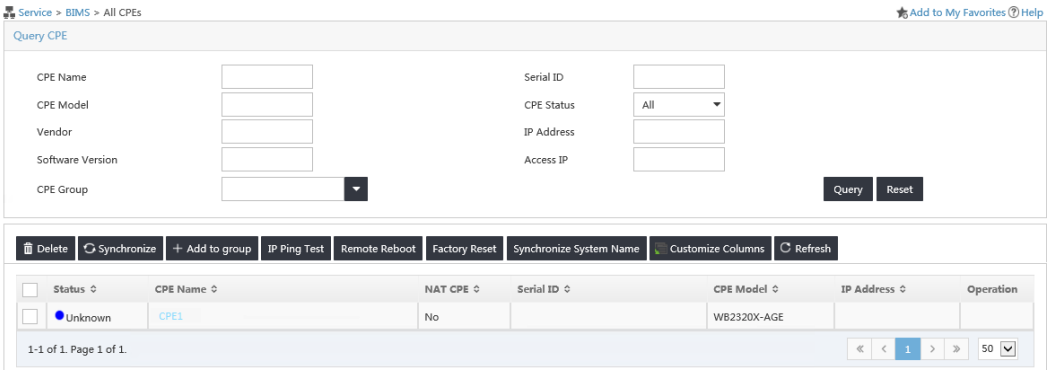


Figure 7 Adding a CPE

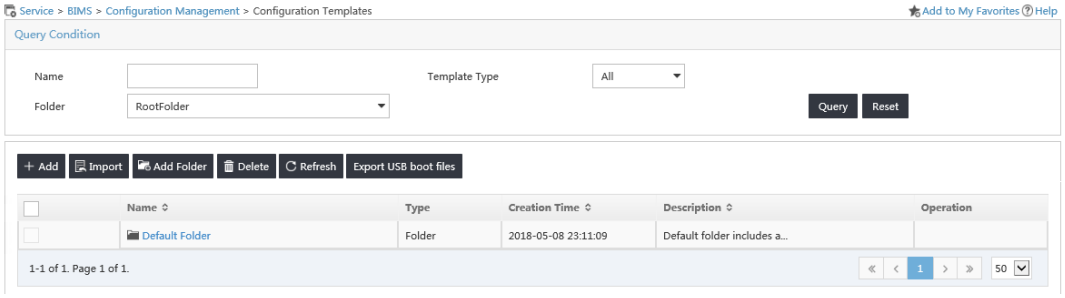
c. Click **OK**.

d. Verify that the CPE has been added successfully from the **All CPEs** page.

Figure 8 Viewing CPEs



e. Repeat the previous steps to add CPE 2 and CPE 3 to the CPE group for Room A, and add CPEs in Room B to the CPE group for Room B.

4. Configure a configuration template for each equipment room:

a. Select **Service** > **BIMS** > **Configuration Management** > **Configuration Templates** from the top navigation bar.

Figure 9 Configuration Templates page

b. Click **Import**.

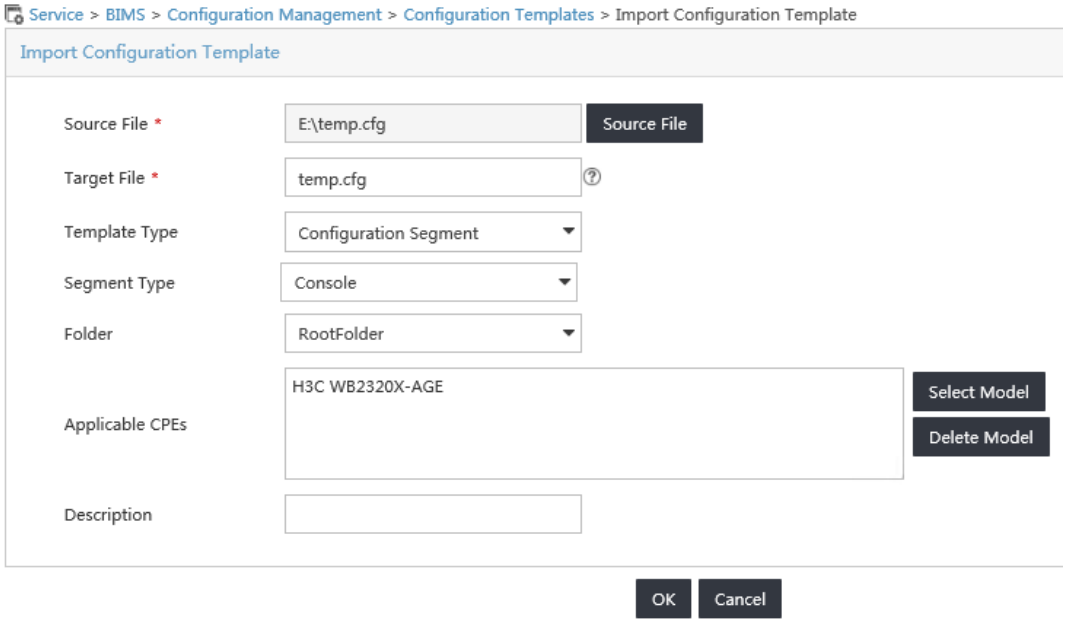
c. Select a source configuration file, select **Configuration Segment** as the template type, and then click **OK**.

The created configuration template will be displayed in the **Configuration Template** list after a successful file import.

IMPORTANT:

If the first command in the configuration template file is **`system-view`**, make sure no characters exist in front of the command.

Figure 10 Importing a configuration template



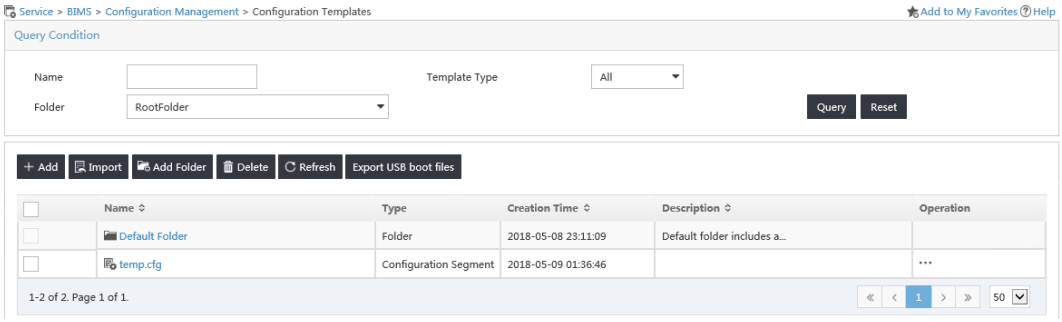


Figure 11 Configuration Template list

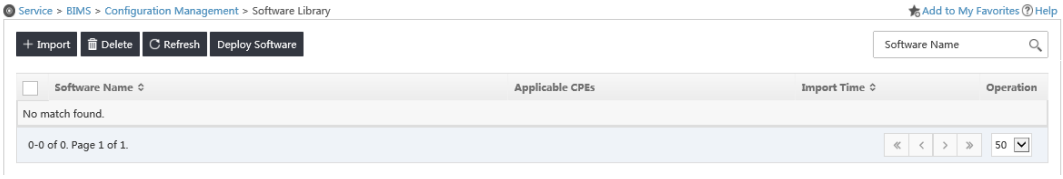

d. Repeat the previous steps to configure a configuration template for Room B.

5. Add software library entries:

a. Select **Service** > **BIMS** > **Configuration Management** > **Software Library** from the top navigation bar.

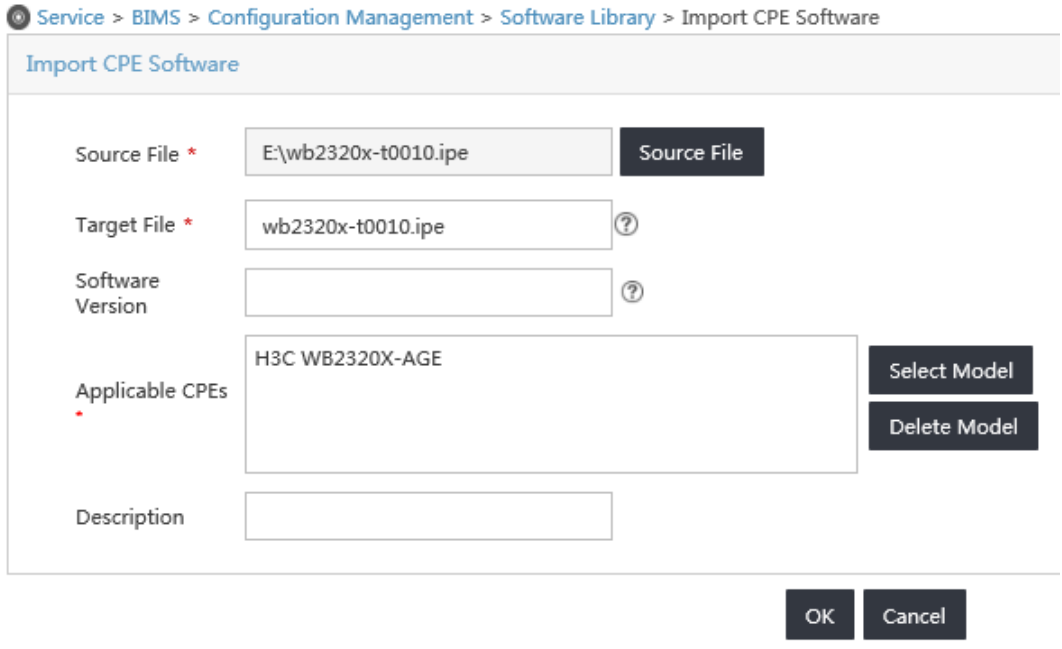

Figure 12 Software Library page

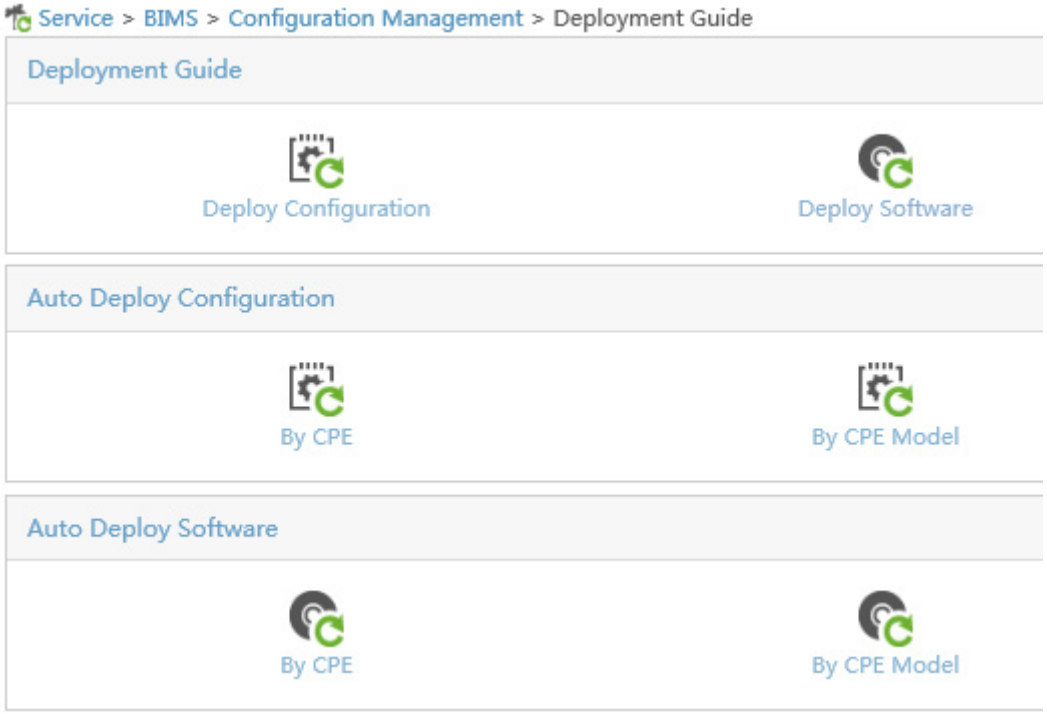
b. Click **Import**.

c. Select a source file, and then click **OK**.

Figure 13 Importing CPE software

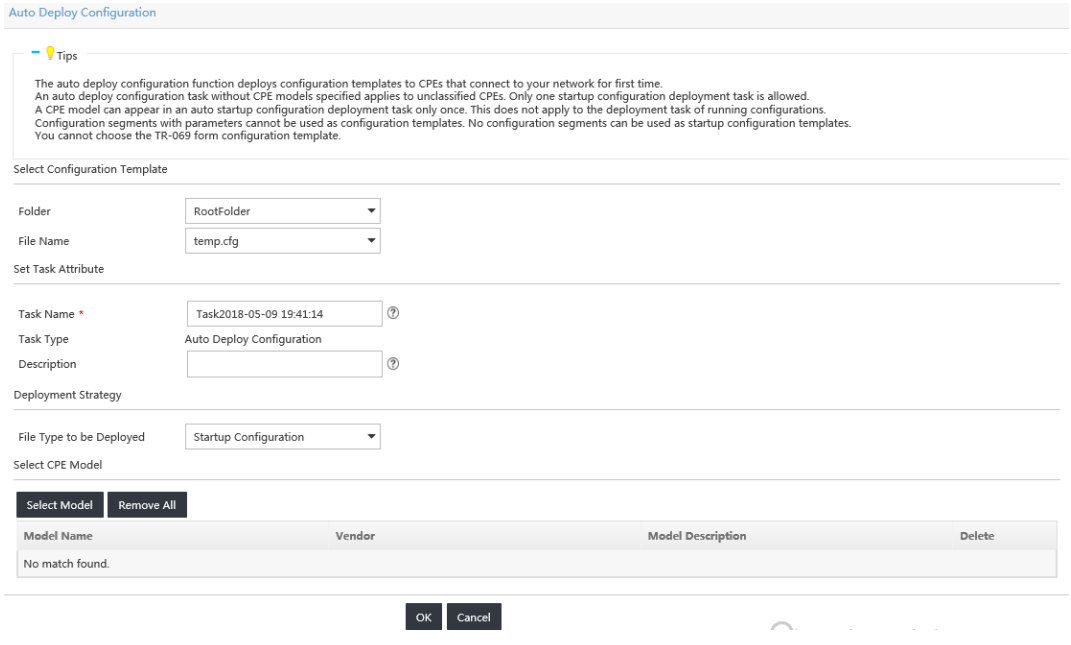


d. Repeat the previous steps to add software library entries for CPEs of different models.

6. Create an auto-deployment task for each equipment room:

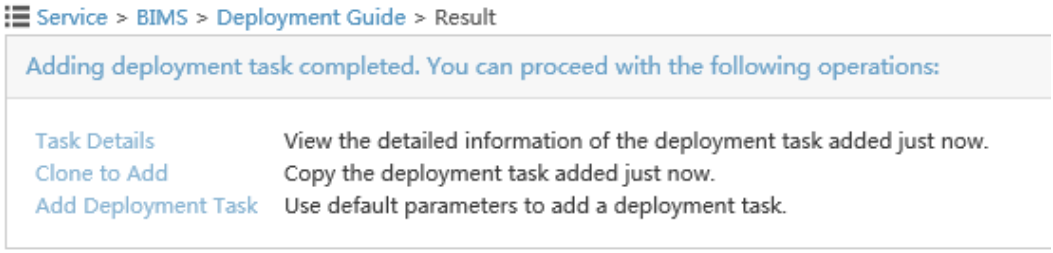
a. Select **Service** > **BIMS** > **Configuration Management** > **Deployment Guide** from the top navigation bar.

Figure 14 Deployment Guide



b. Click **By CPE Model** from the **Auto Deployment Configuration** field.

c. Select a configuration template, select **Startup Configuration** from the **File Type to be Deployed** list, and click **Select Model** to select CPEs in Room A. Then, click **OK**.



You can search for CPEs by CPE group.

Figure 15 Auto deployment configuration

d. Click **OK** on the **Auto Deploy Configuration** page.

Figure 16 Operation result

e. Repeat the previous steps to add a deployment task for CPEs in Room B.

Configuring the DHCP server

In this example, an H3C device is operating as the DHCP server.

1. Configure an IP address pool to assign IP addresses and DNS server address to the CPEs. This example uses subnet 10.185.10.0/24 for IP address assignment.

Enable DHCP.

```
<DHCP_server> system-view
[DHCP_server] dhcp enable
```

Enable DHCP server on VLAN-interface 1.

```
[DHCP_server] interface vlan-interface 1
[DHCP_server-Vlan-interface1] dhcp select server
[DHCP_server-Vlan-interface1] quit
```

Exclude the DNS server address 10.185.10.60 and the ACS IP address 10.185.10.41 from dynamic allocation.

```
[DHCP_server] dhcp server forbidden-ip 10.185.10.41
[DHCP_server] dhcp server forbidden-ip 10.185.10.60
```

Create DHCP address pool 0.

```
[DHCP_server] dhcp server ip-pool 0
```

Assign subnet 10.185.10.0/24 to the address pool, and specify the DNS server address 10.185.10.60 in the address pool.

```
[DHCP_server-dhcp-pool-0] network 10.185.10.0 mask 255.255.255.0
[DHCP_server-dhcp-pool-0] dns-list 10.185.10.60
```

2. Configure DHCP Option 43 to contain the ACS URL, username, and password in hexadecimal format.

```
[DHCP_server-dhcp-pool-0] option 43 hex
013B68747470733A2F2F6163732E6461746162617365 3A393039302F6163732076696 36B7920313233
33435
```

Configuring the DNS server

Map https://acs.database:9090 to https://10.185.1.41:9090 on the DNS server. For more information about DNS configuration, see DNS server documentation.

Connecting the CPEs to the network

Connect CPE 1 to the network, and then power on the CPE. (Details not shown.)

Log in to CPE 1 and configure its VLAN-interface 2 to use DHCP for IP address acquisition and assign interface GigabitEthernet 1/0/1 to VLAN 2.

```
<CPE1> system-view
[CPE1] vlan 2
[CPE1-vlan2] quit
```

```
[CPE1] interface gigabitethernet 1/0/1
[CPE1-GigabitEthernet1/0/1] port access vlan 2
[CPE1-GigabitEthernet1/0/1] quit
[CPE1] interface vlan-interface 2
[CPE1-Vlan-interface2] ip address dhcp-alloc
```

Repeat the previous steps to configure the other CPEs.

Verifying the configuration

Execute the **display current-configuration** command to verify that the running configurations on CPEs are the same as the configurations issued by the ACS.

Restrictions and guidelines: CWMP ACS configuration

To avoid ACS and CPE conflicts, do not configure both ACS and CPE features on the same device.

Configuring ACS authentication parameters

About this task

Application scenarios

CWMP supports mutual authentication. When the ACS initiates a connection with a CPE, the CPE can authenticate the ACS. When a CPE initiates a connection with the ACS, the ACS can authenticate the CPE. Perform this task to configure CPEs to authenticate the ACS.

Operating mechanism

When the ACS initiates a CWMP connection with a CPE, the ACS sends the username or username + password to the CPE for authentication. The CPE verifies whether the ACS is legal based on the configured username and password in this feature. If the authentication succeeds, the CWMP connection is established. If the authentication fails, the CWMP connection cannot be established.

Restrictions and guidelines

By default, CPEs do not authenticate the ACS. For the CPE to successfully authenticate the ACS, make sure the ACS and CPEs are configured with the same authentication parameters.

Procedure

1. Enter system view.
   system-view
2. Enter CWMP view.
   cwmp
3. Configure the username for the CPE to authenticate the ACS.
   cwmp cpe username *username*
   By default, no username has been configured for a CPE to authenticate the ACS.
4. (Optional.) Configure the password for the CPE to authenticate the ACS.
   cwmp cpe password { **cipher** | **simple** } *string*
   By default, no password has been configured for a CPE to authenticate the ACS.
   The password setting is optional. You can specify only a username for authentication.

About CWMP CPEs

After you configure a device as a CWMP CPE, the device automatically initiates a CWMP connection to the ACS. The ACS can manage the CPE through the connection.

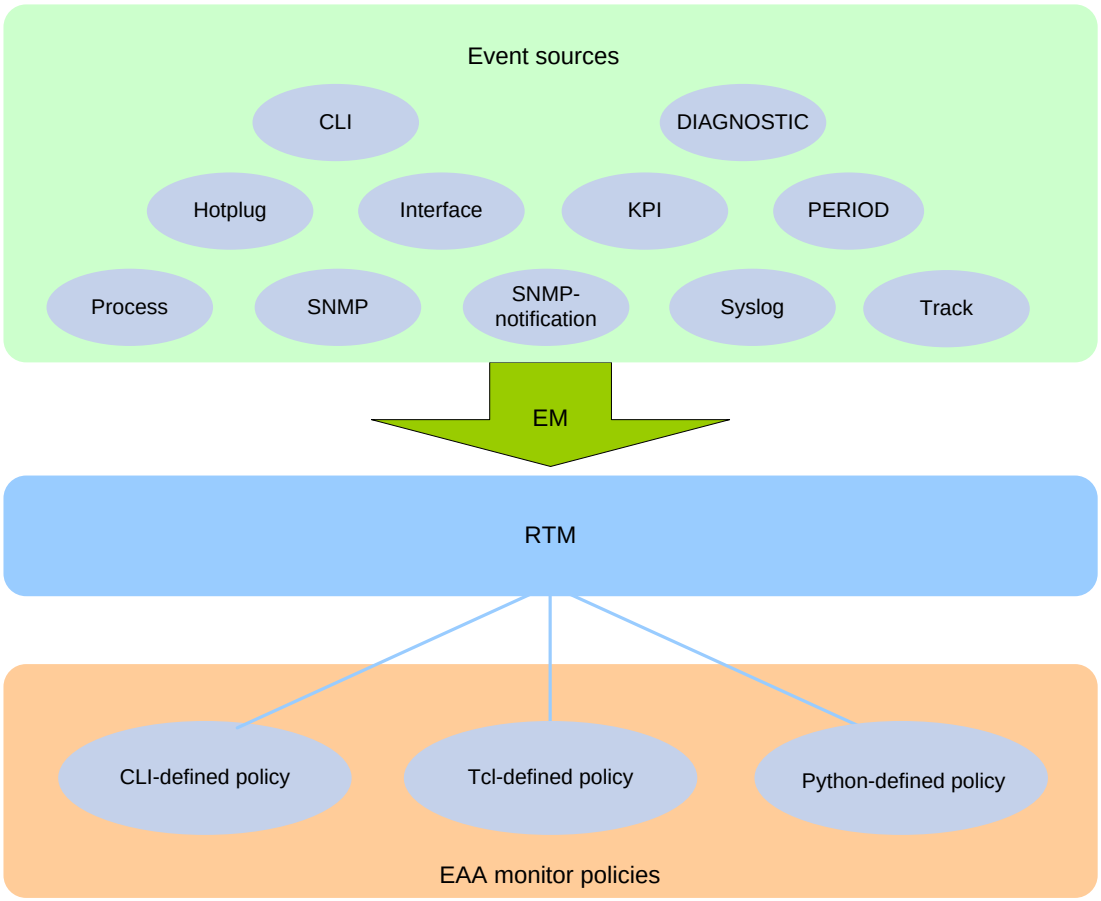
Configuring EAA



About EAA

Embedded Automation Architecture (EAA) is a monitoring framework that enables you to self-define monitored events and actions to take in response to an event. It allows you to create monitor policies by using the CLI or Tcl scripts.

EAA framework

EAA framework includes a set of event sources, a set of event monitors, a real-time event manager (RTM), and a set of user-defined monitor policies, as shown in Figure 1.

Figure 1 EAA framework

Event sources

Event sources are software or hardware modules that trigger events (see EAA framework).

For example, the CLI module triggers an event when you enter a command. The Syslog module (the information center) triggers an event when it receives a log message.

Event monitors

EAA creates one event monitor to monitor the system for the event specified in each monitor policy. An event monitor notifies the RTM to run the monitor policy when the monitored event occurs.

RTM

RTM manages the creation, state machine, and execution of monitor policies.

EAA monitor policies

A monitor policy specifies the event to monitor and actions to take when the event occurs.

The following types of EAA monitor policies are available:

- **CLI-defined EAA monitor policy**—Policy configured from the CLI.
- **Tcl-defined EAA monitor policy**—Policy defined by a Tcl script.
- **Python-defined EAA monitor policy**—Policy defined by a Python script.

Elements in a monitor policy

Elements in an EAA monitor policy include event, action, user role, and runtime.

Event

Table 1 shows types of events that EAA can monitor.

Table 1 Monitored events

Event type	Description
CLI	CLI event occurs in response to monitored operations performed at the CLI. For example, a command is entered, a question mark (?) is entered, or the **Tab** key is pressed to complete a command.
Hotplug	Hot-swapping event occurs when the monitored member device joins or leaves the IRF fabric.
Interface	Each interface event is associated with two user-defined thresholds: start and restart. An interface event occurs when the monitored interface traffic statistic crosses the start threshold in the following situations: • The statistic crosses the start threshold for the first time. • The statistic crosses the start threshold each time after it crosses the restart threshold.
period	Periodic event occurs when the specified interval expires.
process	Process event occurs in response to a state change of the monitored process (such as an exception, shutdown, start, or restart). Both manual and automatic state changes can cause the event to occur.
SNMP	Each SNMP event is associated with two user-defined thresholds: start and restart. SNMP event occurs when the monitored MIB variable's value crosses the start threshold in the following situations: • The monitored variable's value crosses the start threshold for the first time. • The monitored variable's value crosses the start threshold each time after it crosses the restart threshold.
SNMP-Notification	SNMP-Notification event occurs when the monitored MIB variable's value in an SNMP notification matches the specified condition. For example, the broadcast traffic rate on an Ethernet interface reaches or exceeds 30%.
Syslog	Syslog event occurs when the information center receives the monitored log within a specific period. NOTE: The log that is generated by the EAA RTM does not trigger the monitor policy to run.
Track	Track event occurs when the state of the track entry changes from Positive to Negative or from Negative to Positive. If you specify multiple track entries for a policy, EAA triggers the policy only when the state of all the track entries changes from Positive

Event type	Description
	(Negative) to Negative (Positive). If you set a suppress time for a policy, the timer starts when the policy is triggered. The system does not process the messages that report the track entry state change from Positive (Negative) to Negative (Positive) until the timer times out.

Action

You can create a series of order-dependent actions to take in response to the event specified in the monitor policy.

The following are available actions:

- Executing a command.
- Sending an email.
- Executing a reboot without saving the running configuration.
- Enabling an active/standby switchover.
- Sending a log.

User role

For EAA to execute an action in a monitor policy, you must assign the policy the user role that has access to the action-specific commands and resources. If EAA lacks access to an action-specific command or resource, EAA does not perform the action and all the subsequent actions.

For example, a monitor policy has four actions numbered from 1 to 4. The policy has user roles that are required for performing actions 1, 3, and 4. However, it does not have the user role required for performing action 2. When the policy is triggered, EAA executes only action 1.

For more information about user roles, see RBAC in *Fundamentals Configuration Guide*.

Runtime

The runtime limits the amount of time that the monitor policy runs its actions from the time it is triggered. This setting prevents a policy from running its actions permanently to occupy resources.

EAA environment variables

EAA environment variables decouple the configuration of action arguments from the monitor policy so you can modify a policy easily.

An EAA environment variable is defined as a <*variable_name variable_value*> pair and can be used in different policies. When you define an action, you can enter a variable name with a leading dollar sign (**$***variable_name*). EAA will replace the variable name with the variable value when it performs the action.

To change the value for an action argument, modify the value specified in the variable pair instead of editing each affected monitor policy.

EAA environment variables include system-defined variables and user-defined variables.

System-defined variables

System-defined variables are provided by default, and they cannot be created, deleted, or modified by users. System-defined variable names start with an underscore (_) sign. The variable values are set automatically depending on the event setting in the policy that uses the variables.

System-defined variables include the following types:

- **Public variable**—Available for any events.

- **Event-specific variable**—Available only for a type of event. For example, the CLI event-specific variable is _cmd. When an CLI event is triggered, the value of _cmd is the command line matching the monitor policy.

Table 2 shows all system-defined variables.

Table 2 System-defined EAA environment variables by event type

Event	Variable name and description
Any event	_event_id: Event ID. _event_type: Event type. _event_type_string: Event type description. _event_time: Time when the event occurs. _event_severity: Severity level of an event.
CLI	_cmd: Commands that are matched.
Hotplug	_slot: ID of the member device that joins or leaves the IRF fabric
Interface	_ifname: Interface name.
Period	_period_value: Interval.
Process	_process_name: Process name.
SNMP	_oid: OID of the MIB variable where an SNMP operation is performed. _oid_value: Value of the MIB variable.
SNMP-Notification	_oid: OID that is included in the SNMP notification.
Syslog	_syslog_pattern: Log message content.

User-defined variables

You can use user-defined variables for all types of events.

User-defined variable names can contain digits, characters, and the underscore sign (_), except that the underscore sign cannot be the leading character.

Restrictions and guidelines

Make sure the actions in different policies do not conflict. Policy execution result will be unpredictable if policies that conflict in actions are running concurrently.

You can assign the same policy name to a CLI-defined policy, a Tcl-defined policy, or a Python-defined policy. However, you cannot assign the same name to policies that are the same type.

A monitor policy supports only one event and runtime. If you configure multiple events for a policy, the most recent one takes effect.

A monitor policy supports a maximum of 64 valid user roles. User roles added after this limit is reached do not take effect.

EAA tasks at a glance

To configure EAA, perform the following tasks:

- (Optional.) Configuring a user-defined EAA environment variable
- Perform one of the following tasks to configure an EAA policy:
  - Configuring a monitor policy from the CLI

    - Configuring a monitor policy by using Tcl
    - Configuring a monitor policy by using Python
- (Optional.) Suspending monitor policies

Configuring a user-defined EAA environment variable

About this task

Configure user-defined EAA environment variables so that you can use them when creating EAA monitor policies.

Procedure

1. Enter system view.
   system-view
2. Configure a user-defined EAA environment variable.
   rtm environment *var-name var-value*
   For the system-defined variables, see the system-defined EAA environment variables table in "System-defined variables."

Configuring a monitor policy from the CLI

Tasks at a glance

1. Creating a CLI-defined policy
2. (Optional.) Setting the size for the EAA-monitored log buffer
3. (Optional.) Configuring automatic email sending parameters
4. Configuring an event
5. Configuring an action
6. Assigning a user role to a CLI-defined policy
7. Configuring the policy action runtime
8. Enabling the CLI-defined monitor policy

Creating a CLI-defined policy

1. Enter system view.
   system-view
2. Create a CLI-defined policy and enter its view.
   rtm cli-policy *policy-name*

Setting the size for the EAA-monitored log buffer

About this task

This task is required only when a syslog event is specified for a CLI-defined policy.

After you specify and enable a syslog event EAA monitor policy, the system copies a log to the EAA-monitored log buffer upon generation of the log. The EAA module compares the log in the buffer with the log event. If they match, the monitor policy is triggered.

Under normal circumstances, you can use the default size setting for the EAA-monitored log buffer. However, when a feature is abnormal or multiple debugging functions are enabled, a large number of logs might be generated in a short time, causing some logs to be discarded before they are matched. In this case, you can increase the size of the EAA-monitored log buffer according to the device memory usage.

Procedure

1. Enter system view.

   `system-view`
2. Set the size for the EAA-monitored log buffer.

   `rtm event syslog buffer-size` *`buffer-size`*

   By default, the EAA-monitored log buffer can store a maximum of 50000 logs.

Configuring automatic email sending parameters

About this task

Automatic email sending allows EAA to generate and send an email of the specified content to the designated receivers when the specific event occurs. You can use this feature to collect and send device O & M information periodically to the administrators.

To enable email automatic sending, configure the following settings:

- Configure an event for the monitor policy (see "Configuring an event"). For example, execute the **`event period`** command to configure a periodic event.
- Configure automatic email sending parameters, including the email username, email password, and email server domain name.
- Configure actions for the monitor policy (see "Configuring an action").
  - Add a CLI action to the monitory policy to collect device O & M information. The information will be sent out by the email in an attachment file.
  - Add an email sending action to the monitor policy. You can specify the email receivers, subject, and content by using the **`action email`** command. Environment variables can be used in the email subject or content for the system to send traps or logs to the administrators.
- Assign a user role to the CLI-defined monitor policy (see "Assigning a user role to a CLI-defined policy").
- Configure the policy action runtime (see "Configuring the policy action runtime").
- Enable the CLI-defined monitor policy (see "Enabling the CLI-defined monitor policy").

Restrictions and guidelines

As a best practice, pay attention only to important alarms and O & M data, and control the email sending frequency within the acceptable range (typically a maximum of 100 emails per minute). If the mail sending frequency exceeds the acceptable range of the email server, the emails generated after the limit is reached will fail to be sent.

Procedure

1. Enter system view.

   `system-view`
2. Specify the email server domain name.

   `rtm email domain` *`domain-name`*

By default, no email server domain name exists.

3. Specify the email username and password.

   rtm email username *username* **password** { **cipher** | **simple** } *password*

   By default, no email username or password exists.

   For successful email sending, make sure the email username and password are consistent with those registered with the email server.

4. Set the maximum email size.

   rtm email max-size *size*

   By default, the maximum email size is 2 MB.

   For an email to be sent, make sure the email size does not exceed the value set by this command and the maximum email size specified on the email server.

Configuring an event

Restrictions and guidelines

A monitor policy supports only one event. If you configure multiple events for a policy, the most recent one takes effect.

Procedure

1. Enter system view.

   system-view

2. Create a CLI-defined policy and enter its view.

   rtm cli-policy *policy-name*

3. Configure an event for the policy. Choose one option as needed:

   - Configure a CLI event.

     event cli { **async** [**skip**] | **sync** } **mode** { **execute** | **help** | **tab** } **pattern** *regular-exp*

   - Configure a hotplug event.

     event hotplug [**insert** | **remove**] **slot** *slot-number*

   - Configure an interface event.

     event interface *interface-list* **monitor-obj** *monitor-obj* **start-op** *start-op* **start-val** *start-val* **restart-op** *restart-op* **restart-val** *restart-val* [**interval** *interval*]

   - Configure a periodic event.

     event period *interval*

     For the actions of a periodic event monitor policy to be executed completely, the interval configured for the periodic event must be equal to or larger than the action running time.

   - Configure a process event.

     event process { **exception** | **restart** | **shutdown** | **start** } [**name** *process-name* [**instance** *instance-id*]] [**slot** *slot-number*]

   - Configure an SNMP event.

     event snmp oid *oid* **monitor-obj** { **get** | **next** } **start-op** *start-op* **start-val** *start-val* **restart-op** *restart-op* **restart-val** *restart-val* [**interval** *interval*]

   - Configure an SNMP-Notification event.

     event snmp-notification oid *oid* **oid-val** *oid-val* **op** *op* [**drop**]

- Configure a Syslog event.

  event syslog priority { *priority* | **all** } **msg** *msg* **occurs** *times* **period** *period*

- Configure a track event.

  event track *track-list* **state { negative**|**positive** }[**suppress-time** *suppress-time*]

By default, a monitor policy does not contain an event.

Configuring an action

Restrictions and guidelines

You can configure a series of actions to be executed in response to the event specified in a monitor policy. EAA executes the actions in ascending order of action IDs. When you add actions to a policy, you must make sure the execution order is correct. If two actions have the same ID, the most recent one takes effect.

Procedure

1. Enter system view.

   system-view

2. Create a CLI-defined policy and enter its view.

   rtm cli-policy *policy-name*

3. Configure the actions to take when the event occurs. Choose the options to configure as needed:

   - Configure a CLI action.

     action *number* **cli** *command-line*

   - Configure an email sending action.

     action *number* **email receiver** *rx-list* **subject** *subject* [**content** *content*]

   - Configure a reboot action.

     action *number* **reboot** [**slot** *slot-number*]

   - Configure an active/standby switchover action.

     action *number* **switchover**

   - Configure a logging action.

     action *number* **syslog priority** *priority* **facility** *local-number* **msg** *msg-body*

   By default, a monitor policy does not contain any actions.

Assigning a user role to a CLI-defined policy

Restrictions and guidelines

An EAA policy cannot have both the **security-audit** user role and any other user roles. Any previously assigned user roles are automatically removed when you assign the **security-audit** user role to the policy. The previously assigned **security-audit** user role is automatically removed when you assign any other user roles to the policy.

Procedure

1. Enter system view.

   system-view

2. Create a CLI-defined policy and enter its view.
   rtm cli-policy *policy-name*
3. (Optional.) Assign a user role to the policy.
   user-role *role-name*
   By default, a monitor policy contains user roles that its creator had at the time of policy creation.

Configuring the policy action runtime

Restrictions and guidelines

For the actions of a periodic event monitor policy to be executed completely, the action runtime must be equal to or smaller than the interval specified for the periodic event.

Procedure

1. Enter system view.
   system-view
2. Create a CLI-defined policy and enter its view.
   rtm cli-policy *policy-name*
3. (Optional.) Configure the policy action runtime.
   running-time *time*
   The default policy action runtime is 20 seconds.
   If you configure multiple action runtimes for a policy, the most recent one takes effect.

Enabling the CLI-defined monitor policy

About this task

A CLI-defined monitor policy takes effect only after you enable it.

Procedure

1. Enter system view.
   system-view
2. Create a CLI-defined policy and enter its view.
   rtm cli-policy *policy-name*
3. Enable the CLI-defined policy.
   commit

Configuring a monitor policy by using Tcl

About this task

A Tcl script contains two parts: Line 1 and the other lines.

- Line 1
  Line 1 defines the event, user roles, and policy action runtime. After you create and enable a Tcl monitor policy, the device immediately parses, delivers, and executes Line 1.
  Line 1 must use the following format:
  ::platformtools::rtm::event_register *event-type arg1 arg2 arg3* ... **user-role** *role-name1* | [**user-role** *role-name2* | [...]] [**running-time** *running-time*]

- The *arg1 arg2 arg3* … arguments represent event matching rules. If an argument value contains spaces, use double quotation marks ("") to enclose the value. For example, "a b c."
- The configuration requirements for the *event-type*, *user-role*, and *running-time* arguments are the same as those for a CLI-defined monitor policy.

- The other lines

  From the second line, the Tcl script defines the actions to be executed when the monitor policy is triggered. You can use multiple lines to define multiple actions. The system executes these actions in sequence. The following actions are available:

  - Standard Tcl commands.
  - EAA-specific Tcl actions:
    - switchover (**::platformtools::rtm::action switchover**)
    - syslog (**::platformtools::rtm::action syslog priority** *priority* **facility** *local-number* **msg** *msg-body*). For more information about these arguments, see EAA commands in *Network Management and Monitoring Command Reference*.
  - Commands supported by the device.

Restrictions and guidelines

To revise the Tcl script of a policy, you must suspend all monitor policies first, and then resume the policies after you finish revising the script. The system cannot execute a Tcl-defined policy if you edit its Tcl script without first suspending these policies.

Procedure

1. Download the Tcl script file to the device by using FTP or TFTP.

   For more information about using FTP and TFTP, see *Fundamentals Configuration Guide*.
2. Create and enable a Tcl monitor policy.

   a. Enter system view.

   system-view

   b. Create a Tcl-defined policy and bind it to the Tcl script file.

   rtm tcl-policy *policy-name tcl-filename*

   By default, no Tcl policies exist.

   Make sure the script file is saved on all IRF member devices. This practice ensures that the policy can run correctly after a master/subordinate switchover occurs or the member device where the script file resides leaves the IRF.

Configuring a monitor policy by using Python

About this task

A Python script contains two parts: Line 1 and the other lines.

- Line 1

  Line 1 defines the event, user roles, and policy action runtime. After you create and enable a Python monitor policy, the device immediately parses, delivers, and executes Line 1.

  Line 1 must use the following format:

  ::comware::rtm::event_register *event-type arg1 arg2 arg3* … **user-role** *role-name1* | [**user-role** *role-name2* | […]] [**running-time** *running-time*]

  - The *arg1 arg2 arg3* … arguments represent event matching rules. If an argument value contains spaces, use double quotation marks ("") to enclose the value. For example, "a b c."

- The configuration requirements for the *event-type*, *user-role*, and *running-time* arguments are the same as those for a CLI-defined monitor policy.

- The other lines

  From the second line, the Python script defines the actions to be executed when the monitor policy is triggered. For the Python APIs supported by the device, see Python configuration in *Network Programmability Configuration Guide*.

Restrictions and guidelines

To revise the Python script of a policy, you must suspend the policy first, and then resume the policy after you finish revising the script. The system cannot execute a Python-defined policy if you edit its Python script without first suspending it.

Procedure

1. Download the Python script file to the device by using FTP or TFTP.

   For more information about using FTP and TFTP, see *Fundamentals Configuration Guide*.

2. Create and enable a Python monitor policy.

   a. Enter system view.

   system-view

   b. Create a Python-defined policy and bind it to the Python script file.

   rtm tcl-policy *policy-name tcl-filename*

   By default, no Python policies exist.

   Make sure the script file is saved on all IRF member devices. This practice ensures that the policy can run correctly after a master/subordinate switchover occurs or the member device where the script file resides leaves the IRF.

Suspending monitor policies

About this task

This task suspends all CLI-defined and Tcl-defined monitor policies. If a policy is running when you perform this task, the system suspends the policy after it executes all the actions.

Restrictions and guidelines

To restore the operation of the suspended policies, execute the **undo rtm scheduler suspend** command.

Procedure

1. Enter system view.

   system-view

2. Suspend monitor policies.

   rtm scheduler suspend

Display and maintenance commands for EAA

Execute **display** commands except for the **display this** command in any view.

Task	Command
Display the running configuration of all CLI-defined monitor policies.	**display current-configuration**

Task	Command
Display user-defined EAA environment variables.	**display rtm environment** [*var-name*]
Display EAA monitor policies.	**display rtm policy** { **active** | **registered** [**verbose**] } [*policy-name*]
Display history execution records for EAA monitor policies.	**display rtm policy history** [*policy-name*]
Display the running configuration of a CLI-defined monitor policy in CLI-defined monitor policy view.	**display this**

EAA configuration examples

Example: Configuring a CLI event monitor policy by using Tcl

Network configuration

As shown in Figure 2, use Tcl to create a monitor policy on the Device. This policy must meet the following requirements:

- EAA sends the log message "rtm_tcl_test is running" when a command that contains the **display this** string is entered.
- The system executes the command only after it executes the policy successfully.

Figure 2 Network diagram

Procedure

Edit a Tcl script file (rtm_tcl_test.tcl, in this example) for EAA to send the message "rtm_tcl_test is running" when a command that contains the **display this** string is executed.

```
::platformtools::rtm::event_register cli sync mode execute pattern display this
user-role network-admin
::platformtools::rtm::action syslog priority 1 facility local4 msg rtm_tcl_test is
running
```

Download the Tcl script file from the TFTP server at **1.2.1.1**.

```
<Sysname> tftp 1.2.1.1 get rtm_tcl_test.tcl
```

Create Tcl-defined policy **test** and bind it to the Tcl script file.

```
<Sysname> system-view
[Sysname] rtm tcl-policy test rtm_tcl_test.tcl
[Sysname] quit
```

Verifying the configuration

Execute the **display rtm policy registered** command to verify that a Tcl-defined policy named **test** is displayed in the command output.

```
<Sysname> display rtm policy registered
Total number: 1
```

```
Type  Event             TimeRegistered       PolicyName
TCL   CLI               Aug 01 09:47:12 2019 test
```

Enable the information center to output log messages to the current monitoring terminal.

```
<Sysname> terminal monitor
The current terminal is enabled to display logs.
<Sysname> system-view
[Sysname] info-center enable
Information center is enabled.
[Sysname] quit
```

Execute the **display this** command. Verify that the system displays an "rtm_tcl_test is running" message and a message that the policy is being executed successfully.

```
[Sysname] display this
%Aug  1 09:50:04:634 2019 Sysname RTM/1/RTM_ACTION: rtm_tcl_test is running
%Aug  1 09:50:04:636 2019 Sysname RTM/6/RTM_POLICY_SUCCESS: TCL policy test is running
successfully.
#
return
```

Example: Configuring a CLI event monitor policy from the CLI

Network configuration

Configure a policy from the CLI to monitor the event that occurs when a question mark (?) is entered at the command line that contains letters and digits.

When the event occurs, the system executes the command and sends the log message "hello world" to the information center.

Procedure

Create CLI-defined policy **test** and enter its view.

```
<Sysname> system-view
[Sysname] rtm cli-policy test
```

Add a CLI event that occurs when a question mark (?) is entered at any command line that contains letters and digits.

```
[Sysname-rtm-test] event cli async mode help pattern [a-zA-Z0-9]
```

Add an action that sends the message "hello world" with a priority of 4 from the logging facility **local3** when the event occurs.

```
[Sysname-rtm-test] action 0 syslog priority 4 facility local3 msg "hello world"
```

Add an action that enters system view when the event occurs.

```
[Sysname-rtm-test] action 2 cli system-view
```

Add an action that creates VLAN 2 when the event occurs.

```
[Sysname-rtm-test] action 3 cli vlan 2
```

Set the policy action runtime to 2000 seconds.

```
[Sysname-rtm-test] running-time 2000
```

Specify the **network-admin** user role for executing the policy.

```
[Sysname-rtm-test] user-role network-admin
```

Enable the policy.

```
[Sysname-rtm-test] commit
```

Verifying the configuration

Execute the **display rtm policy registered** command to verify that a CLI-defined policy named **test** is displayed in the command output.

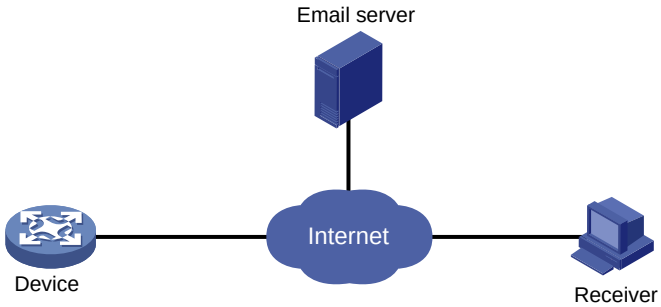
```
[Sysname-rtm-test] display rtm policy registered
Total number: 1
Type  Event      TimeRegistered       PolicyName
CLI   CLI        Aug  1 14:56:50 2019 test
```

Enable the information center to output log messages to the current monitoring terminal.

```
[Sysname-rtm-test] return
<Sysname> terminal monitor
The current terminal is enabled to display logs.
<Sysname> system-view
[Sysname] info-center enable
Information center is enabled.
[Sysname] quit
```

Enter a question mark (?) at a command line that contains a letter **d**. Verify that the system displays a "hello world" message and a message that the policy is being executed successfully on the terminal screen.

```
<Sysname> d?
  debugging
  delete
  diagnostic-logfile
  dir
  display



<Sysname>d%Aug  1 14:57:20:218 2019 Sysname RTM/4/RTM_ACTION: "hello world"
%Aug  1 14:58:11:170 2019 Sysname RTM/6/RTM_POLICY_SUCCESS: CLI policy test is running
successfully.
```

Configuring an automatic email sending action for a CLI-defined monitor policy

Network configuration

Configure a policy from the CLI to enable the system to send an email from a mailbox (username **test** and password **123**) to receivers test1@example.com and test2@example.com each hour to report brief interface information.

Figure 3 Network diagram

Procedure

Specify **example.com** as the email server domain name. Set the email username to **test** and password to **123**.

```
<Sysname> system-view
[Sysname] rtm email domain example.com
[Sysname] rtm email username test password simple 123
```

Create CLI-defined policy **test** and enter its view.

```
[Sysname] rtm cli-policy test
```

Create a periodic event and set the interval to 60 minutes.

```
[Sysname-rtm-test] event period 60
```

Add a CLI action to the policy, enabling the system to display brief interface information when the event occurs.

```
[Sysname-rtm-test] action 1 cli display interface brief
```

Add an email sending action to the policy, enabling the system to send an email with subject "**Interface information**", content "**This is the interface brief information.**", and an attachment file that contains brief interface information to test1@example.com and test2@example.com when the event occurs.

```
[Sysname-rtm-test] action 2 email receiver test1@example.com,test2@example.com subject
interface content "This is the interface brief information."
```

Enable the policy.

```
[Sysname-rtm-test] commit
```

Verifying the configuration

Execute the **display rtm policy registered** command to verify that a CLI-defined policy named **test** with event type **PERIOD** is displayed in the command output.

```
[Sysname-rtm-test] display rtm policy registered
Total number: 1
Type  Event      TimeRegistered       PolicyName
CLI   PERIOD     Sep 21 11:43:09 2019 test
```

Verify that the receivers receive the emails after the interval expires.

Verify that logs are output after the interval expires indicating that the device succeeded in sending the email and the policy was executed successfully.

```
[Sysname-rtm-test] return
<Sysname> terminal monitor
The current terminal is enabled to display logs.
<Sysname> system-view
[Sysname] info-center enable
Information center is enabled.
[Sysname] quit
<Sysname>%Sep 30 09:22:03:224 2020 Sysname RTM/6/RTM_EMAIL_SUCCESS: Succeed in sending
an email with the subject interface to test1@example.com,test2@example.com.
<Sysname>%Sep 30 09:22:03:237 2020 Sysname RTM/6/RTM_POLICY_SUCCESS: CLI policy test is
running successfully.
```

Example: Configuring a track event monitor policy from the CLI

Network configuration

As shown in Figure 4, Device A has established BGP sessions with Device D and Device E. Traffic from Device D and Device E to the Internet is forwarded through Device A.

Configure a CLI-defined EAA monitor policy on Device A to disconnect the sessions with Device D and Device E when GigabitEthernet 1/0/1 connected to Device C is down. In this way, traffic from Device D and Device E to the Internet can be forwarded through Device B.

Figure 4 Network diagram

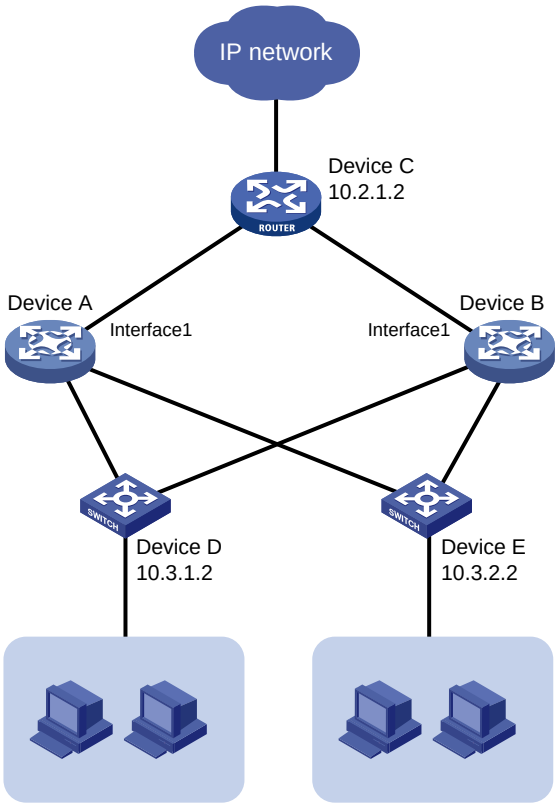


Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

Display BGP peer information for Device A.

```
<DeviceA> display bgp peer ipv4

 BGP local router ID: 1.1.1.1
 Local AS number: 100
 Total number of peers: 3                 Peers in established state: 3

  * - Dynamically created peer
```

```
  Peer                    AS  MsgRcvd  MsgSent OutQ PrefRcv Up/Down  State

  10.2.1.2                200       13       16    0       0 00:16:12 Established
  10.3.1.2                300       13       16    0       0 00:10:34 Established
  10.3.2.2                300       13       16    0       0 00:10:38 Established
```

Create track entry **1** and associate it with the link state of GigabitEthernet 1/0/1.

```
<Device A> system-view
[Device A] track 1 interface gigabitethernet 1/0/1
```

Configure a CLI-defined EAA monitor policy so that the system automatically disables session establishment with Device D and Device E when GigabitEthernet 1/0/1 is down.

```
[Device A] rtm cli-policy test
[Device A-rtm-test] event track 1 state negative
[Device A-rtm-test] action 0 cli system-view
[Device A-rtm-test] action 1 cli bgp 100
[Device A-rtm-test] action 2 cli peer 10.3.1.2 ignore
[Device A-rtm-test] action 3 cli peer 10.3.2.2 ignore
[Device A-rtm-test] user-role network-admin
[Device A-rtm-test] commit
[Device A-rtm-test] quit
```

Verifying the configuration

Shut down GigabitEthernet 1/0/1.

```
[Device A] interface gigabitethernet 1/0/1
[Device A-GigabitEthernet1/0/1] shutdown
```

Execute the **`display bgp peer ipv4`** command on Device A to display BGP peer information to verify that no peer exists in established state.

Example: Configuring a CLI event monitor policy with EAA environment variables from the CLI

Network configuration

Define an environment variable to match the IP address 1.1.1.1.

Configure a policy from the CLI to monitor the event that occurs when a command line that contains **loopback0** is executed. In the policy, use the environment variable for IP address assignment.

When the event occurs, the system performs the following tasks:

- Creates the Loopback 0 interface.
- Assigns 1.1.1.1/24 to the interface.
- Sends the matching command line to the information center.

Procedure

Configure an EAA environment variable for IP address assignment. The variable name is **loopback0IP**, and the variable value is **1.1.1.1**.

```
<Sysname> system-view
[Sysname] rtm environment loopback0IP 1.1.1.1
```

Create the CLI-defined policy **test** and enter its view.

```
[Sysname] rtm cli-policy test
```

Add a CLI event that occurs when a command line that contains **loopback0** is executed.

```
[Sysname-rtm-test] event cli async mode execute pattern loopback0
```

Add an action that enters system view when the event occurs.

```
[Sysname-rtm-test] action 0 cli system-view
```

Add an action that creates the interface Loopback 0 and enters loopback interface view.

```
[Sysname-rtm-test] action 1 cli interface loopback 0
```

Add an action that assigns the IP address 1.1.1.1 to Loopback 0. The **loopback0IP** variable is used in the action for IP address assignment.

```
[Sysname-rtm-test] action 2 cli ip address $loopback0IP 24
```

Add an action that sends the matching **loopback0** command with a priority of 0 from the logging facility **local7** when the event occurs.

```
[Sysname-rtm-test] action 3 syslog priority 0 facility local7 msg $_cmd
```

Specify the **network-admin** user role for executing the policy.

```
[Sysname-rtm-test] user-role network-admin
```

Enable the policy.

```
[Sysname-rtm-test] commit
[Sysname-rtm-test] return
<Sysname>
```

Verifying the configuration

Enable the information center to output log messages to the current monitoring terminal.

```
<Sysname> terminal monitor
The current terminal is enabled to display logs.
<Sysname> terminal log level debugging
<Sysname> system-view
[Sysname] info-center enable
Information center is enabled.
```

Execute the **loopback0** command. Verify that the system displays a "loopback0" message and a message that the policy is being executed successfully on the terminal screen.

```
[Sysname] interface loopback0
[Sysname-LoopBack0]%Aug  1 09:46:10:592 2019 Sysname RTM/7/RTM_ACTION: interface
loopback0
%Aug  1 09:46:10:613 2019 Sysname RTM/6/RTM_POLICY_SUCCESS: CLI policy test is running
successfully.
```

Verify that Loopback 0 has been created and its IP address is 1.1.1.1.

```
<Sysname-LoopBack0> display interface loopback brief
Brief information on interfaces in route mode:
Link: ADM - administratively down; Stby - standby
Protocol: (s) - spoofing
Interface            Link Protocol Primary IP         Description
Loop0                UP   UP(s)    1.1.1.1

<Sysname-LoopBack0>
```

Monitoring and maintaining processes

About monitoring and maintaining processes

The system software of the device is a full-featured, modular, and scalable network operating system based on the Linux kernel. The system software features run the following types of independent processes:

- **User process**—Runs in user space. Most system software features run user processes. Each process runs in an independent space so the failure of a process does not affect other processes. The system automatically monitors user processes. The system supports preemptive multithreading. A process can run multiple threads to support multiple activities. Whether a process supports multithreading depends on the software implementation.
- **Kernel thread**—Runs in kernel space. A kernel thread executes kernel code. It has a higher security level than a user process. If a kernel thread fails, the system breaks down. You can monitor the running status of kernel threads.

Process monitoring and maintenance tasks at a glance

To monitor and maintain processes, perform the following tasks:

- Monitoring and maintaining user processes
  - Monitoring and maintaining processes
  - The commands in this section apply to both user processes and kernel threads.
  - Monitoring and maintaining user processes

    The commands in this section apply only to user processes.
- Monitoring and maintaining kernel threads
  - Monitoring and maintaining processes
  - The commands in this section apply to both user processes and kernel threads.
  - Monitoring and maintaining kernel threads
  - The commands in this section apply only to kernel threads.

Monitoring and maintaining processes

About this task

The commands in this section apply to both user processes and kernel threads. You can use the commands for the following purposes:

- Display the overall memory usage.
- Display the running processes and their memory and CPU usage.
- Locate abnormal processes.

If a process consumes excessive memory or CPU resources, the system identifies the process as an abnormal process.

- If an abnormal process is a user process, troubleshoot the process as described in "Monitoring and maintaining user processes."

- If an abnormal process is a kernel thread, troubleshoot the process as described in "Monitoring and maintaining kernel threads."

Procedure

Execute the following commands in any view.

Task	Command
Display memory usage.	**display memory** [**summary**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display process state information.	**display process** [**all** | **job** *job-id* | **name** *process-name*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display CPU usage for all processes.	**display process cpu** [**slot** *slot-number* [**cpu** *cpu-number*]]
Monitor process running state.	**monitor process** [**dumbtty**] [**iteration** *number*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Monitor thread running state.	**monitor thread** [**dumbtty**] [**iteration** *number*] [**slot** *slot-number* [**cpu** *cpu-number*]]

For more information about the **display memory** command, see *Fundamentals Command Reference*.

Monitoring and maintaining user processes

About monitoring and maintaining user processes

Use this feature to monitor abnormal user processes and locate problems.

Configuring core dump

About this task

The core dump feature enables the system to generate a core dump file each time a process crashes until the maximum number of core dump files is reached. A core dump file stores information about the process. You can send the core dump files to H3C Support to troubleshoot the problems.

Restrictions and guidelines

Core dump files consume storage resources. Enable core dump only for processes that might have problems.

Procedure

Execute the following commands in user view:

1. (Optional.) Specify the directory for saving core dump files.

   exception filepath *directory*

   By default, the directory for saving core dump files is the root directory of the default file system. For more information about the default file system, see file system management in *Fundamentals Configuration Guide*.

2. Enable core dump for a process and specify the maximum number of core dump files, or disable core dump for a process.

   process core { **maxcore** *value* | **off** } { **job** *job-id* | **name** *process-name* }

By default, a process generates a core dump file for the first exception and does not generate any core dump files for subsequent exceptions.

Display and maintenance commands for user processes

Execute **display** commands in any view and other commands in user view.

Task	Command
Display context information for process exceptions.	**display exception context** [**count** *value*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display the core dump file directory.	**display exception filepath** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display log information for all user processes.	**display process log** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display memory usage for all user processes.	**display process memory** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display memory allocation failure information for a user process.	**display process memory alloc-failure job** *job-id* [**slot** *slot-number* [**cpu** *cpu-number*]]
Display heap memory usage for a user process.	**display process memory heap job** *job-id* [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display information about used memory blocks for a user process.	**display process memory fragment free job** *job-id* [**slot** *slot-number* [**cpu** *cpu-number*]]
Display heap memory usage for a user process.	**display process memory fragment used** *used-block* **job** *job-id* [**slot** *slot-number* [**cpu** *cpu-number*]]
Display memory content starting from a specified memory block for a user process.	**display process memory heap job** *job-id* **address** *starting-address* **length** *memory-length* [**slot** *slot-number* [**cpu** *cpu-number*]]
Display the addresses of memory blocks with a specified size used by a user process.	**display process memory heap job** *job-id* **size** *memory-size* [**offset** *offset-size*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Clear context information for process exceptions.	**reset exception context** [**slot** *slot-number* [**cpu** *cpu-number*]]

Monitoring and maintaining kernel threads

Configuring kernel thread deadloop detection

About this task

Kernel threads share resources. If a kernel thread monopolizes the CPU, other threads cannot run, resulting in a deadloop.

This feature enables the device to detect deadloops. If a thread occupies the CPU for a specific interval, the device determines that a deadloop has occurred and generates a deadloop message.

Restrictions and guidelines

CAUTION:

Change kernel thread deadloop detection settings only under the guidance of H3C Support. Inappropriate configuration can cause system breakdown. As a best practice, leave the default unchanged.

Procedure

1. Enter system view.

   system-view

2. Enable kernel thread deadloop detection.

   monitor kernel deadloop enable [**slot** *slot-number* [**cpu** *cpu-number* [**core** *core-number*&<1-64>]]]

   By default, kernel thread deadloop detection is enabled.

3. (Optional.) Set the threshold for identifying a kernel thread deadloop.

   monitor kernel deadloop time *time* [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, the threshold for identifying a kernel thread deadloop is 25 seconds.

4. (Optional.) Exclude a kernel thread from kernel thread deadloop detection.

   monitor kernel deadloop exclude-thread *tid* [**slot** *slot-number* [**cpu** *cpu-number*]]

   When enabled, kernel thread deadloop detection monitors all kernel threads by default.

5. (Optional.) Specify the action to be taken in response to a kernel thread deadloop.

   monitor kernel deadloop action { **reboot** | **record-only** } [**slot** *slot-number* [**cpu** *cpu-number*]]

   The default action is **reboot**.

Configuring kernel thread starvation detection

About this task

Starvation occurs when a thread is unable to access shared resources.

Kernel thread starvation detection enables the system to detect and report thread starvation. If a thread is not executed within a specific interval, the system determines that a starvation has occurred and generates a starvation message.

Thread starvation does not impact system operation. A starved thread can automatically run when certain conditions are met.

Restrictions and guidelines

CAUTION:

Configure kernel thread starvation detection only under the guidance of H3C Support. Inappropriate configuration can cause system breakdown. As a best practice, leave the default unchanged.

Procedure

1. Enter system view.

   system-view

2. Enable kernel thread starvation detection.

   monitor kernel starvation enable [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, kernel thread starvation detection is disabled.

3. (Optional.) Set the threshold for identifying a kernel thread starvation.

   monitor kernel starvation time *time* [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, the threshold for identifying a kernel thread starvation is 120 seconds.

4. (Optional.) Exclude a kernel thread from kernel thread starvation detection.

   monitor kernel starvation exclude-thread *tid* [**slot** *slot-number* [**cpu** *cpu-number*]]

   When enabled, kernel thread starvation detection monitors all kernel threads by default.

Display and maintenance commands for kernel threads

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display kernel thread deadloop detection configuration.	**display kernel deadloop configuration** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread deadloop information.	**display kernel deadloop** *show-number* [*offset*] [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread exception information.	**display kernel exception** *show-number* [*offset*] [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread reboot information.	**display kernel reboot** *show-number* [*offset*] [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread starvation detection configuration.	**display kernel starvation configuration** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread starvation information.	**display kernel starvation** *show-number* [*offset*] [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Clear kernel thread deadloop information.	**reset kernel deadloop** [**slot** *slot-number* [**cpu** *cpu-number*]]
Clear kernel thread exception information.	**reset kernel exception** [**slot** *slot-number* [**cpu** *cpu-number*]]

Task	Command
Clear kernel thread reboot information.	**reset kernel reboot** [**slot** *slot-number* [**cpu** *cpu-number*]]
Clear kernel thread starvation information.	**reset kernel starvation** [**slot** *slot-number* [**cpu** *cpu-number*]]

Configuring samplers 1
About sampler 1
Restrictions: Hardware compatibility with samplers 1
Creating a sampler 1
Display and maintenance commands for a sampler 1

Configuring samplers

About sampler

A sampler selects a packet from sequential packets and sends the packet to other service modules for processing. Sampling is useful when you want to limit the volume of traffic to be analyzed. The sampled data is statistically accurate and sampling decreases the impact on the forwarding capacity of the device.

The device supports random sampling mode.

In random sampling mode, any packet might be selected from sequential packets in each sampling.

Restrictions: Hardware compatibility with samplers

Samplers are supported only on the S5200-HI-G switch series.

Creating a sampler

1. Enter system view.
   system-view
2. Create a sampler.
   sampler *sampler-name* **mode random packet-interval n-power** *rate*
   By default, no samplers exist.

Display and maintenance commands for a sampler

Execute **display** commands in any view.

Task	Command
Display configuration information about the sampler.	**display sampler** [*sampler-name*] [**slot** *slot-number*]

Configuring port mirroring

About port mirroring

Port mirroring copies the packets passing through a port, VLAN, or CPU to a port that connects to a data monitoring device for packet analysis.

Terminology

The following terms are used in port mirroring configuration.

Mirroring source

The mirroring sources can be one or more monitored ports (called source ports), VLANs (called source VLANs), or CPUs (called source CPUs).

Packets passing through mirroring sources are copied to a port connecting to a data monitoring device for packet analysis. The copies are called mirrored packets.

Source device

The device where the mirroring sources reside is called a source device.

Mirroring destination

The mirroring destination connects to a data monitoring device and is the destination port (also known as the monitor port) of mirrored packets. Mirrored packets are sent out of the monitor port to the data monitoring device.

A monitor port might receive multiple copies of a packet when it monitors multiple mirroring sources. For example, two copies of a packet are received on Port A when the following conditions exist:

- Port A is monitoring bidirectional traffic of Port B and Port C on the same device.
- The packet travels from Port B to Port C.

Destination device

The device where the monitor port resides is called the destination device.

Mirroring direction

The mirroring direction specifies the direction of the traffic that is copied on a mirroring source.

- **Inbound**—Copies packets received.
- **Outbound**—Copies packets sent.
- **Bidirectional**—Copies packets received and sent.

Mirroring group

Port mirroring is implemented through mirroring groups. Mirroring groups can be classified into local mirroring groups, remote source groups, and remote destination groups.

Reflector port, egress port, and remote probe VLAN

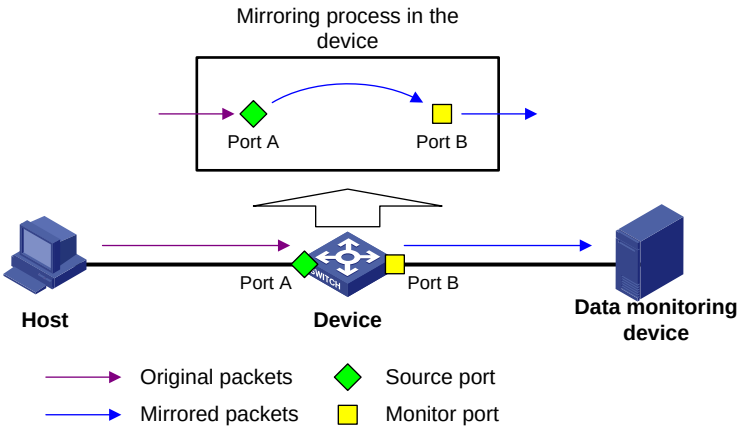
Reflector ports, remote probe VLANs, and egress ports are used for Layer 2 remote port mirroring. The remote probe VLAN is a dedicated VLAN for transmitting mirrored packets to the destination device. Both the reflector port and egress port reside on a source device and send mirrored packets to the remote probe VLAN.

On port mirroring devices, all ports except source, destination, reflector, and egress ports are called common ports.

Egress port and remote probe VLAN

Remote probe VLANs and egress ports are used for Layer 2 remote port mirroring. The remote probe VLAN is a dedicated VLAN for transmitting mirrored packets to the destination device. The egress port resides on a source device and send mirrored packets to the remote probe VLAN.

On port mirroring devices, all ports except source, destination, and egress ports are called common ports.



Port mirroring classification

Port mirroring includes the following types:

- **Local port mirroring**—Also known as Switch Port Analyzer (SPAN). In local port mirroring, the source device is directly connected to a data monitoring device. The source device acts as the destination device to forward mirrored packets to the data monitoring device.
- **Remote port mirroring**—In remote port mirroring, the source device is not directly connected to a data monitoring device. The source device copies mirrored packets to the destination device, which forwards them to the data monitoring device. The source device and destination device are connected through a Layer 2 network. Therefore, remote port mirroring is also called Layer 2 remote port mirroring or remote SPAN (RSPAN).

Local port mirroring (SPAN)

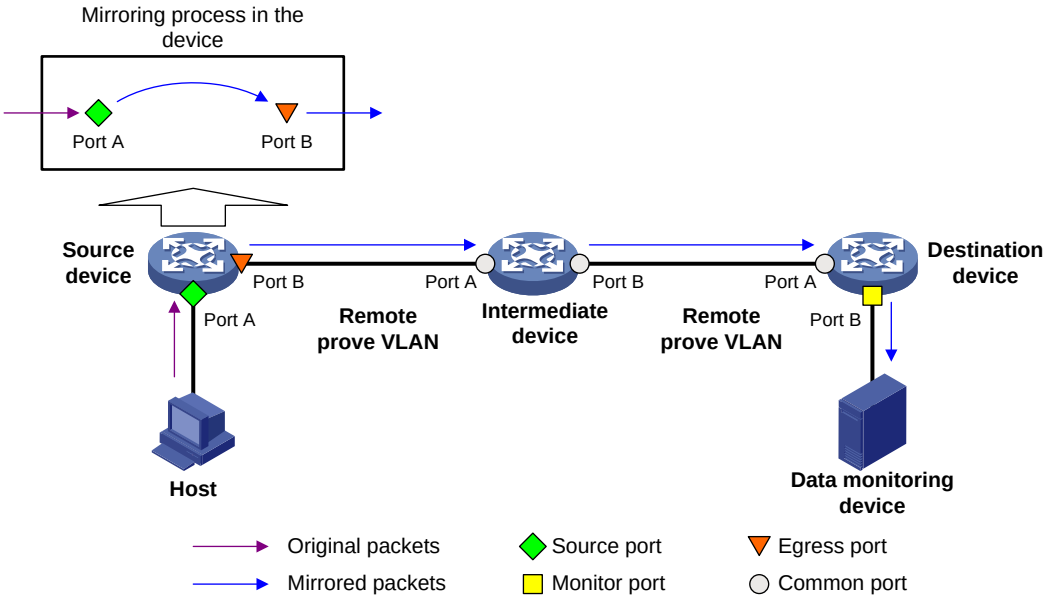
Figure 1 Local port mirroring implementation

As shown in Figure 1, the source port (Port A) and the monitor port (Port B) reside on the same device. Packets received on Port A are copied to Port B. Port B then forwards the packets to the data monitoring device for analysis.

Layer 2 remote port mirroring (RSPAN)

In Layer 2 remote port mirroring, the mirroring sources and destination reside on different devices and are in different mirroring groups.

A remote source group is a mirroring group that contains the mirroring sources. A remote destination group is a mirroring group that contains the mirroring destination. Intermediate devices are the devices between the source device and the destination device.



Layer 2 remote port mirroring can be implemented through the egress port method.

Egress port method

In Layer 2 remote port mirroring that uses the egress port method, packets are mirrored as follows:

1. The source device copies packets received on the mirroring sources to the egress port.
2. The egress port forwards the mirrored packets to the intermediate devices.
3. The intermediate devices flood the mirrored packets in the remote probe VLAN and transmit the mirrored packets to the destination device.
4. Upon receiving the mirrored packets, the destination device determines whether the ID of the mirrored packets is the same as the remote probe VLAN ID. If the two VLAN IDs match, the destination device forwards the mirrored packets to the data monitoring device through the monitor port.

Figure 2 Layer 2 remote port mirroring implementation through the egress port method

Restrictions and guidelines: Port mirroring configuration

The device supports a maximum of nine mirroring groups: four mirroring groups with ports as mirroring sources, four mirroring groups with VLANs as mirroring sources, and one mirroring group with CPUs as mirroring sources.

In a mirroring group, if an aggregation member port is configured as a source port, and an aggregate interface or aggregation member port is configured as the monitor port, make sure one of the corresponding aggregation groups operate in static aggregation mode. For more about the static aggregation mode, see Ethernet link aggregation in *Layer 2—LAN Switching Configuration Guide*.

When a mirroring group contains multiple monitor ports and the monitor ports are aggregation member ports, the mirrored packets will be sent to the related aggregate interfaces. Aggregation member ports not included in the mirroring group will also receive the mirrored packets.

Configuring local port mirroring (SPAN)

Restrictions and guidelines for local port mirroring configuration

A local mirroring group takes effect only after it is configured with the monitor port and mirroring sources.

For port mirroring to work correctly, do not assign a source port to a source VLAN.

Local port mirroring tasks at a glance

To configure local port mirroring, perform the following tasks:

1. Configuring mirroring sources

   Choose one of the following tasks:

   - Configuring source ports
   - Configuring source VLANs
   - Configuring source CPUs
2. Configuring the monitor port

Creating a local mirroring group

1. Enter system view.

   system-view
2. Create a local mirroring group.

   mirroring-group *group-id* **local**

   By default, no local mirroring group is created.

Configuring mirroring sources

Restrictions and guidelines for mirroring source configuration

When you configure source ports for a local mirroring group, follow these restrictions and guidelines:

- A mirroring group can contain multiple source ports.
- A port can act as a source port for only one mirroring group.
- A source port cannot be configured as an egress or monitor port.

When you configure source VLANs for a local mirroring group, follow these restrictions and guidelines:

- A mirroring group can contain multiple source VLANs.
- A VLAN can be configured as a source VLAN for only one local mirroring group.

A local mirroring group can contain multiple source CPUs.

Configuring source ports

- Configure source ports in system view:
  a. Enter system view.

     system-view

b. Configure source ports for a local mirroring group.

mirroring-group *group-id* **mirroring-port** *interface-list* { **both** | **inbound** | **outbound** }

By default, no source port is configured for a local mirroring group.

- Configure source ports in interface view:

c. Enter system view.

system-view

d. Enter interface view.

interface *interface-type interface-number*

e. Configure the port as a source port for a local mirroring group.

mirroring-group *group-id* **mirroring-port** { **both** | **inbound** | **outbound** }

By default, a port does not act as a source port for any local mirroring groups.

Configuring source VLANs

1. Enter system view.

system-view

2. Configure source VLANs for a local mirroring group.

mirroring-group *group-id* **mirroring-vlan** *vlan-list* { **both** | **inbound** | **outbound** }

By default, no source VLAN is configured for a local mirroring group.

Configuring source CPUs

1. Enter system view.

system-view

2. Configure source CPUs for a local mirroring group.

mirroring-group *group-id* **mirroring-cpu slot** *slot-number-list* { **both** | **inbound** | **outbound** }

By default, no source CPU is configured for a local mirroring group.

Configuring the monitor port

Restrictions and guidelines

Do not enable the spanning tree feature on the monitor port.

For a Layer 2 aggregate interface configured as the monitor port of a mirroring group, do not configure its member ports as source ports of the mirroring group.

For a Layer 2 aggregate interface configured as the monitor port of a mirroring group, do not assign its member ports to a source VLAN of the mirroring group.

Use a monitor port only for port mirroring, so the data monitoring device receives only the mirrored traffic.

The monitor port cannot be any member port of an aggregate group.

When you configure a member port of a dynamic aggregation group as the monitor port for a mirroring group, this command does not take effect.

Procedure

- Configure the monitor port in system view:

f. Enter system view.

system-view

g. Configure the monitor port for a local mirroring group.

mirroring-group *group-id* **monitor-port** *interface-list*

By default, no monitor port is configured for a local mirroring group.

- Configure the monitor port in interface view:

h. Enter system view.

system-view

i. Enter interface view.

interface *interface-type interface-number*

j. Configure the port as the monitor port for a mirroring group.

mirroring-group *group-id* **monitor-port**

By default, a port does not act as the monitor port for any local mirroring groups.

Configuring Layer 2 remote port mirroring (RSPAN)

Restrictions and guidelines for Layer 2 remote port mirroring configuration

To ensure successful traffic mirroring, configure devices in the order of the destination device, the intermediate devices, and the source device.

For port mirroring to work correctly, do not assign a source port, monitor port, or egress port to a source VLAN.

If intermediate devices exist, configure the intermediate devices to allow the remote probe VLAN to pass through.

For a mirrored packet to successfully arrive at the remote destination device, make sure its VLAN ID is not removed or changed.

Do not configure both MVRP and Layer 2 remote port mirroring. Otherwise, MVRP might register the remote probe VLAN with incorrect ports, which would cause the monitor port to receive undesired copies. For more information about MVRP, see *Layer 2—LAN Switching Configuration Guide*.

To monitor the bidirectional traffic of a source port, disable MAC address learning for the remote probe VLAN on the source, intermediate, and destination devices. For more information about MAC address learning, see *Layer 2—LAN Switching Configuration Guide*.

Layer 2 remote port mirroring with egress port configuration task list

Configuring the destination device

1. Creating a remote destination group
2. Configuring the monitor port
3. Configuring the remote probe VLAN
4. Assigning the monitor port to the remote probe VLAN

Configuring the source device

1. Creating a remote source group

2. Configuring mirroring sources

   Choose one of the following tasks:

   - Configuring source ports
   - Configuring source VLANs
   - Configuring source CPUs

3. Configuring the egress port
4. Configuring the remote probe VLAN

Creating a remote destination group

Restrictions and guidelines

Perform this task on the destination device only.

Procedure

1. Enter system view.

   system-view

2. Create a remote destination group.

   mirroring-group *group-id* **remote-destination**

Configuring the monitor port

Restrictions and guidelines for monitor port configuration

Perform this task on the destination device only.

Do not enable the spanning tree feature on the monitor port.

For a Layer 2 aggregate interface configured as the monitor port of a mirroring group, do not configure its member ports as source ports of the mirroring group.

For a Layer 2 aggregate interface configured as the monitor port of a mirroring group, do not assign its member ports to a source VLAN of the mirroring group.

Use a monitor port only for port mirroring, so the data monitoring device receives only the mirrored traffic.

A monitor port can belong to only one mirroring group.

An aggregation group member port cannot be configured as the monitor port for a mirroring group.

When you configure a member port of a dynamic aggregation group as the monitor port for a mirroring group, this command does not take effect.

Configuring the monitor port in system view

1. Enter system view.

   system-view

2. Configure the monitor port for a remote destination group.

   mirroring-group *group-id* **monitor-port** *interface-list*

   By default, no monitor port is configured for a remote destination group.

Configuring the monitor port in interface view

1. Enter system view.

   system-view

2. Enter interface view.

interface *interface-type interface-number*

3. Configure the port as the monitor port for a remote destination group.
   mirroring-group *group-id* **monitor-port**
   By default, a port does not act as the monitor port for any remote destination groups.

Configuring the remote probe VLAN

Restrictions and guidelines

This task is required on the both the source and destination devices.

Only an existing static VLAN can be configured as a remote probe VLAN.

When a VLAN is configured as a remote probe VLAN, use the remote probe VLAN for port mirroring exclusively.

Configure the same remote probe VLAN for the remote source group and the remote destination group.

Procedure

1. Enter system view.
   system-view
2. Configure the remote probe VLAN for the remote source or destination group.
   mirroring-group *group-id* **remote-probe vlan** *vlan-id*
   By default, no remote probe VLAN is configured for a remote source or destination group.

Assigning the monitor port to the remote probe VLAN

Restrictions and guidelines

Perform this task on the destination device only.

Procedure

1. Enter system view.
   system-view
2. Enter the interface view of the monitor port.
   interface *interface-type interface-number*
3. Assign the port to the remote probe VLAN.
   - Assign an access port to the remote probe VLAN.
     port access vlan *vlan-id*
   - Assign a trunk port to the remote probe VLAN.
     port trunk permit vlan *vlan-id*
   - Assign a hybrid port to the remote probe VLAN.
     port hybrid vlan *vlan-id* { **tagged** | **untagged** }

   For more information about the **port access vlan**, **port trunk permit vlan**, and **port hybrid vlan** commands, see *Layer 2—LAN Switching Command Reference*.

Creating a remote source group

Restrictions and guidelines

Perform this task on the source device only.

Procedure

1. Enter system view.
   system-view
2. Create a remote source group.
   mirroring-group *group-id* **remote-source**

Configuring mirroring sources

Restrictions and guidelines for mirroring source configuration

Perform this task on the source device only.

When you configure source ports for a remote source group, follow these restrictions and guidelines:

- Do not assign a source port of a mirroring group to the remote probe VLAN of the mirroring group.
- A mirroring group can contain multiple source ports.
- A source port cannot be configured as a monitor port, or egress port.

When you configure source VLANs for a remote source group, follow these restrictions and guidelines:

- A remote source group can contain multiple source VLANs.
- A VLAN can be configured as the source VLAN for only one mirroring group.

Configuring source ports

- Configure source ports in system view:
  k. Enter system view.
     system-view
  l. Configure source ports for a remote source group.
     mirroring-group *group-id* **mirroring-port** *interface-list* { **both** | **inbound** | **outbound** }
     By default, no source port is configured for a remote source group.
- Configure source ports in interface view:
  m. Enter system view.
     system-view
  n. Enter interface view.
     interface *interface-type interface-number*
  o. Configure the port as a source port for a remote source group.
     mirroring-group *group-id* **mirroring-port** { **both** | **inbound** | **outbound** }
     By default, a port does not act as a source port for any remote source groups.

Configuring source VLANs

1. Enter system view.
   system-view
2. Configure source VLANs for a remote source group.
   mirroring-group *group-id* **mirroring-vlan** *vlan-list* { **both** | **inbound** | **outbound** }
   By default, no source VLAN is configured for a remote source group.

Configuring source CPUs

1. Enter system view.
   system-view
2. Configure source CPUs for a remote source group.
   mirroring-group *group-id* **mirroring-cpu slot** *slot-number-list* { **both** | **inbound** | **outbound** }
   By default, no source CPU is configured for a remote source group.

Configuring the egress port

Restrictions and guidelines for egress port configuration

Perform this task on the source device only.

Disable the following features on the egress port:

- Spanning tree.
- 802.1X.
- IGMP snooping.
- Static ARP.
- MAC address learning.

A port of an existing mirroring group cannot be configured as an egress port.

A mirroring group supports only one egress port.

Configuring the egress port in system view

1. Enter system view.
   system-view
2. Configure the egress port for a remote source group.
   mirroring-group *group-id* **monitor-egress** *interface-type interface-number*
   By default, no egress port is configured for a remote source group.
3. Enter the egress port view.
   interface *interface-type interface-number*
4. Assign the egress port to the remote probe VLAN.
   - Assign a trunk port to the remote probe VLAN.
     port trunk permit vlan *vlan-id*
   - Assign a hybrid port to the remote probe VLAN.
     port hybrid vlan *vlan-id* { **tagged** | **untagged** }

   For more information about the **port trunk permit vlan** and **port hybrid vlan** commands, see *Layer 2—LAN Switching Command Reference*.

Configuring the egress port in interface view

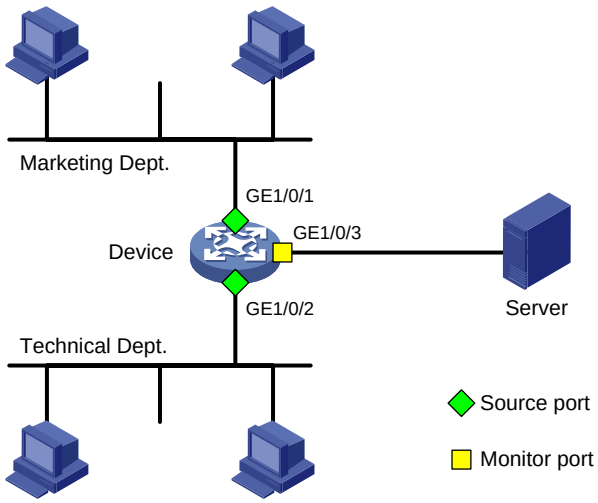
1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the port as the egress port for a remote source group.
   mirroring-group *group-id* **monitor-egress**

By default, a port does not act as the egress port for any remote source groups.

Display and maintenance commands for port mirroring

Execute **display** commands in any view.

Task	Command
Display mirroring group information.	**display mirroring-group** { *group-id* | **all** | **local** | **remote-destination** | **remote-source** }



Port mirroring configuration examples

Example: Configuring local port mirroring (SPAN in source port mode)

Network configuration

As shown in Figure 3, configure local port mirroring in source port mode to enable the server to monitor the bidirectional traffic of the two departments.

Figure 3 Network diagram

Procedure

Create local mirroring group 1.

```
<Device> system-view
[Device] mirroring-group 1 local
```

Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 as source ports for local mirroring group 1.

```
[Device] mirroring-group 1 mirroring-port gigabitethernet 1/0/1 gigabitethernet 1/0/2
both
```

Configure GigabitEthernet 1/0/3 as the monitor port for local mirroring group 1.

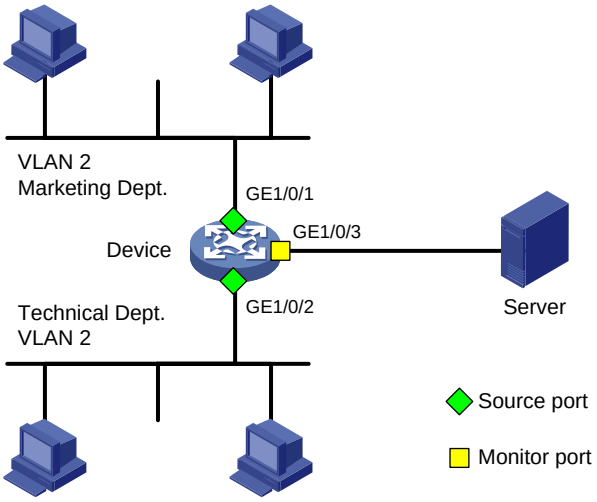
```
[Device] mirroring-group 1 monitor-port gigabitethernet 1/0/3
```

Disable the spanning tree feature on the monitor port (GigabitEthernet 1/0/3).

```
[Device] interface gigabitethernet 1/0/3
[Device-GigabitEthernet1/0/3] undo stp enable
[Device-GigabitEthernet1/0/3] quit
```

Verifying the configuration

Verify the mirroring group configuration.



```
[Device] display mirroring-group all
Mirroring group 1:
    Type: Local
    Status: Active
    Mirroring port:
        GigabitEthernet1/0/1  Both
        GigabitEthernet1/0/2  Both
    Monitor port: GigabitEthernet1/0/3
```

Example: Configuring local port mirroring (SPAN in source VLAN mode)

Network configuration

As shown in Figure 4, configure local port mirroring in source VLAN mode to enable the server to monitor the bidirectional traffic of the two departments.

Figure 4 Network diagram

Procedure

Create local mirroring group 1.

```
<Device> system-view
[Device] mirroring-group 1 local
```

Create VLAN 2, and assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to VLAN 2.

```
[Device] vlan 2
[Device-vlan2] port gigabitethernet 1/0/1 gigabitethernet 1/0/2
[Device-vlan2] quit
```

Configure VLAN 2 as a source VLAN for local mirroring group 1.

```
[Device] mirroring-group 1 mirroring-vlan 2 both
```

Configure GigabitEthernet 1/0/3 as the monitor port for local mirroring group 1.

```
[Device] mirroring-group 1 monitor-port gigabitethernet 1/0/3
```

Disable the spanning tree feature on the monitor port (GigabitEthernet 1/0/3).

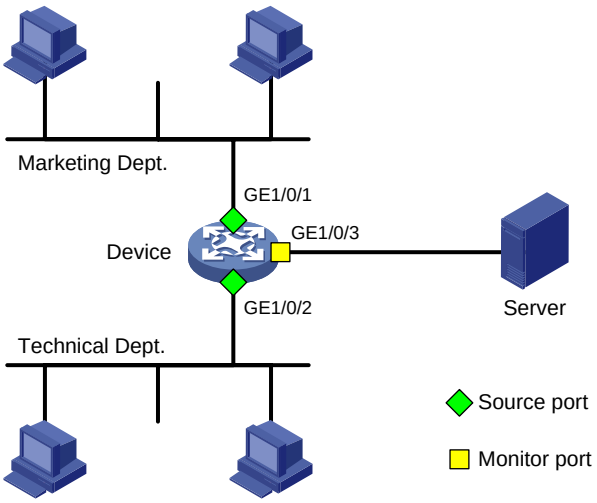
```
[Device] interface gigabitethernet 1/0/3
[Device-GigabitEthernet1/0/3] undo stp enable
[Device-GigabitEthernet1/0/3] quit
```

Verifying the configuration

Verify the mirroring group configuration.

```
[Device] display mirroring-group all
Mirroring group 1:
    Type: Local
    Status: Active
    Mirroring VLAN:
        2  Both
    Monitor port: GigabitEthernet1/0/3
```

Example: Configuring local port mirroring (SPAN in source CPU mode)



Network configuration

As shown in Figure 5, GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are located on the card in slot 1.

Configure local port mirroring in source CPU mode to enable the server to monitor all packets matching the following criteria:

- Received and sent by the Marketing Department and the Technical Department.
- Processed by the CPU in slot 1 of the device.

Figure 5 Network diagram

Procedure

Create local mirroring group 1.

```
<Device> system-view
[Device] mirroring-group 1 local
```

Configure the CPU in slot 1 of the device as a source CPU for local mirroring group 1.

```
[Device] mirroring-group 1 mirroring-cpu slot 1 both
```

Configure GigabitEthernet 1/0/3 as the monitor port for local mirroring group 1.

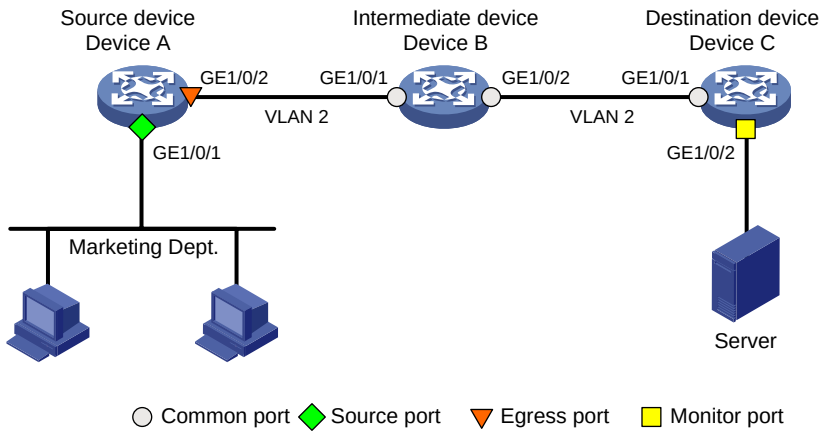
```
[Device] mirroring-group 1 monitor-port gigabitethernet 1/0/3
```

Disable the spanning tree feature on the monitor port (GigabitEthernet 1/0/3).

```
[Device] interface gigabitethernet 1/0/3
[Device-GigabitEthernet1/0/3] undo stp enable
[Device-GigabitEthernet1/0/3] quit
```

Verifying the configuration

Verify the mirroring group configuration.



```
[Device] display mirroring-group all
Mirroring group 1:
    Type: Local
    Status: Active
    Mirroring CPU:
        Slot 1  Both
    Monitor port: GigabitEthernet1/0/3
```

Example: Configuring Layer 2 remote port mirroring (RSPAN with egress port)

Network configuration

On the Layer 2 network shown in Figure 6, configure Layer 2 remote port mirroring to enable the server to monitor the bidirectional traffic of the Marketing Department.

Figure 6 Network diagram

Procedure

1. Configure Device C (the destination device):

   # Configure GigabitEthernet 1/0/1 as a trunk port, and assign the port to VLAN 2.

   ```
   <DeviceC> system-view
   [DeviceC] interface gigabitethernet 1/0/1
   [DeviceC-GigabitEthernet1/0/1] port link-type trunk
   ```

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 2
[DeviceC-GigabitEthernet1/0/1] quit
```

Create a remote destination group.

```
[DeviceC] mirroring-group 2 remote-destination
```

Create VLAN 2.

```
[DeviceC] vlan 2
```

Disable MAC address learning for VLAN 2.

```
[DeviceC-vlan2] undo mac-address mac-learning enable
[DeviceC-vlan2] quit
```

Configure VLAN 2 as the remote probe VLAN for the mirroring group.

```
[DeviceC] mirroring-group 2 remote-probe vlan 2
```

Configure GigabitEthernet 1/0/2 as the monitor port for the mirroring group.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] mirroring-group 2 monitor-port
```

Disable the spanning tree feature on GigabitEthernet 1/0/2.

```
[DeviceC-GigabitEthernet1/0/2] undo stp enable
```

Assign GigabitEthernet 1/0/2 to VLAN 2 as an access port.

```
[DeviceC-GigabitEthernet1/0/2] port access vlan 2
[DeviceC-GigabitEthernet1/0/2] quit
```

2. Configure Device B (the intermediate device):

Create VLAN 2.

```
<DeviceB> system-view
[DeviceB] vlan 2
```

Disable MAC address learning for VLAN 2.

```
[DeviceB-vlan2] undo mac-address mac-learning enable
[DeviceB-vlan2] quit
```

Configure GigabitEthernet 1/0/1 as a trunk port, and assign the port to VLAN 2.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 2
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port, and assign the port to VLAN 2.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 2
[DeviceB-GigabitEthernet1/0/2] quit
```

3. Configure Device A (the source device):

Create a remote source group.

```
<DeviceA> system-view
[DeviceA] mirroring-group 1 remote-source
```

Create VLAN 2.

```
[DeviceA] vlan 2
```

Disable MAC address learning for VLAN 2.

```
[DeviceA-vlan2] undo mac-address mac-learning enable
[DeviceA-vlan2] quit
```

Configure VLAN 2 as the remote probe VLAN of the mirroring group.

```
[DeviceA] mirroring-group 1 remote-probe vlan 2
```

Configure GigabitEthernet 1/0/1 as a source port for the mirroring group.

```
[DeviceA] mirroring-group 1 mirroring-port gigabitethernet 1/0/1 both
```

Configure GigabitEthernet 1/0/2 as the egress port for the mirroring group.

```
[DeviceA] mirroring-group 1 monitor-egress gigabitethernet 1/0/2
```

Configure GigabitEthernet 1/0/2 as a trunk port, and assign the port to VLAN 2.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 2
```

Disable the spanning tree feature on the port.

```
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] quit
```

Verifying the configuration

Verify the mirroring group configuration on Device C.

```
[DeviceC] display mirroring-group all
Mirroring group 2:
    Type: Remote destination
    Status: Active
    Monitor port: GigabitEthernet1/0/2
    Remote probe VLAN: 2
```

Verify the mirroring group configuration on Device A.

```
[DeviceA] display mirroring-group all
Mirroring group 1:
    Type: Remote source
    Status: Active
    Mirroring port:
        GigabitEthernet1/0/1  Both
    Monitor egress port: GigabitEthernet1/0/2
    Remote probe VLAN: 2
```

Configuring flow mirroring

About flow mirroring

Flow mirroring copies packets matching a class to a destination for packet analyzing and monitoring. It is implemented through QoS.

To implement flow mirroring through QoS, perform the following tasks:

- Define traffic classes and configure match criteria to classify packets to be mirrored. Flow mirroring allows you to flexibly classify packets to be analyzed by defining match criteria.
- Configure traffic behaviors to mirror the matching packets to the specified destination.

You can configure an action to mirror the matching packets to one of the following destinations:

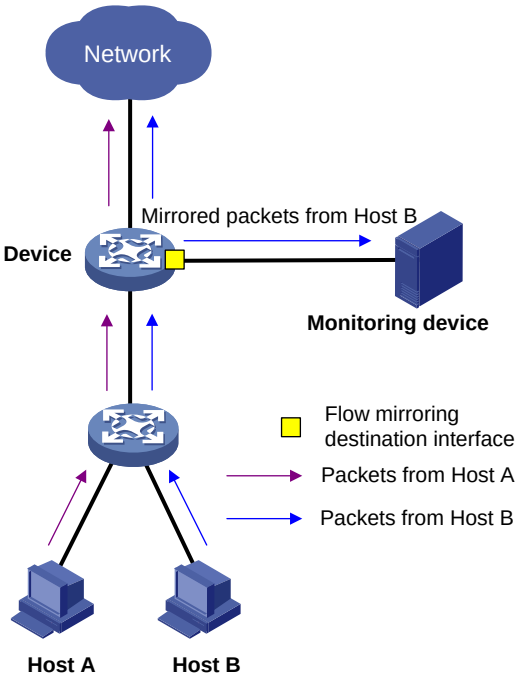
- **Interface**—The matching packets are copied to an interface and then forwarded to a data monitoring device for analysis.
- **CPU**—The matching packets are copied to the CPU of an IRF member device. The CPU analyzes the packets or delivers them to upper layers.

For more information about QoS policies, traffic classes, and traffic behaviors, see *ACL and QoS Configuration Guide*.

Types of flow-mirroring traffic to an interface

Depending on whether the mirroring source and mirroring destination are on the same device, flow-mirroring traffic to an interface includes the following types:

- **Flow mirroring SPAN**—Flow-mirrors traffic to a local interface.
- **Flow mirroring RSPAN**—Flow-mirrors traffic to an interface, and then forwards traffic to a remote Layer 2 interface based on the VLAN of the mirrored traffic or through QoS traffic redirecting.
- **Flow mirroring ERSPAN**—Encapsulates traffic in GRE packets with protocol number 0x88BE (ERSPANv2) and routes the traffic to a remote monitoring device at Layer 3.



