About the S5100[S5500]-D-G&S5130S-G[-V2] Switch Series configuration guides (R8336Pxx)

The S5100[S5500]-D-G&S5130S-G[-V2] Switch Series configuration guides (R8336Pxx) describe the software features for the H3C S5100[S5500]-D-G&S5130S-G[-V2] switch series in Release 8336P05 and later, and guide you through the software configuration procedures. These configuration guides also provide configuration examples to help you apply the software features to different network scenarios.

Configuration guide	Content
Fundamentals Configuration Guide	Covers information about using the command line interface, logging in to and setting up the device, and using the basic management features. This guide includes: • CLI. • RBAC. • Login management. • FTP and TFTP. • File system management. • Configuration file management. • Multichassis configuration sync. • Software upgrade. • ISSU. • GIR. • Automatic. • Target configuration management. • Device management. • Tcl. • Python.
Virtual Technologies Configuration Guide	Covers the IRF technology, which provides data center class availability and scalability.
Layer 2—LAN Switching Configuration Guide	Covers Layer 2 technologies and features used on a LAN switched network, such as VLAN technology and port isolation. You can use these features to divide broadcast domains, remove Layer 2 loops, isolate users within a VLAN, re-mark VLAN tags, or implement VLAN VPNs over the Internet. This guide includes: • MAC address table. • Ethernet link aggregation. • M-LAG. • Port isolation. • VLAN. • MVRP. • QinQ. • VLAN mapping. • Loop detection. • LLDP. • Spanning tree. • L2PT. • Layer 2 forwarding.

Configuration guide	Content
	• Bulk interface. • Ethernet interface. • Loopback, null, and inloopback interface.
Layer 3—IP Services Configuration Guide	Covers IP addressing (including static and dynamic IPv4 and IPv6 address assignment), network performance optimization, ARP, and interoperation between IPv4 and IPv6. This guide includes: • ARP. • IP addressing. • DHCP. • DNS. • mDNS gateway. • mDNS relay. • IP forwarding basics. • Fast forwarding. • Adjacency table. • IRDP. • IP performance optimization. • UDP helper. • IPv6 basics. • DHCPv6. • IPv6 fast forwarding. • Tunneling. • GRE. • HTTP redirect.
Layer 3—IP Routing Configuration Guide	Covers the routing technologies for IPv4 and IPv6 networks of different sizes, route filtering, route control, and policy based routing. This guide includes: • Basic IP routing. • Static routing. • RIP. • OSPF. • IS-IS. • BGP. • Policy-based routing. • IPv6 static routing. • RIPng. • OSPFv3. • IPv6 policy-based routing. • Routing policy. • DCN. • Dual-stack PBR.
IP Multicast Configuration Guide	Covers Layer 2 IPv4 multicast protocols (including IGMP snooping, and multicast VLAN), Layer 3 IPv4 multicast protocols (including IGMP and PIM), Layer 2 IPv6 multicast protocols (including MLD snooping and IPv6 multicast VLAN), and Layer 3 IPv6 multicast protocols (including MLD, IPv6 PIM, and MSDP). This guide includes: • Multicast overview.docx • IGMP snooping. • PIM snooping.

Configuration guide	Content
	• Multicast VLAN. • Multicast routing and forwarding. • IGMP. • PIM. • MSDP. • MLD snooping. • IPv6 PIM snooping. • IPv6 multicast VLAN. • IPv6 multicast routing and forwarding. • MLD. • IPv6 PIM.
MCE Configuration Guide	Covers the *ME* fundamentals and configuration procedures.
ACL and QoS Configuration Guide	Covers information about classifying traffic with ACLs, and allocating network resources and managing congestions with QoS technologies to improve network performance and network use efficiency. This guide includes: • ACL. • QoS. • Data buffer. • Time range.
Security Configuration Guide	Covers security features. Available security features include identity authentication (AAA and PKI), access security (802.1X, MAC authentication, portal, and port security), secure management (SSH), SSL, and attack protection (IP source guard, ARP attack protection, MFF, and uRPF). This guide includes: • AAA. • 802.1X. • MAC authentication. • Portal. • Web authentication. • Triple authentication. • Port security. • User profile. • Password control. • Keychain. • Public key management.docx • PKI. • IPsec. • SSH. • SSL. • Attack detection and prevention. • TCP attack prevention. • IP source guard. • ARP attack protection. • ND attack defense. • uRPF. • SAVI. • MFF. • FIPS.

Configuration guide	Content
	• MACsec. • 802.1X client.
High Availability Configuration Guide	Covers high availability technologies and features available on the switch for failure detection and failover. Failure detection technologies focus on fault detection and isolation. Failover technologies focus on network recovery. This guide includes: • Ethernet OAM. • DLDP. • ERPS. • RRPP. • Smart Link. • Monitor Link. • VRRP. • BFD. • Track. • Process placement. • Interface collaboration.
Network Management and Monitoring Configuration Guide	Covers features that help you manage and monitor your network, for example, manage system events, collect traffic statistics, sample packets, assess network performance, and test network connectivity. This guide includes: • System maintenance and debugging. • NQA. • NTP. • PoE. • SNMP. • RMON. • NETCONF. • Ansible. • SmartMC. • AON Ethernet system. • EPA. • CWMP. • EAA. • Process monitoring and maintenance. • Sampler. • Mirroring. • NetStream. • IPv6 NetStream. • sFlow. • Information center. • Packet capture. • VCF fabric. • Cloud connection. • eMDI. • Performance management. • TCP connection trace.
Telemetry Configuration Guide	Covers the telemetry fundamentals and configuration procedures. You can use the telemetry technologies to remotely collect data from network devices, so as to monitor device performances and network

Configuration guide	Content
	operations. This guide includes: • gRPC. • Flow group. • MOD.
OpenFlow Configuration Guide	Covers the *OpenFlow* fundamentals and configuration procedures. OpenFlow allows a controller to directly access and operate the forwarding plane of the switch, separating the control plane from the data plane. The switch matches and forwards packets according to the flow tables deployed by the controller.
Network slicing Configuration Guide	Covers the *Network slicing* fundamentals and configuration procedures.
TAP Configuration Guide	Covers the *TAP* fundamentals and configuration procedures.
Intelligent Lossless Network Configuration Guide	Covers the *PFC* fundamentals and configuration procedures.

H3C S5100[S5500]-D-G&S5130S-G[-V2] Switch Series Fundamentals Configuration Guide

New H3C Technologies Co., Ltd.
http://www.h3c.com

Software version: Release 8336P11 and later
Document version: 6W101-20260803

Notice

The information in this document is subject to change without notice. All contents in this document, including statements, information, and recommendations, are believed to be accurate, but they are presented without warranty of any kind, express or implied. H3C shall not be liable for technical or editorial errors or omissions contained herein.

Preface

This configuration guide describes features and tasks that help you get started with the device.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

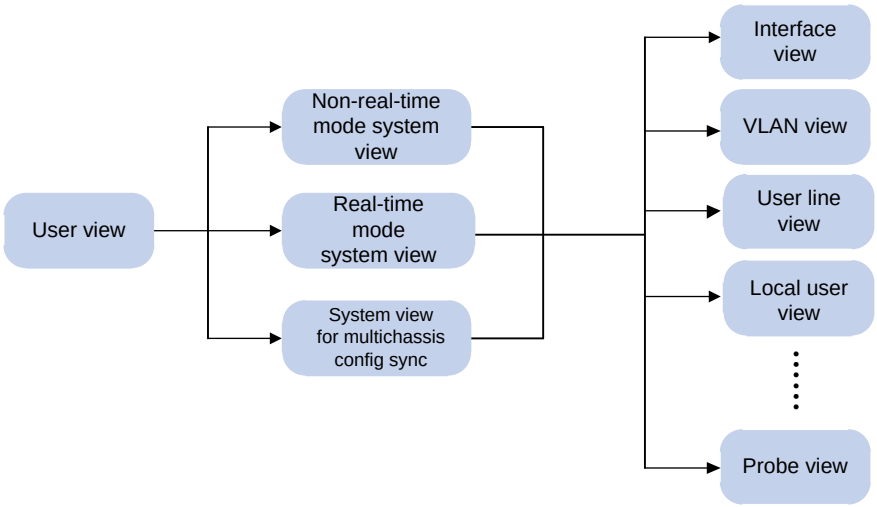
Using the CLI

About the CLI

At the command-line interface (CLI), you can enter text commands to configure, manage, and monitor the device.

You can use different methods to log in to the CLI. For example, you can log in through the console port or Telnet. For more information about login methods, see "Login overview."



Using CLI views

About CLI views

Commands are grouped in different views by feature. To use a command, you must enter its view.

CLI views are hierarchically organized, as shown in Figure 1. Each view has a unique prompt, from which you can identify where you are and what you can do. For example, the prompt [Sysname-vlan100] shows that you are in VLAN 100 view and can configure attributes for that VLAN.

Figure 1 CLI views

You are placed in user view immediately after you log in to the CLI.

In user view, you can perform the following tasks:

- Perform basic operations including display, debug, file management, FTP, Telnet, clock setting, and reboot.
- Enter system view.

In system view, you can perform the following tasks:

- Configure settings that affect the device as a whole, such as the daylight saving time, banners, and hotkeys.
- Enter feature views.

  For example, you can perform the following tasks:
  - Enter interface view to configure interface parameters.

- Enter VLAN view to add ports to the VLAN.
- Enter user line view to configure login user attributes.

A feature view might have child views. For example, NQA operation view has the child view HTTP operation view.

- Enter probe view by using the **probe** command.

  The probe view provides display, debugging, and maintenance commands, which are mainly used by developers and testers for system fault diagnosis and system operation monitoring.

CAUTION:

Use the commands in probe view under the guidance of engineers to avoid system exceptions caused by incorrect operations.

For more information about the commands in probe view, see the probe commands manual for each feature.

To display all commands available in a view, enter a question mark (?) at the view prompt.

Entering common system view (commit command not supported)

Entering common system view from user view

About this task

In common system view and its lower-level views, settings are written to the running configuration and take effect immediately.

Procedure

To enter common system view from user view, execute the following command:

system-view

Entering real-time-mode system view from user view

About this task

In real-time-mode system view and its lower-level views, settings are written to the running configuration and take effect immediately.

Available commands in the system views might vary. For more information, enter a question mark (?) at the system view prompts.

Unless otherwise stated, the term "system view" refers to real-time-mode system view.

Hardware and feature compatibility

Only the S5200-HI-G switch series supoorts this feature.

Procedure

To enter real-time-mode system view from user view, execute the following command:

system-view [**immediate**]

Entering non-real-time-mode system view from user view

About this task

For non-real-time-mode system view, you can enter exclusive-mode system view and private-mode system view.

In exclusive-mode system view, private-mode system view, and their lower-level views, settings are saved to the target configuration, which takes effect after being committed by using the **commit** command. For more information, see "Managing target configuration."

Only one user can enter exclusive-mode system view or its lower-level views.

- When a user is in an exclusive-mode view, users in private-mode views cannot commit their target configuration command lines.
- When no user is in an exclusive-mode view, users in private-mode views can commit their respective target configuration command lines. However, only one user in a private-mode view can commit target configuration command lines at a time.

Available commands in the system views might vary. For more information, enter a question mark (?) at the system view prompts.

Private-mode views and exclusive-mode views have a leading tilde sign (~) in their prompts as compared to their counterpart real-time-mode views. After you execute a command that does not take effect in real time, the prompt will have a leading asterisk sign (*) to indicate that the command has not taken effect in the current mode. After the **commit** command is executed to commit the configuration, the prompt will have a leading tilde sign (~).

Hardware and feature compatibility

Only the S5200-HI-G switch series supoorts this feature.

Procedure

To enter non-real-time-mode system view from user view, execute the following command:

system-view { **exclusive** | **private** }

Entering system view for multichassis configuration sync from user view

About this task

In a network configured with multichassis configuration synchronization, such as an M-LAG network, some commands must be executed on both member devices. For these commands, you have to execute them separately on the local and peer member devices. This is cumbersome and might cause configuration errors.

To resolve this issue, you can execute the **system-view mc-config** command to enter system view for multichassis configuration sync. In system view for multichassis configuration sync and its lower-level views, settings on the local member device are synchronized to the peer member device. This ensures configuration consistency on the local and peer member devices and avoids repeated configuration. For more information about multichassis configuration synchronization, see "Configuring multichassis configuration synchronization."

Hardware and feature compatibility

Only the S5200-HI-G switch series supoorts this feature.

Procedure

To enter system view for multichassis configuration sync from user view, execute the following command:

system-view mc-config

Specifying the default mode of the system view

About this task

By default, the system enters real-time-mode system view after the **system-view** command is executed. To configure the settings in non-real-time-mode, you must specify the **exclusive** or **private** keyword each time the system enters system view. To simplify the configuration, you can execute the **configuration system-view-mode** command to specify the default mode of the system view that the system will enter after the **system-view** command is executed.

Hardware and feature compatibility

Only the S5200-HI-G switch series supoorts this feature.

Procedure

To specify the default mode of the system view that the system will enter after the **system-view** command is executed, execute the following command:

configuration system-view-mode { **immediate** | **private** }

By default, the system enters real-time-mode system view after the **system-view** command is executed.

Returning to the upper-level view from a view

Restrictions and guidelines

Executing the **quit** command in user view terminates your connection to the device.

To return from public key view to system view, you must use the **peer-public-key end** command.

Procedure

To return to the upper-level view from a view, execute the following command:

quit

Returning to user view

About this task

This feature enables you to return to user view from any other view by performing a single operation. You do not need to execute the **quit** command multiple times.

To return directly to user view, you can execute the **abort** or **return** command or press **Ctrl+Z**.

- If you execute **return** or press **Ctrl+Z** to return from private-mode or exclusive-mode view to user view, the system displays a message to notify you of uncommitted target configuration command lines (if any).
- If you execute **abort** to return from private-mode or exclusive-mode view to user view, the system discards uncommitted target configuration command lines (if any) without any prompt.

Procedure

To return directly to user view from any other view except Tcl configuration view and the Python shell, use one of the following methods:

- Execute the **return** command.

- Press **Ctrl+Z**.
- Execute the **abort** command in any private-mode/exclusive-mode view.

To return to user view from Tcl configuration view, use the **tclquit** command.

To return to user view from the Python shell, use the **exit()** command.

Accessing the CLI online help

The CLI online help is context sensitive. Enter a question mark at any prompt or in any position of a command to display all available options.

To access the CLI online help, use one of the following methods:

- Enter a question mark at a view prompt to display the first keyword of every command available in the view. For example:

```
<Sysname> ?
User view commands:
archive             Archive configuration
  arp                 Address Resolution Protocol (ARP) module
  backup              Backup operation
  bash                Enter the bash shell
  boot-loader         Software image file management
  bootrom             Update/read/backup/restore bootrom
...
```

- Enter a space and a question mark after a command keyword to display all available keywords and arguments.
  - If the question mark is in the place of a keyword, the CLI displays all possible keywords, each with a brief description. For example:

```
<Sysname> terminal ?
  debugging  Enable to display debugging logs on the current terminal
  logging    Display logs on the current terminal
  monitor    Enable to display logs on the current terminal
```

  - If the question mark is in the place of an argument, the CLI displays the description for the argument. For example:

```
<Sysname> system-view
[Sysname] interface vlan-interface ?
  <1-4094>  Vlan-interface interface number
[Sysname] interface vlan-interface 1 ?
  <cr>
[Sysname] interface vlan-interface 1
```

    <1-4094> is the value range for the argument. **<cr>** indicates that the command is complete and you can press **Enter** to execute the command.

- Enter an incomplete keyword string followed by a question mark to display all keywords starting with that string. The CLI also displays the descriptions for the keywords. For example:

```
<Sysname> f?
  fdisk    Partition a storage medium
  fixdisk   Check and repair a storage medium
  format    Format a storage medium
  free      Release a connection
  ftp       Open an FTP connection
```

```
<Sysname> display ftp?
  ftp         FTP module
  ftp-server  FTP server information
  ftp-user    FTP user information
```

Using the undo form of a command

Most configuration commands have an **undo** form for the following tasks:

- Canceling a configuration.
- Restoring the default.
- Disabling a feature.

For example, the **`info-center enable`** command enables the information center. The **undo `info-center enable`** command disables the information center.

Entering a command

When you enter a command, you can perform the following tasks:

- Use keys or hotkeys to edit the command line.
- Use abbreviated keywords or keyword aliases.

Editing a command line

To edit a command line, use the keys listed in Table 1 or the hotkeys listed in "Configuring and using hotkeys." When you are finished, you can press **Enter** to execute the command. If the command entered by the user cannot be executed in the current view, the system will try to execute the command in the upper level view of the current view. The execution fails until the command cannot be executed in system view.

The command edit buffer can contain a maximum of 511 characters. If the total length of a command line exceeds the limit after you press **Tab** to complete the last keyword or argument, the system does not complete the keyword.

IMPORTANT:

If the amount of free memory space reaches a free-memory threshold set by the **`memory-threshold`** command, the device displays memory usage information every time you execute a command. For more information about the **`memory-threshold`** command, see *Fundamentals Command Reference.*

Table 1 Command line editing keys

Keys	Function
Common keys	If the edit buffer is not full, pressing a common key inserts a character at the cursor and moves the cursor to the right. The edit buffer can store up to 511 characters. Unless the buffer is full, all common characters that you enter before pressing **Enter** are saved in the edit buffer.
Backspace	Deletes the character to the left of the cursor and moves the cursor back one character.
Left arrow key (←)	Moves the cursor one character to the left.
Right arrow key (→)	Moves the cursor one character to the right.

Keys	Function
Up arrow key (↑)	Displays the previous command in the command history buffer.
Down arrow key (↓)	Displays the next command in the command history buffer.
Tab	If you press **Tab** after typing part of a keyword, the system automatically completes the keyword. • If a unique match is found, the system displays the complete keyword. • If there is more than one match, press **Tab** multiple times to pick the keyword you want to enter. • If there is no match, the system does not modify what you entered but displays it again in the next line.

The device supports the following special commands:

- #—Used by the system in a configuration file as separators for adjacent sections.
- **version**—Used by the system in a configuration file to indicate the software version information. For example, **version 7.1. xxx**, **Release xxx**.

These commands are special because of the following reasons:

- These commands are not intended for you to use at the CLI.
- You can enter the **#** command in any view or the **version** command in system view, or enter any values for them. For example, you can enter **# abc** or **version abc**. However, the settings do not take effect.
- The device does not provide any online help information for these commands.

Entering a text or string type value for an argument

A text type argument value can contain any characters except question marks (?).

A string type argument value can contain any printable characters except question marks (?).

- To include a quotation mark (") or backward slash (\) in a string type argument value, prefix the character with an escape key (\), for example, \" and \\.
- To include a blank space in a string type argument value, enclose the value in quotation marks, for example, "my device".

A specific argument might have more requirements. For more information, see the relevant command reference.

To enter a printable character, you can enter the character or its ASCII code in the range of 32 to 126.

Entering an interface type

You can enter an interface type in one of the following formats:

- Full spelling of the interface type.
- An abbreviation that uniquely identifies the interface type.
- Acronym of the interface type.

For a command line, all interface types are case insensitive. The following table shows the full spellings and acronyms of interface types.

For example, to use the **interface** command to enter the view of interface GigabitEthernet 1/0/1, you can enter the command line in the following formats:

- **interface gigabitethernet 1/0/1**

- **interface g 1/0/1**
- **interface ge 1/0/1**

Spaces between the interface types and interfaces are not required.

Table 2 Full spellings and acronyms of interface types

Full spelling	Acronym
Bridge-Aggregation	BAGG
GigabitEthernet	GE
InLoopBack	InLoop
LoopBack	Loop
M-GigabitEthernet	MGE
NULL	NULL
Register-Tunnel	REG
Route-Aggregation	RAGG
Ten-GigabitEthernet	XGE
Tunnel	Tun
Vlan-interface	Vlan-int

Abbreviating commands

You can enter a command line quickly by entering incomplete keywords that uniquely identify the complete command. In user view, for example, commands starting with an **s** include **startup saved-configuration** and **system-view**. To enter the command **system-view**, you need to type only **sy**. To enter the command **startup saved-configuration**, type **st s**.

You can also press **Tab** to complete an incomplete keyword.

Configuring and using command aliases

About this task

You can configure one or more aliases for a command or the starting keywords of commands. Then, you can use the aliases to execute the command or commands. If the command or commands have **undo** forms, you can also use the aliases to execute the **undo** command or commands.

For example, if you configure the **shiprt** alias for **display ip routing-table**, you can enter **shiprt** to execute the **display ip routing-table** command. If you configure the **ship** alias for **display ip**, you can use **ship** to execute all commands starting with **display ip**, including:

- Enter **ship routing-table** to execute the **display ip routing-table** command.
- Enter **ship interface** to execute the **display ip interface** command.

The device provides a set of system-defined command aliases, as listed in Table 3.

Table 3 System-defined command aliases

Command alias	Command or command keyword
access-list	**acl**

Command alias	Command or command keyword
end	**return**
erase	**delete**
exit	**quit**
hostname	**sysname**
logging	**info-center**
no	**undo**
show	**display**
write	**save**

Restrictions and guidelines

A command alias can be used only as the first keyword of a command or the second keyword of the **undo** form of a command.

After you successfully execute a command by using an alias, the system saves the command, instead of the alias, to the running configuration.

The command string can include up to nine parameters. Each parameter starts with the dollar sign ($) and a sequence number in the range of 1 to 9. For example, you can configure the alias **shinc** for the **display ip $1 | include $2** command. Then, to execute the **display ip routing-table | include Static** command, you need to enter only **shinc routing-table Static**.

To use an alias for a command that has parameters, you must specify a value for each parameter. If you fail to do so, the system informs you that the command is incomplete and displays the command string represented by the alias.

System-defined command aliases cannot be deleted.

Procedure

1. Enter system view.
   system-view
2. Configure a command alias.
   alias *alias command*
   By default, the device has a set of command aliases, as listed in Table 3.
3. (Optional.) Display command aliases.
   display alias [*alias*]
   This command is available in any view.

Configuring and using hotkeys

About this task

The device supports a set of hotkeys. Pressing a hotkey executes the command or function assigned to the hotkey. Table 4 shows the hotkeys and their default definitions. You can configure all the hotkeys except **Ctrl+]**.

If a hotkey is also defined by the terminal software you are using to interact with the device, you can reconfigure the hotkey or remove the hotkey.

Restrictions and guidelines

A hotkey can correspond to only one command or function. If you assign multiple commands or functions to the same hotkey, the most recently assigned command or function takes effect.

A command or function can be assigned to multiple hotkeys. You can use any of the hotkeys to execute the command or function.

If a hotkey is also defined by the terminal software you are using to interact with the device, the terminal software definition takes effect.

Procedure

1. Enter system view.

   system-view

2. Assign a command to a hotkey.

   hotkey *hotkey* { *command* | **function** *function* | **none** }

   Table 4 shows the default definitions for the hotkeys.

3. (Optional.) Display hotkeys.

   display hotkey

   This command is available in any view.

Table 4 Default definitions for hotkeys

Hotkey	Function or command
Ctrl+A	**move_the_cursor_to_the_beginning_of_the_line**: Moves the cursor to the beginning of a line.
Ctrl+B	**move_the_cursor_one_character_to_the_left**: Moves the cursor one character to the left.
Ctrl+C	**stop_the_current_command**: Stops the current command.
Ctrl+D	**erase_the_character_at_the_cursor**: Deletes the character at the cursor.
Ctrl+E	**move_the_cursor_to_the_end_of_the_line**: Moves the cursor to the end of a line.
Ctrl+F	**move_the_cursor_one_character_to_the_right**: Moves the cursor one character to the right.
Ctrl+G	**display current-configuration**: Display the running configuration.
Ctrl+H	**erase_the_character_to_the_left_of_the_cursor**: Deletes the character to the left of the cursor.
Ctrl+L	**display ip routing-table**: Display the IPv4 routing table information.
Ctrl+N	**display_the_next_command_in_the_history_buffer**: Displays the next command in the history buffer. Password configuration commands, if any, are skipped.
Ctrl+O	**undo debugging all**: Disable all debugging functions.
Ctrl+P	**display_the_previous_command_in_the_history_buffer**: Displays the previous command in the history buffer. Password configuration commands, if any, are skipped.
Ctrl+R	**redisplay_the_current_line**: Redisplays the current line.
Ctrl+T	N/A
Ctrl+U	N/A
Ctrl+W	**delete_the_word_to_the_left_of_the_cursor**: Deletes the word to the left of the

Hotkey	Function or command
	cursor.
Ctrl+X	**delete_all_characters_from_the_beginning_of_the_line_to_the_cursor**: Deletes all characters to the left of the cursor.
Ctrl+Y	**delete_all_characters_from_the_cursor_to_the_end_of_the_line**: Deletes all characters from the cursor to the end of the line.
Ctrl+Z	**return_to_the_User_View**: Returns to user view.
Ctrl+]	**kill_incoming_connection_or_redirect_connection**: Terminates the current connection.
Esc+B	**move_the_cursor_back_one_word**: Moves the cursor back one word.
Esc+D	**delete_all_characters_from_the_cursor_to_the_end_of_the_word**: Deletes all characters from the cursor to the end of the word.
Esc+F	**move_the_cursor_forward_one_word**: Moves the cursor forward one word.

Enabling redisplaying entered-but-not-submitted commands

About this task

Your input might be interrupted by system information output. If redisplaying entered-but-not-submitted commands is enabled, the system redisplays your input after finishing the output. You can then continue entering the command line.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable redisplaying entered-but-not-submitted commands.

   ```
   info-center synchronous
   ```

   By default, the system does not redisplay entered-but-not-submitted commands.

   For more information about this command, see *Network Management and Monitoring Command Reference*.

Understanding command-line syntax error messages

After you press **Enter** to submit a command, the command line interpreter examines the command syntax.

- If the command passes syntax check, the CLI executes the command.
- If the command fails syntax check, the CLI displays an error message.

Table 5 Common command-line syntax error messages

Syntax error message	Cause
% Unrecognized command found at '^' position.	The keyword in the marked position is invalid.
% Incomplete command found at '^' position.	One or more required keywords or arguments are missing.

Syntax error message	Cause
% Ambiguous command found at '^' position.	The entered character sequence matches more than one command.
% Too many parameters found at '^' position.	The entered character sequence contains excessive keywords or arguments.
% Wrong parameter found at '^' position.	The argument in the marked position is invalid.

Using the command history feature

About command history buffers

The system automatically saves commands successfully executed by a login user to the following two command history buffers:

- Command history buffer for the user line.
- Command history buffer for all user lines.

Table 6 Comparison between the two types of command history buffers

Item	Command history buffer for a user line	Command history buffer for all user lines
Which commands are saved in the buffer?	Commands successfully executed by the current user of the user line.	Commands successfully executed by all login users.
Can commands in the buffer be displayed?	Yes.	Yes.
Can commands in the buffer be recalled?	Yes.	No.
Are buffered commands cleared when the user logs out?	Yes.	No.
Is the buffer size adjustable?	Yes.	No. The buffer size is fixed at 1024.

Command buffering rules

The system follows these rules when buffering commands:

- If you use incomplete keywords when entering a command, the system buffers the command in the exact form that you used.
- If you use an alias when entering a command, the system transforms the alias to the represented command or command keywords before buffering the command.
- If you enter a command in the same format multiple times in succession, the system buffers the command only once. If you enter a command in different formats multiple times, the system buffers each command format. For example, **`display cu`** and **`display current-configuration`** are buffered as two entries but successive repetitions of **`display cu`** create only one entry.
- To buffer a new command when a buffer is full, the system deletes the oldest command entry in the buffer.

Managing and using the command history buffers

Displaying the commands in command history buffers

To display the commands in command history buffers, execute the following commands in any view:

- Display the commands in command history buffers for a user line.
  `display history-command`
- Display the commands in command history buffers for all user lines.
  `display history-command all`

Recalling commands in the command history buffer for a user line

IMPORTANT:
Password configuration commands cannot be recalled.

Use up and down arrow keys to navigate to a command and press **Enter**.