Flow mirroring SPAN or RSPAN

For flow mirroring SPAN, configure a QoS policy on the source device. Configure the QoS policy as follows:

1. Configure a traffic class to match packets.
2. Configure a traffic behavior to flow-mirror traffic to an interface without specifying the **`destination-ip`** or **`source-ip`** keyword.
3. Associate the traffic class with the traffic behavior.

When the device receives a matching packet, the device sends one copy of the packet to the interface specified by the traffic behavior. The interface forwards the mirrored packet to the monitoring device.

Figure 7 Flow mirroring SPAN

To implement RSPAN, forward the mirrored packet to a remote Layer 2 interface based on the VLAN of the mirrored packet or through QoS traffic redirecting.

Flow mirroring ERSPAN

Flow mirroring ERSPAN can be implemented in encapsulation parameter mode or monitoring group mode.

On all devices from source to destination, configure a unicast routing protocol to ensure Layer 3 reachability between the devices.

Encapsulation parameter mode

In this mode, configure a QoS policy on the source device. Configure the QoS policy as follows:

1. Configure a traffic class to match packets.
2. Configure a traffic behavior to flow-mirror traffic to an interface.
3. Associate the traffic class with the traffic behavior.

You can configure flow-mirroring traffic to an interface in one of the following modes:

- **Directly specifying an outgoing interface**—In this mode, specify both the outgoing interface and encapsulation parameters. The device encapsulates packets with the specified parameters and then forwards packets out of the specified interface.
- **Specifying an outgoing interface through route lookup**—In this mode, specify only encapsulation parameters without specifying an outgoing interface. The device looks up a route for the encapsulated mirrored packets based on the source IP address and destination IP address of the encapsulated packets. The outgoing interface of the route is a destination interface of the mirrored packets.

  In this mode, you can use the load sharing function of a routing protocol to forward mirrored packets to multiple destination interfaces.

As shown in Figure 8, flow mirroring ERSPAN in encapsulation parameter mode works as follows:

4. The source device copies a matching packet.
5. The source device encapsulates the packet with the specified ERSPAN encapsulation parameters.
6. The source device forwards the packet in either of the following methods:
   - Forwards the mirrored packets out of the specified outgoing interface.
   - Looks up a route for the encapsulated mirrored packet based on the source IP address and destination IP address of the encapsulated packet.
7. The encapsulated packet is routed to the monitoring device.
8. The monitoring device decapsulates the packet and analyzes the packet contents.

   The packet sent to the monitoring device through flow mirroring in this mode is encapsulated. In this mode, make sure the monitoring device supports decapsulating packets.

Figure 8 Flow mirroring ERSPAN in encapsulation parameter mode

Restrictions and guidelines: Flow mirroring configuration

For information about the configuration commands except the **mirror-to** command, see *ACL and QoS Command Reference*.

Flow mirroring tasks at a glance

To configure flow mirroring, perform the following tasks:

1. Configuring a traffic class

   A traffic class defines the criteria that filters the traffic to be mirrored.
2. Configuring a traffic behavior

   A traffic behavior specifies mirroring destinations.
3. Configuring a QoS policy
4. Applying a QoS policy

   Choose one of the following tasks:
   - Applying a QoS policy to an interface
   - Applying a QoS policy to a VLAN
   - Applying a QoS policy globally

Configuring a traffic class

1. Enter system view.

   system-view
2. Create a class and enter class view.

traffic classifier *classifier-name* [**operator** { **and** | **or** }]

3. Configure match criteria.

   if-match *match-criteria*

   By default, no match criterion is configured in a traffic class.

4. (Optional.) Display traffic class information.

   display traffic classifier user-defined [*classifier-name*] [**slot** *slot-number*]

   For more information about this command, see *ACL and QoS Command Reference*.

Configuring a traffic behavior

Procedure

1. Enter system view.

   system-view

2. Configure a monitoring group. This step is required for mirroring traffic to a monitoring group.

   p. Create a monitoring group.

   monitoring-group *group-id*

   q. Assign ports to the monitoring group.

   Syntax I:

   monitoring-port *interface-list* [{ **destination-ip** *destination-ip-address* **source-ip** *source-ip-address* | **destination-ipv6** *destination-ipv6-address* **source-ipv6** *source-ipv6-address* } [**dscp** *dscp-value* | **vlan** *vlan-id* | **vrf-instance** *vrf-name*] * [**destination-mac** *mac-address*]]

   Syntax II:

   monitoring-port { **destination-ip** *destination-ip-address* **source-ip** *source-ip-address* | **destination-ipv6** *destination-ipv6-address* **source-ipv6** *source-ipv6-address* } [**dscp** *dscp-value* | **vlan** *vlan-id* | **vrf-instance** *vrf-name*] * [**destination-mac** *mac-address*]

   By default, a monitoring group does not contain any port.

   This feature is not supported on the S5200-EI-G Switch Series.

   r. Return to system view.

   quit

3. Create a traffic behavior and enter traffic behavior view.

   traffic behavior *behavior-name*

4. Configure mirroring destinations for the traffic behavior. Choose one option as needed:

   - Mirror traffic to interfaces.

     S**yntax I:**

     mirror-to interface *interface-type interface-number* [**backup-interface** *interface-type interface-number*] [**truncation**] [{ **destination-ip** *destination-ip-address* **source-ip** *source-ip-address* | **destination-ipv6** *destination-ipv6-address* **source-ipv6** *source-ipv6-address* } [**dscp** *dscp-value* | **vlan** *vlan-id* | **vrf-instance** *vrf-name*] *] [**destination-mac** *mac-address*]]

     Syntax II:

     mirror-to interface { **destination-ip** *destination-ip-address* **source-ip** *source-ip-address* | **destination-ipv6**

destination-ipv6-address **source-ipv6** *source-ipv6-address* }[**truncation**] [**dscp** *dscp-value* | **vlan** *vlan-id* | **vrf-instance** *vrf-name*] * [**destination-mac** *mac-address*]

By default, no mirroring actions exist to mirror traffic to interfaces.

You cannot flow-mirror traffic to tunnel interfaces.

This command is not supported on the S5200-EI-G Switch Series.

- Mirror traffic to the CPU.

  mirror-to cpu

  By default, no mirroring actions exist to mirror traffic to the CPU.

5. (Optional.) Display traffic behavior configuration.

   display traffic behavior user-defined [*behavior-name*] [**slot** *slot-number*]

   For more information about this command, see *ACL and QoS Command Reference*.

Configuring a QoS policy

1. Enter system view.

   system-view

2. Create a QoS policy and enter QoS policy view.

   qos [**mirroring**] **policy** *policy-name*

3. Associate a class with a traffic behavior in the QoS policy.

   classifier *classifier-name* **behavior** *behavior-name*

   By default, no traffic behavior is associated with a class.

4. (Optional.) Display QoS policy configuration.

   display qos policy user-defined mirroring [*policy-name* [**classifier** *classifier-name*]] [**slot** *slot-number*]

   For more information about this command, see *ACL and QoS Command Reference*.

Applying a QoS policy

Applying a QoS policy to an interface

Restrictions and guidelines

You can apply a QoS policy to an interface to mirror the traffic of the interface.

A policy can be applied to multiple interfaces.

In one traffic direction of an interface, only one QoS policy can be applied.

The device does not support mirroring traffic of an aggregate interface.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Apply a policy to the interface.

   qos apply [**mirroring**] **policy** *policy-name* { **inbound** | **outbound** }

4. (Optional.) Display the QoS policy applied to the interface.

   display qos [**mirroring**] **policy interface** [*interface-type interface-number* [**inbound** | **outbound**] [**slot** *slot-number*]

   For more information about this command, see *ACL and QoS Command Reference*.

Applying a QoS policy to a VLAN

Restrictions and guidelines

You can apply a QoS policy to a VLAN to mirror the traffic on all ports in the VLAN.

Procedure

1. Enter system view.

   system-view

2. Apply a QoS policy to a VLAN.

   qos vlan-policy *policy-name* **vlan** *vlan-id-list* { **inbound** | **outbound** }

3. (Optional.) Display the QoS policy applied to the VLAN.

   display qos vlan-policy { **name** *policy-name* | **vlan** [*vlan-id*] } [**inbound** | **outbound**] [**slot** *slot-number*]

   For more information about this command, see *ACL and QoS Command Reference*.

Applying a QoS policy globally

Restrictions and guidelines

You can apply a QoS policy globally to mirror the traffic on all ports.

Procedure

1. Enter system view.

   system-view

2. Apply a QoS policy globally.

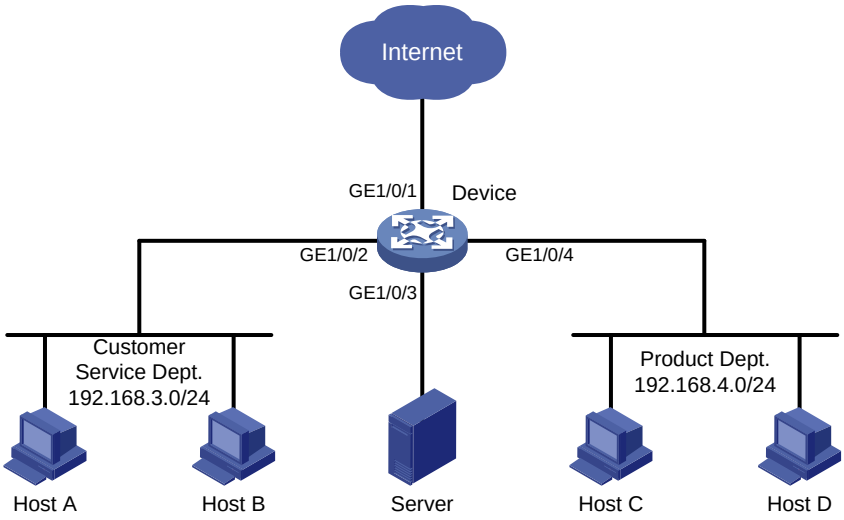
   qos apply [**mirroring**] **policy** *policy-name* **global** { **inbound** | **outbound** }

3. (Optional.) Display global QoS policies.

   display qos [**mirroring**] **policy global** [**inbound** | **outbound**] [**slot** *slot-number*]

   For more information about this command, see *ACL and QoS Command Reference*.

Flow mirroring configuration examples



Example: Configuring flow mirroring

Network configuration

As shown in Figure 9, configure flow mirroring so that the server can monitor the following traffic:

- All traffic that the Product Department sends to access the Internet.
- IP traffic that the Product Department sends to the Customer Service Department during working hours (8:00 to 18:00) on weekdays.

Figure 9 Network diagram

Procedure

Create working hour range **work**, in which working hours are from 8:00 to 18:00 on weekdays.

```
<Device> system-view
[Device] time-range work 8:00 to 18:00 working-day
```

Create IPv4 advanced ACL 3000 to allow packets from the Product Department to access the Internet and the Customer Service Department during working hours.

```
[Device] acl advanced 3000
[Device-acl-ipv4-adv-3000] rule permit tcp source 192.168.4.0 0.0.0.255 destination-port eq www
[Device-acl-ipv4-adv-3000] rule permit ip source 192.168.4.0 0.0.0.255 destination 192.168.3.0 0.0.0.255 time-range work
[Device-acl-ipv4-adv-3000] quit
```

Create traffic class **tech_c**, and configure the match criterion as ACL 3000.

```
[Device] traffic classifier tech_c
[Device-classifier-tech_c] if-match acl 3000
[Device-classifier-tech_c] quit
```

Create traffic behavior **tech_b**, configure the action of mirroring traffic to GigabitEthernet 1/0/3.

```
[Device] traffic behavior tech_b
[Device-behavior-tech_b] mirror-to interface gigabitethernet 1/0/3
[Device-behavior-tech_b] quit
```

Create QoS policy **tech_p**, and associate traffic class **tech_c** with traffic behavior **tech_b** in the QoS policy.

```
[Device] qos policy tech_p
[Device-qospolicy-tech_p] classifier tech_c behavior tech_b
[Device-qospolicy-tech_p] quit
```

Apply QoS policy **tech_p** to the incoming packets of GigabitEthernet 1/0/4.

```
[Device] interface gigabitethernet 1/0/4
[Device-GigabitEthernet1/0/4] qos apply policy tech_p inbound
[Device-GigabitEthernet1/0/4] quit
```

Verifying the configuration

Verify that the server can monitor the following traffic:

- All traffic sent by the Product Department to access the Internet.
- IP traffic that the Product Department sends to the Customer Service Department during working hours on weekdays.

(Details not shown.)

The remote sFlow collector cannot receive sFlow packets 5

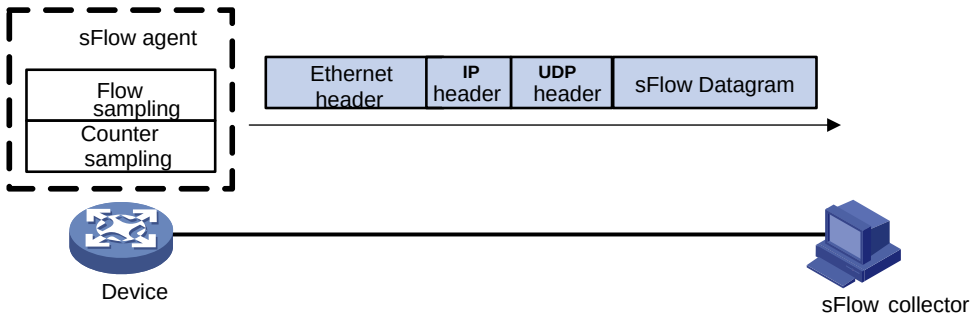
Configuring sFlow

About sFlow

sFlow is a traffic monitoring technology.

As shown in Figure 1, the sFlow system involves an sFlow agent embedded in a device and a remote sFlow collector. The sFlow agent collects interface counter information and packet information and encapsulates the sampled information in sFlow packets. When the sFlow packet buffer is full, or the aging timer (fixed to 1 second) expires, the sFlow agent performs the following actions:

- Encapsulates the sFlow packets in the UDP datagrams.
- Sends the UDP datagrams to the specified sFlow collector.



The sFlow collector analyzes the information and displays the results. One sFlow collector can monitor multiple sFlow agents.

sFlow provides the following sampling mechanisms:

- **Flow sampling**—Obtains packet information.
- **Counter sampling**—Obtains interface counter information.

sFlow can use flow sampling and counter sampling at the same time.

Figure 1 sFlow system

Protocols and standards

- RFC 3176, *InMon Corporation's sFlow: A Method for Monitoring Traffic in Switched and Routed Networks*
- sFlow.org, *sFlow Version 5*

Restrictions: Hardware compatibility with sFlow configuration

sFlow is supported only on the S5200-HI-G switch series.

Restrictions and guidelines: sFlow configuration

When you configure flow sampling or counter sampling on Layer 2 Ethernet interfaces in VLAN 1, the total bandwidth of the single or more Layer 2 Ethernet interfaces to be sampled cannot exceed 22 Gbps.

Configuring basic sFlow information

Restrictions and guidelines

As a best practice, manually configure an IP address for the sFlow agent. The device periodically checks whether the sFlow agent has an IP address. If the sFlow agent does not have an IP address, the device automatically selects an IPv4 address for the sFlow agent but does not save the IPv4 address in the configuration file.

Only one IP address can be configured for the sFlow agent on the device, and a newly configured IP address overwrites the existing one.

Procedure

1. Enter system view.

   system-view

2. Configure an IP address for the sFlow agent.

   sflow agent { **ip** *ipv4-address* | **ipv6** *ipv6-address* }

   By default, no IP address is configured for the sFlow agent.

3. Configure the sFlow collector information.

   sflow collector *collector-id* [**vpn-instance** *vpn-instance-name*] { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**datagram-size** *size* | **description** *string* | **dscp** *dscp-value* | **port** *port-number* | **time-out** *seconds*] *

   By default, no sFlow collector information is configured.

4. Specify the source IP address of sFlow packets.

   sflow source { **ip** *ipv4-address* | **ipv6** *ipv6-address* } *

   By default, the source IP address is determined by routing.

Configuring flow sampling

About this task

Perform this task to configure flow sampling on an Ethernet interface. The sFlow agent performs the following tasks:

1. Samples packets on that interface according to the configured parameters.
2. Encapsulates the packets into sFlow packets.
3. Encapsulates the sFlow packets in the UDP packets and sends the UDP packets to the specified sFlow collector.

Configuring flow sampling on an Ethernet interface

1. Enter system view.

   system-view

2. Enter Layer 2 Ethernet interface view or Layer 3 Ethernet interface view.

   interface *interface-type interface-number*

3. (Optional.) Set the flow sampling mode.

sflow sampling-mode random

By default, random sampling is used.

4. Enable flow sampling and specify the number of packets out of which flow sampling samples a packet on the interface.

   sflow sampling-rate *rate*

   By default, flow sampling is disabled.

5. (Optional.) Set the flow sampling direction.

   sflow sampling-direction { **both** | **inbound** | **outbound** }

   By default, the flow sampling direction is bidirectional.

6. (Optional.) Set the maximum number of bytes (starting from the packet header) that flow sampling can copy per packet.

   sflow flow max-header *length*

   The default setting is 128 bytes.

   As a best practice, use the default setting.

7. Specify the sFlow instance and sFlow collector for flow sampling.

   sflow flow [**instance** *instance-id*] **collector** *collector-id*

   By default, no sFlow instance or sFlow collector is specified for flow sampling.

Configuring counter sampling

About this task

Perform this task to configure counter sampling on an Ethernet interface. The sFlow agent performs the following tasks:

1. Periodically collects the counter information on that interface.
2. Encapsulates the counter information into sFlow packets.
3. Encapsulates the sFlow packets in the UDP packets and sends the UDP packets to the specified sFlow collector.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 2/Layer 3 Ethernet interface view.

   interface *interface-type interface-number*

3. Enable counter sampling and set the counter sampling interval.

   sflow counter interval *interval*

   By default, counter sampling is disabled.

4. Specify the sFlow instance and sFlow collector for counter sampling.

   sflow counter [**instance** *instance-id*] **collector** *collector-id*

   By default, no sFlow instance or sFlow collector is specified for counter sampling.

Display and maintenance commands for sFlow

Execute **display** commands in any view.

Task	Command
Display sFlow configuration.	**display sflow**

sFlow configuration examples

Example: Configuring sFlow

Network configuration

As shown in Figure 2, perform the following tasks:

- Configure flow sampling in random mode and counter sampling on GigabitEthernet 1/0/1 of the device to monitor traffic on the port.
- Configure the device to send sampled information in sFlow packets through GigabitEthernet 1/0/3 to the sFlow collector.

Figure 2 Network diagram

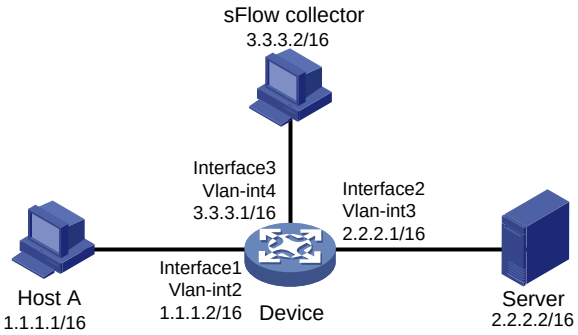


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure VLANs, assign Ethernet interfaces to VLANs, and configure IP addresses and subnet masks for VLAN interfaces, as shown in Figure 2. (Details not shown.)
2. Configure the sFlow agent and configure information about the sFlow collector:

   # Configure the IP address for the sFlow agent.

   ```
   <Device> system-view
   [Device] sflow agent ip 3.3.3.1
   ```

   # Configure information about the sFlow collector. Specify the sFlow collector ID as 1, IP address as 3.3.3.2, port number as 6343 (default), and description as **netserver**.

   ```
   [Device] sflow collector 1 ip 3.3.3.2 description netserver
   ```

3. Configure counter sampling:

   # Enable counter sampling and set the counter sampling interval to 120 seconds on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   ```

```
[Device-GigabitEthernet1/0/1] sflow counter interval 120
```

Specify sFlow collector 1 for counter sampling.

```
[Device-GigabitEthernet1/0/1] sflow counter collector 1
```

4. Configure flow sampling:

Enable flow sampling and set the flow sampling mode to random and sampling interval to 32767.

```
[Device-GigabitEthernet1/0/1] sflow sampling-mode random
[Device-GigabitEthernet1/0/1] sflow sampling-rate 32767
```

Specify sFlow collector 1 for flow sampling.

```
[Device-GigabitEthernet1/0/1] sflow flow collector 1
```

Verifying the configuration

Verify the following items:

- GigabitEthernet 1/0/1 enabled with sFlow is active.
- The counter sampling interval is 120 seconds.
- The flow sampling interval is 32767 (one packet is sampled from every 32767 packets).

```
[Device-GigabitEthernet1/0/1] display sflow
sFlow datagram version: 5
Global information:
Agent IP: 3.3.3.1(CLI)
Source address:
Collector information:
ID    IP              Port  Aging      Size VPN-instance Description       Dscp
1     3.3.3.2         6343  N/A        1400              netserver         0
Port counter sampling information:
Interface   Instance   CID   Interval(s)
GE1/0/1     1          1     120
Port flow sampling information:
Interface   Instance   FID   MaxHLen Rate       Mode      Status
GE1/0/1        1          1     128     32767      Random    Active
```

Troubleshooting sFlow

The remote sFlow collector cannot receive sFlow packets

Symptom

The remote sFlow collector cannot receive sFlow packets.

Analysis

The possible reasons include:

- The sFlow collector is not specified.
- sFlow is not configured on the interface.
- The IP address of the sFlow collector specified on the sFlow agent is different from that of the remote sFlow collector.
- No IP address is configured for the Layer 3 interface that sends sFlow packets.
- An IP address is configured for the Layer 3 interface that sends sFlow packets. However, the UDP datagrams with this source IP address cannot reach the sFlow collector.

- The physical link between the device and the sFlow collector fails.
- The sFlow collector is bound to a non-existent VPN.
- The length of an sFlow packet is less than the sum of the following two values:
  - The length of the sFlow packet header.
  - The number of bytes that flow sampling can copy per packet.

Solution

To resolve the problem:

1. Use the **`display sflow`** command to verify that sFlow is correctly configured.
2. Verify that a correct IP address is configured for the device to communicate with the sFlow collector.
3. Verify that the physical link between the device and the sFlow collector is up.
4. Verify that the VPN bound to the sFlow collector already exists.
5. Verify that the length of an sFlow packet is greater than the sum of the following two values:
   - The length of the sFlow packet header.
   - The number of bytes (as a best practice, use the default setting) that flow sampling can copy per packet.

Configuring the information center

About the information center

The information center on the device receives logs generated by source modules and outputs logs to different destinations according to log output rules. Based on the logs, you can monitor device performance and troubleshoot network problems.

Figure 1 Information center diagram

Log types

Logs are classified into the following types:

- **Standard system logs**—Record common system information. Unless otherwise specified, the term "logs" in this document refers to standard system logs.
- **Diagnostic logs**—Record debugging messages.
- **Security logs**—Record security information, such as authentication and authorization information.
- **Hidden logs**—Record log information not displayed on the terminal, such as input commands.
- **Trace logs**—Record system tracing and debugging messages, which can be viewed only after the devkit package is installed.

Log levels

Logs are classified into eight severity levels from 0 through 7 in descending order. The information center outputs logs with a severity level that is higher than or equal to the specified level. For example, if you specify a severity level of 6 (informational), logs that have a severity level from 0 to 6 are output.

Table 1 Log levels

Severity value	Level	Description
0	Emergency	The system is unusable. For example, the system authorization has expired.
1	Alert	Action must be taken immediately. For example, traffic on an interface exceeds the upper limit.
2	Critical	Critical condition. For example, the device temperature exceeds the upper limit, the power module fails, or the fan tray fails.
3	Error	Error condition. For example, the link state changes.
4	Warning	Warning condition. For example, an interface is disconnected, or the memory resources are used up.
5	Notification	Normal but significant condition. For example, a terminal logs in to the device, or the device reboots.

Severity value	Level	Description
6	Informational	Informational message. For example, a command or a ping operation is executed.
7	Debugging	Debugging message.

Log destinations

The system outputs logs to the following destinations: console, monitor terminal, log buffer, log host, and log file. Log output destinations are independent and you can configure them after enabling the information center. One log can be sent to multiple destinations.

Default output rules for logs

A log output rule specifies the source modules and severity level of logs that can be output to a destination. Logs matching the output rule are output to the destination. Table 2 shows the default log output rules.

Table 2 Default output rules

Destination	Log source modules	Output switch	Severity
Console	All supported modules	Enabled	Debugging
Monitor terminal	All supported modules	Disabled	Debugging
Log host	All supported modules	Enabled	Informational
Log buffer	All supported modules	Enabled	Informational
Log file	All supported modules	Enabled	Informational

Default output rules for diagnostic logs

Diagnostic logs can only be output to the diagnostic log file, and cannot be filtered by source modules and severity levels. Table 3 shows the default output rule for diagnostic logs.

Table 3 Default output rule for diagnostic logs

Destination	Log source modules	Output switch	Severity
Diagnostic log file	All supported modules	Enabled	Debugging

Default output rules for security logs

Security logs can only be output to the security log file, and cannot be filtered by source modules and severity levels. Table 4 shows the default output rule for security logs.

Table 4 Default output rule for security logs

Destination	Log source modules	Output switch	Severity
Security log file	All supported modules	Disabled	Debugging

Default output rules for hidden logs

Hidden logs can be output to the log host, the log buffer, and the log file. Table 5 shows the default output rules for hidden logs.

Table 5 Default output rules for hidden logs

Destination	Log source modules	Output switch	Severity
Log host	All supported modules	Enabled	Informational
Log buffer	All supported modules	Enabled	Informational
Log file	All supported modules	Enabled	Informational

Default output rules for trace logs

Trace logs can only be output to the trace log file, and cannot be filtered by source modules and severity levels. Table 6 shows the default output rules for trace logs.

Table 6 Default output rules for trace logs

Destination	Log source modules	Output switch	Severity
Trace log file in the memory	All supported modules	Enabled	Debugging
Trace log file on the storage device	All supported modules	Enabled	Error

Log formats and field descriptions

Log formats

The format of logs varies by output destinations. The following table shows the original format of log information, which might be different from what you see. The actual format varies by the log resolution tool used.

Table 7 Log formats

Output destination	Format
Console, monitor terminal, log buffer, or log file	Prefix Timestamp Sysname Module/Level/Mnemonic: Content **Example**: `%Nov 24 14:21:43:502 2019 Sysname SHELL/5/SHELL_LOGIN: VTY logged in from 192.168.1.26`

Log host	**Non-customized format**:
	<PRI>Timestamp Sysname %%vvModule/Level/Mnemonic: Location; Content
	Example:
	`<190>Nov 24 16:22:21 2019 Sysname %%10SHELL/5/SHELL_LOGIN: -DevIP=1.1.1.1; VTY logged in from 192.168.1.26<190>Nov 24 16:22:21 2016 Sysname %%10 SHELL/5/SHELL_LOGIN: -DevIP=1.1.1.1; VTY logged in from 192.168.1.26`
	CMCC format:
	<PRI>Timestamp Sysname %vvModule/Level/Mnemonic: Location; Content
	`<189>Oct 9 14:59:04 2019 Sysname %10SHELL/5/SHELL_LOGIN: VTY logged in from 192.168.1.21`

	RFC 5424 format:
	\<PRI\>Version Timestamp Sysname Module - Mnemonic [SysLoc][AppLoc] Content
	`<190>1 2020-09-25T10:42:22.257Z Sysname SHELL – SHELL_LOGIN [SysLoc@25506 VendorID=%%10 Level=6][AppLoc@25506 Line=vty0 IPAddr=192.168.1.21 User=**] VTY logged in from 192.168.1.21`
	SGCC format:

Log field description

Table 8 Log field description

Field	Description
Prefix (information type)	A log to a destination other than the log host has an identifier in front of the timestamp: • An identifier of percent sign (%) indicates a log with a level equal to or higher than informational. • An identifier of asterisk (*) indicates a debugging log or a trace log. • An identifier of caret (^) indicates a diagnostic log.
PRI (priority)	A log destined for the log host has a priority identifier in front of the timestamp. The priority is calculated by using this formula: facility*8+level, where: • **facility** is the facility name. Facility names local0 through local7 correspond to values 16 through 23. The facility name can be configured using the **`info-center loghost`** command. It is used to identify log sources on the log host, and to query and filter the logs from specific log sources. • **level** is in the range of 0 to 7. See Table 1 for more information about severity levels.
Timestamp	Records the time when the log was generated. Logs sent to the log host and those sent to the other destinations have different timestamp precisions, and their timestamp formats are configured with different commands. For more information, see Table 9 and Table 10.
Hostip	Source IP address of the log. If the **`info-center loghost source`** command is configured, this field displays the IP address of the specified source interface. Otherwise, this field displays the sysname. This field exists only in logs that are sent to the log host in unicom format.
Serial number	Serial number of the device that generated the log. This field exists only in logs that are sent to the log host in unicom format.
Sysname (host name or host IP address)	The sysname is the host name or IP address of the device that generated the log. You can use the **`sysname`** command to modify the name of the device.
%% (vendor ID)	Indicates that the information was generated by an H3C device. This field exists only in logs sent to the log host.
vv (version information)	Identifies the version of the log, and has a value of 10. This field exists only in logs that are sent to the log host.

Field	Description
Module	Specifies the name of the module that generated the log. You can enter the **`info-center source ?`** command in system view to view the module list.
Level	Identifies the level of the log. See Table 1 for more information about severity levels.
Mnemonic	Describes the content of the log. It contains a string of up to 32 characters.
Location	Optional field that identifies the log sender. This field exists only in logs that are sent to the log host in non-customized or CMCC format. The field contains the following information: • **DevIp**—IP address of the log sender. • **Slot**—Member ID of the IRF member device that sent the log.
SysLoc	Optional field that identifies the system information of the logs. This field exists only in logs that are sent to the log host in RFC 5424 format. The field contains the following information: • **SysLoc@**—Vendor number of the device that generates logs. • **VendorID**—Vendor ID. Currently, the fixed value is 10. • **Level**—Log level. • **Slot**—Member ID of the IRF member device that sent the log.
AppLoc	Optional field that identifies the module information of the logs. This field exists only in logs that are sent to the log host in RFC 5424 format. The field contains the following information: • **AppLoc@**—Vendor number of the device that generates logs. • **Line**—User line used by the current user for login. • **IPAddr**—IP address used for user login. • **User**—Username for login.
Devtype	Device type. This field exists only in logs that are sent to the log host in SGCC format.
Content	Provides the content of the log.

Table 9 Timestamp precisions and configuration commands

Item	Destined for the log host	Destined for the console, monitor terminal, log buffer, and log file
Precision	Seconds (default) or milliseconds	Milliseconds
Command used to set the timestamp format	**`info-center timestamp loghost`**	**`info-center timestamp`**

Table 10 Description of the timestamp parameters

Timestamp parameters	Description
boot	Time that has elapsed since system startup, in the format of xxx.yyy. xxx represents the higher 32 bits, and yyy represents the lower 32 bits, of milliseconds elapsed. Logs that are sent to all destinations other than a log host support this parameter. **Example**: `%0.109391473 Sysname FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` 0.109391473 is a timestamp in the **boot** format.
date	Current date and time. • For logs output to a log host, the timestamp can be in the format of MMM DD hh:mm:ss YYYY (accurate to seconds) or MMM DD hh:mm:ss.ms YYYY (accurate to milliseconds). • For logs output to other destinations, the timestamp is in the format of MMM DD hh:mm:ss:ms YYYY. All logs support this parameter. **Example**: `%May 30 05:36:29:579 2019 Sysname FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` May 30 05:36:29:579 2019 is a timestamp in the **date** format in logs sent to the console.
iso	Timestamp format stipulated in ISO 8601, accurate to seconds (default) or milliseconds. Only logs that are sent to a log host support this parameter. **Example**: `<189>2019-05-30T06:42:44 Sysname %%10FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` 2019-05-30T06:42:44 is a timestamp in the **iso** format accurate to seconds. A timestamp accurate to milliseconds is like 2019-05-30T06:42:44.708.
none	No timestamp is included. All logs support this parameter. **Example**: `% Sysname FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` No timestamp is included.
no-year-date	Current date and time without year or millisecond information, in the format of MMM DD hh:mm:ss. Only logs that are sent to a log host support this parameter. **Example**: `<189>May 30 06:44:22 Sysname %%10FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` May 30 06:44:22 is a timestamp in the **no-year-date** format.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

Information center tasks at a glance

Managing standard system logs

1. Enabling the information center
2. Outputting logs to various destinations

   Choose the following tasks as needed:
   - Outputting logs to the console
   - Outputting logs to the monitor terminal
   - Outputting logs to log hosts
   - Outputting logs to the log buffer
   - Saving logs to the log file
3. (Optional.) Setting the minimum storage period
4. (Optional.) Enabling synchronous information output
5. (Optional.) Configuring log suppression

   Choose the following tasks as needed:
   - Enabling duplicate log suppression
   - Configuring log suppression for a module
   - Disabling an interface from generating link up or link down logs
6. (Optional.) Enabling SNMP notifications for system logs
7. (Optional.) Performing integrity check for a log file

Managing hidden logs

1. Enabling the information center
2. Outputting logs to various destinations

   Choose the following tasks as needed:
   - Outputting logs to log hosts
   - Outputting logs to the log buffer
   - Saving logs to the log file
3. (Optional.) Setting the minimum storage period
4. (Optional.) Configuring log suppression

   Choose the following tasks as needed:
   - Enabling duplicate log suppression
   - Configuring log suppression for a module

Managing security logs

1. Enabling the information center

2. (Optional.) Configuring log suppression
   Choose the following tasks as needed:
   - Enabling duplicate log suppression
   - Configuring log suppression for a module
3. Managing security logs
   - Saving security logs to the security log file
   - Managing the security log file
4. (Optional.) Performing integrity check for a log file

Managing diagnostic logs

1. Enabling the information center
2. (Optional.) Configuring log suppression
   Choose the following tasks as needed:
   - Enabling duplicate log suppression
   - Configuring log suppression for a module
3. Saving diagnostic logs to the diagnostic log file

Managing trace logs

1. Enabling the information center
2. (Optional.) Configuring log suppression
   Choose the following tasks as needed:
   - Enabling duplicate log suppression
   - Configuring log suppression for a module

Enabling the information center

About this task

The information center can output logs only after it is enabled.

Procedure

1. Enter system view.
   `system-view`
2. Enable the information center.
   `info-center enable`
   The information center is enabled by default.

Outputting logs to various destinations

Outputting logs to the console

Restrictions and guidelines

The **terminal monitor**, **terminal debugging**, and **terminal logging** commands take effect only for the current connection between the terminal and the device. If a new connection is established, the default is restored.

Procedure

1. Enter system view.
   system-view
2. (Optional.) Configure an output rule for sending logs to the console.
   info-center source { *module-name* | **default** } **console** { **deny** | **level** *severity* }
   For information about the default output rules, see "Default output rules for logs."
3. (Optional.) Configure the timestamp format.
   info-center timestamp { **boot** | **date** | **none** }
   The default timestamp format is **date**.
4. Return to user view.
   quit
5. Enable log output to the console.
   terminal monitor
   By default, log output to the console is enabled.
6. Enable output of debugging messages to the console.
   terminal debugging
   By default, output of debugging messages to the console is disabled.
   This command enables output of debugging-level log messages to the console.
7. Set the lowest severity level of logs that can be output to the console.
   terminal logging level *severity*
   The default setting is 6 (informational).

Outputting logs to the monitor terminal

About this task

Monitor terminals refer to terminals that log in to the device through the VTY line.

Restrictions and guidelines

The **terminal monitor**, **terminal debugging**, and **terminal logging** commands take effect only for the current connection between the terminal and the device. If a new connection is established, the default is restored.

Procedure

1. Enter system view.
   system-view
2. (Optional.) Configure an output rule for sending logs to the monitor terminal.

info-center source { *module-name* | **default** } **monitor** { **deny** | **level** *severity* }

For information about the default output rules, see "Default output rules for logs."

3. (Optional.) Configure the timestamp format.

   info-center timestamp { **boot** | **date** | **none** }

   The default timestamp format is **date**.

4. Return to user view.

   quit

5. Enable log output to the monitor terminal.

   terminal monitor

   By default, log output to the monitor terminal is disabled.

6. Enable output of debugging messages to the monitor terminal.

   terminal debugging

   By default, output of debugging messages to the monitor terminal is disabled.

   This command enables output of debugging-level log messages to the monitor terminal.

7. Set the lowest level of logs that can be output to the monitor terminal.

   terminal logging level *severity*

   The default setting is 6 (informational).

Outputting logs to log hosts

About this task

You can use this feature to configure output of device-generated logs to specified log hosts.

When configuring this feature, you can specify the following information for a log host:

- **Log output filters**—Only logs that meet the specified filters are sent to the log host. This prevents logs that you are not concerned about from being sent to the log host and occupying network bandwidth and resources on the log host.
- **Log format**—The device encapsulates logs in the specified format so that the log host can parse the logs according to the corresponding rules.
- **Using TCP to send logs to enhance security**—If the TCP connection is disconnected, the device saves the logs locally in a file for user query.

1. Enter system view.

   system-view

2. (Optional.) Configure a log output filter or a log output rule. Choose one option as needed:
   - Configure a log output filter.

     info-center filter *filter-name* { *module-name* [**mnemonic** *mnemonic-value*] | **default** } { **deny** | **level** *severity* }

     You can create multiple log output filters. When specifying a log host, you can apply a log output filter to the log host to control log output.
   - Configure a log output rule for the log host output destination.

     info-center source { *module-name* | **default** } **loghost** { **deny** | **level** *severity* }

     For information about the default log output rules for the log host output destination, see "Default output rules for logs."

   The system chooses the settings to control log output to a log host in the following order:

   a. Log output filter applied to the log host.

b. Log output rules configured for the log host output destination by using the **info-center source** command.

c. Default log output rules (see "Default output rules for logs").

3. (Optional.) Specify a source IP address for logs sent to log hosts.

   info-center loghost source *interface-type interface-number*

   By default, the source IP address of logs sent to log hosts is the primary IP address of their outgoing interfaces.

4. (Optional.) Specify the format in which logs are output to log hosts.

   info-center format { **cmcc** | **rfc5424** | **sgcc** | **unicom** }

   By default, logs are output to log hosts in non-customized format.

5. (Optional.) Add the device serial number to the location field of logs sent to log hosts.

   info-center loghost locate-info with-sn

   By default, the device does not add the device serial number to the location field of logs sent to log hosts.

6. (Optional.) Configure the timestamp format.

   info-center timestamp loghost { **date** [**with-milliseconds**] | **iso** [**with-milliseconds** | **with-timezone**] * | **no-year-date** | **none** }

   The default timestamp format is **date**.

7. Specify a log host and configure related parameters.

   info-center loghost [**vpn-instance** *vpn-instance-name*] { *hostname* | *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port-number*] [**dscp** *dscp-value*] [**facility** *local-number*] [**filter** *filter-name*] [**format rfc5424-json-v1 tcp** [**end-with-length**] **ssl-client-policy** *policy-name* [**directory** *dir-name* **size-quota** *size*]]

   By default, no log hosts or related parameters are specified.

   The value for the *port-number* argument must be the same as the value configured on the log host. Otherwise, the log host cannot receive logs.

Outputting logs to the log buffer

About this task

This feature enables log output to the log buffer. You can use the **display logbuffer** command to display the log buffer information and the buffered logs.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Configure an output rule for sending logs to the log buffer.

   info-center source { *module-name* | **default** } **logbuffer** { **deny** | **level** *severity* }

   For information about the default output rules, see "Default output rules for logs."

3. (Optional.) Configure the timestamp format.

   info-center timestamp { **boot** | **date** | **none** }

   The default timestamp format is **date**.

4. Enable log output to the log buffer.

   info-center logbuffer

   By default, log output to the log buffer is enabled.

5. (Optional.) Set the maximum log buffer size.

   info-center logbuffer size *buffersize*

   By default, a maximum of 512 logs can be buffered.

Saving logs to the log file

About this task

The log file feature enables log output to the log file. The system saves logs from the log file buffer to the log file. After saving logs to the log file, the system clears the log file buffer.

Log saving from the log file buffer to the log file is triggered by the following situations:

- Periodic saving.
- A manual immediate saving of buffered logs to the log file.
- The log file buffer is full.

A log file is automatically created when needed and has a maximum capacity. The log file capacity restrictions are as follows:

- When log file overwrite-protection is enabled and no log file space is available, the device stops saving new logs.
- When no log file space or storage device space is available, the system creates new log files as needed. The log files are named as **logfile1.log**, **logfile2.log**, and so on.

  When **logfile1.log** is full, the system compresses **logfile1.log** as **logfile1.log.gz** and creates a new log file named **logfile2.log**. The process repeats until the last log file is full.

  After the last log file is full, the device repeats the following process:

  a. The device locates the oldest compressed log file **logfileX.log.gz** and creates a new file using the same name (**logfileX.log**).

  b. When **logfileX.log** is full, the device compresses the log file as **logfileX.log.gz** to replace the existing file **logfileX.log.gz**.

TIP:

- Clean up the storage space of the device regularly to ensure sufficient storage space for the log file feature.
- As a best practice, back up the log files regularly to avoid loss of important logs.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Configure an output rule for sending logs to the log file.

   info-center source { *module-name* | **default** } **logfile** { **deny** | **level** *severity* }

   For information about the default output rules, see "Default output rules for logs."

3. (Optional.) Save log messages in XML format to log files.

   info-center logfile xml-format

   By default, log messages are saved in TXT format to log files.

   This command saves the log messages that are generated on the device in XML format to log files for structured storage and parsing by the log host.

4. Enable the log file feature.

   info-center logfile enable

By default, the log file feature is enabled.

5. (Optional.) Enable log file overwrite-protection.

   info-center logfile overwrite-protection [**all-port-powerdown**]

   By default, log file overwrite-protection is disabled.

   Log file overwrite-protection is supported only in FIPS mode.

6. (Optional.) Set the maximum log file size.

   info-center logfile size-quota *size*

   By default, the maximum log file size is 5 MB.

7. (Optional.) Set the alarm threshold for log file usage.

   info-center logfile alarm-threshold *usage*

   The default alarm threshold for log file usage ratio is 80%. When the usage ratio of the log file reaches 80%, the system outputs a message to inform the user.

   Setting the alarm threshold value to 0 disables the log file usage alarm feature.

8. (Optional.) Specify the log file directory.

   info-center logfile directory *dir-name*

   The default log file directory is **flash:/logfile**.

   This command cannot survive an IRF reboot or a master/subordinate switchover.

9. Save logs in the log file buffer to the log file. Choose one or both options as needed:
   - Configure the automatic log file saving interval.

     info-center logfile frequency *freq-sec*

     The default log file saving interval is 86400 seconds.
   - Immediately save logs from the log file buffer to the log file.

     logfile save

     This command is available in any view.

Setting the minimum storage period

About setting the minimum storage period

Use this feature to set the minimum storage period for logs in the log files and log buffer. This feature ensures that logs will not be overwritten by new logs during a set period of time.

For logs

By default, when the log buffer is full, new logs will automatically overwrite the oldest logs. After the minimum storage period is set, the system identifies the storage period of a log to determine whether to delete the log. The system current time minus a log's generation time is the log's storage period.

- If the storage period of a log is shorter than or equal to the minimum storage period, the system does not delete the log. The new log will not be saved.
- If the storage period of a log is longer than the minimum storage period, the system deletes the log to save the new log.

For log files

By default, when the last log file is full, the device locates the oldest compressed log file **logfileX.log.gz** and creates a new file using the same name (**logfileX.log**). After the minimum storage period is set, the system identifies the storage period of the compressed log file before creating a new log file with the same name. The system current time minus the log file's last modification time is the log file's storage period.

- If the storage period of the compressed log file is shorter than or equal to the minimum storage period, the system stops saving new logs.
- If the storage period of the compressed log file is longer than the minimum storage period, the system creates a new file to save new logs.

Procedure

1. Enter system view.
   system-view
2. Set the minimum storage period for logs in the log files and log buffer.
   info-center syslog min-age *min-age*
   By default, the minimum storage period is not set.

Enabling synchronous information output

About this task

System log output interrupts ongoing configuration operations, obscuring previously entered commands. Synchronous information output shows the obscured commands. It also provides a command prompt in command editing mode, or a [Y/N] string in interaction mode so you can continue your operation from where you were stopped.

Procedure

1. Enter system view.
   system-view
2. Enable synchronous information output.
   info-center synchronous
   By default, synchronous information output is disabled.

Configuring log suppression

Enabling duplicate log suppression

About this task

The information center on the device outputs logs generated by service modules. The device identifies logs that have the same module name, level, mnemonic, location, and text as duplicate logs.

In some scenarios, for example, ARP attack or link failure, the service modules will generate a large volume of duplicate logs during a short period of time. Recording and output of consecutive duplicate logs wastes system and network resources. To resolve this issue, you can enable duplicate log suppression.

With this feature enabled, when a service module generates a log, the information center outputs the log and starts the duplicate log suppression timer. The suppression period of the duplicate log suppression timer varies by phase. The suppression periods in phase 1, 2, and later phases are 30 seconds, 2 minutes, and 10 minutes, respectively.

After you enable duplicate log suppression, the system starts suppression upon outputting a log:

- If only duplicate logs of the log are received during the suppression period of a phase, the information center does not output the duplicate logs. When the suppression period of the

phase expires, the information center outputs the suppressed log and the number of times the log is suppressed, and starts the next suppression phase.

- If a different log is received during the suppression period of a phase, the information center performs the following operations:
  - Stops suppression on the log, and outputs the suppressed log and the number of times the log is suppressed.
  - Outputs the different log and starts phase-1 suppression for that log.
- If no log is received within the suppression period of any phase, the information center deletes the duplicate log suppression timer, stops suppression on the log, and does not output any log.

Procedure

1. Enter system view.

   `system-view`

2. Enable duplicate log suppression.

   `info-center logging suppress duplicates`

   By default, duplicate log suppression is disabled.

Examples

The following example uses SHELL_CMD logs to verify the duplicate log suppression feature. After the user executes a command on the device, the information center receives a SHELL_CMD log generated by the shell module, encapsulates the log, and then outputs the log to the log buffer.

1. Verify the suppression effect in phases 1, 2, 3, and 4 of a log (with suppression period of 30 seconds, 2 minutes, 10 minutes, and 10 minutes):

   # In a lab environment, continuously execute the **`display logbuffer`** command for 25 minutes.

   # View the output logs in the log buffer.

```
<Sysname> display logbuffer
Log buffer: Enabled
Max buffer size: 1024
Actual buffer size: 512
Dropped messages: 0
Overwritten messages: 0
Current messages: 5
%Jul 20 13:01:20:615 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer
%Jul 20 13:01:50:718 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 2 times in last 30 seconds.
%Jul 20 13:03:50:732 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 5 times in last 2 minutes.
%Jul 20 13:13:50:830 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 10 times in last 10 minutes.
%Jul 20 13:23:50:211 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 6 times in last 10 minutes.
```

   The output shows the following information:

   - The information center received the log **SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**; Command is display logbuffer**.
   - In phase 1, the log was suppressed twice by the information center.
   - In phase 2, the log was suppressed five times by the information center.
   - In phase 3, the log was suppressed 10 times by the information center.
   - In phase 4, the log was suppressed six times by the information center.

2. Continue to verify how duplicate log suppression works when a different log is received during the suppression period of a log:

   # Execute the **display logbuffer** command three times, and then execute the **display interface brief** command.

   # View the output logs in the log buffer.

```
<Sysname> display logbuffer
Log buffer: Enabled
Max buffer size: 1024
Actual buffer size: 512
Dropped messages: 0
Overwritten messages: 0
Current messages: 5
%Jul 20 13:01:20:615 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer
%Jul 20 13:01:50:718 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 2 times in last 30 seconds.
%Jul 20 13:03:50:732 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 5 times in last 2 minutes.
%Jul 20 13:13:50:830 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 10 times in last 10 minutes.
%Jul 20 13:23:50:211 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 6 times in last 10 minutes.
%Jul 20 13:24:56:205 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 3 times in last 1 minute 6 seconds.
%Jul 20 13:25:41:205 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display interface brief.
<Sysname>
```

   The output shows the following information:

   - The information center stopped suppression for the log **SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**; Command is display logbuffer**.
   - The information center output the log **SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**; Command is display interface brief**, and started suppression for it.

Configuring log suppression for a module

About this task

This feature suppresses output of logs. You can use this feature to filter out the logs that you are not concerned with.

Perform this task to configure a log suppression rule to suppress output of all logs or logs with a specific mnemonic value for a module.

Procedure

1. Enter system view.

   system-view

2. Configure a log suppression rule for a module.

   info-center logging suppress module *module-name* **mnemonic** { **all** | *mnemonic-value* }

   By default, the device does not suppress output of any logs from any modules.

Disabling an interface from generating link up or link down logs

About this task

By default, an interface generates link up or link down log information when the interface state changes. In some cases, you might want to disable certain interfaces from generating this information. For example:

- You are concerned about the states of only some interfaces. In this case, you can use this function to disable other interfaces from generating link up and link down log information.
- An interface is unstable and continuously outputs log information. In this case, you can disable the interface from generating link up and link down log information.

Use the default setting in normal cases to avoid affecting interface status monitoring.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Disable the interface from generating link up or link down logs.

   undo enable log updown

   By default, an interface generates link up and link down logs when the interface state changes.

Enabling SNMP notifications for system logs

About this task

This feature enables the device to send an SNMP notification for each log message it outputs. The device encapsulates the logs in SNMP notifications and then sends them to the SNMP module and the log trap buffer.

You can configure the SNMP module to send received SNMP notifications in SNMP traps or informs to remote hosts. For more information, see "Configuring SNMP."

To view the traps in the log trap buffer, access the MIB corresponding to the log trap buffer.

Procedure

1. Enter system view.

   system-view
2. Enable SNMP notifications for system logs.

   snmp-agent trap enable syslog

   By default, the device does not send SNMP notifications for system logs.
3. Set the maximum number of traps that can be stored in the log trap buffer.

   info-center syslog trap buffersize *buffersize*

   By default, the log trap buffer can store a maximum of 1024 traps.

Managing security logs

Saving security logs to the security log file

About this task

Security logs are very important for locating and troubleshooting network problems. Generally, security logs are output together with other logs. It is difficult to identify security logs among all logs.

To solve this problem, you can save security logs to the security log file without affecting the current log output rules.

After you enable the security log file feature, the system processes security logs as follows:

1. Outputs security logs to the security log file buffer.
2. Saves logs from the security log file buffer to the security log file at the specified interval.

   If you have the security-audit role, you can also manually save security logs to the security log file.
3. Clears the security log file buffer immediately after the security logs are saved to the security log file.

Restrictions and guidelines

The device supports only one security log file. The system will overwrite old logs with new logs when the security log file is full. To avoid security log loss, you can set an alarm threshold for the security log file usage ratio. When the alarm threshold is reached, the system outputs a message to inform you of the alarm. You can log in to the device with the security-audit user role and back up the security log file to prevent the loss of important data.

Procedure

1. Enter system view.

   system-view
2. Enable the security log file feature.

   info-center security-logfile enable

   By default, the security log file feature is disabled.
3. Set the interval at which the system saves security logs.

   info-center security-logfile frequency *freq-sec*

   The default security log file saving interval is 86400 seconds.
4. (Optional.) Set the maximum size for the security log file.

   info-center security-logfile size-quota *size*

   The default maximum security log file size is 10 MB.
5. (Optional.) Set the alarm threshold of the security log file usage.

   info-center security-logfile alarm-threshold *usage*

   By default, the alarm threshold of the security log file usage ratio is 80. When the usage of the security log file reaches 80%, the system will send a message.

Managing the security log file

Restrictions and guidelines

To use the security log file management commands, you must have the security-audit user role. For information about configuring the security-audit user role, see AAA in *Security Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Change the directory of the security log file.
   info-center security-logfile directory *dir-name*
   By default, the security log file is saved in the **seclog** directory in the root directory of the storage device.
   The device uses the default security log file directory after an IRF reboot or a master/subordinate switchover.
3. Manually save all logs in the security log file buffer to the security log file.
   security-logfile save
   This command is available in any view.
4. (Optional.) Display the summary of the security log file.
   display security-logfile summary
   This command is available in any view.

Performing integrity check for a log file

About this task

When the information center saves a log message to the log file, it uses the device master key to calculate a digest for the log file and saves the digest in the log file. The digest is used to perform integrity check for the log file. You can use the default device master key or a master key configured by using the **set master-key** command. For more information about the master key, see public key management in *Security Configuration Guide*.

When this feature is configured, the information center uses the master key to recalculate a digest for the log file and then compares the digest with that saved in the log file. If the two digests are consistent, the log file passes the integrity check. If they do not match, the log file fails the integrity check.

Restrictions and guidelines

Currently, only standard system log files and security log files support integrity check, while diagnostic log files and trace log files do not support integrity check.

Procedure

To perform integrity check for a log file, execute the following command in user view:

check logfile *file-path*

For successful execution of this command, the file extension must be **.log**, **.log.gz**, **.xml**, or **.xml.gz**.

Saving diagnostic logs to the diagnostic log file

About this task

By default, the diagnostic log file feature saves diagnostic logs from the diagnostic log file buffer to the diagnostic log file at the specified saving interval. You can also manually trigger an immediate saving of diagnostic logs to the diagnostic log file. After saving diagnostic logs to the diagnostic log file, the system clears the diagnostic log file buffer.

The device supports multiple diagnostic log files. Each diagnostic log file has a maximum capacity. The diagnostic log files are named as **diagfile1.log**, **diagfile2.log**, and so on. When **diagfile1.log** is

full, the system compresses **diagfile1.log** as **diagfile1.log.gz** and creates a new diagnostic log file named **diagfile2.log**. The process repeats until the last diagnostic log file is full.

After the last diagnostic log file is full, the device repeats the following process:

1. The device locates the oldest compressed diagnostic log file **diagfileX.log.gz** and creates a new file using the same name (**diagfileX.log**).
2. When **diagfileX.log** is full, the device compresses the log file as **diagfileX.log.gz** to replace the existing file **diagfileX.log.gz**.

To avoid loss of important logs, back up the diagnostic log files regularly.

Procedure

1. Enter system view.
   system-view
2. Enable the diagnostic log file feature.
   info-center diagnostic-logfile enable
   By default, the diagnostic log file feature is enabled.
3. (Optional.) Set the maximum diagnostic log file size.
   info-center diagnostic-logfile quota *size*
   The default maximum diagnostic log file size is 5 MB.
4. (Optional.) Specify the diagnostic log file directory.
   info-center diagnostic-logfile directory *dir-name*
   The default diagnostic log file directory is **flash:/diagfile**.
   The device uses the default diagnostic log file directory after an IRF reboot or a master/subordinate switchover.
5. Save diagnostic logs in the diagnostic log file buffer to the diagnostic log file. Choose one option as needed:
   - Configure the automatic diagnostic log file saving interval.
     info-center diagnostic-logfile frequency *freq-sec*
     The default diagnostic log file saving interval is 86400 seconds.
   - Manually save diagnostic logs to the diagnostic log file.
     diagnostic-logfile save
     This command is available in any view.

Setting the maximum size of the trace log file

About this task

The device has only one trace log file. When the trace log file is full, the device overwrites the oldest trace logs with new ones.

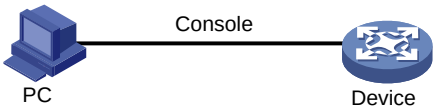
Procedure

1. Enter system view.
   system-view
2. Set the maximum size for the trace log file.
   info-center trace-logfile quota *size*
   The default maximum size of the trace log file is 10 MB.

Display and maintenance commands for information center

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the diagnostic log file configuration.	**display diagnostic-logfile summary**
Display the information center configuration.	**display info-center**
Display information about log output filters.	**display info-center filter** [*filter-name*]
Display log buffer information and buffered logs.	**display logbuffer** [**reverse**] [**level** *severity* | **size** *buffersize* | **slot** *slot-number*] * [**last-mins** *mins*]
Display the log buffer summary.	**display logbuffer summary** [**level** *severity* | **slot** *slot-number*] *
Display the content of the log file buffer.	**display logfile buffer**
Display the log file configuration.	**display logfile summary**
Display the content of the security log file buffer. (To execute this command, you must have the security-audit user role.)	**display security-logfile buffer**
Display summary information of the security log file.	**display security-logfile summary**
Clear the log buffer.	**reset logbuffer**



Information center configuration examples

Example: Outputting logs to the console

Network configuration

Configure the device to output to the console FTP logs that have a minimum severity level of **warning**.

Figure 2 Network diagram

Procedure

Enable the information center.

```
<Device> system-view
[Device] info-center enable
```

Disable log output to the console.

```
[Device] info-center source default console deny
```

To avoid output of unnecessary information, disable all modules from outputting log information to the specified destination (**console** in this example) before you configure the output rule.

Configure an output rule to output to the console FTP logs that have a minimum severity level of **warning**.

```
[Device] info-center source ftp console level warning
[Device] quit
```

Enable log output to the console.

```
<Device> terminal logging level 6
<Device> terminal monitor
The current terminal is enabled to display logs.
```

Now, if the FTP module generates logs, the information center automatically sends the logs to the console, and the console displays the logs.

Example: Outputting logs to a UNIX log host

Network configuration

Configure the device to output to the UNIX log host FTP logs that have a minimum severity level of **informational**.

Figure 3 Network diagram

Procedure

1. Make sure the device and the log host can reach each other. (Details not shown.)
2. Configure the device:

   # Enable the information center.

   ```
   <Device> system-view
   [Device] info-center enable
   ```

   # Specify log host 1.2.0.1/16 with **local4** as the logging facility.

   ```
   [Device] info-center loghost 1.2.0.1 facility local4
   ```

   # Disable log output to the log host.

   ```
   [Device] info-center source default loghost deny
   ```

   To avoid output of unnecessary information, disable all modules from outputting logs to the specified destination (**loghost** in this example) before you configure an output rule.

   # Configure an output rule to output to the log host FTP logs that have a minimum severity level of **informational**.

   ```
   [Device] info-center source ftp loghost level informational
   ```

3. Configure the log host:

   The log host configuration procedure varies by the vendor of the UNIX operating system. The following shows an example:

   a. Log in to the log host as a root user.

   b. Create a subdirectory named **Device** in directory **/var/log/**, and then create file **info.log** in the **Device** directory to save logs from the device.

```
# mkdir /var/log/Device
# touch /var/log/Device/info.log
```

c. Edit file **syslog.conf** in directory **/etc/** and add the following contents:

```
# Device configuration messages
local4.info /var/log/Device/info.log
```

In this configuration, **local4** is the name of the logging facility that the log host uses to receive logs. The value **info** indicates the **informational** severity level. The UNIX system records the log information that has a minimum severity level of **informational** to file **/var/log/Device/info.log**.

NOTE:

Follow these guidelines while editing file **/etc/syslog.conf**:

- Comments must be on a separate line and must begin with a pound sign (#).
- No redundant spaces are allowed after the file name.
- The logging facility name and the severity level specified in the **/etc/syslog.conf** file must be identical to those configured on the device by using the **`info-center loghost`** and **`info-center source`** commands. Otherwise, the log information might not be output to the log host correctly.

d. Display the process ID of **syslogd**, kill the **syslogd** process, and then restart **syslogd** by using the **–r** option to validate the configuration.

```
# ps -ae | grep syslogd
147
# kill -HUP 147
# syslogd -r &
```

Now, the device can output FTP logs to the log host, which stores the logs to the specified file.

Example: Outputting logs to a Linux log host

Network configuration

Configure the device to output to the Linux log host 1.2.0.1/16 FTP logs that have a minimum severity level of **informational**.

Figure 4 Network diagram

Procedure

1. Make sure the device and the log host can reach each other. (Details not shown.)
2. Configure the device:

   # Enable the information center.

   ```
   <Device> system-view
   [Device] info-center enable
   ```

   # Specify log host 1.2.0.1/16 with **local5** as the logging facility.

   ```
   [Device] info-center loghost 1.2.0.1 facility local5
   ```

   # Disable log output to the log host.

```
[Device] info-center source default loghost deny
```

To avoid outputting unnecessary information, disable all modules from outputting log information to the specified destination (**loghost** in this example) before you configure an output rule.

Configure an output rule to enable output to the log host FTP logs that have a minimum severity level of **informational**.

```
[Device] info-center source ftp loghost level informational
```

3. Configure the log host:

The log host configuration procedure varies by the vendor of the Linux operating system. The following shows an example:

a. Log in to the log host as a root user.

b. Create a subdirectory named **Device** in directory **/var/log/**, and create file **info.log** in the **Device** directory to save logs from the device.

```
# mkdir /var/log/Device
# touch /var/log/Device/info.log
```

c. Edit file **syslog.conf** in directory **/etc/** and add the following contents:

```
# Device configuration messages
local5.info /var/log/Device/info.log
```

In this configuration, **local5** is the name of the logging facility that the log host uses to receive logs. The value **info** indicates the **informational** severity level. The Linux system will store the log information with a severity level equal to or higher than **informational** to file **/var/log/Device/info.log**.

NOTE:

Follow these guidelines while editing file **/etc/syslog.conf**:

- Comments must be on a separate line and must begin with a pound sign (#).
- No redundant spaces are allowed after the file name.
- The logging facility name and the severity level specified in the **/etc/syslog.conf** file must be identical to those configured on the device by using the **`info-center loghost`** and **`info-center source`** commands. Otherwise, the log information might not be output to the log host correctly.

d. Display the process ID of **syslogd**, kill the **syslogd** process, and then restart **syslogd** by using the **-r** option to validate the configuration.

Make sure the **syslogd** process is started with the **-r** option on the Linux log host.

```
# ps -ae | grep syslogd
147
# kill -9 147
# syslogd -r &
```

Now, the device can output FTP logs to the log host, which stores the logs to the specified file.

Configuring the packet capture

About packet capture

The packet capture feature captures packets. It can display the captured packets in real time, or save the captured packets to a .pcap file for future analysis.

Packet capture modes

The device supports the following packet capture modes: local packet capture, remote packet capture, and feature image-based packet capture.

Local packet capture

Local packet capture saves captured packets to a remote file on an FTP server or to a local file.

Remote packet capture

Remote packet capture sends captured packets to a remote packet analyzer (for example, Wireshark).

IMPORTANT:

The remote packet analyzer must support the Remote Capture Protocol (RPCAP).

Feature image-based packet capture

Feature image-based packet capture saves the captured packets to a local file or displays the captured packets on the terminal. This mode can also display contents of .pcap and .pcapng files.

Feature image-based packet capture requires you to install a specific image called the packet feature image.

Only feature image-based packet capture requires the packet feature image.

Filter rule elements

Packet capture supports using a capture filter rule to filter packets to be captured or using a display filter rule to filter packets to be displayed.

A filter rule is represented by a filter expression. A filter expression contains a keyword string or multiple keyword strings that are connected by operators.

Keywords include the following types:

- **Qualifiers**—Fixed keyword strings. To use a qualifier, you must enter the qualifier literally as shown.
- **Variables**—Values assigned in the required format.

Operators include the following types:

- **Logical operators**—Perform logical operations, such as the AND operation.
- **Arithmetic operators**—Perform arithmetic operations, such as the ADD operation.
- **Relational operators**—Indicate the relation between keyword strings. For example, the **=** operator indicates equality.

For more information about capture and display filters, go to the following websites:

- https://wiki.wireshark.org/CaptureFilters

- https://wiki.wireshark.org/DisplayFilters

Building a capture filter rule

Capture filter rule keywords

Qualifiers

Table 1 Qualifiers for capture filter rules

Category	Description	Examples
Protocol	Matches a protocol. If you do not specify a protocol qualifier, the filter matches any supported protocols.	• **arp**—Matches ARP. • **icmp**—Matches ICMP. • **ip**—Matches IPv4. • **ip6**—Matches IPv6. • **tcp**—Matches TCP. • **udp**—Matches UDP.
Direction	Matches packets based on its source or destination location (an IP address or port number). If you do not specify a direction qualifier, the **src or dst** qualifier applies. For example, **port 23** is equivalent to **src or dst port 23**.	• **src**—Matches the source IP address field. • **dst**—Matches the destination IP address field. • **src or dst**—Matches the source or destination IP address field.
Type	Specifies the direction type. The **host** qualifier applies if you do not specify any type qualifier. For example, **src 2.2.2.2** is equivalent to **src host 2.2.2.2**.	• **host**—Matches the IP address of a host. • **net**—Matches an IP subnet. • **port**—Matches a service port number. • **portrange**—Matches a service port range.
Others	Any other qualifiers than the previously described qualifiers.	• **broadcast**—Matches broadcast packets. • **multicast**—Matches multicast and broadcast packets. • **less**—Matches packets that are less than or equal to a specific size. • **greater**—Matches packets that are greater than or equal to a specific size. • **len**—Matches the packet length. • **vlan**—Matches VLAN packets.

Variables

A capture filter variable must be modified by one or more qualifiers.

The **broadcast**, **multicast**, and all protocol qualifiers cannot modify variables. The other qualifiers must be followed by variables.

Table 2 Variable types for capture filter rules

Variable type	Description	Examples
Integer	Represented in binary, octal, decimal, or hexadecimal notation.	The **port 23** expression matches traffic sent to or from port number 23.

Variable type	Description	Examples
Integer range	Represented by hyphenated integers.	The **portrange 100-200** expression matches traffic sent to or from any ports in the range of 100 to 200.
IPv4 address	Represented in dotted decimal notation.	The **src 1.1.1.1** expression matches traffic sent from the IPv4 host at 1.1.1.1.
IPv6 address	Represented in colon hexadecimal notation.	The **dst host 1::1** expression matches traffic sent to the IPv6 host at 1::1.
IPv4 subnet	Represented by an IPv4 network ID or an IPv4 address with a mask.	Both of the following expressions match traffic sent to or from the IPv4 subnet 1.1.1.0/24: • **src 1.1.1**. • **src net 1.1.1.0/24**.
IPv6 network segment	Represented by an IPv6 address with a prefix length.	The **dst net 1::/64** expression matches traffic sent to the IPv6 network 1::/64.

Capture filter rule operators

Logical operators

Logical operators are left associative. They group from left to right. The **not** operator has the highest priority. The **and** and **or** operators have the same priority.

Table 3 Logical operators for capture filter rules

Nonalphanumeric symbol	Alphanumeric symbol	Description
!	not	Reverses the result of a condition. Use this operator to capture traffic that matches the opposite value of a condition. For example, to capture non-HTTP traffic, use **not port 80**.
&&	and	Joins two conditions. Use this operator to capture traffic that matches both conditions. For example, to capture non-HTTP traffic that is sent to or from 1.1.1.1, use **host 1.1.1.1 and not port 80**.
||	or	Joins two conditions. Use this operator to capture traffic that matches either of the conditions. For example, to capture traffic that is sent to or from 1.1.1.1 or 2.2.2.2, use **host 1.1.1.1 or host 2.2.2.2**.

Arithmetic operators

Table 4 Arithmetic operators for capture filter rules

Nonalphanumeric symbol	Description
+	Adds two values.
-	Subtracts one value from another.
*	Multiplies one value by another.

Nonalphanumeric symbol	Description
/	Divides the value on the left by the value on the right.
&	Returns the result of the bitwise AND operation on two integral values in binary form.
|	Returns the result of the bitwise OR operation on two integral values in binary form.
<<	Performs the bitwise left shift operation on the operand to the left of the operator. The right-hand operand specifies the number of bits to shift.
>>	Performs the bitwise right shift operation on the operand to the left of the operator. The right-hand operand specifies the number of bits to shift.
[ ]	Specifies a byte offset relative to a protocol layer. This offset indicates the byte where the matching begins. You must enclose the offset value in the brackets and specify a protocol qualifier. For example, **ip[6]** matches the seventh byte of payload in IPv4 packets (the byte that is six bytes away from the beginning of the IPv4 payload).

Relational operators

Table 5 Relational operators for capture filter rules

Nonalphanumeric symbol	Description
=	Equal to. For example, **ip[6]=0x1c** matches an IPv4 packet if its seventh byte of payload is equal to 0x1c.
!=	Not equal to. For example, **len!=60** matches a packet if its length is not equal to 60 bytes.
>	Greater than. For example, **len>100** matches a packet if its length is greater than 100 bytes.
<	Less than. For example, **len<100** matches a packet if its length is less than 100 bytes.
>=	Greater than or equal to. For example, **len>=100** matches a packet if its length is greater than or equal to 100 bytes.
<=	Less than or equal to. For example, **len<=100** matches a packet if its length is less than or equal to 100 bytes.

Capture filter rule expressions

Logical expression

Use this type of expression to capture packets that match the result of logical operations.

Logical expressions contain keywords and logical operators. For example:

- **not port 23 and not port 22**—Captures packets with a port number that is not 23 or 22.
- **port 23 or icmp**—Captures packets with a port number 23 or ICMP packets.

In a logical expression, a qualifier can modify more than one variable connected by its nearest logical operator. For example, to capture packets sourced from IPv4 address 192.168.56.1 or IPv4 network 192.168.27, use either of the following expressions:

- **src 192.168.56.1 or 192.168.27**.
- **src 192.168.56.1 or src 192.168.27**.

The *expr relop expr* expression

Use this type of expression to capture packets that match the result of arithmetic operations.

This expression contains keywords, arithmetic operators (*expr*), and relational operators (*relop*). For example, **len+100>=200** captures packets that are greater than or equal to 100 bytes.

The *proto*[*expr*:*size*] expression

Use this type of expression to capture packets that match the result of arithmetic operations on a number of bytes relative to a protocol layer.

This type of expression contains the following elements:

- *proto*–Specifies a protocol layer.
- []—Performs arithmetic operations on a number of bytes relative to the protocol layer.
- *expr*—Specifies the arithmetic expression.
- *size*—Specifies the byte offset. This offset indicates the number of bytes relative to the protocol layer. The operation is performed on the specified bytes. The offset is set to 1 byte if you do not specify an offset.

For example, **ip[0]&0xf !=5** captures an IP packet if the result of ANDing the first byte with 0x0f is not 5.

To match a field, you can specify a field name for *expr*:*size*. For example, **icmp[icmptype]=0x08** captures ICMP packets that contain a value of 0x08 in the Type field.

The vlan *vlan_id* expression

Use this type of expression to capture 802.1Q tagged VLAN traffic.

This type of expression contains the **vlan** *vlan_id* keywords and logical operators. The *vlan_id* variable is an integer that specifies a VLAN ID. For example, **vlan 1 and ip** captures IPv4 packets in VLAN 1.

To capture packets of a VLAN, set a capture filter as follows:

- To capture tagged packets that are permitted on the interface, you must use the **vlan** *vlan_id* expression prior to any other expressions. For example, use the **vlan 3 and src 192.168.1.10 and dst 192.168.1.1** expression to capture packets of VLAN 3 that are sent from 192.168.1.10 to 192.168.1.1.
- To capture an untagged packet that is received on the interface, do not add **vlan** *vlan_id* to the capture filter expression if the device does not add a VLAN tag to the packet header.

Building a display filter rule

A display filter rule only identifies the packets to display. It does not affect which packets to save in a file.

Display filter rule keywords

Qualifiers

Table 6 Qualifiers for display filter rules

Category	Description	Examples
Protocol	Matches a protocol. If you do not specify a protocol qualifier, the filter matches any supported protocols.	• **eth**—Matches Ethernet. • **ftp**—Matches FTP. • **http**—Matches HTTP. • **icmp**—Matches ICMP. • **ip**—Matches IPv4. • **ipv6**—Matches IPv6. • **tcp**—Matches TCP. • **telnet**—Matches Telnet. • **udp**—Matches UDP.
Packet field	Matches a field in packets by using a dotted string in the *protocol.field*[*.level1-subfield*]…[*.leveln-subfield*] format.	• **tcp.flags.syn**—Matches the SYN bit in the flags field of TCP. • **tcp.port**—Matches the source or destination port field of TCP.

Variables

A packet field qualifier requires a variable.

Table 7 Variable types for display filter rules

Variable type	Description
Integer	Represented in binary, octal, decimal, or hexadecimal notation. For example, to display IP packets that are less than or equal to 1500 bytes, use one of the following expressions: • **ip.len le 1500**. • **ip.len le 02734**. • **ip.len le 0x436**.
Boolean	This variable type has two values: true or false. This variable type applies if you use a packet field string alone to identify the presence of a field in a packet. • If the field is present, the match result is true. The filter displays the packet. • If the field is not present, the match result is false. The filter does not display the packet. For example, to display TCP packets that contain the SYN field, use **tcp.flags.syn**.
MAC address (6 bytes)	Uses colons (:), dots (.), or hyphens (-) to break up the MAC address into two or four segments. For example, to display packets that contain a destination MAC address of ffff.ffff.ffff, use one of the following expressions: • **eth.dst==ff:ff:ff:ff:ff:ff**. • **eth.dst==ff-ff-ff-ff-ff-ff**. • **eth.dst ==ffff.ffff.ffff**.
IPv4 address	Represented in dotted decimal notation. For example: • To display IPv4 packets that are sent to or from 192.168.0.1, use **ip.addr==192.168.0.1**.

Variable type	Description
	• To display IPv4 packets that are sent to or from 129.111.0.0/16, use **ip.addr==129.111.0.0/16**.
IPv6 address	Represented in colon hexadecimal notation. For example: • To display IPv6 packets that are sent to or from 1::1, use **ipv6.addr==1::1**. • To display IPv6 packets that are sent to or from 1::/64, use **ipv6.addr==1::/64**.
String	Character string. For example, to display HTTP packets that contain the string **HTTP/1.1** for the request version field, use **http.request version=="HTTP/1.1"**.

Display filter rule operators

Logical operators are left associative. They group from left to right. The [ ] operator has the highest priority. The **not** operator has the highest priority. The **and** and **or** operators have the same priority.

Logical operators

Table 8 Logical operators for display filter rules

Nonalphanumeric symbol	Alphanumeric symbol	Description
[ ]	No alphanumeric symbol is available.	Used with protocol qualifiers. For more information, see "The proto[…] expression."
!	not	Displays packets that do not match the condition connected to this operator.
&&	and	Joins two conditions. Use this operator to display traffic that matches both conditions.
||	or	Joins two conditions. Use this operator to display traffic that matches either of the conditions.

Relational operators

Table 9 Relational operators for display filter rules

Nonalphanumeric symbol	Alphanumeric symbol	Description
==	eq	Equal to. For example, **ip.src==10.0.0.5** displays packets with the source IP address as 10.0.0.5.
!=	ne	Not equal to. For example, **ip.src!=10.0.0.5** displays packets whose source IP address is not 10.0.0.5.
>	gt	Greater than. For example, **frame.len>100** displays frames with a length greater than 100 bytes.
<	lt	Less than.

Nonalphanumeric symbol	Alphanumeric symbol	Description
		For example, **frame.len<100** displays frames with a length less than 100 bytes.
>=	ge	Greater than or equal to. For example, **frame.len ge 0x100** displays frames with a length greater than or equal to 256 bytes.
<=	le	Less than or equal to. For example, **frame.len le 0x100** displays frames with a length less than or equal to 256 bytes.

Display filter rule expressions

Logical expression

Use this type of expression to display packets that match the result of logical operations.

Logical expressions contain keywords and logical operators. For example, **ftp or icmp** displays all FTP packets and ICMP packets.

Relational expression

Use this type of expression to display packets that match the result of comparison operations.

Relational expressions contain keywords and relational operators. For example, **ip.len<=28** displays IP packets that contain a value of 28 or fewer bytes in the length field.

Packet field expression

Use this type of expression to display packets that contain a specific field.

Packet field expressions contain only packet field strings. For example, **tcp.flags.syn** displays all TCP packets that contain the SYN bit field.

The *proto*[…] expression

Use this type of expression to display packets that contain specific field values.

This type of expression contains the following elements:

- *proto*–Specifies a protocol layer or packet field.
- […]—Matches a number of bytes relative to a protocol layer or packet field. Values for the bytes to be matched must be a hexadecimal integer string. The expression in brackets can use the following formats:
  - [*n*:*m*]—Matches a total of *m* bytes after an offset of *n* bytes from the beginning of the specified protocol layer or field. To match only 1 byte, you can use both [n] and [n:1] formats. For example, **eth.src[0:3]==00:00:83** matches an Ethernet frame if the first three bytes of its source MAC address are 0x00, 0x00, and 0x83. The **eth.src[2] == 83** expression matches an Ethernet frame if the third byte of its source MAC address is 0x83.
  - [*n*-*m*]—Matches a total of (*m*-*n*+*1*) bytes, starting from the (*n*+*1)*th byte relative to the beginning of the specified protocol layer or packet field. For example, **eth.src[1-2]==00:83** matches an Ethernet frame if the second and third bytes of its source MAC address are 0x00 and 0x83, respectively.

Restrictions: Hardware compatibility with the packet capture

The packet capture feature is available only on the S5200-HI-G switch series.

Restrictions and guidelines: Packet capture

To capture packets forwarded through chips, first configure a traffic behavior to mirror the traffic to the CPU.

To capture packets forwarded by the CPU, enable packet capture directly.

The packet capture feature can capture only packets of a frame length equal to or less than 9196 bytes. If the frame length of a packet exceeds 9196 bytes, the system does not capture the packet.

Configuring local packet capture

To configure local packet capture, execute the following command in user view:

packet-capture local interface *interface-type interface-number* [**capture-filter** *capt-expression* | **limit-frame-size** *bytes* | **autostop filesize** *kilobytes* | **autostop duration** *seconds*] * **write** { *filepath* | **url** *url* [**username** *username* [**password** { **cipher** | **simple** } *string*]] }

The packet capture is executed in the background. After issuing this command, you can continue to configure other commands.

Configuring remote packet capture

About this task

To capture packets on an interface and send them to a remote packet analyzer (for example, Wireshark), perform this task. With remote packet capture, the analyzer must establish an RPCAP connection to the default or specified RPCAP service port on the device to receive captured packets.

To make sure a packet analyzer can establish an RPCAP connection to receive packets captured from an interface on the device, use the following procedure to configure remote packet capture:

1. Configure remote packet capture for the interface before you connect the packet analyzer to the device.
2. Configure the device as a server on the packet analyzer and connect the packet analyzer to the device. When you configure the device as a server, specify its IP address and make sure the RPCAP port number is the same as that configured on the device for the interface.

Procedure

1. Configure remote packet capture for an interface in user view:

   packet-capture remote interface *interface-type interface-number* [**port** *port*]
2. Connect the packet analyzer (for example, Wireshark) to the device. For more information about the packet analyzer, see its documentation.

Configuring feature image-based packet capture

Restrictions and guidelines

After configuring feature image-based packet capture, you cannot configure any other commands at the CLI until the capture finishes or is stopped.

There might be a delay for the capture to stop because of heavy traffic.

Prerequisites

1. Use the **display boot-loader** command to check whether the packet capture feature image is installed.
2. If the image is not installed, install the image by using the **boot-loader**, **install**, or **issu** command series.
3. Log out of the device and then log in again.

For more information about the commands, see *Fundamentals Command Reference*.

Saving captured packets to a file

To configure feature image-based packet capture and save the captured packets to a file, execute the following command in user view:

packet-capture interface *interface-type interface-number* [**capture-filter** *capt-expression* | **limit-captured-frames** *limit* | **limit-frame-size** *bytes* | **autostop filesize** *kilobytes* | **autostop duration** *seconds* | **autostop files** *numbers* | **capture-ring-buffer filesize** *kilobytes* | **capture-ring-buffer duration** *seconds* | **capture-ring-buffer files** *numbers*] * **write** *filepath* [**raw** | { **brief** | **verbose** }] *

Displaying specific captured packets

To configure feature image-based packet capture and display specific packet data, execute the following command in user view:

packet-capture interface *interface-type interface-number* [**capture-filter** *capt-expression* | **display-filter** *disp-expression* | **limit-captured-frames** *limit* | **limit-frame-size** *bytes* | **autostop duration** *seconds*] * [**raw** | { **brief** | **verbose** }] *

Stopping packet capture

About this task

Use this task to manually stop packet capture.

Procedure

Choose one option as needed:

- Stop local or remote packet capture.

  packet-capture stop

  Execute this command in user view.

- Stop feature image-based packet capture.

  Press **Ctrl+C**.

Displaying the contents in a packet file

About this task

Use this task to display the contents of a .pcap or .pcapng file on the device. Alternatively, you can transfer the file to a PC and use a packet analyzer (for example, Wireshark) to display the file content.

Prerequisites

1. Use the **display boot-loader** command to check whether the packet capture feature image is installed.
2. If the image is not installed, install the image by using **boot-loader**, **install**, or **issu** commands.
3. Log out of the device and then log in again.

For more information about the commands, see *Fundamentals Command Reference*.

Restrictions and guidelines

To stop displaying the contents, press **Ctrl+C**.

Procedure

To display the contents in a local packet file, execute the following command in user view:

packet-capture read *filepath* [**display-filter** *disp-expression*] [**raw** | { **brief** | **verbose** }] *

Display and maintenance commands for packet capture

Execute **display** commands in any view.

Task	Command
Display status information about local or remote packet capture.	**display packet-capture status**

Packet capture configuration examples

Example: Configuring remote packet capture

Network configuration

As shown in Figure 1, capture packets forwarded through the CPU or chips on Layer 2 interface GigabitEthernet 1/0/1. Use Wireshark to display the captured packets.

Figure 1 Network diagram

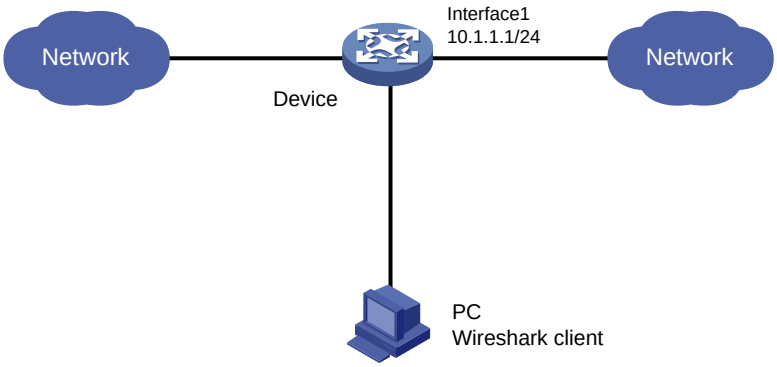

Table 10 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

1. Configure the device:

   # Apply a QoS policy to the incoming direction of GigabitEthernet 1/0/1 to capture packets destined for the 20.1.1.0/16 network that are forwarded through chips.

   a. Create an IPv4 advanced ACL to match packets that are sent to the 20.1.1.0/16 network.

   ```
   <Device> system-view
   [Device] acl advanced 3000
   [Device-acl-ipv4-adv-3000] rule permit ip destination 20.1.1.0 255.255.0.0
   [Device-acl-ipv4-adv-3000] quit
   ```

   b. Configure a traffic behavior to mirror traffic to the CPU.

   ```
   [Device] traffic behavior behavior1
   [Device-behavior-behavior1] mirror-to cpu
   [Device-behavior-behavior1] quit
   ```

   c. Configure a traffic class to use the ACL to match traffic.

   ```
   [Device] traffic classifier classifier1
   [Device-classifier-class1] if-match acl 3000
   [Device-classifier-class1] quit
   ```

   d. Configure a QoS policy. Associate the traffic class with the traffic behavior.

   ```
   [Device] qos policy user1
   [Device-qospolicy-user1] classifier classifier1 behavior behavior1
   [Device-qospolicy-user1] quit
   ```

   e. Apply the QoS policy to the incoming direction of GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] qos apply policy user1 inbound
   [Device-GigabitEthernet1/0/1] quit
   [Device] quit
   ```

   # Configure remote packet capture on GigabitEthernet 1/0/1. Set the RPCAP service port number to 2014.

   ```
   <Device> packet-capture remote interface gigabitethernet 1/0/1 port 2014
   ```

2. Configure Wireshark:

a. Start Wireshark on the PC and select **Capture** > **Options**.
b. Select **Remote** from the **Interface** list.
c. Enter the IP address of the device **10.1.1.1** and the RPCAP service port number **2014**. Make sure there are routes available between the IP address and the PC.
d. Click **OK** and then click **Start**.

   The captured packets are displayed on the Wireshark.

NOTE:

Options and option placement available with Wireshark might differ depending on its version.

Example: Configuring feature image-based packet capture

Network configuration

As shown in Figure 2, capture incoming IP packets of VLAN 3 on Layer 2 interface GigabitEthernet 1/0/1 that meet the following conditions:

- Sent from 192.168.1.10 or 192.168.1.11 to 192.168.1.1.
- Forwarded through the CPU or chips.

Figure 2 Network diagram

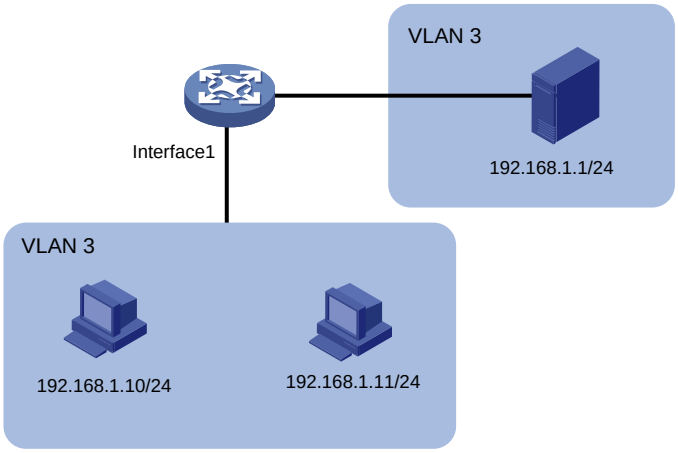

Table 11 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

1. Install the packet capture feature.

   # Identify versions of the boot and system images running on the device. Prepare a packet capture feature image that is compatible with the current boot and system images.

```
<Device> display version
H3C Comware Software, Version 7.1.070, Demo 01
Copyright (c) 2004-2019 New H3C Technologies Co., Ltd. All rights reserved.
H3C XXX uptime is 0 weeks, 0 days, 5 hours, 33 minutes
Last reboot reason : Cold reboot
Boot image: flash:/boot-01.bin
```

```
Boot image version: 7.1.070, Demo 01
  Compiled Oct 20 2019 16:00:00
System image: flash:/system-01.bin
System image version: 7.1.070, Demo 01
  Compiled Oct 20 2019 16:00:00
...
```

Download the packet capture feature image to the device. In this example, download the **packet-capture-01.bin** image stored on the TFTP server at 192.168.1.1.

```
<Device> tftp 192.168.1.1 get packet-capture-01.bin
Press CTRL+C to abort.
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed
100 11.3M    0 11.3M    0     0   155k      0 --:--:--  0:01:14 --:--:--  194k
Writing file...Done.
```

Install the packet capture feature image on all IRF member devices and commit the software change. In this example, there are two IRF member devices.

```
<Device> install activate feature flash:/packet-capture-01.bin slot 1
Verifying the file flash:/packet-capture-01.bin on slot 1....Done.
Identifying the upgrade methods....Done.
Upgrade summary according to following table:

flash:/packet-capture-01.bin
  Running Version             New Version
  None                        Demo 01

  Slot                        Upgrade Way
  1                           Service Upgrade
Upgrading software images to compatible versions. Continue? [Y/N]:y
This operation might take several minutes, please wait...................Done.
<Device> install activate feature flash:/packet-capture-01.bin slot 2
Verifying the file flash:/packet-capture-01.bin on slot 2....Done.
Identifying the upgrade methods....Done.
Upgrade summary according to following table:

flash:/packet-capture-01.bin
  Running Version             New Version
  None                        Demo 01

  Slot                        Upgrade Way
  2                           Service Upgrade
Upgrading software images to compatible versions. Continue? [Y/N]:y
This operation might take several minutes, please wait...................Done.
<Device> install commit
This operation will take several minutes, please wait.....................Done.
```

Log out and then log in to the device again so you can execute the **`packet-capture interface`** and **`packet-capture read`** commands.

2. Apply a QoS policy to the incoming direction of GigabitEthernet 1/0/1 to capture packets from 192.168.1.10 or 192.168.1.11 to 192.168.1.1 that are forwarded through chips.

Create an IPv4 advanced ACL to match packets that are sent from 192.168.1.10 or 192.168.1.11 to 192.168.1.1.

```
<Device> system-view
[Device] acl advanced 3000
[Device-acl-ipv4-adv-3000] rule permit ip source 192.168.1.10 0 destination 192.168.1.1 0
[Device-acl-ipv4-adv-3000] rule permit ip source 192.168.1.11 0 destination 192.168.1.1 0
[Device-acl-ipv4-adv-3000] quit
```

Configure a traffic behavior to mirror traffic to the CPU.

```
[Device] traffic behavior behavior1
[Device-behavior-behavior1] mirror-to cpu
[Device-behavior-behavior1] quit
```

Configure a traffic class to use the ACL to match traffic.

```
[Device] traffic classifier classifier1
[Device-classifier-class1] if-match acl 3000
[Device-classifier-class1] quit
```

Configure a QoS policy. Associate the traffic class with the traffic behavior.

```
[Device] qos policy user1
[Device-qospolicy-user1] classifier classifier1 behavior behavior1
[Device-qospolicy-user1] quit
```

Apply the QoS policy to the incoming direction of GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] qos apply policy user1 inbound
[Device-GigabitEthernet1/0/1] quit
[Device] quit
```

3. Enable packet capture.

Capture incoming traffic on GigabitEthernet 1/0/1. Set the maximum number of captured packets to 10. Save the captured packets to the **flash:/a.pcap** file.

```
<Device> packet-capture interface gigabitethernet 1/0/1 capture-filter "src 192.168.1.10 or 192.168.1.11 and dst 192.168.1.1" limit-captured-frames 10 write flash:/a.pcap
Capturing on 'GigabitEthernet1/0/1'
10
```

Verifying the configuration

Telnet to 192.168.1.1 from 192.168.1.10. (Details not shown.)

Display the contents in the packet file on the device.

```
<Device> packet-capture read flash:/a.pcap
  1  0.000000 192.168.1.10 -> 192.168.1.1 TCP 62 6325 > telnet [SYN] Seq=0 Win=65535 Len=0 MSS=1460 SACK_PERM=1

Managing device performance

About performance management

The performance management feature samples device performance and collects performance statistics, such as packet drop statistics in the inbound and outbound directions on an interface. You can use commands on the device to display the statistics or configure the device to transfer the statistics to a network management server through gRPC or NETCONF.

For more information about gRPC, see gRPC configuration in *Telemetry Configuration Guide*.

Figure 1 Performance management diagram

Restrictions and guidelines: Performance management

This feature supports collecting only statistics for traffic on interfaces in the current software version.

The gRPC feature is supported only on the S5200-HI-G switch series.

Performance management tasks at a glance

To manage device performance, perform the following tasks:

1. Configuring performance statistics tasks
2. Enabling performance statistics

Configuring performance statistics tasks

About this task

A performance statistics task periodically samples performance and collects performance statistics.

A performance statistics task contains the following parameters:

- **Instance**—Object for which you want to collect performance statistics. The current software version supports only physical interfaces and tunnel interfaces.
- **Performance sampling interval**—Intervals at which the device samples performance data.

- **Performance statistics interval**—Intervals at which the device collects performance statistics, including the peak values, valley values, and average values.

Restrictions and guidelines

Changing the sampling interval or statistics interval for a performance statistics task deletes all performance statistics for the task and recollects the performance statistics.

Changing the statistics interval also changes the sampling interval to the default corresponding to the new statistics interval.

Deleting a performance statistics task terminates the task and deletes all performance statistics for the task.

Procedure

1. Enter system view.

   system-view

2. Enter performance management view.

   performance-management

3. Create a performance statistics task and enter its view.

   statistics task *task-name*

   By default, no performance statistics tasks exist in the system.

   The device supports a maximum of 16 performance statistics task.

4. Bind a performance management instance to the performance statistics task.

   binding instance-type *instance-type* { **all** { **physical** | **tunnel** } | **instance** { *instance-name* } &<1-8> }

   By default, no performance management instances are bound to a performance statistics task.

5. Set the performance statistics interval.

   statistics interval *interval*

   The default statistics interval is 15 minutes.

6. Set the performance sampling interval.

   sample interval *interval*

   The default sampling interval and the possible sampling interval values vary by statistics interval, as shown in the following table:

Statistics interval (minutes)	Default sampling interval (seconds)	Available sampling interval values (seconds)
5	5	5, 10, 15, and 30
10	5	5, 10, 15, 30, and 60
15	5	5, 10, 15, 30, and 60
30	60	5, 10, 15, 30, and 60
60	300	5, 10, 15, 30, 60, and 300
1440	900	300, 600, 900, 1800, and 3600

Enabling performance statistics

1. Enter system view.

system-view

2. Enter performance management view.
   performance-management
3. Enable performance statistics.
   statistics enable
   By default, performance statistics is disabled.

Display and maintenance commands for performance management configuration

Execute **display** commands in any view.

Task	Command
Display the performance statistics for a performance statistics task.	**display performance-management statistics** *task-name* **data** *index* [**instance-type** *instance-type-name* [**measure** *measure-name* | **instance** { *instance-name* } &<1-8>] *]
Display performance statistics task information.	**display performance-management task** [*task-name*]

Performance management configuration examples

Example: Configuring performance management (gRPC)

Network configuration

As shown in Figure 2, configure Device B as a gRPC client to report performance statistics for GigabitEthernet 1/0/1 to the gRPC server. Set the sampling interval to 5 seconds and the statistics interval to 15 minutes.

Figure 2 Network diagram

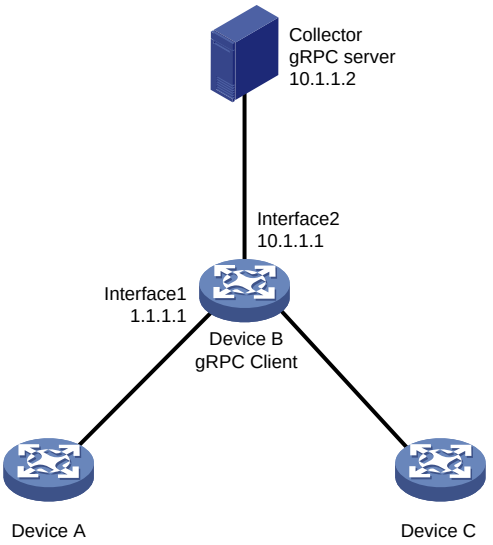

Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Assign IP addresses to interfaces and configure routes. Make sure the network connection is available between the device and the server. (Details not shown.)
2. Configure Device B as a gRPC client:

   # Enable the gRPC service.

   ```
   <DeviceB> system-view
   [DeviceB] grpc enable
   ```

   # Create a sensor group named **test**, and add sensor path **ifmgr/devicecapabilities/**.

   ```
   [DeviceB] telemetry
   [DeviceB-telemetry] sensor-group test
   [DeviceB-telemetry-sensor-group-test] sensor path ifmgr/devicecapabilities
   [DeviceB-telemetry-sensor-group-test] quit
   ```

   # Create a destination group named **collector1**. Specify a collector that uses IPv4 address 10.1.1.2 and port number 50050.

   ```
   [DeviceB-telemetry] destination-group collector1
   [DeviceB-telemetry-destination-group-collector1] ipv4-address 10.1.1.2 port 50050
   [DeviceB-telemetry-destination-group-collector1] quit
   ```

   # Configure a subscription named **A** to bind sensor group **test** with destination group **collector1**. Set the sampling interval to 900 seconds.

   ```
   [DeviceB-telemetry] subscription A
   [DeviceB-telemetry-subscription-A] sensor-group test sample-interval 900
   [DeviceB-telemetry-subscription-A] destination-group collector1
   [DeviceB-telemetry-subscription-A] quit
   [DeviceB-telemetry] quit
   ```
3. Configure performance management for interface GigabitEthernet 1/0/1.

Enter performance management view.

```
<DeviceB> system-view
[DeviceB] performance-management
```

Create a performance statistics task named **task1** and enter its view.

```
[DeviceB-pm] statistics task task1
```

Bind instance GigabitEthernet 1/0/1 to the task.

```
[DeviceB-pm-task-task1] binding instance-type interface instance gigabitethernet
1/0/1
```

Set the statistics interval to 15 minutes.

```
[DeviceB-pm-task-task1] statistics interval 15
```

Set the sampling interval to 5 seconds.

```
[DeviceB-pm-task-task1] sample interval 5
[DeviceB-pm-task-task1] quit
```

Enable performance statistics.

```
[DeviceB-pm] statistics enable
```

Verifying the configuration

Verify that the gRPC server receives performance statistics for GigabitEthernet 1/0/1 from Device B at 900-second intervals. (Details not shown.)

Example: Configuring performance management (NETCONF)

Network configuration

As shown in Figure 3, configure Device B as a NETCONF server to report performance statistics for GigabitEthernet 1/0/1 to the NETCONF client. Set the sampling interval to 5 seconds and the statistics interval to 15 minutes.

Figure 3 Network diagram

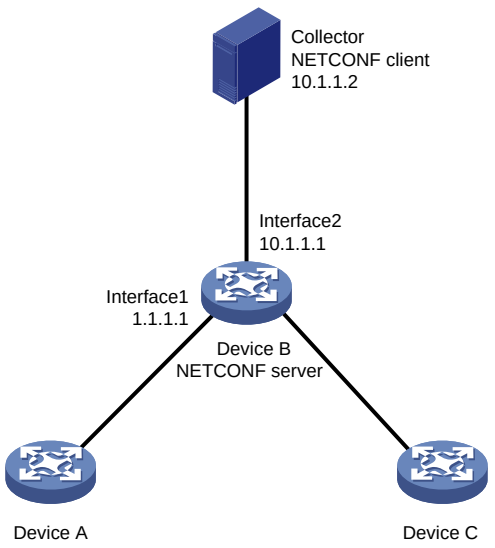

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Interface2	GigabitEthernet1/0/2

Procedure

1. Assign IP addresses to interfaces and configure routes. Make sure the network connection is available between the device and the server. (Details not shown.)
2. Configure performance management for interface GigabitEthernet 1/0/1.

   # Enter performance management view.

   ```
   <DeviceB> system-view
   [DeviceB] performance-management
   ```

   # Create a performance statistics task named **task1** and enter its view.

   ```
   [DeviceB-pm] statistics task task1
   ```

   # Bind instance GigabitEthernet 1/0/1 to the task.

   ```
   [DeviceB-pm-task-task1] binding instance-type interface instance gigabitethernet
   1/0/1
   ```

   # Set the statistics interval to 15 minutes.

   ```
   [DeviceB-pm-task-task1] statistics interval 15
   ```

   # Set the sampling interval to 5 seconds.

   ```
   [DeviceB-pm-task-task1] sample interval 5
   [DeviceB-pm-task-task1] quit
   ```

   # Enable performance statistics.

   ```
   [DeviceB-pm] statistics enable
   ```

3. Configure the NETCONF settings on Device B. (Details not shown.) For more information, see "Configuring NETCONF."

Verifying the configuration

Verify that the NETCONF client receives performance statistics for GigabitEthernet 1/0/1 from Device B at intervals. (Details not shown.)

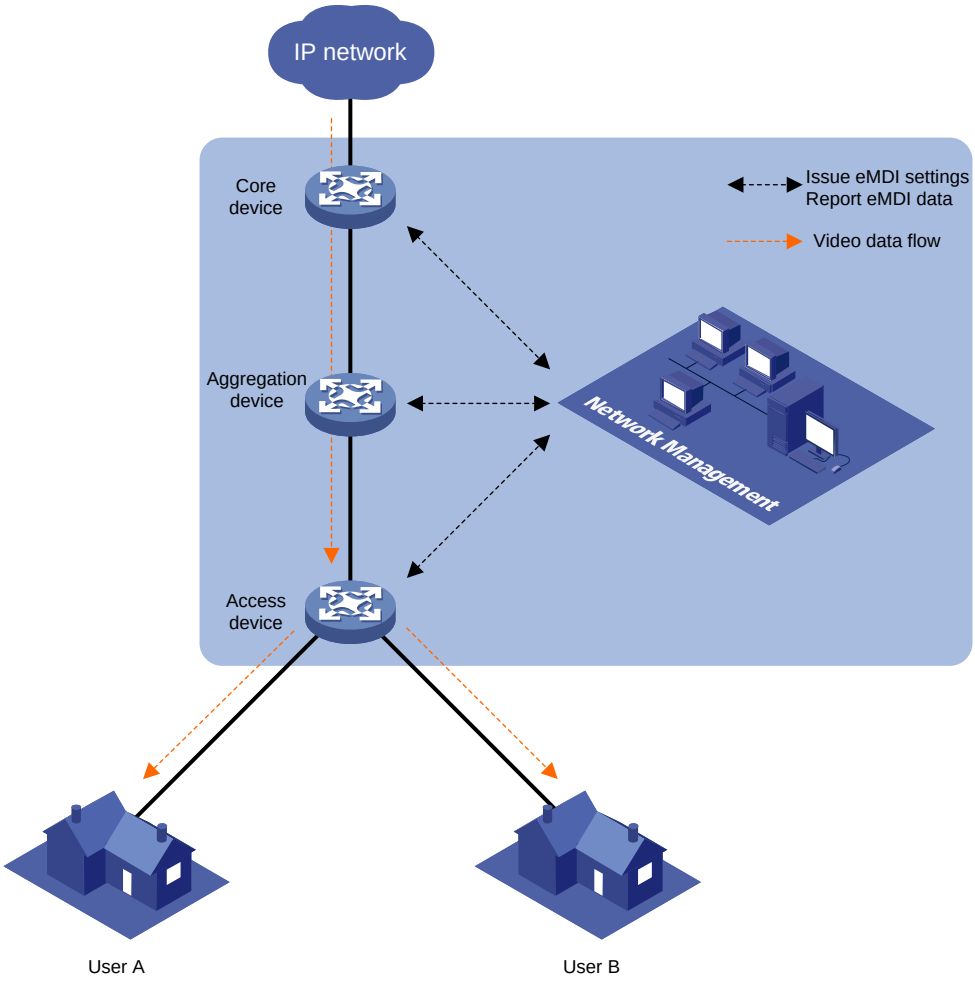
Configuring eMDI

About eMDI

Enhanced Media Delivery Index (eMDI) is a solution to audio and video service quality monitoring and fault locating. It is intended to solve problems caused by packet loss, packet sequence errors, and jitters.

eMDI monitors and analyzes specific TCP or RTP packets on each node of an IP network in real time, providing data for you to quickly locate network faults.



eMDI implementation

The eMDI feature is implemented on the basis of eMDI instances. For an eMDI instance, you can configure parameters, including the target data flow, monitoring period, alarm thresholds, and lifetime. Each eMDI instance monitors one data flow as defined by its parameters. It inspects fields of packets, periodically collects statistics, and reports to the NMS.

Figure 1 shows the eMDI deployment and operating process.

1. Upon service quality deterioration, you can obtain the data flow characteristics from the headers of interested packets, such as the source and destination IP addresses.
2. You deploy eMDI on each device that the data flow traverses by using the NMS or CLI.
3. The devices monitor the data flows, collect statistics, and report monitoring data to the NMS.
4. The NMS collects and analyzes the monitoring data and displays the analysis results graphically.
5. Based on the analysis results, you can quickly locate the network faults.

Figure 1 eMDI network diagram

Monitored items

Table 1 and Table 2 list the monitored items for TCP packets and UDP packets. RTP packets are carried in UDP packets.

Table 1 Monitored items for TCP packets

Item	Description	Calculation formula	Remarks
Rate	Packet input rate, in bps or pps.	• Rate (bps) = Total length of packets received within a monitoring period / Monitoring period • Rate (pps) = Number of packets received within a monitoring period / Monitoring period	This item is intended for unidirectional flows.

Item	Description	Calculation formula	Remarks
Upstream Packet Lost Ratio (UPLR)	Upstream packet loss rate.	UPLR = Number of lost upstream packets / (Number of received packets + Number of lost upstream packets)	If no packets are lost, the sequence number of the current packet plus the length of the current packet is the expected sequence number of the next packet. If the sequence number of the next packet is greater than the expected sequence number, packet loss has occurred on an upstream device. The number of lost packets can be calculated based on the average packet size. This item is intended for unidirectional flows.
Downstream Packet Lost Ratio (DPLR)	Downstream packet loss rate.	• Number of lost downstream packets = Total number of lost packets – Number of lost upstream packets • DPLR = Number of lost downstream packets / Number of received packets	If no packets are lost, the sequence number of the current packet plus the length of the current packet is the expected sequence number of the next packet. If the sequence number of the next packet is smaller than the expected sequence number, the packet is considered to be a retransmitted packet. The number of retransmitted packets is considered to be the total number of lost packets. This item is intended for unidirectional flows.
Downstream average Round Trip Time (DRTT)	Average downstream round trip time, in microseconds.	DRTT = T2 – T1	The timestamp for a received non-retransmitted packet is recorded as T1. The sequence number of the packet plus the length of the packet is the expected sequence number of the next packet. If the sequence number of an ACK packet received from a downstream device is greater than or equal to the expected number, the timestamp of the ACK packet is recorded as T2. DRTT is equal to the average value of the differences between the T2 values and the corresponding T1 values. This item is intended for bidirectional flows.

Item	Description	Calculation formula	Remarks
Upstream average Round Trip Time (URTT)	Average upstream round trip time, in microseconds.	URTT = T2 – T1	T1 indicates the timestamp when the device finds a SYN packet sent by the client for a connection. T2 indicates the timestamp when the device finds a SYN ACK packet returned by the server. Because URTT calculation depends on TCP control packets, it might not be calculated within a monitoring period. This item is intended for bidirectional flows.

Table 2 Monitored items for UDP packets

Item	Description	Calculation formula	Remarks
RTP Lost Rate (RTP-LR)	RTP packet loss rate.	RTP-LR = Number of lost packets / (Number of received packets + Number of lost packets – Number of out-of-order packets)	If the difference between the sequence number of current RTP packet and the greatest sequence number of earlier RTP packets is greater than 1, packet loss has occurred. If the sequence number of the current RTP packet is smaller than the sequence numbers of all earlier RTP packets, the packet is an out-of-order packet. This item is intended for unidirectional flows.
RTP Sequence Error Ratio (RTP-SER)	RTP packet sequence error rate.	RTP-SER = Number of out-of-order packets / (Number of received packets + Number of lost packets – Number of out-of-order packets)	This item is intended for unidirectional flows.
Jitter	RTP packet jitter, in microseconds.	Jitter = T2 – T1	T1 represents the interval between the time when the sender sends the first packet and the time when the sender sends the last packet. T2 represents the interval between the time when the receiver receives the first packet and the time when the receiver receives the last packet. This item is intended for unidirectional flows.

Item	Description	Calculation formula	Remarks
RTP Lost Packet (RTP-LP)	Maximum number of continuously lost RTP packets.	Maximum number of continuously lost RTP packets within a monitoring period.	The network administrators or network management applications can monitor the RTP-LP values to achieve the following purposes: • Determine the network state to promptly respond to network failures and ensure the smooth operation of critical services. For example, if the RTP-LP value increases rapidly, it means that traffic bursts might exist in the network. In this case, you can identify whether these bursts result from an attack and consider rate-limiting the bursts. If the RTP-LP value exceeds the empirical or normal value, it means network congestion or other failures exist. In this case, you can adjust packet retransmission policies, increase bandwidth, or activate backup links to alleviate bandwidth pressure and reduce packet loss effectively. • Quickly locate network failures by monitoring RTP-LP values in sections when service packets travel through various network devices from source to destination. This method helps identify the area where packet loss occurs, narrows down the failure detection range, and increases the troubleshooting efficiency. This item is intended for unidirectional flows.

Item	Description	Calculation formula	Remarks
RTP Effective Loss Factor (RTP-ELF)	RTP effective loss factor for Forward Error Correct (FEC).	RTP-ELF=Total number of packet loss windows in a period / Total number of sliding windows in that period.	The RTP-ELF value is the ratio of the total number of packet loss windows to the total number of sliding windows within a monitoring period. The RTP-ELF value is calculated based on the window size and the predefined packet loss threshold. When the number of service packets sampled within the monitoring period on the device reaches the sliding window size, the first window is generated and the sliding window count becomes 1. Each time a packet is received subsequently, one packet slides back to create a new window, and the sliding window count increments by one. Each window identifies whether the number of lost packets exceeds the predefined threshold. If the threshold is exceeded, the window is considered a packet lost window and the packet loss window count increments by 1. This process continues until the monitoring period ends and the window stops sliding. At this point, the device calculates the RTP-ELF value based on the total number of sliding windows and the total number of packet loss windows during the monitoring period. If the total number of packet loss windows exceeds 0 within a monitoring period, the period is considered to have a transmission failure.

eMDI collaboration with service modules

eMDI instances include static and dynamic types. Static instances are created by using the **instance** command, while dynamic instances are created by service modules through calling eMDI.

The device supports running multiple instances simultaneously. Use the **display emdi instance** command to view information about the current running instances.

Restrictions and guidelines

eMDI is required on each node that monitored data flows traverse.

An eMDI instance can monitor only one data flow. The data flows for different eMDI instances cannot be the same or overlapped.

The following data flows are overlapped:

- **`flow ipv4 tcp source 1.1.1.1 destination 2.2.2.2`**
- **`flow ipv4 tcp source 1.1.1.1 destination 2.2.2.2 destination-port 20`**

For these two flows, if you have configured one data flow for an instance, the system will not allow you to configure the other data flow for a different instance.

The following data flows are not overlapped:

- **`flow ipv4 tcp source 1.1.1.1 destination 2.2.2.2 destination-port 10`**
- **`flow ipv4 tcp source 1.1.1.1 destination 2.2.2.2 destination-port 20`**

The device will detect a configuration conflict and fail to create the later instance if either of the following conditions exists for a dynamic instance created by a service module and a static instance manually created by an administrator:

- The target data flow parameters of the dynamic instance match those of the static instance.
- The target data flow parameters overlap for the dynamic instance and the static instance.

As a best practice, adjust the static instance parameters if dynamic instance creation fails. This ensures successful dynamic instance creation and allows the service module to monitor relevant values through eMDI.

The **`clock-rate`** keyword for the **`flow ipv4 udp`** command does not result in UDP flow overlapping.

A started eMDI instance automatically stops upon a master/subordinate or active/standby switchover or when the eMDI process restarts. You must execute the **`start`** command again to start the instance.

To modify the configuration for an eMDI instance that is already started, stop the instance first by executing the **`stop`** command.

Incomplete eMDI data might cause deviations in the monitoring results. The eMDI data is incomplete in the following situations:

- Not all packets of the monitored data flow pass through the device.
- All packets of the monitored data flow pass through the device, but not all of the packets are forwarded by the same member device.

Restrictions and guidelines: Hardware compatibility with eMDI

Only the S5200-HI-G switch series supports eMDI.

Prerequisites

Identify the characteristics of the data flows to be monitored so you can specify data flows for eMDI instances.

Configure eMDI

Configuring an eMDI instance

1. Enter system view.

   system-view

2. Enable eMDI and enter its view.

   emdi

   By default, eMDI is disabled.

3. Create an eMDI instance and enter its view.

   instance *instance-name*

   By default, no eMDI instance exists.

4. (Optional.) Configure a description for the eMDI instance.

   description *text*

   By default, an eMDI instance does not have a description.

5. Specify the data flow to be monitored by using the eMDI instance.

   Choose one option as needed:

   - Specify a TCP data flow.

     flow ipv4 tcp source *source-ip-address* **destination** *destination-ip-address* [**destination-port** *destination-port-number* | **source-port** *source-port-number* | **vlan** *vlan-id*] *

   - Specify a UDP data flow.

     flow ipv4 udp source *source-ip-address* **destination** *destination-ip-address* [**destination-port** *destination-port-number* | **source-port** *source-port-number* | **vlan** *vlan-id* **pt** *pt-value* | **clock-rate** *clock-rate-value*] *

   By default, no data flow is specified for an eMDI instance.

   Specifying more options defines a more granular data flow and provides more helpful monitoring data and analysis results. For example, to monitor the data from 10.0.0.1 to 10.0.1.1/100, specify the destination port number. If you do not specify the destination port number, the instance monitors the flow that the first received matching packet represents, which might cause deviations on the monitoring results.

6. (Optional.) Set the alarm thresholds for the eMDI instance.

   alarm { **dplr** | **rtp-lr** | **rtp-ser** | **uplr** } **threshold** *threshold-value*

   By default, the alarm thresholds for an eMDI instance are all 100.

   A **TCP data flow** supports only the **dplr** and **uplr keywords and** a **UDP data flow supports only the rtp-lr and rtp-ser keywords.**

7. (Optional.) Set the eMDI alarm logging threshold, that is, the number of consecutive alarms to be suppressed before logging the event.

   alarm suppression times *times-value*

   By default, the eMDI alarm logging threshold is 3.

8. (Optional.) Specify the sliding window size and packet loss threshold for the UDP data flow to be monitored.

   fec { **window** *window-size* | **threshold** *threshold-value* } *

By default, the sliding window size and packet loss threshold for the UDP data flow is 100 and 5, respectively.

9. (Optional.) Specify the eMDI instance lifetime.
   lifetime { **seconds** *seconds* | **minutes** *minutes* | **hours** *hours* | **days** *days* }
   By default, the eMDI instance lifetime is 1 hour.
10. (Optional.) Specify the monitoring period for the eMDI instance.
    monitor-period *period-value*
    By default, the monitoring period for an eMDI instance is 60 seconds.

Starting an eMDI instance

1. Enter system view.
   system-view
2. Enter eMDI view.
   emdi
3. Enter eMDI instance view.
   instance *instance-name*
4. Start the eMDI instance.
   Start

Stopping an eMDI instance

To stop a single eMDI instance:

1. Enter system view.
   system-view
2. Enter eMDI view.
   emdi
3. Enter eMDI instance view.
   instance *instance-name*
4. Stop the eMDI instance.
   Stop

To stop all eMDI instances:

5. Enter system view.
   system-view
6. Enter eMDI view.
   emdi
7. Stop all eMDI instances.
   stop all

Enabling SNMP notifications for eMDI

About this task

With SNMP notifications enabled for the eMDI module, this module can generate alarms to report important events of this module. The generated alarms are sent to the SNMP module of the device. You can specify how the alarms are output through setting the alarm output parameters in SNMP.

For more information about configuring SNMP, see *Network Management and Monitoring Configuration Guide*.

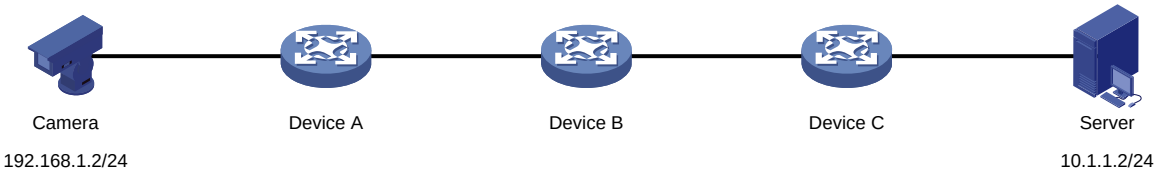
Procedure

1. Enter system view.
   system-view
2. Enable SNMP notifications for the eMDI module.
   snmp-agent trap enable emdi
   By default, SNMP notifications are enabled for eMDI.

Display and maintenance commands for eMDI

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display eMDI instance information.	**display emdi instance** [**name** *instance-name* | **id** *instance-id*] [**verbose**]
Display eMDI instance resource information.	**display emdi resource**
Display monitoring statistics for an eMDI instance.	**display emdi statistics** { **instance-name** *instance-name* | **instance-id** *instance-id* } [**number** *number*] [**abnormal** | **verbose**]
Clear eMDI statistics.	**reset emdi statistics** [**instance-name** *instance-name* | **instance-id** *instance-id-value*]



eMDI configuration examples

Example: Configuring an eMDI instance for a UDP data flow

Network configuration

As shown in Figure 2, the camera sends an RTP video data flow to the server through Device A, Device B, and Device C. The server is experiencing an erratic video display problem. Configure eMDI on Device A, Device B, and Device C to locate the faulty link or device.

Figure 2 Network diagram

Prerequisites

Assign IP addresses to the devices. Make sure all devices can reach each other.

Procedure

1. Configure Device A:

Enable eMDI.

```
<DeviceA> system-view
[DeviceA] emdi
```

Create an eMDI instance named as **test**.

```
[DeviceA-emdi] instance test
```

Specify the UDP data flow for the instance to monitor. Set the source and destination IP addresses to 192.168.1.2 and 10.1.1.2, respectively.

```
[DeviceA-emdi-instance-test] flow ipv4 udp source 192.168.1.2 destination 10.1.1.2
```

Set the monitoring period to 10 seconds.

```
[DeviceA-emdi-instance-test] monitor-period 10
```

Set the eMDI instance lifetime to 30 minutes.

```
[DeviceA-emdi-instance-test] lifetime minutes 30
```

Start the eMDI instance.

```
[DeviceA-emdi-instance-test] start
```

2. Configure Device B and Device C as Device A is configured. (Details not shown.)

Verifying the configuration

After the eMDI instance runs for a while, display brief monitoring statistics for the eMDI instance on each device to locate the fault.

Display brief monitoring statistics for eMDI instance **test** on Device A.

```
<DeviceA> display emdi statistics instance-name test
Instance name    : test
Instance ID      : 1
Monitoring period: 10 sec
Protocol         : UDP

Unit for RTP-LR, RTP-SER and RTP-ELF is 1/100000
Timestamp            Status   RTP-LR  RTP-SER  Jitter(us)  RTP-LP      RTP-ELF

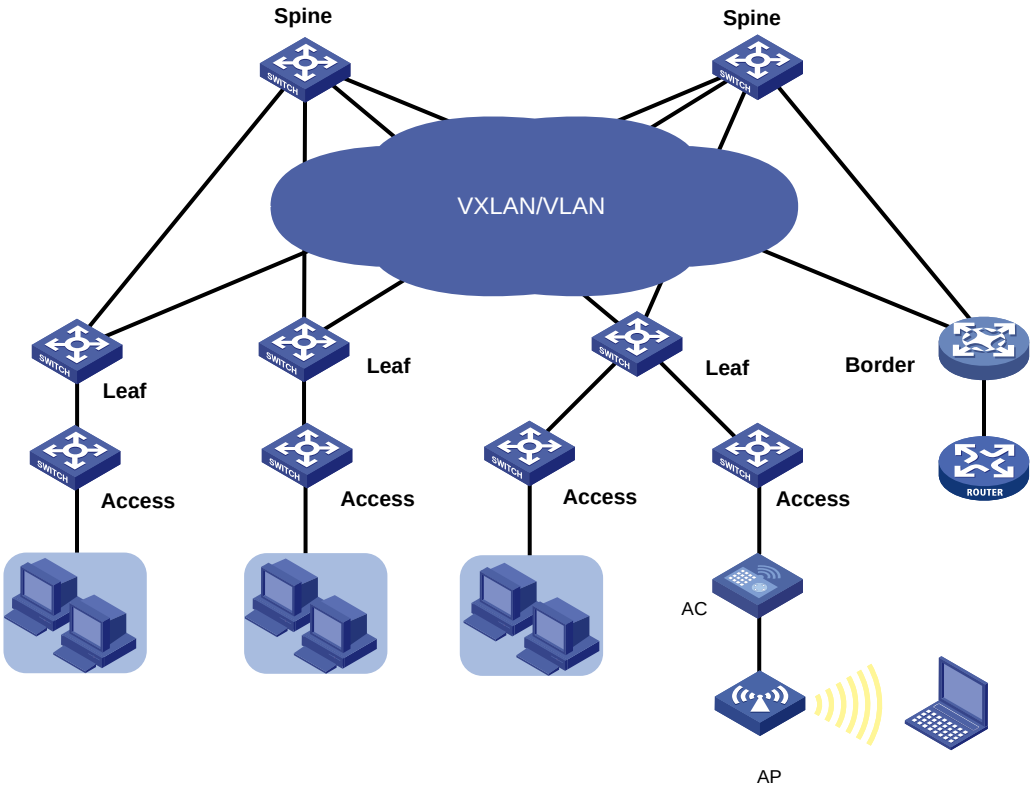
Configuring VCF fabric

About VCF fabric

Based on OpenStack Networking, the Virtual Converged Framework (VCF) solution provides virtual network services from Layer 2 to Layer 7 for cloud tenants. This solution breaks the boundaries between the network, cloud management, and terminal platforms and transforms the IT infrastructure to a converged framework to accommodate all applications. It also implements automated topology discovery and automated deployment of underlay networks to reduce the administrators' workload and speed up network deployment and upgrade.

VCF fabric topology



VCF fabric topology for a campus network

In a campus VCF fabric, a device has one of the following roles:

- **Spine node**—Connects to leaf nodes.
- **Leaf node**—Connects to access nodes.
- **Access node**—Connects to an upstream leaf node and downstream terminal devices. Cascading of access nodes is supported.
- **Border node**—Located at the border of a VCF fabric to provide access to the external network.

Spine nodes and leaf nodes form a large Layer 2 network, which can be a VLAN.

Figure 1 VCF fabric topology for a campus network

Automated VCF fabric deployment

VCF provides the following features to ease deployment:

- Automated topology discovery.

  In a VCF fabric, each device uses LLDP to collect local topology information from directly-connected peer devices. The local topology information includes connection interfaces, roles, MAC addresses, and management interface addresses of the peer devices. If multiple spine nodes exist in an IPv4 VCF fabric, the master spine node collects the topology for the entire network. In an IPv6 VCF fabric, the controller collects the topology automatically.

- Automated underlay network deployment.

  Automated underlay network deployment sets up a Layer 3 underlay network (a physical Layer 3 network) for users. It is implemented by automatically executing configurations (such as IRF configuration and Layer 3 reachability configurations) in user-defined template files.

Process of automated VCF fabric deployment

The device finishes automated VCF fabric deployment as follows:

1. Starts up without loading configuration and then obtains an IP address, the IP address of the TFTP server, and a template file name from the DHCP server.
2. Determines the name of the template file to be downloaded based on the device role and the template file name obtained from the DHCP server. For example, 1_access**.template** represents a template file for access nodes.
3. Downloads the template file from the TFTP server.
4. Parses the template file and performs the following operations:
   - Deploys static configurations that are independent from the VCF fabric topology.
   - Deploys dynamic configurations according to the VCF fabric topology.

     The topology process notifies the automation process of creation, deletion, and status change of neighbors. Based on the topology information, the automation process completes role discovery, IRF fabric setup, and automatic aggregation.

Template file

A template file contains the following contents:

- **System-predefined variables**—The variable names cannot be edited, and the variable values are set by the VCF topology discovery feature.
- **User-defined variables**—The variable names and values are defined by the user. The following are examples of user-defined variables:

  ```
  #USERDEF
  _username = aaa
  _password = hello12345
  _rbacUserRole = network-admin
  _loghost_ip = 172.16.1.136
  …
  ```

- **Static configurations**—Static configurations are independent from the VCF fabric topology and can be directly executed. The following are examples of static configurations:

  ```
  #STATICCFG
  #
   clock timezone beijing add 08:00:00
  #
  ```

```
 lldp global enable
#
 stp global enable
#
```

- **Dynamic configurations**—Dynamic configurations are dependent on the VCF fabric topology. The device first obtains the topology information through LLDP and then executes dynamic configurations. The following are examples of dynamic configurations:

```
#
interface $$_underlayIntfDown
 port link-mode route
 ip address unnumbered interface LoopBack0
 ospf 1 area 0.0.0.0
 ospf network-type p2p
 lldp management-address arp-learning
 lldp tlv-enable basic-tlv management-address-tlv interface LoopBack0
#
```

VCF fabric task at a glance

To configure a VCF fabric, perform the following tasks:

- Configuring automated VCF fabric deployment

  No tasks are required to be made on the device for automated VCF fabric deployment. However, you must make related configuration on the DHCP server and the TFTP server so the device can download and parse a template file to complete automated VCF fabric deployment.

- (Optional.) Adjust VCF fabric deployment

  If the device cannot obtain or parse the template file to complete automated VCF fabric deployment, choose the following tasks as needed:

  - Enabling VCF fabric topology discovery
  - Configuring automated underlay network deployment

Configuring automated VCF fabric deployment

Restrictions and guidelines

On a data center network, if the template file contains software version information, the device first compares the software version with the current software version. If the two versions are inconsistent, the device downloads the new software version to perform software upgrade. After restarting up, the device executes the configurations in the template file.

On a campus network, links between two access nodes cascaded through GigabitEthernet interfaces and links between leaf nodes and access nodes are automatically aggregated. For links between spine nodes and leaf nodes, the **`trunk permit vlan`** command is automatically executed.

On a campus network where multiple leaf nodes that have an access node attached form an IRF fabric, make sure only one link exists between each leaf node and its connected access node.

Do not perform link migration when devices in the VCF fabric are in the process of coming online or powering down after the automated VCF fabric deployment finishes. A violation might cause link-related configuration fails to update.

The version format of a template file for automated VCF fabric deployment is *x*.*y*. Only the *x* part is examined during a version compatibility check. For successful automated deployment, make sure *x* in the version of the template file to be used is not greater than *x* in the supported version. To display the supported version of the template file for automated VCF fabric deployment, use the **display vcf-fabric underlay template-version** command.

If the template file does not include IRF configurations, the device does not save the configurations after executing all configurations in the template file. To save the configurations, use the **save** command.

Two devices with the same role can automatically set up an IRF fabric only when the IRF physical interfaces on the devices are connected.

Two IRF member devices in an IRF fabric use the following rules to elect the IRF master during automated VCF fabric deployment:

- If the uptime of both devices is shorter than two hours, the device with the higher bridge MAC address becomes the IRF master.
- If the uptime of one device is equal to or longer than two hours, that device becomes the IRF master.
- If the uptime of both devices are equal to or longer than two hours, the IRF fabric cannot be set up. You must manually reboot one of the member devices. The rebooted device will become the IRF subordinate.

If the IRF member ID of a device is not 1, the IRF master might reboot during automatic IRF fabric setup.

Procedure

1. Finish the underlay network planning (such as IP address assignment, reliability design, and routing deployment) based on user requirements.
2. Configure the DHCP server.

   Configure the IP address of the device, the IP address of the TFTP server, and names of template files saved on the TFTP server. For more information, see the user manual of the DHCP server.
3. Configure the TFTP server.

   Create template files and save the template files to the TFTP server.

   The H3C DR1000 ADDC or ADCAM network management software can automatically create template files and save the files to the TFTP server. If no H3C DR1000 ADDC or ADCAM is available on the network, you must manually create template files and save the files to the TFTP server. For more information about template files, see "Template file."
4. (Optional.) Configure the NTP server.
5. Connect the device to the VCF fabric and start the device.

   After startup, the device uses a management Ethernet interface or VLAN-interface 1 to connect to the fabric management network. Then, it downloads the template file corresponding to its device role and parses the template file to complete automated VCF fabric deployment.
6. (Optional.) Save the deployed configuration.

   If the template file does not include IRF configurations, the device will not save the configurations after executing all configurations in the template file. To save the configurations, use the **save** command. For more information about this command, see configuration file management commands in *Fundamentals Command Reference*.

Enabling VCF fabric topology discovery

1. Enter system view.

   system-view

2. Enable LLDP globally.

   lldp global enable

   By default, LLDP is disabled globally.

   You must enable LLDP globally before you enable VCF fabric topology discovery, because the device needs LLDP to collect topology data of directly-connected devices.

3. Enable VCF fabric topology discovery.

   vcf-fabric topology enable

   By default, VCF fabric topology discovery is disabled.

Configuring automated underlay network deployment

Restrictions and guidelines

After automated underlay network deployment starts, you cannot use the CLI commands to modify the configuration. A violation might cause automated deployment failure. If you want to modify the configuration, first cancel or pause automated deployment. Additionally, do not start automated deployment after the modification. To cancel automated deployment, use the **undo vcf-fabric underlay autoconfigure** command. To pause automated deployment, use the **vcf-fabric underlay pause** command.

The underlay network can be an IPv4 or IPv6 network.

Specify the template file for automated underlay network deployment

1. Enter system view.

   system-view

2. Specify the template file for automated underlay network deployment.

   vcf-fabric underlay autoconfigure *template*

   By default, no template file is specified for automated underlay network deployment.

Setting the NETCONF username and password

About this task

During automated underlay network deployment, a spine node establishes NETCONF sessions with other devices in the underlay network to collect the global topology. If a user changes the username or password on a device in the undelay network, the NETCONF session between the device and the spine node is disconnected. Thun, the spine node fails to sense the topology change. To resolve the issue, perform this task to change the NETCONF username or password on the spine node.

Restrictions and guidelines

This feature is available on spine nodes. Changing the NETCONF username or password will disconnect NETCONF sessions between the spine node and leaf nodes. If multiple spine nodes exist in the VCF fabric, changing the NETCONF username or password on the master spine node will also disconnect NETCONF sessions between the master spine node and other spine nodes.

Make sure all devices in the underlay network use the same username and password for NETCONF session establishment.

Procedure

1. Enter system view.

   system-view

2. Set the NETCONF username.

   vcf-fabric underlay netconf-username *username*

   By default, the device uses the NETCONF username defined in the template file for automated VCF fabric deployment.

3. Set the NETCONF password.

   vcf-fabric underlay netconf-password { **cipher** | **simple** } *string*

   By default, the device uses the NETCONF password defined in the template file for automated VCF fabric deployment.

Pausing automated underlay network deployment

About this task

If you pause automated underlay network deployment, the VCF fabric will save the current status of the device. It will not respond to new LLDP events, set up the IRF fabric, aggregate links, or discover uplink or downlink interfaces.

Perform this task if all devices in the VCF fabric complete automated deployment and new devices are to be added to the VCF fabric.

Procedure

1. Enter system view.

   system-view

2. Pause automated underlay network deployment.

   vcf-fabric underlay pause

   By default, automated underlay network deployment is not paused.

Display and maintenance commands for VCF fabric

Execute **display** commands in any view.

Task	Command
Display the role of the device in the VCF fabric.	**display vcf-fabric role**
Display information about automated underlay network deployment.	**display vcf-fabric underlay autoconfigure**
Display the supported version and the current version of the template file for automated VCF fabric provisioning.	**display vcf-fabric underlay template-version**

Configuring cloud connections

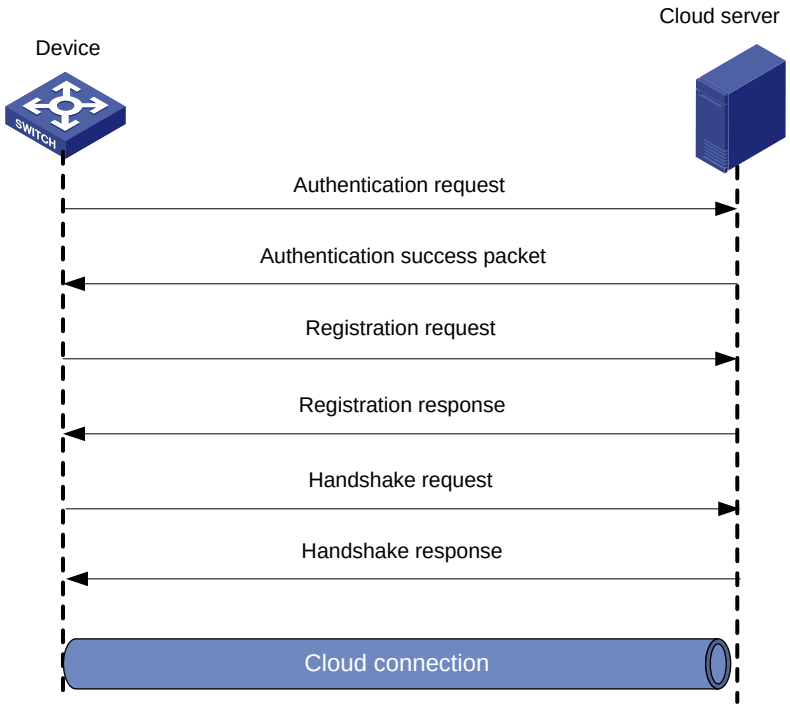
About cloud connections

A cloud connection is a management tunnel established between a local device and the H3C cloud server. It enables you to manage the local device from the cloud server without accessing the network where the device resides.

Multiple subconnections

After a local device establishes a connection with the cloud server, service modules on the local device can establish multiple subconnections with the microservices on the cloud server. These subconnections are independent from each other and provide separate communication channels for different services. This mechanism avoids interference among different services.

Cloud connection establishment



The cloud connection is established as follows:

1. The device sends an authentication request to the cloud server.
2. The cloud server sends an authentication success packet to the device.

   The device passes the authentication only if the serial number of the device has been added to the cloud server. If the authentication fails, the cloud server sends an authentication failure packet to the device.
3. The device sends a registration request to the cloud server.
4. The cloud server sends a registration response to the device.

   The registration response contains the uniform resource locator (URL) used to establish a cloud connection.
5. The device uses the URL to send a handshake request (changing the protocol from HTTP to WebSocket) to the cloud server.
6. The cloud server sends a handshake response to the device to finish establishing the cloud connection.
7. The device sends a subconnection URL request to the cloud server.
8. The cloud server sends a response that contains the microservice list and all subconnection URLs to the device.
9. The service module registers on the cloud connection management module.
10. The cloud connection management module sends the corresponding URLs to the service module.
11. The service module establishes subconnections with the cloud server.

Figure 1 Establishing a cloud connection

Configuring a cloud connection

About this task

For a device to establish a cloud connection to the cloud server, perform either of the following tasks:

- Specify the domain name of the cloud server on the device through CLI.
- Configure the device as a DHCP client and the cloud server as the DHCP server. The device obtains the IP address of the DHCP server and parses the option 253 field in the DHCP packets to obtain the IPv4 domain name of the cloud server. It can parse the option 65253 field in the DHCPv6 packets to obtain the IPv6 domain name of the cloud server. For more information about the option 253 field and the option 65253 field, see DHCP configuration and DHCPv6 configuration in *Layer—3 IP Services Configuration Guide*.

To establish cloud connections to the cloud server, a password is required. A device can use either of the following methods to obtain the password for establishing cloud connections to the cloud server:

- Execute the **`cloud-management server password`** command on the device to specify the password for establishing cloud connections to the cloud server.
- Configure the device as a DHCP client and the cloud server as the DHCP server. The device obtains the IP address of the DHCP server and parses the option 252 field in the DHCP packets to obtain the password for connection to the cloud server. For more information about the option 252 field, see DHCP configuration in *Layer 3—IP Services Configuration Guide*.

After establishing the cloud connection, the local device sends keepalive packets to the cloud server periodically. If the device does not receive a response from the cloud server within three keepalive intervals, the device sends a registration request to re-establish the cloud connection.

Restrictions and guidelines

The domain name obtained through DHCP has a higher priority than the domain name configured manually.

If a device obtains the domain name of the cloud server through DHCP after establishing a cloud connection to the cloud server with the manually configured domain name, the device performs the following tasks:

- If the automatically obtained and manually configured domain names are identical, the device retains the cloud connection.
- If the automatically obtained and manually configured domain names are different, the device tears down the cloud connection and then establishes a cloud connection to the cloud server with the automatically obtained domain name.

The password obtained through DHCP has a higher priority than the password configured manually.

If a device obtains the password for connection to the cloud server through DHCP after establishing a cloud connection to the cloud server with the manually configured password, the device performs the following tasks:

- If the automatically obtained and manually configured passwords are identical, the device retains the cloud connection.
- If the automatically obtained and manually configured passwords are different, the device tears down the cloud connection and then establishes a cloud connection to the cloud server with the automatically obtained password.

Prerequisites

Add the serial number of the device to be managed to the cloud server.

Configure DNS to ensure that the domain name of the cloud server can be translated into an IP address.

Procedure

1. Enter system view.

   system-view

2. Configure the domain name of the cloud server.
   - **Configure the IPv4 domain name of the cloud server.**

     cloud-management server { **domain** *domain-name* [**vpn-instance** *vpn-instance-name*] [**source-ip** *ip-address*] | **port** *port-number* }
   - **Configure the IPv6 domain name of the cloud server.**

     cloud-management server ipv6 domain *domain-name* [**vpn-instance** *vpn-instance-name*] [**source-ip** *ip-address*]

   By default, the domain name of the cloud server is not configured.
3. (Optional) Set the keepalive interval.

   cloud-management keepalive *interval*

   By default, the keepalive interval is 180 seconds.
4. (Optional) Specify the TCP port number used to establish cloud connections.

   cloud-management server port *port-number*

   By default, the TCP port number used to establish cloud connections is 443.
5. (Optional.) Set the password for establishing cloud connections to the cloud server.

   cloud-management server password { **cipher** | **simple** } *string*

   By default, no password is set for establishing cloud connections to the cloud server.

Unbinding the device from the Oasis server

About this task

A device can be registered on the Oasis server by only one user.

To register a device that has been registered by another user, you need to take the following steps:

1. Obtain a verification code for device unbinding from the Oasis server.
2. Execute the command on the device for sending the verification code to the Oasis server.
3. Register the device on the Oasis server.

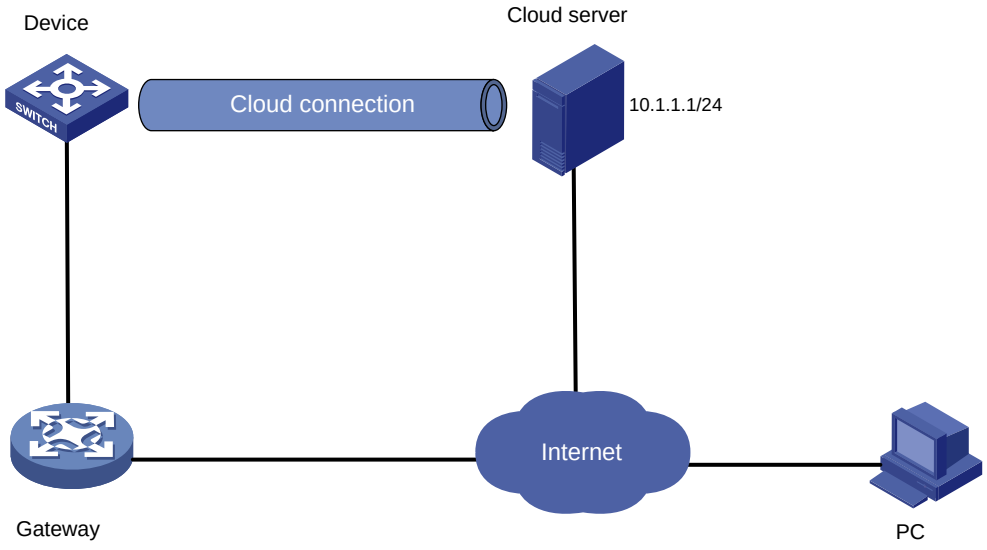
Procedure

1. Enter system view.
   `system-view`
2. Send the verification code for device unbinding to the Oasis server.
   `cloud-management unbinding-code` *code*

Display and maintenance commands for cloud connections

Execute **`display`** commands in any view and **`reset`** commands in user view.

Task	Command
Display cloud connection state information.	**`display cloud-management state`**
Re-establish the cloud connection to the cloud server.	**`reset cloud-management tunnel`**



Cloud connection configuration examples

Example: Configuring a cloud connection

Network configuration

As shown in Figure 2, configure the device to establish a cloud connection with the cloud server.

Figure 2 Network diagram

Procedure

1. Configure IP addresses for interfaces, and configure a routing protocol to ensure that the devices can reach each other. (Details not shown.)
2. Log in to the cloud server to add the serial number of the device to the server. (Details not shown.)

   The IP address of the cloud server is 10.1.1.1/24 and the domain name is **example.com**.
3. Configure the domain name of the cloud server as **example.com**.

   ```
   <Device> system-view
   [Device] cloud-management server domain example.com
   ```

   # Map IP address 10.1.1.1 to host name **example.com**.

   ```
   [Device] ip host example.com 10.1.1.1
   ```

Verifying the configuration

Verify that the device and the cloud server have established a cloud connection.

```
<Device> display cloud-management state
Cloud connection state   : Established
Device state             : Request_success
Cloud server address     : 10.1.1.1
Cloud server domain name : example.com
Cloud server port        : 443
Connected at             : Wed Jan  27 14:18:40 2019
Duration                 : 00d 00h 02m 01s
Process state            : Message received
Failure reason           : N/A

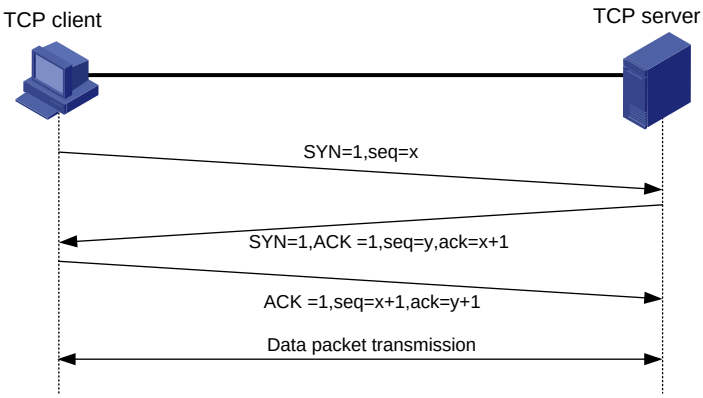
Configuring TCP connection trace

About TCP connection trace

Transmission Control Protocol (TCP) is a reliable connection-oriented network communication protocol. A TCP connection is established before data transmission, and it is released after data transmission is completed. TCP connections are complicated and prone to abnormal terminations due to various reasons.

The TCP connection trace feature traces TCP connections on the device, records information (including packet information) about existing connections, and caches information about abnormally closed connections. The recorded information helps you locate TCP disconnection reasons.

Operating mechanism



Tracing data packets after the connection establishment

As shown in Figure 1, the TCP client and the TCP server transmit data packets after they establish a TCP connection. The TCP connection trace feature traces data packets and records the connection information. If you enable this feature on both the TCP client and the TCP server, the two devices operate as follows:

- The TCP client records information about each sent data packet, including the send sequence number and the packet send time in the TCP header.
- The TCP server records packet information after it receives the packet.

To display packet information, execute the related **display** commands.

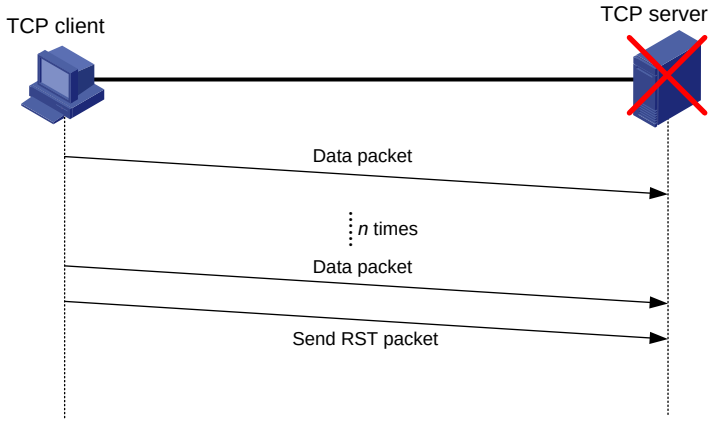


Figure 1 Packet trace after the TCP connection establishment

Caching abnormally closed TCP connections

By default, the TCP connection trace feature records information only about abnormally closed TCP connections. As shown in Figure 2, the TCP connection is unexpectedly closed on the TCP server when the server fails, but the TCP client is not aware of the server failure. With an expectation of an ACK packet from the server, the client sends data packets to the server and starts the retransmission timer. When the timer expires, the TCP client continues to retransmit packets if no ACK packet is received. Without receiving any ACK packet from the server after a number of retransmission attempts, the client sends an RST packet to terminate the connection. In this case, the TCP connection trace feature on the TCP client records the information about retransmitted packets and the disconnection reason in the memory. You can execute related **display** commands to view the information.

Figure 2 Abnormal disconnection of TCP connection

The device does not record the last RST packet sent before the disconnection, but it records the disconnection reason contained in the RST packet.

Common reasons for TCP disconnection

The following are typical reasons for abnormally disconnection of TCP connections:

- **Send reset/Received reset**—The device closes the TCP connection when it receives an RST packet from the peer or sends an RST packet to the peer in one of the following conditions:
  - A TCP server sends an RST packet to a TCP client when the server receives a TCP connection request on a non-open port from the client.
  - The device encounters an exception (for example, application crash) during TCP exchange and sends an RST packet to notify the peer to release TCP connection resources.
  - A TCP server replies an RST packet to a TCP client when the server receives a TCP packet that does not match any existing TCP connection.
  - A TCP client sends an RST packet to the server if the client does not receive any ACK packet after making the maximum number of retransmissions or the retransmission timeout.

  For this disconnection reason, use the following methods to resolve the issue:
  - Verify that the TCP port number is correct on the TCP client.
  - Verify that the TCP server operates normally.
  - Verity that the TCP-based application on the TCP client or TCP server operates correctly.
- **Application abnormal close**—The TCP connection is closed when the application on one end detects abnormal packets and notifies the TCP module to send a FIN packet to the other end.
- **Keepalive timeout**—After a TCP connection is established for a TCP-based application, the device detects the aliveness of the peer as follows:
  - If the application itself supports keepalive probing, the device uses keepalive probing of the application for aliveness detection.
  - If the application does not support keepalive probing, the device uses the keepalive probing of the TCP protocol for aliveness detection.

  When the idle time of the TCP connection exceeds the TCP keepalive duration, the TCP server sends a probe packet without any data to the peer. The server determines the client's status as follows:
  - If the server receives the ACK packet for the probe packet from the client, it determines that the TCP client is working normally.

    - If the server does not receive any ACK packet for multiple probe packets, it determines that the application on the TCP client has been crashed and terminates the connection.
- **Persist timeout**—The device closes the TCP connection if it does not receive any ACK packet from the peer within a period of time.

  If the TCP server does not have any free buffer space, it sends a notification to the TCP client. Upon receiving the notification, the TCP client stops sending packets to the TCP server and starts a timer. When the timer expires, the TCP client sends a space query packet to the TCP server.
    - If the TCP server answers that it has free space, the TCP client sends data packets to the TCP server.
    - If the TCP server answers that it has no free space, the TCP client resets the timer, and sends the query packet again after the timer expires. The client terminates the TCP connection if it does not receive any answer from the server for a long time.
- **Retransmission timeout**—The TCP client expects an ACK packet from the server after sending a data packet to the server. If the client does not receive an ACK packet in a period of time, it retransmits the data packet. If the client does not receive any ACK packet after making 12 retransmission attempts, the client terminates the TCP connection. To troubleshoot this failure, verify that the TCP server operates correctly and the link between the TCP server and client is connected.
- **Backup drop**—After TCP NSR is enabled, a backup TCP connection is established on the subordinate device. When a TCP connection exception occurs on the subordinate device, the TCP connection on the subordinate device is terminated.

TCP connection trace tasks at a glance

To configure TCP connection trace, perform the following tasks:

1. (Optional.) Configuring TCP connection trace rules
2. (Optional.) Setting the maximum number of traced data packets per TCP connection
3. (Optional.) Setting a memory quota for recording TCP connection information
4. Enabling TCP connection trace
5. (Optional.) Specifying a cache mode for TCP connection trace
6. Enabling persistence for TCP connection trace configuration

Configuring TCP connection trace rules

About this task

You can configure TCP connection trace rules to identify TCP connections of important services for monitoring.

Restrictions and guidelines

You can configure TCP connection trace rules only when the TCP connection trace feature is not enabled.

Procedure

To configure TCP connection trace rules, execute the following command in user view:

tcp trace filter { **acl** *acl-number* | **acl6** *ipv6-acl-number* | **only-new-connection** } *

By default, the feature traces all existing TCP connections.

Setting the maximum number of traced data packets per TCP connection

About this task

The device might have lots of TCP connections. If a traced TCP connection has a large number of packets, the device might not have enough memory to trace other TCP connections. To avoid this situation, set the maximum number of packets that can be traced per TCP connection.

This feature counts the number of incoming and outgoing data packets for each TCP connection. When the number of traced packets in a TCP connection exceeds the upper limit, new records of the connection overwrite its old records.

Restrictions and guidelines

You can set the maximum number of packets that can be traced per connection only when the TCP connection trace feature is not enabled. To disable TCP connection trace, execute the **undo tcp trace enable** command.

Procedure

To set the maximum number of data packets that can be traced per TCP connection, execute the following command in user view:

tcp trace max-packet-number *packet-number*

By default, the TCP connection trace feature can trace a maximum of 500 data packets per TCP connection.

Setting a memory quota for recording TCP connection information

About this task

After you enable the TCP connection trace feature, the device starts recording information about packets of specified TCP connections, including the packet sequence number and send time. If a large number of TCP connections exist on the device, it will consume a large amount of memory to record packet information, affecting the performance of other features. To avoid this situation, set a reasonable memory quota.

When the allocated memory is used up, the device does not record packet information about new TCP connections. For an existing connection, new packet records overwrite its old records.

Restrictions and guidelines

You can set the memory quota only when the TCP connection trace feature is not enabled. To disable TCP connection trace, execute the **undo tcp trace enable** command.

Procedure

To set the memory quota for recording TCP connection information, execute the following command in user view:

tcp trace memory-quota *memory-quota*

By default, a 100 MB memory is allocated for recording TCP connection information.

Enabling TCP connection trace

Restrictions and guidelines

You can enable TCP connection trace on either a TCP client or TCP server. Because a TCP server has more TCP connections than a TCP client, this feature on a TCP server consumes more memory resources than on the TCP client. If you want to trace specific TCP connections, enable this feature on the TCP client as a best practice.

Procedure

To enable TCP connection trace, execute the following command in user view:

tcp trace enable

By default, TCP connection trace is disabled.

Specifying a cache mode for TCP connection trace

About this task

By default, the TCP connection trace feature clears information about a connection when the connection is normally closed. To save information about normally closed connections, specify the **all** keyword in the **tcp trace cache-mode** command. The output from the following commands will display information about these connections:

- **display tcp trace cache-connection**
- **display tcp trace cache-packet ip**
- **display tcp trace cache-packet ipv6**

Procedure

To specify a cache mode for TCP connection trace, execute the following commands in user view:

tcp trace cache-mode { **abnormal-close** | **all** }

By default, the TCP connection trace feature records information only about the abnormally closed TCP connections.

Enabling persistence for TCP connection trace configuration

About this task

By default, the TCP connection trace configuration cannot survive a device reboot. To enable the existing TCP connection trace configuration to continue taking effect after the reboot, execute both the **tcp trace persist** and **save** commands.

- The **tcp trace persist** command enables the device to save the TCP connection trace configuration into the database file.
- The **save** command enables the device to save the TCP connection trace configuration in the database file into the .mdb binary configuration file.

When the device reboots, the TCP connection trace configuration is automatically restored from the binary file.

Procedure

To enable persistence for TCP connection trace configuration, execute the following command in user view:

tcp trace persist

By default, persistence for the TCP connection trace configuration is disabled.

Display and maintenance commands for TCP connection trace

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display information about all disconnected TCP connections that have been cached.	**display tcp trace cache-connection** { **ip** | **ipv6** } **slot** *slot-number*
Display packet information about a disconnected IPv4 TCP connection that is traced.	**display tcp trace cache-packet ip source-ip** *source-ipv4-address* **source-port** *source-port-number* **destination-ip** *destination-ipv4-address* **destination-port** *destination-port-number* [**vpn-instance** *vpn-instance-name*] [**verbose** | **wireshark**] [**last** *last-number*] **slot** *slot-number*
Display packet information about a disconnected IPv6 TCP connection that is traced.	**display tcp trace cache-packet ipv6 source-ip** *source-ipv6-address* **source-port** *source-port-number* **destination-ip** *destination-ipv6-address* **destination-port** *destination-port-number* [**vpn-instance** *vpn-instance-name*] [**verbose** | **wireshark**] [**last** *last-number*] **slot** *slot-number*
Display the TCP connection trace configuration and statistics.	**display tcp trace information slot** *slot-number*
Clear the connection and packet information about all disconnected TCP connections.	**reset tcp trace cache**

TCP connection trace configuration examples

Example: Tracing IPv4 TCP connections

Network configuration

As show in Figure 3, you can Telnet to Device B from Device A. Configure TCP connection trace on Device A to trace the TCP connection between Device A and Device B. When the connection is abnormally closed, you can use the trace information to locate disconnection reasons. Enable persistence for TCP connection trace configuration so that the configuration can survive Device A reboot.

Figure 3 Network diagram

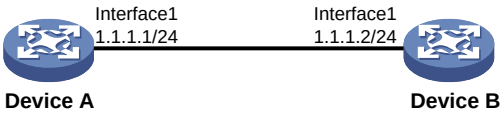

Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Prerequisites

- Configure Device B as a Telnet server. For more information, see login management configuration in *Fundamentals Configuration Guide*.
- Assign an IP address to each interface as shown in Figure 3. (Details not shown.)

Procedure

Allow the TCP connection trace feature to trace a maximum of 600 data packets per TCP connection.

```
<DeviceA> tcp trace max-packet-number 600
```

Set the memory quota to 300 MB for recording TCP connection information.

```
<DeviceA> tcp trace memory-quota 300
```

Enable TCP connection trace.

```
<DeviceA> tcp trace enable
```

Enable persistence for the TCP connection trace configuration.

```
<DeviceA> tcp trace persist
```

Verifying the configuration

1. Telnet to Device B from Device A.

   ```
   <DeviceA> telnet 1.1.1.2
   ```

2. Display TCP connection information when you can correctly log in to Device B from Device A through Telnet.

   # Display information about all disconnected IPv4 TCP connections that have been recorded.

   ```
   <DeviceA> display tcp trace cache-connection ip slot 1
    R (Reason):
     PN: Peer normal close
     RR: Received reset
     SR: Sent reset
     AN: Application normal close
     AA: Application abnormal close
     KT: Keepalive timeout
     PT: Persist timeout
     RT: Retransmit timeout
     BD: Backup drop
     AD: Abnormal packet defend
    Local Addr:port      Foreign Addr:port    VPN name    R   Time
   ```

   # Display packet information about disconnected IPv4 TCP connections.

```
<DeviceA> display tcp trace cache-packet ip source-ip 1.1.1.1 source-port 23
destination-ip 1.1.1.2 destination-port 23 verbose slot 1
```

The TCP connection is normal and no output is displayed.

3. Shut down GigabitEthernet 1/0/1 on Device B.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] shutdown
```

After you shut down GigabitEthernet 1/0/1, the Telnet connection is terminated. Display TCP connection information on Device A after a period of time.

Display information about all disconnected IPv4 TCP connections that have been recorded.

```
<DeviceA> display tcp trace cache-connection ip slot 1
 R (Reason):
  PN: Peer normal close
  RR: Received reset
  SR: Sent reset
  AN: Application normal close
  AA: Application abnormal close
  KT: Keepalive timeout
  PT: Persist timeout
  RT: Retransmit timeout
  BD: Backup drop
  AD: Abnormal packet defend
 Local Addr:port      Foreign Addr:port    VPN name    R   Time
 1.1.1.1:9732         1.1.1.2:23           N/A         RT  20:29:08
                                                           July 1 2019
```

Displays information about the last three packets that were traced before the TCP connection was closed.

```
<DeviceA> display tcp trace cache-packet ip source-ip 1.1.1.1 source-port 9732
destination-ip 1.1.1.2 destination-port 23 verbose last 3 slot 1

```

The output shows that:

- The TCP connection between Device A and Device B has been closed.
- The disconnection reason is retransmission timeout. The client determines retransmission timeout because it does not receive any ACK packet from the server.

To resolve the issue, verify that the TCP server operates correctly and the link between the TCP client and server is connected.

Example: Tracing IPv6 TCP connections

Network configuration

As show in Figure 4, you can Telnet to Device B from Device A. Configure TCP connection trace on Device A to trace the IPv6 TCP connection between Device A and Device B. When the connection is abnormally closed, you can use the trace information to locate disconnection reasons. Enable persistence for TCP connection trace configuration so that the configuration can survive Device A reboot.

Figure 4 Network diagram

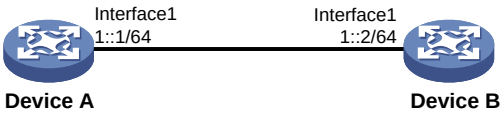

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Prerequisites

- Configure Device B as a Telnet server. For more information, see login management configuration in *Fundamentals Configuration Guide*.
- Assign an IPv6 address to each interface as shown in Figure 4. (Details not shown.)

Procedure

Allow the TCP connection trace feature to trace a maximum of 600 data packets per TCP connection.

```
<DeviceA> tcp trace max-packet-number 600
```

Set the memory quota to 300 MB for recording TCP connection information.

```
<DeviceA> tcp trace memory-quota 300
```

Enable TCP connection trace.

```
<DeviceA> tcp trace enable
```

Enable persistence for the TCP connection trace configuration.

```
<DeviceA> tcp trace persist
```

Verifying the configuration

1. Telnet to Device B from Device A.

   ```
   <DeviceA> telnet ipv6 1::2
   ```

2. Display TCP connection information when you can correctly log in to Device B from Device A through Telnet.

Display information about all disconnected IPv6 TCP connections that have been recorded.

```
<DeviceA> display tcp trace cache-connection ipv6 slot 1
R (Reason):
  PN: Peer normal close
  RR: Received reset
  SR: Sent reset
  AN: Application normal close
  AA: Application abnormal close
  KT: Keepalive timeout
  PT: Persist timeout
  RT: Retransmit timeout
  BD: Backup drop
  AD: Abnormal packet defend
 LAddr->port           FAddr->port           VPN name   R   Time
```

Display packet information about disconnected IPv6 TCP connections.

```
<DeviceA> display tcp trace cache-packet ipv6 source-ip 1::1 source-port 47745
destination-ip 1::2 destination-port 23 verbose slot 1
```

The TCP connection is normal and no output is displayed.

3. Shut down GigabitEthernet 1/0/1 on Device B.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] shutdown
```

After you shut down GigabitEthernet 1/0/1, the Telnet connection is terminated. Display TCP connection information on Device A after a period of time.

Display information about all disconnected IPv6 TCP connections that have been recorded.

```
<DeviceA> display tcp trace cache-connection ipv6 slot 1
 R (Reason):
  PN: Peer normal close
  RR: Received reset
  SR: Sent reset

 1/30/64 5
```

The output shows that:

- The TCP connection between Device A and Device B has been closed.
- The disconnection reason is retransmission timeout. The client determines retransmission timeout because it does not receive any ACK packet from the server.

To resolve the issue, verify that the TCP server operates correctly and the link between the TCP client and server is connected.

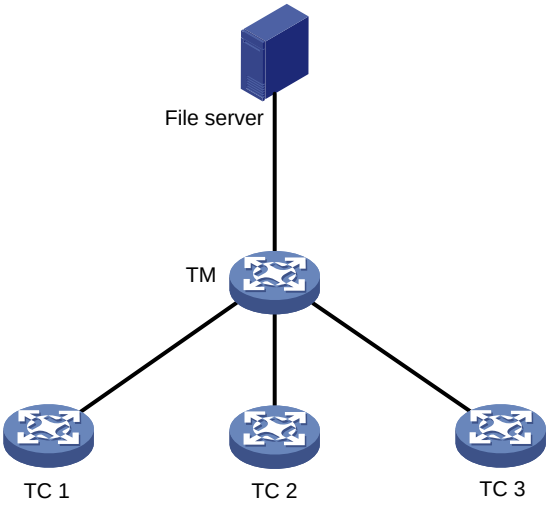
Configuring SmartMC

About SmartMC



Smart Management Center (SmartMC) centrally manages and maintains dispersed network devices at network edges. In a SmartMC network, only one device acts as the commander and the remaining devices all act as members. SmartMC provides the following features for you to manage the members from the commander:

- Configuration file backup and download.
- Software upgrade.
- Configuration deployment.
- Faulty member replacement.

SmartMC network framework

Figure 1 shows the basic framework of a SmartMC network.

Figure 1 SmartMC network framework

The SmartMC network contains the following elements:

- **Commander**—Also called topology master (TM), which manages all members in the SmartMC network.
- **Member**—Also called topology client (TC), which is managed by the commander.
- **File server**—Stores startup software images and configuration files for the commander and members.

SmartMC network establishment

A SmartMC network can be established automatically or manually. In an automatically established SmartMC network, the commander obtains member information through NETCONF sessions to form the network topology. The member information includes port information, LLDP neighbor information, STP information, device type, and software version. In a manually established SmartMC network, the commander obtains member's LLDP neighbor information through NETCONF sessions and member's hardware information through SNMP Get operations.

Automatic SmartMC network establishment

The commander and members use the following procedure to establish a SmartMC network:

1. After SmartMC is enabled, the commander broadcasts a SmartMC packet at an interval of 15 seconds to detect members in the network. The SmartMC packet contains information of the commander, such as its bridge MAC address and the IP address of VLAN-interface 1.
2. When a member receives the packet, it records the commander information, and returns a response packet to the commander. The response packet contains information of the member, such as its bridge MAC address and the IP address of VLAN-interface 1.
3. When the commander receives the response packet, it initiates a NETCONF session to the member with the default username **admin** and the default password **admin** and sets up TCP keepalive. The commander then obtains detailed information about the member through the session, including port information, LLDP neighbor information, STP information, device type, and software version.
4. The commander notifies the member of online success, and adds the member to the SmartMC network.
5. Based on the LLDP neighbor information obtained from all members, the commander forms a SmartMC topology.

After the SmartMC network is established, the commander and members check for the existence of each other by exchanging SmartMC packets.

After the successful establishment of the SmartMC network, the commander becomes aware of members through NETCONF session status, while members become aware of each other through SmartMC broadcast messages sent by the commander:

- When a member receives a SmartMC broadcast packet from the commander, it compares the bridge MAC address in the packet with the recorded bridge MAC address. If the two bridge MAC addresses are the same and the device with the MAC address is offline, the member returns a response packet to the commander. If the member does not receive a broadcast packet from the commander within the time limit, the member determines that the commander does not exist in the network anymore. Then, the member clears the commander information. The time limit is a random value in the range of 60 to 120 seconds.
- When the commander receives a response message from a member, it establishes a NETCONF session with the member and sets up TCP keepalive. If no data packet is exchanged within 40 seconds, TCP keepalive detection will be triggered. The device initiates a detection every 5 seconds. If the detection fails 4 times in a row, the member is considered offline, and the commander sets it to offline status. This means that if the commander does not receive any packets from the member within 60 seconds, it sets the member to offline status.

Manual SmartMC network establishment

You can log in to the Web interface of the commander, and enter the IP address, username, and password of the members to manually add them to the network. The members can join the network without exchanging SmartMC packets with the commander. For more information, see *Comware 7 Web-Based Products User Guide*.

After you specify the information of a member on the commander, the commander performs the following operations to add the member to the network:

- Verify that the member can be accessed through Telnet.
- Obtain basic member information, including LLDP neighbor information through NETCONF.
- Obtain hardware information through SNMP Get operations.

SmartMC features

Bulk configuration deployment for members

This feature allows you to deploy multiple command lines to members from the commander, eliminating the need to log in to members and configure the command one by one.

The procedure for bulk configuration deployment is as follows:

1. The commander acts as a Telnet client and establishes Telnet connections to the members.
2. The commander deploys a batch file to the members through NETCONF sessions. The batch file is created on the commander and contains command lines to be deployed.
3. The members run the command lines in the file.

Bulk configuration deployment for ports connecting APs and IP phones

With batch file deployment enabled, the commander automatically deploys configurations in the specified batch file to a port connecting an AP or IP phone, simplifying access port configuration.

When the commander first detects the association of an AP or IP phone on a port through LLDP, it deploys the command lines in the specified batch file to the port. If no batch file is specified for the device type, the configurations on the port remain unchanged.

If the AP or IP phone disconnects from the port, the configurations on the port remain. When a new device comes online from the port, configurations used by the port depend on the new device type.

- If the new device is an AP or IP phone and has the same type as the disconnected device, the configurations on the port remain unchanged.
- If the new device is an AP or IP phone but has a different type as the disconnected device, the commander deploys the command lines in the specified batch file to the port. If no batch file is specified for the device type, the configurations on the port remain unchanged.
- If the new device is neither an AP nor an IP phone, the configurations on the port remain unchanged.

To disable the commander from deploying a batch file to ports, remove the specified batch file or execute the **`undo smartmc batch-file-apply enable`** command to disable batch file deployment.

Configuration file backup

You can use the following methods to back up the next-startup configuration file on the commander and members:

- **Automatic backup**—Enable this feature for the commander and all members in the network to immediately perform a backup. After that, the commander and members back up the configuration file at a user-specified interval.
- **Manual backup**—Manually trigger a backup on the commander or the specified members or SmartMC groups.

To back up the configuration file on a member, the commander instructs the member by unicasting a SmartMC packet. When a member receives the packet, it saves the running configuration to the next-startup configuration file and uploads the file to the file server.

Startup software and configuration file upgrade

This feature enables users to upgrade startup software and the configuration file of member devices from the commander.

Before upgrade, you must upload the upgrade files from the commander to the file server and specify the upgrade files on the file server for the members to download.

The procedure for startup software and configuration file upgrade is as follows:

1. The commander instructs the members (or SmartMC group) to download the upgrade files from the file server.

2. The members download the upgrade files from the file server.
3. The members upgrade the startup software and configuration file as follows:
    - **Startup software upgrade**—Performs an ISSU with the upgrade startup software files. The members might be restarted during the upgrade process.
    - **Configuration file upgrade**—Replaces the current configuration file with the upgrade configuration file. The members will not be restarted during the upgrade process.

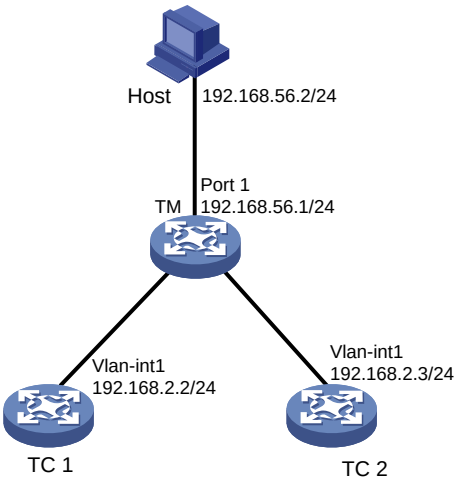
Faulty member replacement

You can use the following methods to replace a faulty member:

- **Automatic replacement**—Enables the commander to record the positions of all members in the topology for replacement. When the commander discovers that the new member has physically replaced the faulty member, it compares the new member with the faulty one. The commander performs a replacement if the following requirements are met:
    - The new member is deployed at the same topological position as the faulty one.
    - The models of the new member and faulty member are the same.

    The commander then instructs the new member to download the configuration file of the faulty member from the file server. After downloading the configuration file, the new member runs the configuration file to complete the replacement.
- **Manual replacement**—After the faulty member is physically replaced, you manually trigger a configuration replacement. The new member will download the configuration file of the faulty member from the file server and run the file to complete the replacement.

Outgoing interface for a SmartMC network



The outgoing interface feature allows hosts connecting to an outgoing interface to access all the members in a SmartMC network. You can configure multiple outgoing interfaces for a SmartMC network.

As shown in Figure 2, the host is connected to port 1 on the TM and TC 1 and TC 2 are in a different network segment than the host. The host can access the Web interface of the TM but cannot access the Web interface of any member.

If port 1 on the TM is configured as the outgoing interface, the system mirrors the IP address of each member to a new address. The new address contains the IP address of the outgoing interface and the port number assigned by the commander to the member in the format of *IP address***:***Port number*. This enables the host to access the Web interfaces of members from the Web interface of the TM.

To access the Web interface of a member, enter the Web interface of the commander, and click **Visibility** from the navigation pane. Then, click the **Topology** tab, select the target member, and click **Login to Web interface**.

Figure 2 SmartMC network

Automatic link aggregation

Automatic link aggregation automatically bundles multiple physical Ethernet links between two members into one logical link, called an aggregate link. This feature provides increased link bandwidth and improved link reliability.

NOTE:

- Automatic link aggregation cannot be performed between the commander and a member, or between a member and a device outside the SmartMC network. You can aggregate the links between the commander and a member manually. For more information about manual link aggregation, see Ethernet link aggregation in *Layer 2—LAN Switching Configuration Guide*.
- If a member enabled with automatic link aggregation joins a SmartMC network whose commander is disabled with the aggregation feature, the feature will be disabled for the member as well. This might affect service traffic forwarding on the member.

VLAN creation for members

To simplify configuration and management, you can create a VLAN for members. Then, all access ports on a member that are not connected to other members or the commander are assigned to the VLAN.

If a member has access ports that are connected to offline devices, you must remove the offline devices before creating a VLAN for the member.

The VLAN creation fails for a member if one or more access ports cannot be assigned to the VLAN. If the VLAN creation fails, the VLAN memberships for the access ports are restored to the state before the VLAN was created.

The failure to create a VLAN for a member does not affect the VLAN creation for other members.

Resource monitoring

Resource monitoring allows you to view CPU usage, memory usage, temperature information, and packet dropping information of commanders and members on the commander. Packet dropping monitoring monitors packet dropping on members and on interfaces.

You can view the usage and temperature information on the commander, and view packet dropping information from the **SmartMC** > **Intelligent O&M** > **Resource monitoring** page of the commander's Web interface.

Restrictions: Hardware compatibility with SmartMC

The S5200-EI-G switch series can only function as a member device, and does not support the role of a commander for SmartMC.

Restrictions and guidelines: SmartMC configuration

Only users with the network-admin role can configure SmartMC. For more information about user roles, see RBAC in *Fundamentals Configuration Guide*.

Devices exchange SmartMC protocol packets and establish and maintain the SmartMC network only in VLAN 1. To ensure the proper functioning of SmartMC, make sure the interfaces connecting member devices within the SmartMC network allow VLAN 1 packets to pass through.

You need to enable SmartMC on both the commander and members and perform all the other SmartMC tasks only on the commander.

SmartMC tasks at a glance

To configure SmartMC, perform the following tasks:

1. Enabling SmartMC
2. Specifying a file server

   This task is required for configuring automatic configuration file backup, replacing faulty members, and upgrading the startup software and configuration file on members.
3. (Optional.) Configuring an outgoing interface for the SmartMC network
4. (Optional.) Enabling automatic Ethernet link aggregation
5. (Optional.) Modifying the password of the default user for members
6. Creating a SmartMC group

   This task is required for upgrading the startup software and configuration file on members and deploying a batch file to a SmartMC group.
7. (Optional.) Deploying and managing configuration
   - Creating a VLAN for members
   - Deploying a batch file to members
   - Configuring a batch file for ports connecting APs or IP phones
   - Backing up configuration files
8. (Optional.) Monitoring and maintaining the SmartMC network
   - Configuring resource monitoring
   - Upgrading the startup software and configuration file on members
   - Managing the network topology
   - Replacing faulty members

Prerequisites for SmartMC

Before you configure SmartMC, perform the following tasks on the commander and members:

- Enable the Telnet service, and configure scheme authentication for VTY user lines. For information about Telnet service and VTY user lines, see CLI login configuration in *Fundamentals Configuration Guide*.
- Configure a local user.
  - Specify the username and password.
    - On the commander, make sure the username and password are the same as the username and password configured by using the **smartmc tm username** *username* **password** { **cipher** | **simple** } *string* **enable** command.
    - On a member, set both the username and password to **admin**, and execute the **password-control length 4**, **password-control composition type-number 1 type-length 1**, and **undo password-control complexity user-name check** commands to lower the password complexity requirements.

      This is because SmartMC requires that the commander use username **admin** and password **admin** to communicate with members, which does not meet the default password complexity requirements. For more information about these commands, see password control commands in *Security Command Reference*.

      After the SmartMC network is established, you can increase the password complexity requirements and use the **smartmc tc password** command to modify the username and password.
  - Specify the Telnet, SSH, HTTP, and HTTPS services for the user.
  - Set the RBAC role of the local user to network-admin.

  For information about local users, see AAA configuration in *Security Configuration Guide*. For information about user roles, see RBAC configuration in *Fundamentals Configuration Guide*.
- Enable NETCONF over SOAP over HTTP. For information about NETCONF over SOAP, see NETCONF configuration in *Network Management and Monitoring Configuration Guide*.
- Enable NETCONF over SSH. For more information about NETCONF over SSH, see "Configuring NETCONF."
- Configure public key management for SSH authentication. Execute the **ssh user** *admin* **service-type netconf authentication-type publickey assign publickey** *-smartmc-publickey-* command on the member to configure the authentication method for SSH users. Digital signature is supported. The username must be **admin** for an SSH user and the public key name must be **-smartmc-publickey-** for the SSH client. For more information about public key management, see *Security Configuration Guide*.
- Enable LLDP globally. For information about LLDP, see *Layer 2—LAN Switching Configuration Guide*.
- To manage the commander and members through a Web interface, you must enable the HTTP and HTTPS services, and set the service type to HTTP and HTTPS for the local user. For information about Web login, HTTP, and HTTPS, see *Fundamentals Configuration Guide*.
- To manually establish a SmartMC network, you must configure the **snmp-agent community read public** and **snmp-agent sys-info version v2c** commands on the members. For information about SNMP, see *Network Management and Monitoring Configuration Guide*.

Enabling SmartMC

About this task

Enable this feature on both the commander and members to enable management of members from the commander.

Restrictions and guidelines

A SmartMC network must have one and only one commander.

If you change the role of the commander to member or disable SmartMC on the commander, all SmartMC settings in its running configuration will be cleared.

SmartMC fails to be enabled if ACL resources are insufficient. If ACL resources are insufficient, use the **undo acl** command to delete unnecessary ACLs and then enable SmartMC. You can execute the **display acl** command to view ACL configuration and match statistics. For more information about ACLs, see *ACL and QoS Configuration Guide*.

SmartMC fails to be enabled if ports 80 and 443 have been used.

If you execute the **smartmc enable** command multiple times, the most recent configuration takes effect. You can execute the command to change the device role or the password.

Procedure

1. Enter system view.

   system-view

2. Enable SmartMC and set the device role.

   smartmc { **tc** | **tm username** *username* **password** { **cipher** | **simple** } *string* } **enable**

   By default, SmartMC is disabled.

Specifying a file server

About this task

In a SmartMC network, a file server is used to store the following files:

- Upgrade startup software files and upgrade configuration file for members.
- Backup configuration files of the commander and members.

The system supports using an FTP or SFTP server as the file server. For information about FTP servers, see configuring FTP in *Fundamentals Configuration Guide*. For information about SFTP servers, see configuring SSH in *Security Configuration Guide*.

Restrictions and guidelines

You can use the following methods to specify a file server:

- Specify the IP address of a file server.
- Specify the IP address of the commander. The commander will act as a file server.

To configure the commander to act as a file server, make sure the commander has enough storage space for storing the files required by members.

To use an independent file server, connect the file server to the commander instead of the members as a best practice. The file server uses VLAN 1 to communicate with the SmartMC network. If you connect the file server to members, creating a VLAN for members will assign member interfaces connecting to the file server to the created VLAN, causing file server disconnection. For more information about member VLAN creation, see "Creating a VLAN for members."

Procedure

1. Enter system view.

   system-view

2. Specify a file server.

   smartmc { **ftp-server** | **sftp-server** } { *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port*] [**vpn-instance** *vpn-instance-name*] [**directory** *directory*] **username** *username* **password** { **cipher** | **simple** } *string*

   By default, no file server is specified.

Configuring an outgoing interface for the SmartMC network

Restrictions and guidelines

VLAN-interface 1 cannot be used as an outgoing interface, because the SmartMC network is established in VLAN 1.

A member port of a Layer 3 aggregation group cannot be used as an outgoing interface for SmartMC, and vice versa. If a configured outgoing interface is a member port of a Layer 3 aggregation group, the outgoing interface does not take effect. For more information about Layer 3 aggregation groups, see Ethernet link aggregation in *Layer 2—LAN Switching Configuration Guide*.

If you specify a Layer 3 Ethernet interface as the outgoing interface, the system issues the command only to VLAN-interface 1. If you remove the outgoing interface configuration, the **service slot** *slot-number* configuration remains, and you can modify the configuration manually as needed.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN interface view or Layer 3 Ethernet interface view.
   - Enter VLAN interface view.
     interface vlan *interface-number*
   - Enter Layer 3 Ethernet interface view.
     interface *interface-type interface-number*
3. Configure the interface as an outgoing interface.
   smartmc outbound
   By default, no interface is used as an outgoing interface.

Enabling automatic Ethernet link aggregation

Restrictions and guidelines

Enabling or disabling automatic link aggregation might cause network flapping, and the members might go offline for a short period of time.

Procedure

1. Enter system view.
   system-view
2. Enable automatic Ethernet link aggregation.
   smartmc auto-link-aggregation enable
   By default, automatic Ethernet link aggregation is disabled.

Modifying the password of the default user for members

About this task

During SmartMC network establishment, the commander uses the default username and password to establish NETCONF sessions to members automatically added to the network. The default

username and password of the members for NETCONF session establishment are **admin** and **admin**.

To enhance security, you can perform this task to change the password for the default user **admin** of the members after the commander adds the members to the network.

Restrictions and guidelines

Do not modify the password for members that are manually added to the SmartMC network. If you modify the password for a manually added member, you will not be able to manage that member from the commander.

You can use the **display smartmc tc verbose** command to identify the method used to add the members.

Procedure

1. Enter system view.
   system-view
2. Modify the password of the default user for members.
   smartmc tc password [**cipher**] *string*

Creating a SmartMC group

About this task

This feature allows you to create a SmartMC group on the commander and add members to the group. When you perform the following operations, you can specify a SmartMC group to apply the operations to all members in the group:

- Startup software upgrade.
- Configuration file upgrade.
- Configuration deployment.

Procedure

1. Enter system view.
   system-view
2. Create a SmartMC group and enter its view.
   smartmc group *group-name*
3. (Optional.) Display predefined device types.
   match device-type ?
4. Set a match criterion.
   match { **device-type** *device-type* | **ip-address** *ip-address* { *ip-mask-length* | *ip-mask* } | **mac-address** *mac-address mac-mask-length* }
   By default, no match criterion is set.
5. If the device type of the members is not predefined on the commander, perform the following tasks to manually define the device type on the commander:
   a. Return to system view.
      quit
   b. Define a device type on the commander.
      smartmc tc sysoid *sysoid* **device-type** *device-type*
      To obtain the SYSOID of a member, execute the **display smartmc tc verbose** command.

You cannot define a predefined member type as another type.

Creating a VLAN for members

Restrictions and guidelines

If you perform this task multiple times to create a VLAN for members, the most recent configuration takes effect.

Procedure

1. Enter system view.

   system-view

2. Creating a VLAN for members and assign access ports on the members to the VLAN.

   smartmc vlan *vlan-id* { **group** *group-name-list* | **tc** *tc-id-list* }

Deploying a batch file to members

About this task

Perform this task to distribute the configurations from a specified configuration file to multiple member devices at once, in order to reduce the workload of configuring each device individually.

Restrictions and guidelines

Make sure the configuration file does not contain the **undo smartmc enable** and **undo telnet server enable** commands as these two commands might cause the configuration link to disconnect, leading to the failure of the remaining configuration distribution.

Procedure

1. Execute the following command in user view to create a batch file and edit the command lines to be deployed to members.

   create batch-file *cmd-filename*

   Each command occupies a line in the batch file. When you finish editing, enter a percent sign (%) to return to user view.

   Make sure the command lines that you enter are correct because the system does not verify whether the command lines are correct.

2. Enter system view.

   system-view

3. Deploy the batch file to a list of members or SmartMC groups.

   smartmc batch-file *cmd-filename* **deploy** { **group** *group-name-list* | **tc** *tc-id-list* }

Configuring a batch file for ports connecting APs or IP phones

Restrictions and guidelines

All commands in the batch file must be commands used in interface view.

The size of the batch file cannot exceed 8190 characters.

Make sure the file name is correct when specifying the batch file because the system does not verify whether the file name is correct. After specifying the batch file, do not delete the file or rename the file.

Procedure

1. Execute the following command in user view to create a batch file and edit the command lines to be deployed to members.

   create batch-file *cmd-filename*

   Each command occupies a line in the batch file. When you finish editing, enter a percent sign (%) to return to user view.

   Make sure the command lines that you enter are correct because the system does not verify whether the command lines are correct.

2. Enter system view.

   system-view

3. Specify the batch file for ports connecting APs or IP phones.

   smartmc batch-file *batch-file-name* **apply** { **ap** | **phone** }

4. (Optional.) Disable batch file deployment.

   undo smartmc batch-file-apply enable

   By default, batch file deployment is enabled.

Backing up configuration files

About this task

Perform this task to back up the configuration file of the commander or the specified members. Configuration files automatically backed up to the file server are named in the format of *device_bridge_MAC_address*_**backup.cfg**.

Restrictions and guidelines

When you change the commander in the SmartMC network, make sure the backup configuration file of the original commander on the file server is deleted. If the file still exists, the new commander might download the file and run the settings. This will cause a conflict in the network.

The maximum number of members that can perform automatic configuration at the same time is limited by the performance of the file server. If automatic configuration backup fails, set the maximum number of members to a smaller value.

Prerequisites

Before performing this task, you must specify a file server (see "Specifying a file server").

Procedure

1. Enter system view.

   system-view

2. Set the maximum number of members that can perform configuration file backup at the same time.

   smartmc backup configuration max-number *max-number*

   By default, a maximum of five members can perform automatic configuration backup at the same time.

3. Back up configuration files.

   Choose one option as needed:

   - Enable automatic configuration file backup and set the backup interval.

smartmc backup startup-configuration interval *interval-time*

By default, automatic configuration file backup is disabled.

- Manually back up the configuration file on the commander or the specified members.

  smartmc backup configuration { **group** *group-name-list* | **tc** [*tc-id-list*] }

  TC ID 0 represents the commander.

Configuring resource monitoring

Restrictions and guidelines

Enable and disable this feature as needed. Enabling resource monitoring when the number of online members reaches a certain threshold may cause the commander's CPU to become busy and memory space to be insufficient.

Procedure

1. Enter system view.

   system-view

2. Set the interval for the commander to obtain resource monitoring information.

   smartmc resource-monitor interval *interval*

   The default setting is 1 minute.

3. Set the aging time for resource monitoring information.

   smartmc resource-monitor max-age *max-age*

   The default setting is 24 hours.

4. Enable resource monitoring.

   smartmc resource-monitor [**cpu** | **memory** | **packet-drop** | **temperature**]* [**group** *group-name-list* | **tc** { *tc-id-list* | **mac-address** *mac-address* } | **tm**]

   By default, resource monitoring is disabled.

   If you do not specify a resource type, this command enables resource monitoring for all resource types.

   If you do not specify a device to monitor (member or commander), this command enables resource monitoring on the commander and all members.

Upgrading the startup software and configuration file on members

About upgrading the startup software and configuration file on members

You can use the following methods to upgrade the startup software and configuration file on members:

- Schedule an upgrade by specifying an upgrade time or upgrade delay.
- Upgrade immediately by not specifying an upgrade time or upgrade delay.

Restrictions and guidelines for startup software and configuration file upgrade

A member can perform only one upgrade task at a time.

An immediate upgrade cannot be cancelled. If you specify a delay time or upgrade time to perform a scheduled upgrade, the upgrade operation can be cancelled by using the **undo smartmc upgrade** command before it starts.

Prerequisites

Before performing this task, you must specify a file server (see "Specifying a file server").

Upgrading the startup software and configuration file on members

Upgrading the startup software and configuration file in one step

1. Enter system view.

   system-view

2. Upgrade the startup software on members in one step.

   smartmc upgrade boot-loader tc { *tc-id-list* { **boot** *boot-filename* **system** *system-filename* | **file** *ipe-filename* }&<1-40> [**delay** *delay-time* | **time** *in-time*]

CAUTION:

Upgrading the startup software might interrupt services. Before upgrading the startup software, make sure no services will be interrupted.

3. Upgrade the configuration file on members in one step.

   smartmc upgrade startup-configuration tc { *tc-id-list* *cfg-filename* }&<1-40> [**delay** *delay-time* | **time** *in-time*]

CAUTION:

After you update the configuration file, the configuration in the new configuration file will become the running configuration. Before upgrading the configuration file, make sure the contents of the new configuration file are correct.

Configuring startup software and configuration file upgrade step by step

1. Enter system view.

   system-view

2. Configure startup software upgrade for members step by step:

   a. Specify the upgrade startup software files.

      smartmc tc *tc-id* **boot-loader** { *ipe-filename* | **boot** *boot-filename* **system** *system-filename* }

   b. Upgrade the startup software on members.

   smartmc upgrade boot-loader tc *tc-id-list*

CAUTION:

Upgrading the startup software might interrupt services. Before upgrading the startup software, make sure no services will be interrupted.

3. Configure configuration file upgrade for members step by step:
   a. Specify the upgrade configuration file.
      smartmc tc *tc-id* **startup-configuration** *cfg-filename*
   b. Upgrade the configuration file on members.
      smartmc upgrade startup-configuration tc *tc-id-list*

CAUTION:

After you update the configuration file, the configuration in the new configuration file will become the running configuration. Before upgrading the configuration file, make sure the contents of the new configuration file are correct.

Upgrading the startup software and configuration file on all members in SmartMC groups

Upgrading the startup software and configuration file in one step

1. Enter system view.
   system-view
2. Upgrade the startup software on all members in SmartMC groups in one step.
   smartmc upgrade boot-loader group { *group-name-list* [**boot** *boot-filename* **system** *system-filename* | **file** *ipe-filename*] }&<1-40> [**delay** *minutes* | **time** *in-time*]

CAUTION:

Upgrading the startup software might interrupt services. Before upgrading the startup software, make sure no services will be interrupted.

3. Upgrade the configuration file on all members in SmartMC groups in one step.
   smartmc upgrade startup-configuration group { *group-name-list* **file** *cfg-filename* }&<1-40> [**delay** *minutes* | **time** *in-time*]

CAUTION:

After you update the configuration file, the configuration in the new configuration file will become the running configuration. Before upgrading the configuration file, make sure the contents of the new configuration file are correct.

Configuring startup software and configuration file upgrade step by step

1. Enter system view.
   system-view
2. Enter SmartMC group view.
   smartmc group *group-name*
3. Specify the upgrade startup software files for the SmartMC group.
   boot-loader file { *ipe-filename* | **boot** *boot-filename* **system** *system-filename* }

   By default, no upgrade startup software files are specified for a SmartMC group.

4. Specify the upgrade configuration file for the SmartMC group.

   startup-configuration *cfgfile*

   By default, no upgrade configuration file is specified for a SmartMC group.
5. Return to system view.

   quit
6. Upgrade the startup software and configuration file on all members in the SmartMC group.

   Choose one option as needed:

   - Upgrade the startup software.

     smartmc upgrade boot-loader group *group-name-list* [**delay** *minutes* | **time** *in-time*]

     CAUTION:

     Upgrading the startup software might interrupt services. Before upgrading the startup software, make sure no services will be interrupted.

   - Upgrade the configuration file.

     smartmc upgrade startup-configuration group *group-name-list* [**delay** *minutes* | **time** *in-time*]

     CAUTION:

     After you update the configuration file, the configuration in the new configuration file will become the running configuration. Before upgrading the configuration file, make sure the contents of the new configuration file are correct.

Managing the network topology

Refreshing the network topology

About this task

You can use the following methods to refresh the network topology:

- **Automatic topology refresh**—Specify the refresh interval to allow the commander to refresh the network topology periodically.
- **Manual topology refresh**—Execute the **smartmc topology-refresh** command to manually refresh the network topology.

Restrictions and guidelines

The topology refresh time depends on the number of members in the network.

When the number of online members in the network is greater than 64, the commander calculates the refresh interval of the network topology based on the number of online members. The calculation formula is (*N*+64)/64 multiplied by the set refresh interval, where *N* represents the number of online members.

Procedure

Choose one option as needed:

- Manually refresh the network topology in any view.

  smartmc topology-refresh
- Configure automatic network topology refresh.

a. Enter system view.

system-view

b. Set the automatic topology refresh interval.

smartmc topology-refresh interval *interval*

By default, the automatic topology refresh interval is 60 seconds.

Saving the network topology

About this task

This task allows you to save the current network topology to the **topology.dba** file in the flash memory. After the commander reboots, it uses the **topology.dba** file to restore the network topology.

Procedure

1. Enter system view.

   system-view

2. Save the network topology.

   smartmc topology-save

Replacing faulty members

Restrictions and guidelines

Make sure the new member for replacement and the faulty member have the same neighbor relationship and device model.

Make sure the new member has a different member ID than all the members in the SmartMC network, including offline members. Faulty members are considered offline.

To automatically replace a faulty member, first enable automatic replacement, and then install the new member at the location where the faulty member was installed and connect all cables.

To manually replace a faulty member, first install the new member at the location where the faulty member was installed, connect all cables, and then execute the manual replacement command.

Prerequisites

Before you replace a faulty member, specify a file server (see "Specifying a file server").

Procedure

1. Enter system view.

   system-view

2. Replace faulty members.

   Choose one option as needed:

   - Enable automatic faulty member replacement.

     smartmc auto-replace enable

     By default, automatic faulty member replacement is disabled.

   - Manually replace a faulty member.

     smartmc replace tc *tc-id1* **faulty-tc** *tc-id2*

Display and maintenance commands for SmartMC

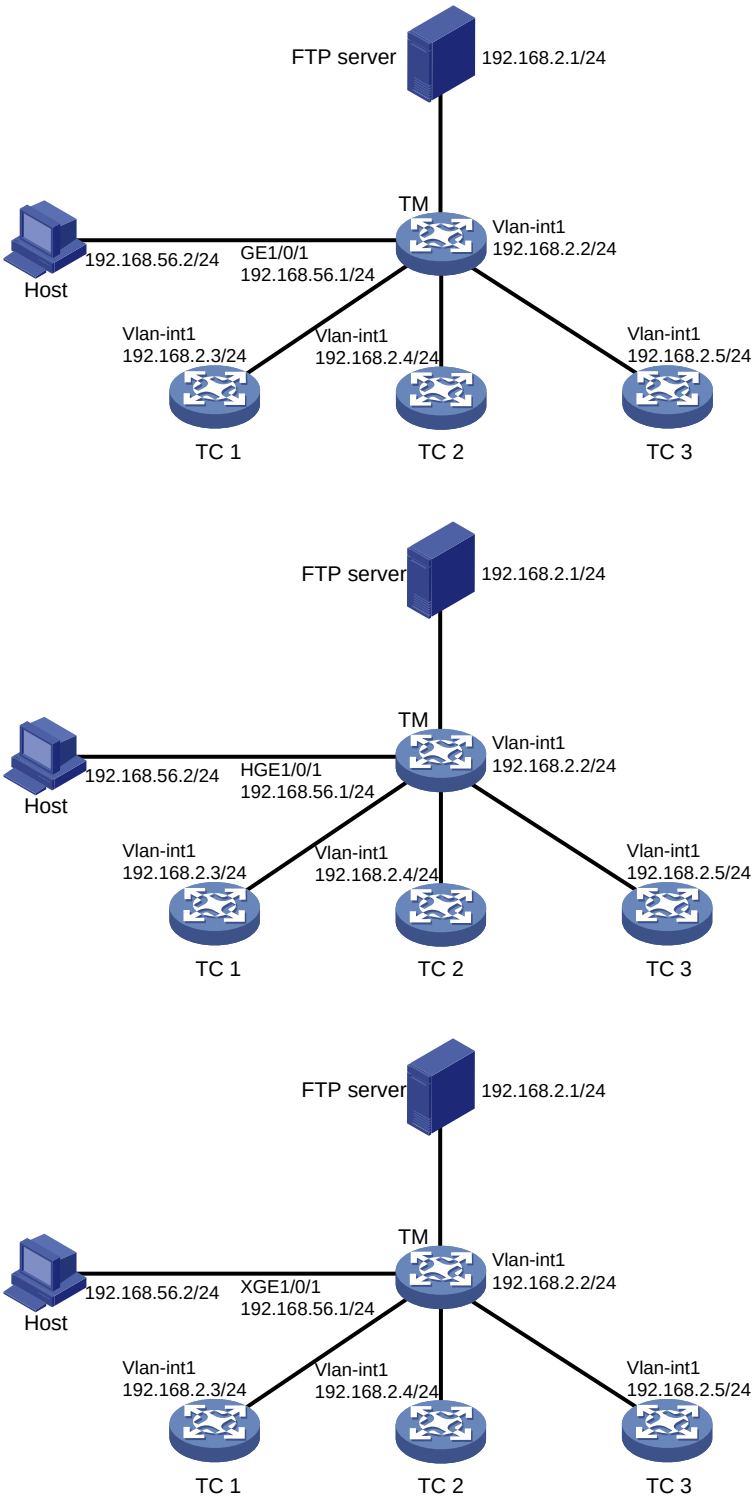
Execute **display** commands in any view.

Task	Command
Display the backup status on members.	**display smartmc backup configuration status**
Display the batch file execution results.	**display smartmc batch-file status** [**ap** | **last** *number* | **phone**]
Display SmartMC configuration.	**display smartmc configuration**
Display connections between the devices in the SmartMC network.	**display smartmc device-link**
Display SmartMC group information.	**display smartmc group** [*group-name*] [**verbose**]
Display the faulty member replacement status.	**display smartmc replace status**
Display resource monitoring information.	**display smartmc resource-monitor** [**cpu** | **memory** | **temperature**] * [**tc** *tc-id* | **tm**]
Display resource monitoring configuration.	**display smartmc resource-monitor configuration**
Display member information.	**display smartmc tc** [*tc-id*] [**verbose**]
Display log information in the log buffer on a member.	**display smartmc tc** *tc-id* **log buffer** [**module** *module-name* [**mnemonic** *mnemonic-value*]]
Display restart log information for a member.	**display smartmc tc** *tc-id* **log restart**
Display VLAN creation results for members.	**display smartmc vlan**
Display member upgrade status.	**display smartmc upgrade status**

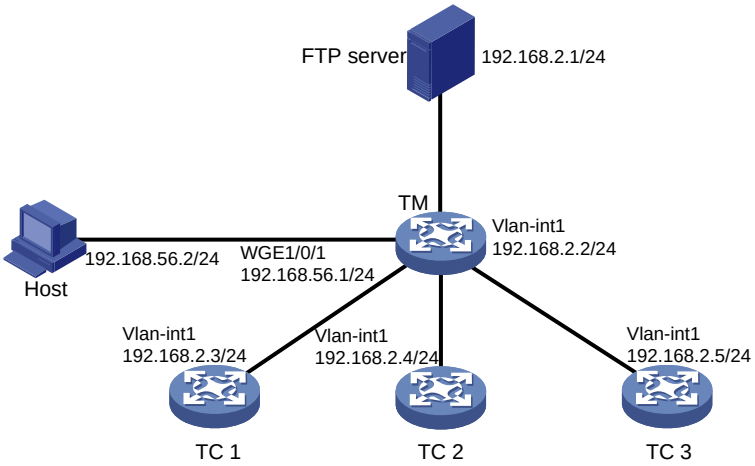
SmartMC configuration examples

Example: Configuring SmartMC

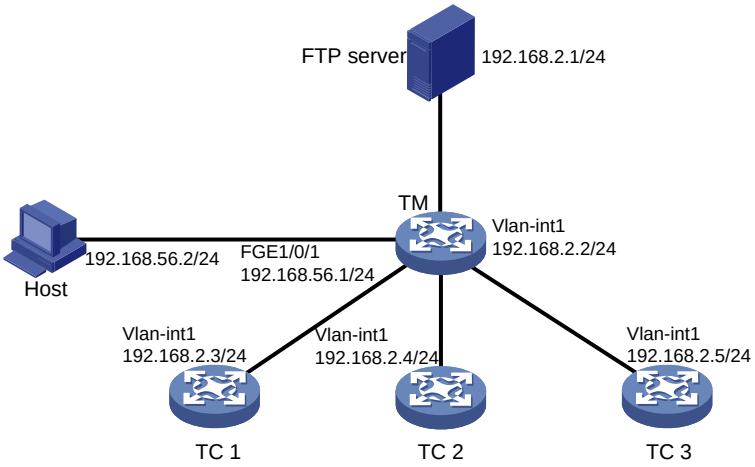
Network configuration



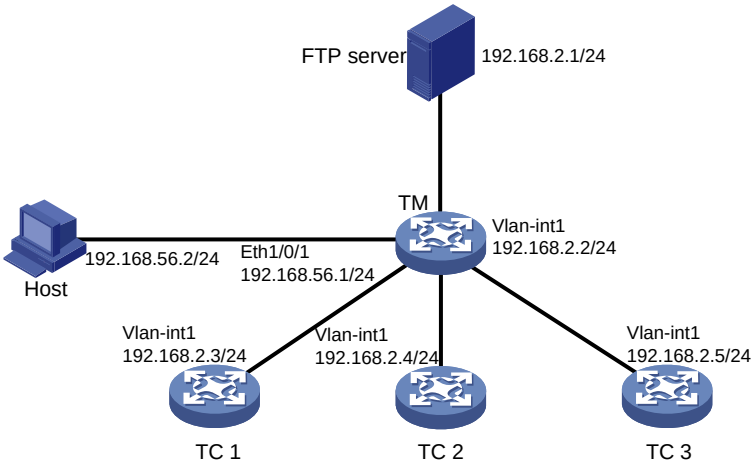
As shown in Figure 3, member 1, member 2, and member 3 belong to the same device type: S5200-EI-G series. The IP address of the file server is 192.168.2.1. The username and password for accessing the file server are **admin** and **hello12345**, respectively.



Perform the following tasks to establish a SmartMC network and upgrade the configuration file on the members:



1. Configure the commander and members to automatically establish a SmartMC network.
2. Configure interface GigabitEthernet 1/0/1 as the outgoing interface for the SmartMC network.



3. Create a SmartMC group and add the members to the group.
4. Upgrade the configuration file on all members in the SmartMC group.
5. Save configuration file **startup.cfg** on the file server.

Procedure

1. Configure TC 1:

   # Configure VLAN-interface 1.

   ```
   <TC1> system-view
   [TC1] interface vlan-interface 1
   [TC1-Vlan-interface1] ip address 192.168.2.3 24
   [TC1-Vlan-interface1] quit
   ```

   # Enable HTTP and HTTPS.

   ```
   [TC1] ip http enable
   [TC1] ip https enable
   ```

   # Enable the Telnet service.

   ```
   [TC1] telnet server enable
   ```

   # Enable NETCONF over SOAP over HTTP.

   ```
   [TC1] netconf soap http enable
   ```

   # Enable NETCONF over SSH.

   ```
   [TC1] netconf ssh server enable
   ```

   # Enable LLDP globally.

   ```
   [TC1] lldp global enable
   ```

   # Create a user.

   ```
   [TC1] local-user admin
   ```

   # Lower password complexity requirements. For more information about these commands, see password control commands in *Security Command Reference*.

   ```
   [TC1-luser-manage-admin] password-control length 4
   [TC1-luser-manage-admin] password-control composition type-number 1 type-length 1
   [TC1-luser-manage-admin] undo password-control complexity user-name check
   ```

   # Set the username and password to **admin**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

   ```
   [TC1-luser-manage-admin] password simple admin
   [TC1-luser-manage-admin] service-type telnet http https ssh
   [TC1-luser-manage-admin] authorization-attribute user-role network-admin
   [TC1-luser-manage-admin] quit
   ```

   # Set the system to support public key authentication for the administrator to login through SSH. The public key name must be **-smartmc-publickey-**.