Setting the size of the command history buffer for a user line

Use the **`history-command max-size`** command in user line or user line class view. For more information, see *Fundamentals Command Reference*.

Repeating commands in the command history buffer for a user line

About this task

You can recall and execute commands in the command history buffer for the current user line multiple times.

Restrictions and guidelines

The **`repeat`** command is available in any view. However, to repeat a command, you must first enter the view for the command. To repeat multiple commands, you must first enter the view for the first command.

The **`repeat`** command executes commands in the order they were executed.

The system starts a timer and waits for your interaction when it repeats an interactive command. If you do not provide the required information at prompt before the timer expires, the system skips the interactive command.

The system skips all password configuration commands.

Procedure

To repeat commands in the command history buffer for the current user line, execute the following command:

`repeat` [*`number`*] [**`count`** *`times`*] [**`delay`** *`seconds`*]

Controlling the CLI output

This section describes the CLI output control features that help you identify the desired output.

Pausing between screens of output

About this task

The device can automatically pause after displaying a specific number of lines if the output is too long to fit on one screen. At a pause, the device displays **----more----**. You can use the keys described in Table 7 to display more information or stop the display.

You can also disable pausing between screens of output for the current session. Then, all output is displayed at one time and the screen is refreshed continuously until the final screen is displayed.

Table 7 Output controlling keys

Keys	Function
Space	Displays the next screen.
Enter	Displays the next line.
Ctrl+C	Stops the display and cancels the command execution.
<PageUp>	Displays the previous page.
<PageDown>	Displays the next page.

Disabling pausing between screens of output

To disable pausing between screens of output, execute the following command in user view:

`screen-length disable`

The default depends on the settings of the **`screen-length`** command in user line view. The following are the default settings for the **`screen-length`** command:

- Pausing between screens of output is enabled.
- The maximum number of lines to be displayed at a time is 24.

For more information about the **`screen-length`** command, see *Fundamentals Command Reference*.

This command is a one-time command and takes effect only for the current CLI session.

Numbering each output line from a display command

About this task

For easy identification, you can use the **`| by-linenum`** option to display a number for each output line from a **`display`** command.

Each line number is displayed as a 5-character string and might be followed by a colon (:) or hyphen (-). If you specify both **`| by-linenum`** and **`| begin`** *`regular-expression`* for a **`display`** command, a hyphen is displayed for all lines that do not match the regular expression.

Procedure

To number each output line from a **`display`** command, execute the following command in any view:

`display` *`command`* **`| by-linenum`**

Example

Display information about VLAN 999, numbering each output line.

```
<Sysname> display vlan 999 | by-linenum
    1:  VLAN ID: 999
```

```
2:  VLAN type: Static
3:  Route interface: Configured
4:  IPv4 address: 192.168.2.1
5:  IPv4 subnet mask: 255.255.255.0
6:  Description: For LAN Access
7:  Name: VLAN 0999
8:  Tagged ports:   None
9:  Untagged ports: None
```

Filtering the output from a display command

About this task

You can use the **[| { count | [by-linenum] { begin | exclude | include } *regular-expression* }]&<1-128>** option to filter the output from a **display** command.

- You can use the option to specify a maximum of 128 filter conditions. The system displays only output lines that meet all the conditions.
- **count**—Displays the number of lines that match the specified regular expressions.
- **by-linenum**—Displays a number before each output line. You need to specify this keyword in only one filter condition.
- **begin**—Displays the first line matching the specified regular expression and all subsequent lines.
- **exclude**—Displays all lines not matching the specified regular expression.
- **include**—Displays all lines matching the specified regular expression.
- *regular-expression*—A case-sensitive string of 1 to 256 characters, which can contain the special characters described in Table 8.

Table 8 Special characters supported in a regular expression

Characters	Meaning	Examples
^	Matches the beginning of a line.	"^u" matches all lines beginning with "u". A line beginning with "Au" is not matched.
$	Matches the end of a line.	"u$" matches all lines ending with "u". A line ending with "uA" is not matched.
. (period)	Matches any single character.	".s" matches "as" and "bs".
*	Matches the preceding character or string zero, one, or multiple times.	"zo*" matches "z" and "zoo", and "(zo)*" matches "zo" and "zozo".
+	Matches the preceding character or string one or multiple times.	"zo+" matches "zo" and "zoo", but not "z".
|	Matches the preceding or succeeding string.	"def|int" matches a line containing "def" or "int".
( )	Matches the string in the parentheses, usually used together with the plus sign (+) or asterisk sign (*).	"(123A)" matches "123A". "408(12)+" matches "40812" and "408121212", but not "408".
\N	Matches the preceding strings in parentheses, with the *Nth* string repeated once.	"(string)\1" matches a string containing "stringstring". "(string1)(string2)\2" matches a string containing "string1string2string2".

Characters	Meaning	Examples
		"(string1)(string2)\1\2" matches a string containing " string1string2string1string2".
[ ]	Matches a single character in the brackets.	"[16A]" matches a string containing 1, 6, or A; "[1-36A]" matches a string containing 1, 2, 3, 6, or A (- is a hyphen). To match the character "]", put it immediately after "[", for example, []abc]. There is no such limit on "[".
[^]	Matches a single character that is not in the brackets.	"[^16A]" matches a string that contains one or more characters except for 1, 6, or A, such as "abc". A match can also contain 1, 6, or A (such as "m16"), but it cannot contain these three characters only (such as 1, 16, or 16A).
{n}	Matches the preceding character *n* times. The number *n* must be a nonnegative integer.	"o{2}" matches "food", but not "Bob".
{n,}	Matches the preceding character *n* times or more. The number *n* must be a nonnegative integer.	"o{2,}" matches "foooood", but not "Bob".
{n,m}	Matches the preceding character *n* to *m* times or more. The numbers *n* and *m* must be nonnegative integers and *n* cannot be greater than *m*.	" o{1,3}" matches "fod", "food", and "foooood", but not "fd".
\<	Matches a string that starts with the pattern following \<. A string that contains the pattern is also a match if the characters preceding the pattern are not digits, letters, or underscores.	"\<do" matches "domain" and "doa".
\>	Matches a string that ends with the pattern preceding \>. A string that contains the pattern is also a match if the characters following the pattern are not digits, letters, or underscores.	"do\>" matches "undo" and "cdo".
\b	Matches a word that starts with the pattern following \b or ends with the pattern preceding \b.	"er\b" matches "never", but not "verb" or "erase". "\ber" matches "erase", but not "verb" or "never".
\B	Matches a word that contains the pattern but does not start or end with the pattern.	"er\B" matches "verb", but not "never" or "erase".
\w	Same as [A-Za-z0-9_], matches a digit, letter, or underscore.	"v\w" matches "vlan" and "service".
\W	Same as [^A-Za-z0-9_], matches a character that is not a digit, letter, or underscore.	"\Wa" matches "-a", but not "2a" or "ba".
\	Escape character. If a special character listed in this table follows \, the specific meaning of the character is removed.	"\\" matches a string containing "\", "\^" matches a string containing "^", and "\\b" matches a string containing "\b".

Restrictions and guidelines

The required filtering time increases with the complexity of the regular expression. To abort the filtering process, press **Ctrl+C**.

If a regular expression contains spaces, you can select whether to enclose the regular expression with double quotation marks, for example, **display current-configuration | include interface A** or **display current-configuration | include "interface A"**.

The following rules apply when you specify regular expressions with or without double quotation marks:

- If a regular expression has double quotation marks, the string enclosed by double quotation marks is the filter condition.
- If a regular expression does not have double quotation marks, the string from the first non-space character to the last non-space character is the filter condition. The device uses this string as a filter condition for exact match of strings in the command output from a **display** command.

For example, *regular-expression*=**"interface A "** and *regular-expression*=**interface A** are different filter conditions.

If a regular expression contains **>**, **>**, or **> |**, enclose the regular expression with double quotation marks (") in case the device mistake these special characters as keywords.

Strings with single quotation marks (') are not supported.

If you specify multiple filter conditions, the system displays the output lines that meet all the conditions.

Examples

Display the running configuration, starting from the first configuration line that contains **line**. (The output depends on the device model and the current configuration.)

```
<Sysname> display current-configuration | begin line
line class console
 user-role network-admin
#
line class vty
 user-role network-operator
#
line con 0
 user-role network-admin
#
line vty 0 63
 authentication-mode none
 user-role network-admin
 user-role network-operator
#
...
```

Display brief information about interfaces in up state.

```
<Sysname> display interface brief | exclude DOWN
Brief information on interfaces in route mode:
Link: ADM - administratively down; Stby - standby
Protocol: (s) - spoofing
Interface            Link Protocol Primary IP      Description
InLoop0              UP   UP(s)    --
```

```
NULL0                UP   UP(s)    --
Vlan1                UP   UP       192.168.1.83

Brief information on interfaces in bridge mode:
Link: ADM - administratively down; Stby - standby
Speed: (a) - auto
Duplex: (a)/A - auto; H - half; F - full
Type: A - access; T - trunk; H - hybrid
Interface            Link Speed    Duplex Type PVID Description
GE1/0/1              UP   100M(a) F(a)A    1
```

Display SNMP-related running configuration lines.

```
<Sysname> display current-configuration | include snmp
snmp-agent
 snmp-agent community write private
 snmp-agent community read public
 snmp-agent sys-info version all
 snmp-agent target-host trap address udp-domain 192.168.1.26 params securityname public
```

Display log entries in the log buffer that contain both **SHELL** and **VTY**.

```
<Sysname> display logbuffer | include SHELL | include VTY
%Sep  6 10:38:12:320 2018 Sysname SHELL/5/SHELL_LOGIN: VTY logged in from 169.254.100.171.
%Sep  6 10:52:32:576 2018 Sysname SHELL/5/SHELL_LOGOUT: VTY logged out from
169.254.100.171.
%Sep  6 16:03:27:100 2018 Sysname SHELL/5/SHELL_LOGIN: VTY logged in from 169.254.100.171.
%Sep  6 16:44:18:113 2018 Sysname SHELL/5/SHELL_LOGOUT: VTY logged out from
169.254.100.171.
```

Displaying information for the peer member device

About this task

In a network configured with multichassis configuration synchronization, perform this task on the local member device to view information for the peer member device as follows:

- To view information for only the peer member device, execute the **display** *command* **peer-device** command on the local device. This facilitates device management and maintenance.
- To view information for both member devices at the same time, execute the **display** *command* **with-peer-device** command. This is convenient for comparison between two member devices.

For more information about multichassis configuration synchronization, see "Configuring multichassis configuration synchronization."

Hardware and feature compatibility

Only the S5200-HI-G switch series supoorts this feature.

Procedure

To view information for only the peer member device or information for both local and peer member devices, execute the following command in any view:

display { **peer-device** | **with-peer-device** }

Configuration examples

Display the running configuration in user view on both the local and peer member devices.

```
<Sysname> display this with-peer-device
#
sysname sysname
#
xbar load-single
password-recovery enable
lpu-type f-series
#
m-lag mad exclude interface GigabitEthernet1/0/1
m-lag system-mac 0001-0001-0001
m-lag system-number 1
m-lag system-priority 123
m-lag keepalive ip destination 1.1.1.1 source 1.1.1.2
#
scheduler logfile size 16
#
domain default enable system
#
security-enhanced level 2
#
return
-----------------------  peer information  -------------------------
#
sysname sysname
#
xbar load-single
password-recovery enable
lpu-type f-series
#
m-lag mad exclude interface GigabitEthernet1/0/1
m-lag system-mac 0001-0001-0001
m-lag system-number 2
m-lag system-priority 123
m-lag keepalive ip destination 1.1.1.2 source 1.1.1.1
#
scheduler logfile size 16
#
domain default enable system
#
security-enhanced level 2
#
return
```

Saving the output from a display command to a file

About this task

A **display** command shows certain configuration and operation information for the device. Its output might vary over time or with user configuration or operation. You can save the output to a file for future retrieval or troubleshooting.

Use one of the following methods to save the output from a **display** command:

- Save the output to a separate file. Use this method if you want to use one file for a single **display** command.
- Append the output to the end of a file. Use this method if you want to use one file for multiple **display** commands.

Procedure

To save the output from a **display** command to a file, use one of the following commands in any view:

- Save the output from a **display** command to a separate file.

  display *command* **>** *filename*
- Append the output from a **display** command to the end of a file.

  display *command* **>>** *filename*

Examples

Save the VLAN 1 settings to a separate file named **vlan.txt**.

```
<Sysname> display vlan 1 > vlan.txt
```

Verify that the VLAN 1 settings are saved to the file **vlan.txt**.

```
<Sysname> more vlan.txt
VLAN ID: 1
 VLAN type: Static
 Route interface: Not configured
 Description: VLAN 0001
 Name: VLAN 0001
 Tagged ports:   None
 Untagged ports: None
```

Append the VLAN 999 settings to the end of the file **vlan.txt**.

```
<Sysname> display vlan 999 >> vlan.txt
```

Verify that the VLAN 999 settings are appended to the end of the file **vlan.txt**.

```
<Sysname> more vlan.txt
VLAN ID: 1
 VLAN type: Static
 Route interface: Not configured
 Description: VLAN 0001
 Name: VLAN 0001
 Tagged ports:   None
 Untagged ports: None
 VLAN ID: 999
 VLAN type: Static
 Route interface: Configured
 IP address: 192.168.2.1
```

```
 Subnet mask: 255.255.255.0
 Description: For LAN Access
 Name: VLAN 0999
 Tagged ports:   None
 Untagged ports: None
```

Viewing and managing the output from a display command effectively

You can use the following methods in combination to filter and manage the output from a **display** command:

- Numbering each output line from a display command
- Filtering the output from a display command
- Saving the output from a display command to a file

Procedure

To use multiple measures to view and manage the output from a **display** command effectively, execute the following command in any view:

display *command* [**|** [**by-linenum**] { **begin** | **exclude** | **include** } *regular-expression*]&<1-128> [**>** *filename* | **>>** *filename*]

Examples

Save the running configuration to a separate file named **test.txt**, with each line numbered.

```
<Sysname> display current-configuration | by-linenum > test.txt
```

Append lines including **snmp** in the running configuration to the file **test.txt**.

```
<Sysname> display current-configuration | include snmp >> test.txt
```

Display the first line that begins with **user-group** in the running configuration and all the following lines.

```
<Sysname> display current-configuration | by-linenum begin user-group
  114:  user-group system
  115-  #
  116-  return
```

// The colon (:) following a line number indicates that the line contains the string user-group. The hyphen (-) following a line number indicates that the line does not contain the string **user-group**.

Enabling reauthentication for disruptive commands

About this task

Disruptive commands might power off or restart the device, interrupt services, cause service anomaly, delete key files, clear configuration, cause user login failure, or make users go offline, for example, the **reboot** command. Only the qualified professionals can execute disruptive commands.

As a best practice to avoid service failure due to misoperation, enable reauthentication for disruptive commands.

The following rules apply if you enable reauthentication for disruptive commands:

- Authentication-free users can execute disruptive commands without reauthentication.

- Non-authentication-free users must enter the login password for re-authentication when they execute disruptive commands.

Procedure

1. Enter system view.

   `system-view`

2. Enable reauthentication for disruptive commands.

   `configuration reauthentication enable`

   By default, reauthentication for disruptive commands is disabled.

Entering MMI mode

About this task

In machine-machine interaction (MMI) mode, interactive commands that require confirmation by pressing Y/N, Y/N/C, or Enter in human-machine interaction mode do not require any confirmation. For example, when the **`reboot`** command is executed in human-machine interaction mode, you must press Y/N to proceed with the reboot operation. In MMI mode, the reboot operation is completed without requiring any confirmation after you execute the **`reboot`** command.

Restrictions and guidelines

If pausing between screens of output for the current CLI session has been enabled before you enter MMI mode, all output is displayed at a time and the screen is refreshed continuously until the final screen is displayed.

After you configure the **`configuration reauthentication enable`** command, disruptive commands that require reauthentication do not need to be confirmed again.

Commands that require strings to be input for execution still require manual input and confirmation.

Procedure

Execute the following command in user view.

`terminal mmi-mode enable`

By default, the user is in human-machine interaction mode.

Configuring RBAC

About RBAC

Role-based access control (RBAC) controls access permissions of users based on user roles.

RBAC assigns access permissions to user roles that are created for different job functions. Users are given permission to access a set of items and resources based on the users' user roles. Separating permissions from users enables simple permission authorization management.

Permission assignment

Use the following methods to assign permissions to a user role:

- Define a set of rules to determine accessible or inaccessible items for the user role. (See "User role rules.")
- Configure resource access policies to specify which resources are accessible to the user role. (See "Resource access policies.")

To use a command related to a system resource, a user role must have access to both the command and the resource.

For example, a user role has access to the **vlan** command and access only to VLAN 10. When the user role is assigned, you can use the **vlan** command to create VLAN 10 and enter its view. However, you cannot create any other VLANs. If the user role has access to VLAN 10 but does not have access to the **vlan** command, you cannot use the command to enter the view of VLAN 10.

When a user logs in to the device with any user role and enters **<?>** in a view, help information is displayed for the system-defined command aliases in the view. However, the user might not have the permission to access the command aliases. Whether the user can access the command aliases depends on the user role's permission to the commands corresponding to the aliases. For information about command aliases, see "Using the CLI."

A user that logs in to the device with any user role has access to the **system-view**, **quit**, and **exit** commands.

User role rules

User role rules permit or deny access to the items, including commands, Web pages, XML elements, or MIB nodes. You can define the following types of rules for different access control granularities:

- **Command rule**—Controls access to a command or a set of commands that match a regular expression.
- **Feature rule**—Controls access to the commands of a feature by command type.
- **Feature group rule**—Controls access to the commands of features in a feature group by command type.
- **Web menu rule**—Controls access to Web pages used for configuring the device. These Web pages are called Web menus.
- **XML element rule**—Controls access to XML elements used for configuring the device.
- **OID rule**—Controls SNMP access to a MIB node and its child nodes. An OID is a dotted numeric string that uniquely identifies the path from the root node to a leaf node.

The items (commands, Web menus, XML elements, and MIB nodes) are controlled based on the following types:

- **Read**—Items that display configuration and maintenance information. For example, the **display** commands and the **dir** command.

- **Write**—Items that configure the features in the system. For example, the **info-center enable** command and the **debugging** command.
- **Execute**—Items that execute specific functions. For example, the **ping** command and the **ftp** command.

A user role can access the set of permitted items specified in the user role rules. The user role rules include predefined (identified by sys-*n*) and user-defined user role rules. For more information about the user role rule priority, see "Configuring user role rules."

Resource access policies

Resource access policies control access of a user role to system resources and include the following types:

- **Interface policy**—Controls access to interfaces.
- **VLAN policy**—Controls access to VLANs.
- **VPN instance policy**—Controls access to VPN instances.

Resource access policies do not control access to the interface, VPN instance, or VLAN options in the **display** commands. You can specify these options in the **display** commands if the options are permitted by any user role rule.

Predefined user roles

The system provides predefined user roles. These user roles have access to all system resources. However, their access permissions differ, as shown in Table 1.

Among all of the predefined user roles, only network-admin, system-admin, and level-15 allow users to create, modify, and delete local users and local user groups. The security-admin user role allows users to change their own passwords and create, modify, and delete network access users. The level-0 to level-14 user roles and user-defined user roles only allow users to modify their own passwords and create, modify, and delete network access users if they have permissions to configure local users and local user groups. They cannot create, modify, or delete device management users or user groups. The other user roles only allow users to modify their own passwords if they have permissions to configure local users and local user groups.

The access permissions of the level-0 to level-14 user roles can be modified through user role rules and resource access policies. However, you cannot make changes on the predefined access permissions of these user roles. For example, you cannot change the access permission of these user roles to the **display history-command all** command.

Table 1 Predefined roles and permissions matrix

User role name	Permissions
network-admin	Accesses all features and resources in the system, except for the **display security-logfile summary**, **info-center security-logfile directory**, and **security-logfile save** commands.
network-operator	• Accesses the **display** commands for features and resources in the system. To display all accessible commands of the user role, use the **display role** command. • Enables local authentication login users to change their own passwords. • Accesses the command used for entering XML view. • Accesses all read-type Web menu items. • Accesses all read-type XML elements. • Accesses all read-type MIB nodes. • Cannot execute the **delete**, **reset**, **logbuffer**, **more**, or **display logbuffer** commands.

User role name	Permissions
level-*n* (*n* = 0 to 15)	• **level-0**—Has access to commands including **ping**, **tracert**, **ssh2**, **telnet**, **mtrace**, and **super**. Level-0 access rights are configurable. • **level-1**—Has access to the **display** commands of features and resources in the system. The **level-1** user role also has all access rights of the level-0 user role. Level-1 access rights are configurable. • **level-2 to level-8, and level-10 to level-14**—Have no access rights by default. Access rights are configurable. • **level-9**—Has access to most of the features and resources in the system. If you are logged in with a local user account that has a level-9 user role, you can change the password in the local user account. The following are the major features and commands that the level-9 user role cannot access: ○ RBAC non-debugging commands. ○ Local users. ○ File management. ○ Device management. ○ The **display history-command all** command. • **level-15**—Has the same rights as network-admin.
security-audit	Security log manager. The user role has the following access rights to security log files: • Accesses the commands for displaying and maintaining security log files (for example, the **dir**, **display security-logfile summary**, and **more** commands). • Accesses the commands for managing security log files and security log file system (for example, the **info-center security-logfile directory**, **mkdir**, and **security-logfile save** commands). For more information about security log management, see *Network Management and Monitoring Configuration Guide*. For more information about file system management, see "Managing file systems." **IMPORTANT:** Only the security-audit user role has access to security log files. You cannot assign the security-audit user role to non-AAA authentication users on a user line.
guest-manager	Accesses only guest-related web pages, and has no access to commands.
system-admin	System administrator. This field is available only on the S5200-HI-G switch. The user role has the following access permissions: • Displays and configures user roles. • Displays, deletes, and configures local users. • Configures VTY user lines. • Enables or disables the Stelnet server. • Executes the **save** command. • Executes the **reboot** command. **IMPORTANT:** You cannot assign the system-admin user role to non-AAA authentication users on a user line.
security-admin	Security administrator. This field is available only on the S5200-HI-G switch. The user role has access to most of the commands in the system except for the following commands:

User role name	Permissions
	• Commands used to display local users. • Commands used to display and configure user roles. • Commands used to configure VTY user lines. • Command used to enable the Stelnet server. • The **save** and **reboot** commands. • Information center-related commands. To display the detailed access permissions of this user role, use the **display role** command. **IMPORTANT:** You cannot assign the security-admin user role to non-AAA authentication users on a user line.
audit-admin	Audit administrator. This field is available only on the S5200-HI-G switch. The user role has access to information center-related commands. To display the detailed access permissions of this user role, use the **display role** command. **IMPORTANT:** You cannot assign the audit-admin user role to non-AAA authentication users on a user line.

User role assignment

You assign access rights to a user by assigning a minimum of one user role. The user can use the collection of items and resources accessible to all user roles assigned to the user. For example, you can access any interface to use the **qos apply policy** command if you are assigned the following user roles:

- User role A denies access to the **qos apply policy** command and permits access only to interface GigabitEthernet 1/0/1.
- User role B permits access to the **qos apply policy** command and all interfaces.

Depending on the authentication method, user role assignment has the following methods:

- **AAA authorization**—If scheme authentication is used, the AAA module handles user role assignment.
  - If the user passes local authorization, the device assigns the user roles specified in the local user account.
  - If the user passes remote authorization, the remote AAA server assigns the user roles specified on the server. The AAA server can be a RADIUS or HWTACACS server.
- **Non-AAA authorization**—When the user accesses the device without authentication or by passing password authentication on a user line, the device assigns user roles specified on the user line. This method also applies to SSH clients that use publickey or password-publickey authentication. User roles assigned to these SSH clients are specified in their respective device management user accounts.

For more information about AAA and SSH, see *Security Configuration Guide*. For more information about user lines, see "Login overview" and "Configuring CLI login."

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

RBAC tasks at a glance

To configure RBAC, perform the following tasks:

1. Creating a user role
2. Configuring user role rules
3. (Optional.) Configuring a feature group
4. Configuring resource access policies
   - Configuring the interface policy for a user role
   - Configuring the VLAN policy for a user role
   - Configuring the VPN instance policy for a user role
5. Assigning user roles
   - Enabling the default user role feature
   - Assigning user roles to remote AAA authentication users
   - Assigning user roles to local AAA authentication users
   - Assigning user roles to non-AAA authentication users on user lines
6. Configuring temporary user role authorization
   a. Setting the authentication mode for temporary user role authorization
   b. Specifying the default target user role for temporary user role authorization
   c. Setting an authentication password for temporary user role authorization
   d. (Optional.) Automatically obtaining the login username for temporary user role authorization
   e. Obtaining temporary user role authorization
   f. (Optional.) Enabling SNMP notification for user role changes

Creating a user role

About this task

In addition to the predefined user roles, you can create a maximum of 64 custom user roles for granular access control.

Procedure

1. Enter system view.
   `system-view`
2. Create a user role and enter its view.
   `role name` *`role-name`*
   By default, the system has the following predefined user roles:
   - network-admin.
   - network-operator.
   - level-*n* (where *n* equals an integer in the range of 0 to 15).
   - security-audit.

- guest-manager.
- system-admin.
- security-admin.
- audit-admin.

Among these user roles, only the permissions and descriptions of the level-0 to level-14 user roles are configurable.

3. (Optional.) Configure a description for the user role.

   description *text*

   By default, a user role does not have a description.

Configuring user role rules

About this task

You can configure user role rules to permit or deny the access of a user role to specific commands, Web pages, XML elements, and MIB nodes.

The following guidelines apply to non-OID rules:

- If two user-defined rules of the same type conflict, the rule with the higher ID takes effect. For example, a user role can use the **tracert** command but not the **ping** command if the user role contains rules configured by using the following commands:
  - **rule** *1* **permit command** *ping*
  - **rule** *2* **permit command** *tracert*
  - **rule** *3* **deny command** *ping*
- If a predefined user role rule and a user-defined user role rule conflict, the user-defined user role rule takes effect.

The following guidelines apply to OID rules:

- The system compares an OID with the OIDs specified in user role rules, and it uses the longest match principle to select a rule for the OID. For example, a user role cannot access the MIB node with OID 1.3.6.1.4.1.25506.141.3.0.1 if the user role contains rules configured by using the following commands:
  - **rule** *1* **permit read write oid** *1.3.6*
  - **rule** *2* **deny read write oid** *1.3.6.1.4.1*
  - **rule** *3* **permit read write oid** *1.3.6.1.4*
- If the same OID is specified in multiple rules, the rule with the higher ID takes effect. For example, a user role can access the MIB node with OID 1.3.6.1.4.1.25506.141.3.0.1 if the user role contains rules configured by using the following commands:
  - **rule** *1* **permit read write oid** *1.3.6*
  - **rule** *2* **deny read write oid** *1.3.6.1.4.1*
  - **rule** *3* **permit read write oid** *1.3.6.1.4.1*

Restrictions and guidelines

- Only the network-admin, and level-15 user roles have access to all of the following commands:

IMPORTANT:

The other predefined user roles, except for those mentioned above, have access to only some of the following commands. For more information, see the command output of the **display role** command.

User-defined user roles cannot access any of the following commands.

- The **display history-command all** command.
- All commands that start with the **display role**, **reboot**, **startup saved-configuration**, and **undo startup saved-configuration** keywords.
- All commands that start with the **role**, **undo role**, **super**, **undo super**, **password-recovery**, and **undo password-recovery** keywords in system view.
- All commands that start with the **snmp-agent community**, **undo snmp-agent community**, **snmp-agent usm-user**, **undo snmp-agent usm-user**, **snmp-agent group**, and **undo snmp-agent group** keywords in system view.
- All commands that start with the **user-role**, **undo user-role**, **authentication-mode**, **undo authentication-mode**, **set authentication password**, and **undo set authentication password** keywords in user line view or user line class view.
- All commands that start with the **user-role** and **undo user-role** keywords in schedule view or in CLI-defined policy view.
- All commands of the event MIB feature.