```
[TC1] ssh user admin service-type netconf authentication-type publickey assign
publickey -smartmc-publickey-
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TC1] line vty 0 63
[TC1-line-vty0-63] authentication-mode scheme
[TC1-line-vty0-63] quit
```

Enable SmartMC and set the device role to **tc**.

```
[TC1] smartmc tc enable
```

2. Configure TC 2 and TC 3 in the same way TC 1 is configured. (Details not shown.)

3. Configure the TM:

Configure GigabitEthernet 1/0/1.

```
<TM> system-view
[TM] interface gigabitethernet 1/0/1
[TM-GigabitEthernet1/0/1] port link-mode route
[TM-GigabitEthernet1/0/1] ip address 192.168.52.2 24
[TM-GigabitEthernet1/0/1] quit
```

Configure VLAN-interface 1.

```
[TM] interface vlan-interface 1
[TM-Vlan-interface1] ip address 192.168.2.2 24
[TM-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TM] ip http enable
[TM] ip https enable
```

Enable the Telnet service.

```
[TM] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TM] netconf soap http enable
```

Enable NETCONF over SSH.

```
[TM] netconf ssh server enable
```

Enable LLDP globally.

```
[TM] lldp global enable
```

Create a user. Set the username to **admin** and the password to **hello12345**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TM] local-user admin
[TM-luser-manage-admin] password simple hello12345
[TM-luser-manage-admin] service-type telnet http https ssh
[TM-luser-manage-admin] authorization-attribute user-role network-admin
[TM-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TM] line vty 0 63
[TM-line-vty0-63] authentication-mode scheme
[TM-line-vty0-63] quit
```

Enable SmartMC, set the device role to commander, and set the username to **admin** and the password (plaintext) to **hello12345**.

```
[TM] smartmc tm username admin password simple hello12345 enable
```

Specify GigabitEthernet 1/0/1 as the outgoing interface.

```
[TM] interface gigabitethernet 1/0/1
```

```
[TM-GigabitEthernet1/0/1] smartmc outbound
[TM-GigabitEthernet1/0/1] quit
```

Set the file server IP address, username, and plaintext password to 192.168.2.1, **admin**, and **hello12345**, respectively.

```
[TM] smartmc ftp-server 192.168.2.1 username admin password simple hello12345
```

Create SmartMC group **S1** and enter its view.

```
[TM] smartmc group S1
```

Create an IP address match criterion to add all members in the specified network segment to SmartMC group **S1**.

```
[TM-smartmc-group-S1] match ip-address 192.168.2.0 24
```

Specify the upgrade configuration file **startup.cfg** for SmartMC group **S1**.

```
[TM-smartmc-group-S1] startup-configuration startup.cfg
[TM-smartmc-group-S1] quit
```

Upgrade the configuration file on all members in SmartMC group **S1**.

```
[TM] smartmc upgrade startup-configuration group S1 file startup.cfg
```

Verifying the configuration

Display brief information about all members after the SmartMC network is established.

```
[TM] display smartmc tc
TCID DeviceType Sysname  IpAddress       MacAddress     Status   Version
1    S5200-EI-G TC1      192.168.2.3     201c-e7c3-0300 Normal   COMWAREV700R001
2    S5200-EI-G TC2      192.168.2.4     201c-e7c3-0301 Normal   COMWAREV700R001
3    S5200-EI-G TC3      192.168.2.5     201c-e7c3-0302 Normal   COMWAREV700R001
```

Display the configuration file upgrade status on the members.

```
[TM] display smartmc upgrade status
ID    IpAddress        MacAddress      Status      UpdateTime        UpdateFile
1     192.168.2.3      201c-e7c3-0300  Finished    Immediately       startup.cfg
2     192.168.2.4      201c-e7c3-0301  Finished    Immediately       startup.cfg
3     192.168.2.5      201c-e7c3-0302  Finished    Immediately       startup.cfg
```

Quicknet commands

About Quicknet

Quicknet is a lightweight network management topology used to centrally manage and maintain dispersed network devices at network edges. In a Quicknet network, only one device acts as the TM and the remaining devices all act as TCs. The TM manages the entire Quicknet network in a unified way.

Benefits

Quicknet provides the following benefits:

- Simplified network setup. Quicknet supports plug-and-play for devices. Once initial settings are configured from the Web interface, devices can automatically form a Quicknet network based on the factory configuration.
- Simplified network maintenance. After the Quicknet network is built, the network administrator can log into the Quicknet management system and, through simple Web operations, can achieve unified management and maintenance of a large number of network devices. This effectively solves operation and maintenance issues for small and medium-sized campus networks.

Quicknet network framework

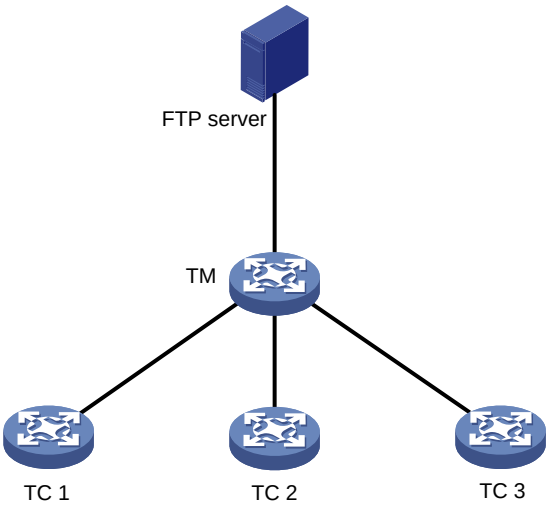

Figure 1 shows the basic framework of a Quicknet network. The Quicknet network contains the following elements:

- Topology master (TM)—Manages all members in the Quicknet network.
- **Topology client (TC)**—Managed by the TM.
- FTP server—Stores startup software images and configuration files for the TM and members.

Quicknet networks can include various models of network devices. The method for determining device roles varies by product positioning.

- Some device models support manually designating the device role as TC through the CLI.
- Some device models support manually designating the device role as TM through the CLI.
- Some device models support using the auto election mechanism to determine their roles (TC or TM) in a Quicknet network. For more information about auto election, see "Quicknet role selection."

Figure 1 Quicknet network framework

Quicknet network management

Introduction

Quicknet provides various flexible network device management solutions, allowing you to select any of the following methods as needed:

- Local unified management (mainly used for initial deployment)

  Through the Quicknet management system, all network devices can be centrally managed on-site, significantly improving operational efficiency, and is especially suitable for rapid deployment and management of small to medium-sized campus networks.

- Cloudnet remote management (recommended for O&M)

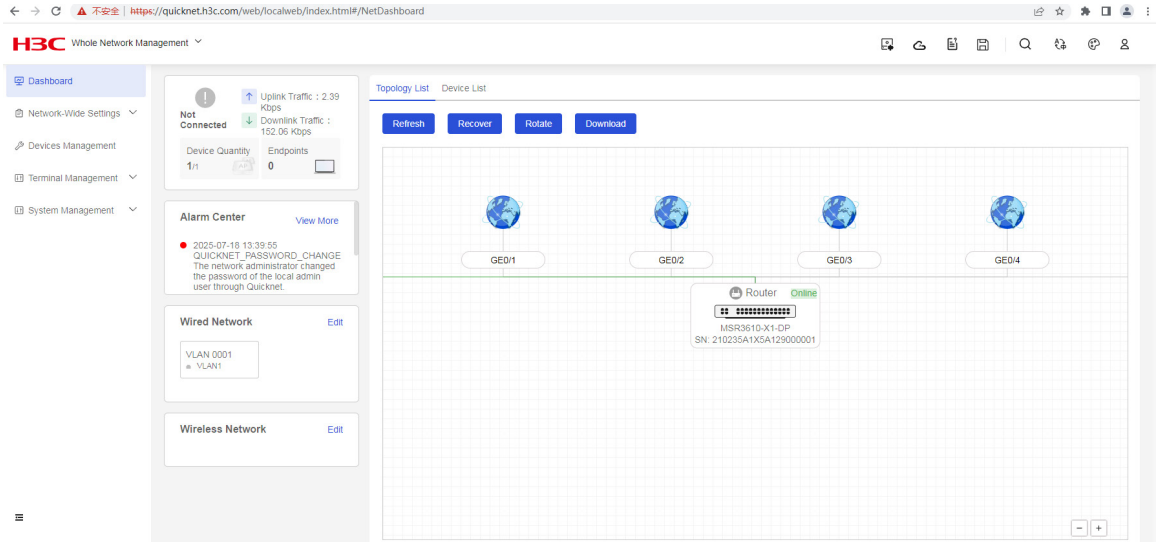
  With the Cloudnet management platform, you can remotely manage all devices in the Quicknet network anytime, anywhere.

- Single-device local configuration
  - Web interface: Access the graphical web page through the device IP to intuitively configure a single device.
  - CLI: Log in to the device command line interface and use commands for advanced configuration.

Quicknet management system

The Quicknet management system is a lightweight web-based network management platform and acts as the unified management entry for the Quicknet network running on TM. You can visit https://quicknet.h3c.com to access the Quicknet management system on the TM. It is mainly used for the deployment of Quicknet networks. After completing the initial deployment, you can perform simple operations and maintenance on all network devices through the Quicknet management system. To perform in-depth O&M, use the one-key onboarding function provided by the Quicknet management system as a best practice.

The Quicknet management system provides the following functions:



- Initialization—Configures the project name, network-wide password, Internet parameters, Wi-Fi settings, and time zone for the Quicknet network.
- Network Dashboard—Displays network connectivity information, alarm messages, wired network information, wireless service information, topology list, device list, and device details, and provides a portal for users to switch to local management.

- Network Configuration—Includes WAN and wired configuration. WAN settings include network access parameters and wired settings include the service VLAN.
- Device Management—Includes adding devices, removing offline devices, rebooting devices, upgrading devices, resetting devices, viewing device details, configuring device interfaces, creating VLANs, editing VLANs, and deleting VLANs.
- Terminal Management—Allows viewing and management of wired and wireless users.
- System Management—Includes upgrading, rebooting, and modifying the network-wide password.

By combining the aforementioned functions, you can achieve the following objectives:

- Management the Quicknet network topology.
- Manage member devices in bulk.

Figure 2 Quicknet management system

Quicknet network deployment

Quicknet provides an intelligent deployment solution, enabling network deployment in a few simple steps. The specific process is as follows:

1. Auto networking (plug and play)
   - Networking conditions:
     - Devices can reach each other at Layer 2 (allowing VLAN 1 packets to pass).
     - Quicknet is enabled (whether Quicknet is enabled by default depends on the device model).
   - Auto TM election: After the conditions are met, the devices automatically elect the TM and establish a Quicknet network.
2. Device role and information query
   - After completing physical connections, you can execute the **`display quicknet configuration`** command on the TM to verify the TM device role and execute the **`display quicknet configuration`** command on a TC to verify the TC device role and view TM information.
   - The network is not deployed yet. Executing the **`display quicknet tc`** command on the TM cannot display TC information.
3. Network deployment methods
   - Wireless access (recommended)

- Connect to the Wi-Fi whose name includes the Quicknet string.
- Use a browser to visit https://quicknet.h3c.com and perform initial deployment as instructed.

- Wired access (login to TM Web interface)
  - Connect your PC to VLAN-interface 1 on any device in the Quicknet network.
  - Use a browser to visit https://quicknet.h3c.com and perform initial deployment as instructed.

  In the Quicknet network, a DHCP server will be automatically deployed to assign IP addresses in the VLAN 1 segment to PCs, and provide translation from https://quicknet.h3c.com to the TM IP address. If a PC accesses the Quicknet management system across network segments, you must configure the mapping relationship between https://quicknet.h3c.com and the IP address of Quicknet on the local PC.

4. Initial deployment configuration
   - You can configure the network-wide password, Wi-Fi, and time zone settings.
   - The configuration will be automatically synchronized to all member devices and take effect.
5. Deployment process on the TM
   a. Generates a unique NetID for the current Quicknet network.
   b. Requires the logged-in administrator to set a management password (the Quicknet network-wide password) and synchronizes this password along with the NetID to all member devices in the Quicknet network.

Set the devices with the network-wide password and NetID to the deployed state. The state will affect the TM election later.

Quicknet network-wide password

The Quicknet network-wide password is used to ensure the security of the NETCONF communication channel between TM and TC devices.

After Layer 2 connections are established in the Quicknet network, the TM must establish Layer 3 communication channels with TCs to synchronize configurations and obtain device information.

To ensure communication security, the TM and TCs must perform identity authentication (the authentication credentials are the local user admin and the corresponding password). The device comes with default credentials from the factory. The username admin in the default credentials cannot be changed, but the password can be modified. This password is also known as the Quicknet network-wide password.

You can use either method to configure the network-wide password:

1. Modify during initial configuration

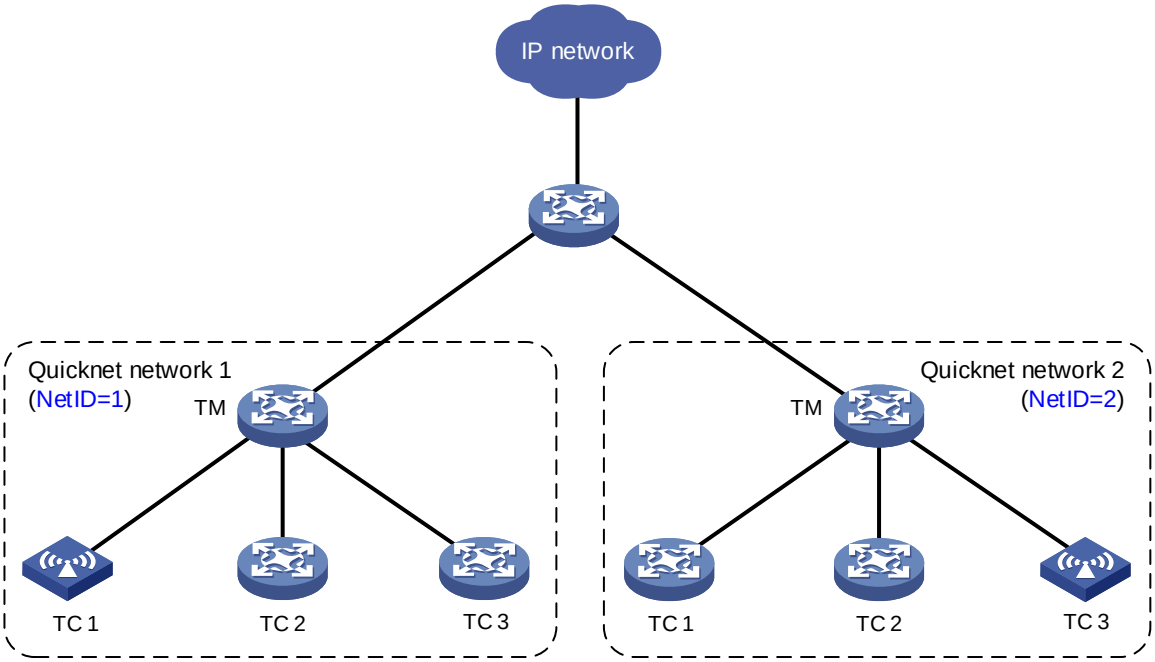
   Set the network-wide password in the Quicknet management system's deployment wizard.
2. Modify during device operation
   - Modify from the Quicknet management system's Web interface.
   - Modify from the TM's CLI.

The network-wide password synchronization mechanism is as follows:

- After the password is changed, the TM automatically synchronizes the new password to all network devices.
- The system will rebuild all communication channels based on the new password.

When you configure the network-wide password, follow these restrictions and guidelines:

- As a best practice for security purposes, change the default password upon initial deployment.
- Change password regularly to comply with corporate security policies.
- The password must contain a minimum of eight characters and contain uppercase and lowercase letters, digits, and special characters.



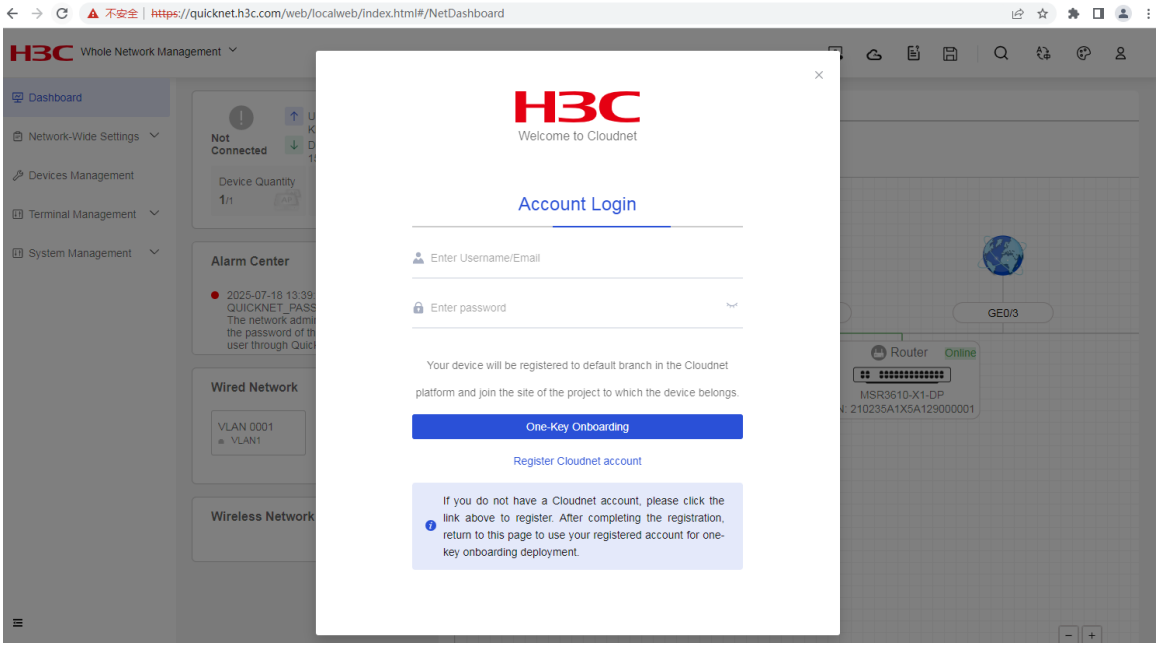
Quicknet NetID

A NetID is the identifier of a Quicknet network in the Quicknet system, and one Quicknet network corresponds to only one NetID.

To adapt to various networking applications, multiple Quicknet networks can be deployed in the same network, and NetID is used to distinguish between different Quicknet networks. One device can only join one Quicknet network. As shown in Figure 3, the TM broadcasts Quicknet protocol packets to discover TCs in the respective Quicknet network. To avoid interference between Quicknet protocol packets of two Quicknet networks, Quicknet uses NetID to distinguish between different Quicknet networks. When a member device in a Quicknet network receives a Quicknet packet with a different NetID, it directly discards it.

The NetID is automatically generated by the Quicknet module at the initial deployment phase.

Figure 3 Multi-Quicknet networking



One-key onboarding

After completing the Quicknet deployment, to manage devices both locally and from the cloud, click the one-key onboarding icon in the top navigation bar of the Quicknet management system to register all network devices to Cloudnet.

After successfully executing one-key onboarding, the administrator can log in to the H3C Cloudnet management platform (https://cloudnet.h3c.com) to implement remote management.

Figure 4 One-key onboarding

Quicknet role selection

Quicknet networks can include various models of network devices. The method for determining device roles varies by product positioning.

- Some device models support manually designating the device role as TC through the CLI.
- Some device models support manually designating the device role as TM through the CLI.
- Some device models support using the auto election mechanism to determine their roles (TC or TM) in a Quicknet network.

For devices that support Quicknet, the role is not determined in the factory settings, and the TM is automatically elected through role election. A Quicknet network conducts role election in the following situations:

- The devices are first interconnected, which triggers Quicknet network formation.
- The TM leaves the network or malfunctions.
- The Quicknet network splits.
- Two (or more) independent Quicknet networks merge into one.

The following priority order is used to select the TM in the role election:

1. The TM specified by command execution is prioritized.
2. The device with a higher Quicknet election priority is prioritized.

   Each device comes with a priority in factory settings, which is determined by the device model and network location and cannot be modified from the CLI. The Quicknet election priorities of the following devices are in descending order: AC, router, security device, AP. The role of a switch requires manual configuration.

   - If none of the devices participating in the role election have finished startup deployment, the device with the highest priority becomes the TM.
   - When a device joins a deployed Quicknet network, if the priority of the new device is higher than the priority of the existing TM, the new device synchronizes configuration and then becomes the TM. If the priority of the new device is the same as or is lower than the priority of the existing TM, the new device joins the network as a TC.

3. Devices that have obtained Quicknet configuration and have been deployed are prioritized.

   If two devices have the same priority, the device that has obtained Quicknet configuration and has been deployed becomes the TM.

4. The TM in the larger Quicknet network is prioritized.

   When two Quicknet networks merge, the TM in the network with more members become the new TM.

5. Devices that have higher heath scores are prioritized.
6. Devices that have lower bridge MAC addresses are prioritized.

During the election process, the devices broadcast election packets at Layer 2 and follow the above rules until the only TM is selected.

Quicknet network establishment and changing

Quicknet network establishment

The network establishment process is as follows:

1. If a device is manually designated as TM or TC in the network, it will not participate in the role election process but will directly enter the TM or TC state. The TM will broadcast discovery packets to announce its identity.
2. For a device that supports automatic election, it will enter the TC(auto) state by default after startup.
   - If the device receives a TM broadcast packet within 5 seconds, its role is determined as TC, and the role election process will not be initiated.
   - If the device does not receive a TM broadcast packet within 5 seconds, it enters the role election phase and broadcasts an election packet (containing information such as bridge MAC, NetID, precedence, network scale, and VLAN-interface1 IP) at 5-second intervals. The optimal device is elected as the TM and other devices become TCs.
     - If the device receives an election packet from a device with better conditions within 20 seconds, it switches to TC. If the local device has better conditions, it becomes the TM.
     - If the device does not receive any election packets from other devices within 20 seconds, it switches to TM.
3. The TM broadcasts discovery packets at intervals of 5 seconds to announce its TM identity.
4. Each TC records the device information of the TM and sends a Quicknet discovery ACK packet back to the TM. At this time, you can use the **`display quicknet configuration`** command on the device to view the Quicknet configuration.
5. The network administrator can use one of the following methods to perform initial deployment:
   - Connect to the TM directly.
   - Connect to the Wi-Fi whose name includes the Quicknet string.

   Visit https://quicknet.h3c.com to log in to the management system. The system will automatically issue the LLDP and NETCONF configuration.
6. During the deployment process, the TM attempts to establish NETCONF sessions with all member devices and authenticates each TC using the username admin and the default password.
   - If the authentication is successful, the NETCONF session is established successfully.
   - If the authentication fails, the NETCONF session fails to be established.

   The TM sends commands to the TC through this NETCONF session to obtain information from the TC.
7. The TM obtains detailed information of the TC (including port, LLDP neighbors, and STP status) through a NETCONF session.
8. The TC sends a login request packet (containing device ID information).

9. The TM confirms the information and adds the TC to the network. You can use the **`display quicknet tc`** command to view TC information.
10. The TM builds the network topology based on LLDP information (the network topology can be viewed in Quicknet).
11. The administrator sets the network-wide password and Internet parameters according to the system guide to complete the deployment.
12. The TM synchronizes the password and rebuilds all NETCONF connections.

The Quicknet network has been officially established and can be uniformly operated and maintained through the management system.

New device joining

The mechanism for automatically electing the TM when a new device joins is as follows:

1. After the Quicknet network is established, the TM broadcast discovery packets at a fixed interval (default to 5 seconds), inquiring if member devices exist in the network.
2. When a new device is connected and powered on:
   - If the configuration of a newly added device specifies the role as TC, the device directly joins the Quicknet network as a TC.
   - If the configuration of a newly added device specifies the role as TM, the device cannot join the Quicknet network.
   - If the configuration of a newly added device uses the self-election function, the new device will enter the role election state and determine whether it acts as a TM or TC according to the role election rules.

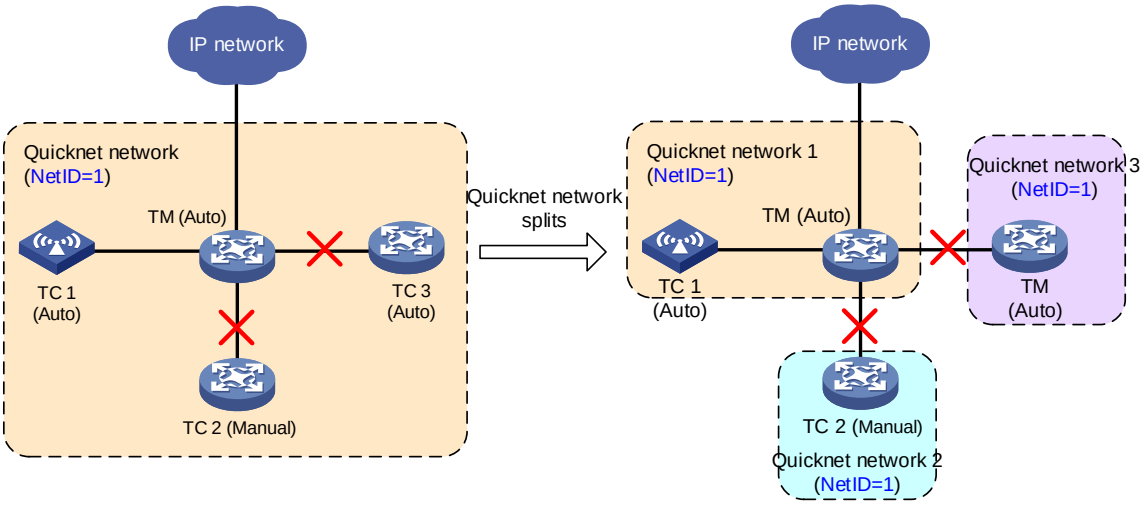
Member device leaving

After the Quicknet network is successfully established, the TM and TCs perceive each other's existence through Quicknet broadcast packets and response packets:

- After the TM leaves, TCs will enter the role election state if they fail to receive Quicknet discovery packets from the TM within 20 seconds. TCs then re-elect an TM according to the role election rules.
- After a TC leaves, the TM considers a TC as offline if it fails to receive any Quicknet discovery ACK packet from the TC within 20 seconds.

Quicknet splitting

If link failures occur between member devices in a Quicknet network, TCs and TM may fail to reach each other, causing the Quicknet network to split into multiple Quicknet networks. After the splitting, one Quicknet network contains the original TM, while other Quicknet networks do not have a TM.



During the splitting, the Quicknet software module handles the situation as follows:

- For the Quicknet network that contains the original TM, the Quicknet network continues to operate normally, and the departing member devices become offline.
- For a Quicknet network that does not contain a TM, if some devices in the network support self-election, they consider the TM as faulty and trigger role election after 20 seconds without receiving any Quicknet broadcast discovery packets from a TM.

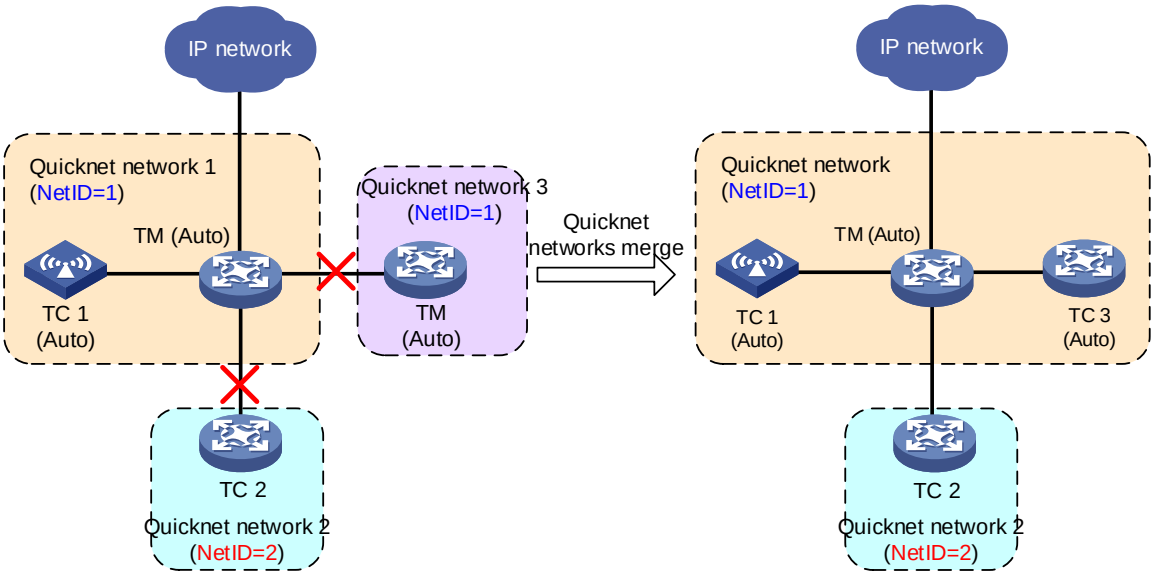
As shown in Figure 5, the roles of TM, TC 1, and TC 3 in the Quicknet network are decided through election, and the role of TC 2 is manually specified. Assuming that this Quicknet network has been established with a NetID of 1, the following scenarios might occur:

- When the link fails between TC 2 and the TM, TC 2 leaves the Quicknet network, but its role remains as TC and its NetID remains as 1.
- When the link fails between TC 3 and the TM, TC 3 leaves the Quicknet network. After 20 seconds without receiving any Quicknet broadcast discovery packets from the TM, TC 3 re-elects itself as the TM with a NetID of 1.

Figure 5 Quicknet splitting

Quicknet merging

The process of multiple stable Quicknet networks interconnecting to form a Quicknet network is called Quicknet merging.



The following rules are followed during the Quicknet merging:

- For Quicknet networks that have already been established, only Quicknet networks with the same NetID can be merged. Quicknet networks with different NetIDs cannot be merged. Restoring factory settings or disabling and then enabling Quicknet can delete the NetID on a device.
- Established Quicknet networks can be merged with non-established Quicknet networks.
- When merging, the two Quicknet networks will compete for the TM role. For more information about the TM election rules, see "Quicknet role selection."

As shown in Figure 6, three Quicknet networks exist in the current network. Quicknet network 1 and Quicknet network 3 have the same NetID, and Quicknet network 2 has a different NetID. When the link failure is recovered, the Quicknet networks will try to merge, as follows:

- Quicknet network 1 has two member devices, which is greater than the number of member devices in Quicknet network 2. Therefore, Quicknet network 1 wins the election and its TM will become the TM of the merged Quicknet network.
- Quicknet network 2 cannot participate in the merge due to its NetID being inconsistent with other Quicknet networks. You can restore the devices to factory settings for them to join the merged Quicknet network.

Figure 6 Quicknet merging

Quicknet configuration synchronization

After the administrator completes the deployment through Quicknet, member devices form a Quicknet network through the Layer 2 network. The TM automatically establishes NETCONF sessions with all TCs through VLAN interface 1 for configuration deployment and parameter retrieval, achieving unified network management.

Quicknet supports the following configuration methods:

- Global configuration

  Administrators can configure settings on the Quicknet management system's web page or from the TM's CLI. These configurations are distributed to and take effect on all member devices. Global synchronized configurations include wireless, wired, Internet, Quicknet network-wide password, and FTP server settings.

- Batch configuration

  Administrators can configure multiple devices by selecting them on the Quicknet management system's web page. These configurations are distributed to and take effect on the selected member devices. Batch synchronization operations include batch reboot and factory reset.

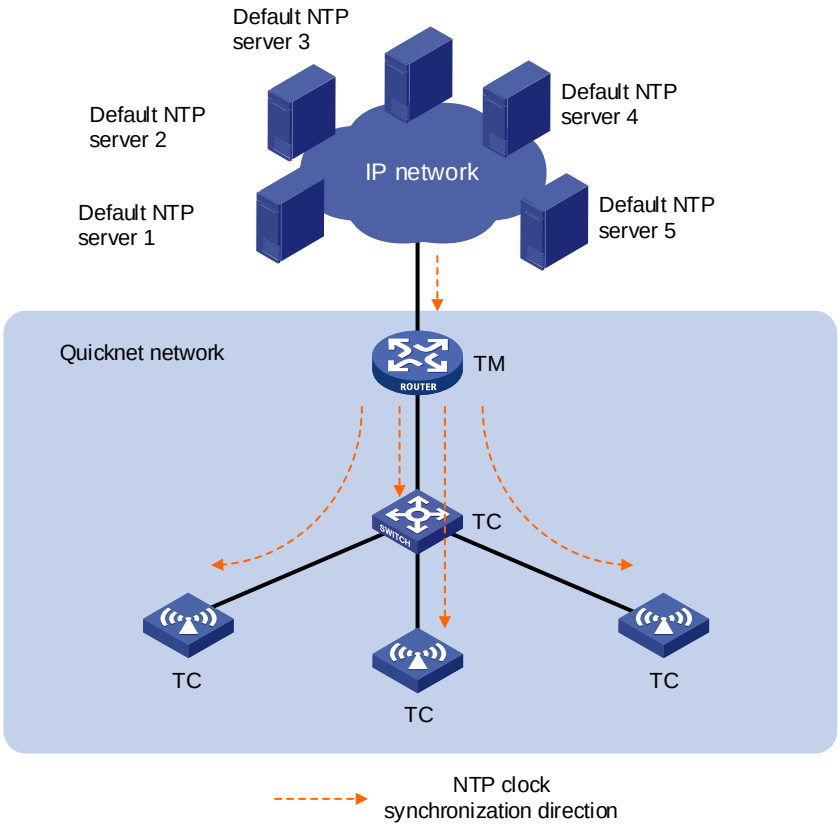
- Single device configuration

  In addition to Quicknet global configuration and batch configuration, administrators can configure parameters for a single member device in the following methods:

  - Configure the settings for the specified device on the web page. These configurations will be distributed to and take effect on that device.
  - For configurations not supported by the web page, such as disabling/enabling interfaces or adding interfaces to VLANs, administrators must log in to the member device and use the CLI to configure the settings. To log in to a member device, use either of the following methods:
    - Use the eWEB or CLI in the Quicknet management system to access the local Web interface or CLI.
    - Use the IP address of the device to log in to the local Web interface or CLI of the device.

Quicknet time synchronization (NTP)

After the Quicknet network is deployed, the TM synchronizes the time to all TCs using Network Time Protocol (NTP). The time synchronization precision of NTP is in milliseconds, which can meet the time synchronization requirements of general computer networks. For more information about NTP, see "Configuring NTP."



Quicknet synchronizes time settings across the network as follows:

1. When the Quicknet network is deployed, the TM automatically deletes the existing NTP configuration on the device and generates a new NTP configuration specific to the Quicknet network.
2. The TM acts as an NTP client and synchronizes time settings with external NTP servers.

   The device supports a default of four external NTP servers. When the device receives clock signals from multiple default NTP servers, it selects the optimal clock signal for synchronization. The addresses of the four clock servers are as follows:

   - s2f.time.edu.cn (Northeast network center)
   - cn.pool.ntp.org (NTP project domestic time server)
   - 1.cn.pool.ntp.org (NTP project domestic time server)
   - asia.pool.ntp.cn (NTP project Asian time server)
3. If all the four external NTP servers are unavailable, the TM modifies the level of the local clock to six and uses the local clock as the clock source for the Quicknet network.
4. The TM acts as an NTP server, and TCs act as NTP clients and synchronize time with the TM.

Figure 7 Quicknet time synchronization

Quicknet management system login with a fixed domain name

Typically, accessing the device's web interface requires its IP address or domain name. If you use a domain name, a DNS server must be deployed in the network and the domain-to-IP mapping must be configured. To simplify network deployment and user operations, Quicknet supports accessing the Quicknet management system using fixed domain name quicknet.h3c.com, even without a DNS server.

The TM automatically establishes a mapping between quicknet.h3c.com and the IP address of the TM's VLAN-interface 1 and synchronizes it with all member devices. Users can log into the Quicknet management system by connecting to any member device and entering the domain name.

Restrictions: Hardware compatibility with Quicknet

Switches of this series can only act as TCs and cannot act as the TM.

Restrictions and guidelines: Quicknet configuration

The device starts up with factory settings. After the administrator completes initial deployment configuration from the Quicknet management system, the device can automatically establish a Quicknet network.

The devices exchange Quicknet protocol packets and establish and maintain the Quicknet network within VLAN 1. For Quicknet to operate normally, make sure the interfaces connecting member devices allow VLAN 1 packets to pass through (by default, the interfaces connecting member devices allow VLAN 1 packets to pass through).

Quicknet tasks at a glance

To configure Quicknet, perform the following tasks:

1. Enabling Quicknet
2. Setting the network-wide Quicknet password

   As a best practice to ensure inter-device communication, configure this feature.

Enabling Quicknet

Restrictions and guidelines

One Quicknet network can have only one TM.

If you switch the device role from TM to TC or disable Quicknet, the system clears all the running configuration related to Quicknet on the device.

Quicknet requires specific ACL resources. If ACL resources are insufficient, Quicknet might fail to be enabled. You can use the **`display acl`** command to view the ACL configuration and operation status and use the **`undo acl`** command to delete useless ACLs based on the actual conditions. After releasing ACL resources, you can try again to enable Quicknet. For more information about ACL, see ACL and QoS Configuration Guide.

When you enable Quicknet, the device checks whether port 80 and port 443 are occupied, as HTTP and HTTPS services require these ports. If port 80 or port 443 is occupied, Quicknet cannot be enabled.

Procedure

1. Enter system view.
   system-view
2. Enable Quicknet. Perform either of the following tasks:
   - Enable Quicknet and specify the device role as TM.
     quicknet enable auto tm
   - Enable Quicknet and specify the device role as TC.
     quicknet tc enable

   By default, Quicknet is disabled and the device role is not specified.

Setting the network-wide Quicknet password

About this task

The TM manages and maintains each TC through NETCONF channels, and uses the local username admin and the default password to perform TC authentication. You can perform this task to edit the default password on the TM. The TM then issues the changed password to all TCs and re-establishes NETCONF channels.

Procedure

1. Enter system view.
   system-view
2. Set the network-wide Quicknet password.
   quicknet password [**cipher**] *string*

   By default, the network-wide Quicknet password is not configured, but the device comes with a preset credential: default username admin and a default password. For APs, the default password is h3capadmin. For other devices, the default password is admin.

Display and maintenance commands for Quicknet

Execute **display** commands in any view.

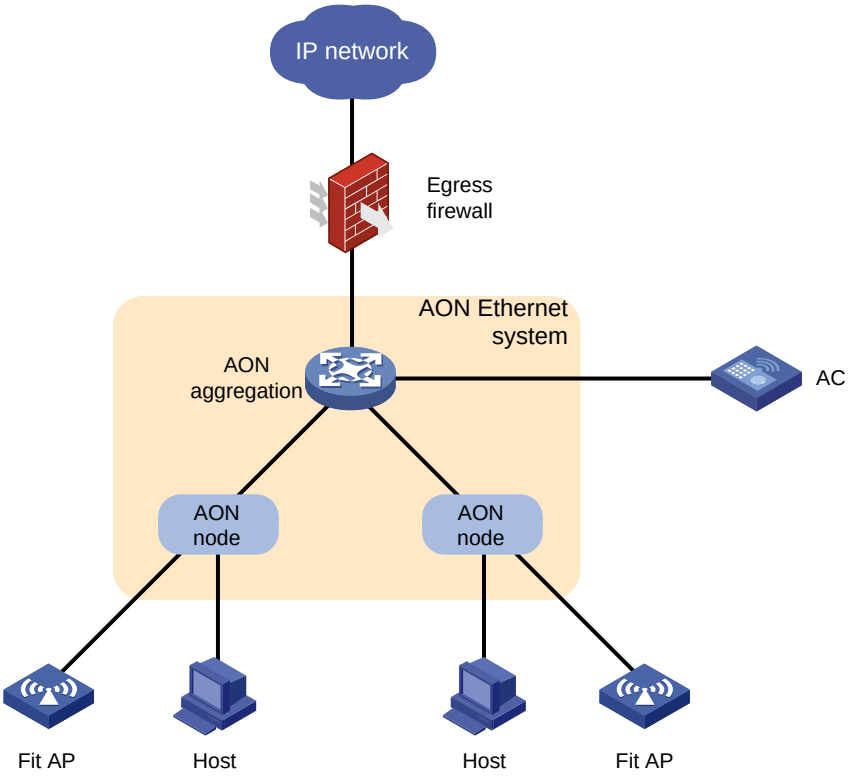
Configuring the AON Ethernet system



About the AON Ethernet system

The AON Ethernet system is a network management and maintenance solution based on a distributed deployment architecture. In the system, the AON aggregation (also called iOptic host) manages and maintains AON nodes (also called iOptic nodes), similar to how an AC manages APs in an AC+fit AP network. The AON aggregation functions like an AC, and the AON nodes function like APs. You can perform centralized control and management over campus access network devices by configuring and managing the AON aggregation.

AON Ethernet system framework

Figure 1 shows the basic framework of the AON Ethernet system.

Figure 1 AON Ethernet system framework

The AON Ethernet system contains the following types of physical devices:

- **AON aggregation**—The AON aggregation, core of the AON Ethernet system, automatically discovers and manages the AON nodes, forwards packets from the AON nodes, and performs centralized O&M on the AON nodes. On the AON aggregation, you can configure the AON nodes and obtain the interface status, interface statistics, PoE power, and transceiver module data of the AON nodes.
- **AON node**—An AON node acts as an expansion module of the AON aggregation, connecting to the external network through the AON aggregation. It is lightweight firmware that uses the manufacturer's built-in Microcontroller Unit (MCU) and achieves fast startup (within 10 seconds). Some AON node models support the Comware system, and others do not have an

operating system. In the AON Ethernet system, the AON nodes require zero configuration and are plug and play, functioning similarly as hubs.

Benefits

The AON Ethernet system offers the following benefits:

- Streamlined architecture. The traditional aggregation + access architecture has been transformed into an AON aggregation + AON nodes architecture, where an AON node operates as an expansion module to extend the capacity of the AON aggregation. This streamlined approach not only makes the network simpler but also allows for flexible expansion of the interface capacity for the AON aggregation.
- Plug-and-play AON nodes, simplifying network planning and deployment, and routine Ops.

AON node IDs

In the AON Ethernet system, an AON node is uniquely identified by its ID. The AON aggregation automatically allocates IDs to AON nodes as follows:

1. Enabled with SmartMC, the AON aggregation automatically broadcasts a discovery packet to discover AON nodes.
2. Upon receiving the discovery packets, the AON nodes automatically register with the AON aggregation.
3. The AON aggregation automatically allocates an ID to each AON node. The ID is bound to the SN and MAC address of an AON node. To view the mappings between AON nodes and their IDs, execute the **`display smartmc light-unit`** command on the AON aggregation. After an AON node goes offline, the AON aggregation still reserves the ID for the AON node until you execute the **`undo smartmc light-unit`** command to delete the AON node. Then, the device reclaims the ID of the AON node and allocates it to another AON node.

The AON aggregation uses AON node IDs to manage AON nodes. You can use the ID of an AON node to enter AON node view, where you can configure the name, description, interface VLANs, and PoE settings for the AON node.

AON node management methods

Managing a single AON node

When an AON node registers with the AON aggregation, the AON aggregation automatically allocates an ID to that AON node. The AON node is uniquely identified by the ID. The AON aggregation can manage AON nodes. After an AON node goes offline, the AON aggregation still reserves the ID for the AON node until you execute the **`undo smartmc light-unit`** command to delete the AON node. You can use the ID to enter AON node view and then configure parameters for the AON node.

Managing AON nodes in bulk

You can use an AON node configuration template to configure multiple AON nodes in bulk.

After you create an AON node configuration template, you can bind it to AON nodes and configure parameters for the AON nodes. When an AON node comes online, the configuration in AON node view, if any, applies. If the AON node does not have any configuration in AON node view and it matches the AON node configuration template, the AON aggregation automatically deploys configuration in AON node configuration template view to the AON node. If the deployment succeeds, the configuration in the template is converted to the configuration in AON node view. If the deployment fails, the configuration in the template is not converted to the configuration in AON node view.

You can bind an AON node configuration template to AON nodes in the following methods:

- Bind the template to the interface connected to the AON nodes on the AON aggregation. In this method, all AON nodes that come online via the interface can use the configuration in the template.

  When the uplink interfaces of an AON node supports aggregation and are connected to the AON aggregation, you must also configure an aggregate interface on the AON aggregation and bind the AON node configuration template to this aggregate interface.

- Bind the template to the device type of the AON nodes. In this method, all AON nodes of that type can use the configuration in the template when they come online.

Bind the template to the serial numbers of the AON nodes. In this method, only AON nodes of the specified serial numbers can use the configuration in the template when they come online. This method allows for both bulk and differentiated configuration.

Hardware compatibility with AON Ethernet system

The S5200-EI-G switch series does not support this feature.

Restrictions and guidelines: AON Ethernet system configuration

The AON Ethernet system uses VLAN 1 to broadcast discovery packets and uses the MAC address of VLAN-interface 1 to construct the discovery packets. Therefore, Vlan-interface 1 must exist on the AON aggregation and cannot be deleted.

If the AON aggregation connects to an AON node through a non-aggregate interface or an aggregate interface with incorrect configuration, it can detect the aggregate link connection error when the AON node comes online. If the aggregate interface configuration or aggregate link topology changes, the AON aggregation cannot immediately detect the aggregate link connection error when the AON node is online. The AON aggregation can detect the error only after the AON node comes online again.

AON Ethernet system tasks at a glance

To configure the AON Ethernet system, perform the following tasks:

1. (Optional.) Configuring the SmartMC management VLAN

   To modify the SmartMC management VLAN, make sure SmartMC is disabled. If you modify the SmartMC management VLAN when SmartMC is enabled, the modification does not take effect. For the modification to take effect, first disable SmartMC and enable SmartMC again.
2. (Optional.) Enabling automatic upgrade for AON nodes
3. Enabling SmartMC for the AON aggregation
4. (Optional.) Managing an AON node in AON node view
   - Configuring a description and a name for an AON node
   - Configuring VLANs for an AON node
   - Enabling interface isolation for an AON node
   - Configuring PoE for an AON node
   - Performing an internal loopback test for an interface of an AON node
   - Shutting down interfaces on an AON node
   - Rebooting an AON node
5. (Optional.) Managing AON nodes in bulk by using an AON node configuration template

Use an AON node configuration template for deployment configuration of AON nodes that come online for the first time. The AON node configuration template does not take effect on an AON node if the following conditions are met:

- The AON node has been online.
- Configuration exists in the corresponding AON node view.

6. (Optional.) Replacing a faulty AON node

Prerequisites

IP address planning

1. The IP address of the management VLAN interface on the AON aggregation and the IP addresses of AON nodes must reside in the same network segment. The default management VLAN is VLAN 1.
2. You can configure IP addresses by using either of the following methods:
   - Manual configuration.
   - DHCP (recommended).

     This method makes sure the IP address of the AON aggregation and the AON nodes reside in the same network segment, allowing for Layer 3 management channel establishment.

DHCP deployment recommendations

- As a best practice, deploy the DHCP server on the AON aggregation.
- Configure the following address pools on the AON aggregation:
  - Address pool for VLAN 1.
  - Address pool for the management VLAN of the AON Ethernet system.

For information about configuring the DHCP server, see DHCP configuration in *Layer 3—IP Services Configuration Guide*.

Configuring a local user

1. Enter system view.

   system-view
2. Create a local user named **admin**. (The name must be **admin**.)

   local-user admin
3. Configure a password for the local user.

   password { **hash** | **simple** } *string*

   The specified password must be the same as that configured by using the **smartmc tm username** *username* **password** { **cipher** | **simple** } *string* **enable** command.
4. Specify the service type for the local user.

   service-type { **http** | **https** | **ssh** | **telnet** } *

   By default, no service type is specified for a local user.
5. Assign the network-admin user role to the user.

   authorization-attribute user-role network-admin
6. Return to system view.

   quit
7. Enable scheme authentication for user lines VTY 0 through VTY 63.

   line vty 0 63

   authentication-mode scheme

By default, password authentication is enabled for VTY lines.

Configuring the SmartMC management VLAN

About this task

Application scenarios

Use the SmartMC management VLAN to separate the management packets from other service packets in the AON Ethernet system.

Operating mechanism

An AON Ethernet system is set up as follows:

1. Enabled with SmartMC, the AON aggregation broadcasts a SmartMC scanning packet in VLAN 1 to discover AON nodes. Upon receiving the scanning packet, an AON node sends a response to register with the AON aggregation.
2. The AON aggregation and AON node establish a CoAP session within the management VLAN. This CoAP session acts as the Layer 3 management channel between them.

   By default, the management VLAN is VLAN 1. In VLAN 1, the AON aggregation and AON node automatically request IP addresses and the AON aggregation actively establishes a CoAP session with the AON node.
3. If the SmartMC management VLAN is configured, the AON aggregation and AON node work as follows:
   a. The downlink interface on the AON aggregation and the uplink interfaces of the AON node automatically permit management VLAN packets.
   b. If you use the AON aggregation as the DHCP server, you must manually configure the IP address of the management VLAN interface, enable DHCP, and configure address pools on the AON aggregation. If you use another device as the DHCP server, the management VLAN interface of the AON aggregation automatically requests an IP address.
   c. The AON node automatically requests an IP address within the management VLAN.
   d. The AON aggregation and AON node re-establish a COAP session by using the IP addresses obtained within the management VLAN.
4. The AON aggregation sends a successful registration packet to the AON node and the AON node joins the AON Ethernet system.

The SmartMC management VLAN is dedicated to transmitting protocol packets for the AON Ethernet system management plane. Broadcast packets are restricted within the management VLAN, effectively separating protocol packets on the AON Ethernet system management plane from the service packets and other protocol packets. This facilitates the construction and maintenance of the AON Ethernet and enhances its security.

Restrictions and guidelines

When the device runs as a SmartMC TC, the system automatically deletes the **smartmc management-vlan** command.

To modify the SmartMC management VLAN, make sure SmartMC is disabled. If you modify the SmartMC management VLAN when SmartMC is enabled, the modification does not take effect. For the modification to take effect, first disable SmartMC and enable SmartMC again.

This feature is supported only when the device acts as an AON aggregation. When the device also acts as the TM in a SmartMC network, if you change the SmartMC management VLAN to a VLAN other than VLAN 1, TCs cannot come online.

Procedure

1. Enter system view.

   system-view

2. Create a management VLAN.

   vlan *vlan-id*

   By default, only VLAN 1 exists on the device.

   To successfully configure the SmartMC management VLAN, first create the management VLAN.

3. Return to system view.

   quit

4. Create a management VLAN interface.

   interface vlan-interface *vlan-id*

   By default, no VLAN interface exists.

5. Return to system view.

   quit

6. Configure the SmartMC management VLAN.

   smartmc management-vlan *vlan-id*

   By default, the SmartMC management VLAN is VLAN 1.

Enabling automatic upgrade for AON nodes

About this task

Configured with this feature, the AON aggregation automatically identifies whether the software version of an onboarding AON node is compatible with its own. If they are not compatible, the AON node software is automatically upgraded.

Restrictions and guidelines

In a distributed deployment scenario, you must also upload the target AON node version to the AON aggregation.

If you do not enable this feature and the AON node software version is incompatible with that of the AON aggregation, an AON node can still come online and forward packets. To avoid affecting AON node management on the AON aggregation, upgrade the AON node immediately.

Prerequisites

1. Execute the **display version** command on the AON aggregation to obtain its running software version.
2. Obtain the most recent software version of the AON nodes that is compatible with the AON aggregation software version based on the release notes of the AON aggregation.
3. Upload the startup software package of the AON nodes to the AON aggregation. For the automatic upgrade feature to take effect, make sure the AON aggregation has the startup software package of the AON nodes.

Procedure

1. Enter system view.

   system-view

2. Enable automatic upgrade for AON nodes.

   smartmc auto-upgrade enable

   By default, automatic upgrade is disabled for AON nodes.

Enabling SmartMC for the AON aggregation

About this task

An AON aggregation and its connected AON nodes form an AON Ethernet system. The members in the AON Ethernet system discover each other at Layer 2 through SmartMC. In this way, the AON Ethernet system is also a SmartMC network. With this feature configured, the AON aggregation acts as the topology master (TM), and the AON nodes act as topology clients (TCs). Enabled with the AON node mode, an AON node is automatically enabled with SmartMC and operates as a TC. In the AON Ethernet system, you only need to enable the AON node mode on AON nodes and no other settings are required for them. For information about the factory default mode of an AON node, see its product documentation. For more information about SmartMC, see *Network Management and Monitoring Configuration Guide*.

An AON aggregation supports both the SmartMC and AON Ethernet system features. For information about configuring a pure SmartMC network, see *Network Management and Monitoring Configuration Guide*. For information about configuring an AON Ethernet, see the configuration guide. Do not deploy both networks on an AON aggregation. An AON aggregation broadcasts scanning packets to discover TCs and determines the network type based on the type of the first TC that responds to the scanning packet.

Restrictions and guidelines

A SmartMC network can have only one AON aggregation.

Disabling SmartMC for the AON aggregation clears the running configuration related to SmartMC.

The SmartMC feature consumes certain ACL resources. If the ACL resources are insufficient, SmartMC will fail to be enabled. To resolve such an issue, perform the following tasks:

1. Obtain the ACL configuration and running status by using the **`display acl`** command.
2. Delete unnecessary ACLs by using the **`undo acl`** command as required.
3. Enable SmartMC again.

For more information about ACL, see *ACL and QoS Configuration Guide*.

When you enable SmartMC, the device identifies whether HTTP port 80, HTTPS port 443, and CoAP port 5683 are in use. If any of these ports is occupied, SmartMC will fail to be enabled.

If you execute this command multiple times, the most recent configuration takes effect. You can use the **`smartmc enable`** command to enable SmartMC on an AON Ethernet or SmartMC network. The SmartMC network requires a username and password, but the AON Ethernet does not.

Procedure

1. Enter system view.

   `system-view`
2. Enable SmartMC for the AON aggregation.

   `smartmc tm username` *`username`* **`password`** { **`cipher`** | **`simple`** } *`string`* **`enable`**

   By default, SmartMC is disabled for the AON aggregation.

Managing an AON node in AON node view

Configuring a description and a name for an AON node

About this task

In the AON Ethernet system, each AON node is uniquely identified by its ID. However, the AON node ID, a string of digits, is difficult to remember. To resolve such an issue, you can configure a name for each AON node for easier management.

To enter the configuration view of an AON node, configure a name for that AON node and then execute the **smartmc light-unit name** *name* command.

The system name of an AON node can contain only 1 to 31 characters. To manage AON nodes efficiently, you can also configure the IDs, geographic locations, and IP addresses as descriptions for them. The AON node description is a string of 1 to 255 characters.

Restrictions and guidelines

Do not configure the name of an AON node as the MAC address of another AON node.

Procedure

1. Enter system view.
   system-view
2. Enter AON node view.
   smartmc light-unit { *id* | **name** *name* }
3. Configure a name for the AON node.
   name *sysname*
   By default, the AON aggregation uses the MAC address of an AON node as its name.
4. Configure a description for the AON node.
   description *text*
   By default, an AON node does not have a description.

Configuring VLANs for an AON node

VLAN modes

An AON node supports the following VLAN modes:

- **Transparent mode**—In this mode, the AON node forwards packets based on the destination MAC address no matter whether service packets carry the VLAN tag or their VLAN IDs or not. In transparent mode, you cannot edit the VLAN settings of interfaces on the AON node. To configure VLANs based on MAC addresses or subnets for service packets, perform the configuration on the interface that connects the AON aggregation to the AON node.
- **Manual mode**—In this mode, an interface operates in hybrid mode and VLANs are configured based on interfaces. After you switch the VLAN mode to manual, the interface uses PVID VLAN 1, which is added to the permitted VLAN list of the interface as an untagged member. To change the PVID of the interface, use the **port hybrid pvid** command. To assign the interface to specified VLANs, use the **port hybrid vlan** command.

VLAN configuration guidelines for the uplink interface on an AON node

An AON node uses a physical interface as the uplink interface to connect to an AON aggregation. For AON nodes that have two uplink interfaces, they can aggregate the two interfaces automatically. Support for auto uplink interface aggregation depends on the model and software version of AON

nodes. An AON aggregation can automatically identify whether an AON node supports uplink interface aggregation. Use the **uplink** keyword or *port-id-list* argument as prompted.

- For AON nodes that aggregate uplink interfaces automatically, the two uplink interfaces operate as follows:
  - In versions earlier than a specific version, the two interfaces back up each other, but only one interface is active for packet forwarding at the same time. In this case, the **uplink** keyword is not supported. Use the *port-id-list* argument when you configure VLANs for AON nodes.
  - In a specific version and later versions, the two interfaces back up each other, and can forward traffic at the same time for load balancing. In this case, use the **uplink** keyword when you configure VLANs for AON nodes. To avoid configuration failures, do not use the *port-id-list* argument.
    - If you upgrade a device from a version that does not support the **uplink** keyword to a version that supports the **uplink** keyword, the *port-id-list* configuration in the configuration file still takes effect for backward compatibility.
    - If you downgrade a device from a version that supports the **uplink** keyword to a version that does not support the **uplink** keyword, and then upgrade the device back to a version that supports the keyword, the configuration file of the device contains both the **uplink** and *port-id-list* configurations. In this case, the **uplink** configuration takes effect.

  For information about the version from which an AON node supports uplink interface aggregation, see the documentation for the AON node.
- For AON nodes that do not support uplink interface aggregation, the two interfaces back up each other, but only one interface is active for packet forwarding at the same time. Use the *port-id-list* argument when you configure VLANs for AON nodes.

Restrictions and guidelines

In transparent mode, user traffic cannot be isolated based on VLANs on an AON node. To isolate user traffic, configure the interface isolation feature for the AON node or isolate user traffic on the AON aggregation.

Procedure

1. Enter system view.

   system-view
2. Enter AON node view.

   smartmc light-unit { *id* | **name** *name* }
3. Specify the VLAN mode for the AON node.

   vlan mode { **manual** | **transparent** }

   By default, the VLAN mode for an AON node is transparent.
4. Set the PVID of hybrid interfaces on the AON node.

   port { **uplink** | *port-id-list* } * **hybrid pvid vlan** *vlan-id*

   By default, the interfaces on an AON node do not check VLAN information for packets and transparently transmit all the packets.
5. Assign hybrid interfaces on the AON node to the specified VLANs.

   port { **uplink** | *port-id-list* } * **hybrid vlan** *vlan-id-list* { **tagged** | **untagged** }

   By default, the interfaces on an AON node do not check VLAN information for packets and transparently transmit all the packets.

Enabling interface isolation for an AON node

About this task

Application scenarios

This feature prevents the endpoints connected to an AON node from accessing each other at Layer 2 to enhance LAN security.

Operating mechanism

By default, all interfaces on an AON node belong to the same VLAN and the endpoints connected to the interfaces can access each other at Layer 2.

This feature isolates the interfaces on an AON node and enables the endpoints connected to the AON node to forward packets through the AON aggregation. This allows you to manage the traffic of AON nodes on the AON aggregation, which enhances LAN security.

Procedure

1. Enter system view.

   system-view

2. Enter AON node view.

   smartmc light-unit { *id* | **name** *name* }

3. Enable interface isolation for the AON node.

   isolate enable

   By default, interface isolation is disabled for an AON node.

Configuring PoE for an AON node

About this task

Enabled with PoE, the PIs on an AON node can provide PoE power for PDs if they support PoE output.

Forced PoE power supply

Before supplying power to a PD, an AON node performs a detection of the PD by default. It supplies power to the PD only after the PD passes the detection. If the PD fails the detection but the power provided by the AON node meets the PD specifications, you can enable forced power supply to the PD.

PoE power supply standards

IEEE released 802.3af (PoE) and 802.3at (PoE+) standards in chronological sequence. The standards are backward compatible but forwards incompatible. Before supplying power to a PD, a PI will detect the PD, determine the power class for the PD based on its power requirement, and supply power to the PD based on the power class.

- **802.3af**—Defines four power classes 0 to 3 and provides a maximum power of 12.95 W.
- **802.3at**—Adds class 4 in addition to the four power classes defined by 802.3af and provides a maximum power of 25.5 W.

Specify a PoE standard based on the power requirement of the PD. If the maximum power allowed by the standard is less than that required by the PD, the PI will not supply power to the PD.

Restrictions and guidelines

The forced PoE power supply feature enables an AON node to supply power to a PD directly without performing a detection of the PD. To avoid damaging the PD, make sure the power provided by the AON node meets the PD specifications before configuring this feature.

Disabling PoE for PIs on an AON node restores the default settings of the **poe force-power** and **standard** commands on the PIs.

Procedure

1. Enter system view.
   system-view
2. Enter AON node view.
   smartmc light-unit { *id* | **name** *name* }
3. Enable PoE for PIs on the AON node.
   poe enable port *port-id-list*
   By default, PoE is enabled for PIs on an AON node.
4. Specify a PoE standard for PIs on the AON node.
   poe standard { **af** | **at** } **port** *port-id-list*
   By default, the IEEE 802.3af standard is used.
5. Enable forced PoE power supply for PIs on the AON node.
   poe force-power port *port-id-list*
   By default, forced PoE power supply is disabled for PIs on an AON node.
6. Restart PoE on PIs of the AON node.
   restart poe port *port-id-list*

Performing an internal loopback test for an interface of an AON node

About this task

Use this feature to identify whether the interfaces on an AON node can forward packets correctly.

After you configure this feature on an interface of an AON node, the interface returns the packets to be forwarded to the device, allowing the packets to loop through the internal line. Then, you can identify whether the Ethernet forwarding path within the device can operate correctly.

Restrictions and guidelines

If you enable loop guard on an interface of an AON node, you cannot perform an internal loopback test for that interface on the AON aggregation.

Procedure

1. Enter system view.
   system-view
2. Enter AON node view.
   smartmc light-unit { *id* | **name** *name* }
3. Perform an internal loopback test for an interface of the AON node.
   loopback-test internal port *port-id*

Shutting down interfaces on an AON node

About this task

Some interface settings might require an interface restart before they can take effect.

Restrictions and guidelines

CAUTION:

Executing the **shutdown** command disconnects the links of the specified interfaces and interrupts communication. Use this command with caution.

The AON Ethernet system automatically discovers and records the uplink interfaces of AON nodes. Do not use this command to shut down the uplink interfaces of AON nodes.

Procedure

1. Enter system view.
   system-view
2. Enter AON node view.
   smartmc light-unit { *id* | **name** *name* }
3. Shut down interfaces on the AON node.
   shutdown port *port-id-list*
   By default, the interfaces on an AON node are up.

Rebooting an AON node

About this task

Use this feature to reboot an AON node when it is faulty.

Procedure

1. Enter system view.
   system-view
2. Enter AON node view.
   smartmc light-unit { *id* | **name** *name* }
3. Reboot the AON node.
   Reboot

Managing AON nodes in bulk by using an AON node configuration template

Restrictions and guidelines

Use an AON node configuration template for deployment configuration of AON nodes that come online for the first time. The AON node configuration template does not take effect on an AON node if the following conditions are met:

- The AON node has been online.
- Configuration exists in the corresponding AON node view.

You can repeat this command to bind a template to different AON nodes. However, the same serial number, model, or connection interface (the interface connecting to AON nodes on the AON aggregation) can be bound to only one template. An AON node can match configuration templates by its serial number, model, and connection interface. When an AON node matches multiple templates, the following AON node configurations are in descending order: configuration in AON node view, configuration of the template bound to the serial number, configuration of the template bound to the device type, and configuration of the template bound to the connection interface.

Procedure

1. Enter system view.
   system-view
2. Create an AON node configuration template and enter its view.
   smartmc light-unit template *template-name*
3. (Optional.) Configure a description for the template.
   description *text*
   By default, an AON node configuration template does not have a description.
4. (Optional.) Configure VLAN parameters.
   - Specify the VLAN mode for the AON node.
     vlan mode { **manual** | **transparent** }
     By default, the VLAN mode for an AON node is transparent.
   - Set the PVID of hybrid interfaces on the AON node.
     port *port-id-list* **hybrid pvid vlan** *vlan-id*
     By default, the interfaces on an AON node do not check VLAN information for packets and transparently transmit all the packets.
   - Assign hybrid interfaces on the AON node to the specified VLANs.
     port *port-id-list* **hybrid vlan** *vlan-id-list* { **tagged** | **untagged** }
     By default, the interfaces on an AON node do not check VLAN information for packets and transparently transmit all the packets.
5. (Optional.) Enable interface isolation for the AON node.
   isolate enable
   By default, interface isolation is disabled for an AON node.
6. (Optional.) Configure PoE.
   - Enable PoE for PIs on the AON node.
     poe enable port *port-id-list*
     By default, PoE is enabled for PIs on an AON node.
   - Specify a PoE standard for PIs on the AON node.
     poe standard { **af** | **at** } **port** *port-id-list*
     By default, IEEE 802.3af is used.
   - Enable forced PoE power supply for PIs on the AON node.
     poe force-power port *port-id-list*
     By default, forced PoE power supply is disabled for PIs on an AON node.
7. Return to system view.
   quit
8. Bind the AON node configuration template to AON nodes.
   smartmc light-unit bind template *template-name* { **with-interface** *interface-type interface-number* | **with-light-unit-type** *light-unit-type* | **with-sn** *sn* }
   By default, an AON node configuration template is not bound to any AON nodes.

Replacing a faulty AON node

About this task

When an AON node in the AON Ethernet system fails, you can use this feature to replace the faulty AON node.

1. Connect a new AON node to the AON aggregation. Make sure the new AON node and the faulty AON node are the same model.
2. The AON aggregation detects that the new AON node comes online. Execute the **display smartmc light-unit** command to view the ID and status of the new AON node. If the new AON node is in **Normal** status, the new AON node successfully comes online.
3. Execute the **smartmc replace** command.
4. The AON Ethernet system replaces the ID of the new AON node with that of the faulty AON node, and runs configuration of the faulty AON node on the new one.

Restrictions and guidelines

Make sure the new member and the faulty member have the same neighbor relationship and model.

Prerequisites

Connect the new AON node to the AON Ethernet system and execute the **display smartmc light-unit** command to obtain the ID and status of the new AON node. You can configure this feature only when the new AON node is in **Normal** status.

Procedure

1. Enter system view.
   system-view
2. Manually replace a faulty AON node.
   smartmc replace tc *tc-id1* **faulty-tc** *tc-id2*

Display and maintenance commands for the AON Ethernet system

Execute **display** commands in any view and the **reset** command in user view.

Task	Command
Display connections between the AON aggregation and AON nodes in the AON Ethernet system.	**display smartmc device-link**
Display AON node information.	**display smartmc light-unit** [*id* | **interface** *interface-type interface-number* | **name** *name*] [**verbose**]
Display the configuration deployed from the AON aggregation to AON nodes and successfully run on the AON nodes.	**display smartmc light-unit configuration history**
Display information about the PoE power supply status of an AON node.	**display smartmc light-unit** { *id* | **name** *name* } **poe**
Display power supply information for PIs on an AON node.	**display smartmc light-unit** { *id* | **name** *name* } **poe port** [*port-id*]

Task	Command
Display information about interfaces on an AON node.	**display smartmc light-unit** { *id* | **name** *name* } **port** [*port-id* | **brief** | **uplink**]
Display key parameters of transceiver modules on an AON node.	**display smartmc light-unit** { *id* | **name** *name* } **transceiver port** [*port-id*]
Display upgrade information for an AON node.	**display smartmc light-unit** { *id* | **name** *name* } **upgrade-info**
Display AON node configuration template information.	**display smartmc light-unit template** [**name** *template-name*] [**match-info**]
Clear the configuration deployed from the AON aggregation to AON nodes.	**reset smartmc light-unit configuration history**

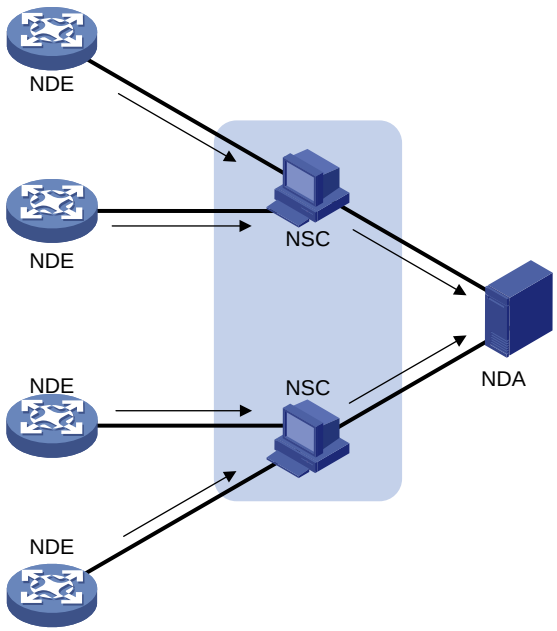
Configuring NetStream

About NetStream

NetStream is an accounting technology that provides statistics on a per-flow basis. An IPv4 flow is defined by the following 7-tuple elements:

- Destination IP address.
- Source IP address.
- Destination port number.
- Source port number.
- Protocol number.
- ToS.
- Inbound or outbound interface.



NetStream architecture

A typical NetStream system includes the following elements:

- **NetStream data exporter**—A device configured with NetStream. The NDE provides the following functions:
  - Classifies traffic flows by using the 7-tuple elements.
  - Collects data from the classified flows.
  - Aggregates the data.
  - Exports the data to the NSC.
- **NetStream collector**—A program running on an operating system. The NSC parses the packets received from the NDEs, and saves the data to its database.
- **NetStream data analyzer**—A network traffic analyzing tool. Based on the data in NSC, the NDA generates reports for traffic billing, network planning, and attack detection and monitoring. The NDA can collect data from multiple NSCs. Typically, the NDA features a Web-based system for easy operation.

NSC and NDA are typically integrated into a NetStream server.

Figure 1 NetStream system

NetStream flow aging

NetStream uses flow aging to enable the NDE to export NetStream data to NetStream servers. NetStream creates a NetStream entry for each flow for storing the flow statistics in the cache.

When a flow is aged out, the NDE performs the following operations:

- Exports the summarized data to NetStream servers in a specific format.
- Clears NetStream entry information in the cache.

NetStream supports the following flow aging methods:

- Periodical aging.
- Forced aging.

Periodical aging

Periodical aging uses the following methods:

- **Inactive flow aging**—A flow is inactive if no packet arrives for the NetStream entry within the inactive flow aging timer. When the timer expires, the following events occur:
  - The inactive flow entry is aged out.
  - The statistics of the flow are sent to NetStream servers and are cleared in the cache. The statistics can no longer be displayed by using the **`display ip netstream cache`** command.

  This method ensures that inactive flow entries are cleared from the cache in a timely manner so new entries can be cached.
- **Active flow aging**—A flow is active if packets arrive for the NetStream entry within the active flow aging timer. When the timer expires, the statistics of the active flow are exported to NetStream servers. The device continues to collect active flow statistics.

  This method periodically exports the statistics of active flows to NetStream servers.

Forced aging

To implement forced aging, execute the **`reset ip netstream statistics`** command to clear the NetStream cache immediately and export the cached entries to NetStream servers.

NetStream data export

Traditional data export

Traditional NetStream collects the statistics of each flow and exports the statistics to NetStream servers.

This method consumes more bandwidth and CPU than the aggregation method, and it requires a large cache size.

Aggregation data export

NetStream aggregation merges the flow statistics according to the aggregation criteria of an aggregation mode, and it sends the summarized data to NetStream servers. The NetStream aggregation data export uses less bandwidth than the traditional data export.

Table 1 lists the available aggregation modes. In each mode, the system merges statistics for multiple flows into statistics for one aggregate flow if each aggregation criterion is of the same value. The system records the statistics for the aggregate flow. These aggregation modes work independently and can take effect concurrently.

For example, when the aggregation mode configured on the NDE is protocol-port, NetStream aggregates the statistics of flow entries by protocol number, source port, and destination port. Four NetStream entries record four TCP flows with the same destination address, source port, and destination port, but with different source addresses. In the aggregation mode, only one NetStream aggregation entry is created and sent to NetStream servers.

Table 1 NetStream aggregation modes

Aggregation mode	Aggregation criteria
AS aggregation	• Source AS number • Destination AS number • Inbound interface index • Outbound interface index
Protocol-port aggregation	• Protocol number • Source port • Destination port
Source-prefix aggregation	• Source AS number • Source address mask length • Source prefix (source network address) • Inbound interface index
Destination-prefix aggregation	• Destination AS number • Destination address mask length • Destination prefix (destination network address) • Outbound interface index
Prefix aggregation	• Source AS number • Destination AS number • Source address mask length • Destination address mask length • Source prefix • Destination prefix • Inbound interface index • Outbound interface index
Prefix-port aggregation	• Source prefix • Destination prefix • Source address mask length

Aggregation mode	Aggregation criteria
	• Destination address mask length • ToS • Protocol number • Source port • Destination port • Inbound interface index • Outbound interface index
ToS-AS aggregation	• ToS • Source AS number • Destination AS number • Inbound interface index • Outbound interface index
ToS-source-prefix aggregation	• ToS • Source AS number • Source prefix • Source address mask length • Inbound interface index
ToS-destination-prefix aggregation	• ToS • Destination AS number • Destination address mask length • Destination prefix • Outbound interface index
ToS-prefix aggregation	• ToS • Source AS number • Source prefix • Source address mask length • Destination AS number • Destination address mask length • Destination prefix • Inbound interface index • Outbound interface index
ToS-protocol-port aggregation	• ToS • Protocol type • Source port • Destination port • Inbound interface index • Outbound interface index
ToS-BGP-nexthop	• ToS • BGP next hop • Outbound interface index

If packets are not forwarded according to the BGP routing table, the AS number or BGP next hop cannot be obtained.

NetStream export formats

NetStream exports data in UDP datagrams in one of the following formats:

- **Version 5**—Exports original statistics collected based on the 7-tuple elements and does not support the NetStream aggregation data export. The packet format is fixed and cannot be extended.

- **Version 8**—Supports the NetStream aggregation data export. The packet format is fixed and cannot be extended.
- **Version 9**—Based on a template that can be configured according to the template formats defined in RFCs. Version 9 supports exporting the NetStream aggregation data and collecting statistics about BGP next hop packets.
- **Version 10**—Similar to version 9. The difference between version 9 and version 10 is that version 10 export format is compliant with the IPFIX standard.

NetStream filtering

NetStream filtering uses an ACL to identify packets. Whether NetStream collects data for identified packets depends on the action in the matching rule.

- NetStream collects data for packets that match permit rules in the ACL.
- NetStream does not collect data for packets that match deny rules in the ACL.

For more information about ACL, see *ACL and QoS Configuration Guide*.

NetStream sampling

NetStream sampling collects statistics on fewer packets and is useful when the network has a large amount of traffic. NetStream on sampled traffic lessens the impact on the device's performance. For more information about sampling, see "Configuring samplers."

Protocols and standards

RFC 5101, *Specification of the IP Flow Information Export (IPFIX) Protocol for the Exchange of IP Traffic Flow Information*

Restrictions: Hardware compatibility with NetStream

NetStream is only supported on the S5200-HI-G switch series.

Restrictions and guidelines: NetStream configuration

If the following features (listed in descending order of priority) are configured, only the feature with the highest priority takes effect:

- NetAnalysis for UDP traffic.
- NetAnalysis unified flow analytics.
- FGLB adaptive routing.
- IPv4 NetStream and IPv6 NetStream.
- MOD and flow group in delay monitoring mode.

For more information about NetAnalysis for UDP traffic and NetAnalysis unified flow analytics, see "Configuring NetAnalysis." For more information about FGLB adaptive routing, see adaptive routing in *Layer 3—IP Routing Configuration Guide*. For more information about MOD and flow groups, see MOD configuration and flow group configuration in *Telemetry Configuration Guide*.

For SF interface modules, if you configure NetStream for incoming traffic on the input interface and outgoing traffic on the output interface for a flow, the NetStream configuration takes effect in only one direction.

NetStream tasks at a glance

To configure NetStream, perform the following tasks:

1.
2. Enabling NetStream
3. (Optional.) Setting the NetStream flow classification key fields
4. (Optional.) Configuring NetStream sampling
5. (Optional.) Configuring the NetStream data export format
6. (Optional.) Configuring the refresh rate for NetStream version 9 or version 10 template
7. (Optional.) Configuring NetStream flow aging
   - Configuring periodical flow aging
8. Configuring the NetStream data export
   a. Configuring the NetStream traditional data export
   b. (Optional.) Configuring the NetStream aggregation data export
9. (Optional.) Enabling SNMP notifications for NetStream

Enabling NetStream

Enabling NetStream on an interface

Restrictions and guidelines

Interface-specific NetStream configuration and interface-specific NetStream filtering are mutually exclusive. Do not use them simultaneously.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable NetStream on the interface.
   ip netstream { **inbound** | **outbound** }
   By default, NetStream is disabled on an interface.

Configuring NetStream filtering

About this task

Perform this task to enable NetStream on an interface and to collect traffic statistics about traffic matching an ACL.

NetStream filtering uses an ACL to identify packets.

- To enable NetStream to collect statistics for specific flows, use the ACL permit statements to identify these flows.

- To disable NetStream from collecting statistics for specific flows, use the ACL deny statements to identify these flows.

Restrictions and guidelines

Interface-specific NetStream configuration and interface-specific NetStream filtering are mutually exclusive. Do not use them simultaneously.

When NetStream filtering and sampling are both configured, packets are filtered first, and then the permitted packets are sampled.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable NetStream filtering on the interface.

   ip netstream { **inbound** | **outbound** } **filter acl** *acl-number*

   By default, NetStream filtering is disabled. NetStream collects statistics of all IPv4 packets passing through the interface.

Setting the NetStream flow classification key fields

About this task

By default, the hardware classifies packets into NetStream flows based on these key fields: source and destination IP addresses, source and destination MAC addresses, and protocol. Packets matching the same key fields are grouped into one flow and sent to NetStream regularly for further tracking.

You can set the flow classification key fields to suit specific traffic monitoring requirements. For example, if you are concerned with only the traffic destination, you can set the destination IP address as the flow classification key field. All packets destined for the same IP address are classified into one flow.

Restrictions and guidelines

To collect traffic flows based on the 7-tuple, configure the following key fields for NetStream flow classification:

- **destination-ip**.
- **destination-port**.
- **ip-tos**.
- **protocol**.
- **source-ip**.
- **source-port**.

If you do not follow this restriction, NetStream will set these fields to fixed values for all flows.

If you execute the command multiple times, the most recent configuration takes effect.

Procedure

1. Enter system view.

   system-view

2. Set the flow classification key fields.

   netstream key [**destination-ip** | **destination-mac** | **destination-port** | **flow-label** | **ip-tos protocol** | **source-ip** | **source-mac** | **source-port**] *

   By default, no flow classification key field is set.

Configuring NetStream sampling

Restrictions and guidelines

By default, NetStream collects all data of target flows. If the flow traffic is heavy, NetStream is resource-consuming and can cause high CPU usage, which impacts the device forwarding performance. NetStream sampling is helpful to decrease the NetStream traffic volume. If the collected statistics can basically reflect the network status, you can enable this feature and set a proper sampling rate. The higher the sampling rate, the less the impact on device performance.

If NetStream sampling and filtering are both configured, packets are filtered first, and then the permitted packets are sampled.

This feature is available only on Layer 2 and Layer 3 Ethernet interfaces. It is not available on Layer 3 Ethernet subinterfaces and other types of interfaces.

Procedure

1. Enter system view.

   system-view

2. Create a sampler.

   sampler *sampler-name* **mode random packet-interval n-power** *rate*

   For more information about a sampler, see "Configuring samplers."

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable NetStream sampling.

   ip netstream { **inbound** | **outbound** } **sampler** *sampler-name*

   By default, NetStream sampling is disabled.

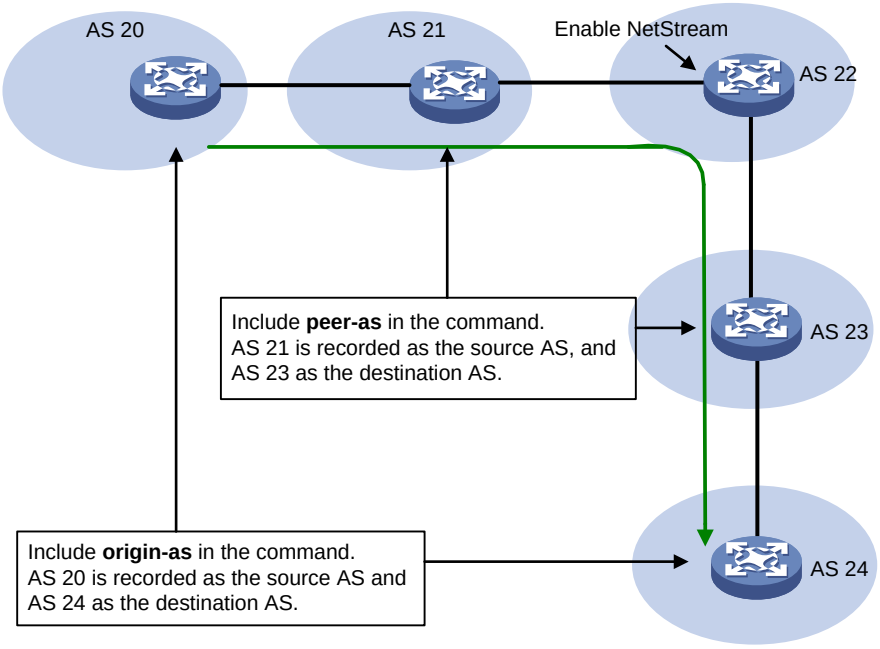
Configuring the NetStream data export format

About this task

When you configure the NetStream data export format, you can also specify the following settings:

- Whether or not to export the BGP next hop and serial number information.

  Only version 9 and version 10 formats support exporting the BGP next hop and serial number information.



- How to export the autonomous system (AS) information: **origin-as** or **peer-as**.
  - **origin-as**—Records the original AS numbers for the flow source and destination.
  - **peer-as**—Records the peer AS numbers for the flow source and destination.

For example, as shown in Figure 2, a flow starts at AS 20, passes AS 21 through AS 23, and then reaches AS 24. NetStream is enabled on the device in AS 22.

- Specify the **origin-as** keyword to export AS 20 as the source AS and AS 24 as the destination AS.

- Specify the **peer-as** keyword to export AS 21 as the source AS and AS 23 as the destination AS.

Figure 2 Recorded AS information varies by different keyword configurations

Procedure

1. Enter system view.

   system-view

2. Configure the NetStream data export format, and configure the AS, BGP next hop, and serial number export attributes. Choose one option as needed:
   - Set NetStream data export format to version 5 and configure the AS export attribute.

     ip netstream export version 5 { **origin-as** | **peer-as** }
   - Set NetStream data export format to version 9 or version 10 and configure the AS, BGP export, and serial number attributes.

     ip netstream export version { **9** | **10** } { **origin-as** | **peer-as** } [**bgp-nexthop**] [**serial-number**]

   By default:
   - NetStream data export uses the version 9 format.
   - The peer AS numbers for the flow source and destination are exported.
   - The BGP next hop and serial number information is not exported.

Configuring the refresh rate for NetStream version 9 or version 10 template

About this task

Version 9 and version 10 are template-based and support user-defined formats. A NetStream device must send the template to NetStream servers regularly to update the template on the servers.

For a NetStream server to use the correct version 9 or version 10 template, configure the time-based or packet count-based refresh rate. If both settings are configured, the template is sent when either of the conditions is met.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Configure the refresh rate for the NetStream version 9 or version 10 template.
   ```
   ip netstream export template refresh-rate { packet packets | time minutes }
   ```
   By default, the packet count-based refresh rate is 20 packets, and the time-based refresh interval is 30 minutes.

Configuring NetStream flow aging

Configuring periodical flow aging

1. Enter system view.
   ```
   system-view
   ```
2. Set the aging timer for active flows.
   ```
   ip netstream timeout active minutes
   ```
   By default, the aging timer for active flows is 5 minutes.
3. Set the aging timer for inactive flows.
   ```
   ip netstream timeout inactive seconds
   ```
   By default, the aging timer for inactive flows is 300 seconds.

Configuring the NetStream data export

Configuring the NetStream traditional data export

1. Enter system view.
   ```
   system-view
   ```
2. Specify a destination host for NetStream traditional data export.
   ```
   ip netstream export host ip-address udp-port [ vpn-instance vpn-instance-name ]
   ```
   By default, no destination host is specified.
3. (Optional.) Specify the source interface for NetStream data packets sent to NetStream servers.
   ```
   ip netstream export source interface interface-type interface-number
   ```
   By default, NetStream data packets take the IP address of their output interface (interface that is connected to the NetStream device) as the source IP address.

   As a best practice, connect the management Ethernet interface to a NetStream server, and configure the interface as the source interface.
4. (Optional.) Limit the data export rate.
   ```
   ip netstream export rate rate
   ```
   By default, the data export rate is not limited.

Configuring the NetStream aggregation data export

About this task

NetStream aggregation is implemented by software.

Restrictions and guidelines

Configurations in NetStream aggregation mode view apply only to the NetStream aggregation data export, and those in system view apply to the NetStream traditional data export. If configurations in NetStream aggregation mode view are not provided, the configurations in system view apply to the NetStream aggregation data export.

If the version 5 format is configured to export NetStream data, NetStream aggregation data export uses the version 8 format.

Procedure

1. Enter system view.

   system-view

2. Specify a NetStream aggregation mode and enter its view.

   ip netstream aggregation { **as** | **destination-prefix** | **prefix** | **prefix-port** | **protocol-port** | **source-prefix** | **tos-as** | **tos-bgp-nexthop** | **tos-destination-prefix** | **tos-prefix** | **tos-protocol-port** | **tos-source-prefix** }

   By default, no NetStream aggregation mode is configured.

3. Enable the NetStream aggregation mode.

   enable

   By default, all NetStream aggregation modes are disabled.

4. Specify a destination host for NetStream aggregation data export.

   ip netstream export host *ip-address udp-port* [**vpn-instance** *vpn-instance-name*]

   By default, no destination host is specified.

   If you expect only NetStream aggregation data, specify the destination host only in the related NetStream aggregation mode view.

5. (Optional.) Specify the source interface for NetStream data packets sent to NetStream servers.

   ip netstream export source interface *interface-type interface-number*

   By default, no source interface is specified for NetStream data packets. The packets take the IP address of the output interface as the source IP address.

   Source interfaces in different NetStream aggregation mode views can be different.

   If no source interface is configured in NetStream aggregation mode view, the source interface configured in system view applies.

Enabling SNMP notifications for NetStream

About this task

Use this feature to report important events for NetStream through SNMP notifications. The generated alarm information will be sent to the SNMP module on the device and you can configure the SNMP notification sending parameters to determine the export attributes of the alarm information. For more information, see "Configuring SNMP."

Procedure

1. Enter system view.

system-view

2. Enable SNMP notifications for NetStream.

   snmp-agent trap enable ip netstream [**entry-limit**]

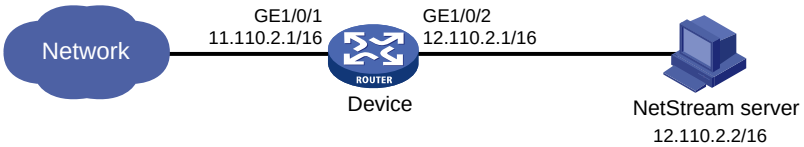
   By default, SNMP notifications are enabled for NetStream.

Display and maintenance commands for NetStream

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display NetStream entry information.	**display ip netstream cache** [**verbose**] [**type** { **ip** | **ipl2** | **l2** }] [**destination** *destination-ip* | **interface** *interface-type interface-number* | **source** *source-ip*] * [**slot** *slot-number*]
Display information about the NetStream data export.	**display ip netstream export**
Display NetStream template information.	**display ip netstream template** [**slot** *slot-number*]
Age out and export all NetStream data, and clear the cache.	**reset ip netstream statistics**

NetStream configuration examples



Example: Configuring NetStream traditional data export

Network configuration

As shown in Figure 3, configure NetStream on the device to collect statistics on packets passing through the device.

- Enable NetStream for incoming and outgoing traffic on GigabitEthernet 1/0/1.
- Configure the device to export NetStream traditional data to UDP port 5000 of the NetStream server.

Figure 3 Network diagram

Procedure

Assign an IP address to each interface, as shown in Figure 3. (Details not shown.)

Enable NetStream for incoming and outgoing traffic on GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
```

```
[Device-GigabitEthernet1/0/1] ip netstream inbound
[Device-GigabitEthernet1/0/1] ip netstream outbound
[Device-GigabitEthernet1/0/1] quit
```

Specify 12.110.2.2 as the IP address of the destination host and UDP port 5000 as the export destination port number.

```
[Device] ip netstream export host 12.110.2.2 5000
```

Verifying the configuration

Display NetStream entry information.

```
[Device] display ip netstream cache

```

Example: Configuring NetStream aggregation data export

Network configuration

As shown in Figure 4, all routers in the network are running EBGP. Configure NetStream on the device to meet the following requirements:

- Use version 5 format to export NetStream traditional data to port 5000 of the NetStream server.
- Perform NetStream aggregation in the modes of protocol-port, source-prefix, destination-prefix, and prefix.
- Export the aggregation data of different modes to 4.1.1.1, with UDP ports 3000, 4000, 6000, and 7000.

Figure 4 Network diagram

Procedure

Assign an IP address to each interface, as shown in Figure 4. (Details not shown.)

Specify version 5 format to export NetStream traditional data and record the original AS numbers for the flow source and destination.

```
<Device> system-view
[Device] ip netstream export version 5 origin-as
```

Enable NetStream for incoming and outgoing traffic on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ip netstream inbound
[Device-GigabitEthernet1/0/1] ip netstream outbound
[Device-GigabitEthernet1/0/1] quit
```

Specify 4.1.1.1 as the IP address of the destination host and UDP port 5000 as the export destination port number.

```
[Device] ip netstream export host 4.1.1.1 5000
```

Set the aggregation mode to protocol-port, and specify the destination host for the aggregation data export.

```
[Device] ip netstream aggregation protocol-port
```

```
[Device-ns-aggregation-protport] enable
[Device-ns-aggregation-protport] ip netstream export host 4.1.1.1 3000
[Device-ns-aggregation-protport] quit
```

Set the aggregation mode to source-prefix, and specify the destination host for the aggregation data export.

```
[Device] ip netstream aggregation source-prefix
[Device-ns-aggregation-srcpre] enable
[Device-ns-aggregation-srcpre] ip netstream export host 4.1.1.1 4000
[Device-ns-aggregation-srcpre] quit
```

Set the aggregation mode to destination-prefix, and specify the destination host for the aggregation data export.

```
[Device] ip netstream aggregation destination-prefix
[Device-ns-aggregation-dstpre] enable
[Device-ns-aggregation-dstpre] ip netstream export host 4.1.1.1 6000
[Device-ns-aggregation-dstpre] quit
```

Set the aggregation mode to prefix, and specify the destination host for the aggregation data export.

```
[Device] ip netstream aggregation prefix
[Device-ns-aggregation-prefix] enable
[Device-ns-aggregation-prefix] ip netstream export host 4.1.1.1 7000
[Device-ns-aggregation-prefix] quit
```

Verifying the configuration

Display information about the NetStream data export.

```
[Device] display ip netstream export
protocol-port aggregation export information:
  Flow source interface                          : Not specified
  Flow destination VPN instance                  : Not specified
  Flow destination IP address (UDP)              : 4.1.1.1 (3000)
  Version 8 exported flow number                 : 2
  Version 8 exported UDP datagram number (failed) : 2 (0)
  Version 9 exported flow number                 : 0
  Version 9 exported UDP datagram number (failed) : 0 (0)
  Version 10 exported flow number                : 0
  Version 10 exported UDP datagram number (failed): 0 (0)

source-prefix aggregation export information:
  Flow source interface                          : Not specified
  Flow destination VPN instance                  : Not specified
  Flow destination IP address (UDP)              : 4.1.1.1 (4000)
  Version 8 exported flow number                 : 2
  Version 8 exported UDP datagram number (failed) : 2 (0)
  Version 9 exported flow number                 : 0

```

Configuring session-based NetStream

About session-based NetStream

Session-based NetStream provides statistics for session-based services and exports the statistics in NetStream version 9 format to NetStream servers.

Session-based NetStream aggregation modes

Session-based NetStream aggregates session statistics according to the aggregation criteria of an aggregation mode and exports the statistics to NetStream servers.

The system merges statistics for multiple sessions if each aggregation criterion is of the same value. The system supports only the session aggregating mode in the current software version.

Table 2 Session-based NetStream aggregation mode

Aggregation mode	Aggregation criteria
Session aggregation	• Source MAC address. • Destination MAC address. • Source IP address. • Destination IP address. • Source port number. • Destination port number. • Protocol type.

Session-based NetStream data export

Session-based NetStream uses an aging mechanism to export session statistics to NetStream servers.

Upon receiving a session packet, the device creates a NetStream entry for the session and collects data for the session. The NetStream data for the session is cleared and exported to the NetStream servers when either of the following conditions is met:

- The aging timer of the inactive session expires. The session is inactive if no packet of the session arrives within its aging timer.
- The aging timer of the NetStream entry expires.

If the NetStream cache has insufficient storage space but none of the above conditions is met, the device stops generating NetStream entries for new sessions. Statistics collection for existing sessions continues.

Restrictions: Hardware compatibility with session-based NetStream

This feature is supported only by the S5200-HI-G switch series.

Configuring session-based NetStream settings

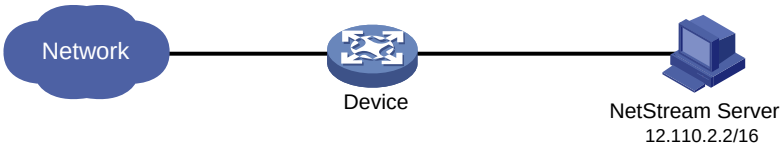
1. Enter system view.
   system-view
2. Enable session-based NetStream.
   session-based netstream enable
   By default, session-based NetStream is disabled.
3. (Optional.) Set the aging timer for session-based NetStream entries.
   session-based netstream timeout *minutes*
   By default, the aging timer for session-based NetStream entries is 5 minutes.
4. Specify a destination host for session-based NetStream data export.
   session-based netstream export host *ip-address udp-port* [**vpn-instance** *vpn-instance-name*]
   By default, no destination host is specified for session-based NetStream data export.
5. (Optional.) Specify a source IP address for session-based NetStream packets.
   session-based netstream export source ip *ip-address*
   By default, the source IP address of session-based NetStream packets is the primary IP address of the output interface.

Display and maintenance commands for session-based NetStream

Execute **display** commands in any view.

Task	Command
Display session-based NetStream statistics in the cache.	**display session-based netstream aggregation-cache session** [**slot** *slot-number*]

Session-based NetStream configuration examples



Example: Configuring session-based NetStream data export

Network configuration

As shown in Figure 5:

1. Enable session-based NetStream in application aggregation mode on the device.
2. Configure the device to export the NetStream statistics to UDP port 5000 on the NetStream server.

Figure 5 Network diagram

Procedure

1. Enable session-based NetStream.

```
<Device> system-view
[Device] session-based netstream enable
```

2. Specify 12.110.2.2 as the IP address of the destination host and UDP port 5000 as the export destination port number.

```
[Device] session-based netstream export host 12.110.2.2 5000
```

Verifying the configuration

Display session-based NetStream statistics in session aggregation mode.

```
<Device> display session-based netstream aggregation-cache session
Active entries                                          :1
Timeout time for session-based NetStream entries        :5
Session-timeout time for session-based NetStream entries :400

SrcMAC          DstMAC          SrcIP          DstIP         SrcPort   DstPort
InPkts          InBytes         OutPkts        OutBytes      Pro       LogType
0001-0001-0001  0002-0002-0002  192.168.1.1    192.168.2.1   4000      5000
4               240             4              240           6         0x1
```

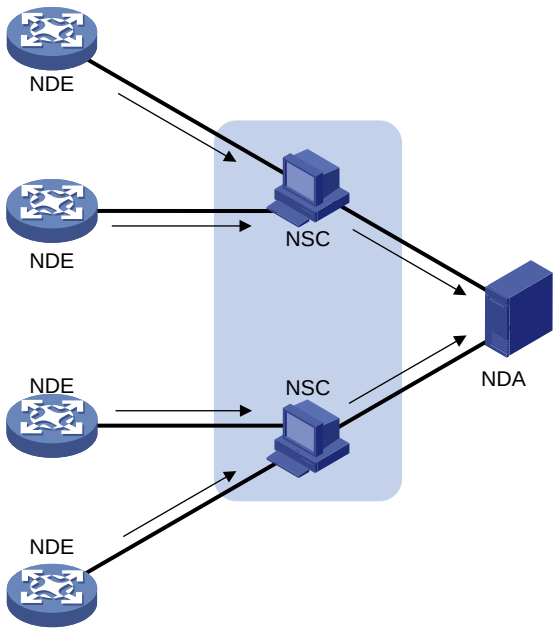
Configuring IPv6 NetStream

About IPv6 NetStream

IPv6 NetStream is an accounting technology that provides statistics on a per-flow basis. An IPv6 flow is defined by the following 8-tuple elements:

- Destination IPv6 address.
- Source IPv6 address.
- Destination port number.
- Source port number.
- Protocol number.
- Traffic class.
- Flow label.
- Input or output interface.



IPv6 NetStream architecture

A typical IPv6 NetStream system includes the following elements:

- **NetStream data exporter**—A device configured with IPv6 NetStream. The NDE provides the following functions:
  - Classifies traffic flows by using the 8-tuple elements.
  - Collects data from the classified flows.
  - Aggregates the data.
  - Exports the data to the NSC.
- **NetStream collector**—A program running in a Unix or Windows operating system. The NSC parses the packets received from the NDEs, and saves the data to its database.
- **NetStream data analyzer**—A network traffic analyzing tool. Based on the data in NSC, the NDA generates reports for traffic billing, network planning, and attack detection and monitoring. The NDA can collect data from multiple NSCs. Typically, the NDA features a Web-based system for easy operation.

NSC and NDA are typically integrated into a NetStream server.

Figure 1 IPv6 NetStream system

IPv6 NetStream flow aging

IPv6 NetStream uses flow aging to enable the NDE to export IPv6 NetStream data to NetStream servers. IPv6 NetStream creates an IPv6 NetStream entry for each flow for storing the flow statistics in the cache.

When a flow is aged out, the NDE performs the following operations:

- Exports the summarized data to NetStream servers in a specific format.
- Clears IPv6 NetStream entry information in the cache.

IPv6 NetStream supports the following flow aging methods:

- Periodical aging.
- Forced aging.

Periodical aging

Periodical aging uses the following methods:

- **Inactive flow aging**—A flow is inactive if no packet arrives for the IPv6 NetStream entry within the inactive flow aging timer. When the timer expires, the following events occur:
  - The inactive flow entry is aged out.
  - The statistics of the flow are sent to NetStream servers and are cleared in the cache. The statistics can no longer be displayed by using the **`display ipv6 netstream cache`** command.

  This method ensures that inactive flow entries are cleared from the cache in a timely manner so new entries can be cached.
- **Active flow aging**—A flow is active if packets arrive for the IPv6 NetStream entry within the active flow aging timer. When the timer expires, the statistics of the active flow are exported to NetStream servers. The device continues to collect its statistics, which can be displayed by using the **`display ipv6 netstream cache`** command.

  The active flow aging method periodically exports the statistics of active flows to NetStream servers.

Forced aging

To implement forced aging, execute the **reset ipv6 netstream statistics** command to clear the IPv6 NetStream cache immediately and export the cached entries to NetStream servers.

IPv6 NetStream data export

Traditional data export

IPv6 NetStream collects the statistics of each flow and exports the statistics to NetStream servers.

This method consumes a lot of bandwidth and CPU usage, and requires a large cache size. In addition, you do not need all of the data in most cases.

Aggregation data export

An IPv6 NetStream aggregation mode merges the flow statistics according to the aggregation criteria of the aggregation mode, and it sends the summarized data to NetStream servers. The IPv6 NetStream aggregation data export uses less bandwidth than the traditional data export.

Table 1 lists the available IPv6 NetStream aggregation modes. In each mode, the system merges multiple flows with the same values for all aggregation criteria into one aggregate flow. The system records the statistics for the aggregate flow. These aggregation modes work independently and can take effect concurrently.

Table 1 IPv6 NetStream aggregation modes

Aggregation mode	Aggregation criteria
AS aggregation	• Source AS number • Destination AS number • Input interface index • Output interface index
Protocol-port aggregation	• Protocol number • Source port • Destination port
Source-prefix aggregation	• Source AS number • Source mask • Source prefix (source network address) • Input interface index
Destination-prefix aggregation	• Destination AS number • Destination mask • Destination prefix (destination network address) • Output interface index
Source-prefix and destination-prefix aggregation	• Source AS number • Source mask • Source prefix (source network address) • Input interface index • Destination AS number • Destination mask • Destination prefix (destination network address) • Output interface index
BGP-nexthop	• BGP next hop • Output interface index

If IPv6 packets are not forwarded according to the BGP routing table, the AS number or BGP next hop cannot be obtained.

IPv6 NetStream data export format

IPv6 NetStream exports data in the version 9 or version 10 format.

Both formats are template-based and support exporting the IPv6 NetStream aggregation data and collecting statistics about BGP next hop.

The version 10 export format is compliant with the IPFIX standard.

IPv6 NetStream filtering

IPv6 NetStream filtering uses an ACL to identify packets. Whether IPv6 NetStream collects data for identified packets depends on the action in the matching rule.

- IPv6 NetStream collects data for packets that match permit rules in the ACL.
- IPv6 NetStream does not collect data for packets that match deny rules in the ACL.

For more information about ACLs, see *ACL and QoS Configuration Guide*.

IPv6 NetStream sampling

IPv6 NetStream sampling collects statistics on fewer packets and is useful when the network has a large amount of traffic. IPv6 NetStream on sampled traffic lessens the impact on the device's performance. For more information about sampling, see "Configuring samplers."

Protocols and standards

RFC 5101, *Specification of the IP Flow Information Export (IPFIX) Protocol for the Exchange of IP Traffic Flow Information*

Restrictions: Hardware compatibility with IPv6 NetStream

IPv6 NetStream is available only on the S5200-HI-G switch series.

Restrictions and guidelines: IPv6 NetStream configuration

If the following features (listed in descending order of priority) are configured, only the feature with the highest priority takes effect:

- NetAnalysis for UDP traffic.
- NetAnalysis unified flow analytics.
- FGLB adaptive routing.
- IPv4 NetStream and IPv6 NetStream.
- MOD and flow group in delay monitoring mode.

For more information about NetAnalysis for UDP traffic and NetAnalysis unified flow analytics, see "Configuring NetAnalysis." For more information about FGLB adaptive routing, see adaptive routing in *Layer 3—IP Routing Configuration Guide*. For more information about MOD and flow groups, see MOD configuration and flow group configuration in *Telemetry Configuration Guide*.

IPv6 NetStream tasks at a glance

To configure IPv6 NetStream, perform the following tasks:

1. Enabling IPv6 NetStream
2. (Optional.) Configuring IPv6 NetStream sampling
3. (Optional.) Configuring the IPv6 NetStream data export format
4. (Optional.) Configuring the refresh rate for IPv6 NetStream version 9 or version 10 template
5. (Optional.) Configuring IPv6 NetStream flow aging
   - Configuring periodical flow aging
6. Configuring the IPv6 NetStream data export
   a. Configuring the IPv6 NetStream traditional data export
   b. (Optional.) Configuring the IPv6 NetStream aggregation data export
7. (Optional.) Enabling SNMP notifications for IPv6 NetStream

Enabling IPv6 NetStream

Enabling IPv6 NetStream on an interface

Restrictions and guidelines

Interface-specific IPv6 NetStream configuration and interface-specific IPv6 NetStream filtering are mutually exclusive. Do not use them simultaneously.

This feature is available only on Layer 2 and Layer 3 Ethernet interfaces. It is not available on Layer 3 Ethernet subinterfaces and other types of interfaces.

Procedure

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
3. Enable IPv6 NetStream on the interface.
   `ipv6 netstream` { **`inbound`** | **`outbound`** }
   By default, IPv6 NetStream is disabled on an interface.

Configuring IPv6 NetStream filtering

About this task

Perform this task to enable IPv6 NetStream on an interface and to collect traffic statistics about traffic matching an ACL.

IPv6 NetStream filtering uses an ACL to identify packets.

- To enable IPv6 NetStream to collect statistics for specific flows, use the ACL permit statements to identify these flows.
- To disable IPv6 NetStream from collecting statistics for specific flows, use the ACL deny statements to identify these flows.

Restrictions and guidelines

If IPv6 NetStream filtering and sampling are both configured, IPv6 packets are filtered first, and then the permitted packets are sampled.

Interface-specific IPv6 NetStream configuration and interface-specific IPv6 NetStream filtering are mutually exclusive. Do not use them simultaneously.

This feature is available only on Layer 2 and Layer 3 Ethernet interfaces. It is not available on Layer 3 Ethernet subinterfaces and other types of interfaces.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure IPv6 NetStream filtering on the interface.
   ipv6 netstream { **inbound** | **outbound** } **filter acl** *acl-number*

   By default, IPv6 NetStream filtering is disabled. IPv6 NetStream collects statistics of all IPv6 packets passing through the interface.

Configuring IPv6 NetStream sampling

Restrictions and guidelines

By default, IPv6 NetStream collects all data of target flows. If the flow traffic is heavy, IPv6 NetStream is resource-consuming and can cause high CPU usage, which impacts the device forwarding performance. IPv6 NetStream sampling is helpful to decrease the IPv6 NetStream traffic volume. If the collected statistics can basically reflect the network status, you can enable this feature and set a proper sampling rate. The higher the sampling rate, the less impact on device performance.

If IPv6 NetStream sampling and filtering are both configured, IPv6 packets are filtered first, and then the permitted packets are sampled.

This feature is available only on Layer 2 and Layer 3 Ethernet interfaces. It is not available on Layer 3 Ethernet subinterfaces and other types of interfaces.

Procedure

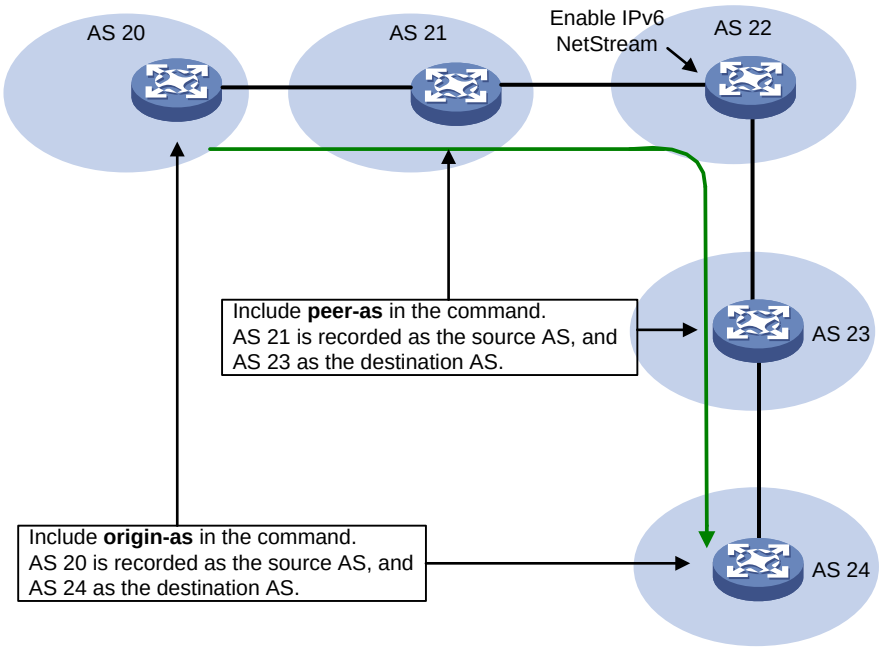
1. Enter system view.
   system-view
2. Create a sampler.
   sampler *sampler-name* **mode random packet-interval n-power** *rate*

   For more information about samplers, see "Configuring samplers."
3. Enter interface view.
   interface *interface-type interface-number*
4. Configure IPv6 NetStream sampling.
   ipv6 netstream { **inbound** | **outbound** } **sampler** *sampler-name*

   By default, IPv6 NetStream sampling is disabled.

Configuring the IPv6 NetStream data export format

About this task



When you configure the IPv6 NetStream data export format, you can also specify the following settings:

- Whether or not to export the BGP next hop and serial number information.
- How to export the autonomous system (AS) information: **origin-as** or **peer-as**.
  - **origin-as**—Records the original AS numbers for the flow source and destination.
  - **peer-as**—Records the peer AS numbers for the flow source and destination.

For example, as shown in Figure 2, a flow starts at AS 20, passes AS 21 through AS 23, and then reaches AS 24. IPv6 NetStream is enabled on the device in AS 22.

- Specify the **origin-as** keyword to export AS 20 as the source AS and AS 24 as the destination AS.
- Specify the **peer-as** keyword to export AS 21 as the source AS and AS 23 as the destination AS.

Figure 2 Recorded AS information varies by different keyword configurations

Procedure

1. Enter system view.

   system-view

2. Configure the IPv6 NetStream data export format, and configure the AS, BGP next hop, and serial number export attributes.
   - Configure the version 9 format.

     ipv6 netstream export version 9 { **origin-as** | **peer-as** } [**bgp-nexthop**] [**serial-number**]
   - Configure the version 10 format.

ipv6 netstream export version 10 [**origin-as** | **peer-as**] [**bgp-nexthop**] [**serial-number**]

By default:

- The version 9 format is used to export IPv6 NetStream data.
- The peer AS numbers for the flow source and destination are exported.
- The BGP next hop and serial number information is not exported.

Configuring the refresh rate for IPv6 NetStream version 9 or version 10 template

About this task

Version 9 and version 10 are template-based and support user-defined formats. An IPv6 NetStream device must send the updated template to NetStream servers regularly, because the servers do not permanently save templates.

For a NetStream server to use the correct version 9 or version 10 template, configure the time-based or packet count-based refresh rate. If both settings are configured, the template is sent when either of the conditions is met.

Procedure

1. Enter system view.

   system-view

2. Configure the refresh rate for the IPv6 NetStream version 9 or version 10 template.

   ipv6 netstream export template refresh-rate { **packet** *packets* | **time** *minutes* }

   By default, the packet count-based refresh rate is 20 packets, and the time-based refresh interval is 30 minutes.

Configuring IPv6 NetStream flow aging

Configuring periodical flow aging

1. Enter system view.

   system-view

2. Set the aging timer for active flows.

   ipv6 netstream timeout active *minutes*

   By default, the aging timer for active flows is 5 minutes.

3. Set the aging timer for inactive flows.

   ipv6 netstream timeout inactive *seconds*

   By default, the aging timer for inactive flows is 300 seconds.

Configuring the IPv6 NetStream data export

Configuring the IPv6 NetStream traditional data export

1. Enter system view.

system-view

2. Specify a destination host for IPv6 NetStream traditional data export.

   ipv6 netstream export host { *ipv4-address* | *ipv6-address* } *udp-port* [**vpn-instance** *vpn-instance-name*]

   By default, no destination host is specified.

3. (Optional.) Specify the source interface for IPv6 NetStream data packets sent to the NetStream servers.

   ipv6 netstream export source interface *interface-type interface-number*

   By default, no source interface is specified for IPv6 NetStream data packets. The packets take the IPv6 address of the output interface (interface that is connected to the NetStream server) as the source IPv6 address.

   As a best practice, connect the management Ethernet interface to a NetStream server, and configure the interface as the source interface.

4. (Optional.) Limit the IPv6 NetStream data export rate.

   ipv6 netstream export rate *rate*

   By default, the data export rate is not limited.

Configuring the IPv6 NetStream aggregation data export

About this task

IPv6 NetStream aggregation is implemented by software.

Restrictions and guidelines

Configurations in IPv6 NetStream aggregation mode view apply only to the IPv6 NetStream aggregation data export. Configurations in system view apply to the IPv6 NetStream traditional data export. When no configuration in IPv6 NetStream aggregation mode view is provided, the configurations in system view apply to the IPv6 NetStream aggregation data export.

Procedure

1. Enter system view.

   system-view

2. Specify an IPv6 NetStream aggregation mode and enter its view.

   ipv6 netstream aggregation { **as** | **bgp-nexthop** | **destination-prefix** | **prefix** | **protocol-port** | **source-prefix** }

   By default, no IPv6 NetStream aggregation mode is specified.

3. Enable the IPv6 NetStream aggregation mode.

   enable

   By default, the IPv6 NetStream aggregation is disabled.

4. Specify a destination host for IPv6 NetStream aggregation data export.

   ipv6 netstream export host { *ipv4-address* | *ipv6-address* } *udp-port* [**vpn-instance** *vpn-instance-name*]

   By default, no destination host is specified.

   If you expect only IPv6 NetStream aggregation data, specify the destination host only in the related IPv6 NetStream aggregation mode view.

5. (Optional.) Specify the source interface for IPv6 NetStream data packets sent to the NetStream servers.

   ipv6 netstream export source interface *interface-type interface-number*

By default, no source interface is specified for IPv6 NetStream data packets. The packets take the IPv6 address of the output interface as the source IPv6 address.

You can configure different source interfaces in different IPv6 NetStream aggregation mode views.

If no source interface is configured in IPv6 NetStream aggregation mode view, the source interface configured in system view applies.

Enabling SNMP notifications for IPv6 NetStream

About this task

Use this feature to report important events for IPv6 NetStream through SNMP notifications. The generated alarm information will be sent to the SNMP module on the device and you can configure the SNMP notification sending parameters to determine the export attributes of the alarm information. For more information, see "Configuring SNMP."

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for IPv6 NetStream.

   snmp-agent trap enable ipv6 netstream [**entry-limit**]

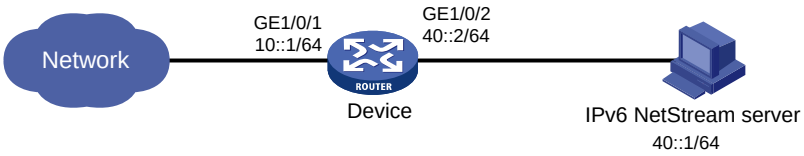
   By default, SNMP notifications are enabled for IPv6 NetStream.

Display and maintenance commands for IPv6 NetStream

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display IPv6 NetStream entry information.	**display ipv6 netstream cache** [**verbose**] [**type** { **ip** | **ipl2** | **l2** }] [**destination** *destination-ipv6* | **interface** *interface-type interface-number* | **source** *source-ipv6*] * [**slot** *slot-number*]
Display information about the IPv6 NetStream data export.	**display ipv6 netstream export**
Display IPv6 NetStream template information.	**display ipv6 netstream template** [**slot** *slot-number*]
Age out, export all IPv6 NetStream data, and clear the cache.	**reset ipv6 netstream statistics**

IPv6 NetStream configuration examples



Example: Configuring IPv6 NetStream traditional data export

Network configuration

As shown in Figure 3, configure IPv6 NetStream on the device to collect statistics on packets passing through the device.

- Enable IPv6 NetStream for incoming and outgoing traffic on GigabitEthernet 1/0/1.
- Configure the device to export the IPv6 NetStream traditional data to UDP port 5000 of the NetStream server.

Figure 3 Network diagram

Procedure

Assign an IP address to each interface, as shown in Figure 3. (Details not shown.)

Enable IPv6 NetStream for incoming and outgoing traffic on GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ipv6 netstream inbound
[Device-GigabitEthernet1/0/1] ipv6 netstream outbound
[Device-GigabitEthernet1/0/1] quit
```

Specify 40::1 as the IP address of the destination host and UDP port 5000 as the export destination port number.

```
[Device] ipv6 netstream export host 40::1 5000
```

Verifying the configuration

Display information about IPv6 NetStream entries.

```
<Device> display ipv6 netstream cache
IPv6 NetStream cache information:
  Active flow timeout             : 5 min
  Inactive flow timeout           : 300 sec
  Max number of entries           : 16384
  IPv6 active flow entries        : 2
  MPLS active flow entries        : 0
  IPL2 active flow entries        : 0
  IPv6 flow entries counted       : 10
  MPLS flow entries counted       : 0
  IPL2 flow entries counted       : 0
  Last statistics resetting time  : 01/01/2019 at 00:01:02

IPv6 packet size distribution (1103746 packets in total):
1-32   64   96  128  160  192  224  256  288  320  352  384  416  448  480
.249 .694 .000 .000 .000 .000 .000 .000 .000 .000 .000 .000 .000 .000 .000

Example: Configuring IPv6 NetStream aggregation data export

Network configuration

As shown in Figure 4, all routers in the network are running IPv6 EBGP. Configure IPv6 NetStream on the device to meet the following requirements:

- Export the IPv6 NetStream traditional data to port 5000 of the NetStream server.
- Perform the IPv6 NetStream aggregation in the modes of protocol-port, source-prefix, destination-prefix, and prefix.
- Export the aggregation data of different modes to the UDP ports 3000, 4000, 6000, and 7000.

Figure 4 Network diagram

Procedure

Assign an IP address to each interface, as shown in Figure 4. (Details not shown.)

Enable IPv6 NetStream for incoming and outgoing traffic on GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ipv6 netstream inbound
[Device-GigabitEthernet1/0/1] ipv6 netstream outbound
[Device-GigabitEthernet1/0/1] quit
```

Specify 40::1 as the IP address of the destination host and UDP port 5000 as the export destination port number.

```
[Device] ipv6 netstream export host 40::1 5000
```

Set the aggregation mode to protocol-port, and specify the destination host for the aggregation data export.

```
[Device] ipv6 netstream aggregation protocol-port
[Device-ns6-aggregation-protport] enable
[Device-ns6-aggregation-protport] ipv6 netstream export host 40::1 3000
[Device-ns6-aggregation-protport] quit
```

Set the aggregation mode to source-prefix, and specify the destination host for the aggregation data export.

```
[Device] ipv6 netstream aggregation source-prefix
[Device-ns6-aggregation-srcpre] enable
[Device-ns6-aggregation-srcpre] ipv6 netstream export host 40::1 4000
[Device-ns6-aggregation-srcpre] quit
```

Set the aggregation mode to destination-prefix, and specify the destination host for the aggregation data export.

```
[Device] ipv6 netstream aggregation destination-prefix
[Device-ns6-aggregation-dstpre] enable
[Device-ns6-aggregation-dstpre] ipv6 netstream export host 40::1 6000
[Device-ns6-aggregation-dstpre] quit
```

Set the aggregation mode to prefix, and specify the destination host for the aggregation data export.

```
[Device] ipv6 netstream aggregation prefix
[Device-ns6-aggregation-prefix] enable
[Device-ns6-aggregation-prefix] ipv6 netstream export host 40::1 7000
[Device-ns6-aggregation-prefix] quit
```

Verifying the configuration

Display information about the IPv6 NetStream data export.

```
[Device] display ipv6 netstream export
protocol-port aggregation export information:
  Flow source interface                          : Not specified
  Flow destination VPN instance                  : Not specified
  Flow destination IP address (UDP)              : 40::1 (3000)
  Version 9 exported flow number                 : 0
  Version 9 exported UDP datagram number (failed) : 0 (0)
  Version 10 exported flow number                : 0
  Version 10 exported UDP datagram number (failed): 0 (0)

source-prefix aggregation export information:
  Flow source interface                          : Not specified
  Flow destination VPN instance                  : Not specified

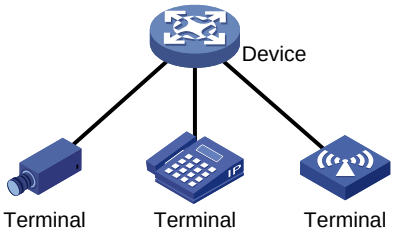
Configuring EPA

About EPA



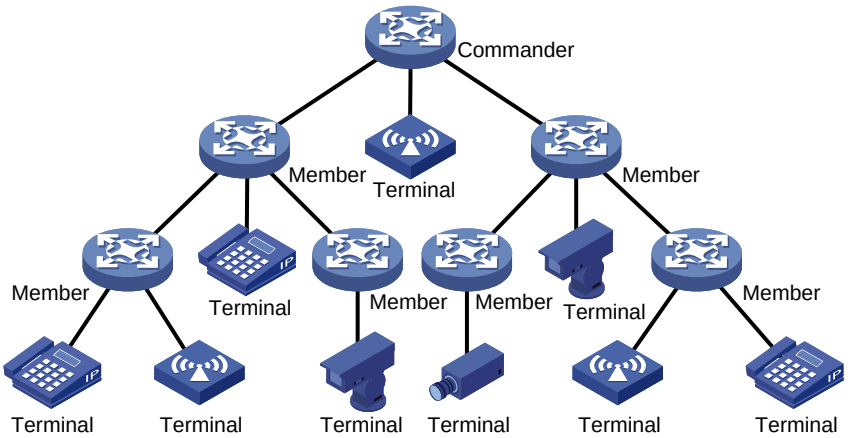
Endpoint Analysis (EPA) allows you to monitor associations and disassociations of endpoints (for example, cameras and IP phones) connecting to an H3C device.

Application scenarios

Non-SmartMC networking

As shown in Figure 1, the device configured with EPA monitors associations and disassociations of endpoints connecting to it. The device can be a standalone device or an IRF fabric. For an IRF fabric, EPA monitors endpoints connecting to all members. The collected association and disassociation information will be reported to the master device for processing.

Figure 1 Non-SmartMC networking



SmartMC networking

In a SmartMC network as shown in Figure 2, EPA settings are configured only on the commander. The members report association and disassociation information about their associated endpoints to the commander. The commander records such information about all associated endpoints in the network, and deploys EPA settings to the members.

You can view EPA information in the entire network on the commander.

Figure 2 SmartMC networking

Endpoint identification methods

EPA supports static endpoint identification. This method identifies associations and disassociations of endpoints by matching MAC addresses of the endpoints. This method requires manual configuration of endpoint MAC addresses on the device and is applicable to networks with a small number of endpoints. This method can only identify cameras and cannot identify the vendor and operating system of cameras.

Static endpoint identification

EPA monitors endpoint associations and disassociations by monitoring the generation and aging of MAC address entries learned by devices. A device configured with EPA can monitor only endpoints in the same subnet as the endpoint access port on the device.

For more information about MAC address entries, see *Layer 2—LAN Switching Configuration Guide*.

Collecting endpoint association information

If a device configured with EPA learns a new MAC address entry, it compares the MAC address and VLAN ID with the configured EPA monitor rules.

- If a match is found, the device determines that a monitored endpoint came online.
  - In a non-SmartMC network, the device records the endpoint association event locally.
  - In a SmartMC network, if the device is the commander, it records the endpoint association event locally. If the device is a member, it reports the event to the commander.
- If no match is found, the device determines that the endpoint is not a monitored endpoint and does not record the endpoint association event.

Collecting endpoint disassociation information

When the MAC address entry of an endpoint ages out, the device determines that the endpoint went offline.

- In a non-SmartMC network, the device records the endpoint disassociation event locally for 7 days.
- In a SmartMC network, the commander records the endpoint disassociation event for 7 days.

Synchronizing information in a SmartMC network

In a SmartMC network, endpoint monitor rules are configured on the commander and deployed to all members by the commander. The rules take effect on both the commander and members. If a member detects an association or disassociation event of a monitored endpoint, it reports the event to the commander for statistics collection and analysis.

You can view endpoint associations and disassociations that occurred in the entire network from the commander. For more information about SmartMC, see "Configuring SmartMC."

Restrictions and guidelines: EPA configuration

Do not use the **mac-address dynamic** command to configure dynamic MAC address entries for monitored endpoints. If you do so, the system might fail to identify endpoint association events.

When you configure EPA in a SmartMC network, follow these restrictions and guidelines:

- Make sure all devices in the network support EPA.
- You can configure endpoint monitor rules only on the commander.
- Configure the same aging time for MAC address entries on all devices in the SmartMC network. Otherwise, endpoint association and disassociation analysis on the commander

might be inaccurate. For more information about MAC address entries, see *Layer 2—LAN Switching Configuration Guide*.

- To view endpoint association and disassociation events in a SmartMC network, execute the **display epa monitor-information** command on the commander instead of a member. If you execute the command on a member, the command displays only association events of endpoints connecting to the member.

Configuring static endpoint identification

Restrictions and guidelines

When you configure static endpoint identification rules, follow these restrictions and guidelines:

- To configure multiple rules to monitor an endpoint in different VLANs, make sure the specified VLAN ranges in these rules do not overlap with each other.
- As a best practice to ensure the optimal EPA performance, specify the VLANs in which an endpoint will be monitored.
- If you configure a rule to monitor an endpoint in all VLANs, make sure the endpoint will not come online from over 10 VLANs.
- You can configure a maximum of 1024 monitor rules. As a best practice to ensure the optimal EPA performance, do not configure over 512 monitor rules.
- You can specify a rule ID when creating a monitor rule. If you do not specify the ID, the system assigns the smallest available ID to the rule.
- You cannot execute the **epa monitor-rule** command multiple times to edit an existing rule. To edit an existing rule, use the **undo epa monitor-rule** command to delete the rule and then create the rule again.

Procedure

1. Enter system view.

   system-view

2. Create a static endpoint identification rule.

   epa monitor-rule [*monitor-rule-id*] **mac** *mac-address* [**mask** *mac-mask*] [**vlan** *vlan-id*]

   By default, no static endpoint identification rules exist.

Disabling EPA logging

About this task

By default, the EPA module logs endpoint associations and disassociations. If a monitored endpoint comes online or goes offline frequently, the device will generate a large number of log entries. In this case, to avoid affecting device performance, disable EPA logging as a best practice.

Procedure

1. Enter system view.

   system-view

2. Disable EPA logging.

   epa online-offline-log disable

   By default, EPA logging is enabled.

Display and maintenance commands for EPA

Execute **display** commands in any view.

Task	Command
Display endpoint association and disassociation information detected by EPA.	**display epa monitor-information** [**online** | **offline**] [**device** *device-id* | **mac** *mac-address* [**vlan** *vlan-id*]] [**verbose**]

EPA configuration examples

Example: Configuring static endpoint identification

Network configuration

As shown in Figure 3, the SmartMC network is established manually. Configure the devices in SmartMC network so EPA can automatically identify camera 1 and camera 2 when they access the SmartMC network.

Figure 3 Network diagram

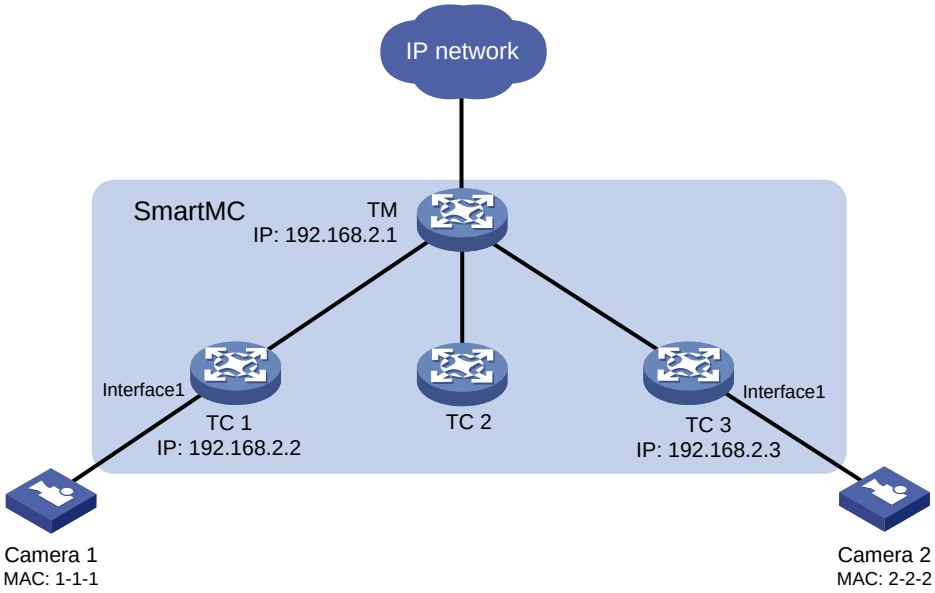


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Configuring the TM

1. Configure SmartMC:

   # Configure VLAN-interface 1.

   ```
   [TM] interface vlan-interface 1
   [TM-Vlan-interface1] ip address 192.168.2.2 24
   ```

```
[TM-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TM] ip http enable
[TM] ip https enable
```

Enable the Telnet service.

```
[TM] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TM] netconf soap http enable
```

Enable SSH-based NETCONF over SSH.

```
[TM] netconf ssh server enable
```

Enable LLDP globally.

```
[TM] lldp global enable
```

Create a user. Set the username to **admin** and password to **hello12345**, add the **telnet**, **http**, **https**, and **ssh** service types, and authorize the user to use the **network-admin** user role.

```
[TM] local-user admin
[TM-luser-manage-admin] password simple hello12345
[TM-luser-manage-admin] service-type telnet http https ssh
[TM-luser-manage-admin] authorization-attribute user-role network-admin
[TM-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TM] line vty 0 63
[TM-line-vty0-63] authentication-mode scheme
[TM-line-vty0-63] quit
```

Enable SmartMC, set the device role to commander, and set the username to **admin** and the password (plaintext) to **hello12345**.

```
[TM] smartmc tm username admin password simple hello12345 enable
```

2. Configure static endpoint identification rules on the commander.

```
[TM] epa monitor-rule mac 1-1-1
[TM] epa monitor-rule mac 2-2-2
```

Configuring TC 1

1. Configure SmartMC:

Configure VLAN-interface 1.

```
<TC1> system-view
[TC1] interface vlan-interface 1
[TC1-Vlan-interface1] ip address 192.168.2.1 24
[TC1-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TC1] ip http enable
[TC1] ip https enable
```

Enable the Telnet service.

```
[TC1] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TC1] netconf soap http enable
```

Enable SSH-based NETCONF over SSH.

```
[TC1] netconf ssh server enable
```

Enable LLDP globally.

```
[TC1] lldp global enable
```

Create a user named **admin**.

```
[TC1] local-user admin
```

Lower password complexity requirements. For more information about these commands, see password control commands in *Security Command Reference*.

```
[TC1-luser-manage-admin] password-control length 4
[TC1-luser-manage-admin] password-control composition type-number 1 type-length 1
[TC1-luser-manage-admin] undo password-control complexity user-name check
```

Set the username and password to **admin**, add the **telnet**, **http**, **https**, and **ssh** service types, and authorize the user to use the **network-admin** user role.

```
[TC1-luser-manage-admin] password simple admin
[TC1-luser-manage-admin] service-type telnet http https ssh
[TC1-luser-manage-admin] authorization-attribute user-role network-admin
[TC1-luser-manage-admin] quit
```

Configure the admin user to support public key authentication when logging in through SSH, and specify the public key name as **-smartmc-publickey-**.

```
[TC1] ssh user admin service-type netconf authentication-type publickey assign
publickey -smartmc-publickey-
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TC1] line vty 0 63
[TC1-line-vty0-63] authentication-mode scheme
[TC1-line-vty0-63] quit
```

Enable SmartMC and set the device role to member.

```
[TC1] smartmc tc enable
```

Configuring TC 3

Configure TC 3 in the same way TC 1 is configured. (Details not shown.)

Verifying the configuration

On TC 1, display the online and offline information of endpoints.

```
[TC1] display epa monitor-information verbose
Auto identification : Disabled
Local device type   : SmartMC TC
Local device ID     : 3acc-58e2-0100
Total endpoints identified by EPA: 1

Access device ID: 3acc-58e2-0100
  MAC address   : 0001-0001-0001           VLAN  : 1
  IP address    : -
  Interface     : GigabitEthernet1/0/1     Status: Online
  Category      : Camera                   Vendor: -
  OS            : -
```

On the TM, display the online and offline information of endpoints.

```
[TM] display epa monitor-information verbose
Auto identification : Disabled
Local device type    : SmartMC TM
Local device ID     : 90bc-1b85-0300
Total endpoints identified by EPA: 2

Access device ID: 3acc-58e2-0100
```

```
  MAC address   : 0001-0001-0001           VLAN  : 1
  IP address    : 192.168.2.11
  Interface     : GigabitEthernet1/0/1     Status: Online
  Category      : Camera                   Vendor: -
  OS            : -

Access device ID: 3acc-58e2-0300
  MAC address   : 0002-0002-0002           VLAN  : 1
  IP address    : 192.168.2.12
  Interface     : GigabitEthernet1/0/1     Status: Online
  Category      : Camera                   Vendor: -
  OS            : -
```

Configuring NETCONF

About NETCONF

Network Configuration Protocol (NETCONF) is an XML-based network management protocol. It provides programmable mechanisms to manage and configure network devices. Through NETCONF, you can configure device parameters, retrieve parameter values, and collect statistics. For a network that has devices from vendors, you can develop a NETCONF-based NMS system to configure and manage devices in a simple and effective way.

NETCONF structure

NETCONF has the following layers: content layer, operations layer, RPC layer, and transport protocol layer.

Table 1 NETCONF layers and XML layers

NETCONF layer	XML layer	Description
Content	Configuration data, status data, and statistics	Contains a set of managed objects, which can be configuration data, status data, and statistics. For information about the operable data, see the NETCONF XML API reference for the device.
Operations	<get>, <get-config>, <edit-config>…	Defines a set of base operations invoked as RPC methods with XML-encoded parameters. NETCONF base operations include data retrieval operations, configuration operations, lock operations, and session operations. For information about operations supported on the device, see "Supported NETCONF operations."
RPC	<rpc> and <rpc-reply>	Provides a simple, transport-independent framing mechanism for encoding RPCs. The <rpc> and <rpc-reply> elements are used to enclose NETCONF requests and responses (data at the operations layer and the content layer).
Transport protocol	In non-FIPS mode: Console, Telnet, SSH, HTTP, HTTPS, and TLS In FIPS mode: Console, SSH, HTTPS, and TLS	Provides reliable, connection-oriented, serial data links. The following transport layer sessions are available in non-FIPS mode: • CLI sessions, including NETCONF over Telnet sessions, NETCONF over SSH sessions, and NETCONF over console sessions. • NETCONF over SOAP sessions, including NETCONF over SOAP over HTTP sessions and NETCONF over SOAP over HTTPS sessions. The following transport layer sessions are available in FIPS mode: • CLI sessions, including NETCONF over SSH sessions and NETCONF over console sessions. • NETCONF over SOAP over HTTPS sessions.

Basic NETCONF concepts

XML

eXtensible Markup Language (XML) is a simple, text-based data storage language. It describes the content and structure of data exchanged between entities on the Internet.

XML is case sensitive.

NETCONF uses XML-based data encoding for the configuration data and protocol messages. NETCONF messages are XML-based and comply with RFC 4741.

Element

Elements are the basic building blocks in an XML document. They act as containers to store various types of content, including text, child elements, and attributes.

An element encloses content in a pair of start and end tags, in <*element-name*>*content*</*element-name*> format. For example, the **capability** element is `<capability>`*content*`</capability>`.

If an element does not have content, that element is called an empty element. You can present an empty element in a self-closing empty tag in <*element-name*/> format, for example, `<ok/>`.

Attribute

Attributes provide meta-level information about an element. They are added in *name=value* format after the element name, within the start tag. For examples, the `xmlns` and `operation` attributes in the following element specify the namespace and operation type, respectively.

```
<Syslog xmlns="http://www.h3c.com/netconf/config:1.0" operation="create">
```

Namespace

A namespace is an abstract container or environment created to hold a logical group of unique identifiers or names. An identifier defined in a namespace is associated only with that namespace. Each data module must have a world-unique namespace to avoid element and attribute naming conflicts.

The device supports the following types of namespaces:

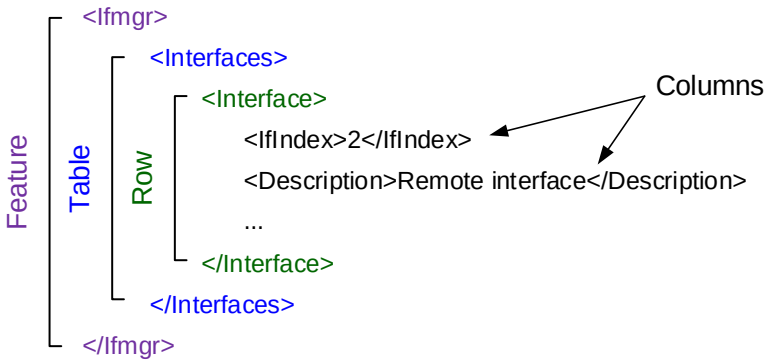
- **urn:ietf:params:xml:ns:netconf:base:1.0 namespace**—This namespace defines all NETCONF elements. All NETCONF messages must declare this namespace in the RPC layer.
- **ietf-netconf namespace**—The **urn:ietf:params:xml:ns:yang:ietf-netconf-monitoring** namespace defined in a NETCONF protocol. NETCONF messages for the <get-schema> and <get><netconf-state/></get> operations must declare this namespace.
- **Common namespace**—A namespace that defines elements across service modules. In a packet that uses a common namespace, the namespace is indicated in the <top> element, and the modules are listed under the <top> element.
- **H3C common namespaces**—The http://www.h3c.com/netconf/*ns*:1.0 namespaces. The *ns* argument represents data, config, and action, which represent the data, configuration, and action namespaces, respectively. The common namespaces are shared by all modules. If used, a common namespace is typically specified for the xmlns attribute in the <top> element, and the modules are listed under the <top> element.

  Example:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <get-bulk>
      <filter type="subtree">
         <top xmlns="http://www.h3c.com/netconf/data:1.0">
            <Ifmgr>
               <Interfaces>
               </Interfaces>
            </Ifmgr>
         </top>
      </filter>
   </get-bulk>
</rpc>
```

- **Module-specific namespaces**—A module has its own namespace to define module-specific elements. A packet that uses a module-specific namespace does not have the <top> element. The namespace follows the module name.

  Example:



```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <get-bulk>
      <filter type="subtree">
            <Ifmgr xmlns="http://www.h3c.com/netconf/data:1.0-Ifmgr">
               <Interfaces>
               </Interfaces>
            </Ifmgr>
      </filter>
   </get-bulk>
</rpc>
```

Node, module, table, row, and column

In H3C NETCONF XML AI references, elements are also called nodes. An element might be a module (or feature), table, row, or column node, as shown in Figure 1.

- **Module**—A feature module defines a hierarchy of related nodes. The element name for a module node is the module name.
- **Table**—A table contains rows and columns, with each row representing an object instance and each column containing a parameter for the instance. A table might also contains subtables.
- **Row**—Each row represents an object instance in the table.
- **Column**—Each column contains a parameter for the instance.

Figure 1 Node, module, table, row, and column in NETCONF messages

In Figure 1, the `Ifmgr` element represents the interface management module (Ifmgr). The `Interfaces` element is a table node in the Ifmgr module and it contains a table of interfaces. The `Interface` element is a row node and it contains data about an interface in the interface table. The `IfIndex` and `Description` elements are column nodes that contain the interface index and description of the interface.

NETCONF message format

NETCONF

An incoming NETCONF message must pass XML schema check before it can be processed. If a NETCONF message fails XML schema check, the device sends an error message to the client.

For information about the NETCONF operations supported by the device and the operable data, see the NETCONF XML API reference for the device.

The following example shows a NETCONF message for getting all parameters of all interfaces on the device:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-bulk>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
                <Interface/>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-bulk>
</rpc>
```

NETCONF over SOAP

All NETCONF over SOAP messages are XML-based and comply with RFC 4741. NETCONF messages are contained in the <Body> element of SOAP messages. NETCONF over SOAP messages also comply with the following rules:

- SOAP messages must use the SOAP Envelope namespaces.
- SOAP messages cannot contain the following information:
  - DTD reference.
  - XML processing instructions.

The following example shows a NETCONF over SOAP message for getting all parameters of all interfaces on the device:

```
<env:Envelope xmlns:env="http://www.w3.org/2003/05/soap-envelope">
  <env:Header>
    <auth:Authentication env:mustUnderstand="1"
xmlns:auth="http://www.h3c.com/netconf/base:1.0">
      <auth:AuthInfo>800207F0120020C</auth:AuthInfo>
    </auth:Authentication>
  </env:Header>
  <env:Body>
    <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <get-bulk>
        <filter type="subtree">
          <top xmlns="http://www.h3c.com/netconf/data:1.0">
            <Ifmgr>
              <Interfaces>
                <Interface/>
              </Interfaces>
            </Ifmgr>
          </top>
        </filter>
      </get-bulk>
    </rpc>
  </env:Body>
```

```
</env:Envelope>
```

How to use NETCONF

You can use NETCONF to manage and configure the device by using the methods in Table 2.

Table 2 NETCONF methods for configuring the device

Configuration tool	Login method	Remarks
CLI	• Console port • SSH • Telnet	To perform NETCONF operations, copy valid NETCONF messages to the CLI in XML view.
Custom user interface	N/A	This method requires a NETCONF over SOAP session or NETCONF over SSH session with the device. To use a NETCONF over SOAP session, you must enable NETCONF over SOAP. Then, NETCONF messages will be encapsulated in SOAP messages for transmission.

Protocols and standards

- RFC 3339, *Date and Time on the Internet: Timestamps*
- RFC 4741, *NETCONF Configuration Protocol*
- RFC 4742, *Using the NETCONF Configuration Protocol over Secure SHell (SSH)*
- RFC 4743, *Using NETCONF over the Simple Object Access Protocol (SOAP)*
- RFC 5277, *NETCONF Event Notifications*
- RFC 5381, *Experience of Implementing NETCONF over SOAP*
- RFC 5539, *NETCONF over Transport Layer Security (TLS)*
- RFC 6241, *Network Configuration Protocol*

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see *Security Configuration Guide*) and non-FIPS mode.

NETCONF tasks at a glance

To configure NETCONF, perform the following tasks:

1. Configuring NETCONF to use module-specific namespaces
2. Establishing a NETCONF session
   a. (Optional.) Setting NETCONF session attributes
   b. Establishing NETCONF over SOAP sessions
   c. Establishing NETCONF over SSH sessions
   d. Establishing NETCONF over Telnet or NETCONF over console sessions
   e. Exchanging capabilities
3. (Optional.) Retrieving device configuration information

- Retrieving device configuration and state information
- Retrieving non-default settings
- Retrieving NETCONF information
- Retrieving YANG file content
- Retrieving NETCONF session information

4. (Optional.) Filtering data
   - Table-based filtering
   - Column-based filtering
5. (Optional.) Locking or unlocking the running configuration
   a. Locking the running configuration
   b. Unlocking the running configuration
6. (Optional.) Modifying the configuration
7. (Optional.) Managing configuration files
   - Saving the running configuration
   - Loading the configuration
   - Rolling back the configuration
8. (Optional.) Managing the candidate configuration
9. (Optional.) Performing CLI operations through NETCONF
10. (Optional.) Subscribing to events
11. (Optional.) Terminating NETCONF sessions
12. (Optional.) Returning to the CLI
13. (Optional.) Enabling SNMP notifications for NETCONF

Configuring NETCONF to use module-specific namespaces

About this task

By default, the device uses the common namespace in the NETCONF responses to the requests for YANG file information. Perform this task to configure the device to use module-specific namespaces in the response messages.

The client performs the <get-schema> and <get><netconf-state/></get> operations to obtain information about YANG files on the device. For more information about the operations, see "Retrieving YANG file content" and "Retrieving NETCONF information."

Restrictions and guidelines

You do not need to perform this task if the client sends a hello message that includes the following capability during capability exchange:

```
<capability>urn:h3c:params:netconf:capability:module-specified-namespace:1.0</capability>
```

Procedure

1. Enter system view.

   `system-view`

2. Configure NETCONF to use module-specific namespaces in messages responding to the client request of retrieving YANG file information.

   `netconf capability specific-namespace`

By default, the common namespace is used in messages responding to the client request of retrieving YANG file information.

Establishing a NETCONF session

Restrictions and guidelines for NETCONF session establishment

After a NETCONF session is established, the device automatically sends its capabilities to the client. You must send the capabilities of the client to the device before you can perform any other NETCONF operations.

Before performing a NETCONF operation, make sure no other users are configuring or managing the device. If multiple users simultaneously configure or manage the device, the result might be different from what you expect.

You can use the **aaa session-limit** command to set the maximum number of NETCONF sessions that the device can support. If the upper limit is reached, new NETCONF users cannot access the device. For information about this command, see AAA in *Security Configuration Guide*.

Setting NETCONF session attributes

About this task

NETCONF supports the following types of namespaces:

- **Common namespace**—The common namespace is shared by all modules. In a packet that uses the common namespace, the namespace is indicated in the <top> element, and the modules are listed under the <top> element.

  Example:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <get-bulk>
      <filter type="subtree">
         <top xmlns="http://www.h3c.com/netconf/data:1.0">
            <Ifmgr>
               <Interfaces>
               </Interfaces>
            </Ifmgr>
         </top>
      </filter>
   </get-bulk>
</rpc>
```

- **Module-specific namespace**—Each module has its own namespace. A packet that uses a module-specific namespace does not have the <top> element. The namespace follows the module name.

  Example:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <get-bulk>
      <filter type="subtree">
            <Ifmgr xmlns="http://www.h3c.com/netconf/data:1.0-Ifmgr">
               <Interfaces>
               </Interfaces>
```

```
            </Ifmgr>
        </filter>
    </get-bulk>
</rpc>
```

The common namespace is incompatible with module-specific namespaces. To set up a NETCONF session, the device and the client must use the same type of namespaces. By default, the common namespace is used. If the client does not support the common namespace, use this feature to configure the device to use module-specific namespaces.

Procedure

1. Enter system view.

   system-view

2. Set the NETCONF session idle timeout time.

   netconf { **agent** | **soap** } **idle-timeout** *minute*

Keyword	Description
agent	Specifies the following sessions: • NETCONF over SSH sessions. • NETCONF over Telnet sessions. • NETCONF over console sessions. By default, the idle timeout time is 0, and the sessions never time out.
soap	Specifies the following sessions: • NETCONF over SOAP over HTTP sessions. • NETCONF over SOAP over HTTPS sessions. The default setting is 10 minutes.

3. Enable NETCONF logging.

   netconf log source { **all** | { **agent** | **soap** | **web** } * } { **protocol-operation** { **all** | { **action** | **config** | **get** | **set** | **session** | **syntax** | **others** } * } | **row-operation** | **verbose** }

   By default, NETCONF logging is disabled.

4. Enable the XML-to-CLI feature for NETCONF logging.

   netconf log xml2cli enable

   The S5200-EI-G switch series does not support this feature.

   By default, the XML-to-CLI feature for NETCONF logging is disabled.

5. Configure NETCONF to use module-specific namespaces.

   netconf capability specific-namespace

   By default, the common namespace is used.

   For the setting to take effect, you must reestablish the NETCONF session.

Establishing NETCONF over SOAP sessions

About this task

You can use a custom user interface to establish a NETCONF over SOAP session to the device and perform NETCONF operations. NETCONF over SOAP encapsulates NETCONF messages into SOAP messages and transmits the SOAP messages over HTTP or HTTPS.

Restrictions and guidelines

You can add an authentication domain to the <UserName> parameter of a SOAP request. The authentication domain takes effect only on the current request.

The mandatory authentication domain configured by using the **netconf soap domain** command takes precedence over the authentication domain specified in the <UserName> parameter of a SOAP request.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Apply an SSL server policy to the NETCONF over SOAP over HTTPS service.

   netconf soap https ssl-server-policy *policy-name*

   By default, no SSL server policy is applied to the NETCONF over SOAP over HTTPS service.

   The NETCONF over SOAP over HTTPS service will use the SSL server policy to enhance service security. For more information about SSL server policies, see SSL configuration in *Security Configuration Guide*.

   If you modify the applied SSL server policy after NETCONF over SOAP over HTTPS is enabled, the changes apply only to the NETCONF over SOAP over HTTPS sessions established subsequently. They do not take effect on the NETCONF over SOAP over HTTPS sessions that have been established before you modify the policy.

3. Enable NETCONF over SOAP.

   In non-FIPS mode:

   netconf soap { **http** | **https** } **enable**

   In FIPS mode:

   netconf soap https enable

   By default, the NETCONF over SOAP feature is disabled.

4. (Optional.) Set the DSCP value for NETCONF over SOAP packets.

   In non-FIPS mode:

   netconf soap { **http** | **https** } **dscp** *dscp-value*

   In FIPS mode:

   netconf soap https dscp *dscp-value*

   By default, the DSCP value is 0 for NETCONF over SOAP packets.

5. (Optional.) Use an IPv4 ACL to control NETCONF over SOAP access. Only clients permitted by the IPv4 ACL can establish NETCONF over SOAP sessions.

   - Apply an ACL to control TCP connections from IPv4 HTTP clients.

     http acl { *advanced-acl-number* | *basic-acl-number* }

     By default, the device permits TCP connections from all IPv4 HTTP clients.

   - Apply an ACL to control TCP connections from IPv4 HTTPS clients.

     https acl { *advanced-acl-number* | *basic-acl-number* }

     By default, the device permits TCP connections from all IPv4 HTTPS clients.

   - Apply an IPv4 ACL to control NETCONF over SOAP access.

     In non-FIPS mode:

     netconf soap { **http** | **https** } **acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* }

     In FIPS mode:

     netconf soap https acl { *ipv4-acl-number* | **name** *ipv4-acl-name* }

By default, no IPv4 ACL is applied to control NETCONF over SOAP access.

6. (Optional.) Specify a mandatory authentication domain for NETCONF users.

   netconf soap domain *domain-name*

   By default, no mandatory authentication domain is specified for NETCONF users. For information about authentication domains, see *Security Configuration Guide*.

7. Use the custom user interface to establish a NETCONF over SOAP session with the device.

   For information about the custom user interface, see the user guide for the interface.

Establishing NETCONF over SSH sessions

Prerequisites

Before establishing a NETCONF over SSH session, make sure the custom user interface can access the device through SSH.

Procedure

1. Enter system view.

   system-view

2. Enable NETCONF over SSH.

   netconf ssh server enable

   By default, NETCONF over SSH is disabled.

3. Specify the listening port for NETCONF over SSH packets.

   netconf ssh server port *port-number*

   By default, the listening port number is 830.

4. Use the custom user interface to establish a NETCONF over SSH session with the device. For information about the custom user interface, see the user guide for the interface.

Establishing NETCONF over Telnet or NETCONF over console sessions

Restrictions and guidelines

To ensure the format correctness of a NETCONF message, do not enter the message manually. Copy and paste the message.

While the device is performing a NETCONF operation, do not perform any other operations, such as pasting a NETCONF message or pressing **Enter**.

For the device to identify NETCONF messages, you must add end mark **]]>]]>** at the end of each NETCONF message. Examples in this document do not necessarily have this end mark. Do add the end mark in actual operations.

Prerequisites

To establish a NETCONF over Telnet session or a NETCONF over console session, first log in to the device through Telnet or the console port.

Procedure

To enter XML view, execute the following command in user view:

xml

If the XML view prompt appears, the NETCONF over Telnet session or NETCONF over console session is established successfully.

Exchanging capabilities

About this task

After a NETCONF session is established, the device sends its capabilities to the client. You must use a hello message to send the capabilities of the client to the device before you can perform any other NETCONF operations.

Hello message from the device to the client

```
<?xml version="1.0" encoding="UTF-8"?><hello
xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"><capabilities>...</capabilities><sess
ion-id>1</session-id></hello>]]>]]>
```

The <capabilities> element carries the capabilities supported by the device. The supported capabilities vary by device model.

The <session-id> element carries the unique ID assigned to the NETCONF session.

Hello message from the client to the device

After receiving the hello message from the device, copy the following hello message to notify the device of the capabilities supported by the client:

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
     capability-set
   </capability>
 </capabilities>
</hello>
```

Item	Description
capability-set	Specifies a set of capabilities supported by the client. Use the <capability> and </capability> tags to enclose each user-defined capability set.

Retrieving device configuration information

Restrictions and guidelines for device configuration retrieval

As a best practice to ensure retrieval performance, limit the number of data entries for each <get-bulk> or <get> operation to 1000. If the number of data entries to retrieve is higher than 1000, use the <get-bulk> operation as a best practice.

During a <get>, <get-bulk>, <get-config>, or <get-bulk-config> operation, NETCONF replaces unidentifiable characters in the retrieved data with question marks (?) before sending the data to the client. If the process for a relevant module is not started yet, the operation returns the following message:

```
<?xml version="1.0"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data/>
</rpc-reply>
```

The <get><netconf-state/></get> operation does not support data filtering.

For more information about the NETCONF operations, see the NETCONF XML API references for the device.

Retrieving device configuration and state information

You can use the following NETCONF operations to retrieve device configuration and state information:

- **<get> operation**—Retrieves all device configuration and state information that matches the specified conditions.
- **<get-bulk> operation**—Retrieves data entries starting from the data entry next to the one with the specified index. One data entry contains a device configuration entry and a state information entry. The returned output does not include the index information.

The <get> message and <get-bulk> message share the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <getoperation>
    <filter>
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
          Specify the module, submodule, table name, and column name
      </top>
    </filter>
  </getoperation>
</rpc>
```

Item	Description
getoperation	Operation name, **get** or **get-bulk**.
filter	Specifies the filtering conditions, such as the module name, submodule name, table name, and column name. • If you specify a module name, the operation retrieves the data for the specified module. If you do not specify a module name, the operation retrieves the data for all modules. • If you specify a submodule name, the operation retrieves the data for the specified submodule. If you do not specify a submodule name, the operation retrieves the data for all submodules. • If you specify a table name, the operation retrieves the data for the specified table. If you do not specify a table name, the operation retrieves the data for all tables. • If you specify only the index column, the operation retrieves the data for all columns. If you specify the index column and any other columns, the operation retrieves the data for the index column and the specified columns.

A <get-bulk> message can carry the **count** and **index** attributes.

Item	Description
index	Specifies the index. If you do not specify this item, the index value starts with 1 by default.
count	Specifies the data entry quantity. The **count** attribute complies with the following rules: • The **count** attribute can be placed in the module node and table node. In other nodes, it cannot be resolved.

Item	Description
	• When the **count** attribute is placed in the module node, a descendant node inherits this count attribute if the descendant node does not contain the count attribute. • The <get-bulk> operation retrieves all the rest data entries starting from the data entry next to the one with the specified index if either of the following conditions occurs: ○ You do not specify the **count** attribute. ○ The number of matching data entries is less than the value of the **count** attribute.

The following <get-bulk> message example specifies the **count** and **index** attributes:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xc="http://www.h3c.com/netconf/base:1.0">
  <get-bulk>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0"
xmlns:base="http://www.h3c.com/netconf/base:1.0">
        <Syslog>
          <Logs xc:count="5">
            <Log>
              <Index>10</Index>
           </Log>
             </Logs>
        </Syslog>
      </top>
    </filter>
  </get-bulk>
</rpc>
```

When retrieving interface information, the device cannot identify whether an integer value for the <IfIndex> element represents an interface name or index. When retrieving VPN instance information, the device cannot identify whether an integer value for the <vrfindex> element represents a VPN name or index. To resolve the issue, you can use the **valuetype** attribute to specify the value type.

The **valuetype** attribute has the following values:

Value	Description
name	The element carries a name.
index	The element carried an index.
auto	Default value. The device uses the value of the element as an index for information matching. If no match is found, the device uses the value as a name for information matching.

The following example specifies an index-type value for the <IfIndex> element:

```
<rpc xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <getoperation>
    <filter>
      <top xmlns="http://www.h3c.com/netconf/config:1.0"
xmlns:base="http://www.h3c.com/netconf/base:1.0">
       <VLAN>
```

```
        <TrunkInterfaces>
          <Interface>
            <IfIndex base:valuetype="index">1</IfIndex>
          </Interface>
        </TrunkInterfaces>
       </VLAN>
      </top>
    </filter >
  </getoperation>
</rpc>
```

If the <get> or < get-bulk> operation succeeds, the device returns the retrieved data in the following format:

```
<?xml version="1.0"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
     Device state and configuration data
  </data>
</rpc-reply>
```

Retrieving non-default settings

The <get-config> and <get-bulk-config> operations are used to retrieve all non-default settings. The <get-config> and <get-bulk-config> messages can contain the <filter> element for filtering data.

The <get-config> and <get-bulk-config> messages are similar. The following is a <get-config> message example:

```
<?xml version="1.0"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <datastore/>
    </source>
    <filter>
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
          Specify the module name, submodule name, table name, and column name
      </top>
    </filter>
  </get-config>
</rpc>
```

The value for *datastore* can be one of the following:

Value	Description
running	Specifies the running configuration datastore.
candidate	Specifies the candidate configuration datastore.

If the <get-config> or <get-bulk-config> operation succeeds, the device returns the retrieved data in the following format:

```
<?xml version="1.0"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
```

```
  <data>
    Data matching the specified filter
  </data>
</rpc-reply>
```

Retrieving NETCONF information

Use the <get><netconf-state/></get> message to retrieve NETCONF information.

Copy the following text to the client to retrieve NETCONF information:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="m-641" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type='subtree'>
      <netconf-state xmlns='urn:ietf:params:xml:ns:yang:ietf-netconf-monitoring'>
         <getType/>
      </netconf-state>
    </filter>
  </get>
</rpc>
```

If you do not specify a value for *getType*, the retrieval operation retrieves all NETCONF information.

The value for *getType* can be one of the following operations:

Operation	Description
capabilities	Retrieves device capabilities.
datastores	Retrieves databases from the device.
schemas	Retrieves the list of the YANG file names from the device.
sessions	Retrieves session information from the device.
statistics	Retrieves NETCONF statistics.

If the <get><netconf-state/></get> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
     Retrieved NETCONF information
  </data>
</rpc-reply>
```

Retrieving YANG file content

YANG files save the NETCONF operations supported by the device. You can identify the supported operations by retrieving and analyzing the content of YANG files.

YANG files are integrated in the device software and are named in the format of *yang_identifier@yang_version.yang*. You cannot view the YANG file names by executing the **dir** command. For information about retrieving the YANG file names, see "Retrieving NETCONF information."

Copy the following text to the client to retrieve the YANG file named **H3C-syslog-data@2019-01-01.yang**:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-schema xmlns='urn:ietf:params:xml:ns:yang:ietf-netconf-monitoring'>
    <identifier>H3C-syslog-data</identifier>
    <version>2019-01-01</version>
    <format>yang</format>
  </get-schema>
</rpc>
```

If the <get-schema> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
     Content of the specified YANG file
  </data>
</rpc-reply>
```

Retrieving NETCONF session information

Use the <get-sessions> operation to retrieve NETCONF session information of the device.

Copy the following message to the client to retrieve NETCONF session information from the device:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-sessions/>
</rpc>
```

If the <get-sessions> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-sessions>
    <Session>
      <SessionID>Configuration session ID</SessionID>
      <Line>Line information</Line>
      <UserName>Name of the user creating the session</UserName>
      <Since>Time when the session was created</Since>
      <LockHeld>Whether the session holds a lock</LockHeld>
    </Session>
  </get-sessions>
</rpc-reply>
```

Example: Retrieving a data entry for the interface table

Network configuration

Retrieve a data entry for the interface table.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>urn:ietf:params:netconf:base:1.0</capability>
  </capabilities>
</hello>
```

Retrieve a data entry for the interface table.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:web="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-bulk>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0"
xmlns:web="http://www.h3c.com/netconf/base:1.0">
        <Ifmgr>
          <Interfaces web:count="1">
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-bulk>
</rpc>
```

Verifying the configuration

If the client receives the following text, the <get-bulk> operation is successful:

```
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:web="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
  <data>
    <top xmlns="http://www.h3c.com/netconf/data:1.0">
      <Ifmgr>
        <Interfaces>
          <Interface>
            <IfIndex>3</IfIndex>
            <Name>GigabitEthernet1/0/2</Name>
            <AbbreviatedName>GE1/0/2</AbbreviatedName>
            <PortIndex>3</PortIndex>
            <ifTypeExt>22</ifTypeExt>
            <ifType>6</ifType>
            <Description>GigabitEthernet1/0/2 Interface</Description>
            <AdminStatus>2</AdminStatus>
            <OperStatus>2</OperStatus>
            <ConfigSpeed>0</ConfigSpeed>
            <ActualSpeed>100000</ActualSpeed>
            <ConfigDuplex>3</ConfigDuplex>
            <ActualDuplex>1</ActualDuplex>
          </Interface>
        </Interfaces>
      </Ifmgr>
    </top>
  </data>
```

```
</rpc-reply>
```

Example: Retrieving non-default configuration data

Network configuration

Retrieve all non-default configuration data.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Retrieve all non-default configuration data.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
  </get-config>
</rpc>
```

Verifying the configuration

If the client receives the following text, the <get-config> operation is successful:

```
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:web="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <data>
        <top xmlns="http://www.h3c.com/netconf/config:1.0">
            <Ifmgr>
                <Interfaces>
                    <Interface>
                        <IfIndex>1307</IfIndex>
                        <Shutdown>1</Shutdown>
                    </Interface>
                    <Interface>
                        <IfIndex>1308</IfIndex>
                        <Shutdown>1</Shutdown>
                    </Interface>
                    <Interface>
                        <IfIndex>1309</IfIndex>
                        <Shutdown>1</Shutdown>
                    </Interface>
                    <Interface>
                        <IfIndex>1311</IfIndex>
```

```
                            <VlanType>2</VlanType>
                    </Interface>
                    <Interface>
                        <IfIndex>1313</IfIndex>
                            <VlanType>2</VlanType>
                    </Interface>
                </Interfaces>
            </Ifmgr>
            <Syslog>
                <LogBuffer>
                    <BufferSize>120</BufferSize>
                </LogBuffer>
            </Syslog>
            <System>
                <Device>
                    <SysName>Sysname</SysName>
                    <TimeZone>
                        <Zone>+11:44</Zone>
                        <ZoneName>beijing</ZoneName>
                    </TimeZone>
                </Device>
            </System>
        </top>
    </data>
</rpc-reply>
```

Example: Retrieving syslog configuration data

Network configuration

Retrieve configuration data for the Syslog module.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Retrieve configuration data for the Syslog module.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
```

```
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Syslog/>
      </top>
    </filter>
  </get-config>
</rpc>
```

Verifying the configuration

If the client receives the following text, the <get-config> operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <data>
        <top xmlns="http://www.h3c.com/netconf/config:1.0">
            <Syslog>
                <LogBuffer>
                    <BufferSize>120</BufferSize>
                </LogBuffer>
            </Syslog>
        </top>
    </data>
</rpc-reply>
```

Example: Retrieving NETCONF session information

Network configuration

Get NETCONF session information.

Procedure

Enter XML view.

```
<Sysname> xml
```

Copy the following message to the client to exchange capabilities with the device:

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
           urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Copy the following message to the client to get the current NETCONF session information on the device:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-sessions/>
</rpc>
```

Verifying the configuration

If the client receives a message as follows, the operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
```

```
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <get-sessions>
        <Session>
            <SessionID>1</SessionID>
            <Line>vty0</Line>
            <UserName></UserName>
            <Since>2019-01-07T00:24:57</Since>
            <LockHeld>false</LockHeld>
        </Session>
    </get-sessions>
</rpc-reply>
```

The output shows the following information:

- The session ID of an existing NETCONF session is 1.
- The login user type is vty0.
- The login time is 2019-01-07T00:24:57.
- The user does not hold the lock of the configuration.

Filtering data

About data filtering

You can define a filter to filter information when you perform a <get>, <get-bulk>, <get-config>, or <get-bulk-config> operation. Data filtering includes the following types:

- **Table-based filtering**—Filters table information.
- **Column-based filtering**—Filters information for a single column.

Restrictions and guidelines for data filtering

For table-based filtering to take effect, you must configure table-based filtering before column-based filtering.

Table-based filtering

About this task

The namespace is **http://www.h3c.com/netconf/base:1.0**. The attribute name is **filter**. For information about the support for table-based match, see the NETCONF XML API references.

Copy the following text to the client to retrieve the longest data with IP address **1.1.1.0** and mask length **24** from the IPv4 routing table:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Route>
         <Ipv4Routes>
           <RouteEntry h3c:filter="IP 1.1.1.0 MaskLen 24 longer"/>
         </Ipv4Routes>
```

```
        </Route>
      </top>
    </filter>
  </get>
</rpc>
```

Restrictions and guidelines

To use table-based filtering, specify a match criterion for the **filter** row attribute.

Column-based filtering

About this task

Column-based filtering includes full match filtering, regular expression match filtering, and conditional match filtering. Full match filtering has the highest priority and conditional match filtering has the lowest priority. When more than one filtering criterion is specified, the one with the highest priority takes effect.

Full match filtering

You can specify an element value in an XML message to implement full match filtering. If multiple element values are provided, the system returns the data that matches all the specified values.

Copy the following text to the client to retrieve configuration data of all interfaces in UP state:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <AdminStatus>1</AdminStatus>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get>
</rpc>
```

You can also specify an attribute name that is the same as a column name of the current table at the row to implement full match filtering. The system returns only configuration data that matches this attribute name. The XML message equivalent to the above element-value-based full match filtering is as follows:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
      <top
xmlns="http://www.h3c.com/netconf/data:1.0"xmlns:data="http://www.h3c.com/netconf/dat
a:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface data:AdminStatus="1"/>
          </Interfaces>
```

```
        </Ifmgr>
      </top>
    </filter>
  </get>
</rpc>
```

The above examples show that both element-value-based full match filtering and attribute-name-based full match filtering can retrieve the same index and column information for all interfaces in up state.

Regular expression match filtering

To implement a complex data filtering with characters, you can add a **regExp** attribute for a specific element.

The supported data types include integer, date and time, character string, IPv4 address, IPv4 mask, IPv6 address, MAC address, OID, and time zone.

Copy the following text to the client to retrieve the descriptions of interfaces, of which all the characters must be upper-case letters from A to Z:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <Description h3c:regExp="^[A-Z]*$"/>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-config>
</rpc>
```

Conditional match filtering

To implement a complex data filtering with digits and character strings, you can add a **match** attribute for a specific element. Table 3 lists the conditional match operators.

Table 3 Conditional match operators

Operation	Operator	Remarks
More than	match="more:*value*"	More than the specified value. The supported data types include date, digit, and character string.
Less than	match="less:*value*"	Less than the specified value. The supported data types include date, digit, and character string.
Not less than	match="notLess:*value*"	Not less than the specified *value*. The supported data types include date, digit, and character string.
Not more than	match="notMore:*value*"	Not more than the specified *value*. The supported data types

Operation	Operator	Remarks
		include date, digit, and character string.
Equal	match="equal:*value*"	Equal to the specified *value*. The supported data types include date, digit, character string, OID, and BOOL.
Not equal	match="notEqual:*value*"	Not equal to the specified *value*. The supported data types include date, digit, character string, OID, and BOOL.
Include	match="include:*string*"	Includes the specified *string*. The supported data types include only character string.
Not include	match="exclude:*string*"	Excludes the specified *string*. The supported data types include only character string.
Start with	match="startWith:*string*"	Starts with the specified *string*. The supported data types include character string and OID.
End with	match="endWith:*string*"	Ends with the specified *string.* The supported data types include only character string.

Copy the following text to the client to retrieve extension information about the entity whose CPU usage is more than 50%:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Device>
          <ExtPhysicalEntities>
            <Entity>
              <CpuUsage h3c:match="more:50"></CpuUsage>
            </Entity>
          </ExtPhysicalEntities>
        </Device>
      </top>
    </filter>
  </get>
</rpc>
```

Example: Filtering data with regular expression match

Network configuration

Retrieve all data including **Gig** in the **Description** column of the Interfaces table under the Ifmgr module.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
           urn:ietf:params:netconf:base:1.0
```

```
    </capability>
  </capabilities>
</hello>
```

Retrieve all data including **Gig** in the **Description** column of the Interfaces table under the Ifmgr module.

```
<?xml version="1.0"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <Description h3c:regExp="(Gig)+"/>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get>
</rpc>
```

Verifying the configuration

If the client receives the following text, the operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0" message-id="100">
    <data>
        <top xmlns="http://www.h3c.com/netconf/data:1.0">
            <Ifmgr>
                <Interfaces>
                    <Interface>
                        <IfIndex>2681</IfIndex>
                        <Description>GigabitEthernet1/0/1 Interface</Description>
                    </Interface>
                    <Interface>
                        <IfIndex>2685</IfIndex>
                        <Description>GigabitEthernet1/0/2 Interface</Description>
                    </Interface>
                    <Interface>
                        <IfIndex>2689</IfIndex>
                        <Description>GigabitEthernet1/0/3 Interface</Description>
                    </Interface>
                 <Interface>
            </Ifmgr>
        </top>
    </data>
</rpc-reply>
```

Example: Filtering data by conditional match

Network configuration

Retrieve data in the **Name** column with the ifindex value not less than 5000 in the Interfaces table under the Ifmgr module.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
           urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Retrieve data in the **Name** column with the ifindex value not less than 5000 in the Interfaces table under the Ifmgr module.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <IfIndex h3c:match="notLess:5000"/>
              <Name/>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get>
</rpc>
```

Verifying the configuration

If the client receives the following text, the operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0" message-id="100">
    <data>
        <top xmlns="http://www.h3c.com/netconf/data:1.0">
            <Ifmgr>
                <Interfaces>
                    <Interface>
                        <IfIndex>7241</IfIndex>
                        <Name>NULL0</Name>
```

```
                    </Interface>
                </Interfaces>
            </Ifmgr>
        </top>
    </data>
</rpc-reply>
```

Locking or unlocking the running configuration

About configuration locking and unlocking

Multiple methods are available for configuring the device, such as CLI, NETCONF, and SNMP. Before configuring, managing, or troubleshooting the device, you can lock the configuration to prevent other users from changing the device configuration. After you lock the configuration, only you can perform <edit-config> operations to change the configuration or unlock the configuration. Other users can only read the configuration.

If you close your NETCONF session, the system unlocks the configuration. You can also manually unlock the configuration.

Restrictions and guidelines for configuration locking and unlocking

The <lock> operation locks the running configuration of the device. You cannot use it to lock the configuration for a specific module.

Locking the running configuration

Copy the following text to the client to lock the running configuration:

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <lock>
      <target>
        <datastore/>
      </target>
    </lock>
  </rpc>
```

The value for *datastore* can be one of the following:

Value	Description
running	Specifies the running configuration datastore.
candidate	Specifies the candidate configuration datastore.

If the <lock> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
     <ok/>
</rpc-reply>
```

Unlocking the running configuration

Copy the following text to the client to unlock the running configuration:

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <unlock>
      <target>
        <datastore/>
      </target>
    </unlock>
  </rpc>
```

The value for *datastore* can be one of the following:

Value	Description
running	Specifies the running configuration datastore.
candidate	Specifies the candidate configuration datastore.

If the <unlock> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Example: Locking the running configuration

Network configuration

Lock the device configuration so other users cannot change the device configuration.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <capabilities>
        <capability>
            urn:ietf:params:netconf:base:1.0
        </capability>
    </capabilities>
</hello>
```

Lock the configuration.

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <lock>
      <target>
        <running/>
      </target>
    </lock>
```

```
  </rpc>
```

Verifying the configuration

If the client receives the following response, the <lock> operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

If another client sends a lock request, the device returns the following response:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<rpc-error>
  <error-type>protocol</error-type>
  <error-tag>lock-denied</error-tag>
  <error-severity>error</error-severity>
  <error-message xml:lang="en"> Lock failed because the NETCONF lock is held by another
session.</error-message>
  <error-info>
    <session-id>1</session-id>
  </error-info>
  </rpc-error>
</rpc-reply>
```

The output shows that the <lock> operation failed. The client with session ID 1 is holding the lock,

Modifying the configuration

About the <edit-config> operation

The <edit-config> operation includes the following operations: merge, create, replace, remove, delete, default-operation, error-option, test-option, and incremental. For more information about the operations, see "Supported NETCONF operations."

Procedure

Copy the following text to perform the <edit-config> operation:

```
<?xml version="1.0"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target><datastore/></target>
    <error-option>
       error-option
    </error-option>
    <config>
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        Specify the module name, submodule name, table name, and column name
      </top>
    </config>
  </edit-config>
```

```
</rpc>
```

The value for *datastore* can be one of the following:

Value	Description
running	Specifies the running configuration datastore.
candidate	Specifies the candidate configuration datastore.

When you modify the running configuration datastore, you can also specify the <error-option> element. This element indicates the action to take in response to an error that occurs during the operation. The following are available error options:

Value	Description
stop-on-error	Stops the <edit-config> operation.
continue-on-error	Continues the <edit-config> operation.
rollback-on-error	Rolls back the configuration to the configuration before the <edit-config> operation was performed. By default, an <edit-config> operation cannot be performed while the device is rolling back the configuration. If the rollback time exceeds the maximum time that the client can wait, the client determines that the <edit-config> operation has failed and performs the operation again. Because the previous rollback is not completed, the operation triggers another rollback. If this process repeats itself, CPU and memory resources will be exhausted and the device will reboot. To allow an <edit-config> operation to be performed during a configuration rollback, perform an <action> operation to change the value of the **DisableEditConfigWhenRollback** attribute to **false**.

If the <edit-config> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0">
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

If the device supports the **netconf log xml2cli enable** command, it includes <capability>urn:h3c:params:netconf:capability:h3c-xml2cli:1.0</capability> in the capability set exchanged with NETCONF clients. If a client also supports this capability, the device will return the commands for the <edit-config> operations it has successfully executed for that client. The following is the response message format:

```
<?xml version="1.0">
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
  <xml2cli>
    Specified module name, submodule name, <cli> column, and target column name and table name in the <edit-config> request
  </xml2cli>
</rpc-reply>
```

The <cli> column contains the commands for the operations on the requested columns in the <edit-config> request. The following is a sample response:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <ok/>
   <xml2cli>
```

```
      <GRPC>
         <Configuration xc:operation="merge"
xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
            <cli>grpc enable
grpc port 50052
grpc idle-timeout 25</cli>
            <State>enable</State>
            <Port>50052</Port>
            <IdleTime>25</IdleTime>
         </Configuration>
      </GRPC>
   </xml2cli>
</rpc-reply>
```

You can also perform the <get> operation to verify that the current element value is the same as the value specified through the <edit-config> operation.

Example: Modifying the configuration

Network configuration

Change the log buffer size for the Syslog module to 512.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>urn:ietf:params:netconf:base:1.0</capability>
  </capabilities>
</hello>
```

Change the log buffer size for the Syslog module to 512.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:web="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config>
      <top xmlns="http://www.h3c.com/netconf/config:1.0" web:operation="merge">
        <Syslog>
          <LogBuffer>
            <BufferSize>512</BufferSize>
          </LogBuffer>
        </Syslog>
      </top>
    </config>
  </edit-config>
</rpc>
```

Verifying the configuration

If the client receives the following text, the <edit-config> operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

Saving the running configuration

About the <save> operation

A <save> operation saves the running configuration to a configuration file and specifies the file as the main next-startup configuration file.

Restrictions and guidelines

The <save> operation is resource intensive. Do not perform this operation when system resources are heavily occupied.

Procedure

Copy the following text to the client:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save OverWrite="false" Binary-only="false" Safely="false">
    <file>Configuration file name</file>
  </save>
</rpc>
```

Item	Description
file	Specifies a .cfg configuration file by its name. The name must start with the storage medium name. If you specify the file column, a file name is required. If the **Binary-only** attribute is **false**, the device saves the running configuration to both the text and binary configuration files. • If the specified .cfg file does not exist, the device creates the binary and text configuration files to save the running configuration. • If you do not specify the file column, the device saves the running configuration to the text and binary next-startup configuration files.
OverWrite	Determines whether to overwrite the specified file if the file already exists. The following values are available: • **true**—Overwrite the file. • **false**—Do not overwrite the file. The running configuration cannot be saved, and the system displays an error message. The default value is **true**.
Binary-only	Determines whether to save the running configuration only to the binary configuration file. The following values are available: • **true**—Save the running configuration only to the binary configuration file. ○ If the file column specifies a nonexistent file, the <save> operation fails.

Item	Description
	○ If you do not specify the file column, the device attempts to save the running configuration to the binary file for the .cfg main next-startup configuration file. If the .cfg main next-startup configuration file does not exist, the <save> operation fails. • **false**—Save the running configuration to both the .cfg and binary configuration files. For more information, see the description for the file column in this table. Saving the running configuration only to the binary configuration file reduces the amount of time required to save the running configuration. The default value is **false**. The current software version does not support setting this column to **true**.
Safely	Determines whether to save the configuration file in safe mode or fast mode. Available values: • **true**—Saves the configuration in safe mode. In this mode, the system saves the configuration in a temporary file and starts overwriting the target next-startup configuration file after the save operation is complete. If a disruptive event such as a reboot or power failure occurs during the save operation, the device can still start up with the original next-startup configuration file. • **false**—Saves the configuration in fast mode. In this mode, the system directly overwrites the target next-startup configuration file. If a disruptive event such as a reboot, power failure, out-of-memory, out-of-storage event occurs during this process, the next-startup configuration file is lost. You must specify a new startup configuration file after the device reboots. By default, the Safely attribute is set to **false** if you do not specify a value for it. Safe mode is slower than fast mode, but more secure. As a best practice, use the safe mode if the power source is not reliable or you are remotely configuring the device.

If the <save> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Example: Saving the running configuration

Network configuration

Save the running configuration to the **config.cfg** file.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Save the running configuration of the device to the **config.cfg** file.

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save>
    <file>config.cfg</file>
  </save>
</rpc>
```

Verifying the configuration

If the client receives the following response, the <save> operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Loading the configuration

About the <load> operation

The <load> operation merges the configuration from a configuration file into the running configuration as follows:

- Loads settings that do not exist in the running configuration.
- Overwrites settings that already exist in the running configuration.

Restrictions and guidelines

When you perform a <load> operation, follow these restrictions and guidelines:

- The <load> operation is resource intensive. Do not perform this operation when the system resources are heavily occupied.
- Some settings in a configuration file might conflict with the existing settings. For the settings in the file to take effect, delete the existing conflicting settings, and then load the configuration file.

Procedure

Copy the following text to the client to load a configuration file for the device:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <load>
   <file>Configuration file name</file>
  </load>
</rpc>
```

The configuration file name must start with the storage media name and end with the **.cfg** extension.

If the <load> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Rolling back the configuration

Restrictions and guidelines

The <rollback> operation is resource intensive. Do not perform this operation when the system resources are heavily occupied.

By default, an <edit-config> operation cannot be performed while the device is rolling back the configuration. To allow an <edit-config> operation to be performed during a configuration rollback, perform an <action> operation to change the value of the **DisableEditConfigWhenRollback** attribute to **false**.

Rolling back the configuration based on a configuration file

Copy the following text to the client to roll back the running configuration to the configuration in a configuration file:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <rollback>
    <file>Specify the configuration file name</file>
  </rollback>
</rpc>
```

If the <rollback> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Rolling back the configuration based on a rollback point

About this task

You can roll back the running configuration based on a rollback point when one of the following situations occurs:

- A NETCONF client sends a rollback request.
- The NETCONF session idle time is longer than the rollback idle timeout time.
- A NETCONF client is unexpectedly disconnected from the device.

Restrictions and guidelines

Multiple users might simultaneously configure the device. As a best practice, lock the system before rolling back the configuration to prevent other users from modifying the running configuration.

Procedure

1. Lock the running configuration. For more information, see "Locking or unlocking the running configuration."
2. Enable configuration rollback based on a rollback point.

   # Copy the following text to the client to perform a <save-point>/<begin> operation:

   ```
   <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
         <save-point>
           <begin>
             <confirm-timeout>100</confirm-timeout>
   ```

```
      </begin>
     </save-point>
</rpc>
```

Item	Description
confirm-timeout	Specifies the rollback idle timeout time in the range of 1 to 65535 seconds. The default is 600 seconds. This item is optional.

If the <save-point/begin> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <save-point>
       <commit>
          <commit-id>1</commit-id>
       </commit>
    </save-point>
  </data>
</rpc-reply>
```

3. Modify the running configuration. For more information, see "Modifying the configuration."
4. Mark the rollback point.

   The system supports a maximum of 50 rollback points. If the limit is reached, specify the **force** attribute for the <save-point>/<commit> operation to overwrite the earliest rollback point.

   # Copy the following text to the client to perform a <save-point>/<commit> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <commit>
      <label>SUPPORT VLAN<label>
      <comment>vlan 1 to 100 and interfaces.</comment>
     </commit>
  </save-point>
</rpc>
```

   The <label> and <comment> elements are optional.

   If the <save-point>/<commit> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <save-point>
       <commit>
          <commit-id>2</commit-id>
       </commit>
    </save-point>
  </data>
</rpc-reply>
```

5. Retrieve the rollback point configuration records.

   The following text shows the message format for a <save-point/get-commits> request:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <get-commits>
      <commit-id/>
```

```
      <commit-index/>
      <commit-label/>
    </get-commits>
  </save-point>
</rpc>
```

Specify the <commit-id/>, <commit-index/>, or <commit-label/> element to retrieve the specified rollback point configuration records. If no element is specified, the operation retrieves records for all rollback point settings.

Copy the following text to the client to perform a <save-point>/<get-commits> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <get-commits>
      <commit-label>SUPPORT VLAN</commit-label>
    </get-commits>
  </save-point>
</rpc>
```

If the <save-point/get-commits> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <data>
      <save-point>
         <commit-information>
           <CommitID>2</CommitID>
           <TimeStamp>Sun Jan 1 11:30:28 2019</TimeStamp>
           <UserName>test</UserName>
           <Label>SUPPORT VLAN</Label>
         </commit-information>
    </save-point>
  </data>
</rpc-reply>
```

6. Retrieve the configuration data corresponding to a rollback point.

The following text shows the message format for a <save-point>/<get-commit-information> request:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <get-commit-information>
       <commit-information>
         <commit-id/>
         <commit-index/>
         <commit-label/>
       </commit-information>
       <compare-information>
         <commit-id/>
         <commit-index/>
         <commit-label/>
       </compare-information>
    </get-commit-information>
  </save-point>
</rpc>
```

Specify one of the following elements: <commit-id/>, <commit-index/>, and <commit-label/>. The <compare-information> element is optional.

Item	Description
commit-id	Uniquely identifies a rollback point.
commit-index	Specifies 50 most recently configured rollback points. The value of 0 indicates the most recently configured one and 49 indicates the earliest configured one.
commit-label	Specifies a unique label for a rollback point.
get-commit-information	Retrieves the configuration data corresponding to the most recently configured rollback point.

Copy the following text to the client to perform a <save-point>/<get-commit-information> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <get-commit-information>
               <commit-information>
                  <commit-label>SUPPORT VLAN</commit-label>
               </commit-information>
    </get-commit-information>
  </save-point>
</rpc>
```

If the <save-point/get-commit-information> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <data>
     <save-point>
        <commit-information>
           <content>
              …
              interface vlan 1
              …
           </content>
        </commit-information>
     </save-point>
   </data>
</rpc-reply>
```

7. Roll back the configuration based on a rollback point.

The configuration can also be automatically rolled back based on the most recently configured rollback point when the NETCONF session idle timer expires.

Copy the following text to the client to perform a <save-point>/<rollback> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <rollback>
      <commit-id/>
      <commit-index/>
      <commit-label/>
    </rollback>
```

```
  </save-point>
</rpc>
```

Specify one of the following elements: <commit-id/>, <commit-index/>, and <commit-label/>. If no element is specified, the operation rolls back configuration based on the most recently configured rollback point.

Item	Description
commit-id	Uniquely identifies a rollback point.
commit-index	Specifies 50 most recently configured rollback points. The value of 0 indicates the most recently configured one and 49 indicates the earliest configured one.
commit-label	Specifies the unique label of a rollback point.

If the <save-point/rollback> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok></ok>
</rpc-reply>
```

8. End the rollback configuration.

   # Copy the following text to the client to perform a <save-point>/<end> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <end/>
  </save-point>
</rpc>
```

   If the <save-point/end> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <ok/>
</rpc-reply>
```

9. Unlock the configuration. For more information, see "Locking or unlocking the running configuration."

Managing the candidate configuration

About this task

The candidate configuration datastore can be used to store or edit configuration data to be committed without impacting the device's running configuration. A commit operation commits the candidate configuration to the running configuration. After a successful commit operation, the system creates a configuration rollback point.

The candidate configuration datastore is globally unique.

Candidate configuration management tasks at a glance

To manage the candidate configuration, perform the following tasks:

1. Creating a candidate configuration datastore
2. Editing the candidate configuration datastore

3. Commit the candidate configuration

   Choose one of the following tasks:

   - Committing the candidate configuration immediately
   - Committing the candidate configuration only after confirmation

4. (Optional.) Deleting the candidate configuration datastore

   Perform this task to release system resources.

Creating a candidate configuration datastore

About this task

By default, the candidate configuration datastore does not exist. To create a candidate configuration datastore, perform the <copy-config> operation. This operation will create the candidate configuration datastore and copy the running configuration to the candidate configuration datastore. If the candidate configuration datastore already exists, the <copy-config> operation will overwrite existing candidate configuration in the datastore.

Procedure

Copy the following text to the client to create a candidate configuration datastore and copy the running configuration to the candidate configuration datastore:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <copy-config>
    <source>
      <running/>
    </source>
    <target>
     <candidate/>
    </target>
  </copy-config>
</rpc>
```

If the <copy-config> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <ok/>
</rpc-reply>
```

Editing the candidate configuration datastore

Restrictions and guidelines

As a best practice to prevent other users from changing the candidate configuration and to avoid configuration conflicts, lock the candidate configuration before editing it.

Procedure

1. Lock the candidate configuration. For more information, see "Locking or unlocking the running configuration." Make sure you specify the candidate configuration datastore.
2. (Optional.) Retrieve non-default settings through a <get-config> or <get-bulk-config> operation. For more information, see "Retrieving non-default settings."

   Skip this step if you know the non-default settings.

3. Edit the candidate configuration datastore through an <edit-config> operation. For more information, see "Modifying the configuration." Make sure you specify the candidate configuration datastore.
4. (Optional.) Restore the candidate configuration to the running configuration through a <discard-changes> operation. To perform a <discard-changes> operation, copy the following text to the client:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <discard-changes/>
</rpc>
```

Committing the candidate configuration immediately

Copy the following text to the client to commit the candidate configuration to the running configuration immediately:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <commit/>
</rpc>
```

If the <commit> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <ok/>
</rpc-reply>
```

Committing the candidate configuration only after confirmation

About this task

A confirmation-required commit supports automatic rollback. If you require confirmation in the commit operation, the system will start a confirmation timeout timer.

- Before the timer expires, you can choose to commit the candidate configuration to the running configuration immediately or roll back the running configuration to the previously committed configuration.
- After the timer expires, the device automatically rolls back the running configuration to the previously committed configuration.

Procedure

1. Copy the following text to the client to commit the candidate configuration to the running configuration only after confirmation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <commit>
    <confirmed/>
    <confirm-timeout>confirm-timeout</confirm-timeout>
    <persist>config-name</persist>
  </commit>
</rpc>
```

Element	Description
confirm-timeout	Specifies the confirmation timeout timer, in seconds. The default is 600 seconds.

Element	Description
config-name	Specifies the name of the candidate configuration to be committed. The <persist> element enables the candidate configuration to survive after the NETCONF session terminates. • If you include the <persist> element in the commit operation, you can confirm the commit in any NETCONF session. Make sure you specify the <persist-id> element with the same candidate configuration name in the commit confirmation operation. • If you do not include the <persist> element in this commit operation, you can confirm the commit only in the current NETCONF session.

2. Choose one of the following tasks before the confirmation timeout timer expires:
   - Commit the candidate configuration to the running configuration immediately by copying the following text to the client:

     ```
     <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
       <commit>
         <persist-id>config-name</persist-id>
       </commit>
     </rpc>
     ```

Item	Description
config-name	Specifies the name of the candidate configuration to be committed. The name must be the same as that specified in the <persist> element. If you do not include the <persist> element in the commit operation, you do not need to include the <persist-id> element in the confirmation.

   - Cancel the commit and roll back the running configuration to the previously committed configuration by copying the following text to the client:

     ```
     <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
       <cancel-commit/>
     </rpc>
     ```

   If the operation succeeds, the device returns a response in the following format:

   ```
   <?xml version="1.0" encoding="UTF-8"?>
   <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
   </rpc-reply>
   ```

Deleting the candidate configuration datastore

Copy the following text to the client to delete the candidate configuration datastore:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <delete-config>
    <target>
      <candidate/>
    </target>
  </delete-config>
```

```
</rpc>
```

If the <delete-config> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <ok/>
</rpc-reply>
```

Performing CLI operations through NETCONF

About CLI operations through NETCONF

You can enclose command lines in XML messages to configure the device.

Restrictions and guidelines

Performing CLI operations through NETCONF is resource intensive. As a best practice, do not perform the following tasks:

- Enclose multiple command lines in one XML message.
- Use NETCONF to perform a CLI operation when other users are performing NETCONF CLI operations.

Procedure

Copy the following text to the client to execute the commands:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
    <Execution>
      Commands
    </Execution>
  </CLI>
</rpc>
```

The <Execution> element can contain multiple commands, with one command on one line.

If the CLI operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
    <Execution>
      <![CDATA[Responses to the commands]]>
    </Execution>
  </CLI>
</rpc-reply>
```

Example: Performing CLI operations

Network configuration

Send the **`display vlan`** command to the device.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Copy the following text to the client to execute the **`display vlan`** command:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
    <Execution>
          display vlan
    </Execution>
  </CLI>
</rpc>
```

Verifying the configuration

If the client receives the following text, the operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
    <Execution><![CDATA[
<Sysname>display vlan
 Total VLANs: Problem 12 1
 The VLANs include:
 1(default)
   ]]>
   </Execution>
  </CLI>
</rpc-reply>
```

Subscribing to events

About event subscription

When an event takes place on the device, the device sends information about the event to NETCONF clients that have subscribed to the event.

Restrictions and guidelines

Event subscription is not supported for NETCONF over SOAP sessions.

A subscription takes effect only on the current session. It is canceled when the session is terminated.

If you do not specify the event stream to be subscribed to, the device sends syslog event notifications to the NETCONF client.

Subscribing to syslog events

Copy the following message to the client to complete the subscription:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <create-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <stream>NETCONF</stream>
      <filter>
        <event xmlns="http://www.h3c.com/netconf/event:1.0">
          <Code>code</Code>
            <Group>group</Group>
              <Severity>severity</Severity>
        </event>
      </filter>
      <startTime>start-time</startTime>
      <stopTime>stop-time</stopTime>
   </create-subscription>
</rpc>
```

Item	Description
stream	Specifies the event stream. The name for the syslog event stream is **NETCONF**.
event	Specifies the event. For information about the events to which you can subscribe, see the system log message references for the device.
code	Specifies the mnemonic symbol of the log message.
group	Specifies the module name of the log message.
severity	Specifies the severity level of the log message.
start-time	Specifies the start time of the subscription.
stop-time	Specifies the end time of the subscription.