- You can configure a maximum of 256 user-defined rules for a user role. The total number of user-defined user role rules cannot exceed 1024.
- Any rule modification, addition, or removal for a user role takes effect only on users who are logged in with the user role after the change.

Procedure

1. Enter system view.

   system-view
2. Enter user role view.

   role name *role-name*
3. Configure rules for the user role. Choose the options to configure as needed:
   - Configure a command rule.

     rule *number* { **deny** | **permit** } **command** *command-string*
   - Configure a feature rule.

     rule *number* { **deny** | **permit** } { **execute** | **read** | **write** } * **feature** [*feature-name*]
   - Configure a feature group rule.

     rule *number* { **deny** | **permit** } { **execute** | **read** | **write** } * **feature-group** *feature-group-name*

     A feature group rule takes effect only after the feature group is created.
   - Configure a Web menu rule.

     rule *number* { **deny** | **permit** } { **execute** | **read** | **write** } * **web-menu** [*web-string*]
   - Configure an XML element rule.

     rule *number* { **deny** | **permit** } { **execute** | **read** | **write** } * **xml-element** [*xml-string*]
   - Configure an OID rule.

     rule *number* { **deny** | **permit** } { **execute** | **read** | **write** } * **oid** *oid-string*

Configuring a feature group

About this task

Use feature groups to bulk assign command access permissions to sets of features. In addition to the predefined feature groups, you can create a maximum of 64 custom feature groups and assign a feature to multiple feature groups.

Procedure

1. Enter system view.
   `system-view`
2. Create a feature group and enter its view.
   `role feature-group name` *`feature-group-name`*
   By default, the system has the following predefined feature groups, which cannot be deleted or modified:
   - **L2**—Includes all Layer 2 commands.
   - **L3**—Includes all Layer 3 commands.
3. Add a feature to the feature group.
   `feature` *`feature-name`*
   By default, a feature group does not have any feature.

Configuring resource access policies

About resource access policies

Every user role has one interface policy, VPN instance policy, and VLAN policy. By default, these policies permit a user role to access any system resources. You can configure the policies of a user-defined user role or a predefined level-*n* user role to limit its access to any resources.

Restrictions and guidelines for resource access policy configuration

The policy configuration takes effect only on users who are logged in with the user role after the configuration.

Configuring the interface policy for a user role

1. Enter system view.
   `system-view`
2. Enter user role view.
   `role name` *`role-name`*
3. Enter user role interface policy view.
   `interface policy deny`
   By default, the interface policy for a user role permits access to all interfaces.

CAUTION:

This command denies the access of the user role to any interfaces if you do not specify accessible interfaces by using the **permit interface** command.

4. (Optional.) Specify a list of interfaces accessible to the user role.

   permit interface *interface-list*

   By default, no accessible interfaces are configured in user role interface policy view.

   Repeat this step to add additional accessible interfaces.

Configuring the VLAN policy for a user role

1. Enter system view.

   system-view

2. Enter user role view.

   role name *role-name*

3. Enter user role VLAN policy view.

   vlan policy deny

   By default, the VLAN policy for a user role permits access to all VLANs.

CAUTION:

This command denies the access of the user role to any VLANs if you do not specify accessible VLANs by using the **permit vlan** command.

4. (Optional.) Specify a list of VLANs accessible to the user role.

   permit vlan *vlan-id-list*

   By default, no accessible VLANs are configured in user role VLAN policy view.

   Repeat this step to add additional accessible VLANs.

Configuring the VPN instance policy for a user role

1. Enter system view.

   system-view

2. Enter user role view.

   role name *role-name*

3. Enter user role VPN instance policy view.

   vpn-instance policy deny

   By default, the VPN instance policy for a user role permits access to all VPN instances.

CAUTION:

This command denies the access of the user role to any VPN instances if you do not specify accessible VPN instances by using the **permit vpn-instance** command.

4. (Optional.) Specify a list of VPN instances accessible to the user role.

   permit vpn-instance *vpn-instance-name*&<1-10>

   By default, no accessible VPN instances are configured in user role VPN instance policy view.

   Repeat this step to add additional accessible VPN instances.

Assigning user roles

Restrictions and guidelines for user role assignment

To control user access to the system, you must assign a minimum of one user role. Make sure a minimum of one user role among the user roles assigned by the server exists on the device.

Enabling the default user role feature

About this task

The default user role feature assigns the default user role to AAA-authenticated users if the authentication server (local or remote) does not assign any user roles to the users. These users are allowed to access the system with the default user role.

You can specify any user role existing in the system as the default user role.

Procedure

1. Enter system view.

   `system-view`

2. Enable the default user role feature.

   `role default-role enable` [*`role-name`*]

   By default, the default user role feature is disabled.

   If you do not use the **`authorization-attribute user role`** command to assign user roles to local users, you must enable the default user role feature. For information about the **`authorization-attribute user role`** command, see AAA commands in *Security Command Reference*.

Assigning user roles to remote AAA authentication users

For remote AAA authentication users, user roles are configured on the remote authentication server. For information about configuring user roles for RADIUS users, see the RADIUS server documentation. For HWTACACS users, the role configuration must use the **roles="***role-1 role-2 … role-n***"** format, where user roles are space separated. For example, configure **roles="level-0 level-1 level-2"** to assign level-0, level-1, and level-2 to an HWTACACS user.

If the AAA server assigns the security-audit user role and other user roles to the same user, only the security-audit user role takes effect.

Assigning user roles to local AAA authentication users

About this task

Configure user roles for local AAA authentication users in their local user accounts. For information about AAA and local user configuration, see AAA configuration in *Security Configuration Guide*.

Restrictions and guidelines

- Every local user has a default user role. If this default user role is not suitable, remove it.
- If a local user is the only user with the security-audit user role, the user cannot be deleted.
- The security-audit user role is mutually exclusive with other user roles.
  - When you assign the security-audit user role to a local user, the system requests confirmation to remove all the other user roles from the user.

- When you assign the other user roles to a local user who has the security-audit user role, the system requests confirmation to remove the security-audit role from the user.

- The system-admin, security-admin, and audit-admin user roles are mutually exclusive in a user account. In addition, these user roles are mutually exclusive with other user roles in a user account. When you assign user roles to a user, the system prompts you to confirm the deletion of the user roles that are mutually exclusive with the new user roles.
- You can assign a maximum of 64 user roles to a local user.

Procedure

1. Enter system view.

   system-view
2. Create a local user and enter its view.

   local-user *user-name* **class** { **manage** | **network** }
3. Assign a user role to the local user.

   authorization-attribute user-role *role-name*

   By default, the network-operator user role is assigned to local users created by a network-admin or level-15 user.

Assigning user roles to non-AAA authentication users on user lines

About this task

Specify user roles for the following two types of login users on the user lines:

- Non-SSH users that use password authentication or no authentication.
- SSH clients that use publickey or password-publickey authentication. User roles assigned to these SSH clients are specified in their respective device management user accounts.

For more information about user lines, see "Login overview" and "Configuring CLI login." For more information about SSH, see *Security Configuration Guide*.

Restrictions and guidelines

- You can assign a maximum of 64 user roles to a non-AAA authentication user on a user line.
- You cannot assign the security-audit user role to non-AAA authentication users on user lines.
- The device cannot assign the following user roles to non-AAA authentication users on user lines:
  - system-admin.
  - security-admin.
  - audit-admin.

Procedure

1. Enter system view.

   system-view
2. Enter user line view or user line class view.
   - Enter user line view.

     line { *first-num1* [*last-num1*] | { **console** | **vty** } *first-num2* [*last-num2*] }
   - Enter user line class view.

     line class { **console** | **vty** }

For information about the priority order and application scope of the settings in user line view and user line class view, see "Configuring CLI login."

3. Specify a user role on the user line.

   user-role *role-name*

   By default, the network-admin user role is specified on the console user line, and the network-operator user role is specified on any other user line.

Configuring temporary user role authorization

About temporary user role authorization

Temporary user role authorization allows you to obtain another user role without reconnecting to the device. This feature is useful when you want to use a user role temporarily to configure a feature.

Temporary user role authorization is effective only on the current login. This feature does not change the user role settings in the user account that you have been logged in with. The next time you are logged in with the user account, the original user role settings take effect.

To enable a user to obtain another user role without reconnecting to the device, you must configure user role authentication. Table 2 describes the available authentication modes and configuration requirements.

Table 2 User role authentication modes

Keywords	Authentication mode	Description
local	Local password authentication only (local-only)	The device uses the locally configured password for authentication. If no local password is configured for a user role in this mode, a console user can obtain the user role by either entering a string or not entering anything.
scheme	Remote AAA authentication through HWTACACS or RADIUS (remote-only)	The device sends the username and password to the HWTACACS or RADIUS server for remote authentication. To use this mode, you must perform the following configuration tasks: • Configure the required HWTACACS or RADIUS scheme, and configure the ISP domain to use the scheme for the user. For more information, see *Security Configuration Guide*. • Add the user account and password on the HWTACACS or RADIUS server.
local scheme	Local password authentication first, and then remote AAA authentication (local-then-remote)	Local password authentication is performed first. If no local password is configured for the user role in this mode: • The device performs remote AAA authentication for VTY users. • A console user can obtain another user role by either entering a string or not entering anything.
scheme local	Remote AAA authentication first, and then local password authentication (remote-then-local)	Remote AAA authentication is performed first. Local password authentication is performed in either of the following situations: • The HWTACACS or RADIUS server does not respond. • The remote AAA configuration on the device is invalid.

Restrictions and guidelines for temporary user role authorization

If HWTACACS authentication is used, the following rules apply:

- If the device is not enabled to automatically obtain the login username as the authentication username, you must enter a username to request role authentication.
- The device sends the username to the server in the *username or username@domain-name* format. Whether the domain name is included in the username depends on the **user-name-format** command in the HWTACACS scheme.
- To obtain a level-*n* user role, the user account on the server must have the target user role level or a level higher than the target user role. A user account that obtains the level-*n* user role can obtain any user role among level-0 through level-*n*.
- To obtain a non-level-*n* user role, make sure the user account on the server meets the following requirements:
  - The account has a user privilege level.
  - The HWTACACS custom attribute is configured for the account in the form of **allowed-roles="***role***"**. The variable *role* represents the target user role.

If RADIUS authentication is used, the following rules apply:

- The device does not use the username you enter or the automatically obtained login username to request user role authentication. It uses a username in the **$enab***n***$** format. The variable *n* represents a user role level, and a domain name is not included in the username. You can always pass user role authentication when the password is correct.
- To obtain a level-*n* user role, you must create a user account for the level-*n* user role in the **$enabn$** format on the RADIUS server. The variable *n* represents the target user role level. For example, to obtain the level-3 user role, you can enter any username. The device uses the username **$enab3$** to request user role authentication from the server.
- To obtain a non-level-*n* user role, you must perform the following tasks:
  - Create a user account named **$enab0$** on the server.
  - Configure the cisco-av-pair attribute for the account in the form of **allowed-roles="***role***"**. The variable *role* represents the target user role.

The device selects an authentication domain for user role authentication in the following order:

1. The ISP domain included in the entered username.
2. The default ISP domain.

If you execute the **quit** command after obtaining user role authorization, you are logged out of the device.

Setting the authentication mode for temporary user role authorization

1. Enter system view.

   system-view
2. Set the authentication mode.

   super authentication-mode { **local** | **scheme** } *

   By default, local-only authentication applies.

Specifying the default target user role for temporary user role authorization

1. Enter system view.
   system-view
2. Specify the default target user role for temporary user role authorization.
   super default role *role-name*
   By default, the default target user role is network-admin.

Setting an authentication password for temporary user role authorization

About this task

Authentication passwords are required only for local password authentication.

Procedure

1. Enter system view.
   system-view
2. Set a local authentication password for a user role.
   In non-FIPS mode:
   super password [**role** *role-name*] [{ **hash** | **simple** } *string*]
   In FIPS mode:
   super password [**role** *role-name*]
   By default, no password is set.
   If you do not specify the **role** *role-name* option, the command sets a password for the default target user role.

Automatically obtaining the login username for temporary user role authorization

About this task

This feature is applicable only to the login from a user line that uses scheme authentication, which requires a username for login. This feature enables the device to automatically obtain the login username when the login user requests a temporary user role authorization from a remote authentication server.

Restrictions and guidelines

If the user was logged in from a user line that uses password authentication or no authentication, the device cannot obtain the login username. The request for temporary user role authorization from a remote authentication server will fail.

This feature does not take effect on local password authentication for temporary user role authorization.

Procedure

1. Enter system view.
   system-view

2. Enable the device to automatically obtain the login username when a login user requests temporary user role authorization from a remote authentication server.

   super use-login-username

   By default, the device prompts for a username when a login user requests temporary user role authorization from a remote authentication server.

Obtaining temporary user role authorization

Restrictions and guidelines

The operation of obtaining temporary user role authorization fails after three consecutive unsuccessful authentication attempts.

You might fail to switch to a non-level-*n* user role if both of the following conditions exist:

- User role switching authentication is performed in the same ISP domain as the current login user.
- User role switching authentication uses a different AAA method than the login authorization method configured for the ISP domain.

To resolve this issue, make sure the AAA methods configured by using the **authentication super** command are consistent with those configured by using the **authorization login** command for the ISP domain.

For more information about AAA, see *Security Configuration Guide*.

Prerequisites

Before you obtain temporary user role authorization, make sure the current user account has the permission to execute the **super** command to obtain temporary user role authorization.

Procedure

To obtain the temporary authorization to use a user role, execute the following command in user view:

super [*role-name*]

If you do not specify the *role-name* argument, you obtain the default target user role for temporary user role authorization.

Enabling SNMP notification for user role changes

About this task

After you enable SNMP notification for user role changes, the following types of SNMP notifications will be generated:

- An SNMP notification to report a successful user role change if you use the **super** command to change a user role successfully.
- An SNMP notification to report a failed user role change if you fail to use the **super** command to change a user role. Typically, you must enter the user role change password for changing a user role. The user role change operation fails if the authentication server does not respond or no user role change password is configured.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notification for user role changes.

snmp-agent trap enable super [**change-failure-warning** | **change-succesful-warning**] *

By default, SNMP notification for user role changes is disabled.

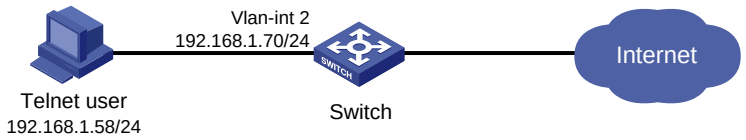
Display and maintenance commands for RBAC

Execute **display** commands in any view.

Task	Command
Display user role information.	**display role** [**name** *role-name*]
Display user role feature information.	**display role feature** [**name** *feature-name* | **verbose**]
Display user role feature group information.	**display role feature-group** [**name** *feature-group-name*] [**verbose**]

RBAC configuration examples

Example: Configuring RBAC for local AAA authentication users



Network configuration

As shown in Figure 1, the switch performs local AAA authentication for the Telnet user. The user account for the Telnet user is **user1@bbb**, which is assigned user role **role1**.

Configure **role1** to have the following permissions:

- Execute the read commands of any feature.
- Access VLANs 10 to 20. Access to any other VLANs is denied.

Figure 1 Network diagram

Procedure

Assign an IP address to VLAN-interface 2 (the interface connected to the Telnet user).

```
<Switch> system-view
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.1.70 255.255.255.0
[Switch-Vlan-interface2] quit
```

Enable the Telnet server.

```
[Switch] telnet server enable
```

Enable scheme authentication on the user lines for Telnet users.

```
[Switch] line vty 0 63

```
[Switch-line-vty0-63] quit
```

Enable local authentication and authorization for ISP domain **bbb**.

```
[Switch] domain bbb
[Switch-isp-bbb] authentication login local
[Switch-isp-bbb] authorization login local
[Switch-isp-bbb] quit
```

Create a user role named **role1**.

```
[Switch] role name role1
```

Configure rule 1 to permit the user role to access the read commands of all features.

```
[Switch-role-role1] rule 1 permit read feature
```

Configure rule 2 to permit the user role to create VLANs and access commands in VLAN view.

```
[Switch-role-role1] rule 2 permit command system-view ; vlan *
```

Change the VLAN policy to permit the user role to configure only VLANs 10 to 20.

```
[Switch-role-role1] vlan policy deny
[Switch-role-role1-vlanpolicy] permit vlan 10 to 20
[Switch-role-role1-vlanpolicy] quit
[Switch-role-role1] quit
```

Create a device management user named **user1** and enter local user view.

```
[Switch] local-user user1 class manage
```

Set a plaintext password of **123456TESTplat&!** for the user.

```
[Switch-luser-manage-user1] password simple 123456TESTplat&!
```

Set the service type to **Telnet**.

```
[Switch-luser-manage-user1] service-type telnet
```

Assign **role1** to the user.

```
[Switch-luser-manage-user1] authorization-attribute user-role role1
```

Remove the default user role (**network-operator**) from the user. This operation ensures that the user has only the permissions of **role1**.

```
[Switch-luser-manage-user1] undo authorization-attribute user-role network-operator
[Switch-luser-manage-user1] quit
```

Verifying the configuration

Telnet to the switch, and enter the username and password to access the switch. (Details not shown.)

Verify that you can create VLANs 10 to 20. This example uses VLAN 10.

```
<Switch> system-view
[Switch] vlan 10
[Switch-vlan10] quit
```

Verify that you cannot create any VLAN other than VLANs 10 to 20. This example uses VLAN 30.

```
[Switch] vlan 30
Permission denied.
```

Verify that you can use all read commands of any feature. This example uses **`display clock`**.

```
[Switch] display clock
09:31:56.258 UTC Sun 01/01/2017
[Switch] quit
```

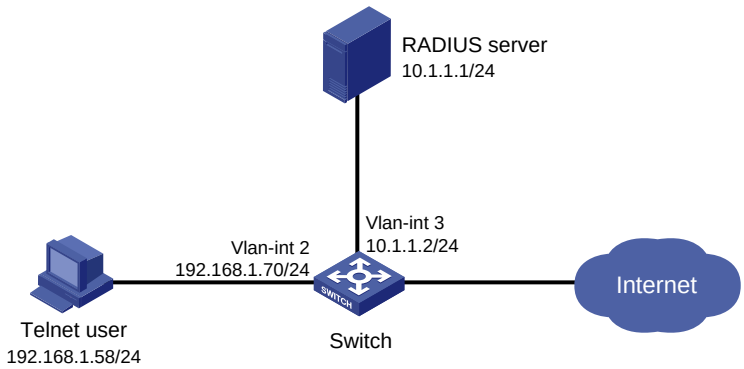
Verify that you cannot use the write or execute commands of any feature.

```
<Switch> debugging role all
```

```
Permission denied.
<Switch> ping 192.168.1.58
Permission denied.
```

Example: Configuring RBAC for RADIUS authentication users

Network configuration



As shown in Figure 2, the switch uses the FreeRADIUS server to provide AAA service for login users, including the Telnet user. The user account for the Telnet user is **hello@bbb**, which is assigned user role **role2**.

User role **role2** has the following permissions:

- Use all commands in ISP domain view.
- Use the read and write commands of the **arp** and **radius** features.
- Cannot access the read commands of the **acl** feature.
- Configure VLANs 1 to 20 and interfaces GigabitEthernet 1/0/1 to GigabitEthernet 1/0/4. Access to any other VLANs and interfaces is denied.

The switch and the FreeRADIUS server use a shared key of **expert** and authentication port **1812**. The switch delivers usernames with their domain names to the server.

Figure 2 Network diagram

Procedure

Make sure the settings on the switch and the RADIUS server match.

1. Configure the switch:

Assign VLAN-interface 2 an IP address from the same subnet as the Telnet user.

```
<Switch> system-view
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.1.70 255.255.255.0
[Switch-Vlan-interface2] quit
```

Assign VLAN-interface 3 an IP address from the same subnet as the RADIUS server.

```
[Switch] interface vlan-interface 3
[Switch-Vlan-interface3] ip address 10.1.1.2 255.255.255.0
[Switch-Vlan-interface3] quit
```

Enable the Telnet server.

```
[Switch] telnet server enable
```

Enable scheme authentication on the user lines for Telnet users.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Create RADIUS scheme **rad** and enter RADIUS scheme view.

```
[Switch] radius scheme rad
```

Specify the primary server address and the service port in the scheme.

```
[Switch-radius-rad] primary authentication 10.1.1.1 1812
```

Set the shared key to **expert** in the scheme for the switch to authenticate to the server.

```
[Switch-radius-rad] key authentication simple expert
[Switch-radius-rad] quit
```

Specify scheme **rad** as the authentication and authorization schemes for ISP domain **bbb**, and configure the ISP domain to not perform accounting for login users.

IMPORTANT:

Because RADIUS user authorization information is piggybacked in authentication responses, the authentication and authorization methods must use the same RADIUS scheme.

```
[Switch] domain bbb
[Switch-isp-bbb] authentication login radius-scheme rad
[Switch-isp-bbb] authorization login radius-scheme rad
[Switch-isp-bbb] accounting login none
[Switch-isp-bbb] quit
```

Create feature group **fgroup1**.

```
[Switch] role feature-group name fgroup1
```

Add the **arp** and **radius** features to the feature group.

```
[Switch-featuregrp-fgroup1] feature arp
[Switch-featuregrp-fgroup1] feature radius
[Switch-featuregrp-fgroup1] quit
```

Create user role **role2**.

```
[Switch] role name role2
```

Configure rule 1 to permit the user role to use all commands available in ISP domain view.

```
[Switch-role-role2] rule 1 permit command system-view ; domain *
```

Configure rule 2 to permit the user role to use the read and write commands of all features in **fgroup1**.

```
[Switch-role-role2] rule 2 permit read write feature-group fgroup1
```

Configure rule 3 to disable access to the read commands of the **acl** feature.

```
[Switch-role-role2] rule 3 deny read feature acl
```

Configure rule 4 to permit the user role to create VLANs and use all commands available in VLAN view.

```
[Switch-role-role2] rule 4 permit command system-view ; vlan *
```

Configure rule 5 to permit the user role to enter interface view and use all commands available in interface view.

```
[Switch-role-role2] rule 5 permit command system-view ; interface *
```

Configure the user role VLAN policy to disable configuration of any VLAN except VLANs 1 to 20.

```
[Switch-role-role2] vlan policy deny
[Switch-role-role2-vlanpolicy] permit vlan 1 to 20
[Switch-role-role2-vlanpolicy] quit
```

Configure the user role interface policy to disable configuration of any interface except GigabitEthernet 1/0/1 to GigabitEthernet 1/0/4.

```
[Switch-role-role2] interface policy deny
[Switch-role-role2-ifpolicy] permit interface gigabitethernet 1/0/1 to
gigabitethernet 1/0/4
[Switch-role-role2-ifpolicy] quit
[Switch-role-role2] quit
```

2. Configure the RADIUS server:

   # Add either of the user role attributes to the dictionary file of the FreeRADIUS server.

   ```
   Cisco-AVPair = "shell:roles=\"role2\""
   Cisco-AVPair = "shell:roles*\"role2\""
   ```

   # Configure the settings required for the FreeRADIUS server to communicate with the switch. (Details not shown.)

Verifying the configuration

Telnet to the switch, and enter the username and password to access the switch. (Details not shown.)

Verify that you can use all commands available in ISP domain view.

```
<Switch> system-view
[Switch] domain abc
[Switch-isp-abc] authentication login radius-scheme abc
[Switch-isp-abc] quit
```

Verify that you can use all read and write commands of the **radius** and **arp** features. This example uses **radius**.

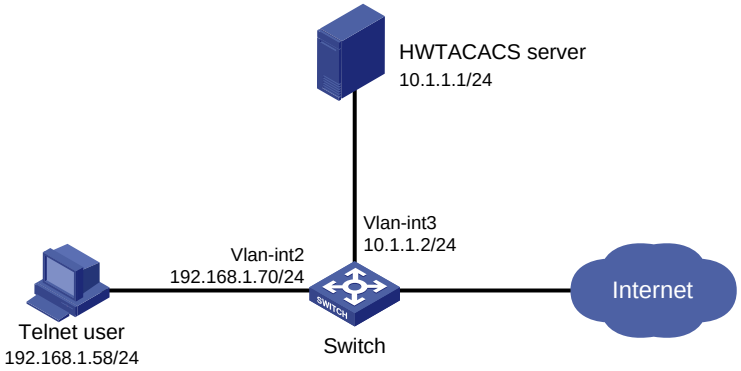
```
[Switch] radius scheme rad
[Switch-radius-rad] primary authentication 2.2.2.2
[Switch-radius-rad] display radius scheme rad
...
```

Verify that you cannot configure any VLAN except VLANs 1 to 20. This example uses VLAN 10 and VLAN 30.

```
[Switch] vlan 10
[Switch-vlan10] quit
[Switch] vlan 30
Permission denied.
```

Verify that you cannot configure any interface except GigabitEthernet 1/0/1 to GigabitEthernet 1/0/4. This example uses GigabitEthernet 1/0/2 and GigabitEthernet 1/0/5.

```
[Switch] vlan 10
[Switch-vlan10] port gigabitethernet 1/0/2
[Switch-vlan10] port gigabitethernet 1/0/5
Permission denied.
```



Example: Configuring RBAC temporary user role authorization (HWTACACS authentication)

Network configuration

As shown in Figure 3, the switch uses HWTACACS authentication for login users, including the Telnet user. The user account for the Telnet user is **test@bbb**, which is assigned user role **level-0**.

Configure the remote-then-local authentication mode for temporary user role authorization. The switch uses the HWTACACS server to provide authentication for changing the user role among **level-0** through **level-3** or changing the user role to **network-admin**. If the AAA configuration is invalid or the HWTACACS server does not respond, the switch performs local authentication.

Figure 3 Network diagram

Procedure

1. Configure the switch:

Assign an IP address to VLAN-interface 2 (the interface connected to the Telnet user).

```
<Switch> system-view
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.1.70 255.255.255.0
[Switch-Vlan-interface2] quit
```

Assign an IP address to VLAN-interface 3 (the interface connected to the HWTACACS server).

```
[Switch] interface vlan-interface 3
[Switch-Vlan-interface3] ip address 10.1.1.2 255.255.255.0
[Switch-Vlan-interface3] quit
```

Enable the Telnet server.

```
[Switch] telnet server enable
```

Enable scheme authentication on the user lines for Telnet users.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Enable remote-then-local authentication for temporary user role authorization.

```
[Switch] super authentication-mode scheme local
```

Create an HWTACACS scheme named **hwtac** and enter HWTACACS scheme view.

```
[Switch] hwtacacs scheme hwtac
```

Specify the primary authentication server address and the service port in the scheme.

```
[Switch-hwtacacs-hwtac] primary authentication 10.1.1.1 49
```

Specify the primary authorization server address and the service port in the scheme.

```
[Switch-hwtacacs-hwtac] primary authorization 10.1.1.1 49
```

Set the shared key to **expert** in the scheme for the switch to authenticate to the authentication server.

```
[Switch-hwtacacs-hwtac] key authentication simple expert
```

Set the shared key to **expert** in the scheme for the switch to authenticate to the authorization server.

```
[Switch-hwtacacs-hwtac] key authorization simple expert
```

Exclude ISP domain names from the usernames sent to the HWTACACS server.

```
[Switch-hwtacacs-hwtac] user-name-format without-domain
[Switch-hwtacacs-hwtac] quit
```

Create ISP domain **bbb** and enter ISP domain view.

```
[Switch] domain bbb
```

Configure ISP domain **bbb** to use HWTACACS scheme **hwtac** for login user authentication.

```
[Switch-isp-bbb] authentication login hwtacacs-scheme hwtac
```

Configure ISP domain **bbb** to use HWTACACS scheme **hwtac** for login user authorization.

```
[Switch-isp-bbb] authorization login hwtacacs-scheme hwtac
```

Configure ISP domain **bbb** to not perform accounting for login users.

```
[Switch-isp-bbb] accounting login none
```

Apply HWTACACS scheme **hwtac** to the ISP domain for user role authentication.