If the subscription succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns:netconf="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

If the subscription fails, the device returns an error message in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<rpc-error>
   <error-type>error-type</error-type>
   <error-tag>error-tag</error-tag>
   <error-severity>error-severity</error-severity>
   <error-message xml:lang="en">error-message</error-message>
```

```
</rpc-error>
</rpc-reply>
```

For more information about error messages, see RFC 4741.

Subscribing to events monitored by NETCONF

After you subscribe to events as described in this section, NETCONF regularly polls the subscribed events and sends the events that match the subscription condition to the NETCONF client.

Copy the following message to the client to complete the subscription:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<create-subscription xmlns='urn:ietf:params:xml:ns:netconf:notification:1.0'>
  <stream>NETCONF_MONITOR_EXTENSION</stream>
  <filter>
    <NetconfMonitor xmlns='http://www.h3c.com/netconf/monitor:1.0'>
      <XPath>XPath</XPath>
      <Interval>interval</Interval>
      <ColumnConditions>
        <ColumnCondition>
          <ColumnName>ColumnName</ColumnName>
          <ColumnValue>ColumnValue</ColumnValue>
          <ColumnCondition>ColumnCondition</ColumnCondition>
        </ColumnCondition>
      </ColumnConditions>
      <MustIncludeResultColumns>
        <ColumnName>columnName</ColumnName>
      </MustIncludeResultColumns>
    </NetconfMonitor>
  </filter>
<startTime>start-time</startTime>
<stopTime>stop-time</stopTime>
</create-subscription>
</rpc>
```

Item	Description
stream	Specifies the event stream. The name for the event stream is **NETCONF_MONITOR_EXTENSION**.
NetconfMonitor	Specifies the filtering information for the event.
XPath	Specifies the path of the event in the format of *ModuleName*[/*SubmoduleName*]/*TableName*.
interval	Specifies the interval for NETCONF to obtain events that matches the subscription condition. The value range is 1 to 4294967 seconds. The default value is 300 seconds.
ColumnName	Specifies the name of a column in the format of [*GroupName*.]*ColumnName.*
ColumnValue	Specifies the baseline value.
ColumnCondition	Specifies the operator:

Item	Description
	• **more**. • **less**. • **notLess**. • **notMore**. • **equal**. • **notEqual**. • **include**. • **exclude**. • **startWith**. • **endWith**. Choose an operator according to the type of the baseline value.
start-time	Specifies the start time of the subscription.
stop-time	Specifies the end time of the subscription.

If the subscription succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns:netconf="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

Subscribing to events reported by modules

After you subscribe to events as described in this section, the specified modules report subscribed events to NETCONF. NETCONF sends the events to the NETCONF client.

Copy the following message to the client to complete the subscription:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xs="http://www.h3c.com/netconf/base:1.0">
<create-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
<stream>XXX_STREAM</stream>
   <filter type="subtree">
<event xmlns="http://www.h3c.com/netconf/event:1.0/xxx-features-list-name:1.0">
       <ColumnName xs:condition="Condition">value</ColumnName>
</event>
</filter>
<startTime>start-time</startTime>
<stopTime>stop-time</stopTime>
</create-subscription>
</rpc>
```

Item	Description
stream	Specifies the event stream. Supported event streams vary by device model.
event	Specifies the event name. An event stream includes multiple events. The events use the same namespaces as the event stream.
ColumnName	Specifies the name of a column.

Item	Description
Condition	Specifies the operator: • **more**. • **less**. • **notLess**. • **notMore**. • **equal**. • **notEqual**. • **include**. • **exclude**. • **startWith**. • **endWith**. Choose an operator according to the type of the baseline value.
value	Specifies the baseline value for the column.
start-time	Specifies the start time of the subscription.
stop-time	Specifies the end time of the subscription.

If the subscription succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns:netconf="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

Canceling an event subscription

Copy the following message to the client to cancel a subscription:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <cancel-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <stream>XXX_STREAM</stream>
  </cancel-subscription>
</rpc>
```

Item	Description
stream	Specifies the event stream.

If the cancelation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <ok/>
</rpc-reply>
```

If the subscription to be canceled does not exist, the device returns an error message in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<rpc-error>
   <error-type>error-type</error-type>
   <error-tag>error-tag</error-tag>
```

```
   <error-severity>error-severity</error-severity>
<error-message xml:lang="en">The subscription stream to be canceled doesn't exist: Stream name=XXX_STREAM.</error-message>
</rpc-error>
</rpc-reply>
```

Canceling an event subscription

Copy the following message to the client to cancel a subscription:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <cancel-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <stream>XXX_STREAM</stream>
  </cancel-subscription>
</rpc>
```

Item	Description
stream	Specifies the event stream.

If the cancelation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <ok/>
</rpc-reply>
```

If the subscription to be canceled does not exist, the device returns an error message in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<rpc-error>
   <error-type>error-type</error-type>
   <error-tag>error-tag</error-tag>
   <error-severity>error-severity</error-severity>
<error-message xml:lang="en">The subscription stream to be canceled doesn't exist: Stream name=XXX_STREAM.</error-message>
</rpc-error>
</rpc-reply>
```

Example: Subscribing to syslog events

Network configuration

Configure a client to subscribe to syslog events with no time limitation. After the subscription, all events on the device are sent to the client before the session between the device and client is terminated.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
```

```
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Subscribe to syslog events with no time limitation.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <create-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <stream>NETCONF</stream>
  </create-subscription>
</rpc>
```

Verifying the configuration

If the client receives the following response, the subscription is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <ok/>
</rpc-reply>
```

When another client (192.168.100.130) logs in to the device, the device sends a notification to the client that has subscribed to all events:

```
<?xml version="1.0" encoding="UTF-8"?>
<notification xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <eventTime>2019-01-04T12:30:52</eventTime>
    <event xmlns="http://www.h3c.com/netconf/event:1.0">
        <Group>SHELL</Group>
        <Code>SHELL_LOGIN</Code>
        <Slot>1</Slot>
        <Severity>Notification</Severity>
        <context>VTY logged in from 192.168.100.130.</context>
    </event>
</notification>
```

Terminating NETCONF sessions

About NETCONF session termination

NETCONF allows one client to terminate the NETCONF sessions of other clients. A client whose session is terminated returns to user view.

Procedure

Copy the following message to the client to terminate a NETCONF session:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <kill-session>
    <session-id>
      Specified session-ID
    </session-id>
```

```
  </kill-session>
</rpc>
```

If the <kill-session> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Example: Terminating another NETCONF session

Network configuration

The user whose session's ID is 1 terminates the session with session ID 2.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Terminate the session with session ID 2.

```
<rpc message-id="100"xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <kill-session>
    <session-id>2</session-id>
  </kill-session>
</rpc>
```

Verifying the configuration

If the client receives the following text, the NETCONF session with session ID 2 has been terminated, and the client with session ID 2 has returned from XML view to user view:

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

Returning to the CLI

Restrictions and guidelines

Before returning from XML view to the CLI, you must first complete capability exchange between the device and the client.

Procedure

Copy the following text to the client to return from XML view to the CLI:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
```

```
   <close-session/>
</rpc>
```

When the device receives the close-session request, it sends the following response and returns to CLI's user view:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <ok/>
</rpc-reply>
```

Enabling SNMP notifications for NETCONF

About this task

To report critical NETCONF events to an SNMP NMS, enable SNMP notifications for NETCONF. For NETCONF SNMP notifications to be sent correctly, you must also configure SNMP on the device. For more information about configuring SNMP, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. Enable SNMP notifications for NETCONF.

   `snmp-agent trap enable netconf`

   By default, SNMP notifications are enabled for NETCONF.

Display and maintenance commands for NETCONF

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display current NETCONF service status and global NETCONF service statistics.	**display netconf service**
Display NETCONF session status and statistics.	**display netconf session**
Clear NETCONF service statistics.	**reset netconf service statistics**
Clear NETCONF session statistics.	**reset netconf session statistics**

Supported NETCONF operations

This chapter describes NETCONF operations available with Comware 7.

NETCONF packet strings are case sensitive.

Candidate configuration datastore operations

This section describes operations specific to the candidate configuration datastore. Besides these operations, you can also perform the following operations on the candidate configuration datastore:

- edit-config: create, edit-config: delete, edit-config: merge, edit-config: remove, and edit-config: replace.
- get-bulk-config and get-config.
- lock and unlock.

cancel-commit

Usage guidelines

This operation cancels an ongoing confirmed commit and roll back the running configuration to the previously committed configuration. Perform this task before the confirmation timeout timer expires.

XML example

Cancel an ongoing commit and roll back the running configuration to the previously committed configuration.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <cancel-commit/>
</rpc>
```

commit (immediate commit)

Usage guidelines

This operation commits the candidate configuration to the running configuration immediately.

XML example

Commit the candidate configuration to the running configuration immediately.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <commit/>
</rpc>
```

commit (confirmation-required commit)

Usage guidelines

This operation commits the candidate configuration to the running configuration only after the user confirms the commit. If the user does not confirm the commit, the device automatically rolls back the running configuration to the previously committed configuration.

When you perform this operation, you must specify the <confirmed> node and can specify the following columns:

- **<confirm-timeout>**—Specifies the confirmation timeout timer, in seconds. The default is 600 seconds.
- **<persist>**—Specifies the name of the candidate configuration and enable the candidate configuration to survive after the NETCONF session terminates. If you do not include the <persist> element in this commit operation, you can confirm the commit only in the current NETCONF session.

XML example

Configure name **test** for the candidate configuration and commit the candidate configuration to the running configuration only after a confirmation. Set the confirmation timeout time to 600 seconds.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <commit>
    <confirmed/>
    <confirm-timeout>600</confirm-timeout>
    <persist>test</persist>
  </commit>
</rpc>
```

commit (commit confirmation)

Usage guidelines

This operation confirms to commit the candidate configuration to the running configuration.

You must confirm the commit operation before the confirmation timeout timer expires.

If you include the <persist> element in the confirming commit operation, you must include the <persist-id> element in the confirmation operation. Make sure the value for the <persist-id> element is the same as that specified in the <persist> element.

If you do not include the <persist> element, the commit confirmation operation is the same as the immediate commit operation.

XML example

Confirm to commit the candidate configuration with name **test** to the running configuration.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <commit>
    <persist-id>test</persist-id>
  </commit>
```

```
</rpc>
```

copy-config

Usage guidelines

This operation copies the running configuration to a target configuration datastore. If the target configuration datastore does not exist, this operation creates the datastore.

In the current software version, this operation can only copy the running configuration to the candidate configuration store.

XML example

Copy the running configuration to the candidate configuration datastore.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <copy-config>
    <source>
      <running/>
    </source>
    <target>
     <candidate/>
    </target>
  </copy-config>
</rpc>
```

delete-config

Usage guidelines

This operation deletes a configuration datastore.

In the current software version, this operation can only delete the candidate configuration store.

XML example

Delete the candidate configuration datastore.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <delete-config>
    <target>
      <candidate/>
    </target>
  </delete-config>
</rpc>
```

discard-changes

Usage guidelines

This operation restores the candidate configuration to the previously committed configuration.

XML example

Restore the candidate configuration to the previously committed configuration.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <discard-changes/>
</rpc>
```

CLI operations

CLI

Usage guidelines

This operation executes CLI commands.

A request message encloses commands in the <CLI> element. A response message encloses the command output in the <CLI> element.

You can use the following elements to execute commands:

- **Execution**—Executes commands in user view.
- **Configuration**—Executes commands in system view.

  To use this element, include the **exec-use-channel** attribute and specify a value for the attribute:

  - **false**—Executes commands without using a channel.
  - **true**—Executes commands by using a temporary channel. The channel is automatically closed after the execution.
  - **persist**—Executes commands by using the persistent channel for the session.

    To use the persistent channel, first perform an <Open-channel> operation to open the persistent channel. If you do not do so, the system will automatically open the persistent channel.

    After using the persistent channel, perform a <Close-channel> operation to close the channel and return to system view. If you do not perform an <Open-channel> operation, the system stays in the view and will execute subsequent commands in the view.

  You can also specify the **error-when-rollback** attribute in the <Configuration> element to indicate whether CLI operations are allowed during a configuration error-triggered configuration rollback. This attribute takes effect only if the value of the <error-option> element in <edit-config> operations is set to **rollback-on-error**. It has the following values:

  - **true**—Rejects CLI operation requests and returns error messages.
  - **false (the default)**—Allows CLI operations.

  For CLI operations to be correctly performed, set the value of the **error-when-rollback** attribute to **true**.

NOTE:

To execute commands in a lower-level view of the system view, use the <Configuration> element to enter the view first.

A NETCONF session can have multiple temporary channels, but it can have only one persistent channel.

This operation does not support executing interactive CLI commands.

You cannot execute the **quit** command by using a channel to exit user view.

XML example

Execute the **vlan 3** command in system view without using a channel.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
     <Configuration exec-use-channel="false" error-when-rollback="true">vlan
3</Configuration>
  </CLI>
```

```
</rpc>
```

Edit operations

edit-config: create

Usage guidelines

This operation creates target configuration items.

To use the **create** attribute in an <edit-config> operation, you must specify the target configuration item.

- If the table supports creating a target configuration item and the item does not exist, the operation creates the item and configures the item.
- If the specified item already exists, a data-exist error message is returned.

XML example

Set the buffer size to 120.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config>
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Syslog xmlns="http://www.h3c.com/netconf/config:1.0" xc:operation="create">
           <LogBuffer>
             <BufferSize>120</BufferSize>
          </LogBuffer>
        </Syslog>
      </top>
    </config>
  </edit-config>
</rpc>
```

edit-config: delete

Usage guidelines

This operation deletes the specified configuration.

- If the specified target has only the table index, the operation removes all configuration of the specified target, and the target itself.
- If the specified target has the table index and configuration data, the operation removes the specified configuration data of this target.
- If the specified target does not exist, an error message is returned, showing that the target does not exist.

XML example

The syntax is the same as the edit-config message with the **create** attribute. Change the operation attribute from **create** to **delete**.

edit-config: merge

Usage guidelines

This operation commits target configuration items to the running configuration.

To use the **merge** attribute in an <edit-config> operation, you must specify the target configuration item (on a specific level):

- If the specified item exists, the operation directly updates the setting for the item.
- If the specified item does not exist, the operation creates the item and configures the item.
- If the specified item does not exist and it cannot be created, an error message is returned.

XML example

The XML data format is the same as the edit-config message with the **create** attribute. Change the operation attribute from **create** to **merge**.

edit-config: remove

Usage guidelines

This operation removes the specified configuration.

- If the specified target has only the table index, the operation removes all configuration of the specified target, and the target itself.
- If the specified target has the table index and configuration data, the operation removes the specified configuration data of this target.
- If the specified target does not exist, or the XML message does not specify any targets, a success message is returned.

XML example

The syntax is the same as the edit-config message with the **create** attribute. Change the operation attribute from **create** to **remove**.

edit-config: replace

Usage guidelines

This operation replaces the specified configuration.

- If the specified target exists, the operation replaces the configuration of the target with the configuration carried in the message.
- If the specified target does not exist but is allowed to be created, the operation creates the target and then applies the configuration.
- If the specified target does not exist and is not allowed to be created, the operation is not conducted and an invalid-value error message is returned.

XML example

The syntax is the same as the edit-config message with the **create** attribute. Change the operation attribute from **create** to **replace**.

edit-config: *test-option*

Usage guidelines

This operation determines whether to commit a configuration item in an <edit-configure> operation. The <test-option> element has one of the following values:

- **test-then-set**—Performs a syntax check, and commits an item if the item passes the check. If the item fails the check, the item is not committed. This is the default test-option value.
- **set**—Commits the item without performing a syntax check.
- **test-only**—Performs only a syntax check. If the item passes the check, a success message is returned. Otherwise, an error message is returned.

XML example

Test the configuration for an interface.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <test-option>test-only</test-option>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr xc:operation="merge">
          <Interfaces>
            <Interface>
              <IfIndex>262</IfIndex>
              <Description>222</Description>
                <ConfigSpeed>2</ConfigSpeed>
                <ConfigDuplex>1</ConfigDuplex>
               </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </config>
  </edit-config>
</rpc>
```

edit-config: default-operation

Usage guidelines

This operation modifies the running configuration of the device by using the default operation method.

NETCONF uses one of the following operation attributes to modify configuration: **merge**, **create**, **delete**, and **replace**. If you do not specify an operation attribute for an edit-config message, NETCONF uses the default operation method. The value specified for the <default-operation> element takes effect only once. If you do not specify an operation attribute or the default operation method for an <edit-config> message, **merge** always applies.

The <default-operation> element has the following values:

- **merge**—Default value for the <default-operation> element.
- **replace**—Value used when the operation attribute is not specified and the default operation method is specified as **replace**.
- **none**—Value used when the operation attribute is not specified and the default operation method is specified as **none**. If this value is specified, the <edit-config> operation is used only for schema verification rather than issuing a configuration. If the schema verification is passed, a successful message is returned. Otherwise, an error message is returned.

XML example

Issue an empty operation for schema verification purposes.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <default-operation>none</default-operation>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <IfIndex>262</IfIndex>
              <Description>222222</Description>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </config>
  </edit-config>
</rpc>
```

edit-config: error-option

Usage guidelines

This operation determines the action to take in case of a configuration error.

The <error-option> element has the following values:

- **stop-on-error**—Stops the operation and returns an error message. This is the default error-option value.
- **continue-on-error**—Continues the operation and returns an error message.
- **rollback-on-error**—Rolls back the configuration.

XML example

Issue the configuration for two interfaces, setting the <error-option> element to **continue-on-error**.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>   <error-option>continue-on-error</error-option>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr xc:operation="merge">
          <Interfaces>
            <Interface>
              <IfIndex>262</IfIndex>
              <Description>222</Description>
                <ConfigSpeed>1024</ConfigSpeed>
```

```
            <ConfigDuplex>1</ConfigDuplex>
          </Interface>
          <Interface>
            <IfIndex>263</IfIndex>
            <Description>333</Description>
              <ConfigSpeed>1024</ConfigSpeed>
              <ConfigDuplex>1</ConfigDuplex>
          </Interface>
        </Interfaces>
      </Ifmgr>
    </top>
  </config>
 </edit-config>
</rpc>
```

edit-config: incremental

Usage guidelines

This operation adds configuration data to a column without affecting the original data.

The **incremental** attribute applies to a list column such as the vlan permitlist column.

You can use the **incremental** attribute for <edit-config> operations with an attribute other than **replace**.

Support for the **incremental** attribute varies by module. For more information, see NETCONF XML API references.

XML example

Add VLANs 1 through 10 to an untagged VLAN list that has untagged VLANs 12 through 15.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <VLAN xc:operation="merge">
          <HybridInterfaces>
            <Interface>
              <IfIndex>262</IfIndex>
              <UntaggedVlanList  h3c:incremental="true">1-10</UntaggedVlanList>
               </Interface>
          </HybridInterfaces>
        </VLAN>
      </top>
    </config>
  </edit-config>
</rpc>
```

Get operations

get

Usage guidelines

This operation retrieves device configuration and state information.

XML example

Retrieve device configuration and state information for the Syslog module.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xc="http://www.h3c.com/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Syslog>
        </Syslog>
      </top>
    </filter>
  </get>
</rpc>
```

get-bulk

Usage guidelines

This operation retrieves a number of data entries (including device configuration and state information) starting from the data entry next to the one with the specified index.

XML example

Retrieve device configuration and state information for all interfaces.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-bulk>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Ifmgr>
          <Interfaces xc:count="5" xmlns:xc="http://www.h3c.com/netconf/base:1.0">
            <Interface/>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-bulk>
</rpc>
```

get-bulk-config

Usage guidelines

This operation retrieves a number of non-default configuration data entries starting from the data entry next to the one with the specified index.

XML example

Retrieve non-default configuration for all interfaces.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-bulk-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr>
        </Ifmgr>
      </top>
    </filter>
  </get-bulk-config>
</rpc>
```

get-config

Usage guidelines

This operation retrieves non-default configuration data. If no non-default configuration data exists, the device returns a response with empty data.

XML example

Retrieve non-default configuration data for the interface table.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xc="http://www.h3c.com/netconf/base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr>
           <Interfaces>
              <Interface/>
            </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-config>
</rpc>
```

get-sessions

Usage guidelines

This operation retrieves information about all NETCONF sessions in the system. You cannot specify a session ID to retrieve information about a specific NETCONF session.

XML example

Retrieve information about all NETCONF sessions in the system.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<get-sessions/>
</rpc>
```

Other operations

action

Usage guidelines

This operation sends a non-configuration operation instruction to the device, for example, a reset instruction.

XML example

Clear statistics information for all interfaces.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <action>
    <top xmlns="http://www.h3c.com/netconf/action:1.0">
      <Ifmgr>
            <ClearAllIfStatistics>
                <Clear>
                </Clear>
        </ClearAllIfStatistics>
      </Ifmgr>
    </top>
  </action>
</rpc>
```

close-session

Usage guidelines

This operation terminates the current NETCONF session, unlocks the configuration, and releases the resources (for example, memory) used by the session. After this operation, you exit the XML view.

XML example

Terminate the current NETCONF session.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<close-session/>
</rpc>
```

kill-session

Usage guidelines

This operation terminates the NETCONF session for another user. This operation cannot terminate the NETCONF session for the current user.

XML example

Terminate the NETCONF session with session ID 1.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <kill-session>
    <session-id>1</session-id>
  </kill-session>
</rpc>
```

load

Usage guidelines

This operation loads the configuration. After the device finishes a <load> operation, the configuration in the specified file is merged into the running configuration of the device.

XML example

Merge the configuration in file **a1.cfg** to the running configuration of the device.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <load>
    <file>a1.cfg</file>
  </load>
</rpc>
```

lock

Usage guidelines

This operation locks the configuration. After you lock the configuration, other users cannot perform <edit-config> operations. Other NETCONF operations are allowed.

After a user locks the configuration, other users cannot use NETCONF or any other configuration methods such as CLI and SNMP to configure the device.

XML example

Lock the configuration.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
 <lock>
    <target>
        <running/>
    </target>
</lock>
</rpc>
```

rollback

Usage guidelines

This operation rolls back the configuration. To do so, you must specify the configuration file in the <file> element. After the device finishes the <rollback> operation, the current device configuration is totally replaced with the configuration in the specified configuration file.

XML example

Roll back the running configuration to the configuration in file **1A.cfg**.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <rollback>
    <file>1A.cfg</file>
  </rollback>
</rpc>
```

save

Usage guidelines

This operation saves the running configuration. You can use the <file> element to specify a file for saving the configuration. If the text does not include the file column, the running configuration is automatically saved to the main next-startup configuration file.

The **OverWrite** attribute determines whether the running configuration overwrites the original configuration file when the specified file already exists.

The **Binary-only** attribute determines whether to save the running configuration only to the binary configuration file.

The **Safely** attribute determines whether to save the configuration file in safe mode or fast mode.

XML example

Save the running configuration to file **test.cfg**.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save OverWrite="false">
    <file>test.cfg</file>
  </save>
</rpc>
```

unlock

Usage guidelines

This operation unlocks the configuration, so other users can configure the device.

Terminating a NETCONF session automatically unlocks the configuration.

XML example

Unlock the configuration.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<unlock>
    <target>
        <running/>
    </target>
</unlock>
</rpc>
```

xml2cli

Usage guidelines

This operation retrieves the CLI command for an operation issued in XML format.

The returned commands are enclosed in a pair of <cli> and </cli> tags.

XML example

Retrieve the commands for an operation on the GRPC/Configuration table.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<xml2cli>
    <GRPC>
        <Configuration>
            <State>enable</State>
            <Port>50052</Port>
            <IdleTime>25</IdleTime>
        </Configuration>
    </GRPC>
 </xml2cli>
</rpc>
```

The device returns the commands for the operation, as shown below:

```
<?xml version="1.0">
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<xml2cli>
    <GRPC>
        <Configuration>
            <cli>grpc enable
            grpc port 50052
            grpc idle-timeout 25</cli>
            <State>enable</State>
            <Port>50052</Port>
            <IdleTime>25</IdleTime>
        </Configuration>
    </GRPC>
</xml2cli>
</rpc-reply>
```

Except for the trademarks of New H3C Technologies Co., Ltd., any trademarks that may be mentioned in this document are the property of their respective owners.

Notice

The information in this document is subject to change without notice. All contents in this document, including statements, information, and recommendations, are believed to be accurate, but they are presented without warranty of any kind, express or implied. H3C shall not be liable for technical or editorial errors or omissions contained herein.

Preface

This configuration guide describes the Telemetry fundamentals and configuration procedures.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

Configuring gRPC

About gRPC

gRPC is an open source remote procedure call (RPC) system initially developed at Google. It uses HTTP 2.0 and provides network device configuration and management methods that support multiple programming languages.

gRPC protocol stack layers

Table 1 describes the gRPC protocol stack layers.

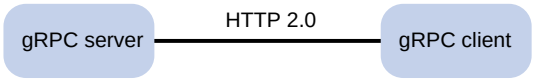

Table 1 gRPC protocol stack layers

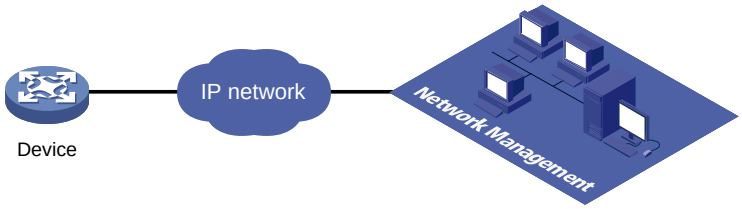
Layer	Description
Content layer	Defines the data of the service module. Two peers must notify each other of the data models that they are using.
Protocol buffer encoding layer	Encodes data by using the protocol buffer code format.
gRPC layer	Defines the protocol interaction format for remote procedure calls.
HTTP 2.0 layer	Carries gRPC.
TCP layer	Provides connection-oriented reliable data links.

Network architecture

As shown in Figure 1, the gRPC network uses the client/server model. It uses HTTP 2.0 for packet transport.

Figure 1 gRPC network architecture

The gRPC network uses the following mechanism:



1. The gRPC server listens to connection requests from clients at the gRPC service port.
2. A user runs the gRPC client application to log in to the gRPC server, and uses methods provided in the .proto file to send requests.
3. The gRPC server responds to requests from the gRPC client.

The device can act as the gRPC server or client.

Telemetry technology based on gRPC

Telemetry is a remote data collection technology for monitoring device performance and operating status. H3C telemetry technology uses gRPC to push data from the device to the collectors on the NMSs. As shown in Figure 2, after a gRPC connection is established between the device and NMSs, the NMSs can subscribe to data of modules on the device.

Figure 2 Telemetry technology based on gRPC

Telemetry modes

The device supports the following telemetry modes:

- **Dial-in mode**—The device acts as a gRPC server and the collectors act as gRPC clients. A collector initiates a gRPC connection to the device to subscribe to device data.

  Dial-in mode supports the following operations:

  - **Get**—Obtains device status and settings.
  - **CLI**—Executes commands on the device.
  - **gNMI**—gRPC Network Management Interface operations, which include the following subtypes of operations:
    - **gNMI Capabilities**—Obtains the capacities of the device.
    - **gNMI Get**—Obtains the status and settings of the device.
    - **gNMI Set**—Deploys settings to the device.
    - **gNMI Subscribe**—Subscribes to data push services provided by the device. The data might be generated by periodical data collection, event-triggered data collection, or condition-triggered data collection.
- **Dial-out mode**—The device acts as a gRPC client and the collectors act as gRPC servers. The device initiates gRPC connections to the collectors and pushes device data to the collectors as configured.

Telemetry data model architectures

The device supports the following telemetry data model architectures:

- **Three-layer data model architecture**—Contains the following three layers:
  - **RPC layer**—Defined in public proto definition files **grpc_dialout.proto** and **grpc_dialout_v3.proto**. This layer provides public RPC methods such as the message format.
  - **Telemetry layer**—Defined in the public proto definition file **telemetry.proto**. This layer provides data collection-related services.
  - **Content layer**—Carries GPB or JSON encoded service data.

  The RPC and telemetry layers are identical to the gRPC layer in the gRPC protocol stack.
- **Two-layer data model architecture**—Contains the RPC and content layers. Two-layer data models support only JSON for service data encoding.

gNMI

gRPC Network Management Interface (gNMI) is a gRPC-based protocol for network device management. It defines a series of RPC methods to obtain or configure the states of devices.

The device supports gNMI and non-gNMI subscriptions for pushing data to a collector.

Protocols

RFC 7540, *Hypertext Transfer Protocol version 2 (HTTP/2)*

Restrictions: Hardware compatibility with gRPC

gRPC is available only on the S5200-HI-G switch series.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

gRPC is not supported in FIPS mode.

Restrictions and guidelines: gRPC configuration

Disabling the gRPC service deletes all gRPC-related settings.

If you do not specify the source IP address for packets sent to collectors on the device, the **deviceIpAddr** field displays **not-config** in data pushed to the collectors in dial-out mode when the two-layer telemetry data model is used. To specify the source IP address for packets sent to collectors, use the **`source-address`** command.

gRPC configuration tasks at a glance

Configure gRPC dial-in and dial-out modes as needed:

1. Configuring the gRPC dial-in mode

   Configure gRPC dial-in when the device acts as a gRPC server to communicate with collectors that act as gRPC clients.

   a. Configuring the gRPC service
   b. Configuring a gRPC user
   c. (Optional.) Enabling gRPC logging in dial-in mode
2. Configuring the gRPC dial-out mode

   Configure gRPC dial-out when the device acts as a gRPC client to communicate with collectors that act as gRPC servers.

   a. Enabling the gRPC service
   b. Configuring sensors
   c. Configuring collectors
   d. Configuring a subscription
   e. (Optional.) Enabling gRPC logging in dial-out mode
3. (Optional.) Specifying the PKI domain for secure communication with collectors
4. (Optional.) Setting the maximum CPU usage for gRPC
5. (Optional.) Enabling event-triggered data to be pushed in a prioritized manner

Configuring the gRPC dial-in mode

Configuring the gRPC service

1. Enter system view.
   system-view
2. Enable the gRPC service.
   grpc enable
   By default, the gRPC service is disabled.
3. (Optional.) Specify an ACL to identify the gRPC clients allowed to establish gRPC sessions.
   grpc acl [**ipv6**] { *acl-number* | **name** *acl-name* }
   By default, no ACL is used for identifying the gRPC clients allowed to establish gRPC sessions.
   Associating an ACL with gRPC causes the gRPC service to restart, disconnecting the ongoing sessions. The clients must re-establish gRPC sessions.
   You can use this command to specify only one IPv4 ACL and one IPv6 ACL. If you execute this command multiple times, the most recent specified IPv4 ACL and IPv6 ACL take effect.
4. (Optional.) Set the gRPC service port number.
   grpc port *port-number*
   By default, the gRPC service port number is 50051.
5. (Optional.) Set the gRPC session idle timeout timer.
   grpc idle-timeout *minutes*
   By default, the gRPC session idle timeout timer is 5 minutes.
6. (Optional.) Specify a data compression method for the gRPC server.
   grpc compression gzip
   By default, the gRPC server does not compress the transmitted data.
   Changing the data compression method for the gRPC server reboots the gRPC service and disconnects all sessions established between the gRPC server and its gRPC clients. The gRPC clients must reinitiate the sessions.
7. (Optional.) Disable the gRPC dial-in mode.
   undo grpc server enable
   By default, the gRPC dial-in mode is enabled.

Configuring a gRPC user

About this task

For gRPC clients to establish gRPC sessions with the device, you must configure local users for the gRPC clients.

Procedure

1. Enter system view.
   system-view
2. Add a local user with the device management right.
   local-user *user-name* [**class manage**]
3. Configure a password for the user.
   password [{ **hash** | **simple** } *password*]

By default, no password is configured for a local user. A non-password-protected user can pass authentication after providing the correct username and passing attribute checks.

4. Assign user role network-admin to the user.

   authorization-attribute user-role *user-role*

   By default, a local user is assigned the network-operator role.

5. Authorize the user to use the HTTPS service.

   service-type https

   By default, no service types are authorized to a local user.

For more information about the **local-user**, **password**, **authorization-attribute**, and **service-type** commands, see AAA configuration in *Security Command Reference*.

Enabling gRPC logging in dial-in mode

About this task

To identify issues with gRPC in dial-in mode, enable gRPC operations logging in dial-in mode.

This feature generates gRPC operation logs in dial-in mode and sends them to the information center.

With the information center, you can configure log destinations and output rules. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

gRPC operation logging might degrade device performance if gRPC operations are frequent. As a best practice, use gRPC operation logging only when necessary and log only gRPC operations of interest if gRPC operation logging is enabled.

Procedure

1. Enter system view.

   system-view

2. Enable gRPC logging in dial-in mode. Choose the options to configure as needed:

   - Enable gRPC logging for RPC operations in dial-in mode.

     grpc log dial-in rpc { **all** | { **cli** | **get** }* }

     By default, gRPC logging is disabled for RPC operations in dial-in mode.

   - Enable gRPC logging for gNMI operations in dial-in mode.

     grpc log dial-in gnmi { **all** | { **capabilities** | **get** | **set** | **subscribe** }* }

     By default, gRPC logging is enabled for gNMI Set operations and disabled for other gNMI operations in dial-in mode.

Configuring the gRPC dial-out mode

Enabling the gRPC service

1. Enter system view.

   system-view

2. Enable the gRPC service.

   grpc enable

By default, the gRPC service is disabled.

3. (Optional.) Specify the architecture of telemetry data models.

   grpc data-model { **2-layer** | **3-layer** }

   By default, the device uses two-layer telemetry data models to push data.

   With the two-layer telemetry data model architecture, the device can only encode pushed data in JSON format.

Configuring sensors

About this task

A sensor is a data path from which the device collects data and then pushes the data to a collector. You can create a sensor group and then specify sensor paths in the group. Sensor groups include non-gNMI sensor groups and gNMI sensor groups. If the collector uses gNMI, you must create gNMI sensor groups.

Sensor paths have the following types:

- **Event-triggered**—The device pushes data from the sensor path to the collector when certain events occur. For information about event-triggered sensor paths, see *NETCONF XML API Event Reference* for the module.
- **Periodic**—The device pushes data from the sensor path to the collector at intervals. For information about periodic sensor paths, see the NETCONF XML API references for the module except for *NETCONF XML API Configuration Reference* and *NETCONF XML API Data Reference*.
- **Condition-triggered**—The device checks the data of the sensor path periodically and pushes the data from the sensor path to the collector when certain conditions are met. For information about condition-triggered sensor paths, the sensor path check interval, and data push conditions, contact H3C Support.

  Condition-triggered sensor paths are supported only by gNMI sensor groups.

Restrictions and guidelines

As a best practice for the device to push data from sensor paths, specify sensor paths of the same type in a sensor group.

Configuring a non-gNMI sensor group

1. Enter system view.

   system-view

2. Enter telemetry view.

   telemetry

3. Create a non-gNMI sensor group and enter sensor group view.

   sensor-group *group-name*

4. Specify a sensor path.

   sensor path *path* [**selection-nodes** *node-list*]

   To specify multiple sensor paths, execute this command multiple times. If you execute this command multiple times with the same sensor path specified, the most recent configuration takes effect.

Configuring a gNMI sensor group

1. Enter system view.

   system-view

2. Enter telemetry view.

telemetry

3. Create a gNMI sensor group and enter sensor group view.

   sensor-group *group-name* **gnmi**

   To enter the view of an existing gNMI sensor group, you do not need to specify the **gnmi** keyword.

4. Specify a sensor path.

   sensor path *path* [**selection-nodes** *node-list*]

   To specify multiple sensor paths, execute this command multiple times.

Configuring collectors

About this task

Collectors receive sampled data from network devices. For the device to communicate with collectors, you must create a destination group and add collectors to the destination group.

You can add collectors to a destination group by their IP addresses or domain names. When you specify collectors by their domain names, use the following restrictions and guidelines:

- You must configure DNS to make sure the device can translate the domain names of the collectors to IP addresses. For more information about DNS, see *Layer 3—IP Services Configuration Guide*.
- To view domain name and IP address mappings, use the **display dns host** command. If a domain name maps to multiple IP addresses, the device will push data to the first reachable IP address.

To encrypt the gRPC connections between the device and the target collector, use one of the following methods:

- Enable TLS encryption globally for all gRPC connections by executing the **grpc pki domain** command in system view. The device uses the TLS certificates in the specified PKI domain for encryption.
- Enable collector-specific TLS encryption by specifying the **tls** keyword when you add a collector to a destination group. The device uses one root TLS certificate that came with it to encrypt the gRPC connection to the specified collector.

For a collector, the setting in system view has higher priority than the collector-specific setting.

Restrictions and guidelines

As a best practice, configure a maximum of five destination groups. If you configure too many destination groups, system performance might degrade.

Prerequisites

To configure a collector that resides in a VPN instance, configure the VPN instance first. For more information about VPN instance configuration, see MCE configuration in *MCE Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter telemetry view.

   telemetry

3. Create a destination group and enter destination group view.

   destination-group *group-name*

4. Add a collector to the destination group by its IP address.

   IPv4:

ipv4-address *ipv4-address* [**port** *port-number*] [**vpn-instance** *vpn-instance-name*] [**tls**]

IPv6:

ipv6-address *ipv6-address* [**port** *port-number*] [**vpn-instance** *vpn-instance-name*] [**tls**]

The IPv6 address cannot be a link-local address. For more information about link-local addresses, see IPv6 basics configuration in *Layer 3—IP Services Configuration Guide*.

To add multiple collectors, repeat this command. A collector is uniquely identified by a combination of the IP address, VPN instance name, and port number elements. One collector must have a different element than the other collectors in the destination group.

5. Add a collector to the destination group by its domain name.

   IPv4:

   domain-name *domain-name* [**port** *port-number*] [**vpn-instance** *vpn-instance-name*] [**tls**]

   IPv6:

   ipv6 domain-name *domain-name* [**port** *port-number*] [**vpn-instance** *vpn-instance-name*] [**tls**]

   To add multiple collectors, repeat this command. A collector is uniquely identified by a combination of the domain name, VPN instance name, and port number elements. One collector must have a different element than the other collectors in the destination group.

Configuring a subscription

About this task

A subscription binds sensor groups to destination groups. Then, the device pushes data from the specified sensors to the collectors in the destination groups.

Subscriptions include non-gNMI subscriptions and gNMI subscriptions. To push data to a collector that uses gNMI, you must configure a gNMI subscription.

Restrictions and guidelines

For a non-gNMI subscription, specify non-gNMI sensor groups.

For a gNMI subscription, specify gNMI sensor groups.

You cannot use a destination group in both a gRPC subscription and a gNMI subscription.

For the device to correctly push data from sensor paths in a sensor group, make sure the subscription settings for the sensor paths are compliant with Table 2.

Table 2 Compatibility of sensor path types and subscription settings

Sensor path type	Push mode	Data push interval	Data push suppression interval
Periodical	Default	Configured	Not configured
Event-triggered	Default	Not configured	Not configured
Condition-triggered	Condition-triggered	Not configured	Configured

Configuring a non-gNMI subscription

1. Enter system view.

   system-view

2. Enter telemetry view.

telemetry

3. Create a non-gNMI subscription and enter subscription view.

   subscription *subscription-name*

4. (Optional.) Specify a transport protocol and a data compression method for the device to send packets to collectors.

   protocol grpc compression gzip

   By default, the device uses gRPC (TCP) as the transport protocol to send packets to collectors and does not compress the packet data.

5. (Optional.) Set the DSCP value for packets sent to collectors.

   dscp *dscp-value*

   By default, the DSCP value for packets sent to collectors is 0.

   A greater DSCP value represents a higher priority.

6. (Optional.) Specify the source IP address for packets sent to collectors.

   source-address { *ipv4-address* | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

   By default, the device uses the primary IPv4 address of the output interface for the route to the collectors as the source address.

   Changing the source IP address for packets sent to collectors causes the device to re-establish the connection to the gRPC server.

7. (Optional.) Specify the encoding format for pushed data.

   encoding { **gpb** | **json** }

   By default, the device uses the JSON format to encode pushed data.

   The device can use the GPB format to encode pushed data only when it uses three-layer telemetry data models to push data.

8. (Optional.) Enable per-row time-stamping for JSON-encoded subscription data.

   json row-timestamp enable

   By default, the device time-stamps JSON-encoded subscription data on a per-message basis.

   This command is not supported when the device uses the three-layer telemetry data model architecture.

9. Specify a sensor group.

   sensor-group *group-name* [**sample-interval** [**msec**] *interval* | **suppress-time** *suppress-time*]

   By default, no sensor groups are specified.

10. Specify a destination group.

    destination-group *group-name*

    By default, no destination groups are specified.

Configuring a gNMI subscription

1. Enter system view.

   system-view

2. Enter telemetry view.

   telemetry

3. *Create a gNMI subscription* and enter subscription view.

   subscription *subscription-name* **gnmi**

   To enter the view of an existing gNMI *subscription*, you do not need to specify the **gnmi** keyword.

4. (Optional.) Set the data push mode.

   push-mode condition-triggered

   Perform this step only if a sensor group specified for a subscription contains condition-triggered sensor paths.

   By default, the data push mode for a sensor path in a subscription is periodical or event-triggered.

5. (Optional.) Set the DSCP value for packets sent to collectors.

   dscp *dscp-value*

   By default, the DSCP value for packets sent to collectors is 0.

   A greater DSCP value represents a higher priority.

6. (Optional.) Specify the source IP address for packets sent to collectors.

   source-address { *ipv4-address* | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

   By default, the device uses the primary IPv4 address of the output interface for the route to the collectors as the source address.

   Changing the source IP address for packets sent to collectors causes the device to re-establish the connection to the gRPC server.

7. Specify a sensor group.

   sensor-group *group-name* [**sample-interval** [**msec**] *interval* | **suppress-time** *suppress-time*]

   By default, no sensor groups are specified.

8. Specify a destination group.

   destination-group *group-name*

   By default, no destination groups are specified.

Enabling gRPC logging in dial-out mode

About this task

To identify issues with gRPC in dial-out mode, enable gRPC data collection logging in dial-out mode.

This feature generates gRPC data collection logs in dial-out mode and sends them to the information center.

With the information center, you can configure log destinations and output rules. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

gRPC logging in dial-out mode is unavailable for gNMI subscriptions.

Procedure

1. Enter system view.

   system-view

2. Enable gRPC logging in dial-out mode.

   grpc log dial-out { **all** | { **event** | **sample** }* }

   By default, gRPC logging is disabled in dial-out mode.

Specifying the PKI domain for secure communication with collectors

About this task

By default, the gRPC connection between the device and a collector does not provide data encryption service or require authentication. After you specify a PKI domain, the device and the collector will use TLS for data encryption and bidirectional certificate-based authentication to improve communication security.

Restrictions and guidelines

The specified PKI domain must already exist and has correct certificate and key settings. For more information about PKI domains, see PKI configuration in *Security Configuration Guide*.

After you specify the PKI domain, the gRPC function will reboot, closing the connections to collectors. In dial-in mode, the collectors must re-initiate the connections. In dial-out mode, the device will automatically re-initiate the connections.

Procedure

1. Enter system view.
   `system-view`
2. Specify the PKI domain for secure communication with collectors.
   `grpc pki domain` *`domain-name`*
   By default, no PKI domain is specified for secure communication with collectors.

Setting the maximum CPU usage for gRPC

About this task

gRPC data sampling is CPU intensive. To prevent gRPC from negatively affecting other services, limit its maximum CPU usage. If the specified maximum CPU usage is exceeded during data sampling, gRPC suspends data sampling until after its CPU usage drops below the specified limit.

Procedure

1. Enter system view.
   `system-view`
2. Specify the PKI domain for secure communication with collectors.
   `grpc cpu-usage max-percent` *`percentage`*
   By default, no CPU usage limit is set for gRPC.

Enabling event-triggered data to be pushed in a prioritized manner

About this task

The gRPC feature might consume a large number of CPU resources during sampling and data pushing. To avoid affecting other services, configure this feature to control the amount of data pushed to the collector.

After you enable this feature, if the CPU usage reaches the threshold and triggers an alarm, only some event-triggered data (such as CPU usage and memory threshold) is pushed to the collector. Reporting of other event-triggered data is delayed or stopped to reduce CPU usage.

Procedure

1. Enter system view.

   system-view

2. Enable event-triggered data to be pushed in a prioritized manner.

   grpc event-trigger priority enable

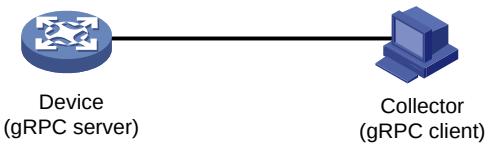
   By default, event-triggered data is disabled from being pushed in a prioritized manner.

Display and maintenance commands for gRPC

Execute **display** commands in any view.

Task	Command
Display gRPC information.	**display grpc** [**verbose**]
Display periodic sensor paths that have the minimum sampling interval.	**display telemetry sensor-path**

gRPC configuration examples



These configuration examples describe only CLI configuration tasks on the device. The collectors need to run an extra application. For information about collector-side application development, see "Developing the collector-side application (dial-in mode)."

Example: Configuring the gRPC dial-in mode

Network configuration

As shown in Figure 3, configure the gRPC dial-in mode on the device so the device acts as the gRPC server and the gRPC client can subscribe to LLDP events on the device.

Figure 3 Network diagram

Procedure

1. Assign IP addresses to interfaces on the gRPC server and client and configure routes. Make sure the server and client can reach each other.
2. Configure the device as the gRPC server:

   # Enable the gRPC service.

   ```
   <Device> system-view
   [Device] grpc enable
   ```

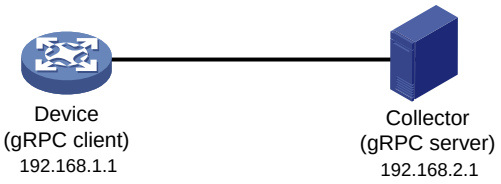
   # Create a local user named **test**. Set the password of the user, and assign user role network-admin and the HTTPS service to the user.

```
[Device] local-user test
[Device-luser-manage-test] password simple 123456TESTplat&!
[Device-luser-manage-test] authorization-attribute user-role network-admin
[Device-luser-manage-test] service-type https
[Device-luser-manage-test] quit
```

3. Configure the gRPC client.
   a. Prepare a PC and install the gRPC environment on the PC. For more information, see the user guide for the gRPC environment.
   b. Obtain the H3C proto definition file and uses the protocol buffer compiler to generate code of a specific language, for example, Java, Python, C/C++, or Go.
   c. Create a client application to call the generated code.
   d. Start the application to log in to the gRPC server.

Verifying the configuration

When an LLDP event occurs on the gRPC server, verify that the gRPC client receives the event.



Example: Configuring event-triggered telemetry in gRPC dial-out mode

Network configuration

As shown in Figure 4, the device acts as a gRPC client and connects to the telemetry data collector (a gRPC server). The collector receives data on port 50050.

Configure the device to operate in dial-out mode to push interface event data to the collector.

Figure 4 Network diagram

Restrictions and guidelines

When you execute the **sensor-group** command in subscription view to specify a sensor group that contains event-triggered sensor paths for a subscription, do not use the **sample-interval** to set a data push interval.

NOTE:

An event-triggered sensor path typically contains a string of **event** in its path name.

Procedure

Configure IP addresses as required so the device and the collector can reach each other. (Details not shown.)

Enable gRPC.

```
<Device> system-view
[Device] grpc enable
```

Create a sensor group named **Test**, and add sensor path **ifmgr/interfaceevent** to it.

```
[Device] telemetry
[Device-telemetry] sensor-group Test
```

```
[Device-telemetry-sensor-group-Test] sensor path ifmgr/interfaceevent
[Device-telemetry-sensor-group-Test] quit
```

Create a destination group named **collector1** and add a collector to the group. In this example, the collector receives data on port 50050 at IPv4 address 192.168.2.1.

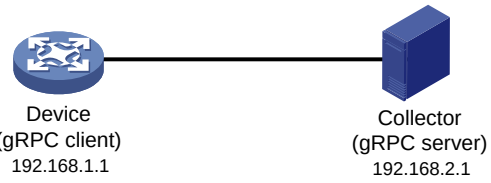
```
[Device-telemetry] destination-group collector1
[Device-telemetry-destination-group-collector1] ipv4-address 192.168.2.1 port 50050
[Device-telemetry-destination-group-collector1] quit
```

Configure a subscription named **B** to bind sensor group **Test** with destination group **collector1**.

```
[Device-telemetry] subscription B
[Device-telemetry-subscription-B] sensor-group Test
[Device-telemetry-subscription-B] destination-group collector1
[Device-telemetry-subscription-B] quit
```

Verifying the configuration

Access the collector and verify that the collector can receive the interface event data pushed by the device. (Details not shown.)



Example: Configuring the gRPC dial-out mode

Network configuration

As shown in Figure 5, the device is connected to a collector. The collector uses port 50050.

Configure gRPC dial-out mode on the device so the device pushes the device capability information of its interface module to the collector at 10-second intervals.

Figure 5 Network diagram

Procedure

Configure IP addresses as required so the device and the collector can reach each other. (Details not shown.)

Enable the gRPC service.

```
<Device> system-view
[Device] grpc enable
```

Create a sensor group named **test**, and add sensor path **ifmgr/devicecapabilities/**.

```
[Device] telemetry
[Device-telemetry] sensor-group test
[Device-telemetry-sensor-group-test] sensor path ifmgr/devicecapabilities/
[Device-telemetry-sensor-group-test] quit
```

Create a destination group named **collector1**. Specify a collector that uses IPv4 address 192.168.2.1 and port number 50050.

```
[Device-telemetry] destination-group collector1
[Device-telemetry-destination-group-collector1] ipv4-address 192.168.2.1 port 50050
[Device-telemetry-destination-group-collector1] quit
```

Configure a subscription named **A** to bind sensor group **test** with destination group **collector1**. Set the data push interval to 10 seconds.

```
[Device-telemetry] subscription A
[Device-telemetry-subscription-A] sensor-group test sample-interval 10
[Device-telemetry-subscription-A] destination-group collector1
[Device-telemetry-subscription-A] quit
```

Verifying the configuration

Verify that the collector receives the device capability information of the interface module from the device at 10-second intervals. (Details not shown.)

Protocol buffer code

Protocol buffer code format

Google Protocol Buffers provide a flexible mechanism for serializing structured data. Different from XML code and JSON code, the protocol buffer code is binary and provides higher performance.

Table 3 compares a protocol buffer code format example and the corresponding JSON code format example.

Proto definition files

You can define data structures in a proto definition file. Then, you can compile the file with utility protoc to generate code in a programing language such as Java and C++. Using the generated code, you can develop an application for a collector to communicate with the device.

H3C provides proto definition files for both dial-in mode and dial-out mode.

Proto definition files in dial-in mode

Public proto definition files

Dial-in mode supports the following public proto definition files:

- **grpc_service.proto**—Defines the public RPC methods in dial-in mode.
- **gnmi.proto**—Defines the public RPC methods for gNMI operations.
- **gnmi_ext.proto**—Defines the extended message structures required by file **gnmi.proto**.

Files **gnmi.proto** and **gnmi_ext.proto** are from Google. For information about the download paths, see "Obtaining proto definition files."

The **grpc_service.proto** file is provided by H3C. The following are the contents of the file:

```
syntax = "proto2";
package grpc_service;
message GetJsonReply {   // Reply to the Get method
    required string result = 1;
}
message SubscribeReply { // Subscription result
    required string result = 1;
}
message ConfigReply {    // Configuration result
    required string result = 1;
}
message ReportEvent {    // Subscribed event
    required string token_id = 1;    // Login token_id
    required string stream_name = 2; // Event stream name
    required string event_name = 3;  // Event name
    required string json_text = 4;   // Subscription result, a JSON string
}
message GetReportRequest{ // Obtains the event subscription result
    required string token_id = 1; // Returns the token_id upon a successful login
}
message LoginRequest {  // Login request parameters
    required string user_name = 1; // Username
    required string password = 2; // Password
}
message LoginReply {  // Reply to a login request
    required string token_id = 1; // Returns the token_id upon a successful login
}
message LogoutRequest { // Logout parameter
    required string token_id = 1; // token_id
}
```

```
message LogoutReply { // Reply to a logout request
    required string result = 1; // Logout result
}
message SubscribeRequest { // Event stream name
    required string stream_name = 1;
}
message CliConfigArgs { // Sends a configuration command and the parameters to the device
    required int64 ReqId = 1; // Command request ID
    required string cli = 2;  // Command string
}
message CliConfigReply { // Reply to a configuration command execution request
    required int64 ResReqId = 1; // Request ID, which corresponds to that in CliConfigArgs
  required string output = 2;    // Output from the command
    required string errors = 3;  // Command execution result
}
message DisplayCmdArgs { // Sends a display command and the parameters to the device
    required int64 ReqId = 1; // Command request ID
    required string cli = 2;  // Command string
}
message DisplayCmdReply { // Reply to a display command execution request
    required int64 ResReqId =1; // Request ID, which corresponds to that in DisplayCmdArgs
    required string output = 2;  // Output from the command
    required string errors = 3;  // Command execution result
}
service GrpcService {    // gRPC methods
    rpc Login (LoginRequest) returns (LoginReply) {}      // Login method
    rpc Logout (LogoutRequest) returns (LogoutReply) {}   // Logout method
    rpc SubscribeByStreamName (SubscribeRequest) returns (SubscribeReply) {} // Event
subscription method
    rpc GetEventReport (GetReportRequest) returns (stream ReportEvent) {} // Method for
obtaining the subscribed event
    rpc CliConfig (CliConfigArgs)  returns (stream CliConfigReply) {} // Method for
executing a configuration command and returning the execution result
    rpc DisplayCmdTextOutput(DisplayCmdArgs)  returns(stream DisplayCmdReply) {} //
Method for executing a display command and returning the execution result
}
```

Proto definition files for service modules

The dial-in mode supports proto definition files for the following service modules: Device, Ifmgr, IPFW, LLDP, and Syslog.

The following are the contents of the **Device.proto** file, which defines the RPC methods for the Device module:

```
syntax = "proto2";
import "grpc_service.proto";
package  device;
message DeviceBase { // Structure for obtaining basic device information
    optional string HostName = 1;    // Device name
    optional string HostOid = 2;     // sysoid
    optional uint32 MaxChassisNum = 3;    // Maximum number of chassis
```

```
    optional uint32 MaxSlotNum = 4;  // Maximum number of slots
    optional string HostDescription = 5; // Device description
}
message DevicePhysicalEntities { // Structure for obtaining physical entity information
of the device
    message Entity {
        optional uint32 PhysicalIndex = 1;    // Entity index
        optional string VendorType = 2;       // Vendor type
        optional uint32 EntityClass = 3;      // Entity class
        optional string SoftwareRev = 4;      // Software version
        optional string SerialNumber = 5;     // Serial number
        optional string Model = 6;            // Model
    }
    repeated Entity entity = 1;
}
service DeviceService { // RPC methods
    rpc GetJsonDeviceBase(DeviceBase) returns (grpc_service.GetJsonReply) {} // Method
for obtaining basic device information
    rpc GetJsonDevicePhysicalEntities(DevicePhysicalEntities) returns
(grpc_service.GetJsonReply) {}   // Method for obtaining physical entity information of
the device
}
```

Proto definition file in dial-out mode

Public proto definition files

Dial-out mode supports the following public proto definition files:

- **grpc_dialout.proto**—Defines the public RPC methods in dial-out mode.
- **grpc_dialout_v3.proto**—Defines the public RPC methods for three-layer telemetry data models in dial-out mode.
- **telemetry.proto**—Defines data sampling parameters for three-layer telemetry data models in dial-out mode.
- **dial_out.proto**—Defines the subscription message formats for gNMI subscriptions in dial-out mode.
- **gnmi.proto**—Defines the public RPC methods in gNMI subscriptions.
- **gnmi_ext.proto**—Defines the extended message structures required by file **gnmi.proto**.

File **dial_out.proto** is from SONIC, and files **gnmi.proto** and **gnmi_ext.proto** are from Google. For information about the download paths, see "Obtaining proto definition files."

The **grpc_dialout.proto** file is provided by H3C. The following are the contents of the file:

```
syntax = "proto2";
package grpc_dialout;
message DeviceInfo{  // Pushed device information
    required string producerName = 1; // Vendor name
    required string deviceName = 2;   // Device name
    required string deviceModel = 3;  // Device model
}
message DialoutMsg{   // Format of the pushed data
    required DeviceInfo deviceMsg = 1; // Device information described by DeviceInfo
```

```
    required string sensorPath = 2; // Sensor path, which corresponds to xpath in NETCONF
    required string jsonData = 3;  // Sampled data, a JSON string
}
message DialoutResponse{  // Response from the collector. Reserved. The value is not
processed.
    required string response = 1;
}
service GRPCDialout {  // Data push method
    rpc Dialout(stream DialoutMsg) returns (DialoutResponse);
}
```

The following is the content of the **grpc_dialout_v3.proto** file:

```
syntax = "proto3";
package grpc_dialout_v3;

message DialoutV3Args{
    int64 ReqId = 1;// Request ID
    bytes data = 2;// Carried data
    string errors = 3;// Error description.
    int32 totalSize = 4;// Total size of the message when fragmented. Value 0 indicates
that the message is not fragmented.
}
service gRPCDialoutV3{
    rpc DialoutV3(stream DialoutV3Args) returns (stream DialoutV3Args) {};
}
```

The following is the content of the **telemetry.proto** file:

```
syntax = "proto3";
package telemetry;
message Telemetry {
    string producer_name = 1;// Vendor name
    string node_id_str = 2;// Device name
    string product_name = 3;// Product name
    string subscription_id_str = 15;// Subscription name
    string sensor_path = 16;// Sensor path
    uint64 collection_id = 17;// Sampling ID
    uint64 collection_start_time = 18;// Start time of the sampling period
    uint64 msg_timestamp = 19;// Timestramp when this message was generated
    uint64 collection_end_time = 20;// End time of the sampling period
    uint32 current_period = 21;// Sampling accuracy
    string except_desc = 22;// Error description
    enum Encoding {
        Encoding_JSON = 0;// GPB encoding format
        Encoding_GPB = 1;// JSON encoding format
        };
    Encoding encoding = 23;// Data encoding format
    string data_str = 24;// This field is valid only when a non-GPB encoding is used. If
GPB encoding is used, this field is null.
    TelemetryGPBTable data_gpb = 25;// This filed indicates that the data carried is
defined in TelemetryGPBTable.
}
```

```
message TelemetryGPBTable {
    repeated TelemetryRowGPB row = 1;// Array definition, which indicates that the data
contains multiple TelemetryRowGPB structures.
}
message TelemetryRowGPB {
    uint64 timestamp = 1;// Timestramp of the current sampling instance
    bytes keys = 10;// Reserved field
    bytes content = 11;// Data carried by the sampling instance
}
```

Proto definition files for service modules

If service data is in GPB format, the device must use the proto definition file for the service module to decode the data.

The dial-out mode supports proto definition files for the Device and Ifmgr service modules.

Obtaining proto definition files

To obtain proto files, contact H3C Support.

You can also download files **gnmi.proto**, **gnmi_ext.proto**, and **dial-out.proto** from the following websites respectively:

- https://github.com/openconfig/gnmi/tree/master/proto/gnmi/gnmi.proto
- https://github.com/openconfig/gnmi/tree/master/proto/gnmi_ext/gnmi_ext.proto
- https://github.com/Azure/sonic-telemetry/blob/master/proto/dial_out.proto

Example: Developing a gRPC collector-side application

Use a language (for example, C++) to develop a gRPC collector-side application on Linux to achieve the following goals:

- Collect device data by using Get, gNMI Capabilities, gNMI Get, or gNMI Subscribe operations in dial-in mode or by using dial-out mode.
- Send settings to the device by using gNMI Set or CLI operations in dial-in mode.

Prerequisites

1. Obtain proto definition files.
   - For Get operations in dial-in mode, obtain the **grpc_service.proto** file and proto definition files for service modules.
   - For gNMI operations in dial-in mode, obtain files **grpc_service.proto**, **gnmi.proto**, and **gnmi_ext.proto**.
   - For CLI operations in dial-in mode, obtain the **grpc_service.proto** file.
   - For non-gNMI subscriptions in dial-out mode, obtain the **grpc_dialout.proto** file.
   - For gNMI subscriptions in dial-out mode, obtain the **dial_out.proto**, **gnmi.proto**, and **gnmi_ext.proto** files.
2. Obtain utility protoc from https://github.com/google/protobuf/releases.
3. Obtain the protobuf plug-in for C++ (**protobuf-cpp**) from https://github.com/google/protobuf/releases.

Generating the C++ code for the proto definition files

Dial-in mode

Copy the required proto definition files to the current directory, for example, **grpc_service.proto** and **BufferMonitor.proto**.

```
$protoc --plugin=./grpc_cpp_plugin  --grpc_out=. --cpp_out=. *.proto
```

Dial-out mode

Copy proto definition file **grpc_dialout.proto** to the current directory.

```
$ protoc --plugin=./grpc_cpp_plugin  --grpc_out=.  --cpp_out=. *.proto
```

Developing the collector-side application (dial-in mode)

In dial-in mode, the application needs to provide the code to be run on the gRPC client.

The C++ code generated from the proto definition files already encapsulates the service classes. For the gRPC client to initiate RPC requests, you only need to call the RPC method in the application.

The application performs the following operations:

- Log in to obtain the token_id.
- Prepare parameters for the RPC method, use the service classes generated from the proto definition files to call the RPC method, and resolve the returned result.
- Log out.

Using Get operations

Service classes GrpcService and BufferMonitorService are used in this example.

To develop the collector-side application in dial-in mode:

1. Create a GrpcServiceTest class.

   # In the class, use the GrpcService::Stub class generated from grpc_service.proto. Implement login and logout with the Login and Logout methods generated from grpc_service.proto.

```
class GrpcServiceTest
{
public:
    /* Constructor functions */
   GrpcServiceTest(std::shared_ptr<Channel> channel):
GrpcServiceStub(GrpcService::NewStub(channel))  {}

    /* Member functions */
    int Login(const std::string& username, const std::string& password);
   void Logout();
   void listen();
Status listen(const std::string& command);

    /* Member variable */
    std::string token;

private:
    std::unique_ptr<GrpcService::Stub> GrpcServiceStub;  // Use the
GrpcService::Stub class generated from grpc_service.proto.
};
```

2. Customize the Login method.

   # Call the Login method of the GrpcService::Stub class to allow a user who provides the correct the username and password to log in.

```
int GrpcServiceTest::Login(const std::string& username, const std::string& password)
{
    LoginRequest request;   // Username and password.
    request.set_user_name(username);
    request.set_password(password);

LoginReply reply;
ClientContext context;

    // Call the Login method.
    Status status = GrpcServiceStub->Login(&context, request, &reply);
    if (status.ok())
    {
        std::cout << "login ok!" << std::endl;
        std::cout <<"token id is :" << reply.token_id() << std::endl;
        token = reply.token_id();  // The login succeeds. The token is obtained.
        return 0;
    }
    else{
        std::cout << status.error_code() << ": " << status.error_message()
                  << ". Login failed!" << std::endl;
        return -1;
    }
}
```

3. Initiate an RPC request to the device. In this example, the application subscribes to interface packet drop events.

```
rpc SubscribePortQueDropEvent(PortQueDropEvent) returns
(grpc_service.SubscribeReply) {}
```

4. Create the BufMon_GrpcClient class to encapsulate the RPC method.

   # Use the BufferMonitorService::Stub class generated from BufferMonitor.proto to call the RPC method.

```
class BufMon_GrpcClient
{
public:
    BufMon_GrpcClient(std::shared_ptr<Channel> channel):
mStub(BufferMonitorService::NewStub(channel))
    {}

    std::string BufMon_Sub_AllEvent(std::string token);
    std::string BufMon_Sub_BoardEvent(std::string token);
    std::string BufMon_Sub_PortOverrunEvent(std::string token);
    std::string BufMon_Sub_PortDropEvent(std::string token);

    /* Get entries */
    std::string BufMon_Sub_GetStatistics(std::string token);
    std::string BufMon_Sub_GetGlobalCfg(std::string token);
```

```
    std::string BufMon_Sub_GetBoardCfg(std::string token);
    std::string BufMon_Sub_GetNodeQueCfg(std::string token);
    std::string BufMon_Sub_GetPortQueCfg(std::string token);

private:
    std::unique_ptr<BufferMonitorService::Stub> mStub; // Use the class generated
from BufferMonitor.proto.
};
```

5. Use std::string BufMon_Sub_PortDropEvent(std::string token) to implement interface packet drop event subscription.

```
std::string BufMon_GrpcClient::BufMon_Sub_PortDropEvent(std::string token)
{
    std::cout << "-------BufMon_Sub_PortDropEvent-------- " << std::endl;

    PortQueDropEvent stNodeEvent;
    PortQueDropEvent_PortQueDrop* pstParam = stNodeEvent.add_portquedrop();

    UINT uiIfIndex = 0;
    UINT uiQueIdx = 0;
    UINT uiAlarmType = 0;

    std::cout<<"Please input interface queue info : ifIndex queIdx alarmtype " <<
std::endl;
    cout<<"alarmtype : 1 for ingress; 2 for egress; 3 for port headroom"<<endl;

    std::cin>>uiIfIndex>>uiQueIdx>>uiAlarmType; // Set the subscription parameters
and interface index.
    pstParam->set_ifindex(uiIfIndex);
    pstParam->set_queindex(uiQueIdx);
    pstParam->set_alarmtype(uiAlarmType);

    ClientContext context;

    /* Token needs to be added to context */ // Set the token_id to be returned after
a successful login
    std::string key = "token_id";
    std::string value = token;
    context.AddMetadata(key, value);

    SubscribeReply reply;
    Status status = mStub->SubscribePortQueDropEvent(&context,stNodeEvent,&reply);
// Call the RPC method.

    return reply.result();
}
```

6. Use a loop to listen for event reports.

Implement this method in the GrpcServiceTest class.

```
void GrpcServiceTest::listen()
{
```

```
    GetReportRequest reportRequest;
    ClientContext context;
    ReportEvent reportedEvent;

   /* Add the token to the request */
   reportRequest.set_token_id(token);

    std::unique_ptr< ClientReader< ReportEvent>>
reader(GrpcServiceStub->GetEventReport(&context, reportRequest)); // Use
GetEventReport (which is generated from grpc_service.proto) to obtain event
information.

    std::string streamName;
    std::string eventName;
    std::string jsonText;
   std::string token;

    JsonFormatTool jsonTool;

   std::cout << "Listen to server for Event" << std::endl;
    while(reader->Read(&reportedEvent) ) // Read the received event report.
    {
        streamName = reportedEvent.stream_name();
        eventName = reportedEvent.event_name();
        jsonText = reportedEvent.json_text();
        token = reportedEvent.token_id();

          std::cout << "/***********EVENT COME**************/" << std::endl;
        std::cout << "TOKEN: " << token << std::endl;
        std::cout << "StreamName: "<< streamName << std::endl;
        std::cout << "EventName: " << eventName << std::endl;
        std::cout << "JsonText without format: " << std::endl << jsonText << std::endl;
        std::cout << std::endl;
        std::cout << "JsonText Formated: " << jsonTool.formatJson(jsonText) <<
std::endl;
        std::cout << std::endl;
    }

    Status status = reader->Finish();
    std::cout << "Status Message:" << status.error_message() << "ERROR code :" <<
status.error_code();
}  // Login and RPC request finished.
```

7. Call the Logout method to log out.

```
void GrpcServiceTest:: Logout ()
{
    LogoutRequest request;
   request.set_token_id(token);
   LogoutReply reply;
   ClientContext context;
```

```
    Status status = mStub->Logout(&context, request, &reply);
std::cout << "Logout! :" << reply.result() << std::endl;
}
```

Using gNMI Capabilities operations

1. Create a GrpcServiceTest class.
   See step 1 in "Using Get operations."
2. Customize the Login method.
   See step 2 in "Using Get operations."
3. Initiate an RPC request to the device.
   ```
   rpc Capabilities(CapabilityRequest) returns (CapabilityResponse);
   ```
4. Create the gnmi_client class to encapsulate the RPC method.
   ```
   class gnmi_client
   {
   public:
       explicit gnmi_client(const std::string &address,const std::string &tokenId);

       bool TestCapabilities();
       bool TestGet();
       bool TestSet();
       bool TestSubscribePool();
       bool TestSubscribeOnce();
       bool TestSubscribeStream();
       bool TestSubscribeStreamWithAlias();

   private:
       void PrintCapabilityResponse(const gnmi::CapabilityResponse &response);
       void PrintGetResponse(const gnmi::GetResponse &response);
       void PrintSubscribeResponse(const gnmi::SubscribeResponse &response);
       void PrintSubscribeRequest(const gnmi::SubscribeRequest &request);
       void PrintGetRequest(const gnmi::GetRequest &request);
       void PrintSetRequest(const gnmi::SetRequest &request);

       void FillGetRequest(gnmi::GetRequest &request);
       void FillSetRequest(gnmi::SetRequest &request);
       void FillSubscribeRequestByOnce(gnmi::SubscribeRequest &request);
       void FillSubscribeRequestByPool(gnmi::SubscribeRequest &request);
       void FillSubscribeRequestByStream(gnmi::SubscribeRequest &request);
       void FillSubscribePool(gnmi::SubscribeRequest &request);
       void FillSubscribeAlias(gnmi::SubscribeRequest &request);

   private:
       std::unique_ptr<gnmi::gNMI::Stub> mStubGnmiService;
       std::string mTokenID;
   };
   ```
5. Use the TestCapabilities() method to obtain the capabilities.
   ```
   bool gnmi_client::TestCapabilities()
   ```

```
{
    CapabilityRequest request;
    CapabilityResponse response;
    ClientContext context;

  context.AddMetadata("token_id", mTokenID);

    std::cout << std::endl << "CapabilitiesRequest => " << std::endl;
    Status ret = mStubGnmiService->Capabilities(&context,request,&response);

    if( StatusCode::OK != ret.error_code() )
    {
        cout << "TestCapabilities ErrorMessage:" << ret.error_message() << endl;
        return false;
    }
    else
    {
        PrintCapabilityResponse(response);
        return true;
    }
}
```

6. Call the Logout method to log out.
   See step 7 in "Using Get operations."

Using gNMI Get operations

1. Create a GrpcServiceTest class.
   See step 1 in "Using Get operations."
2. Customize the Login method.
   See step 2 in "Using Get operations."
3. Initiate an RPC request to the device.
   ```
   rpc Get(GetRequest) returns (GetResponse);
   ```
4. Create the gnmi_client class to encapsulate the RPC method.
   See step 4 in "Using gNMI Capabilities operations."
5. Use the TestGet() method to obtain the Device/Base/HostName.
   ```
   bool gnmi_client::TestGet()
   {
     GetRequest request;
     FillGetRequest(request);
     PrintGetRequest(request);
     GetResponse response;
     ClientContext context;

     context.AddMetadata("token_id", mTokenID);

     Status ret = mStubGnmiService->Get(&context,request,&response);

     if( StatusCode::OK != ret.error_code() )
     {
   ```

```
    cout << "TestGet ErrorMessage:" << ret.error_message() << endl;
    return false;
  }
  else
  {
    PrintGetResponse(response);
    return true;
  }
}

void gnmi_client::FillGetRequest(gnmi::GetRequest &request)
{
    auto prefix = request.mutable_prefix();
    auto pathelem01 = prefix->add_elem();
    pathelem01->set_name("Device");

    auto path1 = request.add_path();
    auto pathelem02 = path1->add_elem();
    pathelem02->set_name("Base");
    auto pathelem03 = path1->add_elem();
    pathelem03->set_name("HostName");
}
```

6. Call the Logout method to log out.
   See step 7 in "Using Get operations."

Using gNMI Set operations

1. Create a GrpcServiceTest class.
   See step 1 in "Using Get operations."
2. Customize the Login method.
   See step 2 in "Using Get operations."
3. Initiate an RPC request to the device.
   This example uses the Device module.
   ```
   rpc Set(SetRequest) returns (SetResponse)
   ```
4. Create a gNMITest class to encapsulate the RPC method.
   Use the gNMI::Stub class that is automatically created by gnmi.proto to call the RPC method.
   ```
   class gNMITest
   {
   public:
   gNMITest(std::shared_ptr<Channel> channel, const std::string tokenId ):

   mStubGrpcService(GrpcService::NewStub(channel)),

   mStubgNMIService(gNMI::NewStub(channel)),
                                                mTokenID(tokenId ){}
        SetResponse TestSetResponseInformation(SetRequest &request, const std::string
   tokenId);
   /*---delete: Device/Base/HostName. Restore the default for HostName -----------*/
   SetResponse DeleteDeviceBaseHostName();      /* delete: Device Base/HostName*/
   ```

```
/* update: Device/Base/HostName, string_val("string_hostname") */
SetResponse UpdateDeviceBaseHostNameStringVal();

/* replace: Device/Base/HostName, string_val("string_hostname") */
REPL_001 SetResponse ReplaceDeviceBaseHostNameStringVal();

private:
std::unique_ptr<GrpcService::Stub> mStubGrpcService;
std::unique_ptr<gNMI::Stub> mStubgNMIService;
std::string mTokenID;
};
```

5. Use customized methods to perform gNMI Set operations on service data, for example, on the Device module.

```
// Call the Set method to implement communication between client and server and get
the response.
SetResponse gNMITest::TestSetResponseInformation(SetRequest &request, const
std::string tokenId)
{
SetResponse reply;
ClientContext context;
context.AddMetadata("token_id", tokenId);

/* Call the Set method */
Status ret = mStubgNMIService->Set(&context,request,&reply);
if( StatusCode::OK != ret.error_code())
{
std::cout<<"error: "<<ret.error_message()<<std::endl;
}
return reply;
}
// Delete operation
SetResponse gNMITest:: DeleteDeviceBaseHostName ()       /* prefix == Device/Base
*/
{
SetRequest  request;
/* SetRequest->prefix */
Path        *path01 = request.mutable_prefix();
PathElem    *pathelem01 = path01->add_elem();
pathelem01->set_name("Device");
PathElem    *pathelem02 = path01->add_elem();
pathelem02->set_name("Base");

/* SetRequest->delete */
Path        *path02 = request.add_delete_();
PathElem    *pathelem03 = path02->add_elem();
pathelem03->set_name("HostName");
/* Gather response info. */
return TestSetResponseInformation(request, mTokenID);
```

```
}
// Update operation
SetResponse gNMITest::UpdateDeviceBaseHostNameStringVal()
{
SetRequest  request;

/* SetRequest->prefix */
Path        *path01 = request.mutable_prefix();
PathElem    *pathelem01 = path01->add_elem();
pathelem01->set_name("Device");
PathElem    *pathelem02 = path01->add_elem();
pathelem02->set_name("Base");

/* SetRequest->update */
Update      *update01 = request.add_update();
Path        *path02 = update01->mutable_path();
PathElem    *pathelem03 = path02->add_elem();
pathelem03->set_name("HostName");

TypedValue  *typevalue01 = update01->mutable_val();
typevalue01->set_string_val("string_hostname");

/* Gather response info. */
return TestSetResponseInformation(request, mTokenID);
}
// Replace operation
SetResponse gNMITest::ReplaceDeviceBaseHostNameStringVal()
{
SetRequest  request;

/* SetRequest->prefix */
Path        *path01 = request.mutable_prefix();
PathElem    *pathelem01 = path01->add_elem();
pathelem01->set_name("Device");
PathElem    *pathelem02 = path01->add_elem();
pathelem02->set_name("Base");

/* SetRequest->replace */
Update      *replace01 = request.add_replace();
Path        *path02 = replace01->mutable_path();
PathElem    *pathelem03 = path02->add_elem();
pathelem03->set_name("HostName");

TypedValue  *typevalue01 = replace01->mutable_val();
typevalue01->set_string_val("string_hostname");

/* Gather response info. */
return TestSetResponseInformation(request, mTokenID);
```

```
}
```

6. Call the Logout method to log out.
   See step 7 in "Using Get operations."

Using gNMI Subscribe operations

1. Create a GrpcServiceTest class.
   See step 1 in "Using Get operations."
2. Customize the Login method.
   See step 2 in "Using Get operations."
3. Initiate an RPC request to the device.
   ```
   rpc Subscribe(stream SubscribeRequest) returns (stream SubscribeResponse);
   ```
4. Create the gnmi_client class to encapsulate the RPC method.
   See step 4 in "Using gNMI Capabilities operations."
5. Create a subscribe method.
   ```
   void gnmi_client::FillSubscribeRequestByOnce(gnmi::SubscribeRequest &request)
   {
     auto subscribeList = request.mutable_subscribe();

     auto prefix = subscribeList->mutable_prefix();
     auto pathelem01 = prefix->add_elem();
     pathelem01->set_name("LLDP");

     auto subscribe = subscribeList->add_subscription();

     auto path = subscribe->mutable_path();
     auto pathelem02 = path->add_elem();
     pathelem02->set_name("NeighborEvent");

     auto pathelem03 = path->add_elem();
     pathelem03->set_name("Neighbor");
     (*pathelem03->mutable_key())["IfName"] = "xxx";

       subscribeList->set_mode(::gnmi::SubscriptionList_Mode_ONCE);
       subscribeList->set_encoding(::gnmi::JSON);
   }

   void gnmi_client::FillSubscribeRequestByPool(gnmi::SubscribeRequest &request)
   {
       auto subscribeList =  request.mutable_subscribe();

       auto prefix = subscribeList->mutable_prefix();
       auto pathelem01 = prefix->add_elem();
       pathelem01->set_name("Device");

       auto subscribe = subscribeList->add_subscription();

       auto path = subscribe->mutable_path();
       auto pathelem02 = path->add_elem();
   ```

```
    pathelem02->set_name("CPUs");
    auto pathelem03 = path->add_elem();
    pathelem03->set_name("CPU");
    auto pathelem04 = path->add_elem();
    pathelem04->set_name("CPUUsage");

    subscribeList->set_mode(::gnmi::SubscriptionList_Mode_POLL);
    subscribeList->set_encoding(::gnmi::JSON);
}

void gnmi_client::FillSubscribeRequestByStream(gnmi::SubscribeRequest &request)
{
     auto subscribeList =  request.mutable_subscribe();

     auto prefix = subscribeList->mutable_prefix();
     auto pathelem01 = prefix->add_elem();
     pathelem01->set_name("Diagnostic");

     auto subscribe = subscribeList->add_subscription();

     auto path = subscribe->mutable_path();
     auto pathelem02 = path->add_elem();
     pathelem02->set_name("CPUEvent");
     auto pathelem03 = path->add_elem();
     pathelem03->set_name("CPU");
     (*pathelem03->mutable_key())["Chassis#condition"] = "equal:1";
     subscribe->set_mode(::gnmi::ON_CHANGE);
     subscribe->set_sample_interval(1000);
     subscribe->set_suppress_redundant(false);
     subscribe->set_heartbeat_interval(1000);

     subscribeList->set_mode(::gnmi::SubscriptionList_Mode_STREAM);
     subscribeList->set_encoding(::gnmi::JSON);
}

void gnmi_client::FillSubscribeAlias(gnmi::SubscribeRequest &request)
{
    auto aliases = request.mutable_aliases();
    auto alias = aliases->add_alias();

    auto path = alias->mutable_path();
    auto pathelem01 = path->add_elem();
    pathelem01->set_name("Device");
    auto pathelem02 = path->add_elem();
    pathelem02->set_name("CPUs");
    auto pathelem03 = path->add_elem();
    pathelem03->set_name("CPU");
    auto pathelem04 = path->add_elem();
```

```
    pathelem04->set_name("CPUUsage");

    alias->set_alias("#cpu_usage");
}
```

6. Call the Logout method to log out.

   See step 7 in "Using Get operations."

Using CLI operations

1. Create a GrpcServiceTest class.

   See step 1 in "Using Get operations."

2. Customize the Login method.

   See step 2 in "Using Get operations."

3. Initiate an RPC request to the device.

   This example uses the CliConfig method in file **grpc_service.proto**.

   ```
   rpc CliConfig (CliConfigArgs)  returns (stream CliConfigReply) {}
   ```

4. Use the GrpcServiceTest class to encapsulate the RPC method in the same way you do for Get operations.

5. Use a customized method to support CliConfig operations.

```
// Make a thread to listen to the sever and get messages
Status GrpcServiceTest::listen(const std::string& command)
{
CliConfigArgs reportRequest;
ClientContext context;
CliConfigReply reportedEvent;
std::string key = "token_id";
std::string value = token;
context.AddMetadata(key, value);
/* Add token to request */
reportRequest.set_reqid(12345678);
reportRequest.set_cli(command);

std::unique_ptr< ClientReader< CliConfigReply>> reader(mStub->CliConfig(&context,
reportRequest));

std::string streamName;
std::string output;
int64 resreqid;

std::cout << "Command result" << std::endl;
while( reader->Read(&reportedEvent) )
{
streamName = reportedEvent.errors();
output = reportedEvent.output();
resreqid = reportedEvent.resreqid();
std::cout << "resreqid: "<< resreqid << std::endl;
std::cout << "errors: "<< streamName << std::endl;
std::cout << "output: \n"<< output << "\n"<< std::endl;
}
```

```
Status status = reader->Finish();
return status;
}
```

6. Use a loop in the main function to wait for commands.

   Use the GrpcServiceTest class.

```
int main(int argc, char *argv[])
{
const char *cmd;
unsigned int i = 0;
unsigned int cycle = 0;

if (4 == argc)
{
g_server_address = argv[1];
g_username = argv[2];
g_password = argv[3];
std::cout << "server_address: " << g_server_address <<std::endl;
std::cout << "username: " << g_username << " " << "password: " << g_password <<
std::endl;
auto channel =
grpc::CreateChannel(g_server_address,grpc::InsecureChannelCredentials());
 // 1. Log in
GrpcServiceTest reporter(channel);
if(0 != reporter.Login(g_username, g_password))
        {
            return 0;
        }
        while(1)
        {// 2. Read a command and execute the command
                std::cout<<"\n\nPlease Input Command:\n";
                getline(std::cin,g_command);          // Read a command
                Status status = reporter.listen(g_command);
                if (!status.ok())
               {
                   std::cout << status.error_code() << ": " << status.error_message()
<< std::endl;
                    break;
               }
        }
    }
    std::cout<<"Complete exec Command."<<std::endl;
    return 0;
}
```

7. Call the Logout method to log out.

   See step 7 in "Using Get operations."

Developing the collector-side application (dial-out mode)

In dial-out mode, the application needs to provide the gRPC server code so the collector can receive and resolve data obtained from the device.

The application performs the following operations:

- Inherit the automatically generated GRPCDialout::Service class, reload the automatically generated RPC Dialout service, and resolve the fields.
- Register the RPC service with the specified listening port.

To develop the collector-side application in dial-out mode:

1. Inherit and overload RPC service Dialout.

Create class DialoutTest and inherit GRPCDialout::Service.

```
class DialoutTest final : public GRPCDialout::Service { // Overload the automatically generated abstract class.
    Status Dialout(ServerContext* context, ServerReader< DialoutMsg>* reader, DialoutResponse* response) override; // Implement RPC method Dialout.
};
```

2. Register the DialoutTest service as a gRPC service and specify the listening port.

```
using grpc::Server;
using grpc::ServerBuilder;
std::string server_address("0.0.0.0:60057"); // Specify the address and port to listen to.
DialoutTest dialout_test; // Define the object declared in step 1.
ServerBuilder builder;
builder.AddListeningPort(server_address, grpc::InsecureServerCredentials());// Add the listening port.
builder.RegisterService(&dialout_test); // Register the service.
std::unique_ptr<Server> server(builder.BuildAndStart()); // Start the service.
server->Wait();
```

3. Implement the Dialout method and data resolution.

```
Status DialoutTest::Dialout(ServerContext* context, ServerReader< DialoutMsg>* reader, DialoutResponse* response)
{
        DialoutMsg msg;

        while( reader->Read(&msg))
        {
            const DeviceInfo &device_msg = msg.devicemsg();
            std::cout<< "Producer-Name: " << device_msg.producername() << std::endl;
            std::cout<< "Device-Name: " << device_msg.devicename() << std::endl;
            std::cout<< "Device-Model: " << device_msg.devicemodel() << std::endl;
            std::cout<<"Sensor-Path: " << msg.sensorpath()<<std::endl;
            std::cout<<"Json-Data: " << msg.jsondata()<<std::endl;
            std::cout<<std::endl;
        }
        response->set_response("test");

        return Status::OK;
}
```

4. After obtaining the DialoutMsg object (generated from the proto definition file) through the Read method, call the method to obtain the field values.

Appendix: Methods and attributes for gNMI operations

gNMI operations are intended for data tables and event tables.

- Some data tables are periodically reported and some data tables are reported only when triggered. The latter data tables are not supported in the current software version.
- All event tables are reported only when triggered.

Methods for adding columns in gNMI operations

Table 4 describes the methods for adding columns in gNMI operations.

Table 4 Methods for adding columns in gNMI operations

Request description	Sample request	Sample client-side code

Set a column of the key.
For example:
ifTypeExt=*colvalue*
	path:
	<
	elem:
	<
	name:"Interface"
	key:
	<
	name:"ifTypeExt"
	value:"*colvalue*"
	>
	>
	>
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("Interface");
		
		(*pathelem01->mutable_key())["ifTypeExt"] = "*colvalue*";

Set an attribute for a column of the key.
For example, set the attr attribute of ifTypeExt:
attr=*attrvalue*
	path:
	<
	elem:
	<
	name:"Interface"
	key:
	<
	name:"ifTypeExt#attr"
	value:"*attrvalue*"
	>
	>
	>
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("Interface");
		
		(*pathelem01->mutable_key())["ifTypeExt#attr"] = "*attrvalue*";

Set a column in a group of the key.
For example, set the Upper column of the Broadcast group:
Upper=*colvalue*
	path:
	<
	elem:
	<
	name:"Interface"
	key:
	<
	name:"Broadcast:Upper"
	value:"*colvalue*"
	>
	>
	>
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("Interface");
		
		(*pathelem01->mutable_key())["Broadcast:Upper"] = "*colvalue*";

Set an attribute for a column in a group of the key.
For example, set the attr attribute of the Upper column of the Broadcast group:
attr=*attrvalue*
	path:
	<
	elem:
	<
	name:"Interface"
	key:
	<
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("Interface");
		
		(*pathelem01->mutable_key())["Br

Request description	Sample request	Sample client-side code
	name:"Broadcast:Upper#attr" value:"*attrvalue*" > > >	oadcast:Upper#attr"] = "*attrvalue*";

Set an attribute of a column through the key:
For example, set the attr attribute of Interface: attr=*attrvalue*
	path:
	
	elem:
	
	name:"Interface"
	key:
	
	name:"#attr"
	value:"*attrvalue*"
	>
	>
	>
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("Interface");
		
		(*pathelem01->mutable_key())["#attr"] = "*attrvalue*";

Set a column or column attribute in JSON:
For example:
Set Upper to *colvalue* and set the attr attribute of Upper to *attrvalue*.
	{
	"Upper": {
	"#text": "*colvalue*",
	"@#attr": "*attrvalue*"
	}
	}
		{
		"Upper": {
		"#text": "*colvalue*",
		"@#attr": "*attrvalue*"
		}
		}

The YANG files for different YANG models might have a top-level node with the same name. To specify the top-level node in the YANG file for a particular YANG model, add the YANG model name before the top-level node name. If you do not add the YANG model name, the top-level node in the first YANG file is specified.
For example, add oc-if before node interfaces to specify the interfaces node in the YANG file for OpenConfig.
	path:
	
	elem:
	
	name:"oc-if:interfaces"
	>
	>
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("oc-if:interfaces");

gNMI Get operation attributes

gNMI Get operations support the following attributes:

- **regExp**—Regular expression.

  To implement a complex filtering with characters, you can add a **regExp** attribute for a specific column.

  The following example obtains the interface descriptions that contain only characters in upper case:

```
auto prefix = request.mutable_prefix();
 auto pathelem01 = prefix->add_elem();
 pathelem01->set_name("Ifmgr");

 auto path1 = request.add_path();
 auto pathelem02 = path1->add_elem();
 pathelem02->set_name("Interfaces");
 auto pathelem03 = path1->add_elem();
 pathelem03->set_name("Interface");
```

```
auto pathelem04 = path1->add_elem();
pathelem04->set_name("Description");
(*pathelem04->mutable_key())["#regExp"] = "^[A-Z]*$";
```

- **match**—Conditional match.

  Table 5 describes the conditional match operators.

  Table 5 Conditional match operators

Operation	Operator	Description
More than	match="more:*value*"	More than the specified value. The supported data types include date, digit, and character string.
Less than	match="less:*value*"	Less than the specified value. The supported data types include date, digit, and character string.
Not less than	match="notLess:*value*"	Not less than the specified *value*. The supported data types include date, digit, and character string.
Not more than	match="notMore:*value*"	Not more than the specified *value*. The supported data types include date, digit, and character string.
Equal to	match="equal:*value*"	Equal to the specified *value*. The supported data types include date, digit, character string, OID, and BOOL.
Not equal to	match="notEqual:*value*"	Not equal to the specified *value*. The supported data types include date, digit, character string, OID, and BOOL.
Include	match="include:*string*"	Includes the specified *string*. The supported data types include only character string.
Not include	match="exclude:*string*"	Excludes the specified *string*. The supported data types include only character string.
Start with	match="startWith:*string*"	Starts with the specified *string*. The supported data types include character string and OID.
End with	match="endWith:*string*"	Ends with the specified *string*. The supported data types include only character string.

  The following example obtains extension information about the entity whose CPU usage is more than 50%:

```
auto prefix = request.mutable_prefix();
 auto pathelem01 = prefix->add_elem();
 pathelem01->set_name("Device");

 auto path1 = request.add_path();
 auto pathelem02 = path1->add_elem();
 pathelem02->set_name("ExtPhysicalEntities");
 auto pathelem03 = path1->add_elem();
 pathelem03->set_name("Entity");
 auto pathelem04 = path1->add_elem();
 pathelem04->set_name("CpuUsage");
 (*pathelem04->mutable_key())["#match"] = "more:50";
```

- **valuetype**—Attribute value type.

  When obtaining interface information, the device cannot identify whether an integer value for the IfIndex or vrfindex column represents an interface name or index. To resolve the issue, you can use the **valuetype** attribute to specify the value type.

  The **valuetype** attribute has the following values:

Value	Description
name	The column is carrying a name.
index	The column is carrying an index.
auto	Default value. The device uses the value of the column as a name for interface matching. If no match is found, the device uses the value as an index for interface matching.

The following example sets the valuetype attribute to index and set the index to 1 for IfIndex:

```
auto prefix = request.mutable_prefix();
 auto pathelem01 = prefix->add_elem();
 pathelem01->set_name("VLAN");

 auto path1 = request.add_path();
 auto pathelem02 = path1->add_elem();
 pathelem02->set_name("TrunkInterfaces");
 auto pathelem03 = path1->add_elem();
 pathelem03->set_name("Interface");
(*pathelem03->mutable_key())["IfIndex"] = "1";
(*pathelem03->mutable_key())["IfIndex#valuetype"] = "index";
```

- **count**—Specifies the data entry quantity.

  The example sets the count attribute:

  ```
  auto prefix = request.mutable_prefix();
   auto pathelem01 = prefix->add_elem();
   pathelem01->set_name("Syslog");

   auto path1 = request.add_path();
   auto pathelem02 = path1->add_elem();
   pathelem02->set_name("Logs");
  (*pathelem03->mutable_key())["count"] = "5";
   auto pathelem03 = path1->add_elem();
   pathelem03->set_name("Log");
  (*pathelem03->mutable_key())["Index"] = "10";
  ```

- Value filtering

  You can specify a value for a column in a table to implement full match filtering. If you specify values for multiple columns, the system returns the data that matches all the specified values.

  The following example obtains information about interface whose IfIndex is 1.

  ```
  auto prefix = request.mutable_prefix();
   auto pathelem01 = prefix->add_elem();
   pathelem01->set_name("VLAN");

   auto path1 = request.add_path();
   auto pathelem02 = path1->add_elem();
   pathelem02->set_name("TrunkInterfaces");
   auto pathelem03 = path1->add_elem();
   pathelem03->set_name("Interface");
  (*pathelem03->mutable_key())["IfIndex"] = "1";
  ```

gNMI Set operation attributes

gNMI Set operations support the following attributes:

- **incremental**—Adds configuration data to a column without affecting the original data. This attribute applies to a list column such as the vlan permitlist column.

  This example adds VLANs 1 through 10 to an untagged VLAN list that has untagged VLANs 12 through 15.