```
[Switch-isp-bbb] authentication super hwtacacs-scheme hwtac
[Switch-isp-bbb] quit
```

Set the local authentication password to **654321TESTplat&!** for user role **level-3**.

```
[Switch] super password role level-3 simple 654321TESTplat&!
```

Set the local authentication password to **654321TESTplat&!** for user role **network-admin**.

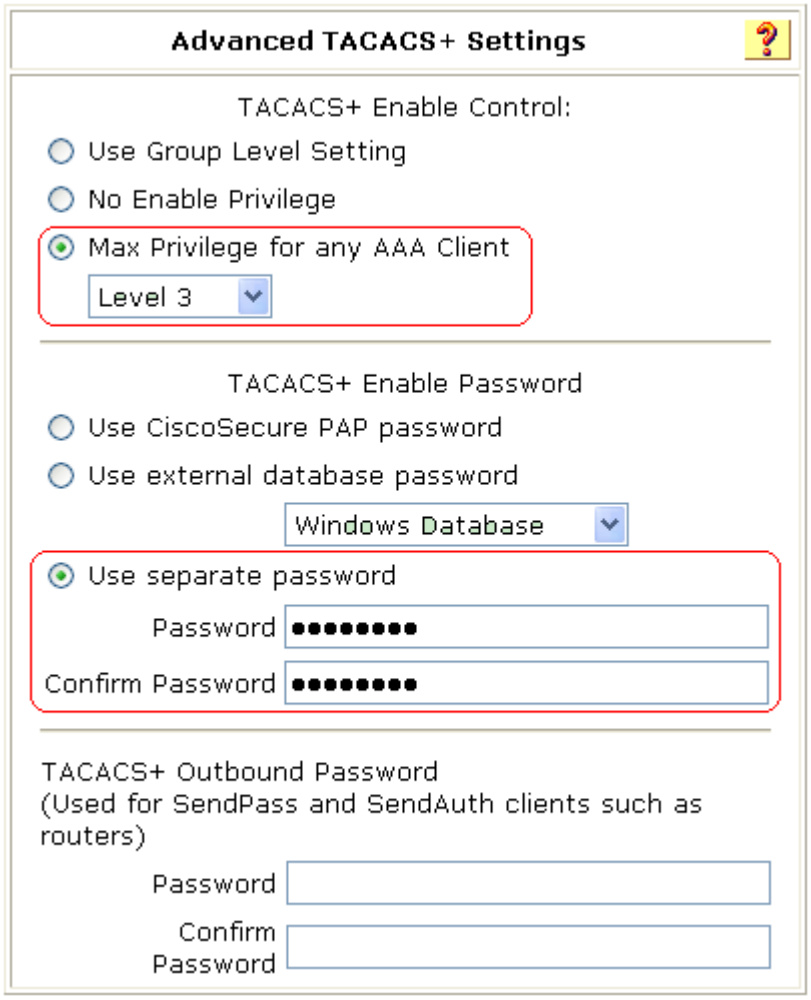
```
[Switch] super password role network-admin simple 654321TESTplat&!
[Switch] quit
```

2. Configure the HWTACACS server:

This example uses ACSv4.0. This example provides only the key configuration steps. For more information about configuring a HWTACACS server, see the server documentation.

a. Access the **User Setup** page.

b. Add a user account named **test** and set its password to **123456TESTplat&!**. (Details not shown.)



c. In the **Advanced TACACS+ Settings** area, configure the following parameters:

- Select **Level 3** for the **Max Privilege for any AAA Client** option.

  If the target user role is only **network-admin** for temporary user role authorization, you can select any level for the option.

- Select the **Use separate password** option, and specify **enabpass** as the password.

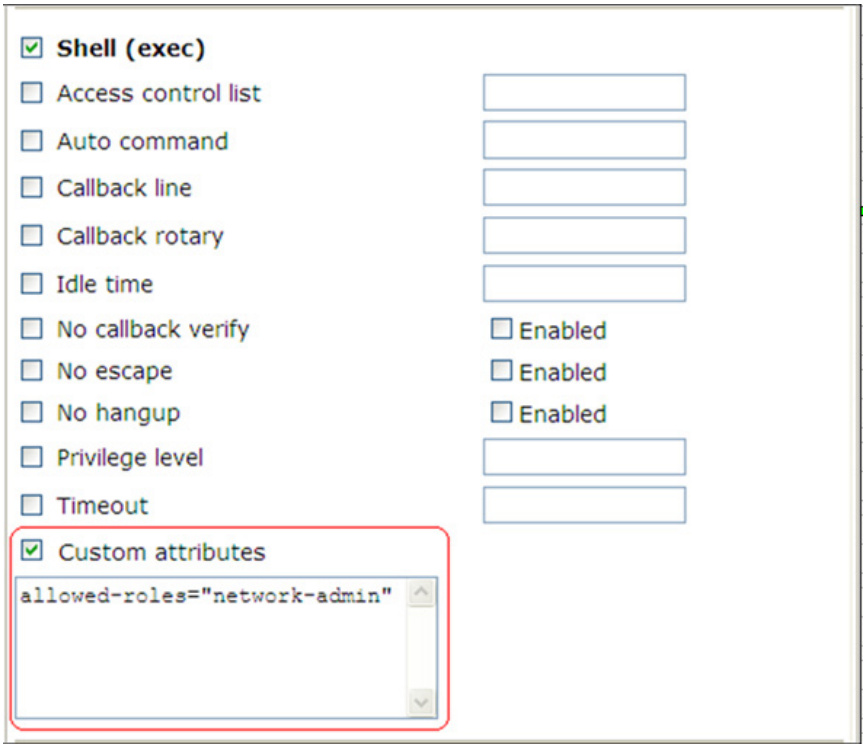


Figure 4 Configuring advanced TACACS+ settings

d. Select **Shell (exec)** and **Custom attributes**, and enter **allowed-roles="network-admin"** in the **Custom attributes** field.

Use a blank space to separate the allowed roles.

Figure 5 Configuring custom attributes for the Telnet user

Verifying the configuration

1. Telnet to the switch, and enter username **test@bbb** and password **123456TESTplat&!** to access the switch. Verify that you have access to diagnostic commands.

```
<Switch> telnet 192.168.1.70
Trying 192.168.1.70 ...
Press CTRL+K to abort
Connected to 192.168.1.70 ...
login: test@bbb
Password:
******************************************************************************

* Without the owner's prior written consent,                                 *
* no decompiling or reverse-engineering shall be allowed.                    *
******************************************************************************

<Switch>?
User view commands:
  erase        Alias for 'delete'
  exit         Alias for 'quit'
  mtrace       Configure the multicast traceroute
  no           Alias for 'undo'
  ping         Ping function
  quit         Exit from current command view
  show         Alias for 'display'
  ssh2         Establish an Stelnet connection to an Stelnet server
  super        Switch to a user role
```

```
  system-view  Enter the System View
  telnet       Establish a telnet connection
  tracert      Tracert function
  write        Alias for 'save'
<Switch>
```

2. Verify that you can obtain the level-3 user role:

   # Use the super password to obtain the level-3 user role. When the system prompts for a username and password, enter username **test@bbb** and password **enabpass**.

   ```
   <Switch> super level-3
   Username: test@bbb
   Password:
   ```

   The following output shows that you have obtained the level-3 user role.

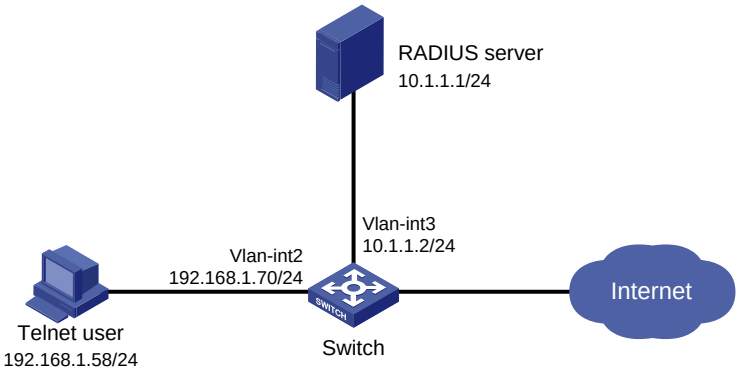
   ```
   User privilege role is level-3, and only those commands that authorized to the role
   can be used.
   ```

   # If the ACS server does not respond, enter local authentication password **654321TESTplat&!** at the prompt.

   ```
   Invalid configuration or no response from the authentication server.
   Change authentication mode to local.
   Password:
   User privilege role is level-3, and only those commands that authorized to the role
   can be used.
   ```

   The output shows that you have obtained the level-3 user role.

3. Use the method in step 2 to verify that you can obtain the level-0, level-1, level-2, and network-admin user roles. (Details not shown.)



Example: Configuring RBAC temporary user role authorization (RADIUS authentication)

Network configuration

As shown in Figure 6, the switch uses RADIUS authentication for login users, including the Telnet user. The user account for the Telnet user is **test@bbb**, which is assigned user role **level-0**.

Configure the remote-then-local authentication mode for temporary user role authorization. The switch uses the RADIUS server to provide authentication for the **network-admin** user role. If the AAA configuration is invalid or the RADIUS server does not respond, the switch performs local authentication.

Figure 6 Network diagram

Procedure

1. Configure the switch:

   # Assign an IP address to VLAN-interface 2 (the interface connected to the Telnet user).

   ```
   <Switch> system-view
   [Switch] interface vlan-interface 2
   [Switch-Vlan-interface2] ip address 192.168.1.70 255.255.255.0
   [Switch-Vlan-interface2] quit
   ```

   # Assign an IP address to VLAN-interface 3 (the interface connected to the RADIUS server).

   ```
   [Switch] interface vlan-interface 3
   [Switch-Vlan-interface3] ip address 10.1.1.2 255.255.255.0
   [Switch-Vlan-interface3] quit
   ```

   # Enable the Telnet server.

   ```
   [Switch] telnet server enable
   ```

   # Enable scheme authentication on the user lines for Telnet users.

   ```
   [Switch] line vty 0 15
   [Switch-line-vty0-15] authentication-mode scheme
   [Switch-line-vty0-15] quit
   ```

   # Enable remote-then-local authentication for temporary user role authorization.

   ```
   [Switch] super authentication-mode scheme local
   ```

   # Create RADIUS scheme **radius** and enter RADIUS scheme view.

   ```
   [Switch] radius scheme radius
   ```

   # Specify the primary authentication server address and the shared key in the scheme for secure communication between the switch and the server.

   ```
   [Switch-radius-radius] primary authentication 10.1.1.1 key simple expert
   ```

   # Exclude ISP domain names from the usernames sent to the RADIUS server.

   ```
   [Switch-radius-radius] user-name-format without-domain
   [Switch-radius-radius] quit
   ```

   # Create ISP domain **bbb** and enter ISP domain view.

   ```
   [Switch] domain bbb
   ```

   # Configure ISP domain **bbb** to use RADIUS scheme **radius** for login user authentication.

   ```
   [Switch-isp-bbb] authentication login radius-scheme radius
   ```

   # Configure ISP domain **bbb** to use RADIUS scheme **radius** for login user authorization.

   ```
   [Switch-isp-bbb] authorization login radius-scheme radius
   ```

   # Configure ISP domain **bbb** to not perform accounting for login users.

   ```
   [Switch-isp-bbb] accounting login none
   ```

   # Apply RADIUS scheme **radius** to the ISP domain for user role authentication.

   ```
   [Switch-isp-bbb] authentication super radius-scheme radius
   [Switch-isp-bbb] quit
   ```

   # Set the local authentication password to **abcdef654321TESTplat&!** for user role **network-admin**.

   ```
   [Switch] super password role network-admin simple abcdef654321TESTplat&!
   [Switch] quit
   ```

2. Configure the RADIUS server:

   This example uses ACSv4.2. This example provides only the key configuration steps. For more information about configuring a RADIUS server, see the server documentation.

   a. Add a Telnet user account for login authentication. Set the username to **test@bbb** and the password to **123456TESTplat&!**. (Details not shown.)

b. Add a user account for temporary user role authorization. Set the username to **$enab0$** and the password to **123456**. (Details not shown.)

c. Access the **Cisco IOS/PIX 6.x RADIUS Attributes** page.

d. Configure the **cisco-av-pair** attribute, as shown in Figure 7.

Figure 7 Configuring the cisco-av-pair attribute

Verifying the configuration

1. Telnet to the switch, and enter username **test@bbb** and password **123456TESTplat&!** to access the switch. Verify that you have access to diagnostic commands.

```
<Switch> telnet 192.168.1.70
Trying 192.168.1.70 ...
Press CTRL+K to abort
Connected to 192.168.1.70 ...
login: test@bbb
Password:
******************************************************************************
* Copyright (c) 2004-2017 New H3C Technologies Co., Ltd. All rights reserved.*
* Without the owner's prior written consent,                                 *
* no decompiling or reverse-engineering shall be allowed.                    *
******************************************************************************

<Switch>?
User view commands:
  erase        Alias for 'delete'
  exit         Alias for 'quit'
  mtrace       Configure the multicast traceroute
  no           Alias for 'undo'
  ping         Ping function
  quit         Exit from current command view
  show         Alias for 'display'
  ssh2         Establish an Stelnet connection to an Stelnet server
  super        Switch to a user role
  system-view  Enter the System View
  telnet       Establish a telnet connection
  tracert      Tracert function
  write        Alias for 'save'
<switch>
```

2. Verify that you can obtain the network-admin user role:

Use the super password to obtain the network-admin user role. When the system prompts for a username and password, enter username **test@bbb** and password **123456**.

```
<Switch> super network-admin
Username: test@bbb
Password:
```

The following output shows that you have obtained the network-admin user role.

```
User privilege role is network-admin, and only those commands that authorized to the role can be used.
```

If the ACS server does not respond, enter local authentication password **abcdef654321TESTplat&!** at the prompt.