```
Path        *path01 = request.mutable_prefix();
PathElem    *pathelem01 = path01->add_elem();
pathelem01->set_name("VLAN");
PathElem    *pathelem02 = path01->add_elem();
pathelem02->set_name("HybridInterfaces");

Update  *Update01 = request.add_update();
Path        *path02 = Update01->mutable_path();
PathElem    *pathelem03 = path02->add_elem();
pathelem03->set_name("Interface");
(*pathelem03->mutable_key())["IfName"] = "262";
(*pathelem03->mutable_key())["UntaggedVlanList#incremental"] = "true";
(*pathelem03->mutable_key())["UntaggedVlanList"] = "1-10";
```

- **valuetype**—Attribute value type.

  When configuring an interface, the device cannot identify whether an integer value for the IfIndex or vrfindex column represents an interface name or index. To resolve the issue, you can use the **valuetype** attribute to specify the value type.

  The **valuetype** attribute has the following values:

Value	Description
name	The column is carrying a name.
index	The column is carrying an index.
auto	Default value. The device uses the value of the column as a name for interface matching. If no match is found, the device uses the value as an index for interface matching.

  The following example sets the valuetype attribute to index and set the index to 1 for IfIndex:

```
    Path    *path01 = request.mutable_prefix();
    PathElem*pathelem01 = path01->add_elem();
    pathelem01->set_name("VLAN");
    PathElem*pathelem02 = path01->add_elem();
    pathelem02->set_name("TrunkInterfaces");

    /* SetRequest->delete */
    Path    *path02 = request.add_delete_();
    PathElem*pathelem04 = path02->add_elem();
    pathelem04->set_name("Interface ");
(*pathelem04->mutable_key())["IfIndex"] = "1";
(*pathelem04->mutable_key())["IfIndex#valuetype"] = "index";
```

gNMI Subscribe operation attributes

gNMI Subscribe operations support the following attributes:

- All gNMI Get operation attributes. See "gNMI Get operation attributes."

These attributes are used for subscription to periodically reported data tables.

- **condition**—Data pushing condition.

  This attribute is used for event table subscription. Values for this attribute are as follows:

  - **more**—More than.
  - **less**—Less than.
  - **notLess**—Not less than.
  - **notMore**—Not more than.
  - **equal**—Equal to.
  - **notEqual**—Not equal to.
  - **include**—Include.
  - **exclude**—Not include.
  - **startWith**—Start with.
  - **endWith**—End with.

  The following example monitors LLDP events:

```
auto prefix = subscribeList->mutable_prefix();
auto pathelem01 = prefix->add_elem();
pathelem01->set_name("LLDP");

auto subscribe = subscribeList->add_subscription();
auto path = subscribe->mutable_path();
auto pathelem02 = path->add_elem();
pathelem02->set_name("NeighborEvent");
auto pathelem03 = path->add_elem();
pathelem03->set_name("Neighbor");
(*pathelem03->mutable_key())["IfName"] = "GigabitEthernet1/0/1";
(*pathelem03->mutable_key())["IfName#condition"] = "equal";
```

- **match**—Conditional match.

  This attribute is used for data table subscription.

  The matching object can be a fixed value or another column. The latter supports only data tables that are reported only when triggered.

  The conditional match operators table in "gNMI Get operation attributes" describes the conditional match operators for matching a fixed value. Attribute values for matching another column are as follows:

  - **refMore**—More than.
  - **refLess**—Less than.
  - **refNotLess**—Not less than.
  - **refNotMore**—Not more than.
  - **refEqual**—Equal to.
  - **refNotEqual**—Not equal to.

  In the following example, a report is triggered only if the current-usage column has a greater value than the alarm-threshold column:

```
auto subscribe = subscribeList->add_subscription();
auto path = subscribe->mutable_path();
auto pathelem02 = path->add_elem();
pathelem02->set_name("queue");
auto pathelem03 = path->add_elem();
pathelem03->set_name("state");
```

```
(*pathelem03->mutable_key())["current-usage#match"] = "refMore:alarm-threshold";
```

- **select**—Reports certain columns in a data table that is reported only when triggered

  The following example reports only the current-usage column and the available-usage column:

```
auto subscribe = subscribeList->add_subscription();
auto path = subscribe->mutable_path();
auto pathelem02 = path->add_elem();
pathelem02->set_name("queue");
auto pathelem03 = path->add_elem();
pathelem03->set_name("state");
(*pathelem03->mutable_key())["current-usage#select"] = "";
(*pathelem03->mutable_key())["available-usage#select"] = "";
```

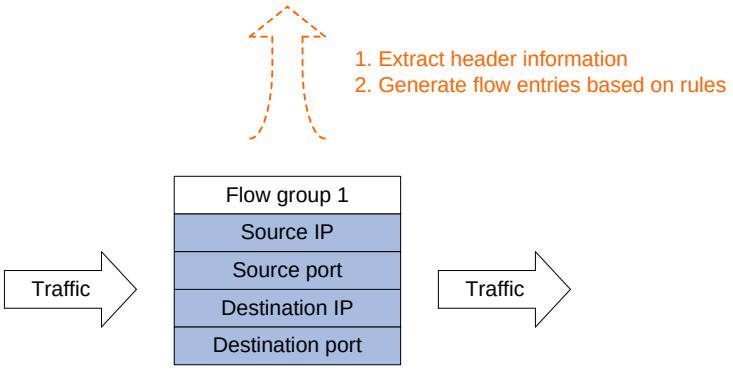
Configuring flow groups



About flow groups

A flow group allows you to identify flows based on flow generation rules. The device extracts traffic characteristics (for example, 5-tuples in the packet header) and generates flow entries according to the header fields specified in a flow generation rule.

A flow group can use an ACL to limit the traffic for which flow entries are generated. A flow entry is aged out if no matching packets are received before the aging timer expires.

Figure 1 Flow entry generation

Flow table					
Src IP	Src Port	Dst IP	Dst Port	Aging	Count
10.0.0.2	2000	10.0.0.20	3000	20	5120
10.0.0.2	2002	10.0.0.20	3002	18	25
10.0.0.2	2020	10.0.1.20	3000	15	813

The flow entries generated by a flow group can be used by other features. A flow group can be in one of the following modes:

- **Common MOD mode**—Used by MOD. This mode occupies hardware resources but has a lower burden on the CPU. For more information about MOD, see *Telemetry Configuration Guide*.
- **Simple MOD mode**—Used by MOD. This mode has a higher burden on the CPU but saves hardware resources.

Restrictions: Hardware compatibility with flow group

The S5200-EI-G switch series does not support this feature.

Restrictions and guidelines: Flow group configuration

A flow group can reference only one ACL.

Because a flow can belong to only one flow group, make sure the same flow is not assigned to more than one flow group when specifying ACLs. For information about ACLs, see *ACL and QoS Configuration Guide*.

To delete an applied flow group, first remove the application and then delete the flow group.

Only one flow group can be applied.

Procedure

1. Enter system view.
   system-view
2. Create a flow group and enter its view.
   telemetry flow-group *group-id* [**name** *group-name*] [**mode simple-mod**]
3. Specify an ACL.
   if-match acl [**ipv6** | **mac**] { *acl-number* | **name** *acl-name* }
   By default, no ACL is specified.
4. Configure the header fields used for generating flow entries.
   template { **destination-ip** | **destination-port** | **protocol** | **source-ip** | **source-port** } *
   By default, no header fields are used for generating flow entries.
5. Return to system view.
   quit
6. (Optional.) Set the aging time for flow entries.
   telemetry flow-group aging-time *aging-time*
   The default setting is 15 minutes.
7. (Optional.) Set the maximum number of flow entries generated.
   telemetry flow-group max-entry *max-entries*
   By default, the number of flow entries is not limited.
8. Apply the flow group.
   telemetry apply flow-group { *group-id* | **name** *group-name* }
   By default, no flow group is applied.

Display and maintenance commands for flow group

Execute **display** commands in any view.

Task	Command
Display the configuration and application status of flow groups.	**display telemetry flow-group** [*group-id*	**name** *group-name*] [**slot** *slot-number*]
Display flow entries.	**display telemetry flow-group flow-table** [[*group-id*	**name** *group-name*]	**mod**] [**destination-ip** { *dst-ipv4*	*dst-ipv6* }	**destination-port** *dst-port*	**protocol** *protocol*	**source-ip** { *src-ipv4*	*src-ipv6* }	**source-port** *src-port*] *

Task	Command
	{ **slot** *slot-number* }

Configuring MOD

Overview

Mirror On Drop (MOD) can detect packet drops during the forwarding process on the device. When a packet is dropped, MOD can send the packet drop reason and the characteristics of the dropped packet to the collector.

MOD uses the flow entries generated based on a flow group to detect dropped packets. For more information about flow groups, see flow group configuration in Telemetry Configuration Guide.

MOD works as follows:

1. The device generates flow entries based on a flow group.
2. Based on the packet drop reason list of MOD, the device monitors packet drops for packets matching the flow entries.
3. If a packet is dropped for a reason on the packet drop reason list, the device sends the packet drop reason and the characteristics of the dropped packet (flow entry matching the packet) to the collector.

Restrictions and guidelines: MOD configuration

MOD takes effect only on packets matching ACLs referenced by flow groups.

MOD monitors only packets dropped for reasons on the configured packet drop reason list. MOD does not monitor packets dropped for other reasons.

Only the S5200-HI-G switch series supports this feature.

Procedure

1. Enter system view.

   system-view
2. Enter MOD view.

   telemetry mod
3. Configure the device ID for MOD.

   device-id *address*

   By default, no device ID is configured for MOD.
4. Enable sampling for MOD.

   sampler *sampler-name*

   By default, sampling is disabled for MOD.
5. Specify a protocol that MOD uses to send packets to the collector.

   transport-protocol { **grpc** | **udp** }

   By default, MOD uses UDP to send packets to the collector.
6. (Optional.) Configure the encapsulation information for packets sent to the collector by MOD.

   collector source-ip *source-address* **destination-ip** *destination-address* **source-port** *source-port* **destination-port** *destination-port* [**vlan** *vlan-id*]

   By default, the encapsulation information for packets sent to the collector by MOD is not configured.

This command takes effect only if MOD uses UDP to send packets to the collector.

7. Configure the packet drop reason list monitored by MOD.

   reason-list { *reason-list* | **all** }

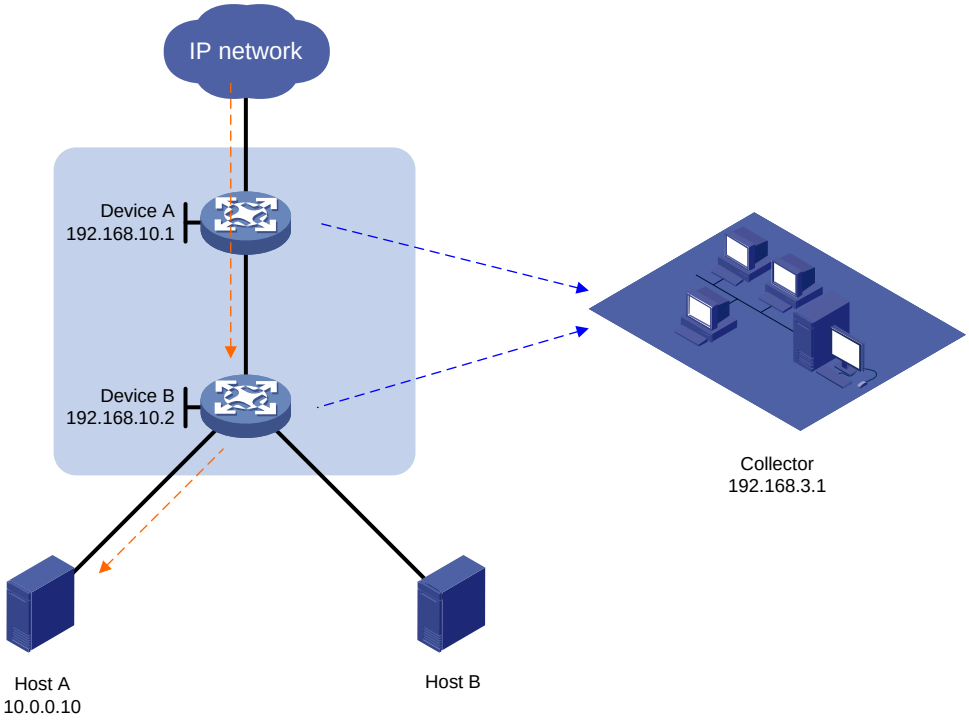
   By default, no packet drop reasons is configured, and the device does not monitor packet drops.

   For more information about the packet drop reason list, see the **reason-list** command in Telemetry Command Reference.

Display and maintenance commands for MOD

Execute **display** commands in any view.

Task	Command
Display MOD configuration information.	**display telemetry mod** [**slot** *slot-number*]



MOD configuration examples

Example: Configuring MOD to send packets through UDP

Network configuration

As shown in Figure 1, Host A and Host B access the external network through Device A and Device B. Some packets from the external network are missing on Host A. Configure MOD on the access device and aggregation device to identify whether packets are dropped during the forwarding process on the two devices.

Figure 1 Network diagram

Prerequisites

Configure IP addresses for devices, and make sure they can reach each other at Layer 3.

Procedures

1. Configure Device A:
   a. Configure a flow group:

      # Create advanced IPv4 ACL 3000, and configure a rule to match packets with destination IP address 10.0.0.10 for the ACL.

      ```
      <DeviceA> system-view
      [DeviceA] acl advanced 3000
      [DeviceA-acl-ipv4-adv-3000] rule permit ip destination 10.0.0.10 0
      [DeviceA-acl-ipv4-adv-3000] quit
      ```

      # Create flow group 1 and configure it to reference ACL 3000.

      ```
      [DeviceA] telemetry flow-group 1
      [DeviceA-telemetry-flow-group-1] if-match acl 3000
      ```

      # Configure the flow group to generate flow entries based on the destination IP address.

      ```
      [DeviceA-telemetry-flow-group-1] template destination-ip
      [DeviceA-telemetry-flow-group-1] quit
      ```

      # Set the flow entry aging time to 10 minutes.

      ```
      [DeviceA] telemetry flow-group aging-time 10
      ```

      # Apply flow group 1.

      ```
      [DeviceA] telemetry apply flow-group 1
      ```

   b. Configure MOD:

      # Configure the device ID for MOD as 192.168.10.1.

      ```
      [DeviceA] telemetry mod
      [DeviceA-telemetry-mod] device-id 192.168.10.1
      [DeviceA-telemetry-mod] quit
      ```

      # Create sampler samp, set the sampling mode to random, and set the sampling rate to 2 to the 8th power.

      ```
      [DeviceA] sampler samp mode random packet-interval n-power 8
      ```

      # Enable sampling for MOD, and reference sampler samp.

      ```
      [DeviceA] telemetry mod
      [DeviceA-telemetry-mod] sampler samp
      ```

      # Encapsulate the packets sent to the collector by MOD with the following information: source IP address 192.168.10.1, destination IP address 192.168.3.1, source port number 1000, and destination port number 2333.

      ```
      [DeviceA-telemetry-mod] collector source-ip 192.168.10.1 destination-ip
      192.168.3.1 source-port 1000 destination-port 2333
      ```

      # Configure MOD to monitor all packet drop reasons.

      ```
      [DeviceA-telemetry-mod] reason-list all
      [DeviceA-telemetry-mod] quit
      ```

2. Configure Device B.

   Configure Device B in the same way Device A is configured except the device ID for MOD and the source IP address encapsulated in the packets sent to the collector.

Verifying the configuration

1. Verify the configuration on Device A:

   # Display the ACL configuration.

```
<DeviceA> display acl 3000
Advanced IPv4 ACL 3000, 1 rule,
ACL's step is 5, start ID is 0
 rule 0 permit ip destination 10.0.0.10 0
```

Display the flow group configuration.

```
<DeviceA> display telemetry flow-group 1
Flow group 1 (Successful)
  ACL       : 3000
  Template  :
    destination-ip
Aging time: 10 minutes
Rate limit: -
Max  entry: -
```

Display the MOD configuration.

```
<DeviceA> display telemetry mod
Status          : Successful
Drop reason list:
...
Sampler            : samp
DeviceID           : 192.168.10.1
Transport protocol : UDP
Collector
  Source IP        : 192.168.10.1
  Destination IP   : 192.168.3.1
  Source port      : 1000
  Destination port : 2333
```

2. Verify the configuration on Device B.

   The configuration on Device B is the same as the configuration on Device A except the device ID for MOD and the source IP address encapsulated in the packets sent to the collector. (Details not shown.)

3. Verify the configuration on the collector.

   When a packet destined for IP address 10.0.0.10 is dropped during the forwarding process on Device A and Device B, the collector can receive the packet drop reason and the characteristics of the dropped packet from the devices.

Example: Configuring MOD to send packets through gRPC

Network configuration

As shown in Figure 2, Host A and Host B access the external network through Device A and Device B. Some packets from the external network are missing on Host A. Configure MOD on the access device and aggregation device to identify whether packets are dropped during the forwarding process on the two devices.

Figure 2 Network diagram

Prerequisites

Configure IP addresses for devices, and make sure they can reach each other at Layer 3.

Procedures

1. Configure Device A:
   a. Configure a flow group:

      # Create advanced IPv4 ACL 3000, and configure a rule to match packets with destination IP address 10.0.0.10 for the ACL.

      ```
      <DeviceA> system-view
      [DeviceA] acl advanced 3000
      [DeviceA-acl-ipv4-adv-3000] rule permit ip destination 10.0.0.10 0
      [DeviceA-acl-ipv4-adv-3000] quit
      ```

      # Create flow group 1 and configure it to reference ACL 3000.

      ```
      [DeviceA] telemetry flow-group 1
      [DeviceA-telemetry-flow-group-1] if-match acl 3000
      ```

      # Configure the flow group to generate flow entries based on the destination IP address.

      ```
      [DeviceA-telemetry-flow-group-1] template destination-ip
      [DeviceA-telemetry-flow-group-1] quit
      ```

      # Set the flow entry aging time to 50 minutes.

      ```
      [DeviceA] telemetry flow-group aging-time 50
      ```

      # Apply flow group 1.

      ```
      [DeviceA] telemetry apply flow-group 1
      ```

   b. Configure MOD:

      # Configure the device ID for MOD as 192.168.10.1.

      ```
      [DeviceA] telemetry mod
      [DeviceA-telemetry-mod] device-id 192.168.10.1
      ```

```
[DeviceA-telemetry-mod] quit
```

Create sampler **samp**, set the sampling mode to random, and set the sampling rate to 2 to the 8th power.

```
[DeviceA] sampler samp mode random packet-interval n-power 8
```

Enable sampling for MOD, and reference sampler **samp**.

```
[DeviceA] telemetry mod
[DeviceA-telemetry-mod] sampler samp
```

Configure MOD to use gRPC to send packets to the collector.

```
[DeviceA-telemetry-mod] transport-protocol grpc
```

Configure MOD to monitor all packet drop reasons.

```
[DeviceA-telemetry-mod] reason-list all
[DeviceA-telemetry-mod] quit
```

c. Configure gRPC:

Enable the gRPC service.

```
[DeviceA] grpc enable
```

Create a sensor group named **test**, and add sensor path **telemetryftrace/Genevent**.

```
[DeviceA] telemetry
[DeviceA-telemetry] sensor-group test
[DeviceA-telemetry-sensor-group-test] sensor path telemetryftrace/Genevent
[DeviceA-telemetry-sensor-group-test] quit
```

Create a destination group named **collector1**. Specify a collector that uses IPv4 address 192.168.3.1 and port number 50050.

```
[DeviceA-telemetry] destination-group collector1
[DeviceA-telemetry-destination-group-collector1] ipv4-address 192.168.3.1 port 50050
[DeviceA-telemetry-destination-group-collector1] quit
```

Configure a subscription named **A** to bind sensor group **test** with destination group **collector1**.

```
[DeviceA-telemetry] subscription A
[DeviceA-telemetry-subscription-A] sensor-group test
[DeviceA-telemetry-subscription-A] destination-group collector1
[DeviceA-telemetry-subscription-A] quit
[DeviceA-telemetry] quit
```

2. Configure Device B.

Configure Device B in the same way Device A is configured except the device ID for MOD.

Verifying the configuration

1. Verify the configuration on Device A:

Display the ACL configuration.

```
<DeviceA> display acl 3000
Advanced IPv4 ACL 3000, 1 rule,
ACL's step is 5, start ID is 0
 rule 0 permit ip destination 10.0.0.10 0
```

Display the flow group configuration.

```
<DeviceA> display telemetry flow-group 1
Flow group 1 (Successful)
  ACL       : 3000
  Template  :
```

```
    destination-ip
Aging time: 50 minutes
Rate limit: -
Max  entry: -
```

Display the MOD configuration.

```
<DeviceA> display telemetry mod
Status          : Successful
Drop reason list:
...
Sampler            : samp
DeviceID           : 192.168.10.1
Transport protocol : gRPC
```

2. Verify the configuration on Device B.

The configuration on Device B is the same as the configuration on Device A except the device ID for MOD. (Details not shown.)

3. Verify the configuration on the collector.

When a packet destined for IP address 10.0.0.10 is dropped during the forwarding process on Device A and Device B, the collector (gRPC server) can receive the packet drop reason and the characteristics of the dropped packet from the devices (gRPC clients).

Preface

This configuration guide describes the OpenFlow fundamentals and configuration procedures.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

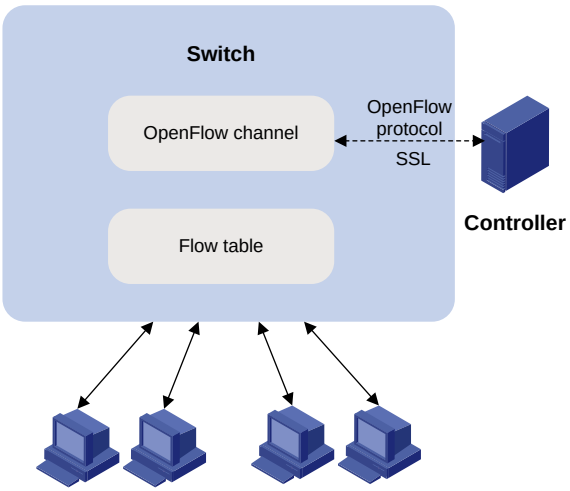
Configuring OpenFlow

About OpenFlow

OpenFlow is the communications interface defined between the control and forwarding layers of a Software-Defined Networking architecture. With OpenFlow, you can perform centralized data forwarding management for physical and virtual devices through controllers.



OpenFlow network components

OpenFlow separates the data forwarding and routing decision functions. It keeps the flow-based forwarding function and employs a separate controller to make routing decisions. An OpenFlow switch communicates with the controller through an OpenFlow channel. An OpenFlow channel can be encrypted by using TLS or run directly over TCP. An OpenFlow switch exchanges control messages with the controller through an OpenFlow channel to perform the following operations:

- Receive flow table entries or data from the controller.
- Report information to the controller.

Unless otherwise stated, a switch refers to an OpenFlow switch throughout this document.

Figure 1 OpenFlow network diagram

OpenFlow switch

OpenFlow switches include the following types:

- **OpenFlow-only**—Supports only OpenFlow operation.
- **OpenFlow-hybrid**—Supports both OpenFlow operation and traditional Ethernet switching operation.

OpenFlow port

OpenFlow supports the following types of ports:

- **Physical port**—Corresponds to a hardware interface, such as an Ethernet interface. A physical port can be either an ingress port or an output port.

- **Logical port**—Does not correspond to a hardware interface and might be defined by non-OpenFlow methods. For example, aggregate interfaces are logical ports. An aggregate interface can only be an ingress port.
- **Reserved port**—Defined by OpenFlow to specify forwarding actions. Reserved ports include the following types:
  - **Controller**—OpenFlow controller.
  - **Local**—Local CPU.
  - **Normal**—Normal forwarding process.

OpenFlow instance

Unless otherwise stated, an OpenFlow switch refers to an OpenFlow instance throughout this document.

You can configure one or more OpenFlow instances on the same device. A controller considers each OpenFlow instance as a separate OpenFlow switch and deploys forwarding instructions to it.

OpenFlow instance mode

An OpenFlow instance operates in one of the following modes:

- **Global mode**—When the global mode is enabled for an OpenFlow instance, the flow entries take effect on packets within the network. All service interfaces on the device belong to the OpenFlow instance.
- **VLAN mode**—When the VLAN mode is enabled for an OpenFlow instance, the flow entries take effect only on packets within VLANs associated with the OpenFlow instance. You must associate the OpenFlow instance with VLANs. All interfaces in the associated VLANs belong to the OpenFlow instance.

Activation and reactivation

The configurations for an OpenFlow instance take effect only after the OpenFlow instance is activated.

The controller can deploy flow entries to an OpenFlow instance only after the OpenFlow instance reports the following device information to the controller:

- Capabilities supported by OpenFlow.
- Information about ports that belong to the OpenFlow instance.

An activated OpenFlow instance must be reactivated when any of the OpenFlow instance configurations are changed.

After reactivation, the OpenFlow instance is disconnected from all controllers and then reconnected to them.

OpenFlow instance port

An OpenFlow switch sends information about the following ports to the controller:

- Physical ports.
- Logical ports.
- Reserved ports of the **Local** type.

In loosen mode, a port belongs to the OpenFlow instance when VLANs associated with the OpenFlow instance overlap with the port's allowed VLANs. Otherwise, a port belongs to an OpenFlow instance only when VLANs associated with the OpenFlow instance are within the port's allowed VLAN list.

OpenFlow flow table

An OpenFlow switch matches packets with one or more flow tables. A flow table contains flow entries, and packets are matched based on the matching precedence of flow entries.

Flow table types

OpenFlow flow tables include the following types:

- **MAC-IP**—Combines the MAC address table and FIB table.

  A MAC-IP flow table provides the following match fields:

  - Destination MAC address.
  - VLAN.
  - Destination IP address.

  A MAC-IP flow table provides the following actions:

  - Modifying the destination MAC address.
  - Modifying the source MAC address.
  - Modifying the VLAN.
  - Modifying the tunnel ID.
  - Specifying the output port.
- **Extensibility**—Uses ACLs to match packets.

Flow entry

A flow entry contains the following fields:

- **Match fields**—Matching rules of the flow entry. These contain the ingress port, packet headers, and metadata specified by the previous table.
- **Priority**—Matching precedence of the flow entry. When a packet is matched with the flow table, only the highest priority flow entry that matches the packet is selected.
- **Counters**—Counts of the packets and bytes that match the flow entry.
- **Instructions**—Used to modify the action set or pipeline processing. Instructions include the following types:
  - **Meter**—Directs the packets to the specified meter to rate limit the packets.
  - **Apply-Actions**—Applies the specified actions in the action list immediately.
  - **Clear-Actions**—Clears all actions in the action set immediately.
  - **Write-Actions**—Modifies all actions in the action set immediately.
  - **Write-Metadata**—Modifies packets between two flow tables if multiple flow tables exist.
  - **Goto-Table**—Indicates the next flow table in the processing pipeline.

  Actions are executed in one of the following ways:

  - **Action Set**—When the instruction set of a flow entry does not contain a **Goto-Table** instruction, pipeline processing stops. Then, the actions in the action set are executed in the order specified by the instruction list. An action set contains a maximum of one action of each type.
  - **Action List**—The actions in the action list are executed immediately in the order specified by the action list. The effect of those actions is cumulative.

  Actions include the following types:

  - **(Required.) Output**—The Output action forwards a packet to the specified OpenFlow port. OpenFlow switches must support forwarding packets to physical ports, logical ports, and reserved ports.

- **(Required.) Drop**—No explicit action exists to represent drops. Packets whose action sets have no output actions are dropped. Typically, packets are dropped due to empty instruction sets, empty action sets, or the executing a Clear-Actions instruction.
- **(Required.) Group**—Process the packet through the specified group. The exact interpretation depends on group type.
- **(Optional.) Set-Queue**—The Set-Queue action sets the queue ID for a packet. When the packet is forwarded to a port by the output action, the packet is assigned to the queue attached to this port for scheduling and forwarding. The forwarding behavior is dictated by the configuration of the queue and provides basic QoS support.
- **(Optional.) Push-Tag/Pop-Tag**—Switches support the ability to push or pop tags, such as VLAN tags.
- **(Optional.) Set-Field**—The Set-Field actions are identified by their field type and modify the values of corresponding header fields in the packet. Set-Field actions are always applied to the outermost header. For example, a Set VLAN ID action always sets the ID of the outermost VLAN tag.
- **(Optional.) Change-TTL**—The Change-TTL actions modify the values of the IPv4 TTL or IPv6 Hop Limit in the packet. Change-TTL actions are always applied to the outermost header. The Change-TTL actions include the following the actions: Set TTL, Decrement TTL, and Copy TTL (outwards or inwards).

- **Timeouts**—Maximum amount of idle time or hard time for the flow entry.
  - **idle time**—The flow entry is removed if it has matched no packets within the idle time.
  - **hard time**—The flow entry is removed when the hard time timeout is exceeded, regardless of whether or not it has matched packets.
- **Cookie**—Custom data specified by the controller. The data is not used for processing packets, and might be used by the controller for matching flow entries.

Figure 2 Flow entry components

OpenFlow pipeline

The OpenFlow pipeline processing defines how packets interact with flow tables contained by a switch.

The flow tables of an OpenFlow switch are sequentially numbered, starting at 0. The packet is first matched with flow entries of the first flow table, which is flow table 0. A flow entry can only direct a packet to a flow table number that is greater than its own flow table number.

When a packet matches a flow entry, the OpenFlow switch updates the action set for the packet and passes the packet to the next flow table. In the last flow table, the OpenFlow switch executes all actions to modify packet contents and specify the output port for packet forwarding. If the instruction set of a flow table contains an action list, the OpenFlow switch immediately executes the actions for a copy of the packet in this table.

Figure 3 OpenFlow forwarding workflow

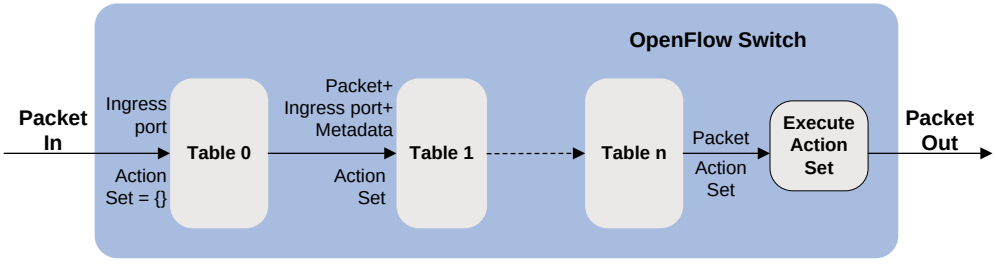


Table-miss flow entry

Every flow table must support a table-miss flow entry to process table misses. The table-miss flow entry specifies how to process packets that were not matched by other flow entries in the flow table.

The table-miss flow entry wildcards all match fields (all fields omitted) and has the lowest priority 0.

The table-miss flow entry behaves in most ways like any other flow entry.

Group table

The ability for a flow entry to point to a group enables OpenFlow to represent additional methods of forwarding. A group table contains group entries.

Figure 4 Group entry components

A group entry contains the following fields:

- **Group Identifier**—A 32 bit unsigned integer uniquely identifying the group.
- **Group Type**—Type of the group:
  - **All**—Execute all buckets in the group. This group is used for multicast or broadcast forwarding.
  - **Select**—Execute one bucket in the group.
  - **Indirect**—Execute the one defined bucket in the group.
  - **Fast failover**—Execute the first live bucket.
- **Counters**—Updated when packets are processed by a group.
- **Action Buckets**—An ordered list of action buckets, where each action bucket contains a set of actions to execute and associated parameters. Table 1 shows the actions supported by action buckets.

  Table 1 Actions supported by action buckets

Action	Type	Description
Output	Required	Forwards a packet to a specific OpenFlow port, for example, physical port, logical port, and reserved port.

Meter table

Meters enable OpenFlow to implement various simple QoS operations, such as rate-limiting. A meter table contains meter entries.

A meter entry contains the following fields:

- **Meter Identifier**—A 32 bit unsigned integer uniquely identifying the meter.
- **Meter Bands**—Each meter can have one meter band, which specifies the rate at which the band applies and the way packets should be processed. If the current rate of packets exceeds the rate of the band, packets are processed according to the method defined in the band.
- **Counters**—Updated when packets are processed by a meter.

Figure 5 Meter entry components

A meter band contains the following fields:

- **Band Type**—(Optional.) Packet processing methods. Options are:
  - **Drop**—Discards the packet when the rate of the packet exceeds the band rate.
  - **DSCP Remark**—Remarks the DSCP field in the IP header of the packet.
- **Rate**—Defines the lowest rate at which the band can apply.
- **Counters**—Updated when packets are processed by a band.
- **Type Specific Arguments**—Some band types have specific arguments.

Figure 6 Band components

OpenFlow channel

The OpenFlow channel is the interface that connects each OpenFlow switch to a controller. The controller uses the OpenFlow channel to exchange control messages with the switch to perform the following operations:

- Configure and manage the switch.
- Receive events from the switch.
- Send packets out the switch.

The OpenFlow channel is usually encrypted by using TLS. Also, an OpenFlow channel can be run directly over TCP.

The OpenFlow protocol supports the following message types: controller-to-switch, asynchronous, and symmetric. Each message type has its own subtypes.

Controller-to-switch messages

Controller-to-switch messages are initiated by the controller and used to directly manage or inspect the state of the switch. Controller-to-switch messages might or might not require a response from the switch.

The controller-to-switch messages include the following subtypes:

- **Features**—The controller requests the basic capabilities of a switch by sending a features request. The switch must respond with a features reply that specifies the basic capabilities of the switch.
- **Configuration**—The controller sets and queries configuration parameters in the switch. The switch only responds to a query from the controller.
- **Modify-State**—The controller sends Modify-State messages to manage state on the switches. Their primary purpose is to add, delete, and modify flow or group entries in the OpenFlow tables and to set switch port properties.
- **Read-State**—The controller sends Read-State messages to collect various information from the switch, such as current configuration and statistics.
- **Packet-out**—These are used by the controller to send packets out of the specified port on the switch, or to forward packets received through packet-in messages. Packet-out messages must contain a full packet or a buffer ID representing a packet stored in the switch. The message must also contain a list of actions to be applied in the order they are specified. An empty action list drops the packet.
- **Barrier**—Barrier messages are used to confirm the completion of the previous operations. The controller send s Barrier request. The switch must send a Barrier reply when all the previous operations are complete.

- **Role-Request**—Role-Request messages are used by the controller to set the role of its OpenFlow channel, or query that role. It is typically used when the switch connects to multiple controllers.
- **Asynchronous-Configuration**—These are used by the controller to set an additional filter on the asynchronous messages that it wants to receive, or to query that filter. It is typically used when the switch connects to multiple controllers.

Asynchronous messages

Switches send asynchronous messages to controllers to inform a packet arrival or switch state change. For example, when a flow entry is removed due to timeout, the switch sends a flow-removed message to inform the controller.

The asynchronous messages include the following subtypes:

- **Packet-In**—Transfer the control of a packet to the controller. For all packets forwarded to the Controller reserved port using a flow entry or the table-miss flow entry, a packet-in event is always sent to controllers. Other processing, such as TTL checking, can also generate packet-in events to send packets to the controller. The packet-in events can include the full packet or can be configured to buffer packets in the switch. If the packet-in event is configured to buffer packets, the packet-in events contain only some fraction of the packet header and a buffer ID. The controller processes the full packet or the combination of the packet header and the buffer ID. Then, the controller sends a packet-out message to direct the switch to process the packet.
- **Flow-Removed**—Inform the controller about the removal of a flow entry from a flow table. These are generated due to a controller flow delete request or the switch flow expiry process when one of the flow timeouts is exceeded.
- **Port-status**—Inform the controller of a state or setting change on a port.
- **Error**—Inform the controller of a problem or error.

Symmetric messages

Symmetric messages are sent without solicitation, in either direction.

The symmetric messages contain the following subtypes:

- **Hello**—Hello messages are exchanged between the switch and controller upon connection startup.
- **Echo**—Echo request or reply messages can be sent from either the switch or the controller, and must return an echo reply. They are mainly used to verify the liveness of a controller-switch connection, and might also be used to measure its latency or bandwidth.
- **Experimenter**—This is a staging area for features meant for future OpenFlow revisions.

OpenFlow timers

An OpenFlow switch supports the following timers:

- **Connection detection interval**—Interval at which the OpenFlow switch sends an Echo Request message to a controller. When the OpenFlow switch receives no Echo Reply message within three intervals, the OpenFlow switch is disconnected from the controller.
- **Reconnection interval**—Interval for the OpenFlow switch to wait before it attempts to reconnect to a controller.

OpenFlow controller

Controller roles

A switch can establish connections with multiple controllers. When OpenFlow operation is initiated, a switch is simultaneously connected to multiple controllers in Equal state. A controller can request its role to be changed at any time. The controller role contains the following types:

- **Equal**—In this role, the controller has full access to the switch and is equal to other controllers in the same role. By default, the controller receives all switch asynchronous messages such as packet-in and flow-removed messages. The controller can send controller-to-switch messages to modify the state of the switch.
- **Master**—This role is similar to the Equal role and has full access to the switch. The difference is that up to one controller in this role is allowed for a switch.
- **Slave**—In this role, the controller has read-only access to the switch.

  The controller cannot send controller-to-switch messages to perform the following operations:

  - Deploy flow entries, group entries, and meter entries.
  - Modify the port and switch configurations.
  - Send packet-out messages.

  By default, the controller does not receive switch asynchronous messages except Port-status messages. The controller can send Asynchronous-Configuration messages to set the asynchronous message types it wants to receive.

Controller connection modes

An OpenFlow instance can connect to one or more controllers, depending on the controller connection mode the OpenFlow instance uses:

- **Single**—The OpenFlow instance connects to only one controller at a time. When communication with the current controller fails, the OpenFlow instance uses another controller.
- **Multiple**—The OpenFlow instance can simultaneously connect to multiple controllers. When communication with any controller fails, the OpenFlow instance attempts to reconnect to the controller after a reconnection interval.

Main and auxiliary connections

The OpenFlow channel can have one main connection and multiple auxiliary connections.

- **Main connection**—Processes control messages to complete operations such as deploying entries, obtaining data, and sending information. The main connection must be a reliable TCP or SSL connection.
- **Auxiliary connection**—Improves the communication performance between the controller and OpenFlow switches. An auxiliary connection can have the different destination IP address and port number than the main connection.

Connection interruption mode

When an OpenFlow switch is disconnected from all controllers, the OpenFlow switch is set to either of the following modes:

- **Secure**—The OpenFlow switch forwards traffic based on flow tables and does not remove unexpired flow entries. If the output action in a matching flow entry is to forward traffic to a controller, the traffic is discarded. This is the default forwarding mode.
- **Smart**—The OpenFlow switch forwards traffic based on flow tables and does not remove unexpired flow entries. If the output action in a matching flow entry is to forward traffic to a controller, the traffic is forwarded in normal process.
- **Standalone**—The OpenFlow switch uses the normal forwarding process.

The OpenFlow switch forwards traffic based on flow tables when it reconnects to a controller successfully.

Protocols and standards

OpenFlow Switch Specification Version 1.3.3

Restrictions: Hardware compatibility with OpenFlow

OpenFlow is not supported on the S5200-EI-G Switch Series.

Restrictions and guidelines: OpenFlow configuration

Layer 3 Ethernet interfaces, Layer 3 aggregate interfaces, Layer 3 Ethernet subinterfaces, and Layer 3 aggregate subinterfaces do not support OpenFlow in the current software version.

The device does not support group entries with the output ports as Layer 3 Ethernet interfaces, Layer 3 aggregate interfaces, Layer 3 Ethernet subinterfaces, or Layer 3 aggregate subinterfaces.

The output port for the output action of a group entry cannot be a Layer 3 Ethernet interface.

The device does not support extensibility flow entries with the Set-Field action of setting the ip_ecn (the ECN field in IP packets). For more information about ECN, see *ACL and QoS Configuration Guide*.

When configuring a global instance, follow these restrictions and guidelines:

- When the action of a flow entry is output, the output port cannot be Flood or All.
- When the action of a flow entry is to set the destination MAC or source MAC, you must specify the output action and the output port must be an Ethernet interface or aggregate interface.
- When local first load sharing is enabled for Ethernet link aggregation, the OpenFlow controller cannot create group entries on the device. The two features are mutually exclusive. For more information about load sharing for Ethernet link aggregation, see Ethernet link aggregation in *Layer 2—LAN Switching Configuration Guide*.
- The OpenFlow controller supports creating only group entries with the output port as physical ports or aggregate interfaces.
- The OpenFlow controller does not support creating group entries with the action of setting the IPv6 address.
- A group entry with the action of setting the UDP port number takes effect only on IPv4 UDP packets.
- When the OpenFlow controller creates a group entry on the device, the packets sent out of the output port might carry VLAN tags. Modify the VLAN configuration of the output port as needed. For more information about port VLAN configuration, see VLAN in *Layer 2—LAN Switching Configuration Guide*.

If the output port is also the input port for a packet matching an OpenFlow flow entry, you must execute the **`port bridge enable`** command on the output port to enable bridging. Otherwise, traffic cannot be forwarded properly. For more information about bridging, see Ethernet interface in *Layer 2—LAN Switching Configuration Guide*.

Group entries are mutually exclusive with the **`link-aggregation load-sharing mode local-first`** command. For the group table to operate normally, do not execute the **`link-aggregation load-sharing mode local-first`** command on the device.

For an OpenFlow flow entry deployed by the controller to match IPv6 packets, you must specify an IPv6 packet field in the match fields in the flow entry (for example, set the Ethernet type to 0x86DD).

OpenFlow tasks at a glance

To configure OpenFlow, perform the following tasks:

1. Configuring OpenFlow instances
   a. Creating an OpenFlow instance
   b. Configuring the OpenFlow instance mode
   c. (Optional.) Configuring inband management VLANs
   d. (Optional.) Configuring flow tables and flow entries for an OpenFlow instance

      This task is applicable if the OpenFlow instance does not use TTP flow tables.
   e. (Optional.) Setting the controller connection mode
   f. (Optional.) Preventing an OpenFlow instance from reporting the specified types of ports to controllers
   g. (Optional.) Enabling support for smart group entries

      Perform this task to optimize the IPTV service. A controller supporting smart group entries is required to cooperate with the OpenFlow instance.
   h. Activating or reactivating an OpenFlow instance
   i. (Optional.) Configuring OpenFlow instance attributes
2. Configuring controllers for an OpenFlow switch
3. (Optional.) Refreshing all Layer 3 flow entries in the MAC-IP flow tables for an OpenFlow instance
4. (Optional.) Ignoring the permit flag added by OpenFlow
5. (Optional.) Shutting down an interface by OpenFlow
6. (Optional.) Enabling SNMP notifications for OpenFlow
7. (Optional.) Configuring OpenFlow flow monitor parameters

Configuring OpenFlow instances

Creating an OpenFlow instance

1. Enter system view.

   system-view
2. Create an OpenFlow instance and enter its view.

   openflow instance *instance-id*
3. (Optional) Set the datapath ID.

   datapath-id *id*

   By default, the datapath ID of an OpenFlow instance contains the instance ID and the bridge MAC address of the device. The upper 16 bits are the instance ID and the lower 48 bits are the bridge MAC address of the device.

   The datapath ID uniquely identifies an OpenFlow switch (OpenFlow instance). Do not set the same datapath ID for different OpenFlow switches.
4. Set a DSCP value for OpenFlow packets.

   tcp dscp *dscp-value*

   By default, no DSCP value is set for OpenFlow packets.

Configuring the OpenFlow instance mode

Restrictions and guidelines

When you associate an OpenFlow instance with VLANs, follow these guidelines:

- For VLAN traffic to be processed correctly, associate different OpenFlow instances with different VLANs.
- When you activate an OpenFlow instance that is associated with nonexistent VLANs, the system automatically creates the VLANs.
- Do not associate VLANs permitted on a port with different OpenFlow instances. Otherwise, port modification messages of different OpenFlow instances deployed from different controllers overwrite each other.
- Do not configure BFD MAD on the VLAN interface for a VLAN that is associated with an OpenFlow instance. For more information about BFD MAD, see *Virtual Technologies Configuration Guide*.

Enabling the global mode for an OpenFlow instance

1. Enter system view.
   system-view
2. Enter OpenFlow instance view.
   openflow instance *instance-id*
3. Enable the global mode for the OpenFlow instance.
   Classification global
   By default, the OpenFlow instance mode is not configured.

Enabling the VLAN mode for an OpenFlow instance

1. Enter system view.
   system-view
2. Enter OpenFlow instance view.
   openflow instance *instance-id*
3. Configure the OpenFlow instance mode.
   classification vlan *vlan-id* [**mask** *vlan-mask*] [**loosen**]
   By default, the OpenFlow instance mode is not configured.

Configuring inband management VLANs

About this task

Traffic in the inband management VLANs are forwarded in the normal forwarding process instead of the OpenFlow forwarding process. Inband management VLANs are used by an OpenFlow instance to establish OpenFlow channels to controllers.

Restrictions and guidelines

The ports that are assigned only to inband management VLANs are not OpenFlow ports.

Inband management VLANs configured for an OpenFlow instance in VLAN mode must be within the list of the VLANs associated with the OpenFlow instance.

If an OpenFlow instance in global or VLAN mode connects to a controller through a non-management Ethernet interface, configure the VLAN to which the interface belongs as an inband management VLAN.

Procedure

1. Enter system view.
   system-view
2. Enter OpenFlow instance view.
   openflow instance *instance-id*
3. Configure inband management VLANs for the OpenFlow instance.
   in-band management vlan *vlan-id-list*
   By default, no inband management VLANs are configured for an OpenFlow instance.

Configuring flow tables and flow entries for an OpenFlow instance

Restrictions and guidelines

The extensibility flow table ID must be greater than the MAC-IP flow table ID.

Procedure

1. Enter system view.
   system-view
2. Enter OpenFlow instance view.
   openflow instance *instance-id*
3. Configure flow tables for the OpenFlow instance.
   flow-table { **mac-ip** *mac-ip-table-id* | **extensibility** *extensibility-table-id* }*
   By default, an OpenFlow instance contains one extensibility flow table with an ID of 0.
4. Set the maximum number of flow entries that each extensibility flow table supports.
   flow-entry max-limit *limit-value*
   By default, each extensibility flow table supports a maximum of 65535 flow entries.
   When the maximum number is reached, the OpenFlow instance does not accept new flow entries for that table and sends a deployment failure notification to the controller.
5. Configure the OpenFlow instance to allow dynamic ARP entries to overwrite OpenFlow ARP entries.
   precedence dynamic arp
   By default, an OpenFlow instance does not allow dynamic ARP entries to overwrite OpenFlow ARP entries.
   Only MAC-IP flow tables support this feature.
6. Allow the deployed flow tables to include link aggregation member ports.
   permit-port-type member-port
   By default, the deployed flow tables cannot include link aggregation member ports.
7. Configure the default action of table-miss flow entries to forward packets to the normal pipeline.
   default table-miss permit
   By default, the default action of table-miss flow entries is to drop packets.

Setting the controller connection mode

Procedure

1. Enter system view.
   system-view
2. Enter OpenFlow instance view.
   openflow instance *instance-id*
3. Set the controller connection mode.
   controller mode { **multiple** | **single** }
   By default, the **multiple** mode is used.

Preventing an OpenFlow instance from reporting the specified types of ports to controllers

About this task

Perform this task to prevent an OpenFlow instance from reporting controllers information about the following types of interfaces that belong to the OpenFlow instance:

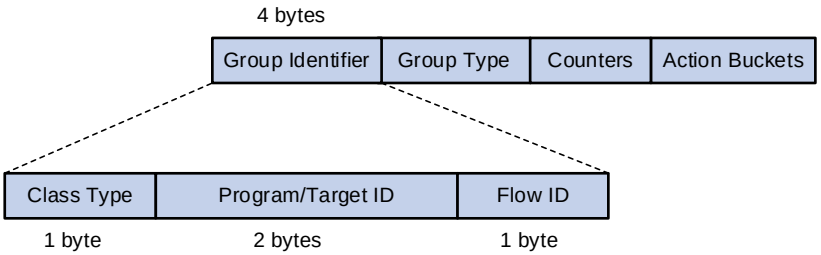
- Layer 3 Ethernet interface.
- Layer 3 aggregate interface.
- VLAN interface.

Procedure

1. Enter system view.
   system-view
2. Enter OpenFlow instance view
   openflow instance *instance-id*
3. Prevent an OpenFlow instance from reporting the specified types of ports to controllers.
   forbidden port { **l3-physical-interface** | **vlan-interface** } *
   By default, no port types are prevented from being reported to the controllers. All ports that belong to an OpenFlow instance are reported to the controllers.

Enabling support for smart group entries

About this task



On an IPTV service network, the traffic of an IPTV program might contain multiple types of traffic, such as flows of videos, audios in different languages, and subtitles in different languages. The controller needs to issue multiple flow entries for the OpenFlow instance to forward the traffic flows of an IPTV program to target users. The speed of program switchover might be affected due to the controller performance, which will further decrease the user experience.

To address this issue, support for smart group entries is introduced. The controller can issue smart group entries that define all possible forwarding actions for the IPTV service in advance. Once a program switchover occurs, the controller sends only a controller-to-switch message instead of multiple flow entries to the OpenFlow switch. This message will instruct the switch to combine smart group entries to forward the traffic flows of the new program to the target user.

Smart group entries include the following types:

- **Program group entry**—Identifies forwarding actions for flows of an IPTV program. A program group entry can be used by an OpenFlow flow entry to provide extra forwarding functions. By default, a program group entry does not contain any buckets. To include buckets in the program group entry, bind the program group entry to target group entries.
- **Target group entry**—Identifies a target user for an IPTV program. A target group entry contains only a bucket, which defines the output port. Target group entries cannot be used by OpenFlow flow entries but they can be bound to a program group entry. A program group entry can be bound to multiple target group entries to forward flows of an IPTV program to multiple target users.

Figure 7 Smart group entry components

A smart group entry contains the following fields:

- **Class Type**—Identifies the type of a smart group entry. This field contains one byte. 0x00 indicates a program group entry and 0x01 indicates a target group entry.
- **Program/Target ID**—Identifies the ID of a program or target user. This field contains two bytes.
- **Flow ID**—Identifies the ID of a flow for a program or target user. This field contains one byte.

Restrictions and guidelines

To modify a target group entry issued to an OpenFlow instance, the controller must first delete the target group entry and then re-issue the target group entry.

Procedure

1. Enter system view.
   `system-view`
2. Enter OpenFlow instance view.
   `openflow instance` *`instance-id`*
3. Enable the OpenFlow instance to support smart group entries.
   `smart-group enable`
   By default, support for smart group entries is disabled for an OpenFlow instance.

Activating or reactivating an OpenFlow instance

Restrictions and guidelines

To avoid failure to activate an OpenFlow instance containing a MAC-IP flow table, first execute the **`default table-miss permit`** command.

Procedure

1. Enter system view.
   `system-view`
2. Enter OpenFlow instance view.
   `openflow instance` *`instance-id`*

3. Activate or reactivate the OpenFlow instance.

   active instance

   By default, an OpenFlow instance is not activated.

Configuring OpenFlow instance attributes

Restrictions and guidelines

The OpenFlow instance attribute configurations of an OpenFlow instance can take effect without activation for the OpenFlow instance.

Procedure

1. Enter system view.

   system-view

2. Enter OpenFlow instance view.

   openflow instance { *instance-id* }

3. Configure a description for the OpenFlow instance.

   description *text*

   By default, an OpenFlow instance does not have a description.

4. Set OpenFlow timers.
   - Set the connection detection interval.

     controller echo-request interval *interval*

     The default setting is 5 seconds.
   - Set the reconnection interval.

     controller connect interval *interval*

     The default setting is 60 seconds.

5. Configure MAC address-related features.
   - Forbid MAC address learning for VLANs associated with the OpenFlow instance.

     mac-learning forbidden

     By default, MAC address learning is allowed for VLANs associated with an OpenFlow instance.

     The configuration does not take effect on inband management VLANs.
   - Configure the OpenFlow instance to support matching the dynamic MAC addresses in the query and deletion flow entry instructions sent from controllers.

     mac-ip dynamic-mac aware

     By default, an OpenFlow instance ignores dynamic MAC addresses in the query and deletion flow entry instructions sent from controllers.

     Only MAC-IP flow tables support this feature.

6. Prevent the OpenFlow instance from reporting ARP packets to the specified controllers.

   forbidden packet-in arp controller *controller-id-list*

   By default, no controllers to which ARP packets are forbidden to be reported are configured.

   This feature forbids an OpenFlow instance to report ARP packets to the specified controllers to prevent the controllers from being affected by a large number of packets.

7. Disable logging for successful flow table modifications.

   flow-log disable

   By default, logging for successful flow table modifications is enabled.

8. Enable loop guard for the OpenFlow instance.

loop-protection enable

By default, loop guard is disabled for an OpenFlow instance.

After an OpenFlow instance is deactivated, you can enable loop guard for the OpenFlow instance to avoid loops. This feature enables the deactivated OpenFlow instance to create a flow entry for dropping all traffic in these VLANs.

Configuring controllers for an OpenFlow switch

Restrictions and guidelines

Make sure the configuration of an auxiliary connection does not conflict with the configuration of the main connection. Otherwise, the auxiliary connection cannot be established.

Procedure

1. Enter system view.

   system-view

2. Enter OpenFlow instance view.

   openflow instance *instance-id*

3. Specify a controller and configure the main connection to the controller.

   controller *controller-id* **address** { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port-number*] [**local address** { **ip** *local-ipv4-address* | **ipv6** *local-ipv6-address* } [**port** *local-port- number*]] [**ssl** *ssl-policy-name* [**access-control-policy** *acp-policy-name*]]

   By default, an OpenFlow instance does not have a main connection to a controller.

   The source IP address must be the IP address of a port belonging to an OpenFlow instance. Otherwise, the OpenFlow switch might fail to establish a connection with the controller.

4. (Optional) Specify a controller and configure an auxiliary connection to the controller.

   controller *id* **auxiliary** *auxiliary-id* **transport** { **tcp** | **udp** | **ssl** *ssl-policy-name* } [**address** { **ip** *ipv4-address* | **ipv6** *ipv6-address* }] [**port** *port-number*]

   By default, an OpenFlow instance does not have auxiliary connections to a controller.

   If no destination IP address and port number are specified, the auxiliary connection uses the destination IP address and port number configured for the main connection.

5. (Optional) Set the connection interruption mode.

   fail-open mode { **secure** | **smart** | **standalone** }

   By default, the **secure** mode is used.

6. (Optional) Enable OpenFlow connection backup.

   tcp-connection backup

   By default, OpenFlow connection backup is enabled.

   This feature prevents connection interruption when an active/standby switchover occurs.

   This feature is available only on an IRF fabric with two member devices.

   This feature is available for only OpenFlow connections established over TCP.

Refreshing all Layer 3 flow entries in the MAC-IP flow tables for an OpenFlow instance

About this task

Perform this task to obtain all Layer 3 flow entries in the MAC-IP flow tables from the controller again if the Layer 3 flow entries have been overwritten.

Restrictions and guidelines

1. Enter system view.
   system-view
2. Enter OpenFlow instance view.
   openflow instance *instance-id*
3. Refresh all Layer 3 flow entries in the MAC-IP flow tables.
   refresh ip-flow

Ignoring the permit flag added by OpenFlow

About this task

Packets matching an OpenFlow flow entry with the output action as Normal are permitted to pass through and marked with a permit flag. Packets with a permit flag are not dropped by a discard action in a QoS policy (for example, a CAR discard action).

This feature allows the device to drop packets with a permit flag by using a discard action in a QoS policy.

Procedure

1. Enter system view.
   system-view
2. Ignore the permit flag added by OpenFlow.
   openflow permit-flag ignore
   By default, the permit flag added by OpenFlow is not ignored.

Shutting down an interface by OpenFlow

About this task

After an interface is shut down by OpenFlow, the **Current state** field displays **OFP DOWN** in the **display interface** command output.

You can use the **undo openflow shutdown** command to bring up an interface shut down by OpenFlow. The interface can also be brought up by port modification messages from controllers.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Shut down an interface by OpenFlow.

openflow shutdown

By default, an interface is not shut down by OpenFlow.

Enabling SNMP notifications for OpenFlow

About this task

This feature enables OpenFlow to generate SNMP notifications for important OpenFlow events. For the notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see SNMP configuration in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for OpenFlow.

   snmp-agent trap enable openflow [**connect-state**]

   By default, SNMP notifications are enabled for OpenFlow.

Configuring OpenFlow flow monitor parameters

About this task

The controller can use NETCONF to enable the flow monitor feature for flow entries on the device. On the device, you can configure flow monitor parameters at the CLI.

For an OpenFlow flow entry with flow monitor enabled, the device monitors the changes in the numbers of bytes and packets matching the flow entry at the flow monitor interval. If these counters do not change consecutively for the specified times, the device uses NETCONF to report to the controller the event that the traffic matching the flow entry does not increase. If these counters increase later, the device uses NETCONF to report to the controller the event that the traffic matching the flow entry increases.

NOTE:

Use the **display openflow flow-table** command to view flow entries. In the command output, the byte count and packet count fields for a flow entry represent the number of bytes matching the flow entry and the number of packets matching the flow entry.

The controller deploys the <action> operation to enable flow monitor for a flow entry on the device. The following NETCONF message enables flow monitor for all flow entries with CookieID 1 in flow table 0 for the OpenFlow instance corresponding to the specified datapath ID.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <action>
    <error-option>stop-on-error</error-option>
    <top xmlns="http://www.h3c.com/netconf/action:1.0">
       <OFP>
         <FlowMonitor>
            <Application>
               <DatapathID>410026760491999</DatapathID>
               <TableID>0</TableID>
               <CookieID>1</CookieID>
               <Enable>1</Enable>
```

```
            </Application>
          </FlowMonitor>
        </OFP>
      </top>
    </action>
</rpc>
```

Restrictions and guidelines

With OpenFlow flow monitor enabled for a large number of flow entries, the CPU load of the device might be too heavy if the configured flow monitor interval is small.

The OpenFlow flow monitor feature monitors only the traffic matching the flow entries deployed by the controller to an OpenFlow instance, and does not monitor flow entries with the default and local attributes.

After the OpenFlow flow monitor feature is enabled for a flow entry, the idle time attribute (the flow entry is removed if the flow entry does not match any data stream during the idle time) that the controller deploys to the flow entry does not take effect.

Procedure

1. Enter system view.
   system-view
2. Enter OpenFlow instance view.
   openflow instance *instance-id*
3. Configure the flow monitor interval.
   flow-monitor interval *interval*

   By default, the flow monitor interval is not configured.

   If you do not configure the flow monitor interval, the OpenFlow flow monitor feature does not take effect.
4. (Optional.) Set the monitor threshold for consecutive traffic interruptions.
   flow-monitor threshold *threshold*

   By default, the monitor threshold for consecutive traffic interruptions is 2.

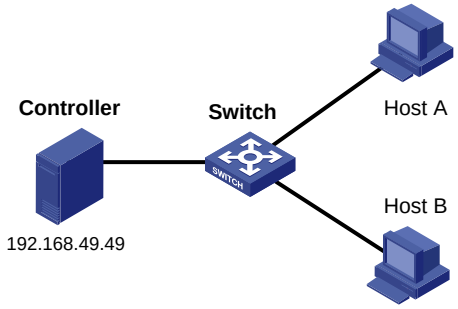
Display and maintenance commands for OpenFlow

Execute **display** commands in any view.

Task	Command
Display the detailed information for an OpenFlow instance.	**display openflow instance** [*instance-id*]
Display controller information for an OpenFlow instance.	**display openflow instance** *instance-id* { **controller** [*controller-id*] | **listened** }
Display auxiliary connection information.	**display openflow instance** *instance-id* **auxiliary** [*controller-id* [**auxiliary** *auxiliary-id*]]
Display flow table entries for an OpenFlow instance.	**display openflow instance** *instance-id* **flow-table** [*table-id*]

Task	Command
Display group table information for an OpenFlow instance.	**display openflow instance** *instance-id* **group** [*group-id*]
Display meter table information for an OpenFlow instance.	**display openflow instance** *instance-id* **meter** [*meter-id*]
Display smart group entry information for an OpenFlow instance.	**display openflow instance** *instance-id* **smart-group** { **program-group** [*program-id*] | **target-group** [*target-id*] }
Display summary OpenFlow instance information.	**display openflow summary**
Clear statistics on packets that a controller sends and receives for an OpenFlow instance.	**reset openflow instance** *instance-id* { **controller** { **controller** [*controller-id*] | **listened** }

OpenFlow configuration examples



Example: Configuring OpenFlow in VLAN mode

Network configuration

As shown in Figure 8, an OpenFlow switch communicates with the controller. Perform the following tasks on the OpenFlow switch:

- Create OpenFlow instance 1, associate VLANs 4092 and 4094 with the OpenFlow instance, and activate the OpenFlow instance.
- Configure the IP address for controller 1 to have the controller manage the OpenFlow switch.

Figure 8 Network diagram

Procedure

Create VLANs 4092 and 4094.

```
<Switch> system-view
[Switch] vlan 4092
[Switch-vlan4092] quit
[Switch] vlan 4094
[Switch-vlan4094] quit
```

Create OpenFlow instance 1 and associate VLANs with it.

```
[Switch] openflow instance 1
```

```
[Switch-of-inst-1] classification vlan 4092 mask 4093
```

Specify controller 1 for OpenFlow instance 1 and activate the instance.

```
[Switch-of-inst-1] controller 1 address ip 192.168.49.49
[Switch-of-inst-1] active instance
[Switch-of-inst-1] quit
```

Verifying the configuration

View detailed information about the OpenFlow instance.

```
[Switch] display openflow instance 1
Instance 1 information:

Configuration information:
 Description   : --
 Active status : Active
 Inactive configuration:
  None
 Active configuration:
  Classification VLAN, total VLANs(2)
   4092, 4094
...
Port information:
 GigabitEthernet1/0/3
Active channel information:
 Controller 1 IP address: 192.168.49.49 port: 6633
```

Appendix A Application restrictionsFlow entry restrictions

Matching restrictions

VLAN matching

Table 2 describes the VLAN matching restrictions when an OpenFlow instance is associated with VLANs.

Table 2 VLAN matching

VLAN	Mask	Matching packets
-	-	All packets in the VLANs that are associated with the OpenFlow instance.
0	-	Packets without a VLAN tag. The PVID of the ingress port must be associated with the OpenFlow instance.
0	Value	Unsupported.
Valid VLAN	-/value	Unsupported.
0x1000	-/value (except 0x1000)	Unsupported.
0x1000	0x1000	Packets with a VLAN tag. The VLAN ID of the VLAN tag must be associated with the OpenFlow instance.
Valid VLAN | 0x1000	-/value	Matching packets by the combination of the VLAN ID and VLAN mask. The VLANs obtained through the combination of the VLAN ID and VLAN mask must be associated with the OpenFlow instance.
Other	Other	Unsupported.

Protocol packet matching

If protocols are enabled, protocol packets (except LLDP frames) are processed by the corresponding protocols instead of the OpenFlow protocol.

For more information about LLDP frame matching, see "LLDP frame matching."

Metadata matching

Metadata passes matching information between flow tables. The controller deploys metadata matching entries only to non-first flow tables. If the controller deploys a metadata matching entry to the first flow table, the switch returns an unsupported flow error.

Instruction restrictions

Table 3 Instruction restrictions

Instruction type	Restrictions
Clear-Actions	The Clear-Actions instruction has the following restrictions: • For the single flow table, the flow entries of the table cannot include this instruction and other instructions at the same time. • For multiple flow tables of the pipeline, only the flow entries of the first flow table can include this instruction and other instructions at the same time.
Apply-Actions	The action list of the Apply-Actions instruction cannot include multiple Output actions.

Instruction type	Restrictions
	When the action list includes only one Output action, the switch processes the action list as described in "Restrictions for merging the action list into the action set."
Write-Metadata/mask	The flow entries of the last table of the pipeline cannot include this instruction. Otherwise, the switch returns an unsupported flow error.
Goto-Table	

Restrictions for merging the action list into the action set

The switch follows the following restrictions to merge the action list into the action set.

Non-output actions

When the action set and the action list do not contain the Output or Group action, the following rules apply:

- If actions in the action set do not conflict with actions in the action list, the switch merges the action list into the action set.
- If actions in the action set conflict with actions in the action list, actions in the action list are replaced with actions in the action set.

Output actions

When the action set and the action list contain the Output action or the Group action, the following rules apply:

- If both the action list and the action set contain an Output action, the Output action in the action list takes precedence. The Output action in the action list does not modify the packet. The Output action in the action set is executed at the last step of the pipeline processing to modify the packet.
- If either the action list or the action set contains an Output action, the port specified by the Output action is treated as the output port. The actions are executed in the order defined by the action set rules.
- If the action list contains an Output action and the action set contains a Group action, the following rules apply:
  - The Output action does not modify the packet.
  - The Group action is executed.

Packet-out messages restrictions

Ingress port

The ingress port must be a physical or logical port when one of the following reserved ports is the output port in a packet-out message:

- Normal.
- Local.
- In Port.
- Controller.

Buffer ID co-existing with packet

If a packet-out message contains both the packet and the buffer ID representing the packet stored in the switch, the switch processes only the buffered packet. The switch ignores the packet in the message.

Packets without a VLAN tag

If the packet contained in a packet-out message has no VLAN tag, the switch performs the following operations:

- Tags the packet with the PVID of the ingress port.
- Forwards the packet within the VLAN.

The switch processes the packet as follows when the ingress port is a reserved port:

- If the output port is a physical or logical port, the switch tags the packet with the PVID of the output port and forwards the packet within the VLAN.
- If the output port is the Flood or All reserved port, the switch processes the packet as described in "Output port."

Output port

If the output port in a packet-out message is the Flood or All reserved port, the switch processes the packet contained in the packet-out message as follows:

- When the output port is the Flood reserved port:
  - If the packet has a VLAN tag, the switch broadcasts the packet within the VLAN.
  - If the packet has no VLAN tag and the ingress port is a physical or logical port, the switch tags the packet with the PVID of the ingress port. The switch then forwards the packet within the VLAN.
  - If the packet has no VLAN tag and the ingress port is the Controller reserved port, the switch forwards the packet out all OpenFlow ports.
- When the output port is the All reserved port:
  - If the packet has a VLAN tag, the switch broadcasts the packet within the VLAN.
  - If the packet has no VLAN tag, the switch forwards the packet out of all OpenFlow ports regardless of the ingress port type.

Packet-in messages restrictions

Processing VLAN tags

When sending a packet-in message to the controller, the switch processes the VLAN tag of the packet contained in the packet-out message as follows:

- If the VLAN tag of the packet is the same as the PVID of the ingress port, the switch removes the VLAN tag.
- If the VLAN tag of the packet is different from the PVID of the ingress port, the switch does not remove the VLAN tag.

Packet buffer

If a packet-in message is sent to controller due to no matching flow entry, the switch supports buffering the packet contained in the packet-in message. The buffer size is 1K packets.

If a packet-in message is sent to controller for other reasons, the switch does not support buffering the packet contained in the packet-in message. The switch must send the full packet to the controller, and the cookie field of the packet is set to 0xFFFFFFFFFFFFFFFF.

LLDP frame matching

LLDP is used to perform topology discovery in an OpenFlow network. LLDP must be enabled globally on a device. A switch sends a LLDP frame to the controller through the packet-in message when the following conditions exist:

- The port that receives the LLDP frame from the controller belongs to OpenFlow instances.

- The flow tables in the OpenFlow instance have a flow entry that matches the LLDP frame (the output port is the Controller reserved port).

Flow table modification messages restrictions

The flow table modification messages have the following restrictions for the table-miss flow entry and common flow entries.

Table-miss flow entry

The controller deploys the table-miss flow entry (the action is Drop) to an OpenFlow instance after the OpenFlow instance is activated.

The controller cannot query the table-miss flow entry through Multipart messages.

The controller cannot modify the table-miss flow entry through the Modify request. The controller can only modify the table-miss flow entry through the Add request.

The controller can modify or delete the table-miss flow entry only through the strict version of the Modify or Delete request. The controller cannot modify or remove the table-miss flow entry through the non-strict version of the Modify or Delete request despite that the match fields are wildcarded.

The controller deploys a table-miss flow entry (the action is Drop) to an OpenFlow instance after the current table-miss flow entry is deleted.

Common flow entries

The controller cannot modify or remove all common flow entries through the non-strict version of the Modify or Delete request despite that the match fields are wildcarded.

Appendix B MAC-IP flow tableCapabilities supported by the MAC-IP flow table

The controller must include the required match fields and actions and can include the optional match fields and actions in the flow entries deployed to the MAC-IP flow table. If the controller does not include the optional match fields and actions in the flow entries, the switch adds them to the flow entries by default.

The Layer 2 flow entries are implemented by using MAC address entries. Table 4 describes the capabilities supported by Layer 2 flow entries.

Table 4 Capabilities supported by Layer 2 flow entries

Item	Capabilities
Required match fields	The MAC-IP flow table must support the following match fields: • VLAN ID. • Unicast destination MAC address.
Optional match fields	N/A
Required actions	Specifying the output port.
Optional actions	The MAC-IP flow table can optionally support the following instructions: • **Goto-Table**—When the switch has multiple tables, the switch adds this instruction by default if the controller does not deploy it. • **Write-Metadata**—When the switch has multiple tables, the switch adds this instruction by default if the controller does not deploy it.

The Layer 3 flow entries are implemented by using routing entries. Table 5 describes the capabilities supported by Layer 3 flow entries.

Table 5 Capabilities supported by Layer 3 flow entries

Item	Capabilities
Required match fields	The MAC-IP flow table must support the following match fields: • VLAN ID. • Unicast destination IP address. • Unicast destination MAC address, which must be the MAC address of the VLAN interface for the VLAN that is matched.
Optional match fields	N/A
Required actions	Specifying the output port.
Optional actions	The MAC-IP flow table can optionally support the following actions: • **Modify source MAC address**—The switch modifies the source MAC address to the MAC address of the VLAN interface for the VLAN to which the output port belongs. • **Decrement TTL by one**. • **Goto-Table**—When the switch has multiple tables, the switch adds this instruction by default if the controller does not deploy it. • **Write-Metadata**—When the switch has multiple tables, the switch adds this instruction by default if the controller does not deploy it.

MAC-IP flow table restrictions

Controller must follow the restrictions in the following tables to deploy flow entries for MAC-IP flow table. Otherwise, forwarding failure might occur.

Table 6 Restrictions for deploying Layer 2 flow entries for the MAC-IP flow table

Item	Restrictions
Match fields	The destination MAC address cannot be the MAC address of the switch to which the flow entry is deployed.
Actions	The output port must belong to the VLAN that is matched.

Table 7 Restrictions for deploying Layer 3 flow entries for the MAC-IP flow table

Item	Restrictions
Match fields	The VLAN interface of the VLAN that is matched is in up state. The destination MAC address is the MAC address of the VLAN interface for the VLAN that is matched. The destination IP address cannot be the IP address of the switch to which the flow entry is deployed.
Actions	The specified output port must belong to the destination VLAN. The destination MAC address cannot be the MAC address of the switch to which the flow entry is deployed. If the switch modifies the source MAC address, the source MAC address must be the MAC address of the VLAN interface for the VLAN to which the output port belongs.

To deploy a Layer 3 flow entry, make sure the following requirements are met:

- The VLAN interface of the matched VLAN is in up state.

- The switch sends the controller a packet that indicates the VLAN interface acts as an OpenFlow port. The link state and the MAC address of the VLAN interface are also included in the packet.

The switch reports the VLAN interface deletion to the controller and the controller removes the corresponding Layer 3 flow entry.

The controller ensures the correctness of Layer 3 flow entries. The switch does not check for the restrictions for Lay 3 flow entries.

Table-miss flow entry of MAC-IP flow tables

The table-miss flow entry of a MAC-IP flow table supports the following output actions:

- **Goto-Table**—Direct the packet to the next table.
- **Drop**—Drop the packet.
- **Controller**—Send the packet to the controller.
- **Normal**—Forward the packet to the normal pipeline.

Dynamic aware

On an OpenFlow switch that supports MAC-IP flow tables, you can configure OpenFlow to support querying and deleting dynamic MAC address flow entries.

The controller can query and delete dynamic MAC address flow entries by specifying a VLAN, a MAC address, or the combination of a MAC address and a VLAN.

MAC-IP flow table cooperating with extensibility flow table

Metadata/mask

The MAC-IP flow table supports the Write Metadata/mask instruction and the extensibility flow table supports metadata/mask matching. The MAC-IP flow table can cooperate with an extensibility flow table to perform the pipeline process of multiple tables by using metadata/mask.

Each metadata mask bit has a different meaning. The corresponding metadata bit being set indicates that the metadata mask bit is matched. When the corresponding metadata bit is not set, the metadata mask bit is wildcarded.

Table 8 Metadata mask meanings

Metadata mask bit	Meaning	Metadata
Bit 0	Destination MAC address	• **1**—Set. Matches the destination MAC address. • **0**—Not set. Does not match the destination MAC address.
Bit 1	Source MAC address	• **1**—Set. Matches the source MAC address. • **0**—Not set. Does not match the source MAC address.
Bit 2	Destination IP address	• **1**—Set. Matches the destination IP address. • **0**—Not set. Does not match the destination IP address.
Others	Reserved	Reserved.

Matching restrictions

When the output action in an extensibility flow table is not Normal, the following rules apply:

- The MAC-IP flow table does not take effect.
- All actions are executed according to the extensibility flow table.

When the output action in an extensibility flow table is Normal, the following rules apply:

- The output action is executed according to the MAC-IP flow table.
- The other actions are executed according to the extensibility flow table.

Capabilities supported by the VLAN tagging flow table

The controller must include the required match fields and actions and can include the optional match fields and actions in the flow entries deployed to the VLAN tagging flow table. If the controller does not include the optional match fields and actions in the flow entries, the switch adds them to the flow entries by default.

Table 9 describes the capabilities supported by the flow entries in the VLAN tagging flow table.

Table 9 Capabilities supported by flow entries in the VLAN tagging flow table

Item	Capabilities
Required match fields	The VLAN tagging flow table must support the following match fields: • **input-port**. • **vlan**.
Optional match fields	N/A
Required actions	The following actions in the action list of the Apply-Actions instruction must be applied immediately: • **Push-Tag**. • **Set-Field (VLAN)**.
Optional actions	The VLAN tagging flow table can optionally support the following actions: • **Output (normal)**. • **Goto-Table**.

The Push-Tag and Set-Field (VLAN) actions must be in the action list of the Apply-Actions instruction. The Push-Tag and Set-Field (VLAN) actions can be used as follows:

- **Push-Tag + Set-Field (value1)**—Adds a VLAN tag **value1**.
- **Set-Field (value1) + Push-Tag + Set-Field (value2)**—Modifies the VLAN tag of the packet to **value1** and adds a VLAN tag **value2**.
- **Push-Tag + Set-Field (value1) + Push-Tag + Set-Field (value2)**—Adds inner VLAN tag **value2** and outer VLAN tag **value1**.

The **Goto-Table** instruction is optional and does not take effect. The flow table specified by this instruction can only be the next of the VLAN tagging flow table.

Capabilities supported by the VLAN untagging flow table

Table 10 Capabilities supported by flow entries in the VLAN untagging flow table

Item	Capabilities
Required match fields	The VLAN untagging flow table must support the following match fields: • **egress port**—Matches the egress port of packets.

Item	Capabilities
	• **vlan**—Matches the outer VLAN tag of packets.
Optional match fields	The VLAN untagging flow table can optionally support the **inner vlan** match field that matches the inner VLAN tag of double-tagged packets.
Required actions	The following actions in the action list of the Apply-Actions instruction must be applied immediately: • **Pop-Tag**. • **Set-Field (VLAN)**.
Optional actions	The VLAN untagging flow table can optionally support the **Output (normal)** action.

The VLAN untagging flow table applies only to double-tagged packets.

The **egress port** and **inner vlan** are extended match fields that use the Experimenter ID H3C (0xFE2) and take the private match field values 47 and 48, respectively. To deploy flow entries that contain the extended match fields, make sure the controllers are developed to be compatible with the Experimenter ID and the extended match fields.

The Pop-Tag and Set-Field (VLAN) actions must be in the action list of the Apply-Actions instruction. The Pop-Tag and Set-Field (VLAN) actions can be used as follows:

- **Pop-Tag**—Removes the outer VLAN tag.
- **Pop-Tag + Pop-Tag**—Removes the inner and outer VLAN tags.
- **Pop-Tag + Set-Field (value)**—Removes the outer VLAN tag and modifies the inner VLAN tag to **value**.

Multi-level table-based TTP pipeline

A TTP pipeline can include multiple types of flow tables and the tables can be cascaded. Figure 9 shows the forwarding workflow of a TTP pipeline.

Figure 9 Multi-level table-based TTP pipeline

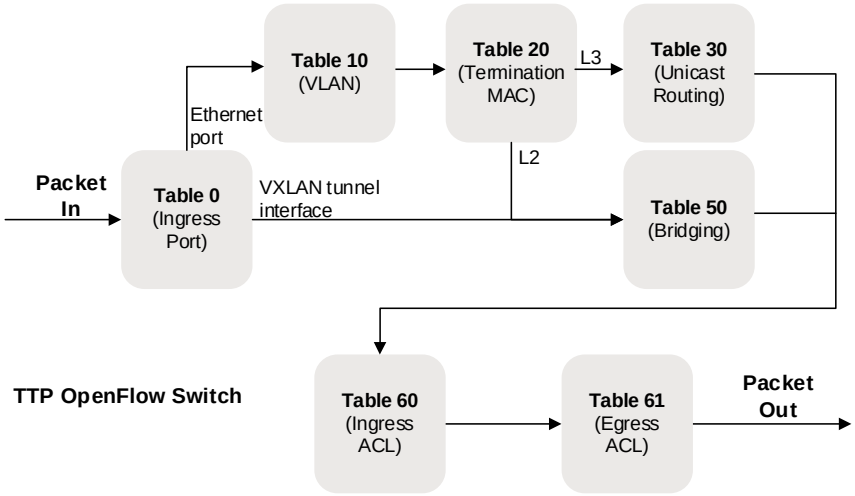


Table-miss flow entry of TTP flow tables

The table-miss flow entry of a TTP flow table supports the following output actions:

- **Normal**—Forward the packet to the normal pipeline.
- **Goto-table-50**—Direct the packet to table 50 (the TTP-Bridging flow table).

- **Controller**—Send the packet to the controller.

Table 11 describes the instruction supported by the table-miss flow entry of different types in TTP flow tables. The instruction in the table-miss entry of TTP flow tables 0 through 50 cannot be modified.

Table 11 Instruction supported by the table-miss flow entry of TTP flow tables

Table ID	TTP flow table	Instruction in the table-miss entry
0	TTP-ingress-port	Normal
10	TTP-VLAN	Normal
20	TTP-termination-MAC	Goto-table-50
30	TTP-unicast-routing	Normal
50	TTP-bridging	Controller
60	TTP-ingress-ACL	N/A
61	TTP-egress-ACL	N/A

Capabilities supported by the TTP-VLAN flow table

A TTP-VLAN flow entry is used to match untagged or tagged packets arriving at a physical interface, direct the packets to the TTP-termination-MAC flow table, and transmit VXLAN ID information.

Table 12 Capabilities supported by TTP-VLAN flow entries (for untagged packets)

Item	Capabilities
Required match fields	N/A
Optional match fields	**In-Port**—Type of the input port (physical interface).
Required actions	• **Write-metadata**—Writes the VNI information. • **Goto-table-20**—Directs the packet to table 20 (TTP-termination-MAC flow table).
Optional actions	N/A

Table 13 Capabilities supported by TTP-VLAN flow entries (for tagged packets)

Item	Capabilities
Required match fields	N/A
Optional match fields	• **In-Port**—Type of the input port (physical interface). • **VLAN ID**—VLAN ID.
Required actions	• **Write-metadata**—Writes the VNI information. • **Goto-table-20**—Directs the packet to table 20 (TTP-termination-MAC flow table).
Optional actions	N/A

Capabilities supported by the TTP-termination-MAC flow table

A TTP-termination-MAC flow entry is used to select Layer 2 or 3 forwarding based on the destination MAC address of a packet, direct the packet to a flow table, and transmit the VRF information.

Table 14 Capabilities supported by TTP-termination-MAC flow entries

Item	Capabilities
Required match fields	N/A
Optional match fields	• **ETH_TYPE**—Ethernet type. Value 0x800 indicates Ethernet. • **Metadata**—VNI. • **ETH_DST**—Destination MAC address (the MAC address of the local gateway).
Required actions	• **Write-metadata**—Writes VRF index information. Value 0 indicates the public network. • **Goto-table**—Directs the packet to a table. ○ If the packet matches the value of the ETH_DST field, the switch directs the packet to table 30 (TTP-unicast-routing flow table) for Layer 3 forwarding. ○ If the packet does not match the value of the ETH_DST field, the switch directs the packet to table 50 (TTP-bridging flow table) for Layer 2 forwarding.
Optional actions	N/A

Capabilities supported by the TTP-unicast-routing flow table

A TTP-unicast-routing flow entry is used to forward Layer 3 packets.

Table 15 Capabilities supported by TTP-unicast-routing flow entries (for normal IPv4 unicast packets)

Item	Capabilities
Required match fields	N/A
Optional match fields	• **ETH_TYPE**—Ethernet type. Value 0x800 indicates Ethernet. • **Metadata**—VNI. • **IP_DST**—Destination IP address.
Required actions	The TTP-unicast-routing flow table must support the following actions: • **Write-actions**—Writes actions in to the action set. ○ **Set L3_Unicast_Group_ID**—Specifies actions in a Layer 3 unicast group entry ID. For more information about Layer 3 unicast group entries, see "Capabilities supported by the TTP-L3-unicast-group flow table." ○ **Set L3_ECMP_Group_ID**—Specifies actions in a Layer 3 ECMP group entry ID. For more information about Layer 3 ECMP group entries, see "Capabilities supported by the TTP-L3-ECMP-group table." • **Set TTL**—Decreases the TTL by 1. • **Goto-table-60**—Directs the packet to table 60 (TTP-ingress-ACL flow table).
Optional actions	N/A

Table 16 Capabilities supported by TTP-unicast-routing flow entries (for IPv4 unicast packets with special destination IP addresses)

Item	Capabilities
Required match fields	N/A
Optional match fields	• **ETH_TYPE**—Ethernet type. Value 0x800 indicates Ethernet. • **Metadata**—VNI. • **IP_DST**—Destination IP address (a subnet or an IP address of the switch).

Required actions	**Controller**—Sends the packet to the controller.
Optional actions	N/A

Capabilities supported by the TTP-bridging flow table

A TTP-bridging flow entry is used to forward a Layer 2 packet, determine the type of the output port based on the destination MAC address of the packet, and perform one of the following actions:

- If the output port is a local physical interface, the switch tags or untags the packet before forwarding.
- If the output port is a VXLAN tunnel interface, the switch sets the VNI for the packet and untags the packet before forwarding.

Table 17 Capabilities supported by TTP-bridging flow entries

Item	Capabilities
Required match fields	N/A
Optional match fields	• **ETH_DST**—Destination MAC address. • **Metadata**—VNI.
Required actions	• **Write-actions**—Writes actions in to the action set by using the Set L2_Interface_Group_ID field. For more information about the action set, see "Capabilities supported by the TTP-L2-interface-group flow table." • **Goto-table-60**—Directs the packet to table 60 (TTP-ingress-ACL flow table).
Optional actions	N/A

Capabilities supported by the TTP-ingress-ACL flow table

The TTP-ingress-ACL flow entry is used to rate limit, redirect, mirror, or discard matching packets in the inbound direction or send the packets to the controller.

The TTP-ingress-ACL flow table does not contain a table-miss entry and executes all actions in the action set on a packet that does not match any flow entry.

Table 18 Capabilities supported by TTP-ingress-ACL flow entries (for LLDP and ARP packets)

Item	Capabilities
Required match fields	N/A
Optional match fields	**ETH_TYPE**—Ethernet type.
Required actions	**Controller**—Sends the packet to the controller.
Optional actions	N/A

Table 19 Capabilities supported by TTP-ingress-ACL flow entries (for DHCP packets)

Item	Capabilities
Required match fields	N/A
Optional match fields	• **ETH_TYPE**—Ethernet type. • **IP_PROTO**—IP protocol type. • **UDP_SRC**—Source UDP port number. • **UDP_DST**—Destination UDP port number.

Required actions	**Controller**—Sends the packet to the controller.
Optional actions	N/A

Table 20 Capabilities supported by TTP-ingress-ACL flow entries (for all packets)

Item	Capabilities
Required match fields	N/A
Optional match fields	• **In-Port**—Input port. • **Metadata**—VNI or VRF. • **IPv4SRC**—Source IPv4 address. • **IPv4DST**—Destination IPv4 address. • **IP_PROTO**—IP protocol type. • **TCP_SRC/UDP_SRC**—Source TCP or UDP port number. • **TCP_DST/UDP_DST**—Destination TCP or UDP port number.
Required actions	**A TTP-ingress-ACL flow entry must contain one of the following actions:** • **Write meter-ID**—Sets a meter entry for rate limit. • **Clear-actions + Output port number**—Clears the action set and specifies an output port for packet redirection. • **Output port number**—Specifies an output port to mirror the packet. • **Clear-actions**—Clears the action set to discard the packet.
Optional actions	N/A

Capabilities supported by the TTP-egress-ACL flow table

A TTP-egress-ACL flow entry is used to rate limit, mirror, or discard matching packets in the outbound direction.

The TTP-egress-ACL flow table does not contain a table-miss entry and uses the normal forwarding process to forward a packet that does not match any flow entry.

All packets processed by the TTP-ingress-ACL flow table will be directed to the TTP-egress-ACL flow table for processing by default.

Table 21 Capabilities supported by TTP-egress-ACL flow entries

Item	Capabilities
Required match fields	N/A
Optional match fields	• **Metadata**—VNI. • **IPv4SRC**—Source IPv4 address. • **IPv4DST**—Destination IPv4 address. • **IP_PROTO**—IP protocol type. • **TCP_SRC/UDP_SRC**—Source TCP or UDP port number. • **TCP_DST/UDP_DST**—Destination TCP or UDP port number.
Required actions	**A TTP-egress-ACL flow entry must contain one of the following actions:** • **Write meter-ID**—Sets a meter table for rate limit. • **Output port number**—Specifies an output port to mirror the packet. • **Clear-actions**—Clears the action set to discard the packet.
Optional actions	N/A

Capabilities supported by the TTP-L2-interface-group flow table

A TTP-L2-interface-group flow entry is used to tag or untag a packet and set the VXLAN ID of the packet.

For a TTP-L2-interface-group flow entry, the group type is indirect and the group entry contains only one action bucket.

Table 22 Capabilities supported by TTP-L2-interface-group flow entries (for VXLAN interfaces)

Item	Capabilities
Required actions	• **Set Tunnel_ID**—Sets the VNI. • **POP VLAN**—Untags the packet. Do not execute this action on an untagged packet. • **Output-port-number**—Sets the output port to the VXLAN tunnel interface.
Optional actions	N/A

Table 23 Capabilities supported by TTP-L2-interface-group flow entries (for untagging physical interfaces)

Item	Capabilities
Required actions	• **POP VLAN**—Untags the packet. Do not execute this action on an untagged packet. • **Output-port-number**—Sets the output port.
Optional actions	N/A

Table 24 Capabilities supported by TTP-L2-interface-group flow entries (for tagging physical interfaces)

Item	Capabilities
Required actions	• **PUSH VLAN**—Tags the packet with a VLAN ID. • **POP VLAN**—Untags the packet. Do not execute this action on an untagged packet. • **Output-port-number**—Sets the output port.
Optional actions	N/A

Capabilities supported by the TTP-L3-unicast-group flow table

A TTP-L3-unicast-group flow table is used to perform the following actions on a packet:

- Set the destination MAC address and source MAC address.
- Specify a TTP-L2-interface-group entry.

In a TTP-L3-unicast-group flow entry, the group type is indirect and the group entry contains only one action bucket.

Table 25 Capabilities supported by TTP-L3-unicast-group flow entries

Item	Capabilities
Required actions	• **Set ETH_DST**—Sets the destination MAC address. • **Set ETH_SRC**—Sets the source MAC address. • **Set L2_Interface_Group_ID**—Specifies a TTP-L2-interface-group flow table.
Optional actions	N/A

Capabilities supported by the TTP-L3-ECMP-group table

A TTP-L3-ECMP-group table is used to direct a packet to multiple TTP-L3-unicast-group entries for processing.

For a TTP-L3-ECMP-group entry, the group type is select, and the group entry contains multiple action buckets.

Table 26 Capabilities supported by TTP-L3-ECMP-group flow entries

Item	Capabilities
Required actions	• Bucket 1:{Set L3_Unicast_Group_ID} • Bucket 2:{Set L3_Unicast_Group_ID} • … • Bucket n:{Set L3_Unicast_Group_ID}
Optional actions	N/A

Preface

This configuration guide describes the Network Slicing fundamentals and configuration procedures.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Configuring network slicing

About network slicing

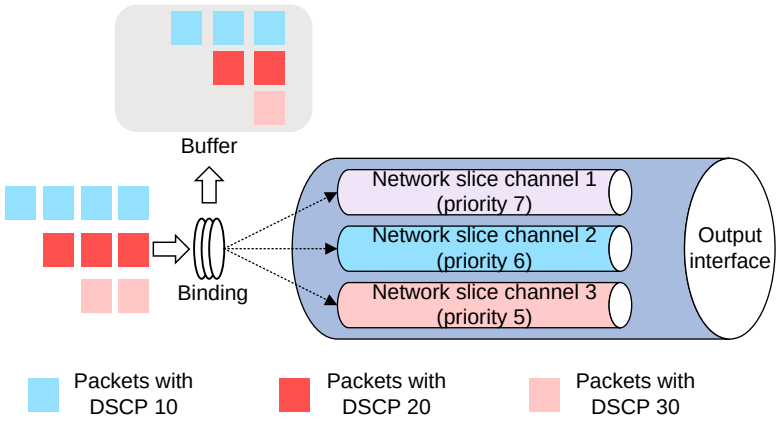
In the era of IoT, with a massive amount of devices and various applications connected to the network, home and industry users have diversified demands. A single network or unified policy can no longer meet the evolving demands of new services and scenarios. Building separate networks for each scenario is costly and time-consuming. The network slicing technology allows partitioning a physical network into multiple independent virtual networks. It enables on-demand resource allocation for different services and provides differentiated queue scheduling capabilities, meeting various business demands without affecting existing networks.

Figure 1 Network slicing architecture

Basic concepts

Network slicing has the following concepts:

- Network slice instance (NSI)—An independent virtual network in a network with network slicing deployed. A virtual network is identified by its unique NSI ID (also called slice ID).
- Network slice packet—Based on DSCP/VLAN information, you can bind common packets to specific NSI IDs for transmission. The packets can then be forwarded through the associated NSIs, which are known as network slice packets.
- Network slice channel—A logical channel on an interface, used for forwarding network slice packets. A network slice channel is associated with an NSI by the NSI ID. You can create multiple network slice channels on an interface and assign an independent scheduling queue to



each network slice channel. In this way, the scheduling queues for network slice channels do not affect each other.

Operating mechanism

Figure 2 shows the specific operating mechanism for network slicing as follows:

1. The device maps packets to a network slice channel on the output interface based on the configured bindings between packets and NSI IDs. In the current software version, you can bind packets to NSI IDs based on only the DSCP values, VLAN IDs, and input interfaces of packets. In this example, packets with DSCP 10 are mapped to network slice channel 2. Packets with DSCP 20 are mapped to network slice channel 3. Packets with DSCP 30 are mapped to network slice channel 1.
2. Before being forwarded through a network slice channel on the output interface, the packets first passes through the buffer in the outbound direction. If network congestion occurs in the outbound direction, the buffer helps prevent packet loss. For packets bound to different NSI IDs, you can adjust their buffer classes. A higher buffer class allows the packets in the network slice channel to occupy more buffer space.
3. You can specify guaranteed bandwidth for each network slice channel on the interface. The network slice channels can use different queues for scheduling without affecting each other, ensuring service bandwidth resources.
4. When forwarding packets through network slice channels, the device performs strict priority-based scheduling according to the priority of the network slice channels. If network congestion occurs on the output interface, packets in higher-priority network slice channels are forwarded first. Packets in lower-priority network slice channels can be scheduled in sequence only after all packets from the high-priority network slice channels are forwarded out of the queue.

Figure 2 Network slice packet forwarding process

Network slicing tasks at a glance

To configure network slicing, perform the following tasks:

1. Creating an NSI and configuring parameters
2. Configuring a network slice channel on an interface
3. Configuring bindings between packets and NSI IDs
4. (Optional.) Configuring network slice packet statistics

Creating an NSI and configuring parameters

Restrictions and guidelines

If an NSI is associated with an interface through the **slice-id flex-channel** command, use the **undo slice-id flex-channel** command to cancel the association before you delete the NSI.

When multiple network slice channels exist on the output interface, the device performs strict priority-based scheduling according to the scheduling priority of the network slice channels. If network congestion occurs on the output interface, packets in higher-priority network slice channels are forwarded first. Packets in lower-priority network slice channels can be scheduled in sequence only after all packets from the high-priority network slice channels are forwarded out of the queue.

Procedure

1. Enter system view.

   system-view

2. Enable network slicing and enter network slice view.

   network-slice

   By default, network slicing is disabled.

3. Create an NSI and enter its view.

   instance *slice-instance-id*

4. (Optional.) Configure a description for the NSI.

   description *text*

   By default, no description is configured for an NSI.

5. (Optional.) Configure the queue buffer class for the network slice channel.

   queue-buffer-class *number*

   By default, the queue buffer class for the network slice channel is 7.

Configuring a network slice channel on an interface

About this task

After enabling network slicing on an interface, you can create network slice channels on the interface. The device allocates independent scheduling queue resources for network slice channels on the interface. Packets matching an NSI ID are forwarded through the associated network slice channel. The bandwidth specified for the network slice channel created on the interface serves as both the guaranteed bandwidth and the upper limit for the channel. Traffic exceeding this bandwidth is processed by traffic shaping for buffering.

Restrictions and guidelines

Before enabling network slicing on an interface, you must use the **instance** command to create an NSI.

You can configure multiple network slice channels for an interface.

If you configure the **network-slice enable** command to enable network slicing for the interface, you cannot add the interface to a link aggregate group.

This feature is supported only on physical interfaces and Layer 2 aggregate interfaces. In the current software version, this feature is not supported by Layer 3 aggregate interfaces and their member ports (including the associated Layer 3 aggregate subinterfaces).

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable network slicing for the interface and enter network slice view of the interface.

   network-slice enable

   By default, network slicing is disabled on the interface.

4. Create a network slice channel for the interface, and specify the bandwidth for the network slice channel.

   slice-id *slice-instance-id* **flex-channel** *flex-channel-value*

   By default, no network slice channels are configured on the interface.

Configuring bindings between packets and NSI IDs

About this task

With this feature configured, the device binds the specified packets to NSI IDs. When forwarding the packets through an output interface, the device searches for the network slice channel configured on the output interface. The device then schedules and forwards the packets through the network slice channel identified by the bound NSI ID. If no network slice channel identified by the bound NSI ID exists on the output interface, the device forwards the packets according to routing table lookup.

You can repeatedly execute the **index binding-type** command to configure multiple bindings between packets and NSI IDs identified by different *index-value* values. Upon receiving a packet, the system compares it with packet match criteria in ascending order of index values specified with the **index binding-type** command. If a match is found, the system does not continue to compare the packet with other bindings.

Restrictions and guidelines

If you repeatedly execute the **index binding-type** command and specify the same index value, the most recent configuration takes effect.

If you bind a DSCP/VLAN value or interface to an NSI ID, you cannot bind the DSCP/VLAN value or interface to any other NSI IDs.

In the current software version, only Layer 2 Ethernet interfaces, Layer 2 aggregate interfaces, and Layer 3 Ethernet interfaces support scheduling and forwarding the packets through the network slice channel identified by the bound NSI ID.

For a queue-mode network slice, if a queue on the interface has been configured as a network slice channel, a binding rule exists between packets with that slice ID and the NSI ID. If a packet in that queue does not match any slice binding rule, the local priority for that packet is changed to 0, and the packet is forwarded through queue 0.

Procedure

1. Enter system view.

   system-view

2. Enable network slicing and enter network slice view.

   network-slice

   By default, network slicing is disabled.

3. Create and enter NSI-to-packet mapping view.

   nsi-mapping

4. Configure bindings between packets and NSI IDs.

index *index-value* **binding-type** { **dscp** { *dscp-startvalue* [**to** *dscp-endvalue*] } &<1-32> | **interface** *interface-type interface-number* | **vlan** { *vlan-startvalue* [**to** *vlan-endvalue*] } &<1-32> } **slice** *slice-id* [**replace dscp** *dscp-value*]

By default, the bindings between packets and NSI IDs are not configured. That is, no packets are scheduled or forwarded through the network slice channels identified by NSI IDs on an interface.

Configuring network slice packet statistics

About this task

With network slice packet statistics enabled, you can use the **display network-slice statistics** command to display statistics of packets forwarded through the specified network slice.

Restrictions and guidelines

After you create a mapping rule by executing the **index binding-type** command in NSI-to-packet mapping view, packets can be assigned to the configured slice. At this point, you must execute the **slice-id flex-channel** command for the interface to configure the network slice channel for the interface, so that packets can be counted for the corresponding network slice channel. Without the configuration, no slice channel is configured, and the network slice traffic data cannot be collected.

Procedure

1. Enter system view.

   system-view

2. Enter network slice view.

   network-slice

3. Enable network slice packet statistics.

   statistics enable

   By default, network slice packet statistics is disabled.

4. (Optional.) configure the interval for collecting network slice packet statistics.

   statistics interval *time*

   By default, the device collects network slice packet statistics at 30-second intervals.

Display and maintenance commands for network slicing

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display network slice configuration information.	**display network-slice instance** [**slice-id** *slice-id*]
Display the bandwidth usage of network slices on interfaces.	**display network-slice bandwidth usage statistics** [**interface** *interface-type interface-number*]
Display the associations between NSIs and interfaces.	**display network-slice binding-list** [**slice-id** *slice-instance-id*] [**interface** *interface-type interface-number*]
Display network slice packet statistics.	**display network-slice statistics** [**slice-id** *slice-instance-id*] [**interface** *interface-type interface-number*] [**verbose**]
Clear network slice packet statistics.	**reset network-slice statistics** [**slice-id** *slice-instance-id*] [**interface** *interface-type interface-number*]

Configuring TAP

About TAP

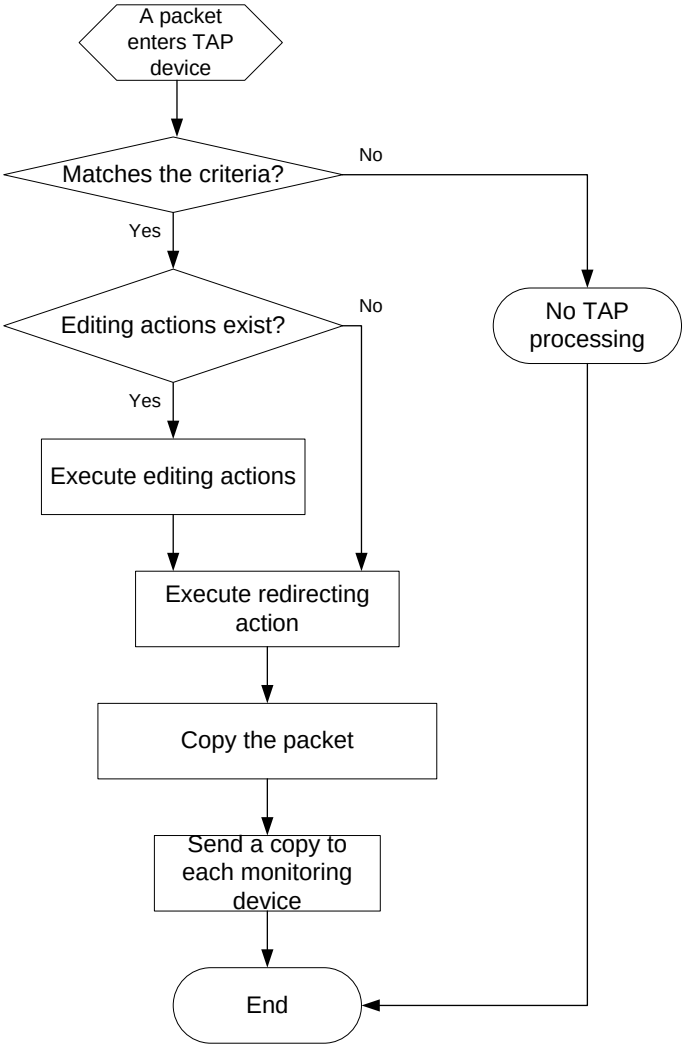
The growing scale of data center networks places more and more stringent requirements on security and performance. Monitoring network traffic and extracting data from the traffic is an important aspect to be addressed.

The test access point (TAP) feature can copy and forward traffic in real time without interrupting the traffic. Specifically, it copies traffic and sends a copy of the traffic to each of multiple monitoring devices for Internet access behavior analysis, abnormal traffic monitoring, and application monitoring.

How TAP works

The TAP feature is implemented through a QoS policy. Such a QoS policy is also called a TAP policy. In a TAP policy, you can use match criteria to mark packets and use actions to edit the packets and redirecting them to a monitoring group. A monitoring group can contain multiple interfaces, from which copies of traffic are sent.