```
Invalid configuration or no response from the authentication server.
Change authentication mode to local.
Password:
User privilege role is network-admin, and only those commands that authorized to the role can be used.
```

The output shows that you have obtained the network-admin user role.

Troubleshooting RBAC

This section describes several typical RBAC issues and their solutions.

Local users have more access permissions than intended

Symptom

A local user can use more commands than should be permitted by the assigned user roles.

Analysis

The local user might have been assigned to user roles without your knowledge. For example, the local user is automatically assigned the default user role when you create the user.

Solution

To resolve the issue:

1. Use the **`display local-user`** command to examine the local user accounts for undesirable user roles, and remove them.
2. If the issue persists, contact H3C Support.

Login attempts by RADIUS users always fail

Symptom

Attempts by a RADIUS user to log in to the network access device always fail, even though the following conditions exist:

- The network access device and the RADIUS server can communicate with one another.
- All AAA settings are correct.

Analysis

RBAC requires that a login user have a minimum of one user role. If the RADIUS server does not authorize the login user to use any user role, the user cannot log in to the device.

Solution

To resolve the issue:

1. Use one of the following methods:
   - Configure the **`role default-role enable`** command. A RADIUS user can log in with the default user role when no user role is assigned by the RADIUS server.
   - Add the user role authorization attributes on the RADIUS server.
2. If the issue persists, contact H3C Support.

Login overview

The device supports the following types of login methods:

- **CLI login**—At the CLI, you can enter text commands to configure and manage the device.

  To log in to the CLI, you can use one of the following methods:

  - Connect to the console port.
  - Use Telnet.
  - Use SSH.
- **Web login**—Through the Web interface, you can configure and manage the device visually.
- **SNMP access**—You can run SNMP on an NMS to access the device MIB, and perform Get and Set operations to configure and manage the device.
- **RESTful access**—You can use RESTful API operations to configure and manage the device.

The first time you access the device, you can only log in to the CLI through the console port unless the device is automatically configured at startup. After login, you can change console login parameters or configure other access methods.

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

Telnet, HTTP-based Web login, and HTTP-based RESTful access are not supported in FIPS mode.

In login management related descriptions, it is assumed that the device does not enter the automatic configuration process at startup.

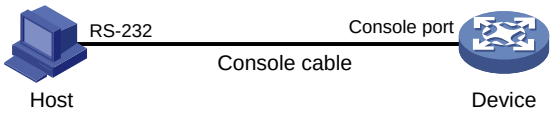
Using the console port for the first device access

About this task

Console login is the fundamental login method.

Prerequisites

To log in through the console port, prepare a terminal, for example, a PC. Make sure the terminal has a terminal emulation program, such as HyperTerminal or PuTTY. For information about how to use terminal emulation programs, see the programs' user guides.



Procedure

1. Connect the DB-9 female connector of the console cable shipped with the device to the serial port of the PC.
2. Identify the console port of the device carefully and connect the RJ-45 connector of the console cable to the console port.

IMPORTANT:

- If the serial port on the PC do not support hot swapping, power off the PC before you connect the console cable to or disconnect the cable from the serial port.
- When you connect a PC to an operating device, first connect the PC end. To disconnect a PC from an operating device, first disconnect the device end.

Figure 1 Connecting a terminal to the console port

3. On the PC, launch the terminal emulation program, and create a connection that uses the serial port connected to the device. Set the port properties so the port properties match the following console port default settings:
   - **Bits per second**—9600 bps.
   - **Flow control**—None.
   - **Parity**—None.
   - **Stop bits**—1.
   - **Data bits**—8.
4. Power on the device and press **Enter** as prompted.

   The user view prompt appears. You can enter commands to configure or manage the device. To get help, enter a question mark (?).

Configuring CLI login

About CLI login

The device uses user lines (also called user interfaces) to manage CLI sessions and monitor user behavior. For a user line, you can configure access control settings, including the login authentication method and user roles.

User lines

User line types

The device supports the following types of user lines, and different user lines require different login methods:

- **Console line**—Login through the console port.
- **Virtual type terminal (VTY) line**—Telnet or SSH login.

User line numbering

A user line has an absolute number and a relative number.

An absolute number uniquely identifies a user line among all user lines. The user lines are numbered starting from 0 and incrementing by 1, in the sequence of console and VTY lines. You can use the **`display line`** command without any parameters to view supported user lines and their absolute numbers.

A relative number uniquely identifies a user line among all user lines of the same type. The number format is *user line type* + *number*. All types of user lines are numbered starting from 0 and incrementing by 1. For example, the first VTY line is VTY 0.

User line assignment

The device assigns user lines to CLI login users depending on their login methods, as described in "User lines." When a user logs in, the device checks the idle user lines for the login method, and assigns the lowest numbered user line to the user. For example, if VTY 0 and VTY 3 are idle when a user Telnets to the device, the device assigns VTY 0 to the user.

Each user line can be assigned only to one user at a time. If no user line is available, a CLI login attempt will be rejected.

Login authentication modes

You can configure login authentication to prevent illegal access to the device CLI.

In non-FIPS mode, the device supports the following login authentication modes:

- **None**—Disables authentication. This mode allows access without authentication and is insecure.
- **Password**—Requires password authentication. A user must provide the correct password at login.
- **Scheme**—Uses the AAA module to provide local or remote login authentication. A user must provide the correct username and password at login.

In FIPS mode, the device supports only the scheme authentication mode.

Different login authentication modes require different user line configurations, as shown in Table 1.

Table 1 Configuration required for different login authentication modes

Authentication mode	Configuration tasks
None	Set the authentication mode to none.
Password	**1.** Set the authentication mode to password. **2.** Set a password.
Scheme	**3.** Set the authentication mode to scheme. **4.** Configure login authentication methods in ISP domain view. For more information, see *Security Configuration Guide*.

User roles

A user is assigned user roles at login. The user roles control the commands available for the user. For more information about user roles, see "Configuring RBAC."

The device assigns user roles based on the login authentication mode and user type.

- In none or password authentication mode, the device assigns the user roles specified for the user line.
- In scheme authentication mode, the device uses the following rules to assign user roles:
  - For an SSH login user who uses publickey or password-publickey authentication, the device assigns the user roles specified for the local device management user with the same name.
  - For other users, the device assigns user roles according to the user role configuration of the AAA module. If the AAA server does not assign any user roles and the default user role feature is disabled, a remote AAA authentication user cannot log in.

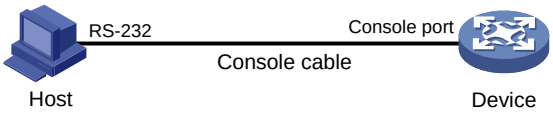
FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

Telnet login is not supported in FIPS mode.

Restrictions and guidelines: CLI login configuration

For commands that are available in both user line view and user line class view, the following rules apply:



- A setting in user line view applies only to the user line. A setting in user line class view applies to all user lines of the class.
- A non-default setting in either view takes precedence over the default setting in the other view. A non-default setting in user line view takes precedence over the non-default setting in user line class view.
- A setting in user line class view takes effect only on users who log in after the setting is made. It does not affect users who are already online when the setting is made.

Configuring console login

About console, AUX, and USB login

You can connect a terminal to the console port of the device to log in and manage the device, as shown in Figure 2. For information about the login procedure, see "Using the console port for the first device access."

Figure 2 Logging in through the console port

By default, console login is enabled and does not require authentication. The default user role is network-admin for a console user. To improve device security, configure password or scheme authentication for console login immediately after you log in to the device for the first time.

Restrictions and guidelines

A console login configuration change takes effect only on users who log in after the change is made. It does not affect users who are already online when the change is made.

In FIPS mode, the device supports only scheme authentication. You cannot disable authentication or configure password authentication.

The device displays the current memory usage when you log in to the device through the console port if the following conditions exist:

- The **memory-threshold** command has been used to set free-memory thresholds.
- The amount of free memory space has decreased to or below the minor, severe, or critical alarm threshold or the early-warning threshold.

Console login configuration tasks at a glance

To configure console login, perform the following tasks:

1. Configuring console login authentication
   - Disabling authentication for console login
   - Configuring password authentication for console login
   - Configuring scheme authentication for console login
2. (Optional.) Configuring common console login settings

Configuring console login authentication

Disabling authentication for console login

1. Enter system view.
   system-view
2. Enter console line view or class view.
   - Enter console line view.
     line console *first-number* [*last-number*]
   - Enter console line class view.

line class console

3. Disable authentication.

   authentication-mode none

   By default, authentication is disabled for console login.

> **CAUTION:**
> When authentication is disabled, users can log in to the device through the line or line class without authentication. For security purpose, disable authentication with caution.

4. Assign a user role.

   user-role *role-name*

   By default, a console user is assigned the **network-admin** user role.

Configuring password authentication for console login

1. Enter system view.

   system-view

2. Enter console line view or class view.
   - Enter console line view.

     line console *first-number* [*last-number*]
   - Enter console class view.

     line class console

3. Enable password authentication.

   authentication-mode password

   By default, authentication is disabled for console login.

4. Set a password.

   set authentication password { **hash** | **simple** } *password*

   By default, no password is set.

5. Assign a user role.

   user-role *role-name*

   By default, a console user is assigned the **network-admin** user role.

Configuring scheme authentication for console login

1. Enter system view.

   system-view

2. Enter console line view or class view.
   - Enter console line view.

     line console *first-number* [*last-number*]
   - Enter console line class view.

     line class console

3. Enable scheme authentication.

   In non-FIPS mode:

   authentication-mode scheme

   By default, authentication is disabled for console login.

   In FIPS mode:

   authentication-mode scheme

By default, scheme authentication is enabled.

CAUTION:

When you enable scheme authentication, make sure an authentication user account is available. If no authentication user account is available, you cannot log in to the device through the line or line class at the next time.

4. Configure user authentication parameters in ISP domain view.

   To use local authentication, configure a local user and set the relevant attributes. To use remote authentication, configure a RADIUS, LDAP, or HWTACACS scheme. For more information, see AAA in *Security Configuration Guide*.

Configuring common console login settings

Restrictions and guidelines

Some common console login settings take effect immediately and can interrupt the current session. Use a login method different from console login to log in to the device before you change console login settings.

After you change console login settings, adjust the settings on the configuration terminal accordingly for a successful login.

Procedure

1. Enter system view.

   system-view

2. Enter console line view or class view.
   - Enter console line view.

     line console *first-number* [*last-number*]
   - Enter console line class view.

     line class console

3. Configure transmission parameters.
   - Set the transmission rate.

     speed *speed-value*

     By default, the transmission rate is 9600 bps.

     This command is not available in user line class view.
   - Specify the parity mode.

     parity { **even** | **mark** | **none** | **odd** | **space** }

     By default, a user line does not use parity.

     This command is not available in user line class view.
   - Configure flow control.

     flow-control { **hardware** | **none** | **software** }

     By default, the device does not perform flow control.

     This command is not available in user line class view.
   - Specify the number of data bits for a character.

     databits { **5** | **6** | **7** | **8** }

     The default is 8.

     This command is not available in user line class view.

Parameter	Description
7	Uses standard ASCII characters.
8	Uses extended ASCII characters.

- Specify the number of stop bits for a character.

  stopbits { **1** | **1.5** | **2** }

  The default is 1.

  Stop bits indicate the end of a character. The more the stop bits, the slower the transmission.

  This command is not available in user line class view.

4. Configure terminal attributes.
   - Enable the terminal service.

     shell

     Be default, the terminal service is enabled on all user lines.

     The **undo shell** command is not available in console line view.
   - Specify the terminal display type.

     terminal type { **ansi** | **vt100** }

     By default, the terminal display type is ANSI.

     The device supports ANSI and VT100 terminal display types. As a best practice, specify VT100 type on both the device and the configuration terminal. You can also specify the ANSI type for both sides, but a display problem might occur if a command line has more than 80 characters.
   - Set the maximum number of lines of command output to send to the terminal at a time.

     screen-length *screen-length*

     By default, the device sends a maximum of 24 lines to the terminal at a time.

     To disable pausing between screens of output, set the value to 0.
   - Set the size for the command history buffer.

     history-command max-size *value*

     By default, the buffer size is 10. The buffer for a user line can save a maximum of 10 history commands.
   - Set the CLI connection idle-timeout timer.

     idle-timeout *minutes* [*seconds*]

     By default, the CLI connection idle-timeout timer is 10 minutes.

     If no interaction occurs between the device and the user within the idle-timeout interval, the system automatically terminates the user connection on the user line.

     If you set the timeout timer to 0, the connection will not be aged out.
5. Specify the command to be automatically executed for login users on the lines.

   auto-execute command *command*

   By default, no command is specified for auto execution.

CAUTION:

Use this command with caution. If this command is used on a user line, users that log in to the device through this user line might fail to configure the system.

The device will automatically execute the specified command when a user logs in through the user line, and close the user connection after the command is executed.

This command is not available in console line view or console line class view.

6. Configure shortcut keys.
   - Specify the terminal session activation key.
     activation-key *character*
     By default, pressing **Enter** starts the terminal session.
   - Specify the escape key.
     escape-key { *character* | **default** }
     By default, pressing **Ctrl+C** terminates a command.
   - Set the user line locking key.
     lock-key *key-string*
     By default, no user line locking key is set.

Configuring Telnet login

About Telnet login

The device can act as a Telnet server to allow Telnet login, or as a Telnet client to Telnet to other devices.

Restrictions and guidelines

Telnet login is not supported in FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

A Telnet login configuration change takes effect only on users who log in after the change is made. It does not affect users who are already online when the change is made.

Telnet might be insecure because it transmits all data in plaintext form.

The device displays the current memory usage when you Telnet to the device if the following conditions exist:

- The **memory-threshold** command has been used to set free-memory thresholds.
- The amount of free memory space has decreased to or below the minor, severe, or critical alarm threshold or the early-warning threshold.

Configuring the device as a Telnet server

Telnet server configuration tasks at a glance

To configure the device as a Telnet server, perform the following tasks:

1. Enabling the Telnet server
2. Configuring Telnet login authentication
   - Disabling authentication for Telnet login
   - Configuring password authentication for Telnet login
   - Configuring scheme authentication for Telnet login
3. (Optional.) Configuring common Telnet server settings
4. (Optional.) Configuring the alarm threshold and alarm clearance threshold for Telnet login failures
5. (Optional.) Configuring common VTY line settings

Enabling the Telnet server

1. Enter system view.
   system-view
2. Enable the Telnet server.
   telnet server enable
   By default, the Telnet server is disabled.

Disabling authentication for Telnet login

1. Enter system view.
   system-view
2. Enter VTY line view or class view.
   - Enter VTY line view.
     line vty *first-number* [*last-number*]
   - Enter VTY line class view.
     line class vty
3. Disable authentication.
   authentication-mode none
   By default, password authentication is enabled for Telnet login.

CAUTION:
When authentication is disabled, users can log in to the device through the line or line class without authentication. For security purpose, disable authentication with caution.

   In VTY line view, this command is associated with the **protocol inbound** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.
4. (Optional.) Assign a user role.
   user-role *role-name*
   By default, a VTY line user is assigned the **network-operator** user role.

Configuring password authentication for Telnet login

1. Enter system view.
   system-view
2. Enter VTY line view or class view.
   - Enter VTY line view.
     line vty *first-number* [*last-number*]
   - Enter VTY line class view.
     line class vty
3. Enable password authentication.
   authentication-mode password
   By default, password authentication is enabled for Telnet login.

CAUTION:
When you enable password authentication, you must also configure an authentication password for the line or line class. If no authentication password is configured, you cannot log in to the device through the line or line class at the next time.

In VTY line view, this command is associated with the **protocol inbound** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

4. Set a password.

   set authentication password { **hash** | **simple** } *password*

   By default, no password is set.

5. (Optional.) Assign a user role.

   user-role *role-name*

   By default, a VTY line user is assigned the **network-operator** user role.

Configuring scheme authentication for Telnet login

1. Enter system view.

   system-view

2. Enter VTY line view or class view.

   - Enter VTY line view.

     line vty *first-number* [*last-number*]

   - Enter VTY line class view.

     line class vty

3. Enable scheme authentication.

   authentication-mode scheme

   By default, password authentication is enabled for Telnet login.

CAUTION:

When you enable scheme authentication, make sure an authentication user account is available. If no authentication user account is available, you cannot log in to the device through the line or line class at the next time.

In VTY line view, this command is associated with the **protocol inbound** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

4. Configure user authentication parameters in ISP domain view.

   To use local authentication, configure a local user and set the relevant attributes.

   To use remote authentication, configure a RADIUS, LDAP, or HWTACACS scheme. For more information, see AAA in *Security Configuration Guide*.

Configuring common Telnet server settings

1. Enter system view.

   system-view

2. Set the DSCP value for outgoing Telnet packets.

   IPv4:

   telnet server dscp *dscp-value*

   IPv6:

   telnet server ipv6 dscp *dscp-value*

   By default, the DSCP value is 48.

   The DSCP value is carried in the ToS field of an IPv4 packet and in the Traffic class field of an IPv6 packet to indicate the packet transmission priority.

3. Specify the Telnet service port number.

   IPv4:

telnet server port *port-number*

IPv6:

telnet server ipv6 port *port-number*

By default, the Telnet service port number is 23.

4. Set the maximum number of concurrent Telnet users.

aaa session-limit telnet *max-sessions*

By default, the maximum number of concurrent Telnet users is 32.

Changing this setting does not affect users who are currently online. If the new limit is less than the number of online Telnet users, no additional users can Telnet in until the number drops below the new limit.

For more information about this command, see *Security Command Reference*.

Configuring the alarm threshold and alarm clearance threshold for Telnet login failures

1. Enter system view.

system-view

2. Set the alarm threshold and alarm clearance threshold for Telnet login failures in a statistics period.

telnet server login-failed threshold-alarm upper-limit *report-times* **lower-limit** *resume-times* **period** *period-time*

By default, the statistics period is five minutes and the alarm threshold and alarm clearance threshold for Telnet login failures in the statistics period is 30 and 20, respectively.

After you execute this command, if the number of Telnet login failures reaches the alarm threshold in a statistics period, an alarm message is generated. If the number of Telnet login failures drops below the alarm clearance threshold in a statistics period, an alarm clearance message is generated. This helps you obtain real-time information about Telnet logins.

Configuring common VTY line settings

1. Enter system view.

system-view

2. Enter VTY line view or class view.
   - Enter VTY line view.

     line vty *first-number* [*last-number*]
   - Enter VTY line class view.

     line class vty
3. Configure VTY terminal attributes.
   - Enable the terminal service.

     shell

     By default, the terminal service is enabled on all user lines.
   - Specify the terminal display type.

     terminal type { **ansi** | **vt100** }

     By default, the terminal display type is ANSI.
   - Set the maximum number of lines of command output to send to the terminal at a time.

     screen-length *screen-length*

     By default, the device sends a maximum of 24 lines to the terminal at a time.

     To disable pausing between screens of output, set the value to 0.
   - Set the size for the command history buffer.

     history-command max-size *value*

By default, the buffer size is 10. The buffer for a user line can save a maximum of 10 history commands.

- Set the CLI connection idle-timeout timer.

  idle-timeout *minutes* [*seconds*]

  By default, the CLI connection idle-timeout timer is 10 minutes.

  If no interaction occurs between the device and the user within the idle-timeout interval, the system automatically terminates the user connection on the user line.

  If you set the timeout timer to 0, the connection will not be aged out.

4. Specify the supported protocols.

   protocol inbound { **all** | **ssh** | **telnet** }

   By default, Telnet and SSH are supported.

   A protocol change takes effect only on users who log in after the setting is made. It does not affect users who are already online when the setting is made.

   In VTY line view, this command is associated with the **authentication-mode** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

5. Specify the command to be automatically executed for login users on the user lines.

   auto-execute command *command*

   By default, no command is specified for auto execution.

IMPORTANT:

Before you execute this command and save the configuration, make sure you can access the CLI to modify the configuration through other VTY lines or console lines.

For a VTY line, you can specify a command that is to be automatically executed when a user logs in. After executing the specified command, the system automatically disconnects the Telnet session.

6. Configure shortcut keys.

   - Specify the shortcut key for terminating a task.

     escape-key { *character* | **default** }

     The default setting is **Ctrl+C**.

   - Set the user line locking key.

     lock-key *key-string*

     By default, no user line locking key is set.

Using the device to log in to a Telnet server

About this task

You can use the device as a Telnet client to log in to a Telnet server.

Figure 3 Telnetting from the device to a Telnet server

Prerequisites

Assign an IP address to the device and obtain the IP address of the Telnet server. If the device resides on a different subnet than the Telnet server, make sure the device and the Telnet server can reach each other.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Specify the source IPv4 address or source interface for outgoing Telnet packets.

   telnet client source { **interface** *interface-type interface-number* | **ip** *ip-address* }

   By default, no source IPv4 address or source interface is specified. The device uses the primary IPv4 address of the output interface as the source address for outgoing Telnet packets.

3. Return to user view.

   quit

4. Use the device to log in to a Telnet server.

   IPv4:

   telnet *remote-host* [*service-port*] [**vpn-instance** *vpn-instance-name*] [**source** { **interface** *interface-type interface-number* | **ip** *ip-address* } | **dscp** *dscp-value*] *

   IPv6:

   telnet ipv6 *remote-host* [**-i** *interface-type interface-number*] [*port-number*] [**vpn-instance** *vpn-instance-name*] [**source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* } | **dscp** *dscp-value*] *

Configuring SSH login

About SSH login

SSH offers a secure remote login method. By providing encryption and strong authentication, it protects devices against attacks such as IP spoofing and plaintext password interception. For more information, see *Security Configuration Guide*.

The device can act as an SSH server to allow Telnet login, or as an SSH client to log in to an SSH server.

Configuring the device as an SSH server

About this task

This section provides the SSH server configuration procedure used when the SSH client authentication method is password. For more information about SSH and publickey authentication configuration, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Create local key pairs.

   In non-FIPS mode:

public-key local create { **dsa** | **ecdsa** [**secp192r1** | **secp256r1** | **secp384r1** | **secp521r1**] | **rsa** } [**name** *key-name*]

In FIPS mode:

public-key local create { **dsa** | **ecdsa** [**secp256r1** | **secp384r1** | **secp521r1**] | **rsa** } [**name** *key-name*]

3. Enable the SSH server.

   ssh server enable

   By default, the SSH server is disabled.

4. (Optional.) Create an SSH user and specify the authentication mode.

   ssh user *username* **service-type stelnet authentication-type password**

5. Enter VTY line view or class view.
   - Enter VTY line view.

     line vty *first-number* [*last-number*]
   - Enter VTY line class view.

     line class vty

6. Enable scheme authentication.

   In non-FIPS mode:

   authentication-mode scheme

   By default, password authentication is enabled for VTY lines.

   In VTY line view, this command is associated with the **protocol inbound** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

   In FIPS mode:

   authentication-mode scheme

   By default, scheme authentication is enabled for VTY lines.

   In VTY line view, this command is associated with the **protocol inbound** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

CAUTION:

When you enable scheme authentication, make sure an authentication user account is available. If no authentication user account is available, you cannot log in to the device through the line or line class at the next time.

7. (Optional.) Specify the protocols for the user lines to support.

   In non-FIPS mode:

   protocol inbound { **all** | **ssh** | **telnet** }

   By default, Telnet and SSH are supported.

   A protocol change takes effect only on users who log in after the setting is made. It does not affect users who are already online when the setting is made.

   In VTY line view, this command is associated with the **authentication-mode** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

   In FIPS mode:

   protocol inbound ssh

   By default, SSH is supported.

A protocol change takes effect only on users who log in after the setting is made. It does not affect users who are already online when the setting is made.

In VTY line view, this command is associated with the **authentication-mode** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

8. (Optional.) Set the maximum number of concurrent SSH users.

   aaa session-limit ssh *max-sessions*

   By default, the maximum number of concurrent SSH users is 32.

   Changing this setting does not affect users who are currently online. If the new limit is less than the number of online SSH users, no additional SSH users can log in until the number drops below the new limit.

   For more information about this command, see *Security Command Reference*.

9. (Optional.) Configure common settings for VTY lines:

   a. Return to system view.

      quit

   b. Configure common settings for VTY lines.

      See "Configuring common VTY line settings."

Using the device to log in to an SSH server

About this task

You can use the device as an SSH client to log in to an SSH server.

Figure 4 Logging in to an SSH server from the device

Prerequisites

Assign an IP address to the device and obtain the IP address of the SSH server. If the device resides on a different subnet than the SSH server, make sure the device and the SSH server can reach each other.

Procedure

To use the device to log in to an SSH server, execute one of the following commands in user view:

IPv4:

ssh2 *server*

IPv6:

ssh2 ipv6 *server*

To work with the SSH server, you might need to specify a set of parameters. For more information, see *Security Configuration Guide*.

Display and maintenance commands for CLI login

Execute **display** commands in any view.

Task	Command	Remarks
Display user line information.	**display line** [*num1* | { **console** | **vty** } *num2*] [**summary**]	N/A
Display the packet source setting for the Telnet client.	**display telnet client**	N/A
Display online CLI users.	**display users** [**all**]	N/A
Release a user line.	**free line** { *num1* | { **console** | **vty** } *num2* }	Multiple users can log in to the device to simultaneously configure the device. When necessary, you can execute this command to release some connections. You cannot use this command to release the connection you are using. This command is available in user view.
Lock the current user line and set the password for unlocking the line.	**lock**	By default, the system does not lock any user lines. This command is not supported in FIPS mode. This command is available in user view.
Lock the current user line and enable unlocking authentication.	**lock reauthentication**	By default, the system does not lock any user lines or initiate reauthentication. To unlock the locked user line, you must press **Enter** and provide the login password to pass reauthentication. This command is available in any view.
Send messages to user lines.	**send** { **all** | *num1* | { **console** | **vty** } *num2* }	This command is available in user view.

Configuring Web login

About Web login

The device provides a built-in Web server that supports HTTP 1.0, HTTP 1.1, and HTTPS. You can use a Web browser to log in to and configure the device.

HTTPS uses SSL to ensure the integrity and security of data exchanged between the client and the server, and is more secure than HTTP. You can define a certificate-based access control policy to allow only legal clients to access the Web interface.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

HTTP is not supported in FIPS mode.

Restrictions and guidelines: Web login configuration

To improve device security, the system automatically enables the HTTPS service when you enable the HTTP service. When the HTTP service is enabled, you cannot disable the HTTPS service.

Web login configuration tasks at a glance

To configure Web login, perform the following tasks:

1. Configuring Web login
   - Configuring HTTP login
   - Configuring HTTPS login
2. (Optional.) Enabling slow HTTP attack defense
3. Configuring a Web login local user
4. Managing Web connections
5. Enabling Web operation logging

Prerequisites for Web login

Before logging in to the Web interface of the device, log in to the device by using any other method and assign an IP address to the device. Make sure the configuration terminal and the device can communicate over the IP network.

Configuring HTTP login

1. (Optional.) Specify a fixed verification code for Web login.
   web captcha *verification-code*

By default, no fixed verification code is specified. A Web user must enter the verification code displayed on the login page at login.

Execute this command in user view.

2. Enter system view.

   system-view

3. Enable the HTTP service.

   ip http enable

   By default, the HTTP service is disabled.

4. (Optional.) Specify the HTTP service port number.

   ip http port *port-number*

   The default HTTP service port number is 80.

5. (Optional.) Specify the HTTP methods to be added to the reply to an OPTIONS request.

   http method { **delete** | **get** | **head** | **options** | **post** | **put** } *

   By default, no HTTP methods are specified.

6. (Optional.) Specify the timeout timer for the HTTP connection.

   http idle-timeout minutes

   By default, the timeout timer for the HTTP connection is 30 minutes.

Configuring HTTPS login

About this task

The device supports the following HTTPS login modes:

- **Simplified mode**—Using this mode is easy in configuration but has low security. The device uses a self-signed certificate (a certificate that is generated and signed by the device itself) and the default SSL settings. The device operates in simplified mode after you enable HTTPS service on the device. You do not need to configure an SSL server policy with the HTTPS service. However, a self-signed certificate is not signed by a CA, so it is not trusted by a browser. The browser will prompt a security risk message when you access the device through HTTPS. If you do not have high security requirements and can accept the security risk with a self-signed certificate, you can choose to ignore this message and continue browsing the webpage.
- **Secure mode**—Using this mode is complicated in configuration but has high security. The device uses a certificate signed by a CA and a set of user-defined security protection settings to ensure security. For the device to operate in secure mode, you must perform the following tasks:
  - Obtain a CA certificate and apply a local certificate from the CA.
  - Enable HTTPS service on the device.
  - Specify an SSL server policy for the service.
  - Configure PKI domain-related parameters.

IMPORTANT:

To use secure mode for HTTPS login, first purchase a local certificate for SSL from an official third-party CA organization. H3C does not provide the device with a CA certificate issued by an authoritative organization.

For more information about SSL, self-signed certificates, CA-signed certificates, and PKI, see *Security Configuration Guide*.

Restrictions and guidelines

- If the HTTPS service and the SSL VPN service use the same port number, they must use the same SSL server policy. If they use different SSL server policies, only one of them can be enabled.

  To modify the SSL server policy used by both the HTTPS service and the SSL VPN service, you must perform the following tasks:

  a. Disable the two services before you modify the SSL server policy.

  b. Enable the two services again after the modification.

  If you fail to complete the required tasks, the new settings do not take effect.

- To associate a different SSL server policy with the HTTPS service, you must perform the following tasks:

  c. Disable the HTTP service and HTTPS service before you associate the new SSL server policy.

  d. Enable the HTTP service and HTTPS service again after the association.

  If you fail to complete the required tasks, the new SSL server policy does not take effect.

- For the HTTP service to use its self-signed certificate after you associate an SSL server policy with the HTTPS service, you must follow these steps:

  e. Disable the HTTP service and HTTPS service.

  f. Execute the **undo ip https ssl-server-policy** command to remove the existing SSL server policy association.

  g. Enable the HTTP service and HTTPS service again.

- Enabling the HTTPS service triggers the SSL handshake negotiation process.
  - If the device has a local certificate, the SSL handshake negotiation succeeds and the HTTPS service starts up.
  - If the device does not have a local certificate, the certificate application process starts. Because the certificate application process takes a long time, the SSL handshake negotiation might fail and the HTTPS service might not be started. To solve the problem, execute the **ip https enable** command again until the HTTPS service is enabled.

- To use a certificate-based access control policy to control HTTPS access, you must perform the following tasks:
  - Execute the **client-verify enable** command in the SSL server policy that is associated with the HTTPS service.
  - Configure a minimum of one **permit** rule in the certificate-based access control policy.

  If you fail to complete the required tasks, HTTPS clients cannot log in.

Procedure

1. (Optional.) Specify a fixed verification code for Web login.

web captcha *verification-code*

By default, no fixed verification code is configured. A Web user must enter the verification code displayed on the login page at login.

2. Enter system view.

system-view

3. (Optional.) Apply policies to the HTTPS service.
  - Apply an SSL server policy.

    ip https ssl-server-policy *policy-name*

    By default, no SSL server policy is associated. The HTTP service uses a self-signed certificate.
  - Apply a certificate-based access control policy to control HTTPS access.

ip https certificate access-control-policy *policy-name*

By default, no certificate-based access control policy is applied.

For more information about certificate-based access control policies, see PKI in *Security Configuration Guide*.

4. Enable the HTTPS service.

   ip https enable

   By default, HTTPS is disabled.

5. (Optional.) Specify the HTTPS service port number.

   ip https port *port-number*

   The default HTTPS service port number is 443.

6. (Optional.) Set the HTTPS login authentication mode.

   web https-authorization mode { **auto** | **manual** }

   By default, manual authentication mode is used for HTTPS login.

Enabling slow HTTP attack defense

About this task

Slow HTTP attack is a DoS attack. It sends legitimate HTTP traffic according to HTTP and TCP protocols at a very low speed, which consumes many resources of the server. The server has to keep the connections open and wait for the rest of the request data. This occupies HTTP connections and causes the normal HTTP requests to fail to be processed.

Slow HTTP attacks are typically of three types as follows:

- **Slow Headers**—Also referred to as Slowloris. A Web application must receive a complete HTTP header before processing an HTTP request. The Web server considers an HTTP header incomplete before it receives two consecutive \r\n. A Slow Headers attacker sends part of an HTTP request header to the server many times at a low speed, thus occupying the connections and memory resources of the server.
- **Slow Body**—Also referred to as Slow HTTP POST. An attacker sends an HTTP POST request with a big header value. The Web server or proxy assumes the client wants to send a large amount of data. The server will keep the connection alive to receive data while the attacker sends only a little data each time, consuming the server's connections and memory resources.
- **Slow Read**—The attacking client establishes a connection to the server and sends a valid HTTP request. Then, the client keeps the connection alive by reading the response from the server slowly, making the server mistakenly consider the client busy. The client might read one byte until the connection is about to time out to consume the connections and memory resources of the server.

After slow HTTP attack defense is enabled, you can use **http slow-attack** to specify timeout timers for the device to determine whether an attack occurs. The device will disconnect an illegitimate connection if the timer expires.

Procedure

1. Enter system view.

   system-view

2. Enable slow HTTP attack defense.

   http slow-attack defense enable

   By default, slow HTTP attack defense is disabled.

3. (Optional.) Specify the timeout timers for slow HTTP attacks.

http slow-attack { **packet-header-timeout** *seconds* | **packet-body-timeout** *seconds* | **client-read-timeout** *seconds* } *

By default, the timeout timer is 10 seconds for Slow Headers attacks, 20 seconds for Slow Body attacks, and 30 seconds for Slow Read attacks.

Configuring a Web login local user

1. Enter system view.

   system-view
2. Create a local user and enter local user view.

   local-user *user-name* [**class manage**]
3. (Optional.) Configure a password for the local user.

   In non-FIPS mode:

   password [{ **hash** | **simple** } *password*]

   By default, no password is configured for a local user. The local user can pass authentication after entering the correct username and passing attribute checks.

   In FIPS mode:

   password

   By default, no password is configured for a local user. The local user cannot pass authentication.
4. Configure user attributes.
   - Assign a user role to the local user.

     authorization-attribute user-role *user-role*

     The default user role is network-operator for a Web user.
   - Specify the service type for the local user.

     service-type { **http** | **https** }

     By default, no service type is specified for a local user.

Managing Web connections

Setting the Web connection idle-timeout timer

1. Enter system view.

   system-view
2. Set the Web connection idle-timeout timer.

   web idle-timeout *minutes*

   By default, the Web connection idle-timeout timer is 10 minutes.

Specifying the maximum number of online HTTP or HTTPS users

1. Enter system view.

   system-view
2. Specify the maximum number of online HTTP or HTTPS users.

   aaa session-limit { **http** | **https** } *max-sessions*

   By default, the device supports a maximum number of 32 online HTTP users and 32 online HTTPS users.

   Changing this setting does not affect users who are currently online. If the new setting is less than the number of online HTTP or HTTPS users, no additional HTTP or HTTPS users can log

in until the number drops below the new limit. For more information about this command, see *Security Command Reference*.

Logging off Web users

To log off Web users, execute the following command in user view:

free web users { **all** | **user-id** *user-id* | **user-name** *user-name* }

Enabling Web operation logging

1. Enter system view.
   system-view
2. Enable Web operation logging.
   webui log enable
   By default, Web operation logging is disabled.

Display and maintenance commands for Web login

Execute **display** commands in any view.

Task	Command
Display HTTP service configuration and status information.	**display ip http**
Display HTTPS service configuration and status information.	**display ip https**
Display Web interface navigation tree information.	**display web menu** [**chinese**]
Display online Web users.	**display web users**

Web login configuration examples

Example: Configuring HTTP login

Network configuration

As shown in Figure 5, the PC and the device can communicate over the IP network.

Configure the device to allow the PC to log in by using HTTP.

Figure 5 Network diagram

Procedure

Create a local user named **admin**. Set the password to **hello12345**, the service type to HTTP, and the user role to network-admin.

```
<Sysname> system-view
```

```
[Sysname] local-user admin
[Sysname-luser-manage-admin] service-type http
[Sysname-luser-manage-admin] authorization-attribute user-role network-admin
[Sysname-luser-manage-admin] password simple hello12345
[Sysname-luser-manage-admin] quit
```

Enable HTTP.

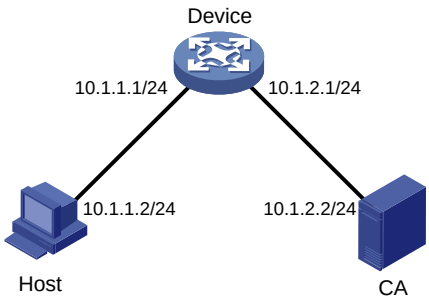
```
[Sysname] ip http enable
```

Verifying the configuration

1. On the PC, run a Web browser and enter the IP address of the device in the address bar.
2. On the login page, enter the username, password, and verification code. Select **English** and click **Login**.

   After you pass authentication, the homepage appears and you can configure the device.

Example: Configuring HTTPS login with a Windows Server 2003 CA server



Network configuration

As shown in Figure 6, the host, device, and CA can communicate over the IP network.

Perform the following tasks to allow only authorized users to access the device's Web interface:

- Configure the device as the HTTPS server and request a certificate for the device.
- Configure the host as the HTTPS client and request a certificate for the host.

Figure 6 Network diagram

Restrictions and guidelines

If the Windows Server 2003 CA server is used to issue certificates for the device and the host, a security risk prompt will pop up when a user accesses the device over HTTPS. If the user can accept the risk brought by this type of authentication, choose to ignore the prompt and continue to browse the webpage.

Prerequisites

Assign IP addresses to relevant interfaces. Make sure the host, device, and CA can communicate over the IP network. (Details not shown.)

This example uses a Windows Server 2003 CA server. Configure the Windows Server 2003 CA server as required. For more information, see PKI configuration in *Security Configuration Guide*.

Procedure

1. Configure the device (HTTPS server):

   # Create PKI entity **en** and set entity parameters.

```
<Device> system-view
[Device] pki entity en
[Device-pki-entity-en] common-name http-server1
[Device-pki-entity-en] fqdn ssl.example.com
[Device-pki-entity-en] quit
```

Create PKI domain **1** and set domain parameters.

```
[Device] pki domain 1
[Device-pki-domain-1] ca identifier new-ca
[Device-pki-domain-1] certificate request url
https://10.1.2.2/certsrv/mscep/mscep.dll
[Device-pki-domain-1] certificate request from ra
[Device-pki-domain-1] certificate request entity en
```

Configure the PKI domain to use the 1024-bit long RSA key pair **hostkey** for both signing and encryption.

```
[Device-pki-domain-1] public-key rsa general name hostkey length 1024
[Device-pki-domain-1] quit
```

Create RSA local key pairs.

```
[Device] public-key local create rsa
```

Retrieve the CA certificate.

```
[Device] pki retrieve-certificate domain 1 ca
```

Configure the device to request a local certificate through SCEP.

```
[Device] pki request-certificate domain 1
```

Create SSL server policy **myssl**. Specify PKI domain 1 for the SSL server policy, and enable certificate-based SSL client authentication.

```
[Device] ssl server-policy myssl
[Device-ssl-server-policy-myssl] pki-domain 1
[Device-ssl-server-policy-myssl] client-verify enable
[Device-ssl-server-policy-myssl] quit
```

Create certificate attribute group **mygroup1**. Configure a certificate attribute rule that matches statements with the **new-ca** string in the distinguished name of the subject name.

```
[Device] pki certificate attribute-group mygroup1
[Device-pki-cert-attribute-group-mygroup1] attribute 1 issuer-name dn ctn new-ca
[Device-pki-cert-attribute-group-mygroup1] quit
```

Create certificate-based access control policy **myacp**. Configure a certificate access control rule that uses the matching criteria in certificate attribute group **mygroup1**.

```
[Device] pki certificate access-control-policy myacp
[Device-pki-cert-acp-myacp] rule 1 permit mygroup1
[Device-pki-cert-acp-myacp] quit
```

Associate SSL server policy **myssl** with the HTTPS service.

```
[Device] ip https ssl-server-policy myssl
```

Use certificate-based access control policy **myacp** to control HTTPS access.

```
[Device] ip https certificate access-control-policy myacp
```

Enable the HTTPS service.

```
[Device] ip https enable
```

Create local user **usera**. Set the password to **hello12345**, the service type to HTTPS, and the user role to network-admin.