Packet editing action



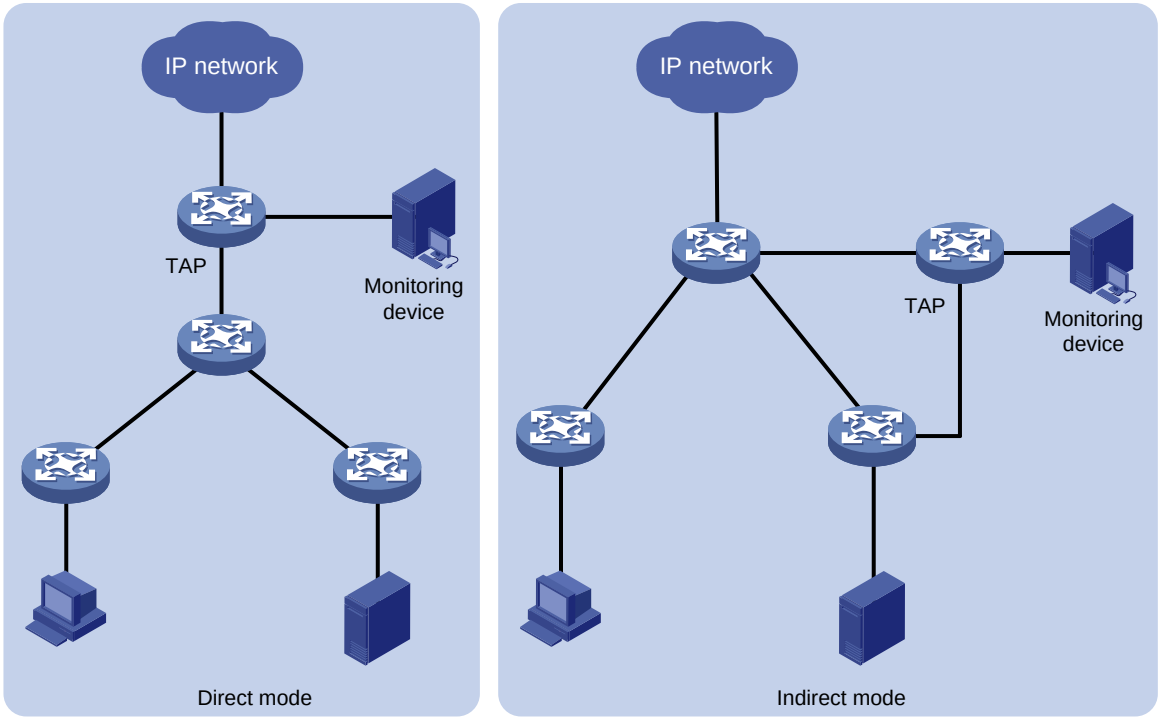
Packet editing actions include the following:

- Mark the IP address or MAC address of packets.
- Add, delete, or mark the VLAN tag of packets.
- Truncate packets.
- Add the timestamp and Ethernet header.
- Strip the tunnel header.

TAP workflow

Figure 1 shows the TAP workflow.

Figure 1 TAP workflow



TAP deployment mode

A TAP device can be deployed in the following modes:

- **Direct**—The TAP device is deployed in the user network and can directly copy user traffic without affecting traffic forwarding and send copied traffic to monitoring devices. In this mode, packet editing actions cannot be configured.
- **Indirect**—The TAP device is deployed beside the user network. The user network device sends monitored traffic to the TAP device, which then sends the received traffic to monitoring devices. In this mode, packet editing actions can be configured as needed.

Figure 2 Deployment modes

Restrictions: Hardware compatibility with TAP

Only the S5200-HI-G switch series supports TAP.

Restrictions and guidelines: TAP configuration

In a TAP policy, you must configure the action of redirecting packets to a monitoring group, and you can configure packet editing actions as needed. If both the redirecting action and a packet editing action are configured, the packet editing action is executed before the redirecting action.

A TAP policy cannot take effect if the monitoring group in a redirecting action contains unsupported configurations. For such a TAP policy to take effect, perform the following tasks:

1. Delete the unsupported configurations in the monitoring group.
2. Delete the redirecting action and then reconfigure it, or remove the TAP policy and reapply it.

If you configure a packet header stripping action by executing the **`strip-header position`** command and specify an odd value for the *`offset-value`* argument, the deleted part is the odd value minus 1.

A TAP policy can be applied to only a Layer 2 or Layer 3 Ethernet interface.

A TAP policy is implemented through a QoS policy. For more information about related commands, see *ACL and QoS Command Reference*.

TAP tasks at a glance

To configure TAP, perform the following tasks:

3. Enabling TAP globally

4. Configuring a traffic class
5. Configuring a traffic behavior
   - Configuring an M:N copying action
   - Configuring a VLAN ID marking action
   - Configuring an outer VLAN tag deleting action
   - Configuring an outer VLAN tag adding action
   - Configuring an IP or MAC address marking action
   - Configuring a timestamp and Ethernet header adding action
   - Configuring a packet truncation action
   - Configuring a tunnel header stripping action
6. Configuring a TAP policy
7. Applying a TAP policy to the inbound direction of an interface

Prerequisites for TAP configuration

Before configuring the redirecting action, configure a monitoring group (see flow monitoring configuration in *Network Management and Monitoring Configuration Guide*.

Enabling TAP globally

About this task

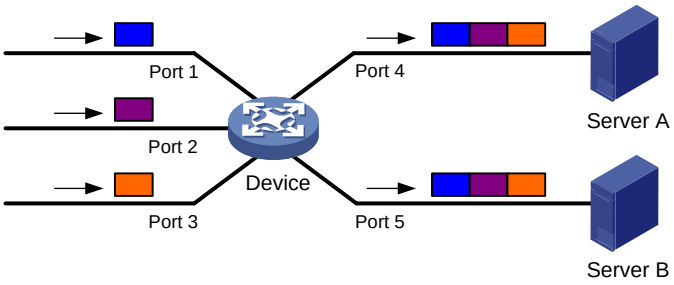
Perform this task if the device acts as a pure TAP device between a production network and a monitoring device. After TAP is enabled globally, the device disables unnecessary packet forwarding functions to prevent loops and broadcast storms.

Procedure

8. Enter system view.
   system-view
9. Enable TAP globally.
   tap enable
   By default, TAP is disabled globally.

Configuring a traffic class

10. Enter system view.
    system-view
11. Create a traffic class and enter traffic class view.
    traffic classifier *classifier-name* [**operator** { **and** | **or** }]
12. Configure match criteria.
    if-match *match-criteria*
    By default, no match criterion is configured in a traffic class.
    For more information, see *ACL and QoS Command Reference*.



Configuring a traffic behavior

Configuring an M:N copying action

About this task

This feature allows the device to forward packets it receives from multiple (M) interfaces to multiple (N) data monitoring devices (Server A and Server B), as shown in Figure 3.

Figure 3 Network diagram

Restrictions and guidelines

You can implement this feature by performing the following steps:

13. Configure a monitoring group with N member interfaces.
14. Create M TAP policies, and configure an action of redirecting packets to the monitoring group with N member interfaces for each QoS policy.
15. Apply the M TAP policies to M interfaces.

Procedure

16. Enter system view.

    `system-view`

17. Create a traffic behavior and enter traffic behavior view.

    `traffic behavior` *`behavior-name`*

18. Configure an action of redirecting packets to a monitoring group.

    `redirect monitoring-group` *`group-id`*

    By default, no action of redirecting packets to a monitoring group is configured.

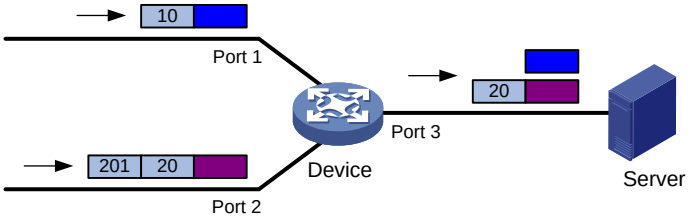
Configuring a VLAN ID marking action

About this task

This feature allows the device to mark packets received on different interfaces with different VLAN IDs. Then, the data monitoring device (the server) can identify the input interfaces of packets according to the marked VLAN IDs, as shown in Figure 4.

Figure 4 Network diagram

Procedure



19. Enter system view.
    system-view
20. Create a traffic behavior and enter traffic behavior view.
    traffic behavior *behavior-name*
21. Configure a VLAN ID marking action. Choose one option as needed:
    - Configure a CVLAN ID marking action.
      remark customer-vlan-id *vlan-id*
      By default, no CVLAN ID marking action is configured.
    - Configure an SVLAN ID marking action.
      remark service-vlan-id *vlan-id*
      By default, no SVLAN ID marking action is configured.
22. Configure an action of redirecting packets to a monitoring group.
    redirect monitoring-group *group-id*
    By default, no action of redirecting packets to a monitoring group is configured.

Configuring an outer VLAN tag deleting action

About this task

This feature is used in scenarios where the data monitoring device (the server) can only receive packets without VLAN tags or with one VLAN tag, as shown in Figure 5.

Figure 5 Network diagram

Procedure

23. Enter system view.
    system-view
24. Create a traffic behavior and enter traffic behavior view.
    traffic behavior *behavior-name*
25. Configure an outer VLAN tag deleting action.
    strip-header top-most-vlan

By default, no outer VLAN tag deleting action is configured.

26. Configure an action of redirecting packets to a monitoring group.

    redirect monitoring-group *group-id*

    By default, no action of redirecting packets to a monitoring group is configured.

Configuring an outer VLAN tag adding action

About this task

In some scenarios, the device receives packets with different CVLAN IDs on different interfaces. However, the data monitoring device (the server) must receive packets with the same SVLAN ID, as shown in Figure 6. This feature is used in such scenarios.

Figure 6 Network diagram

Procedure

27. Enter system view.

    system-view

28. Create a traffic behavior and enter traffic behavior view.

    traffic behavior *behavior-name*

29. Configure an outer VLAN tag adding action.

    nest top-most vlan *vlan-id* [**dot1p** *802.1p*]

    By default, no outer VLAN tag adding action is configured.

30. Configure an action of redirecting packets to a monitoring group.

    redirect monitoring-group *group-id*

    By default, no action of redirecting packets to a monitoring group is configured.

Configuring an IP or MAC address marking action

About this task

In some scenarios, the data monitoring device (the server) must receive packets with its own address as the destination address or identify the input interfaces of packets based on source addresses. This feature allows the device to modify the IP address and MAC address of packets, as shown in Figure 7.

Figure 7 Network diagram

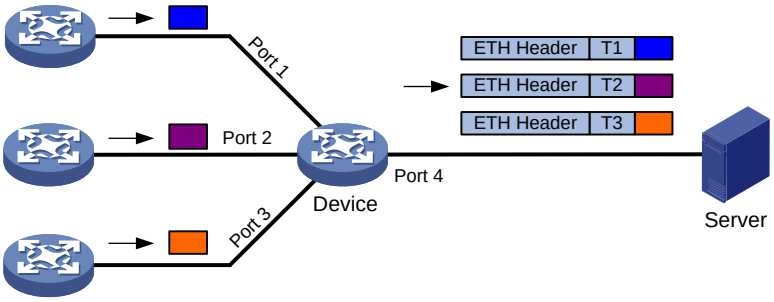
Procedure

31. Enter system view.

system-view

32. Create a traffic behavior and enter traffic behavior view.
    traffic behavior *behavior-name*
33. Configure an IP or MAC address marking action. Choose one option as needed:
    - Configure a destination IPv4 address marking action.
      remark destination-ip *ipv4-address*
      By default, no destination IPv4 address marking action is configured.
    - Configure a source IPv4 address marking action.
      remark source-ip *ipv4-address*
      By default, no source IPv4 address marking action is configured.
    - Configure a destination IPv6 address marking action.
      remark destination-ipv6 *ipv6-address*
      By default, no destination IPv6 address marking action is configured.
    - Configure a source IPv6 address marking action.
      remark source-ipv6 *ipv6-address*
      By default, no source IPv6 address marking action is configured.
    - Configure a destination MAC address marking action.
      remark destination-mac *mac-address*
      By default, no destination MAC address marking action is configured.
    - Configure a source MAC address marking action.
      remark source-mac *mac-address*
      By default, no source MAC address marking action is configured.
34. Configure an action of redirecting packets to a monitoring group.
    redirect monitoring-group *group-id*
    By default, no action of redirecting packets to a monitoring group is configured.

Configuring a timestamp and Ethernet header adding action



About this task

This feature allows a network to monitor the traffic of its internal devices.

Traditional TAP applications monitor the traffic on the egress device of a network. As the network grows and the performance requirements become higher, monitoring the traffic of the internal network devices is required. This feature is used in such scenarios.

As shown in Figure 8, interfaces on a TAP-enabled device connect to different devices. The device adds a timestamp, an Ethernet header, and a user-defined Ethernet protocol number to packets received on an interface, and redirects the packets to a monitoring group. Then, the device sends the packets to the data monitoring device (server). The server identifies the packets according to the Ethernet protocol number in the **ETH Header** field. The server calculates the network delay according to the timestamps TI, T2, and T3.

Figure 8 Network diagram

Procedure

35. Enter system view.

    system-view

36. Create a traffic behavior and enter traffic behavior view.

    traffic behavior *behavior-name*

37. Configure a timestamp and Ethernet header adding action.

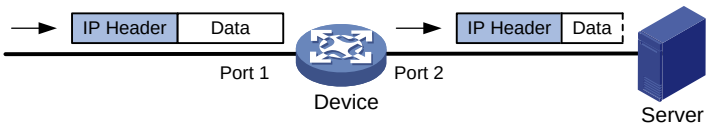
    timestamp-over-ether destination-mac *mac-address* **source-mac** *mac-address* **ethtype-id** *ethtype-id*

    By default, no timestamp and Ethernet header adding action is configured.

38. Configure an action of redirecting packets to a monitoring group.

    redirect monitoring-group *group-id*

    By default, no action of redirecting packets to a monitoring group is configured.



Configuring a packet truncation action

About this task

This feature reduces the packet processing pressure on the data monitoring device (the server) or prevents the device from sending packet payloads to the server.

This feature truncates packets beginning from the Layer 2 header. The CRC is recalculated for the truncated part. The packet length after truncation is the truncated part plus the CRC length.

Figure 9 Network diagram

Procedure

39. Enter system view.

    system-view

40. Create a traffic behavior and enter traffic behavior view.

    traffic behavior *behavior-name*

41. Enable packet truncation.

    truncation enable

    By default, packet truncation is disabled.

42. Configure an action of redirecting packets to a monitoring group.

redirect monitoring-group *group-id*

By default, no action of redirecting packets to a monitoring group is configured.

43. Return to system view.

    quit

44. Set the packet length after truncation.

    qos truncation length *length*

    The default setting is 128 bytes.

Configuring a tunnel header stripping action

About this task

In some scenarios, the data monitoring device (the server) cannot parse GRE, NVGRE, or VXLAN packets.

This feature allows the device to strip the tunnel header from the start of the outer Layer 2 header to the specified position.

Figure 10 GRE packet header stripping

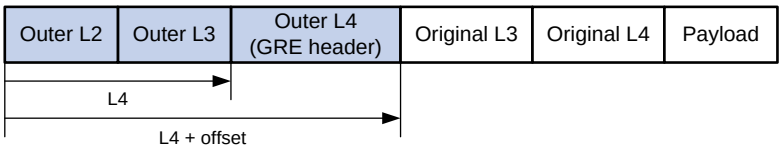


Figure 11 NVGRE packet header stripping

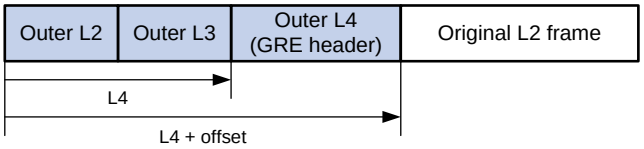

Figure 12 VXLAN packet header stripping

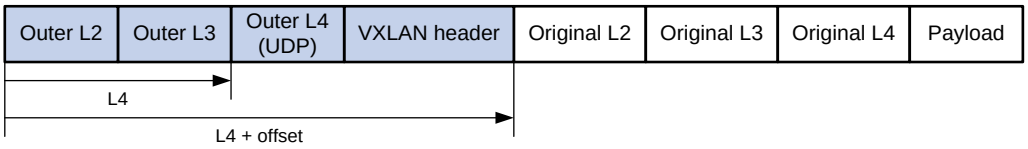

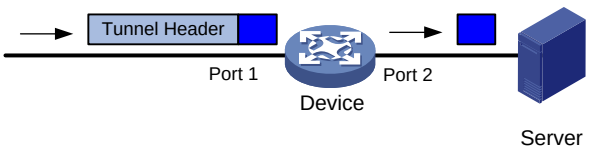

Figure 13 Network diagram for tunnel packet header stripping

Procedure

45. Enter system view.

    system-view

46. Create a traffic behavior and enter traffic behavior view.

    traffic behavior *behavior-name*

47. Configure a tunnel header stripping action.
    - Delete a tunnel header by using the user-defined method.
      strip-header position { **l2** | **l3** | **l4** } [**offset** *offset-value*]
    - Delete the GRE header.
      strip-header gre header-length *header-length* **encap-eth-header destination-mac** *mac-address* **source-mac** *mac-address* [**vlan** *vlan-id* [**dot1p** *dot1p-value*]] **ethtype-id** *ethtype-id*
    - Delete the NVGRE header.
      strip-header nvgre
    - Delete the VXLAN header.
      strip-header vxlan

    By default, no tunnel header stripping action is configured.
48. Configure an action of redirecting packets to a monitoring group.
    redirect monitoring-group *group-id*
    By default, no action of redirecting packets to a monitoring group is configured.

Configuring a TAP policy

49. Enter system view.
    system-view
50. Create a TAP policy and enter TAP policy view.
    qos tap policy *policy-name*
51. Associate a traffic class with a traffic behavior in the TAP policy.
    classifier *classifier-name* **behavior** *behavior-name*
    By default, no traffic behavior is associated with a traffic class.

Applying a TAP policy to the inbound direction of an interface

52. Enter system view.
    system-view
53. Enter interface view.
    interface *interface-type interface-number*
54. Apply a TAP policy to the interface.
    qos apply tap policy *policy-name* **inbound** [**inner-match**]
    By default, no TAP policy is applied to an interface.

Display and maintenance commands for TAP

Execute **display** commands in any view.

Task	Command
Display traffic class configuration.	**display traffic classifier user-defined** [*classifier-name*] [**slot** *slot-number*]

Task	Command
	For more information about this command, see flow mirroring commands in *ACL and QoS Command Reference*.
Display traffic behavior configuration.	**display traffic behavior user-defined** [*behavior-name*] [**slot** *slot-number*] For more information about this command, see flow mirroring commands in *ACL and QoS Command Reference*.
Display monitoring group information.	**display monitoring-group** { *group-id* | **all** } For more information about this command, see flow mirroring commands in *Network Management and Monitoring Command Reference*.
Display TAP policy configuration.	**display qos policy user-defined tap** [*policy-name* [**classifier** *classifier-name*]] [**slot** *slot-number*]
Display the configuration and statistics of TAP policies applied to interfaces.	**display qos tap policy interface** [*interface-type interface-number* [**inbound**] [**slot** *slot-number*]

TAP configuration examples

Example: Configuring basic M:N copying

Network configuration

As shown in Figure 14, Device D is a TAP device. Configure M:N copying on Device D to forward all packets received on GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 to Server A and Server B through GigabitEthernet 1/0/4 and GigabitEthernet 1/0/5.

Figure 14 Network diagram

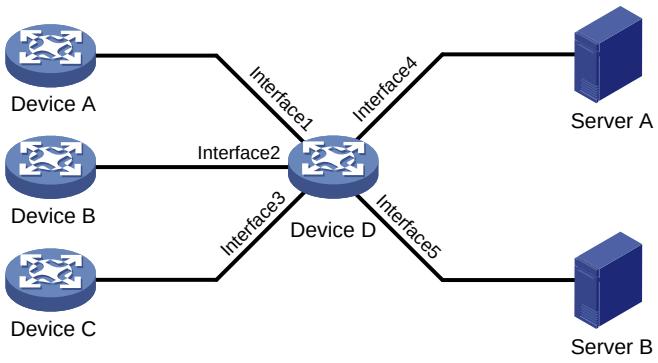

Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4
Interface5	GigabitEthernet1/0/5

Procedure

55. Enable TAP globally.

```
<DeviceD> system-view
[DeviceD] tap enable
```

56. Create monitoring group 1, and assign GigabitEthernet 1/0/4 and GigabitEthernet 1/0/5 to the monitoring group.

```
[DeviceD] monitoring-group 1
[DeviceD-monitoring-group-1] monitoring-port gigabitethernet 1/0/4 to
gigabitethernet 1/0/5
[DeviceD-monitoring-group-1] quit
```

57. Create a traffic class named **classifier_tap**, and configure the traffic class to match all packets.

```
[DeviceD] traffic classifier classifier_tap
[DeviceD-classifier-classifier_tap] if-match any
[DeviceD-classifier-classifier_tap] quit
```

58. Create a traffic behavior named **behavior_tap**, and configure an action of redirecting packets to monitoring group 1.

```
[DeviceD] traffic behavior behavior_tap
[DeviceD-behavior-behavior_tap] redirect monitoring-group 1
[DeviceD-behavior-behavior_tap] quit
```

59. Create a TAP policy named **policy_tap**, and associate the traffic class with the traffic behavior in the TAP policy.

```
[DeviceD] qos tap policy policy_tap
[DeviceD-qospolicy-policy_tap] classifier classifier_tap behavior behavior_tap
[DeviceD-qospolicy-policy_tap] quit
```

60. Applying the TAP policy.

    # Applying the TAP policy to the inbound direction of GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] qos apply tap policy policy_tap inbound
[DeviceD-GigabitEthernet1/0/1] quit
```

    # Applying the TAP policy to the inbound direction of GigabitEthernet 1/0/2.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] qos apply tap policy policy_tap inbound
[DeviceD-GigabitEthernet1/0/2] quit
```

    # Applying the TAP policy to the inbound direction of GigabitEthernet 1/0/3.

```
[DeviceD] interface gigabitethernet 1/0/3
[DeviceD-GigabitEthernet1/0/3] qos apply tap policy policy_tap inbound
[DeviceD-GigabitEthernet1/0/3] quit
```

Example: Configuring M:N copying for aggregate interfaces

Network configuration

As shown in Figure 15, Device B is a TAP device. Packets from Device A to Device C enter Device B on GigabitEthernet 1/0/1 and are sent to Device C on GigabitEthernet 1/0/2. Packets from Device C to Device A enter Device B on GigabitEthernet 1/0/2 and are sent to Device A on GigabitEthernet 1/0/1.

Configure M:N copying and link aggregation load sharing on Device B to meet the following requirements:

- Incoming packets on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are redirected to the aggregate interface.
- The aggregate interface loads share packets based on source IP addresses and destination IP addresses.
- The aggregate interface sends incoming packets on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to Device D over the same link by using algorithm 1 as the link aggregation load sharing algorithm.

Figure 15 Network diagram

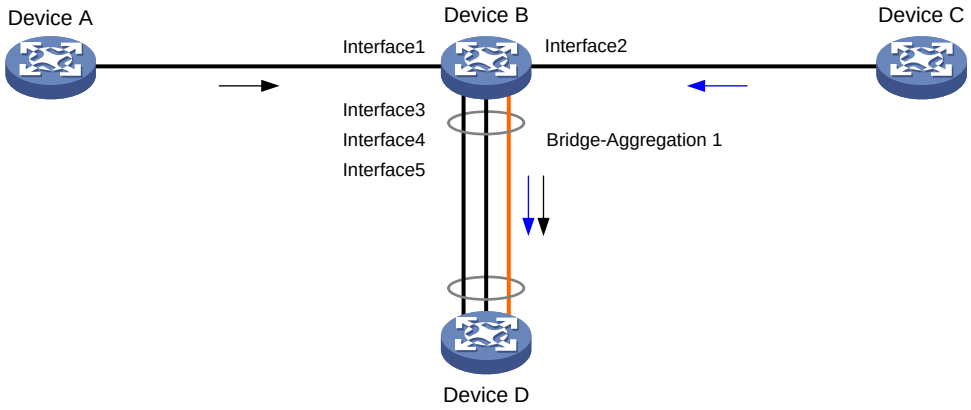

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4
Interface5	GigabitEthernet1/0/5

Procedure

61. Enable TAP globally.

```
<DeviceB> system-view
[DeviceB] tap enable
```

62. Configure an aggregate interface:

Create a Layer 2 aggregate interface named Bridge-Aggregation 1.

```
[DeviceB] interface bridge-aggregation 1
[DeviceB-Bridge-Aggregation1] quit
```

Assign GigabitEthernet 1/0/3, GigabitEthernet 1/0/4, and GigabitEthernet 1/0/5 to the aggregation group.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-aggregation group 1
[DeviceB-GigabitEthernet1/0/3] quit
[DeviceB] interface gigabitethernet 1/0/4
[DeviceB-GigabitEthernet1/0/4] port link-aggregation group 1
[DeviceB-GigabitEthernet1/0/4] quit
[DeviceB] interface gigabitethernet 1/0/5
```

```
[DeviceB-GigabitEthernet1/0/5] port link-aggregation group 1
[DeviceB-GigabitEthernet1/0/5] quit
```

NOTE:

You can use the **port link-mode** command to configure an Ethernet port as a Layer 2 or Layer 3 interface (see *Layer 2—LAN Switching Configuration Guide*).

63. Configure a monitoring group:

Create monitoring group 1, and assign the Layer 2 aggregate interface to the monitoring group.

```
[DeviceB] monitoring-group 1
[DeviceB-monitoring-group-1] monitoring-port bridge-aggregation 1
[DeviceB-monitoring-group-1] quit
```

64. Configure traffic classes:

Create IPv4 advanced ACL 3001, and configure a rule to match packets with source IP address 192.168.1.1 and destination IP address 192.168.2.1.

```
[DeviceB] acl advanced 3001
[DeviceB-acl-ipv4-adv-3001] rule permit ip source 192.168.1.1 0 destination
192.168.2.1 0
[DeviceB-acl-ipv4-adv-3001] quit
```

Create a traffic class named **classifier1**, and use ACL 3001 as the match criterion.

```
[DeviceB] traffic classifier classifier1
[DeviceB-classifier-classifier1] if-match acl 3001
[DeviceB-classifier-classifier1] quit
```

Create IPv4 advanced ACL 3002, and configure a rule to match packets with source IP address 192.168.2.1 and destination IP address 192.168.1.1.

```
[DeviceB] acl advanced 3002
[DeviceB-acl-ipv4-adv-3002] rule permit ip source 192.168.2.1 0 destination
192.168.1.1 0
[DeviceB-acl-ipv4-adv-3002] quit
```

Create a traffic class named **classifier2**, and use ACL 3002 as the match criterion.

```
[DeviceB] traffic classifier classifier2
[DeviceB-classifier-classifier2] if-match acl 3002
[DeviceB-classifier-classifier2] quit
```

65. Configure a traffic behavior:

Create a traffic behavior named **behavior1**, and configure an action of redirecting packets to monitoring group 1.

```
[DeviceD] traffic behavior behavior_tap
[DeviceD-behavior-behavior_tap] redirect monitoring-group 1
[DeviceD-behavior-behavior_tap] quit
```

66. Configure TAP policies:

Create a TAP policy named **policy1**, and associate traffic class **classifier1** with traffic behavior **behavior1** in the TAP policy.

```
[DeviceB] qos tap policy policy1
[DeviceB-qospolicy-policy1] classifier classifier1 behavior behavior1
[DeviceB-qospolicy-policy1] quit
```

Create a TAP policy named **policy2**, and associate traffic class **classifier2** with traffic behavior **behavior1** in the TAP policy.

```
[DeviceB] qos tap policy policy2
[DeviceB-qospolicy-policy2] classifier classifier2 behavior behavior1
[DeviceB-qospolicy-policy2] quit
```

67. Applying TAP policies:

Applying TAP policy **policy1** to the inbound direction of GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] qos apply tap policy policy1 inbound
[DeviceD-GigabitEthernet1/0/1] quit
```

Applying TAP policy **policy2** to the inbound direction of GigabitEthernet 1/0/2.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] qos apply tap policy policy2 inbound
[DeviceD-GigabitEthernet1/0/2] quit
```

68. Set the global load sharing mode to load share packets based on source IP addresses and destination IP addresses.

```
[DeviceB] link-aggregation global load-sharing mode source-ip destination-ip
```

69. Specify algorithm 1 as the link aggregation load sharing algorithm.

```
[DeviceB] link-aggregation global load-sharing algorithm 1
```

Example: Configuring VLAN ID marking

Network configuration

As shown in Figure 16, Device C is a TAP device. Configure VLAN ID marking on Device C to meet the following requirements:

- Mark CVLAN 10 for packets received on GigabitEthernet 1/0/1.
- Mark CVLAN 20 for packets received on GigabitEthernet 1/0/2.
- Forward packets with CVLAN 10 and packets with CVLAN 20 to the server through GigabitEthernet 1/0/3, enabling the server to identify the input interfaces of packets according to VLAN IDs.

Figure 16 Network diagram

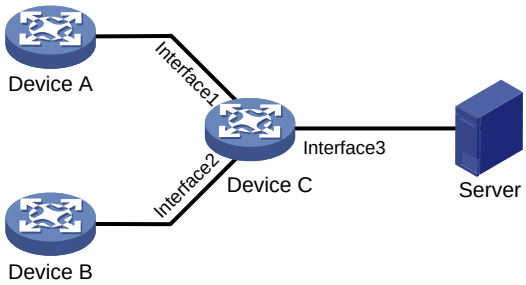

Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

70. Enable TAP globally.

```
<DeviceC> system-view
[DeviceC] tap enable
```

71. Create monitoring group 1, and assign GigabitEthernet 1/0/3 to the monitoring group.

```
[DeviceC] monitoring-group 1
[DeviceC-monitoring-group-1] monitoring-port gigabitethernet 1/0/3
[DeviceC-monitoring-group-1] quit
```

72. Create a traffic class named **classifier_tap**, and configure the traffic class to match all packets.

```
[DeviceC] traffic classifier classifier_tap
[DeviceC-classifier-classifier_tap] if-match any
[DeviceC-classifier-classifier_tap] quit
```

73. Configure traffic behaviors:

Create a traffic behavior named **behavior_tap1**, and configure an action of marking CVLAN 10 and an action of redirecting packets to monitoring group 1.

```
[DeviceC] traffic behavior behavior_tap1
[DeviceC-behavior-behavior_tap1] remark customer-vlan-id 10
[DeviceC-behavior-behavior_tap1] redirect monitoring-group 1
[DeviceC-behavior-behavior_tap1] quit
```

Create a traffic behavior named **behavior_tap2**, and configure an action of marking CVLAN 20 and an action of redirecting packets to monitoring group 1.

```
[DeviceC] traffic behavior behavior_tap2
[DeviceC-behavior-behavior_tap2] remark customer-vlan-id 20
[DeviceC-behavior-behavior_tap2] redirect monitoring-group 1
[DeviceC-behavior-behavior_tap2] quit
```

74. Configure TAP policies:

Create a TAP policy named **policy_tap1**, and associate traffic class **classifier_tap** with traffic behavior **behavior_tap1** in the TAP policy.

```
[DeviceC] qos tap policy policy_tap1
[DeviceC-qospolicy-policy_tap1] classifier classifier_tap behavior behavior_tap1
[DeviceC-qospolicy-policy_tap1] quit
```

Create a TAP policy named **policy_tap2**, and associate traffic class **classifier_tap** with traffic behavior **behavior_tap2** in the TAP policy.

```
[DeviceC] qos tap policy policy_tap2
[DeviceC-qospolicy-policy_tap2] classifier classifier_tap behavior behavior_tap2
[DeviceC-qospolicy-policy_tap2] quit
```

75. Apply the TAP policies.

Apply TAP policy **policy_tap1** to the inbound direction of GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] qos apply tap policy policy_tap1 inbound
[DeviceC-GigabitEthernet1/0/1] quit
```

Apply TAP policy **policy_tap2** to the inbound direction of GigabitEthernet 1/0/2.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] qos apply tap policy policy_tap2 inbound
[DeviceC-GigabitEthernet1/0/2] quit
```

Example: Configuring outer VLAN tag deleting

Network configuration

As shown in Figure 17, Device C is a TAP device, and GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 receive double-tagged packets.

Configure Device C to meet the following requirements:

- Delete the outer VLAN tag of the packets received on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.
- Forward the packets to the server through GigabitEthernet 1/0/3.

Figure 17 Network diagram

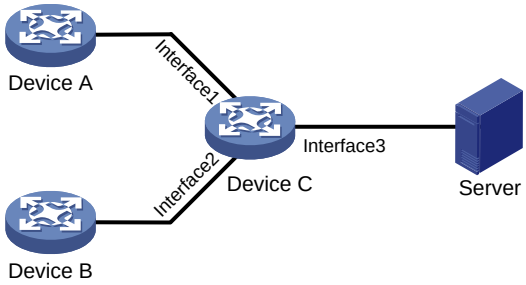

Table 4 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

76. Enable TAP globally.

```
<DeviceC> system-view
[DeviceC] tap enable
```

77. Create monitoring group 1, and assign GigabitEthernet 1/0/3 to the monitoring group.

```
[DeviceC] monitoring-group 1
[DeviceC-monitoring-group-1] monitoring-port gigabitethernet 1/0/3
[DeviceC-monitoring-group-1] quit
```

78. Create a traffic class named **classifier_tap**, and configure the traffic class to match all packets.

```
[DeviceC] traffic classifier classifier_tap
[DeviceC-classifier-classifier_tap] if-match any
[DeviceC-classifier-classifier_tap] quit
```

79. Create a traffic behavior named **behavior_tap**, and configure an outer VLAN tag deleting action and an action of redirecting packets to monitoring group 1.

```
[DeviceC] traffic behavior behavior_tap
[DeviceC-behavior-behavior_tap] strip-header top-most-vlan
[DeviceC-behavior-behavior_tap] redirect monitoring-group 1
[DeviceC-behavior-behavior_tap] quit
```

80. Create a TAP policy named **policy_tap**, and associate the traffic class with the traffic behavior in the TAP policy.

```
[DeviceC] qos tap policy policy_tap
[DeviceC-qospolicy-policy_tap] classifier classifier_tap behavior behavior_tap
[DeviceC-qospolicy-policy_tap] quit
```

81. Apply the TAP policy.

Apply TAP policy **policy_tap** to the inbound direction of GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] qos apply tap policy policy_tap inbound
[DeviceC-GigabitEthernet1/0/1] quit
```

Apply TAP policy **policy_tap** to the inbound direction of GigabitEthernet 1/0/2.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] qos apply tap policy policy_tap inbound
[DeviceC-GigabitEthernet1/0/2] quit
```

Example: Configuring outer VLAN tag adding

Network configuration

As shown in Figure 18, Device C is a TAP device, and GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 receive single-tagged packets.

Configure Device C to meet the following requirements:

- Add an outer VLAN tag for the packets received on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.
- Forward the packets to the server through GigabitEthernet 1/0/3.

Figure 18 Network diagram

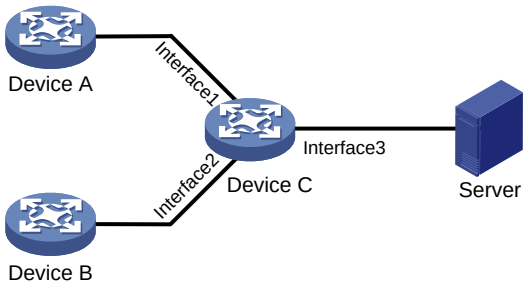

Table 5 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

82. Enable TAP globally.

```
<DeviceC> system-view
[DeviceC] tap enable
```

83. Create monitoring group 1, and assign GigabitEthernet 1/0/3 to the monitoring group.

```
[DeviceC] monitoring-group 1
[DeviceC-monitoring-group-1] monitoring-port gigabitethernet 1/0/3
```

```
[DeviceC-monitoring-group-1] quit
```

84. Create a traffic class named **classifier_tap**, and configure the traffic class to match all packets.

```
[DeviceC] traffic classifier classifier_tap
[DeviceC-classifier-classifier_tap] if-match any
[DeviceC-classifier-classifier_tap] quit
```

85. Create a traffic behavior named **behavior_tap**, and configure an outer VLAN tag adding action and an action of redirecting packets to monitoring group 1.

```
[DeviceC] traffic behavior behavior_tap
[DeviceC-behavior-behavior_tap] nest top-most vlan 10
[DeviceC-behavior-behavior_tap] redirect monitoring-group 1
[DeviceC-behavior-behavior_tap] quit
```

86. Create a TAP policy named **policy_tap**, and associate the traffic class with the traffic behavior in the TAP policy.

```
[DeviceC] qos tap policy policy_tap
[DeviceC-qospolicy-policy_tap] classifier classifier_tap behavior behavior_tap
[DeviceC-qospolicy-policy_tap] quit
```

87. Apply the TAP policy.

    # Apply TAP policy **policy_tap** to the inbound direction of GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] qos apply tap policy policy_tap inbound
[DeviceC-GigabitEthernet1/0/1] quit
```

    # Apply TAP policy **policy_tap** to the inbound direction of GigabitEthernet 1/0/2.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] qos apply tap policy policy_tap inbound
[DeviceC-GigabitEthernet1/0/2] quit
```

Example: Configuring destination MAC address marking

Network configuration

As shown in Figure 19, Device B is a TAP device. Configure Device B to meet the following requirements:

- Modify the destination MAC address of the packets received on GigabitEthernet 1/0/1 as the MAC address of the server.
- Forward the packets to the server through GigabitEthernet 1/0/2.

Figure 19 Network diagram

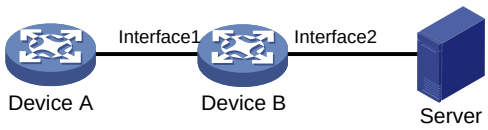

Table 6 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

88. Enable TAP globally.

```
<DeviceB> system-view
[DeviceB] tap enable
```

89. Create monitoring group 1, and assign GigabitEthernet 1/0/2 to the monitoring group.

```
[DeviceB] monitoring-group 1
[DeviceB-monitoring-group-1] monitoring-port gigabitethernet 1/0/2
[DeviceB-monitoring-group-1] quit
```

90. Create a traffic class named **classifier_tap**, and configure the traffic class to match all packets.

```
[DeviceB] traffic classifier classifier_tap
[DeviceB-classifier-classifier_tap] if-match any
[DeviceB-classifier-classifier_tap] quit
```

91. Create a traffic behavior named **behavior_tap**, and configure a destination MAC address marking action and an action of redirecting packets to monitoring group 1.

```
[DeviceB] traffic behavior behavior_tap
[DeviceB-behavior-behavior_tap] remark destination-mac 0050-ba27-bed3
[DeviceB-behavior-behavior_tap] redirect monitoring-group 1
[DeviceB-behavior-behavior_tap] quit
```

92. Create a TAP policy named **policy_tap**, and associate the traffic class with the traffic behavior in the TAP policy.

```
[DeviceB] qos tap policy policy_tap
[DeviceB-qospolicy-policy_tap] classifier classifier_tap behavior behavior_tap
[DeviceB-qospolicy-policy_tap] quit
```

93. Apply TAP policy **policy_tap** to the inbound direction of GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] qos apply tap policy policy_tap inbound
[DeviceB-GigabitEthernet1/0/1] quit
```

Example: Configuring timestamp and Ethernet header adding

Network configuration

As shown in Figure 20, Device D is a TAP device. Configure timestamp and Ethernet header adding on Device D to meet the following requirements:

- Add destination MAC address 0050-ba27-bed4, source MAC address 0050-ba27-bed1, and Ethernet protocol number FF for packets received on GigabitEthernet 1/0/1.
- Add destination MAC address 0050-ba27-bed4, source MAC address 0050-ba27-bed2, and Ethernet protocol number FF for packets received on GigabitEthernet 1/0/2.
- Add destination MAC address 0050-ba27-bed4, source MAC address 0050-ba27-bed3, and Ethernet protocol number FF for packets received on GigabitEthernet 1/0/3.
- Forward the packets to the server through GigabitEthernet 1/0/4.

Figure 20 Network diagram

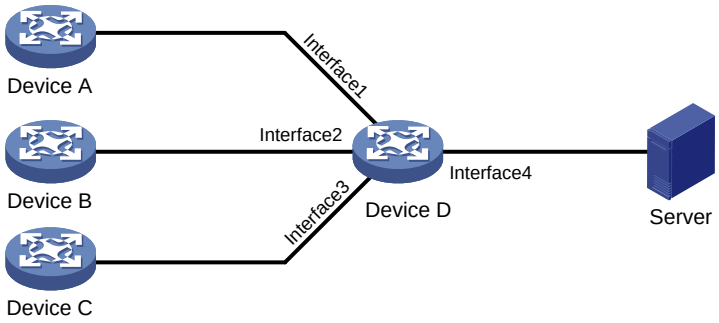

Table 7 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4

Procedure

94. Enable TAP globally.

```
<DeviceD> system-view
[DeviceD] tap enable
```

95. Create monitoring group 1, and assign GigabitEthernet 1/0/4 to the monitoring group.

```
[DeviceD] monitoring-group 1
[DeviceD-monitoring-group-1] monitoring-port gigabitethernet 1/0/4
[DeviceD-monitoring-group-1] quit
```

96. Configure a traffic class.

Create IPv4 advanced ACL 3001, and configure a rule to match all TCP packets.

```
[DeviceD] acl advanced 3001
[DeviceD-acl-ipv4-adv-3001] rule permit tcp
[DeviceD-acl-ipv4-adv-3001] quit
```

Create a traffic class named **classifier_tap**, and use ACL 3001 as the match criterion.

```
[DeviceD] traffic classifier classifier_tap
[DeviceD-classifier-classifier_tap] if-match acl 3001
[DeviceD-classifier-classifier_tap] quit
```

97. Configure traffic behaviors:

Create a traffic behavior named **behavior_tap1**, and configure an action of add destination MAC address 0050-ba27-bed4, source MAC address 0050-ba27-bed1, and Ethernet protocol number FF, and an action of redirecting packets to monitoring group 1.

```
[DeviceD] traffic behavior behavior_tap1
[DeviceD-behavior-behavior_tap1] timestamp-over-ether destination-mac
0050-ba27-bed4 source-mac 0050-ba27-bed1 ethtype-id ff
[DeviceD-behavior-behavior_tap1] redirect monitoring-group 1
[DeviceD-behavior-behavior_tap1] quit
```

Create a traffic behavior named **behavior_tap2**, and configure an action of adding destination MAC address 0050-ba27-bed4, source MAC address 0050-ba27-bed2, and Ethernet protocol number FF, and an action of redirecting packets to monitoring group 1.

```
[DeviceD] traffic behavior behavior_tap2
[DeviceD-behavior-behavior_tap2] timestamp-over-ether destination-mac
0050-ba27-bed4 source-mac 0050-ba27-bed2 ethtype-id ff
[DeviceD-behavior-behavior_tap2] redirect monitoring-group 1
[DeviceD-behavior-behavior_tap2] quit
```

Create a traffic behavior named **behavior_tap3**, and configure an action of adding destination MAC address 0050-ba27-bed4, source MAC address 0050-ba27-bed3, and Ethernet protocol number FF, and an action of redirecting packets to monitoring group 1.

```
[DeviceD] traffic behavior behavior_tap3
[DeviceD-behavior-behavior_tap3] timestamp-over-ether destination-mac
0050-ba27-bed4 source-mac 0050-ba27-bed3 ethtype-id ff
[DeviceD-behavior-behavior_tap3] redirect monitoring-group 1
[DeviceD-behavior-behavior_tap2] quit
```

98. Configure TAP policies:

Create a TAP policy named **policy_tap1**, and associate traffic class **classifier_tap** with traffic behavior **behavior_tap1** in the TAP policy.

```
[DeviceD] qos tap policy policy_tap1
[DeviceD-qospolicy-policy_tap1] classifier classifier_tap behavior behavior_tap1
[DeviceD-qospolicy-policy_tap1] quit
```

Create a TAP policy named **policy_tap2**, and associate traffic class **classifier_tap** with traffic behavior **behavior_tap2** in the TAP policy.

```
[DeviceD] qos tap policy policy_tap2
[DeviceD-qospolicy-policy_tap2] classifier classifier_tap behavior behavior_tap2
[DeviceD-qospolicy-policy_tap2] quit
```

Create a TAP policy named **policy_tap3**, and associate traffic class **classifier_tap** with traffic behavior **behavior_tap3** in the TAP policy.

```
[DeviceD] qos tap policy policy_tap3
[DeviceD-qospolicy-policy_tap3] classifier classifier_tap behavior behavior_tap3
[DeviceD-qospolicy-policy_tap3] quit
```

99. Apply the TAP policies:

Apply TAP policy **policy_tap1** to the inbound direction of GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] qos apply tap policy policy_tap1 inbound
[DeviceD-GigabitEthernet1/0/1] quit
```

Apply TAP policy **policy_tap2** to the inbound direction of GigabitEthernet 1/0/2.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] qos apply tap policy policy_tap2 inbound
[DeviceD-GigabitEthernet1/0/2] quit
```

Apply TAP policy **policy_tap3** to the inbound direction of GigabitEthernet 1/0/3.

```
[DeviceD] interface gigabitethernet 1/0/3
[DeviceD-GigabitEthernet1/0/3] qos apply tap policy policy_tap2 inbound
[DeviceD-GigabitEthernet1/0/3] quit
```

Example: Configuring packet truncation

Network configuration

As shown in Figure 21, Device B is a TAP device. Configure Device B to meet the following requirements:

- Truncate the packets received on GigabitEthernet 1/0/1.
- Forward the truncated packets to the server through GigabitEthernet 1/0/2.

Figure 21 Network diagram

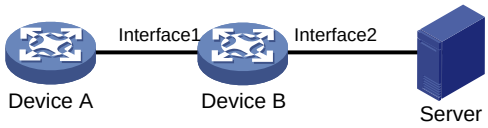

Table 8 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

100. Enable TAP globally.

```
<DeviceB> system-view
[DeviceB] tap enable
```

101. Create monitoring group 1, and assign GigabitEthernet 1/0/2 to the monitoring group.

```
[DeviceB] monitoring-group 1
[DeviceB-monitoring-group-1] monitoring-port gigabitethernet 1/0/2
[DeviceB-monitoring-group-1] quit
```

102. Configure a traffic class.

Create IPv4 advanced ACL 3001, and configure a rule to match TCP packets with source IP address 10.0.0.1 and mask 255.255.255.0.

```
[DeviceB] acl advanced 3001
[DeviceB-acl-ipv4-adv-3001] rule permit tcp source 10.0.0.1 255.255.255.0
[DeviceB-acl-ipv4-adv-3001] quit
```

Create a traffic class named **classifier_tap**, and use ACL 3001 as the match criterion.

```
[DeviceB] traffic classifier classifier_tap
[DeviceB-classifier-classifier_tap] if-match acl 3001
[DeviceB-classifier-classifier_tap] quit
```

103. Create a traffic behavior named **behavior_tap**, and configure a packet truncation enabling action and an action of redirecting packets to monitoring group 1.

```
[DeviceB] traffic behavior behavior_tap
[DeviceB-behavior-behavior_tap] truncation enable
[DeviceB-behavior-behavior_tap] redirect monitoring-group 1
[DeviceB-behavior-behavior_tap] quit
```

104. Configure packet truncation.

Set the packet truncation length to 100 bytes.

```
[DeviceB] qos truncation length 100
```

105. Create a TAP policy named **policy_tap**, and associate the traffic class with the traffic behavior in the TAP policy.

```
[DeviceB] qos tap policy policy_tap
[DeviceB-qospolicy-policy_tap] classifier classifier_tap behavior behavior_tap
[DeviceB-qospolicy-policy_tap] quit
```

106. Apply TAP policy **policy_tap** to the inbound direction of GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] qos apply tap policy policy_tap inbound
[DeviceB-GigabitEthernet1/0/1] quit
```

Example: Configuring NVGRE header stripping

Network configuration

As shown in Figure 22, Device B is a TAP device, and the server does not support parsing NVGRE packets.

Configure NVGRE header stripping on GigabitEthernet 1/0/1 and traffic redirecting to GigabitEthernet 1/0/2.

Figure 22 Network diagram

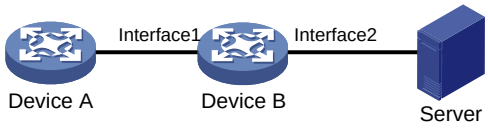

Table 9 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

107. Enable TAP globally.

```
<DeviceB> system-view
[DeviceB] tap enable
```

108. Create monitoring group 1, and assign GigabitEthernet 1/0/2 to the monitoring group.

```
[DeviceB] monitoring-group 1
[DeviceB-monitoring-group-1] monitoring-port gigabitethernet 1/0/2
[DeviceB-monitoring-group-1] quit
```

109. Create a traffic class named **classifier_tap**, and configure the traffic class to match NVGRE packets with VSID FFFF28.

```
[DeviceB] traffic classifier classifier_tap
[DeviceB-classifier-classifier_tap] if-match nvgre-vsid ffff28
[DeviceB-classifier-classifier_tap] quit
```

110. Create a traffic behavior named **behavior_tap**, and configure an action of stripping the outer Layer 2 header, outer Layer 3 header, and the GRE header of NVGRE packets, and an action of redirecting packets to monitoring group 1.

```
[DeviceB] traffic behavior behavior_tap
[DeviceB-behavior-behavior_tap] strip-header position l4 offset 4
[DeviceB-behavior-behavior_tap] redirect monitoring-group 1
```

```
[DeviceB-behavior-behavior_tap] quit
```

111. Create a TAP policy named **policy_tap**, and associate the traffic class with the traffic behavior in the TAP policy.

```
[DeviceB] qos tap policy policy_tap
[DeviceB-qospolicy-policy_tap] classifier classifier_tap behavior behavior_tap
[DeviceB-qospolicy-policy_tap] quit
```

112. Apply TAP policy **policy_tap** to the inbound direction of GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] qos apply tap policy policy_tap inbound
[DeviceB-GigabitEthernet1/0/1] quit
```

All contents in this document, including statements, information, and recommendations, are believed to be accurate, but they are presented without warranty of any kind, express or implied. H3C shall not be liable for technical or editorial errors or omissions contained herein.

Preface

This configuration guide describes the Intelligent Lossless Network fundamentals and configuration procedures.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

Configuring PFC

About PFC

Priority-based flow control (PFC) provides a finer flow control mechanism to implement lossless packet transmission on Ethernet.

PFC performs flow control for packets based on the 802.1p priorities carried in packets. As shown in Figure 1, PFC establishes eight virtual channels over an Ethernet link, each corresponding to an 802.1p priority. Any virtual channel can be paused or restarted independent of the other channels. This mechanism allows multiple types of traffic to coexist on and share an Ethernet link.

Figure 1 How PFC works

When congestion occurs on the local end, the device determines how to process received packets based on the 802.1p priorities carried in packets as follows:

- If PFC is enabled for the 802.1p priority carried in a packet, the local end accepts the packet and sends PFC pause frames to notify the remote end to stop sending packets carrying the 802.1p priority. The remote end stops sending packets carrying the 802.1p priority after receiving the PFC pause frames. This process is repeated until congestion is eliminated.
- If PFC is not enabled for the 802.1p priority carried in a packet, the local end drops the packet.

Restrictions and guidelines

You can configure PFC in system view or Ethernet interface view. When you configure PFC in system view and Ethernet interface view multiple times, the most recent configuration takes effect.

If you do not enable PFC on an interface, the interface can receive but cannot process PFC pause frames. To make PFC take effect, you must enable PFC on both ends.

To avoid packet loss, apply the same PFC configuration to all interfaces that the packets pass through.

Generic flow control and PFC are mutually exclusive on an interface. For more information about generic flow control, see Ethernet interface configuration in *Interface Configuration Guide*.

In an IRF network, follow these restrictions and guidelines:

- For IRF and other protocols to operate correctly, as a best practice, do not enable PFC for 802.1p priority 0, 6, or 7.

- To perform PFC on an IRF port, configure PFC on the IRF port and the IRF physical ports that are bound to the IRF port.

For information about IRF, see *IRF configuration Guide*.

Configuring PFC on interfaces

Configuring PFC on an Ethernet interface

1. Enter system view.
   system-view
2. Enable PFC on all Ethernet interfaces.
   priority-flow-control { **auto** | **enable** }
   By default, PFC is disabled on all Ethernet interfaces.
3. Enable PFC for 802.1p priorities on all Ethernet interfaces.
   priority-flow-control no-drop dot1p *dot1p-list*
   By default, PFC is disabled for all 802.1p priorities on all Ethernet interfaces.
4. Enter Ethernet interface view.
   interface *interface-type interface-number*
5. Enable PFC on the Ethernet interface.
   priority-flow-control { **auto** | **enable** }
   By default, PFC is disabled.
6. Enable PFC for 802.1p priorities.
   priority-flow-control no-drop dot1p *dot1p-list*
   By default, PFC is disabled for all 802.1p priorities.

Configuring the early warning thresholds for PFC packets

About this task

You can configure the early warning threshold for incoming or outgoing PFC packets of an interface as needed. The early warning threshold notifies a situation where the PFC packet transmission rate is still within a normal range but needs attention.

When the rate of PFC packets that an interface sends or receives reaches the early warning threshold, the system generates traps and logs to notify the user. According to the traps and logs, the user can discover some exceptions in the network, for example:

- The NIC of the peer device fails and continuously sends PFC packets at a high speed. In this case, you can set the early warning threshold for incoming PFC packets.
- The device fails and continuously sends PFC frames. In this case, you can set the early warning threshold for outgoing PFC packets.

To monitor bidirectional PFC packets, you can set the early warning thresholds for incoming packets and outgoing packets separately.

Restrictions and guidelines

The number of PFC pause frames that an interface sends or receives is counted and the early warning threshold configuration takes effect only when PFC is enabled.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Configure the early warning threshold for incoming PFC packets.
   priority-flow-control early-warning inpps *pps-value*
   By default, no early warning threshold is configured for incoming PFC packets.
4. Configure the early warning threshold for outgoing PFC packets.
   priority-flow-control early-warning outpps *pps-value*
   By default, no early warning threshold is configured for outgoing PFC packets.

Verifying and maintaining PFC

Execute **display** commands in any view.

Task	Command
Display the PFC information of interfaces.	**display priority-flow-control interface** [*interface-type* [*interface-number*]]

C-BSR	Candidate-BSR
CBT	Core-Based Tree
CBTS	Class-of-service Based Tunnel Selection
CBWFQ	Class Based Weighted Fair Queuing
CC	Continuity Check
CC	Call Control
CC	Control Channel
CC	Challenge Collapsar
CC	Common Criteria
CCA	Clear Channel Assessment
CCC	Circuit Cross Connect
CCF	Congestion Controlled Flow
CCM	Continuity Check Message
CD	Computed Distance
C-DCC	Circular DCC
CDCP	S-Channel Discovery and Configuration Protocol
CDP	Cisco Discovery Protocol
CDR	Call Detail Record

CDV	Cell Delay Variation
CE	Customer Edge
CED	Called Station Identifier
CEDCNG	Called Station Identifier
CEE	Converged Enhanced Ethernet
CEM	Circuit Emulation
CEM Class	Circuit Emulation Class
CESoPSN	Circuit Emulation Services over PSN
CFD	Connectivity Fault Detection
CFI	Canonical Format Indicator
CFM	Connectivity Fault Management
CGN	Carrier Grade NAT
CHAP	Challenge Handshake Authentication Protocol
CID	Calling Identity Delivery
CIDR	Classless Inter-Domain Routing
CIR	Committed Information Rate
CIR ALLOW	Committed Information Rate ALLOW
CIST	Common and Internal Spanning Tree
CLC	Channel Link Control
CLI	Command Line Interface
CLI	Calling Line Identification
CLNP	Connection-Less Network Protocol
CLP	Cell Loss Priority
CMC	Call Management Center
CNAME	Canonical Name
CND	Congestion Notification Domain
CNG	Comfortable Noise Generation
CNG	Calling Tone
CNGCED	Calling Tone
CNM	Congestion Notification Message
CNPV	Congestion Notification Priority Value
CO	Central Office
COPS	Common Open Policy Service
CoS	Class of Service
CP	Congestion Point
CP	Control Plane
CPE	Customer Premises Equipment
CPOS	Channelized POS
CPS	Certification Practice Statement
CPTone	Call Progress Tone

CQ	Custom Queuing
CR	Constraint-based Routing
CR	Core Router
CRC	Cyclic Redundancy Check
CRC	Cyclic Redundancy Code
CRC4	Cyclic Redundancy Check 4
CRL	Certificate Revocation List
CRLDP	Constraint-based Routed Label Distribution Protocol
CRLSP	Constraint-based Routed Label Switched Paths
C-RP	Candidate-RP
CS	Class Selector
CSMA/CD	Carrier Sense Multiple Access/Collision Detect
CSNP	Complete Sequence Number PDU
CSP	Port Extender Control and Status Protocol
CSPF	Constraint-based Shortest Path First
CST	Common Spanning Tree
CSV	Comma Separated Value
CT	Class Type
CTR	Counter mode
CTS	Clear to Send
CUG	Closed User Group
CV	Connectivity Verification
CWMP	CPE WAN Management Protocol
D	Return
DAC	Data Analysis Center
DAC	Digital to Analog Converter
DAD	Duplicate Address Detection
DAE	Dynamic Authorization Extensions
DAR	Deeper Application Recognition
Data-MDT	Data-Multicast Distribution Tree
DBA	Dynamic Bandwidth Allocation
DCBX	Data Center Bridging Exchange Protocol
DCC	Dial Control Center
DCD	Data Carrier Detection
DCE	Data Center Ethernet
DCE	Data Circuit-terminating Equipment
DCF	Distributed Coordination Function
DCN	Data Communication Network
DCR	Differential Clock Recovery

DD	Database Description
DDN	Digital Data Network
DDNS	Dynamic Domain Name System
DDoS	Distributed Denial of Service
DDR	Dial-on-Demand Routing
DDT	Delegated Database Tree
DE	Discard Eligibility
DED	Designated Edge Device
Default-MDT	Default-Multicast Distribution Tree
DER	Distinguished Encoding Rules
DF	Designated Forwarder
DGAF	Downstream Group-Addressed Forwarding
DH	Diffie-Hellman
DHCP	Dynamic Host Configuration Protocol
DHCPv6	Dynamic Host Configuration Protocol for IPv6
DID	Direct Inward Dialing
DID	Device ID
DiffServ	Differentiated Service
DIS	Designated IS
DLCI	Data Link Connection Identifier
DLDP	Device Link Detection Protocol
DLSw	Data Link Switching
DM	Diagnostic and Monitoring
DM	Delay Measurement
DMC	Device Management Controller
DMM	Delay Measurement Message
DMR	Delay Measurement Reply
DMZ	Demilitarized Zone
DN	Distinguished Name
DN	Directory Number
DNAT	Destination Network Address Translation
DND	Do-not Disturb
DNS	Domain Name System
DNSSL	DNS Search List
DNU	Do Not Use for synchronization
DoD	Downstream On Demand
DoS	Denial of Service
DP	Drop Profile
DP	Data Plane
DPD	Dead Peer Detection

DPI	Deep Packet Inspection
DR	Designated Router
DR device	Distributed Relay device
DRB	Designated Routing Bridge
DRCP	Distributed Relay Control Protocol
DRCPDU	Distributed Relay Control Protocol Data Unit
DRE	Data Redundancy Elimination
DRNI	Distributed Resilient Network Interconnect
DRS	DPI Report Statistics
DS	Differentiated Services
DSA	Digital Signature Algorithm
DSCP	Differentiated Services Code Point
DSL	Digital Subscriber Line
DS-Lite	Dual Stack Lite
DSU	Data Service Unit
DTD	Document Type Definition
DTE	Data Terminal Equipment
DTIM	Delivery Traffic Indication Message
DTLS	Datagram Transport Layer Security
DTMF	Dual Tone Multi-Frequency
DU	Downstream Unsolicited
DUAL	Diffusing Update Algorithm
DUID	DHCP Unique Identifier
DUID-LL	DUID Based on Link-layer Address
D-V	Distance Vector
DVMRP	Distance Vector Multicast Routing Protocol
DVPN	Dynamic Virtual Private Network
DWDM	Dense Wavelength Division Multiplexing
E	Return
E2ETC	End-to-End Transparent Clock
EAA	Embedded Automation Architecture
EACL	Enhanced ACL
EAD	Endpoint Admission Defense
EAIS	Ethernet Alarm Indication Signal
EAN	Ethernet Access Node
EAP	Extensible Authentication Protocol
EAPOL	Extensible Authentication Protocol over LAN
EAPOL KCK	EAPOL-Key Confirmation Key
EAPOL KEK	EAPOL-Key Encryption Key

EAP-TLS	Extensible Authentication Protocol -Transport Layer Security
EBS	Excess Burst Size
ECDSA	Elliptic Curve Digital Signature Algorithm
ECID	E-channel Identifier
ECM	Encapsulated Control Message
ECM	Error Correction Mode
ECN	Explicit Congestion Notification
ECP	Edge Control Protocol
ECT	Equal Cost Tree
ECWmax	Exponent form of CWmax
ECWmin	Exponent form of CWmin
ED	Edge Device
EDCA	Enhanced Distributed Channel Access
EDSG	Enhanced Dynamic Service Gateway
EEE	Energy Efficient Ethernet
EF	Expedited Forwarding
EFM	Ethernet First Mile
EGP	Exterior Gateway Protocol
EID	Endpoint Identifier
EIGRP	Enhanced Interior Gateway Routing Protocol
EIRP	Effective Isotropic Radiated Power
EM	Event Monitor
EMO	Endpoint Mobile Office
EMR	Ensure Minimum Rate
ENDC	EVI Neighbor Discovery Client
ENDC	Enhanced Neighbor Discovery Client
End-Of-RIB	End of Routing-Information-Base
ENDP	Enhanced Neighbor Discovery Protocol
ENDP	EVI Neighbor Discovery Protocol
ENDS	Enhanced Neighbor Discovery Server
ENDS	EVI Neighbor Discovery Server
eNodeB	evolved Node B
ENUM	Telephone Number Mapping
EOAM	Ethernet Operation, Administration and Maintenance
EoPW	Ethernet over Pseudo Wire
EPC	External Path Computation
EPC	Evolved Packet Core
EPON	Ethernet Passive Optical Network
EPS	Endpoints Profiling System
ER	Edge Relay

ERPS	Ethernet Ring Protection Switching
ERSPAN	Encapsulated Remote Switch Port Analyzer
ERT	Export Route-target
ES	End System
ES	Ethernet Segment
ESF	Extended Super Frame
ESI	Ethernet Segment Identifier
ESMC	Ethernet Synchronous Message Channel
ESN	Extended Sequence Number
ESP	Encapsulating Security Payload
ESS	Extended Service Set
ESS	Exchange Switch Support
ETR	Egress Tunnel Router
ETS	Enhanced Transmission Selection
ETSI	European Telecommunications Standards Institute
EUI	Extended Unique Identifier
EUI-64	64-bit Extended Unique Identifier
EVB	Edge Virtual Bridging
Event MIB	Event Management Information Base
EVFP	Exchange Virtual Fabrics Parameter
EVI	Ethernet Virtual Interconnect
EVPN	Ethernet Virtual Private Network
Extended-MAM	Extended Maximum Allocation Model
F	Return
FA	Foreign Agent
FA	Foreign-AC
FAC	Feature Access Code
FAS	Frame Alignment Signal
FC	Forwarding Class
FC	Fibre Channel
FC	Feasibility Condition
FCF	FCoE Forwarder
FCM	Fast Connect Modem
FCoE	Fibre Channel over Ethernet
FCPS	FC Port Security
FCS	Fabric Configuration Server
FCS	Frame Check Sequence
FD	Feasible Distance
FDB	Forwarding Database

FDMI	Fabric Device Management Interface
FE	Fast Ethernet
FEAC	Far End Alarm and Control signal
FEC	Forward Error Correction
FEC	Forwarding Equivalence Class
FECN	Forward Explicit Congestion Notification
FEP	Front End Processor
FF	Fixed-Filter
FFD	Fast Failure Detection
FFT	Fast Fourier Transform
FG	Forwarding Group
FHR	First Hop Router
FIB	Forwarding Information Base
FIFO	First In First Out
FIFO	First In First Out Queuing
FIP	FCoE Initialization Protocol
FIP Snooping	FCoE Initialization Protocol Snooping
FIPS	Federal Information Processing Standards
Flowspec	Flow Specification
FNG	Fault Notification Generator
FP	Forwarding Profile
FPGA	Field Programmable Gate Array
FPMA	Fabric Provided MAC Address
FQ	Fair Queuing
FQDN	Fully Qualified Domain Name
FR	Frame Relay
FRR	Fast Reroute
FRTP	Frame Relay Traffic Policing
FRTS	Frame Relay Traffic Shaping
FRU	Field Replaceable Unit
FS	Forced Switch
FS	Feasible Successor
FSK	Frequency Shift Keying
FSPF	Fabric Shortest Path First
FT	Fault Tolerance
FT	Fast BSS Transition
FTN	FEC to NHLFE map
FTP	File Transfer Protocol
FXO	Foreign Exchange Office
FXS	Foreign Exchange Station

G	Return
GAL	G-ACh Label
GARP	Generic Attribute Registration Protocol
GAS	Generic Advertisement Service
GDOI	Group Domain of Interpretation
GE	Gigabit Ethernet
GI	Guard Interval
GK	GateKeeper
GLB	Global Load Balance
GM	Group Member
GM	Grandmaster Clock
GMK	Group Master Key
GNE	Gateway Network Element
GNS	Get Nearest Server
GOLD	Generic OnLine Diagnostics
GPS	Global Positioning System
GR	Graceful Restart
GRE	Generic Routing Encapsulation
Group Domain VPN	Group Domain Virtual Private Network
gRPC	Google Remote Procedure Call
GSMPv3	General Switch Management Protocol Version 3
GTC	Generic Token Card
GTK	Group Temporal Key
GTP	GPRS Tunneling Protocol
GTP-U	GPRS Tunneling Protocol User
GTS	Generic Traffic Shaping
GTSM	Generalized TTL Security Mechanism
GVRP	GARP VLAN Registration Protocol
GW	Gateway
GWMP	Gateway Message Protocol
H	Return
HA	Home-AC
HA	High Availability
HA	Home Agent
HABP	HW Bypass Protocol
HBA	Host Bus Adapter
HDB3	High-density bipolar 3
HDLC	High-level Data Link Control
HDSL	High-speed Digital Subscriber Line

HESSID	Homogenous Extended Service Set IDentifier
HGMP	HW Group Management Protocol
HGMPv2	HW Group Management Protocol version 2
HMAC	Hash-based Message Authentication Code
HoPE	Hierarchy of PE
HoVPN	Hierarchy of VPN
HQoS	Hierarchical Quality of Service
HS	High-performance Switch
HTTP	Hypertext Transfer Protocol
HTTPS	Hypertext Transfer Protocol Secure
H-VPLS	Hierarchical VPLS
HWTACACS	HW Terminal Access Controller Access Control System
I	Return
IA	Identity Association
IACTP	Inter Access Controller Tunneling Protocol
IAD	Integrated Access Device
IANA	Internet Assigned Numbers Authority
IBGP	Internal Border Gateway Protocol
ICANN	Internet Corporation for Assigned Names and Numbers
ICMP	Internet Control Message Protocol
ICMPv6	Internet Control Message Protocol for IPv6
ICP	IMA Control Protocol
ICPIF	Calculated Planning Impairment Factor
ICRQ	Incoming Call Request
IDN	Integrated Digital Network
IDS	Intrusion Detection System
IE	Information Element
IE	Interconnect Element
IEEE	Institute of Electrical and Electronics Engineers
IETF	Internet Engineering Task Force
IGMP	Internet Group Management Protocol
IGMP Snooping	Internet Group Management Protocol Snooping
IGP	Interior Gateway Protocol
IGTK	Integrity Group Temporal Key
IIH	Intermediate System-to-Intermediate System Hello
IKE	Internet Key Exchange
IKEv2	Internet Key Exchange Version 2
ILM	Incoming Label Map
ILS	Internet Locator Service

IM	Instant Messaging
IMA	Inverse Multiplexing for ATM
IMAP	Internet Mail Access Protocol
iMC	Intelligent Management Center
IMSI	International Mobile Subscriber Identification Number
InARP	Inverse Address Resolution Protocol
IND	Inverse Neighbor Discovery
INT	In-band Network Telemetry
IntServ	Integrated Service
IPC	Inter-process Communication
IPE	Image Package Envelope
IPHC	IP Header Compression
IPL	Intra-Portal Link
IPN	IGTK Packet Number
IPng	IP Next Generation
IPoA	IP over ATM
IPoEoA	IP over Ethernet over ATM
IPP	Intra-Portal Port
IPS	Intrusion Prevention System
IPsec	IP Security
IPTA	IP Terminal Access
IPv6	Internet Protocol version 6
IPv6 MBGP	IPv6 Multicast BGP
IPv6 ND	IPv6 Neighbor Discovery
IPv6 PIM	IPv6 Protocol Independent Multicast
IPv6 PIM Snooping	IPv6 Protocol Independent Multicast Snooping
IPX	Internetwork Packet Exchange
IRB	Integrated Bridging and Routing
IRB	Integrated Routing and Bridging
IRB	Integrated Routing Bridging and Bridging Routing
IRDP	ICMP Router Discovery Protocol
IRF	Intelligent Resilient Framework
IS	Intermediate System
ISAKMP	Internet Security Association and Key Management Protocol
ISATAP	Intra-Site Automatic Tunnel Addressing Protocol
ISDN	Integrated Services Digital Network
I-SID	Backbone Service Instance Identifier
IS-IS	Intermediate System-to-Intermediate System
ISO	International Organization for Standardization
ISP	Internet Service Provider

ISPF	Incremental Shortest Path First
ISSU	In-Service Software Upgrade
IST	Internal Spanning Tree
ITA	Intelligent Target Accounting
ITR	Ingress Tunnel Router
ITSP	Internet Telephone Service Provider
ITU	International Telecommunication Union
ITU-T	International Telecommunication Union Telecommunication
IV	Initialization Vector
IVR	Interactive Voice Response
K	Return
KAT	Known-Answer Test
KCK	EAPOL-Key Confirmation Key
KEK	Key Encrytion Key
KEK	EAPOL-Key Encryption Key
KS	Key Server
L	Return
L2F	Layer 2 Forwarding
L2PT	Layer 2 Protocol Tunneling
L2TP	Layer 2 Tunneling Protocol
L2VPN	Layer 2 Virtual Private Network
L3VNI	Layer 3 VNI
L3VPN	Layer 3 Virtual Private Network
LAC	L2TP Access Concentrator
LACP	Link Aggregation Control Protocol
LACPDU	Link Aggregation Control Protocol Data Unit
LAN	Local Area Network
LB	Loopback
LB	Label Base
LB	Load Balance
LBM	Loopback Message
LBR	Loopback Reply
LC	Logic Channel
LCFO	Loop Current Feed Open
LCI	Logic Channel Identifier
LCP	Link Control Protocol
LDAP	Lightweight Directory Access Protocol
LDN	Local Dialing Number
LDP	Label Distribution Protocol

LDP ID	LDP Identifier
LDPC	Low-Density Parity Check
LER	Label Edge Router
LFI	Link Fragmentation and Interleaving
LFIB	Label Forwarding Information Base
LGS	Loop-start & Ground-start Signaling
LHR	Last-Hop Router
LI	Leap Indicator
LLC	Logical Link Control
LLDP	Link Layer Discovery Protocol
LLDPDU	Link Layer Discovery Protocol Data Unit
LLDP-MED	Link Layer Discovery Protocol Media Endpoint Discovery
LLID	Logical Link ID
LLQ	Low Latency Queuing
LM	Loss Measurement
LMI	Local Management Interface
LMM	Loss Measurement Message
LMR	Loss Measurement Reply
LNS	L2TP Network Server
LO	Label-block Offset
LOCV	Loss of Connectivity Verification defect
LOID	Logical ONU Identifier
LoRaWAN	Long Range Wide Area Network
LOS	Loss of Signal
LPU	Line Processing Unit
LPU Port	Line Processing Unit Port
LQR	Link Quality Reports
LR	Line Rate
LR	Label Range
LS	Link State
LSA	Link State Acknowledgment
LSA	Link State Advertisement
LSAck	Link State Acknowledgment
LSDB	Link State Database
LSDB	Link State DataBase
LSN	Large-scale NAT
LSP	Label Switched Path
LSP	Link State PDU
LSPDU	Link State Protocol Data Unit
LSR	Link State Request

LSR	Link State Record
LSR	Label Switching Router
LSU	Link State Update
LT	Linktrace
LTM	Linktrace Message
LTR	Linktrace Reply
LTS	L2TP Tunnel Switch
LVF	Listening Virtual Forwarder
LZ	Lempel-Ziv compression
M	Return
M flag	Managed Address Configuration Flag
MA	Mobility Agent
MA	Maintenance Association
MAC	Message Authentication Code
MAC	Media Access Control
MACsec	Media Access Control Security
MAD	Multi-Active Detection
MAM	Maximum Allocation Model
MAN	Metropolitan Area Network
MAP	Mesh Access Point
MBGP	Multicast BGP
MBS	Maximum Burst Size
MC	Mobility Controller
MCC	Mobile Country Code
MCE	Multi-VPN-Instance Customer Edge
MCS	Modulation and Coding Scheme
MCU	Multipoint Control Unit
MD	Maintenance Domain
MD	Multicast Domain
MDC	Multitenant Device Context
MDI	Medium Dependent Interface
MDL	Maintenance Data Link
mDNS	Multicast DNS
MDT	Multicast Distribution Tree
ME	Maintenance Entity
MEC	Multi-access Edge Computing
MED	Multi-Exit Discriminator
MEG	Maintenance Entity Group
MEP	Maintenance association End Point

MEP	MEG End Point
MFAS	Multiframe FAS
MFC	Multi-Frequency Compelled
MFF	MAC-Forced Forwarding
MFR	Multilink Frame Relay
MGCP	Media Gateway Control Protocol
mGRE	Multipoint Generic Routing Encapsulation
MIB	Management Information Base
MIC	Message Integrity Check
MIMO	Multiple Input, Multiple Output
MIP	Maintenance association Intermediate Point
MIP	Mobile IP
MKA	MACsec Key Agreement
MKD	Mesh Key Distributor
MKI	Master Key Identifier
MLD	Multicast Listener Discovery Protocol
MLD Snooping	Multicast Listener Discovery Snooping
MLSP	Mobile Link Switch Protocol
MME	Management MIC IE
MNC	Mobile Network Code
MoH	Music on Hold
MOS	Mean Opinion Scores
MOTD	Message of The Day
MP	Maintenance Point
MP	Mesh Point
MP	Merge Point
MP_REACH_NLRI	Multiprotocol Reachable NLRI
MP_UNREACH_NLRI	Multiprotocol Unreachable NLRI
MP-BGP	Multiprotocol Border Gateway Protocol
MPCP	Multipoint Control Protocol
MPDU	MAC Protocol Data Unit
MPE	Middle-Level PE
MPLS	Multiprotocol Label Switching
MPLS SR	Segment Routing with MPLS
MPLS TE	Multiprotocol Label Switching Traffic Engineering
MPLS VPN	MPLS Virtual Private Network
MPLS-TP	MPLS Transport Profile
MPP	Mesh Portal Point
MQC	Model QoS Command
MR	Map Resolver

MR	Merge Request
MRIB	Multicast Routing Information Base
MRP	Multiple Registration Protocol
MRPDU	MRP Protocol Data Unit
MRRA	Merge Request Resource Allocation
MRU	Maximum-Receive-Unit
MS	Manual Switch
MS	Map Server
MSCHAP	Microsoft Challenge Handshake Authentication Protocol
MSDP	Multicast Source Discovery Protocol
MSDU	MAC Service Data Unit
MSK	Multicast Session Key
MSOH	Multiplex Section Overhead
MSS	Maximum Segment Size
MSTI	Multiple Spanning Tree Instance
MSTP	Multiple Spanning Tree Protocol
MT	Multicast Tunnel
MTI	Multicast Tunnel Interface
MTP	Maintain Probe
MTR	Multi-Topology Routing
MTU	Maximum Transmission Unit
MTU-s	Multi-Tenant Unit switch
MU	Mobile Unit
MVPN	Multicast Virtual Private Network
MVRP	Multiple VLAN Registration Protocol
MVXLAN	Multicast VXLAN
MWI	Message Waiting Indication
MX	Mail Exchanger
N	Return
NA	Neighbor Advertisement
NAI	Network Access Identifier
NAPT	Network Address Port Translation
NAPT-PT	Network Address Port Translation-Protocol Translation
NAS	Network Access Service
NAS	Network Access Server
NAS-ID	Network Access Server Identifier
NAS-Port-ID	Network Access Server Port Identifier
NAS-VLAN-ID	Network Access Server VLAN Identifier
NAT	Network Address Translation

NAT-PT	Network Address Translation-Protocol Translation
NBAR	Network Based Application Recognition
NBMA	Non-Broadcast Multi-Access
NCP	Network Control Protocol
ND	Neighbor Discovery
NDA	NetStream Data Analyzer
NDE	NetStream Data Exporter
NDP	Neighbor Discovery Protocol
NDPP	Network Device Protection Profile
NE	Network Element
NEMO	Network Mobility
NET	Network Entity Title
NetBIOS	Network Basic Input/Output System
NETCONF	Network Configuration Protocol
NFAS	non–FAS
NFV	Network Function Virtualisation
NHLFE	Next Hop Label Forwarding Entry
NHRP	Next Hop Resolution Protocol
NI	National ISDN
NIB	Nexthop Information Base
NII	Network International Identifier
NIST	National Institute of Standards and Technology
NIT	Not Initial Terminal
NLB	Network Load Balancing
NLBS	Network Load Balancing Service
NLPID	Network Layer Protocol Identifier
NLRI	Network Layer Reachability Information
NM	Network Management
NMFAS	Non-Multiframe FAS
NMS	Network Management Station
NMS	Network Management System
NMS	Network Management Server
NNI	Network-to-Network Interface
NO-PAT	Not Port Address Translation
NPDU	Network Protocol Data Unit
NPE	Network Provider Edge
NPTv6	IPv6-to-IPv6 Network Prefix Translation
NPV	N_Port Virtualization
NQA	Network Quality Analyzer
NR	No Request

nrt-VBR	non-real-time Variable Bit Rate
NS	Neighbor Solicitation
NS	Name Server
NSAP	Network Service Access Point
NSC	NetStream Collector
NSF	Non-Standard Facilities
NSR	Nonstop Routing
NSS	Number of Spatial Streams
NTDP	Neighbor Topology Discover Protocol
NTE	Named Telephone Event
NTP	Network Time Protocol
NTT	Nippon Telegraph and Telephone Corpration
NVC	Network Virtualization Controller
NVE	Network Virtualization Edge
NVGRE	Network Virtualization using Generic Routing Encapsulation
O	Return
O Flag	Other Stateful Configuration Flag
OAA	Open Application Architecture
OAMPDU	OAM Protocol Data Unit
OAP	Open Application Platform
OC	Optical Carrier
OC	Ordinary Clock
ODAP	On-Demand Address Pool
ODF	Optical Distribution Frame
ODN	Optical Distribution Network
ODU	Optical Data Unit
OEM	Original Equipment Manufacturer
OFDM	Orthogonal Frequency Division Multiplexing
OI	Organization Identifier
OID	Object Identifier
OLT	Optical Line Terminal
ONU	Optical Network Unit
OOB	Out-of-Band
OPU	Optical Payload Unit
ORF	Outbound Route Filtering
OSI	Open System Interconnection
OSPF	Open Shortest Path First
OSU	Online Sign Up
OTN	Optical Transport Network

OTU	Optical Transmit Unit
OUI	Organizationally Unique Identifier
OVSDB	Open vSwitch Database
P	Return
P2MP	Point-to-MultiPoint
P2P	PW to PW
P2P	Peer-to-Peer
P2P	Point-to-Point
P2PTC	Peer-to-Peer Transparent Clock
PA	Provider Allocated
PADT	PPPoE Active Discovery Terminate
PAGP	Port Aggregation Protocol
PAM	Port to Application Map
PAM	Pulse Amplitude Modulation
PAN ID	Personal Area Network Identifier
PAP	Password Authentication Protocol
Passive-Stateful PCC	Passive-Stateful Path Computation Client
Passive-Stateful PCE	Passive-Stateful Path Computation Element
PAT	Port Address Translation
PBAR	Port Based Application Recognition
PBB	Provider Backbone Bridge
PBBN	Provider Backbone Bridge Network
PBN	Provider Bridge Network
PBR	Policy-based Routing
PBX	Private Branch Exchange
PCB	Protocol Control Block
PCC	Path Computation Client
PCE	Path Computation Element
PCEP	Path Computation Element Communication Protocol
PCM	Pulse Code Modulation
PCR	Peak Cell Rate
PD	Powered Device
PD	Prefix Delegation
PDH	Plesiochronous Digital Hierarchy
PDP	Policy Decision Point
PDU	Protocol Data Unit
PE	Provider Edge
PE-agg	PE Aggregation
PEAP	Protected Extensible Authentication Protocol

PEAP-GTC	Protected Extensible Authentication Protocol-Microsoft Generic Token Card
PEAP-MSCHAPv2	Protected Extensible Authentication Protocol-Microsoft Challenge Handshake Authentication Protocol v2
PEM	Privacy Enhanced Mail
PEM	Power Entry Module
PEP	Policy Enforcement Point
PFC	Power Free Connector
PFC	Priority-based Flow Control
PFC	Protocol-Field-Compression
PFS	Perfect Forward Secrecy
PHB	Per-hop Behavior
PHP	Penultimate Hop Popping
PI	Power Interface
PI	Provider Independent
PI	Progress Indicator
PIC	Prefix Independent Convergence
PIM	Protocol Independent Multicast
PIM Snooping	Protocol Independent Multicast Snooping
PIM-DM	Protocol Independent Multicast-Dense Mode
PIM-SM	Protocol Independent Multicast-Sparse Mode
PIM-SSM	Protocol Independent Multicast Source-Specific Multicast
PIN	Personal Identification Number
PIR	Peak Information Rate
PKCS	Public Key Cryptography Standards
PKI	Public Key Infrastructure
PLCP	Physical Layer Convergence Procedure
PLMN	Public Land Mobile Network
PLR	Point of Local Repair
PMK	Pairwise Master Key
PMTU	Path MTU
PoE	Power over Ethernet
POH	Path Overhead
POP3	Post Office Protocol - Version 3
POS	Passive Optical Splitter
POS	Point of Sale
PPP	Point-to-Point Protocol
PPPoA	PPP over ATM
PPPoE	Point-to-Point Protocol over Ethernet
PPPoEoA	PPPoE over ATM

PPTP	Point-to-Point Tunneling Protocol
PQ	Priority Queuing
PRBS	Pseudo Random Bit Sequence
PRC	Primary Reference Clock
PRI	Primary Rate Interface
PRL	Preferred Roaming List
PS	Protection Switching
PSB	Path State Block
PSC	Protection State Coordination
PSD	Power Spectral Density
PSE	Power Sourcing Equipment
PSK	Pre-Shared Key
PSN	Packet Switched Network
PSNP	Partial Sequence Number PDU
PSST	Principal Switch Selection Timer
PSTN	Public Switched Telephone Network
PTK	Pairwise Transient Key
PTP	Precision Time Protocol
PTR	Pointer Record
PTY	Pseudo-Terminals
PUK	PIN Unlocking Key
PVC	Permanent Virtual Circuit
PVC PQ	PVC Priority Queuing
PVID	Port VLAN ID
PVP	Permanent Virtual Path
PVST	Per-VLAN Spanning Tree
PW	Pseudowire
PW-ACH	PW Associated Channel Header
PWCT	Pairwise Conditional Test
PWE3	Pseudo Wire Emulation Edge-to-Edge
PXE	Preboot eXecution Environment
Q	Return
QCN	Quantized Congestion Notification
QL	Quality Level
QoS	Quality of Service
QPPB	QoS Policy Propagation Through the Border Gateway Protocol
R	Return
RA	Router Alert
RA	Router Advertisement

RA	Registration Authority
RADIUS	Remote Authentication Dial-In User Service
RAI	Remote Alarm Indication
RALM	RADIUS Authenticated Login Using MAC-address
R-APS	Ring Automatic Protection Switching
RAS	Registration, Admission, and Status
RB	Routing Bridge
RBAC	Role Based Access Control
RBM	Remote Backup Management
RCA	Release Change Authorization
RCF	Reconfigure Fabric
RCPI	Received Channel Power Indicator
RD	Routing Domain
RD	Reported Distance
RD	Route Distinguisher
RDI	Remote Defect Indication
RDM	Russian Dolls Model
RDP	Read Diagnostic Parameters
RED	Random Early Detection
RedisDBM	Redis Database Manager
REG	Registration Center
RFID	Radio Frequency Identification
RIB	Routing Information Base
RIP	Routing Information Protocol
RIP-2	Routing Information Protocol version 2
RIPng	RIP next generation
RIR	Resilient Intelligent Route
RLOC	Routing Locator
RLSN	Remote Link Status Notification
RMON	Remote Network Monitoring
ROA	Recognized operating Agency
Roam OI	Roam Organization Identifier
RP	Rendezvous Point
RP	Reflective Relay
RP	Reaction Point
RPA	Register Port Attributes
RPA	Rendezvous Point Address
RPC	Remote Procedure Call
RPF	Reverse Path Forwarding
RPI	Receive Power Indication

RPKI	Resource Public Key Infrastructure
RPL	Rendezvous Point Link
RPL	Ring Protection Link
RPR	Resilient Packet Ring
RPRT	Register Port
RPS	Redundant Power System
RP-Set	Rendezvous Point Set
RPT	Rendezvous Point Tree
RR	Route Reflector
RR	Reflective Relay
RR	Router Renumber
RRI	Reverse Route Injection
RRM	Radio Resource Management
RRPP	Rapid Ring Protection Protocol
RS	Router Solicitation
RSB	Reservation State Block
RSCN	Registered State Change Notification
RS-DCC	Resource-Shared DCC
RSH	Remote Shell
RSN	Robust Security Network
RSNA	Robust Security Network Association
RSNI	Received Signal to Noise Indicator
RSOH	Regenerator Section Overhead
RSSI	Received Signal Strength Indicator
RSSI	Received Signal Strength Indication
RSTP	Rapid Spanning Tree Protocol
RSVP	Resource Reservation Protocol
RT	Route Target
RTC	Remote Terminal Connection
RTCP	Real-Time Transport Control Protocol
RTM	Real-Time Event Manager
RTP	Reliable Transport Protocol
RTP	Real-Time Transport Protocol
RTPQ	Real-Time Transport Protocol Priority Queuing
RTS	Request to Send
RTSP	Real Time Streaming Protocol
RTT	Round-Trip Time
rt-VBR	Real-time Variable Bit Rate
RU	Rack Unit

S	Return
S/MIME	Secure/Multipurpose Internet Mail Extensions
SA	Security Association
SA	Source Active
SA Query	Security Association Query
SABM	Set Asynchronous Balanced Mode
SACK	Selective Acknowledgment
SAE	Simultaneous authentication of equals
SAFI	Subsequent Address Family Identifier
SAII	Source Attachment Individual Identifier
SAM	Security Accounting Management
SAN	Storage Area Networks
SAP	Service Advertising Protocol
SAToP	Structure-Agnostic TDM over Packet
SAVI	Source Address Validation Improvement
SB	Service Bridge
SBFD	Seamless BFD
SBM	Subnetwork Bandwidth Management
SCCP	Skinny Client Control Protocol
SCEP	Simple Certificate Enrollment Protocol
SCFF	Single Choke Fairness Frame
SCR	Sustainable Cell Rate
SCR	State Change Registration
SD	Signal Degrade
SDH	Synchronous Digital Hierarchy
SDLC	Synchronous Data Link Control
SDN	Software Defined Network
SDP	Session Description Protocol
SDSL	Symmetric Digital Subscriber Line
SDU	Service Data Unit
SE	Shared-Explicit
SEC	SDH Equipment Clock
SF	Super Frame
SF	Signal Fail
SFC	Stage Fabric Configuration Update
sFlow	Sampled Flow
SFM	Source-Filtered Multicast
SFP	Small Form-factor Pluggable
SFTP	Secure FTP

Short GI	Short Guard Interval
SIA	Stuck In Active
SID	Segment Identifier
SIP	Session Initiation Protocol
SIPS	SIP Secure
SLA	Service Level Agreement
SLAAC	Stateless Address Autoconfiguration
SLB	Server Load Balance
SLC	Service Logic Control
SLIP	Serial Line Internet Protocol
SLM	Single-ended Loss Measurement
SMA	State Machine based Anti-spoofing
SmartMC	Smart Management Center
SMET	Selective Multicast Ethernet Tag Route
S-MLAG	Simple Multichassis Link Aggregation
SMTP	Simple Mail Transfer Protocol
SN	Serial Number
SNA	System Network Architecture
SNAP	Subnet Access Protocol
SNAT	Source Network Address Translation
SNMP	Simple Network Management Protocol
SNMP-DCA	SNMP Data Collection Agent
SNP	Sequence Number PDU
SNPA	Subnetwork Point of Attachment
SNR	Signal-to-Noise Ratio
SNTP	Simple NTP
SOA	Start of Authority
SOAP	Simple Object Access Protocol
SOH	Section Overhead
SONET	Synchronous Optical Network
SoO	Site of Origin
SP	Strict Priority
SP	Service Provider
SP	Scheduler Policy
SPB	Shortest Path Bridging
SPBM	Shortest Path Bridging MAC Mode
SPBM	Shortest Path Bridging MAC
SPBN	Shortest Path Bridging Network
SPCS	Stored Program Control Switching System
SPE	Superstratum PE or Service Provider-end PE

SPF	Shortest Path First
SPI	Security Parameter Index
SPID	Service Profile Identification
SPM	Smart PoE Manager
SPSource ID	Shortest Path Source Identifier
SPT	Shortest Path Tree
SQL	Structured Query Language
SR	Segment Routing
Srefresh	Summary Refresh
SRGB	Segment Routing Global Block
SRLB	Segment Routing Local Block
SRLSP	Segment Routing Label Switched Path
SRMC	Segment Routing Mapping Client
SRMS	Segment Routing Mapping Server
SRST	Survivable Remote Site Telephony
sr-TCM	single rate TCM
SRTP	Secure Real-Time Transport Protocol
SRV	Service
SSA	SIP Stack Adapt
SSH	Secure Shell
SSID	Service Set Identifier
SSL	Secure Sockets Layer
SSM	Synchronization Status Message
SSM	Source-Specific Multicast
SSP	Switch-to-Switch Protocol
SSU-A	primary level SSU
SSU-B	second level SSU
ST	Shared Tree
Stateful PCE	Stateful Path Computation Element
Stateless PCC	Stateless Path Computation Client
Stateless PCE	Stateless Path Computation Element
STBC	Space-Time Block Coding
STP	Spanning Tree Protocol
STR	Switch Trace Route
SVC	Static Virtual Circuit
SVC	Switched Virtual Circuit
SVP	SpectraLink Voice Priority
T	Return
TA	Terminal Adapter

TACACS	Terminal Access Controller Access Control System
TACL	Temporary Access Control List
TAI	International Atomic Time
TAII	Target Attachment Individual Identifier
T-BC	Telecom Boundary Clock
TC	Topology Checksum
TC	Topology Change
TC	Topology client
TC	Traffic Class
TC	Transparent Clock
TCA	Topology Change Acknowledge
TCAM	Ternary Content Addressable Memory
TCI	Tag Control Information
Tcl	Tool Command Language
TCN BPDU	Topology Change Notification BPDU
TCP	Transmission Control Protocol
TCT-BC	Transparent Telecom Boundary Clock
TDM	Time Division Multiplexing
TDMA	Time Division Multiple Access
TE	Traffic Engineering
TEDB	TE DataBase
TEI	Terminal Endpoint Identifier
TEID	Tunnel Endpoint Identifier
TEK	Tranfic Encrytion Key
TFO	Transport Flow Optimization
TFTP	Trivial File Transfer Protocol
TI-LFA FRR	Topology-Independent Loop-free Alternate Fast Reroute
TIM	Traffic Indication Map
TK	Temporal Key
TKIP	Temporal Key Integrity Protocol
TLS	Transport Layer Security
TLS	Transparent LAN Service
TLV	Type/Length/Value
TM	Topology Master
ToS	Type of Service
TP	Traffic Policing
TP	Topology Protection
TPA	Third-part Application
TPC	Transmit Power Control
TPDU	Transport Protocol Data Unit

TPID	Tag Protocol Identifier
TPMR	Two-Port MAC Relay
TQ	Time Quantum
TRILL	TRansparent Interconnection of Lots of Links
TRIP	Triggered RIP
tr-TCM	two-rate TCM
TS	Traffic Shaping
TSA	Tunnel Switching Aggregator
TST	Test
T-TC	Telecom Transparent Clock
TTI	Trail Trace Identifier
TTL	Time to Live
TTLS	Tunneled Transport Layer Security
TTLS-GTC	Tunneled Transport Layer Security-Microsoft Generic Token Card
TTLS-MSCHAPv2	Tunneled Transport Layer Security-Microsoft Challenge Handshake Authentication Protocol v2
T-TSC	Telecom Time Slave Clock
TTY	True Type Terminal
TU	Tributary Unit
TUG	Tributary Unit Group
TWAMP	Two-Way Active Measurement Protocol
TxBF	Tx Beamforming
TXOP Limit	Transmission Opportunity Limit
TXT	Text
U	Return
UA	Unnumbered Acknowledge
UA	User Agent
UAC	User Agent Client
U-APSD	Unscheduled Automatic Power-Save Delivery
UAS	User Agent Server
UBR	Unspecified Bit Rate
UCM	User Connection Management
UDLD	Uni-directional Link Direction
UDP	User Data Protocol
UE	User Equipment
UFC	Update Fabric Configuration
UIM	User Identity Module
UNI	User-to-Network Interface
UNI	User Network Interface

UPE	User facing-Provider Edge
UPE	Underlayer PE or User-end PE
URI	Uniform Resource Identifier
URL	Uniform Resource Locator
uRPF	Unicast Reverse Path Forwarding
USK	Unicast Session Key
USM	User-Based Security Model
UTC	Coordinated Universal Time
UTM	Unified Threat Management
V	Return
V2V	Video to Video
VA	Virtual Access
VACM	View-based Access Control Model
VAD	Voice Activity Detection
VAM	VPN Address Management
VBR-NRT	Variable Bit Rate-Non Real Time
VBR-RT	Variable Bit Rate-Real Time
VC	Virtual Circuit
VC	Virtual Container
VCC	Virtual Circuit Connection
VCCV	Virtual Circuit Connectivity Verification
VCF	Vertical Converged Framework
VCFC	VCF Controller
VCI	Virtual Channel Identifier
VCN	Virtual Circuit Number
VCPM	Voice Co-processing Module
VD	Virtual Device
VDP	VSI Discovery and Configuration Protocol
VDSL	Very high-speed Digital Subscriber Line
VE	Virtual Ethernet
VE-Bridge	Virtual Ethernet Bridge
VEth	Virtual Ethernet
VF Owner	Virtual Forwarder Owner
VFW	Virtual Firewall
VLAN	Virtual Local Area Network
VM	Virtual Machine
VMM	Virtual Machine Management
VN	Version Number
VNC	Virtual Network Computing

VNI	VXLAN Network Identifier
VoD	Video on Demand
VoIP	Voice over IP
VP	Virtual Path
VPC	Virtual Path Connection
VPC	Virtual Private Cloud
VPDN	Virtual Private Dial-up Network
VPI	Virtual Path Identifier
VPLS	Virtual Private LAN Service
VPM	Voice Processing Module
VPN	Virtual Private Network
VPWS	Virtual Private Wire Service
VR	Virtual Router
VRF	Virtual Routing and Forwarding
VRRP	Virtual Router Redundancy Protocol
VSAN	Virtual Storage Area Network
VSD	Virtual Security Domain
VSI	Virtual Switch Instance
VSI	Virtual Station Interface
VSID	Virtual Subnet Identifier
VSIP	Virtual Service IP
VSRP	Virtual Service Redundancy Protocol
vSwitch	Virtual Switch
VT	Virtual Template
VTEP	VXLAN Tunnel End Point
VTP	VLAN Trunking Protocol
VTY	Virtual Type Terminal
VXLAN	Virtual eXtensible LAN
VXLAN-DCI	VXLAN Data Center Interconnection
W	Return
WAAS	Wide Area Application Services
WAF	Web Application Firewall
WAI	WLAN Authentication Infrastructure
WAN	Wide Area Network
WAP	Wireless Application Protocol
WAPI	WLAN Authentication and Privacy Infrastructure
WASS	Wide Area Application Services
WDS	Wireless Distribution System
WEP	Wired Equivalent Privacy

WFQ	Weighted Fair Queuing
WHA	WLAN High Availability
WIDS	Wireless Intrusion Detection System
WiNet	Wisdom Network
WINS	Windows Internet Naming Service
WIPS	Wireless Intrusion Prevention System
WLAN	Wireless Local Area Network
WLAN RRM	Radio Resource Management
WMM	Wi-Fi Multimedia
WPA	Wi-Fi Protected Access
WPAD	Web Proxy Auto-Discovery
WPI	WLAN Privacy Infrastructure
WRED	Weighted Random Early Detection
WRR	Weighted Round Robin
WSA	Wireless Spectrum Analysis
WT	Wireless Terminator
WTU	Wireless Terminator Unit
WWN	World Wide Name
X	Return
XFP	10-Gigabit Small Form-factor Pluggable
XML	Extensible Markup Language
XSD	XML Schema Document
XSD	XML Schema Definition
Z	Return
ZBR	Zone Border Router