```
[Device] local-user usera
[Device-luser-usera] password simple hello12345
```

```
[Device-luser-usera] service-type https
[Device-luser-usera] authorization-attribute user-role network-admin
```

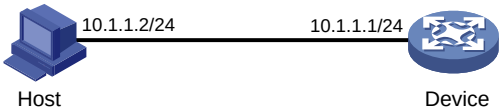
2. Configure the host (HTTPS client):

   # On the host, run a Web browser and enter **https://10.1.2.2/certsrv** in the address bar.

   # Request a certificate for the host as prompted.

Verifying the configuration

1. On the host, enter **https://10.1.1.1** in the Web browser's address bar, and select the certificate issued by **new-ca**.
2. When the Web login page appears, enter username **usera** and password **hello12345** to log in to the Web interface.



For more information about PKI and SSL configuration commands and the **`public-key local create rsa`** command, see *Security Command Reference.*

Example: Configuring HTTPS login with CA certificate and local certificate obtained

Network configuration

As shown in Figure 7, users can access and manage the device via the Web interface of the device. To avoid illegal user access, users must log in to the Web interface of the device through HTTPS.

Figure 7 Network diagram

Restrictions and guidelines

When the host browser authenticates a local certificate provided by the HTTPS website, it identifies whether the alternative subject name in the certificate matches the domain name of the current access website. Therefore, you must configure the alternative subject name as the domain name of the HTTPS website as prompted by the CA when applying for a local certificate. This ensures that when you use the domain name to access the HTTPS website, the local certificate of the device Web interface can be successfully verified by the browser.

To manage multiple devices at the same time, you can apply for a wildcard certificate when applying for a local certificate from the CA. For example, you can configure the alternative subject name as ***.example.com**, and map IP addresses for Web login to different domain names such as device1.example.com and device2.example.com. When you log in to any device through HTTPS, the local certificate of the Web interface can be successfully verified by the browser.

Prerequisites

- Make sure the following requirements are met:
  - The host has obtained and installed a CA certificate that can verify the validity of the local certificate on the device.
  - When the host accesses the device through the domain name in the alternative subject name field of the local certificate, the domain name can be resolved to an IP address that can log in to the device Web interface.
- A CA certificate and a local certificate file (with a key pair) have been uploaded to the file system of the device over FTP or TFTP. For more information about FTP and TFTP, see "Configuring FTP" and "Configuring TFTP."

- To import a local certificate containing an encrypted key pair, you must provide the challenge password. Make sure you have obtained the password from the CA administrator.

Procedure

1. Configure a PKI domain:

   # Create PKI domain **aaa** and enter its view.

   ```
   <Device> system-view
   [Device] pki domain aaa
   ```

   # Disable CRL checking. (You can configure CRL checking as required. This example assumes CRL checking is not required.)

   ```
   [Device-pki-domain-aaa] undo crl check enable
   ```

   # Configure a general-purpose RSA key pair named **abc** for certificate request in the view of PKI domain **aaa**.

   ```
   [Device-pki-domain-aaa] public-key rsa general name abc
   [Device-pki-domain-aaa] quit
   ```

2. Import the certificate files:

   # Import a CA certificate in PEM format to PKI domain **aaa**. This example imports a CA certificate named **ca.pem**.

   ```
   [Device] pki import domain aaa pem ca filename ca.pem
   ```

   # Import local certificate file **xyz.example.com.cert.pem** in PEM format to the PKI domain and enter the password obtained from the CA administrator. The certificate file contains a key pair.

   ```
   [Device] pki import domain aaa pem local filename xyz.example.com.cert.pem
   Please input the password:******
   ```

3. Configure an SSL server policy and HTTPS service:

   # Create SSL server policy **myssl** and specify PKI domain **aaa** for the SSL server policy.

   ```
   [Device] ssl server-policy myssl
   [Device-ssl-server-policy-myssl] pki-domain aaa
   [Device-ssl-server-policy-myssl] quit
   ```

   # Associate SSL server policy **myssl** with the HTTPS service.

   ```
   [Device] ip https ssl-server-policy myssl
   ```

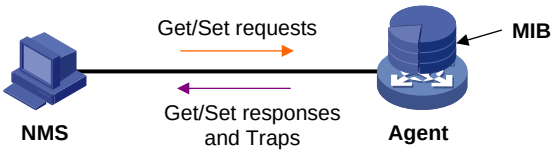
   # Enable the HTTPS service.

   ```
   [Device] ip https enable
   ```

   # Create local user **usera**. Set the password to **hello12345**, the service type to HTTPS, and the user role to network-admin.

   ```
   [Device] local-user usera
   [Device-luser-usera] password simple hello12345
   [Device-luser-usera] service-type https
   [Device-luser-usera] authorization-attribute user-role network-admin
   ```

For more information about PKI and SSL configuration commands, see *Security Command Reference.*



Verifying the configuration

1. On the host, enter the domain name of the device Web interface in the Web browser's address bar.
2. When the Web login page appears, enter username **usera** and password **hello12345** to log in to the Web interface.

Accessing the device through SNMP

You can run SNMP on an NMS to access the device MIB and perform Get and Set operations to configure and manage the device.

Figure 8 SNMP access diagram

For more information about SNMP, see *Network Management and Monitoring Configuration Guide*.

Configuring RESTful access

About RESTful access

The device provides the Representational State Transfer application programming interface (RESTful API). Based on this API, you can use programming languages such as Python, Ruby, or Java to write programs to perform the following tasks:

- Send RESTful requests to the device to pass authentication.
- Use RESTful API operations to configure and manage the device. RESTful API operations include Get, Put, Post, and Delete.

The device supports using HTTP or HTTPS to transfer RESTful packets.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

RESTful access over HTTP is not supported in FIPS mode.

Configuring RESTful access over HTTP

1. Enter system view.
   system-view
2. (Optional.) Specify the service port number for RESTful access over HTTP.
   restful http port *port-number*
   By default, the service port number for RESTful access over HTTP is 80.
3. Enable RESTful access over HTTP.
   restful http enable
   By default, RESTful access over HTTP is disabled.
4. Create a local user and enter local user view.
   local-user *user-name* [**class manage**]
5. Configure a password for the local user.
   password [{ **hash** | **simple** } *password*]
6. (Optional.) Assign a user role to the local user.
   authorization-attribute user-role *user-role*
   The default user role is network-operator for a RESTful access user.
7. Specify the HTTP service for the local user.
   service-type http
   By default, no service type is specified for a local user.
8. (Optional.) Use an ACL to control TCP connections from RESTful clients.
   IPv4:
   http acl { *advanced-acl-number* | *basic-acl-number* }
   IPv6:

http ipv6 acl { *advanced-acl-number* | *basic-acl-number* }

By default, all RESTful clients can establish TCP connections to the device.

Configuring RESTful access over HTTPS

1. Enter system view.

   system-view

2. (Optional.) Apply an SSL server policy to the RESTful access over HTTPS service.

   restful https ssl-server-policy *policy-name*

   By default, no SSL server policy is applied to the RESTful access over HTTPS service.

   The RESTful access over HTTPS service will use the SSL server policy to enhance service security. For more information about SSL server policies, see SSL configuration in *Security Configuration Guide*.

3. (Optional.) Specify the service port number for RESTful access over HTTPS.

   restful https port *port-number*

   By default, the service port number for RESTful access over HTTPS is 443.

4. Enable RESTful access over HTTPS.

   restful https enable

   By default, RESTful access over HTTPS is disabled.

5. Create a local user and enter local user view.

   local-user *user-name* [**class manage**]

6. Configure a password for the local user.

   In non-FIPS mode:

   password [{ **hash** | **simple** } *password*]

   In FIPS mode:

   password

7. (Optional.) Assign a user role to the local user.

   authorization-attribute user-role *user-role*

   The default user role is network-operator for a RESTful access user.

8. Specify the HTTPS service for the local user.

   service-type https

   By default, no service type is specified for a local user.

9. (Optional.) Use an ACL to control TCP connections from RESTful clients.

   IPv4:

   https acl { *advanced-acl-number* | *basic-acl-number* }

   IPv6:

   https ipv6 acl { *advanced-acl-number* | *basic-acl-number* }

   By default, all RESTful clients can establish TCP connections to the device.

Controlling user access to the device

About login user access control

Use ACLs to prevent unauthorized access, and configure command authorization and accounting to monitor and control user behavior.

To control user access, specify an ACL that has rules so only users permitted by the ACL can access the device.

- If no ACL is applied, all users can access the device.
- If the ACL for Web user access control does not exist or does not have rules, all Web users can access the device.
- If the ACL for Telnet, SSH, or SNMP access control does not exist or does not have rules, no Telnet, SSH, or SNMP users can access the device.
- If a VPN instance is specified in an ACL rule, the rule applies only to the packets of the VPN instance. If no VPN instance is specified in an ACL rule, the rule applies only to the packets on the public network.

For more information about ACLs, see *ACL and QoS Configuration Guide.*

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

Telnet and HTTP are not supported in FIPS mode.

Controlling Telnet and SSH logins

Controlling Telnet logins

1. Enter system view.

   system-view

2. Apply an ACL to control Telnet logins.

   IPv4:

   telnet server acl { *advanced-acl-number* | *basic-acl-number* | **mac** *mac-acl-number* }

   IPv6:

   telnet server ipv6 acl { **ipv6** { *advanced-acl-number* | *basic-acl-number* } | **mac** *mac-acl-number* }

   By default, no ACL is used to control Telnet logins.

3. (Optional.) Enable logging for Telnet login attempts that are denied by the Telnet login control ACL.

   telnet server acl-deny-log enable

   By default, logging is disabled for Telnet login attempts that are denied by the Telnet login control ACL.

Controlling SSH logins

1. Enter system view.

   system-view

2. Apply an ACL to control SSH logins.

   IPv4:

   ssh server acl { *advanced-acl-number* | *basic-acl-number* | **mac** *mac-acl-number* }

   IPv6:

   ssh server ipv6 acl { **ipv6** { *advanced-acl-number* | *basic-acl-number* } | **mac** *mac-acl-number* }

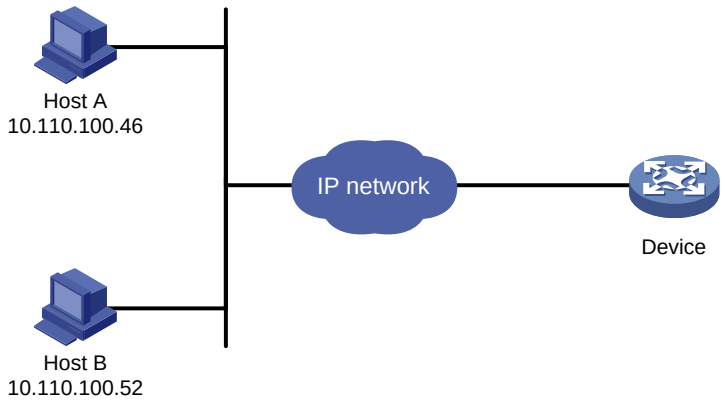
   By default, no ACL is used to control SSH logins.

3. (Optional.) Enable logging for SSH login attempts that are denied by the SSH login control ACL.

   ssh server acl-deny-log enable

   By default, logging is disabled for SSH login attempts that are denied by the SSH login control ACL.

For more information about **ssh** commands, see *Security Command Reference*.



Example: Controlling Telnet login

Network configuration

As shown in Figure 9, the device is a Telnet server.

Configure the device to permit only Telnet packets sourced from Host A and Host B.

Figure 9 Network diagram

Procedure

Configure an ACL to permit packets sourced from Host A and Host B.

```
<Sysname> system-view
[Sysname] acl basic 2000 match-order config
[Sysname-acl-ipv4-basic-2000] rule 1 permit source 10.110.100.52 0
[Sysname-acl-ipv4-basic-2000] rule 2 permit source 10.110.100.46 0
[Sysname-acl-ipv4-basic-2000] quit
```

Apply the ACL to filter Telnet logins.

```
[Sysname] telnet server acl 2000
```

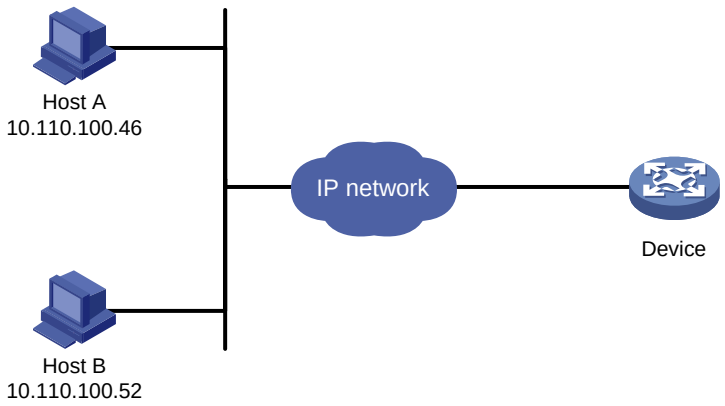
Controlling Web logins

Configuring source IP-based Web login control

1. Enter system view.
   system-view
2. Apply a basic ACL to control Web logins.
   - Control HTTP logins.
     ip http acl { *acl-number* | **name** *acl-name* }
   - Control HTTPS logins.
     ip https acl { *acl-number* | **name** *acl-name* }

   By default, no ACL is applied to control Web logins.
3. (Optional.) Apply an ACL to control TCP connections.
   - Control TCP connections from HTTP clients.
     IPv4:
     http acl { *advanced-acl-number* | *basic-acl-number* }
     IPv6:
     http ipv6 acl { *advanced-acl-number* | *basic-acl-number* }
   - Control TCP connections from HTTPS clients.
     IPv4:
     https acl { *advanced-acl-number* | *basic-acl-number* }
     IPv6:
     https ipv6 acl { *advanced-acl-number* | *basic-acl-number* }

   By default, all HTTP clients and HTTPS clients can establish TCP connections to the device.



Example: Controlling Web login

Network configuration

As shown in Figure 10, the device is an HTTP server.

Configure the device to provide HTTP service only to Host B.

Figure 10 Network diagram

Procedure

Create an ACL and configure rule 1 to permit packets sourced from Host B.

```
<Sysname> system-view
[Sysname] acl basic 2030 match-order config
[Sysname-acl-ipv4-basic-2030] rule 1 permit source 10.110.100.52 0
```

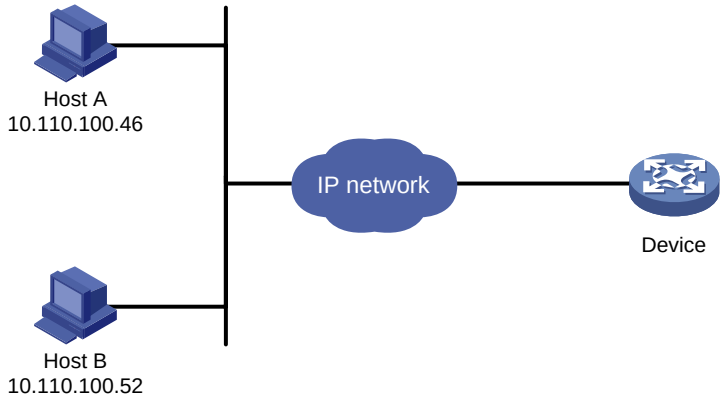
Apply the ACL to the HTTP service so only a Web user on Host B can access the device.

```
[Sysname] ip http acl 2030
```

Controlling SNMP access

About SNMP access control

For information about SNMP access control, see SNMP in *Network Management and Monitoring Configuration Guide.*



Example: Controlling SNMP access

Network configuration

As shown in Figure 11, the device is running SNMP.

Configure the device to allow Host A and Host B to access the device through SNMP.

Figure 11 Network diagram

Procedure

Create an ACL to permit packets sourced from Host A and Host B.

```
<Sysname> system-view
[Sysname] acl basic 2000 match-order config
[Sysname-acl-ipv4-basic-2000] rule 1 permit source 10.110.100.52 0
[Sysname-acl-ipv4-basic-2000] rule 2 permit source 10.110.100.46 0
[Sysname-acl-ipv4-basic-2000] quit
```

Associate the ACL with the SNMP community and the SNMP group.

```
[Sysname] snmp-agent community read aaa acl 2000
[Sysname] snmp-agent group v2c groupa acl 2000
[Sysname] snmp-agent usm-user v2c usera groupa acl 2000
```

Configuring command authorization

About command authorization

By default, commands available for a user depend only on the user's user roles. When the authentication mode is scheme, you can configure the command authorization feature to further control access to commands.

After you enable command authorization, a user can use only commands that are permitted by both the AAA scheme and user roles.

Restrictions and guidelines

When command authorization is enabled, commands available for a user vary by the user's login authentication mode.

- If authentication is disabled or password authentication is enabled, command authorization does not take effect, and the user cannot use any commands.
- If scheme authentication is enabled, commands available for a user vary by the user's access authentication method.
  - If local authentication is used, the device uses the user roles assigned to the user to perform command authorization.
  - If remote authentication is used, the remote authorization server performs command authorization to determine whether a command entered by a login user is permitted. If remote authorization fails, the device uses the user roles of a local user with the same name as the login user to determine whether the command can be used. If the authorization also fails, the login user cannot use the command.

Command authorization configuration changes in user line class view do not take effect on the current session. The changes take effect only on subsequent login sessions. Command authorization configuration changes in user line view take effect immediately on all users that access the user line.

If the remote server performs command authorization, you must configure a command authorization method in ISP domain view. For more information, see AAA configuration in *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Enter user line view or user line class view.
   - Enter user line view.

     line { *first-number1* [*last-number1*] | { **console** | **vty** } *first-number2* [*last-number2*] }
   - Enter user line class view.

     line class { **console** | **vty** }

   A setting in user line view applies only to the user line. A setting in user line class view applies to all user lines of the class. A non-default setting in either view takes precedence over the default setting in the other view. A non-default setting in user line view takes precedence over the non-default setting in user line class view.

   A setting in user line class view takes effect only on users who log in after the setting is made. It does not affect users who are already online when the setting is made.

3. Enable scheme authentication.

   In non-FIPS mode:

   authentication-mode scheme

   By default:

   - Authentication is disabled for console login.
   - Password authentication is enabled for VTY login.

   In VTY line view, this command is associated with the **protocol inbound** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

   In FIPS mode:

   authentication-mode scheme

   By default, scheme authentication is enabled.

   In VTY line view, this command is associated with the **protocol inbound** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

CAUTION:

When you enable scheme authentication, make sure an authentication user account is available. If no authentication user account is available, you cannot log in to the device through the line or line class at the next time.

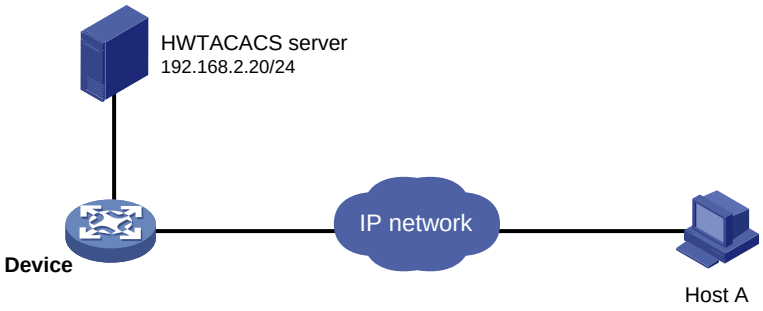
4. Enable command authorization.

   command authorization

   By default, command authorization is disabled, and the commands available for a user depend only on the user role.

   If the **command authorization** command is executed in user line class view, command authorization is enabled on all user lines in the class. You cannot execute the **undo command authorization** command in the view of a user line in the class.

Example: Configuring command authorization



Network configuration

As shown in Figure 12, Host A needs to log in to the device to manage the device.

Configure the device to perform the following operations:

- Allow Host A to Telnet in after authentication.
- Use the HWTACACS server to control the commands that the user can execute.
- If the HWTACACS server is not available, use local authorization.

Figure 12 Network diagram

Procedure

Assign IP addresses to relevant interfaces. Make sure the device and the HWTACACS server can reach each other. Make sure the device and Host A can reach each other. (Details not shown.)

Enable the Telnet server.

```
<Device> system-view
[Device] telnet server enable
```

Enable scheme authentication for user lines VTY 0 through VTY 63.

```
[Device] line vty 0 63
[Device-line-vty0-63] authentication-mode scheme
```

Enable command authorization for the user lines.

```
[Device-line-vty0-63] command authorization
[Device-line-vty0-63] quit
```

Create HWTACACS scheme **tac**.

```
[Device] hwtacacs scheme tac
```

Configure the scheme to use the HWTACACS server at 192.168.2.20:49 for authentication and authorization.

```
[Device-hwtacacs-tac] primary authentication 192.168.2.20 49
[Device-hwtacacs-tac] primary authorization 192.168.2.20 49
```

Set the shared keys to **expert**.

```
[Device-hwtacacs-tac] key authentication simple expert
[Device-hwtacacs-tac] key authorization simple expert
```

Remove domain names from usernames sent to the HWTACACS server.

```
[Device-hwtacacs-tac] user-name-format without-domain
[Device-hwtacacs-tac] quit
```

Configure the system-defined domain (**system**).

```
[Device] domain system
```

Use HWTACACS scheme **tac** for login user authentication and command authorization. Use local authentication and local authorization as the backup method.

```
[Device-isp-system] authentication login hwtacacs-scheme tac local
[Device-isp-system] authorization command hwtacacs-scheme tac local
[Device-isp-system] quit
```

Create local user **monitor**. Set the simple password to **hello12345**, the service type to Telnet, and the default user role to level-1.

```
[Device] local-user monitor
[Device-luser-manage-monitor] password simple hello12345
[Device-luser-manage-monitor] service-type telnet
```

```
[Device-luser-manage-monitor] authorization-attribute user-role level-1
```

Configuring command accounting

About command accounting

Command accounting uses the HWTACACS server to record all executed commands to monitor user behavior on the device.

If command accounting is enabled but command authorization is not, every executed command is recorded. If both command accounting and command authorization are enabled, only authorized commands that are executed are recorded.

Restrictions and guidelines

The command accounting method can be the same as or different from the command authorization method and user login authorization method.

For the command accounting feature to take effect, you must configure a command accounting method in ISP domain view. For more information, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter user line view or user line class view.

   - Enter user line view.

     line { *first-number1* [*last-number1*] | { **console** | **vty** } *first-number2* [*last-number2*] }

   - Enter user line class view.

     line class { **console** | **vty** }

   A setting in user line view applies only to the user line. A setting in user line class view applies to all user lines of the class. A non-default setting in either view takes precedence over the default setting in the other view. A non-default setting in user line view takes precedence over the non-default setting in user line class view.

   A setting in user line class view takes effect only on users who log in after the setting is made. It does not affect users who are already online when the setting is made.

3. Enable scheme authentication.

   In non-FIPS mode:

   authentication-mode scheme

   By default:

   - Authentication is disabled for console login.
   - Password authentication is enabled for VTY login.

   In VTY line view, this command is associated with the **protocol inbound** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

   In FIPS mode:

   authentication-mode scheme

   By default, scheme authentication is enabled.

In VTY line view, this command is associated with the **protocol inbound** command. If one command has a non-default setting in VTY line view, the other command uses its setting in VTY line view, regardless of its setting in VTY line class view.

CAUTION:

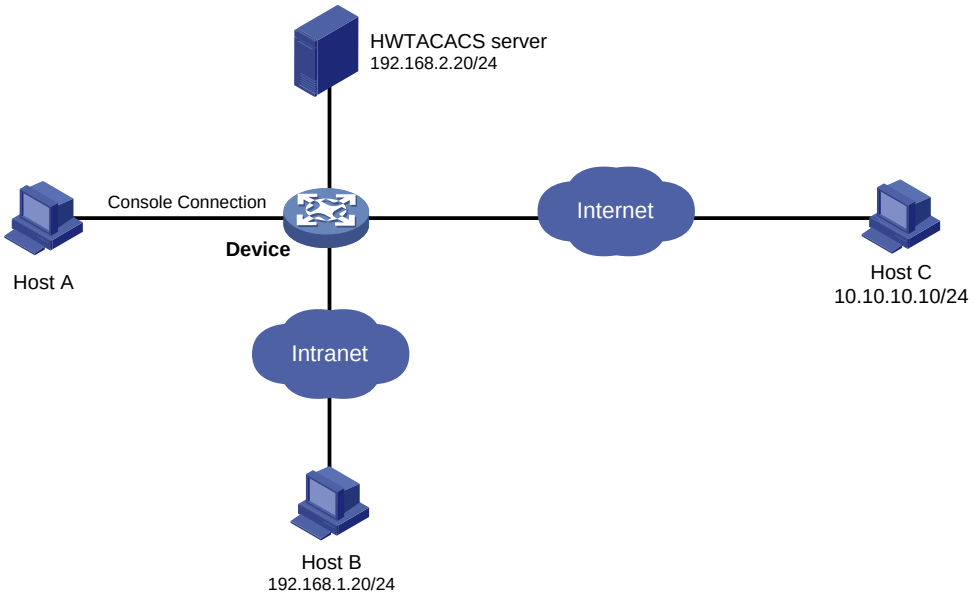
When you enable scheme authentication, make sure an authentication user account is available. If no authentication user account is available, you cannot log in to the device through the line or line class at the next time.

4. Enable command accounting.

   command accounting

   By default, command accounting is disabled. The accounting server does not record the commands executed by users.

   If the **command accounting** command is executed in user line class view, command accounting is enabled on all user lines in the class. You cannot execute the **undo command accounting** command in the view of a user line in the class.



Example: Configuring command accounting

Network configuration

As shown in Figure 13, users need to log in to the device to manage the device.

Configure the device to send commands executed by users to the HWTACACS server to monitor and control user operations on the device.

Figure 13 Network diagram

Procedure

Enable the Telnet server.

```
<Device> system-view
[Device] telnet server enable
```

Enable command accounting for user line console 0.

```
[Device] line console 0
[Device-line-console0] command accounting
[Device-line-console0] quit
```

Enable command accounting for user lines VTY 0 through VTY 63.

```
[Device] line vty 0 63
[Device-line-vty0-63] command accounting
[Device-line-vty0-63] quit
```

Create HWTACACS scheme **tac**.

```
[Device] hwtacacs scheme tac
```

Configure the scheme to use the HWTACACS server at 192.168.2.20:49 for accounting.

```
[Device-hwtacacs-tac] primary accounting 192.168.2.20 49
```

Set the shared key to **expert**.

```
[Device-hwtacacs-tac] key accounting simple expert
```

Remove domain names from usernames sent to the HWTACACS server.

```
[Device-hwtacacs-tac] user-name-format without-domain
[Device-hwtacacs-tac] quit
```

Configure the system-defined domain (**system**) to use the HWTACACS scheme for command accounting.

```
[Device] domain system
[Device-isp-system] accounting command hwtacacs-scheme tac
[Device-isp-system] quit
```

Configuring FTP

About FTP

File Transfer Protocol (FTP) is an application layer protocol for transferring files from one host to another over an IP network. It uses TCP port 20 to transfer data and TCP port 21 to transfer control commands.

FTP is based on the client/server model. The device can act as the FTP server or FTP client.

FTP file transfer modes

FTP supports the following transfer modes:

- **Binary mode**—Used to non-text files, such as **.app**, **.bin**, and **.btm** files.
- **ASCII mode**—Used to transfer text files, such as **.txt**, **.bat**, and **.cfg** files.

When the device acts as the FTP client, you can set the transfer mode (**binary** by default). When the device acts as the FTP server, the transfer mode is determined by the FTP client.

FTP operation modes

FTP can operate in either of the following modes:

- **Active mode (PORT)**—The FTP server initiates the TCP connection. This mode is not suitable when the FTP client is behind a firewall, for example, when the FTP client resides in a private network.
- **Passive mode (PASV)**—The FTP client initiates the TCP connection. This mode is not suitable when the server does not allow the client to use a random unprivileged port greater than 1024.

FTP operation mode varies depending on the FTP client program.

FIPS compliance

FTP is not supported in FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

Using the device as an FTP server

To use the device as an FTP server, you must enable the FTP server and configure authentication and authorization on the device. Other commands are optional.

FTP server configuration tasks at a glance

To use the device as an FTP server, perform the following tasks:

1. Enabling the FTP server
2. Configuring client authentication and authorization
3. (Optional.) Configuring FTP server access control
4. (Optional.) Setting connection management parameters
5. (Optional.) Specifying an SSL server policy for SFTP connections

6. (Optional.) Setting the DSCP value for outgoing FTP packets
7. (Optional.) Configuring the alarm threshold and alarm clearance threshold for FTP login failures
8. (Optional.) Manually releasing FTP connections

Restrictions and guidelines for FTP server configuration

FTP might be insecure because it transmits data in plaintext form.

Enabling the FTP server

1. Enter system view.
   `system-view`
2. Enable the FTP server.
   `ftp server enable`
   By default, the FTP server is disabled.

Configuring client authentication and authorization

Perform this task on the FTP server to authenticate FTP clients and set the authorized directories that authenticated clients can access.

The following authentication modes are available:

- **Local authentication**—The device looks up the client's username and password in the local user account database. If a match is found, authentication succeeds.
- **Remote authentication**—The device sends the client's username and password to a remote authentication server for authentication. The user account is configured on the remote authentication server rather than the device.

The following authorization modes are available:

- **Local authorization**—The device assigns authorized directories to FTP clients based on the locally configured authorization attributes.
- **Remote authorization**—A remote authorization server assigns authorized directories on the device to FTP clients.

For more information about configuring authentication and authorization, see AAA in *Security Configuration Guide*.

Configuring FTP server access control

About this task

To control FTP access, specify an ACL that exists and has rules so that only FTP clients permitted by the ACL can access the FTP server.

Restrictions and guidelines

When no ACL is applied, all FTP clients can access the FTP server. To control FTP access, specify an ACL that exists and has rules so only FTP clients permitted by the ACL can access the FTP server. If you specify an ACL that does not exist or does not have rules, no FTP clients can access the FTP server.

If a VPN instance is specified in an ACL rule, the rule applies only to the packets of the VPN instance. If no VPN instance is specified in an ACL rule, the rule applies only to the packets on the public network.

The ACL takes effect only for FTP connections to be established. It does not impact existing FTP connections.

For more information about ACL, see *ACL and QoS Configuration Guide.*

If you configure FTP server access control multiple times, the most recent configuration takes effect.

Procedure

1. Enter system view.

   system-view

2. Use an ACL to control access to the FTP server.

   ftp server acl { *advanced-acl-number* | *basic-acl-number* | **ipv6** { *advanced-acl-number* | *basic-acl-number* } }

   By default, no ACL is used for access control.

3. Enable logging for FTP login attempts that are denied by the FTP login control ACL.

   ftp server acl-deny-log enable

   By default, logging is disabled for FTP login attempts that are denied by the FTP login control ACL.

Setting connection management parameters

1. Enter system view.

   system-view

2. Set the FTP connection idle-timeout timer.

   ftp timeout *minutes*

   By default, the FTP connection idle-timeout timer is 30 minutes.

   If no data transfer occurs on an FTP connection before the idle-timeout timer expires, the FTP server closes the FTP connection.

3. Set the maximum number of concurrent FTP users.

   aaa session-limit ftp *max-sessions*

   By default, the maximum number of concurrent FTP users is 32.

   Changing this setting does not affect users who are currently online. If the new limit is less than the number of online FTP users, no additional FTP users can log in until the number drops below the new limit. For more information about this command, see *Security Command Reference*.

Specifying an SSL server policy for SFTP connections

About this task

After you associate an SSL server policy with the device, a client that supports SFTP will establish a secure connection to the device to ensure data security.

Procedure

1. Enter system view.

   system-view

2. Associate an SSL server policy with the FTP server to ensure data security.

   ftp server ssl-server-policy *policy-name*

   By default, no SSL server policy is associated with the FTP server.

Setting the DSCP value for outgoing FTP packets

1. Enter system view.
   system-view
2. Set the DSCP value for outgoing FTP packets.
   IPv4:
   ftp server dscp *dscp-value*
   IPv6:
   ftp server ipv6 dscp *dscp-value*
   By default, the DSCP value is 0.

Configuring the alarm threshold and alarm clearance threshold for FTP login failures

1. Enter system view.
   system-view
2. Set the alarm threshold and alarm clearance threshold for FTP login failures in a statistics period.
   ftp server login-failed threshold-alarm upper-limit *report-times* **lower-limit** *resume-times* **period** *period-time*
   By default, the statistics period is five minutes and the alarm threshold and alarm clearance threshold for FTP login failures in the statistics period is 30 and 20, respectively.
   After you execute this command, if the number of FTP login failures reaches the alarm threshold in a statistics period, an alarm message is generated. If the number of FTP login failures drops below the alarm clearance threshold in a statistics period, an alarm clearance message is generated. This helps you obtain real-time information about FTP logins.

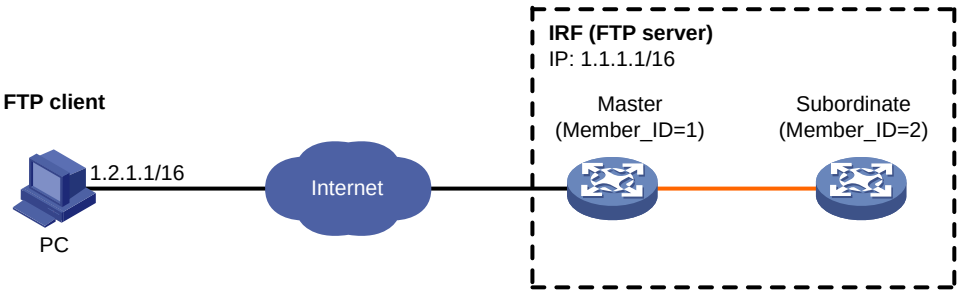
Manually releasing FTP connections

To manually release FTP connections, execute the following commands in user view:

- Release the FTP connection established by using a specific user account:
  free ftp user *username*
- Release the FTP connection to a specific IP address:
  free ftp user-ip [**ipv6**] *ip-address* [**port** *port*]

Display and maintenance commands for the FTP server

Execute **display** commands in any view.



Task	Command
Display FTP server configuration and status information.	**display ftp-server**
Display detailed information about online FTP users.	**display ftp-user**

Example: Using the device as an FTP server

Network configuration

- Configure the IRF fabric as an FTP server.
- Create a local user account named **abc** on the FTP server. Set the password to **hello12345**.
- Use the user account to log in to the FTP server from the FTP client.
- Upload the **temp.bin** file from the FTP client to the FTP server.

Figure 1 Network diagram

Note: The orange line represents an IRF connection.

Procedure

1. Configure IP addresses as shown in Figure 1. Make sure the IRF fabric and the PC can reach each other. (Details not shown.)
2. Configure the FTP server:

   # Examine the storage space on the member devices. If the free space is insufficient, use the **`delete/unreserved`** *`file`* command to delete unused files. (Details not shown.)

   # Create a local user with username **abc** and password **hello12345**.

   ```
   <Sysname> system-view
   [Sysname] local-user abc class manage
   [Sysname-luser-manage-abc] password simple hello12345
   ```

   # Assign the **network-admin** user role to the user. Set the working directory to the root directory of the flash memory on the master. (To set the working directory to the root directory of the flash memory on the subordinate member, you must include the slot number in the directory path.)

   ```
   [Sysname-luser-manage-abc] authorization-attribute user-role network-admin
   work-directory flash:/
   ```

   # Assign the service type FTP to the user.

   ```
   [Sysname-luser-manage-abc] service-type ftp
   [Sysname-luser-manage-abc] quit
   ```

   # Enable the FTP server.

   ```
   [Sysname] ftp server enable
   [Sysname] quit
   ```

3. Perform FTP operations from the FTP client:

   # Log in to the FTP server at 1.1.1.1 using username **abc** and password **hello12345**.

   ```
   c:\> ftp 1.1.1.1
   Connected to 1.1.1.1.
   220 FTP service ready.
   User(1.1.1.1:(none)):abc
   ```

```
331 Password required for abc.
Password:
230 User logged in.
```

Use the ASCII mode to download configuration file **config.cfg** from the FTP server to the PC for backup.

```
ftp> ascii
200 TYPE is now ASCII
ftp> get config.cfg back-config.cfg
```

Use the binary mode to upload the **temp.bin** file from the PC to the root directory of the flash memory on the master.

```
ftp> binary
200 TYPE is now 8-bit binary
ftp> put temp.bin
```

Exit FTP.

```
ftp> bye
```

Using the device as an FTP client

FTP client configuration tasks at a glance

To use the device as an FTP server, perform the following tasks:

1. Establishing an FTP connection
2. (Optional.) Displaying command help information
3. (Optional.) Displaying directories and files on the FTP server
4. (Optional.) Managing directories on the FTP server
5. (Optional.) Working with files on the FTP server
6. (Optional.) Changing to another user account
7. (Optional.) Maintaining and troubleshooting the FTP connection
8. (Optional.) Terminating the FTP connection

Establishing an FTP connection

FTP connection establishment task list

To establish an FTP connection, perform the following tasks:

1. (Optional.) Specifying a source IP address for outgoing FTP packets
2. Establishing an FTP connection
3. Setting the FTP file transfer mode and operation mode

Restrictions and guidelines

The source IP address specified in the **ftp** command takes precedence over the one set by the **ftp client source** command.

The source IP address specified in the **ftp ipv6** command takes precedence over the one set by the **ftp client ipv6 source** command.

Specifying a source IP address for outgoing FTP packets

1. Enter system view.

   system-view

2. Specify a source IP address for outgoing FTP packets.

   IPv4:

   ftp client source { **interface** *interface-type interface-number* | **ip** *source-ip-address* }

   By default, no source IP address is specified. The device uses the primary IP address of the output interface as the source IP address.

   IPv6:

   ftp client ipv6 source { **interface** *interface-type interface-number* | **ipv6** *source-ipv6-address* }

   By default, no source IPv6 address is specified. The source address is automatically selected as defined in RFC 3484.

Establishing an FTP connection

- Log in to the FTP server from user view.

  IPv4:

  ftp [*ftp-server* [*service-port*] [**vpn-instance** *vpn-instance-name*] [**dscp** *dscp-value* | **source** { **interface** *interface-type interface-number* | **ip** *source-ip-address* } | **-d**] *]

  IPv6:

  ftp ipv6 [*ftp-server* [*service-port*] [**vpn-instance** vpn-instance-name] [**dscp** *dscp-value* | **source** { **interface** *interface-type interface-number* | **ipv6** *source-ipv6-address* } | **-d**] * [**-i** *interface-type interface-number*]]

- Log in to the FTP server from FTP client view.

  a. Enter FTP client view.

     ftp [**ipv6**]

  b. Log in to the FTP server.

     open *server-address* [*service-port*]

Setting the FTP file transfer mode and operation mode

1. Enter FTP client view from user view.

   ftp

2. Set the file transfer mode.

   - Set the file transfer mode to ASCII.

     ascii

   - Set the file transfer mode to binary.

     binary

   The default file transfer mode is binary.

3. Change the FTP operation mode.

   passive

   The default FTP operation mode is passive.

Displaying command help information

1. Enter FTP client view from user view.

   ftp

2. Display command help information.

- **help** [*command-name*]
- **?** [*command-name*]

Displaying directories and files on the FTP server

1. Enter FTP client view from user view.
   ftp
2. Display directories and files on the FTP server.
   - **dir** [*remotefile* [*localfile*]]
   - **ls** [*remotefile* [*localfile*]]

Managing directories on the FTP server

Prerequisites

Use the **dir** or **ls** command to display the directories and files on the FTP server.

Procedure

1. Enter FTP client view from user view.
   ftp
2. Manage directories on the FTP server.
   - Display the working directory that is being accessed on the FTP server.
     pwd
   - Change the working directory on the FTP server.
     cd { *directory* | **..** | **/** }
   - Return to the upper level directory on the FTP server.
     cdup
   - Create a directory on the FTP server.
     mkdir *directory*
   - Delete a directory from the remote FTP server.
     rmdir *directory*

CAUTION:
Delete a directory from the FTP server with caution. When you delete a directory from the FTP server, make sure the directory is no longer in use.

Managing directories on the FTP client

1. Enter FTP client view from user view.
   ftp
2. Display or change the local working directory of the FTP client.
   lcd [*directory* | **/**]
   To upload a file, use this command to change to the directory where the file resides. Downloaded files are saved in the working directory.

Working with files on the FTP server

Prerequisites

Use the **dir** or **ls** command to display the directories and files on the FTP server.

Procedure

1. Enter FTP client view from user view.
   ftp
2. Work with files on the FTP server.
   - Delete a file from the FTP server permanently.
     delete *remotefile*

     CAUTION:
     Delete a file from the FTP server permanently with caution. When you delete a file from the FTP server permanently, make sure the file is no longer in use.

     This command requires that you have the delete right.
   - Rename a file.
     rename [*oldfilename* [*newfilename*]]
   - Upload a file to the FTP server.
     put *localfile* [*remotefile*]
   - Download a file from the FTP server.
     get *remotefile* [*localfile*]
   - Add the content of a file on the FTP client to a file on the FTP server.
     append *localfile* [*remotefile*]
   - Specify the retransmit marker.
     restart *marker*

     Use this command together with the **put**, **get**, or **append** command.
   - Update a local file.
     newer *remotefile*
   - Get the missing part of a file.
     reget *remotefile* [*localfile*]

Changing to another user account

About this task

After you log in to the FTP server, you can initiate an FTP authentication to change to a new account. By changing to a new account, you can get a different privilege without re-establishing the FTP connection.

Restrictions and guidelines

For successful account change, you must enter the new username and password correctly. A wrong username or password can cause the FTP connection to be disconnected.

Procedure

1. Enter FTP client view from user view.
   ftp

2. Initiate an FTP authentication on the current FTP connection.
   user *username* [*password*]

Maintaining and troubleshooting the FTP connection

About this task

After you use the device to establish an FTP connection to the FTP server, use the commands in this section to locate and troubleshoot problems about the FTP connection.

Procedure

1. Enter FTP client view from user view.
   ftp
2. Maintain and troubleshoot the FTP connection.
   - Display FTP commands supported by the FTP server.
     rhelp
   - Display help information about an FTP command that is supported by the FTP server.
     rhelp *protocol-command*
   - Display FTP server status.
     rstatus
   - Display detailed information about a directory or file on the FTP server.
     rstatus *remotefile*
   - Display FTP connection status.
     status
   - Display the system information of the FTP server.
     system
   - Enable or disable FTP operation information display.
     verbose

     By default, this function is enabled.
   - Enable FTP client debugging.
     debug

     By default, FTP client debugging is disabled.
   - Clear the reply information in the buffer.
     reset

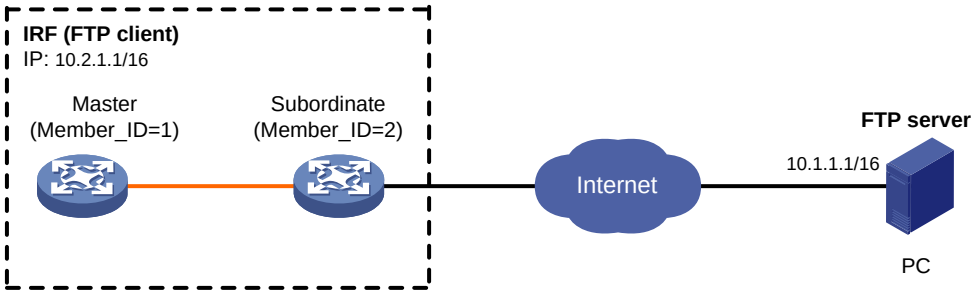
Terminating the FTP connection

1. Enter FTP client view from user view.
   ftp
2. Terminate the connection.
   - Terminate the connection to the FTP server without exiting FTP client view.
     disconnect
     close
   - Terminate the connection to the FTP server and return to user view.
     bye
     quit

Display and maintenance commands for the FTP client

Execute the **display** command in any view.

Task	Command
Display source IP address information on the FTP client.	**display ftp client source**



Example: Using the device as an FTP client

Network configuration

As shown in Figure 2, the PC is acting as an FTP server. A user account with username **abc** and password **hello12345** has been created on the PC.

- Use the IRF fabric as an FTP client to log in to the FTP server.
- Download the **temp.bin** file from the FTP server to the FTP client.

Figure 2 Network diagram

Note: The orange line represents an IRF connection.

Procedure

Configure IP addresses as shown in Figure 2. Make sure the IRF fabric and PC can reach each other. (Details not shown.)

Examine the storage space on the member devices. If the free space is insufficient, use the **delete/unreserved** *file* command to delete unused files. (Details not shown.)

Log in to the FTP server at 10.1.1.1 using username **abc** and password **hello12345**.

```
<Sysname> ftp 10.1.1.1
Press CTRL+C to abort.
Connected to 10.1.1.1 (10.1.1.1).
220 WFTPD 2.0 service (by Texas Imperial Software) ready for new user
User (10.1.1.1:(none)): abc
331 Give me your password, please
Password:
230 Logged in successfully
Remote system type is MSDOS.
ftp>
```

Set the file transfer mode to binary.

```
ftp> binary
200 TYPE is now 8-bit binary
```

Download the **temp.bin** file from the PC to the root directory of the flash memory on the master device.

```
ftp> get temp.bin
local: temp.bin remote: temp.bin
150 Connecting to port 47457
226 File successfully transferred
23951480 bytes received in 95.399 seconds (251.0 kbyte/s)
```

Download the **temp.bin** file from the PC to the root directory of the flash memory on the subordinate member (with member ID of 2).

```
ftp> get temp.bin slot2#flash:/temp.bin
```

Use the ASCII mode to upload configuration file **config.cfg** from the IRF fabric to the PC for backup.

```
ftp> ascii
200 TYPE is now ASCII
ftp> put config.cfg back-config.cfg
local: config.cfg remote: back-config.cfg
150 Connecting to port 47461
226 File successfully transferred
3494 bytes sent in 5.646 seconds (618.00 kbyte/s)
ftp> bye
221-Goodbye. You uploaded 2 and downloaded 2 kbytes.
221 Logout.
<Sysname>
```

Configuring TFTP

About TFTP

Trivial File Transfer Protocol (TFTP) is a simplified version of FTP for file transfer over secure reliable networks. TFTP uses UDP port 69 for data transmission. In contrast to TCP-based FTP, TFTP does not require authentication or complex message exchanges, and is easier to deploy. TFTP is suited for reliable network environments.

FIPS compliance

TFTP is not supported in FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

Restrictions and guidelines: TFTP configuration

You can upload a file from a TFTP client to the TFTP server or download a file from the TFTP server to a TFTP client. As a best practice, specify a file name that has not been used in the destination directory. If the destination file name has been used in the destination directory, the device deletes the existing file before saving the new file.

Configuring and using the IPv4 TFTP client

1. Enter system view.

system-view

2. Specify the source IP address for TFTP packets sent by the TFTP client.

   tftp client source { **interface** *interface-type interface-number* | **ip** *source-ip-address* }

   By default, no source IP address is specified. The device uses the primary IP address of the output interface as the source IP address.

3. Return to user view.

   quit

4. Download or upload a file in an IPv4 network.

   tftp *tftp-server* { **get** | **put** | **sget** } *source-filename* [*destination-filename*] [**vpn-instance** *vpn-instance-name*] [**dscp** *dscp-value* | **source** { **interface** *interface-type interface-number* | **ip** *source-ip-address* }] *

   The source IP address specified in this command takes precedence over the source IP address set by using the **tftp client source** command.

Configuring and using the IPv6 TFTP client

1. Enter system view.

   system-view

2. Specify the source IPv6 address for TFTP packets sent by the TFTP client.

   tftp client ipv6 source { **interface** *interface-type interface-number* | **ipv6** *source-ipv6-address* }

   By default, no source IPv6 address is specified. The source address is automatically selected as defined in RFC 3484.

3. Return to user view.

   quit

4. Download or upload a file in an IPv6 network.

   tftp ipv6 *tftp-server* [**-i** *interface-type interface-number*] { **get** | **put** | **sget** } *source-filename* [*destination-filename*] [**vpn-instance** *vpn-instance-name*] [**dscp** *dscp-value* | **source** { **interface** *interface-type interface-number* | **ipv6** *source-ipv6-address* }] *

   The source IP address specified in this command takes precedence over the one set by the **tftp client ipv6 source** command.

Managing file systems

This chapter describes how to manage file systems.

About file system management

Storage media and file systems

The device supports both fixed (the flash memory) and hot swappable (USB disk) storage media.

- The fixed storage medium has one file system.
- The hot swappable storage media can be partitioned. Each unpartitioned storage medium has one file system. On a partitioned storage medium, each partition has one file system.

Storage medium and file system naming conventions

The file system on the flash memory has the same name as the flash memory. The name has the following parts:

- Storage medium type **flash**.
- Colon (:).

A USB disk name and the file system names share the following parts:

- Storage medium type **usb**.
- Sequence number, a lower-case English letter such as a, b, or c.
- Partition number, a digit that starts at 0 and increments by 1. If the storage medium is not partitioned, the system determines that the storage medium has one partition. (The storage medium name does not contain a partition number.)
- Colon (:).

For example, the first USB disk is named **usba:**, and the file system on the first partition of the first USB disk is named **usba0:**.

IMPORTANT:

File system names are case sensitive and must be entered in lower case.

File system location

To identify a file system on the master device, you do not need to specify the file system location. To identify a file system on a subordinate member device, you must specify the file system location in the **slot***n***#** format. The *n* argument represents the IRF member ID of the member device. For example, the location is **slot2#** for a file system that resides on member device 2.

IMPORTANT:

The file system location string is case sensitive and must be entered in lower case.

Default file system

You are working with the default file system by default after you log in. To specify a file or directory on the default file system, you do not need to specify the file system name. For example, you do not need to specify any location information if you want to save the running configuration to the root directory of the default file system.

To change the default file system, use the Boot ROM menu. For more information, see the software release notes.

Directories

Directories in a file system are structured in a tree form.

Root directory

The root directory is represented by a forwarding slash (/). For example, **flash:/** represents the root directory of the flash memory.

Working directory

The working directory is also called the current directory.

Directory naming conventions

When you specify a name for a directory, follow these conventions:

- A directory name can contain letters, digits, and special characters except for asterisks (*), vertical bars (|), forward slashes (/), backward slashes (\), question marks (?), left angle brackets (<), right angle brackets (>), quotation marks ("), and colons (:).
- A directory whose name starts with a dot character (.) is a hidden directory. To prevent the system from hiding a directory, make sure the directory name does not start with a dot character.

Commonly used directories

The device has some factory-default directories. The system automatically creates directories during operation. These directories include:

- **diagfile**—Stores diagnostic information files.
- **logfile**—Stores log files.
- **seclog**—Stores security log files.
- **versionInfo**—Stores software version information files.

Files

File naming conventions

When you specify a name for a file, follow these conventions:

- A file name can contain letters, digits, and special characters except for asterisks (*), vertical bars (|), forward slashes (/), backward slashes (\), question marks (?), left angle brackets (<), right angle brackets (>), quotation marks ("), and colons (:).
- A file whose name starts with a dot character (.) is a hidden file. To prevent the system from hiding a file, make sure the file name does not start with a dot character.

Common file types

The device has some factory-default files and might create some files automatically during operation. The types of these files include:

- **.ipe file**—Compressed software image package file.
- **.bin file**—Software image file.
- **.cfg file**—Configuration file.
- **.mdb file**—Binary configuration file.
- **.log file**—Log file.

Specifying a directory name or file name

Specifying a directory name

To specify a directory, you can use the absolute path or a relative path. For example, the working directory is **flash:/**. To specify the **test2** directory in Figure 1, you can use the following methods:

- **flash:/test/test1/test2** (absolute path)
- **flash:/test/test1/test2/** (absolute path)
- **test/test1/test2** (relative path)
- **test/test1/test2/** (relative path)

Figure 1 Sample directory hierarchy

Specifying a file name

To specify a file, use the following methods:

- Enter the absolute path of the file and the file name in the format of *filesystem*/*directory1*/*directory2*/…/*directoryn*/*filename*, where *directoryn* is the directory in which the file resides.
- Enter the relative path of the file and the file name.

For example, the working directory is **flash:/**. The **samplefile.cfg** file is in the **test2** directory shown in Figure 1. To specify the file, you can use the following methods:

- **flash:/test/test1/test2/samplefile.cfg**
- **test/test1/test2/samplefile.cfg**

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

Restrictions and guidelines: File system management

To avoid file system corruption, do not perform the following tasks during file system management:

- Install or remove storage media.
- Perform a master/subordinate switchover.

If you remove a storage medium while a directory or file on the medium is being accessed, the device might not recognize the medium when you reinstall it. To reinstall this kind of storage medium, perform one of the following tasks:

- If you were accessing a directory on the storage medium, change the working directory.
- If you were accessing a file on the storage medium, close the file.
- If another administrator was accessing the storage medium, unmount all partitions on the storage medium.

Make sure a USB disk is not write protected before an operation that requires the write right on the disk.

You cannot access a storage medium that is being partitioned, or a file system that is being formatted or repaired.

Before managing file systems, directories, and files, make sure you know the possible impact.

Managing storage media and file systems

Partitioning a storage medium

About this task

A storage medium can be divided into logical devices called partitions. Operations on one partition do not affect the other partitions.

Restrictions and guidelines

IMPORTANT:

Partitioning a storage medium clears all data on the medium.

The flash memory does not support partitioning.

Before partitioning a storage medium, perform the following tasks:

- Make sure no other users are accessing the medium.
- To partition a USB disk, make sure the disk is not write protected. If the disk is write protected, the partition operation will fail. To restore access to the USB disk, you must reinstall the disk or remount the file systems on the disk.

A partition must have a minimum of 32 MB of storage space.

The actual partition size and the specified partition size might have a difference of less than 5% of the storage medium's total size.

Prerequisites

Back up the files in the storage medium.

Procedure

To partition a storage medium, execute the following command in user view:

fdisk *medium* [*partition-number*]

To partition a storage medium evenly, specify the *partition-number* argument. To customize the sizes of partitions, do not specify the *partition-number* argument. The command will require you to specify a size for each partition.

Mounting or unmounting a file system

Restrictions and guidelines

You can mount or unmount only a file system that is on a hot-swappable storage medium.

You can unmount a file system only when no other users are accessing the file system.

To prevent a USB disk and the USB interface from being damaged, make sure the following requirements are met before unmounting file systems on the USB disk:

- The system has recognized the USB disk.
- The USB disk LED is not blinking.

Mounting a file system

To mount a file system, execute the following command in user view:

mount *filesystem*

File systems on a hot-swappable storage medium are automatically mounted when the storage medium is connected to the device. If the system cannot recognize a file system, you must mount the file system before you can access it.

Unmounting a file system

To unmount a file system, execute the following command in user view:

umount *filesystem*

To remove a hot-swappable storage medium from the device, you must first unmount all file systems on the storage medium to disconnect the medium from the device. Removing a connected hot-swappable storage medium might damage files on the storage medium or even the storage medium itself.

Formatting a file system

Restrictions and guidelines

You can format a file system only when no other users are accessing the file system.

Procedure

To format a file system, execute the following command in user view:

format *filesystem* [**low-level**]

CAUTION:

Formatting a file system permanently deletes all files and directories in the file system. If low-level formatting is performed, you will be unable to restore the deleted data. You cannot restore the deleted files or directories. If a startup configuration file exists in the file system, back up the file if necessary.

Repairing a file system

Restrictions and guidelines

If part of a file system is inaccessible, use this task to examine and repair the file system.

You can repair a file system only when no other users are accessing the file system.

Procedure

To repair a file system, execute the following command in user view:

fixdisk *filesystem*

Managing files and directories

Setting the operation mode for files and directories

About this task

The device supports the following operation modes:

- **alert**—The system prompts for confirmation when your operation might cause problems such as file corruption or data loss. This mode provides an opportunity for you to cancel a disruptive operation.
- **quiet**—The system does not prompt for confirmation when you perform a file or directory operation except the recycle bin emptying operation.

Procedure

1. Enter system view.
   system-view
2. Set the operation mode for files and directories.
   file prompt { **alert** | **quiet** }
   The default mode is alert.

Displaying file and directory information

To display file and directory information, execute the following command in user view:

dir [**/all**] [*file* | *directory* | **/all-filesystems**]

If multiple users perform file operations (for example, creating or deleting files or directories) at the same time, the output from this command might be incorrect.

Displaying the contents of a text file

To display the contents of a text file, execute the following command in user view:

more *file*

Displaying the working directory

To display the working directory, execute the following command in user view:

pwd

Changing the working directory

About this task

The default working directory is the root directory of the default file system on the master device.

Procedure

To change the working directory, execute the following command in user view:

cd { *directory* | **..** }

Creating a directory

To create a directory, execute the following command in user view:

mkdir *directory*

Renaming a file or directory

To rename a file or directory, execute the following command in user view:

rename { *source-file* | *source-directory* } { *dest-file* | *dest-directory* }

Copying a file

To copy a file, execute the command in user view.

In non-FIPS mode:

copy *source-file* { *dest-file* | *dest-directory* } [**vpn-instance** *vpn-instance-name*] [**source interface** *interface-type interface-number*]

In FIPS mode:

copy *source-file* { *dest-file* | *dest-directory* }

Moving a file

To move a file, execute the following command in user view:

move *source-file* { *dest-file* | *dest-directory* }

Deleting and restoring files

About this task

You can delete a file permanently or move it to the recycle bin of the file system. A file moved to the recycle bin can be restored, but a permanently deleted file cannot.

Each file system has a recycle bin. A recycle bin is a directory named **.trash** in the root directory of the file system.

Restrictions and guidelines

Files in the recycle bin occupy storage space. To release the occupied storage space, delete files from the recycle bin.

To delete files from the recycle bin, use the **reset recycle-bin** command. If you use the **delete** command, the recycle bin might not be able to operate correctly.

To display files in a recycle bin, use one of the following methods:

- Access the root directory of the file system and execute the **dir /all .trash** command.
- Access the recycle bin directory of the file system and execute the **dir** command.

Deleting a file

To delete a file, execute one of the following commands in user view:

- Delete a file by moving it to the recycle bin.
  delete *file*
- Delete a file permanently.
  delete /unreserved *file*

CAUTION:
The **delete /unreserved** *file* command deletes a file permanently. The file cannot be restored.

- Delete files from the recycle bin.

reset recycle-bin [**/force**]

CAUTION:

The files in a recycle bin can be restored by using the **undelete** command. If you delete a file from the recycle bin, that file cannot be restored. Before you delete files from a recycle bin, make sure the files are no longer in use.

Restoring a file

To restore a file from the recycle bin, execute the following command in user view:

undelete *file*

Deleting a directory

To delete a directory, execute the following command in user view:

rmdir *directory*

CAUTION:

To delete a directory, you must first delete all files and subdirectories in the directory permanently or move them to the recycle bin. If you move them to the recycle bin, executing the **rmdir** command to delete the directory will delete them permanently. Before you use the **rmdir** command to delete a directory, you must make sure the directory and its files and subdirectories are no longer in use.

Archiving files and directories

About this task

You can archive files and directories to a single file for purposes such as file backup. The original files and directories still exist.

When you archive files and directories, you can choose to compress the archive files so the archive files use less storage space.

Procedure

To archive files and directories, execute the following command in user view:

tar create [**gz**] **archive-file** *dest-file* [**verbose**] **source** { *source-file* | *source-directory* }&<1-5>

Extracting files and directories

About this task

Use this feature to extract files and directories from archive files.

Restrictions and guidelines

To specify the **screen** keyword for the **tar extract** command, first use the **tar list** command to identify the types of the archived files. As a best practice, specify the keyword only if all archived files are text files. Displaying the content of an archived non-text file that contains terminal control characters might result in garbled characters and even cause the terminal unable to operate correctly. To use the terminal again, you must close the current connection and log in to the device again.

Procedure

To extract files and directories, execute the following commands in user view:

1. (Optional.) Display archived files and directories.
   tar list archive-file *file*
2. Extract files and directories.
   tar extract archive-file *file* [**verbose**] [**screen** | **to** *directory*]

Compressing a file

To compress a file, execute the following command in user view:

gzip *file*

Decompressing a file

To decompress a file, execute the following command in user view:

gunzip *file*

Calculating the file digest

About this task

File digests are used to verify file integrity.

Procedure

To calculate the digest of a file, execute one of the following commands in user view:

- Use the SHA-256 algorithm.
  sha256sum *file*
- Use the MD5 algorithm.
  md5sum *file*

Executing a batch file

About this task

A batch file contains a set of commands. Executing a batch file executes the commands in the file one by one.

When executing an interactive command in a batch file, the system uses the default inputs.

Restrictions and guidelines

To execute a batch file on the device, create a batch file on a PC and load the batch file to the device.

As a best practice, try every command on the device to make sure the command line can be executed correctly before adding the command to a batch file. If a command is invalid or a condition for executing the command is not met, the command fails and the system continues to execute the next command.

Procedure

1. Enter system view.
   system-view
2. Execute a batch file.

execute *filename*

Managing configuration files

About configuration file management

You can manage configuration files from the CLI or the BootWare menu. The following information explains how to manage configuration files from the CLI.

A configuration file saves a set of commands for configuring software features on the device. You can save any configuration to a configuration file so the configuration can survive a reboot. You can also back up configuration files to a host for future use.

Configuration types

Initial configuration

Initial configuration is the collection of initial default settings for the configuration commands in software.

The device starts up with the initial configuration if you access the BootWare menu and select the **Skip Current System Configuration** option. In this situation, the device might also be described as starting up with empty configuration.

No commands are available to display the initial configuration. To view the initial default settings for the configuration commands, see the Default sections in the command references.

Factory defaults

Factory defaults are custom basic settings that came with the device. Factory defaults vary by device models and might differ from the initial default settings for the commands.

The device starts up with the factory defaults if no next-startup configuration files are available.

To display the factory defaults, use the **`display default-configuration`** command.

Startup configuration

The device uses startup configuration to configure software features during startup. After the device starts up, you can specify the configuration file to be loaded at the next startup. This configuration file is called the next-startup configuration file. The configuration file that has been loaded is called the current startup configuration file.

You can display the startup configuration by using one of the following methods:

- To display the contents of the current startup configuration file, execute the **`display current-configuration`** command before changing the configuration after the device reboots.
- To display the contents of the next-startup configuration file, use the **`display saved-configuration`** command.
- Use the **`display startup`** command to display names of the current startup configuration file and next-startup configuration files. Then, you can use the **`more`** command to display the contents of the specified startup configuration file.

Running configuration

The running configuration includes unchanged startup settings and new settings. The running configuration is stored in memory and is cleared at a device reboot or power off. To use the running configuration after a power cycling or reboot, save it to a configuration file.

To display the running configuration, use the **`display current-configuration`** command.

Configuration file types and file selection process at startup

When you save the configuration, the system saves the settings to a .cfg configuration file and to an .mdb file.

- A .cfg configuration file is a human-readable text file and its contents can be displayed by using the **more** command. Configuration files you specify for saving the configuration must use the .cfg extension.
- An .mdb file is a user-inaccessible binary file that has the same name as the .cfg file. The device loads an .mdb file faster than loading a .cfg file.

At startup, the device uses the following procedure to identify the configuration file to load:

1. The device searches for a valid .cfg next-startup configuration file. For more information about the file selection rules, see "Next-startup configuration file redundancy."
2. If a valid .cfg next-startup configuration file is found, the device searches for an .mdb file that has the same name and checksum as the .cfg file.
3. If a matching .mdb file is found, the device starts up with the .mdb file. If none is found, the device starts up with the .cfg file.

If no .cfg next-startup configuration files are available, the device starts up with the factory defaults.

Unless otherwise stated, the term "configuration file" in this document refers to a .cfg configuration file.

Next-startup configuration file redundancy

You can specify one main next-startup configuration file and one backup next-startup configuration file for redundancy.

At startup, the device tries to select the .cfg startup configuration in the following order:

1. The main next-startup configuration file.
2. The backup next-startup configuration file if the main next-startup configuration file does not exist or is corrupt.

If no next-startup configuration files are available, the device starts up with the factory defaults.

Configuration file content organization and format

IMPORTANT:

To run on the device, a configuration file must meet the content and format requirements. To ensure a successful configuration load, rollback, or restoration, use a configuration file created on the device. To edit a configuration file, you must edit, save, and obtain it on the device, and make sure all edits are compliant with the requirements. To avoid a configuration file becoming invalid because of incompliant settings, do not download the configuration file locally for editing.

Configuration restoration or rollback might fail for a set of interdependent commands if the operation fails for one of them.

A configuration file must meet the following requirements:

- All commands are saved in their complete form.
- No command lines contain invalid characters. The spaces between keywords or arguments must be in English.

IMPORTANT:

Some command lines (for example, the **sysname** command) cannot contain question marks

(?) or horizontal tabs (\t). If the system loads a configuration file that contains the **sysname abc??** command line at startup, the system will ignore the command line and use the default system name. If the system uses that configuration file to roll back or restore the configuration, the system name will not be rolled back or restored.

- Commands are sorted into sections by different command views, including system view, interface views, protocol views, and user line views.
- Two adjacent sections are separated by a pound sign (#).
- The configuration file starts with a pound sign (#).
- The configuration file ends with the word **return**.

The following is a sample configuration file excerpt:

```
#
local-user root class manage
 password hash
$h$6$Twd73mLrN8O2vvD5$Cz1vgdpR4KoTiRQNE9pg33gU14Br2p1VguczLSVyJLO2huV5Syx/LfDIf8ROLtV
ErJ/C31oq2rFtmNuyZf4STw==
 service-type ssh telnet terminal
 authorization-attribute user-role network-admin
 authorization-attribute user-role network-operator
#
interface Vlan-interface1
 ip address 192.168.1.84 255.255.255.0
#
```

Configuration rollback

Configuration rollback allows you to replace the running configuration with the configuration in a configuration file without rebooting the device. You can use this feature for the following purposes:

- Reverting to a previous configuration state.
- Adapting the running configuration to different network environments.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

Enabling configuration encryption

About this task

Configuration encryption enables the device to use the master key to encrypt a startup configuration file automatically when it saves the running configuration. For more information about the master key, see public key management in *Security Configuration Guide*.

Restrictions and guidelines

After a configuration file is encrypted by using this feature on the device, only devices that use the same master key as the device can decrypt the encrypted configuration file.

You cannot use the **more** command to view the contents of an encrypted configuration file.

Procedure

1. Enter system view.

   system-view

2. Enable configuration encryption.

   configuration encrypt

   By default, configuration encryption is disabled.

Disabling automatic system-wide next-startup configuration file operations

About this task

By default, automatic system-wide next-startup configuration file operations are enabled. The system performs the following operations on all IRF subordinate devices in addition to the master device:

- Saves the running configuration to the next-startup configuration file on each member device when you execute the **save** [**safely**] [**backup** | **main**] [**force**] [**changed**] command.
- Deletes the next-startup configuration file on each member device when you execute the **reset saved-configuration** command.

If you disable automatic system-wide next-startup configuration file operations, the system saves the running configuration or deletes the next-startup configuration file only on the master device.

Automatic system-wide operations ensure start-up configuration file consistency between the master and subordinate devices. However, a system-wide operation takes more time than an operation performed only on the master device. In addition, the amount of time required to complete a system-wide configuration operation increases as the amount of configuration data grows.

If you are disabling automatic system-wide operations for faster configuration saving, be aware that the next-startup configuration files will be inconsistent between the master device and the subordinate devices.

Procedure

1. Enter system view.

   system-view

2. Disable automatic system-wide next-startup configuration file operations.

   undo standby auto-update config

   By default, next-startup configuration file operations are automatically synchronized across the entire system.

Saving the running configuration

About this task

The running configuration is stored only in memory. If you have not saved the running configuration before a reboot, any changes you have made to the configuration will be lost and the device will restart with the factory defaults. To keep the current running configuration after a reboot, save it to a configuration file, or to the main or backup next-startup configuration file.

Restrictions and guidelines

To prevent the loss of next-startup configuration, make sure no one reboots or power cycles the device while the device is saving the running configuration.

If there are settings that must be read from the .cfg configuration file at startup, using the binary-only saving mode will cause the loss of those settings at startup. As a best practice, use this mode only when you must save a large number of table entries such as NAT entries, IP static routes, or VPN instances.

When an IRF member device splits from the IRF fabric, its settings are retained in memory but removed from the running configuration on the IRF fabric. Saving the running configuration before the IRF fabric recovers will remove the member device's settings from the next-startup configuration file.

If you have saved the running configuration before the member device rejoins the IRF fabric, perform the following steps to restore the member device settings to the next-startup configuration file:

1. Resolve the split issue.
2. Reboot the member device to rejoin the IRF fabric.
3. After the member device rejoins the IRF fabric, execute the **display current-configuration** command to verify that the member device's settings have been restored from memory to the running configuration.
4. Save the running configuration to the next-startup configuration file on the IRF fabric.

IMPORTANT:

To ensure a successful configuration restoration, make sure the IRF fabric has not rebooted after the member device left.

By default, the **save** [**safely**] [**backup** | **main**] [**force**] [**changed**] command saves the configuration to all IRF member devices. To save the configuration only to the master device, disable automatic system-wide next-startup configuration file operations. For more information, see "Disabling automatic system-wide next-startup configuration file operations."

Automatic configuration saving saves the running configuration to all member devices.

Automatic configuration saving saves the running configuration to both active and standby MPUs.

Automatic configuration saving saves the running configuration to each MPU on each member device.

Procedure

To save the running configuration, perform one of the following tasks in any view:

- Save the running configuration to a configuration file without specifying the file as a next-startup configuration file.

  save *file-url* [**all** | **slot** *slot-number*]

- Save the running configuration to a configuration file in the root directory of the storage medium on each member device, and specify the file as a next-startup configuration file.

  save [**safely**] [**backup** | **main**] [**force**] [**changed**]

  As a best practice, specify the **safely** keyword for reliable configuration saving.

CAUTION:

Use the **save** command with caution. This command will overwrite the settings in the target configuration file. Carefully read the messages you receive when you use this command and make sure you fully understand the impact of this command when you execute it.

Comparing configurations for their differences

About this task

You can compare configuration files or compare a configuration file with the running configuration for their differences.

If you specify the next-startup configuration for a comparison, the system selects the next-startup configuration file to be compared with in the following order:

1. The main next-startup configuration file.
2. The backup next-startup configuration file if the main next-startup configuration file is unavailable.

If both configuration files are unavailable, the system displays a message indicating that no next-startup configuration files exist.

Procedure

To compare configurations for their differences, perform one of the following tasks in any view:

- Display the differences that a configuration file, the running configuration, or the next-startup configuration has as compared with the specified source configuration file.

  display diff configfile *file-name-s* { **configfile** *file-name-d* | **current-configuration** | **startup-configuration** }
- Display the differences that a configuration file or next-startup configuration has as compared with the running configuration.

  display diff current-configuration { **configfile** *file-name-d* | **startup-configuration** }
- Display the differences that a configuration file has as compared with the next-startup configuration.

  display diff startup-configuration configfile *file-name-d*
- Display the differences that the running configuration has as compared with the next-startup configuration.
  - Method 1:

    display diff startup-configuration current-configuration
  - Method 2:

    display current-configuration diff

Archiving the running configuration

Running configuration archive tasks at a glance

To configure running configuration archive, perform the following tasks:

1. Setting configuration archive parameters
2. Archiving the running configuration

   Perform either of the following tasks:
   - Enabling automatic configuration archiving
   - Manually archiving the running configuration

Setting configuration archive parameters

About this task

Before archiving the running configuration, you must set a file directory and file name prefix for configuration archives.

The archive directory can be located on the local device or on a remote SCP server.

If you use local archiving, configuration archives are named in the format of *prefix_serial number***.cfg**, for example, **archive_1.cfg** and **archive_2.cfg**. The serial number is automatically assigned from 1 to 1000, increasing by 1. After the serial number reaches 1000, it restarts from 1.

If you change the file directory or file name prefix on the local device, the following events occur:

- The old configuration archives change to common configuration files.
- The configuration archive counter is reset. The serial number for new configuration archives starts at 1.
- The **`display archive configuration`** command no longer displays the old configuration archives.

The configuration archive counter does not restart when you delete configuration archives from the archive directory. However, if the device reboots after all configuration archives have been deleted, the configuration archive counter restarts. The serial number for new configuration archives starts at 1.

If you archive the running configuration to a remote SCP server, configuration archives are named in the format of *prefix_YYYYMMDD_HHMMSS***.cfg** (for example, **archive_20170526_203430.cfg**). The *YYYYMMDD_HHMMSS* string represents the device system date and time when the configuration archive was saved.

If you change the file directory or file name prefix on the remote SCP server, the **`display archive configuration`** command no longer displays the old configuration archives saved before the change.

Restrictions and guidelines for setting configuration archive parameters

Local archiving (the **`archive configuration location`** command) and remote archiving (the **`archive configuration server`** command) are mutually exclusive. You cannot use the two features at the same time.

IMPORTANT:

In FIPS mode, the device does not support archiving the running configuration to a remote SCP server.

With local configuration archiving, the system deletes the oldest archive to make room for the new archive after the maximum number of configuration archives is reached.

The following information applies to remote configuration archiving:

- The maximum number of configuration archives on a remote SCP server depends on the SCP server setting and is not restricted by the **`archive configuration max`** command.
- If the remote SCP server already contains an archive file with the same name as the new configuration archive file being transferred, the new archive file overwrites the existing file. To avoid an undesirable overwrite, back up the configuration archives on the SCP server to a different directory.

The **`undo archive configuration location`** command removes the local configuration archive directory and file name prefix settings, but it does not delete the configuration archives on the device. The command also performs the following operations:

- Disables both the manual and automatic configuration archiving features.

- Restores the default settings for the **archive configuration interval** and **archive configuration max** commands.
- Clears the configuration archive information displayed by using the **display archive configuration** command.

The **undo archive configuration server** command removes the remote configuration archive directory and file name prefix settings, but it does not delete the configuration archives on the server. The command also performs the following operations:

- Disables both the manual and automatic configuration archiving features.
- Restores the default setting for the **archive configuration interval** command.
- Clears the configuration archive information displayed by using the **display archive configuration** command.

Configuring local archiving parameters

1. Enter system view.

   system-view

2. Set the directory and file name prefix for archiving the running configuration to the local device.

   archive configuration location *directory* **filename-prefix** *filename-prefix*

   By default, no path or file name prefix is set for configuration archives on the device, and the system does not regularly save configuration.

   In an IRF fabric, the configuration archive directory must already exist on the master device and cannot include a member ID.

3. (Optional.) Set the maximum number of configuration archives.

   archive configuration max *file-number*

   The default number is 5.

   Change the setting depending on the amount of storage available on the device.

Configuring remote archiving parameters

1. Enter system view.

   system-view

2. Set the directory and file name prefix for archiving the running configuration on a remote SCP server.

   archive configuration server scp { *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port-number*] [**vpn-instance** *vpn-instance-name*] [**directory** *directory*] [**source-ip** *source-ip-address*] **filename-prefix** *filename-prefix*

   By default, no path or file name prefix is set for archiving the running configuration to a remote SCP server.

3. Configure the username and password for accessing the SCP server.

   a. Configure the username.

      archive configuration server user *user-name*

      By default, no username is configured for accessing the SCP server.

   b. Configure the password.

      archive configuration server password { **cipher** | **simple** } *string*

      By default, no password is configured for accessing the SCP server.

   Make sure the username and password are the same as the SCP account settings on the SCP server.

Archiving the running configuration

About this task

The following are methods for archiving the running configuration:

- **Automatic configuration archiving**—The system automatically archives the running configuration at intervals as configured.
- **Manual configuration archiving**—You can disable automatic configuration archiving and manually archive the running configuration if the configuration will not be changed very often. You can also use this method before performing complicated configuration tasks. If the configuration attempt fails, you can use the archive for configuration recovery.

Restrictions and guidelines for archiving the running configuration

If you use local archiving, the configuration archive feature saves the running configuration only on the master device. To make sure the system can archive the running configuration after a master/subordinate switchover, create the configuration archive directory on all IRF members.

If a local archiving has started based on the existing archive parameters when an archive parameter is changed, the archive will still be retained in the old directory. However, the **`display archive configuration`** command will not display the record about this archiving.

When you modify parameters (for example, the username or password) for remote archiving, make sure the changes are consistent between the device and the server. A manual or automatic remote archiving will fail if it has started before you change the device and the server settings to be consistent.

Enabling automatic configuration archiving

1. Enter system view.

   `system-view`
2. Enable automatic configuration archiving and set the archiving interval.

   `archive configuration interval` *`interval`*

   By default, automatic configuration archiving is disabled.

Manually archiving the running configuration

Manually archive the running configuration in user view.

`archive configuration`

Rolling back configuration

About this task

When you roll back the running configuration or commit target configuration command lines, the system creates a rollback point and assigns a unique commit ID to the rollback point.

The configuration rollback feature compares the running configuration against the specified rollback point or replacement configuration file and handles configuration differences as follows:

- If a command in the running configuration is not in the rollback point or replacement file, the rollback feature executes the **undo** form of the command.
- If a command in the rollback point or replacement file is not in the running configuration, the rollback feature adds the command to the running configuration.
- If a command has different settings in the running configuration and the rollback point or replacement file, the rollback feature replaces the running command setting with the setting in the rollback point or replacement file.

Restrictions and guidelines

To ensure a successful rollback, do not perform a master/subordinate switchover while the system is rolling back the configuration.

The configuration rollback feature might fail to reconfigure some commands in the running configuration for one of the following reasons:

- A command cannot be undone because prefixing the **undo** keyword to the command does not result in a valid **undo** command. For example, if the **undo** form designed for the **A** [**B**] **C** command is **undo A C**, the configuration rollback feature cannot undo the **A B C** command. This is because the system does not recognize the **undo A B C** command.
- A command (for example, a hardware-dependent command) cannot be deleted, overwritten, or undone due to system restrictions.
- The commands in different views are dependent on each other.
- Commands or command settings that the device does not support cannot be added to the running configuration.

Make sure the replacement configuration file is created by using the configuration archive feature or the **save** command on the local device. If the configuration file is not created on the local device, make sure the command lines in the configuration file are fully compatible with the local device.

If the replacement configuration file is encrypted, make sure the device can decrypt it.

Rolling back the running configuration based on a rollback point

1. Enter system view.

   system-view
2. Roll back the running configuration based on the specified rollback point.

   configuration replace { **last** *number* | **commit-id** *commit-id* | **label** *labelname* }
3. (Optional) Set the maximum number of rollback points.

   configuration commit max-number *max-number*

   By default, the maximum number of rollback points is 100.

Rolling back the running configuration based on a local configuration file

1. Enter system view.

   system-view
2. Roll the running configuration back to the configuration contained in a local configuration file.

   configuration replace file *filename*

CAUTION:

This operation will cause settings not in the replacement configuration file to be lost, which might cause service interruption. When you perform configuration rollback, make sure you fully understand its impact on your network.

Configuring configuration commit delay

About this task

This feature enables the system to automatically remove the settings you made during a configuration commit delay interval if you have not manually committed them.

You specify the configuration commit delay interval by using the configuration commit delay timer. The system creates a rollback point to record the configuration status when you start the configuration commit delay timer. The settings you made during the configuration commit delay interval takes effect immediately. However, these settings will be removed automatically if you have not manually committed them before the configuration commit delay timer expires. Then, the system returns to the configuration status when the configuration commit delay timer started.

This feature prevents a misconfiguration from causing the inability to access the device and is especially useful when you configure the device remotely.

Restrictions and guidelines

When you use this feature, follow these restrictions and guidelines:

- In a multi-user context, make sure no one else is configuring the device.
- To avoid unexpected errors, do not perform any operations during the configuration rollback.
- You can reconfigure the configuration commit delay timer before it expires to shorten or extend the commit delay interval. However, the rollback point will not change.
- The configuration commit delay feature is a one-time setting. The feature is disabled with the rollback point removed when the commit delay timer expires or after a manual commit operation is performed. To use this feature again, you must restart the timer.

Procedure

1. Enter system view.
   `system-view`
2. Enable the configuration commit delay feature and start the commit delay timer.
   `configuration commit delay` *`delay-time`*
3. (Optional.) Commit the settings configured after the commit delay timer started.
   `configuration commit`

Specifying a next-startup configuration file

Restrictions and guidelines

> **CAUTION:**
> Using the **`undo startup saved-configuration`** command can cause an IRF split after the IRF fabric or an IRF member reboots. When you execute this command, make sure you understand its impact on your network.

As a best practice, specify different files as the main and backup next-startup configuration files.

The **`undo startup saved-configuration`** command changes the attribute of the main or backup next-startup configuration file to NULL instead of deleting the file.

If you use the **`save`** command without any parameters, the device saves the running configuration to a configuration file and automatically specifies the file as the main next-startup configuration file. For more information, see "Saving the running configuration."

Prerequisites

In an IRF fabric, make sure the specified configuration file is valid and has been saved to the root directory of a storage medium on each member device. In addition, make sure the storage media are the same type across all IRF member devices.

Procedure

1. Specify a next-startup configuration file. Choose one of the following methods:
   - Execute the following command in user view to specify a next-startup configuration file:

startup saved-configuration *cfgfile* [**backup** | **main**]

By default, no next-startup configuration files are specified.

- Execute the following command in any view to save the running configuration to a file and specify the file as a next-startup configuration file:

  save [**safely**] [**backup** | **main**] [**force**]

  For more information about this command, see "Saving the running configuration."

If you do not specify the **backup** or **main** keyword, this command specifies the configuration file as the main next-startup configuration file.

2. (Optional.) Verify the configuration. Use one of the following commands in any view:
   - Display the names of the configuration files for this startup and the next startup.

     display startup
   - Display the contents of the configuration file for the next system startup.

     display saved-configuration

Backing up and restoring the main next-startup configuration file

About backing up and restoring the main next-startup configuration file

You can back up the main next-startup configuration file to a TFTP server or restore the main next-startup configuration file from a TFTP server.

Restrictions and guidelines for configuration backup and restoration

Configuration backup and restoration are not supported in FIPS mode.

Prerequisites for configuration backup and restoration

Before you back up or restore the main next-startup configuration file, perform the following tasks:

- Make sure the following requirements are met:
  - The server is reachable.
  - The server is enabled with TFTP service.
  - You have read and write permissions to the server.
- For configuration backup, use the **display startup** command to verify that the main next-startup configuration file has been specified in user view. If no next-startup configuration file has been specified or the specified configuration file does not exist, the backup operation will fail.

Backing up the main next-startup configuration file to a TFTP server

To back up the main next-startup configuration file to a TFTP server, execute the following command in user view:

backup startup-configuration to { *ipv4-server* | **ipv6** *ipv6-server* } [*dest-filename*] [**vpn-instance** *vpn-instance-name*]

Restoring the main next-startup configuration file from a TFTP server

1. Restore the main next-startup configuration file from a TFTP server in user view.

   restore startup-configuration from { *ipv4-server* | **ipv6** *ipv6-server* } *src-filename* [**vpn-instance** *vpn-instance-name*]
2. (Optional.) Verify that the specified configuration file has been set as the main next-startup configuration file. Use one of the following commands in any view:
   - Display the names of the configuration files for this startup and the next startup.

     display startup
   - Display the contents of the configuration file for the next system startup.

     display saved-configuration

Deleting a next-startup configuration file

About this task

You can perform this task to delete a next-startup configuration file.

If both the main and backup next-startup configuration files are deleted, the device uses the factory defaults at the next startup.

To delete a file that is set as both main and backup next-startup configuration files, you must execute both the **reset saved-configuration backup** command and the **reset saved-configuration main** command. Using only one of the commands removes the specified file attribute instead of deleting the file.

For example, if the **reset saved-configuration backup** command is executed, the backup next-startup configuration file setting is set to NULL. However, the file is still used as the main file. To delete the file, you must also execute the **reset saved-configuration main** command.

Procedure

To delete a next-startup configuration file, execute the following command in user view:

reset saved-configuration [**backup** | **main**]

CAUTION:

By default, this task permanently deletes a next-startup configuration file from all IRF member devices. To delete the configuration file only from the master device, disable automatic system-wide next-startup configuration file operations. For more information, see "Disabling automatic system-wide next-startup configuration file operations."

If you do not specify the **backup** or **main** keyword, the main next-startup configuration is deleted.

Display and maintenance commands for configuration files

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display configuration archive information.	**display archive configuration**
Display configuration differences between a rollback point and the running configuration or between two rollback points.	**display configuration commit diff** [**at** *commit-id* | **last** *number* | **since** *commit-id*]
Display rollback point information.	**display configuration commit list** [*number* | **label**] [**verbose**]
Display device configuration sessions.	**display configuration sessions**
Display the running configuration.	**display current-configuration** [[**configuration** [*module-name*] | **exclude-provision** | **interface** [*interface-type* [*interface-number*]]] [**all**] | **slot** *slot-number*] [**by-section** { **begin** | **exclude** | **include** } *regular-expression*]
Display the differences that the running configuration has as compared with the next-startup configuration.	**display current-configuration diff**
Display the factory defaults.	**display default-configuration**
Display the differences between configurations.	• **display diff configfile** *file-name-s* { **configfile** *file-name-d* | **current-configuration** | **startup-configuration** } • **display diff current-configuration** { **configfile** *file-name-d* | **startup-configuration** } • **display diff startup-configuration** { **configfile** *file-name-d* | **current-configuration** }
Display the contents of the configuration file for the next system startup.	**display saved-configuration** [**by-section** { **begin** | **exclude** | **include** } *regular-expression*]
Display the names of the configuration files for this startup and the next startup.	**display startup**
Display the valid configuration in the current view.	**display this** [**all**] [**by-section** { **begin** | **exclude** | **include** } *regular-expression*]
Display information about user-based configuration locking.	**display configuration exclusive by-user-name**
Delete next-startup configuration files.	**reset saved-configuration** [**backup** | **main**]
Clear rollback points.	**reset configuration commit** *number*

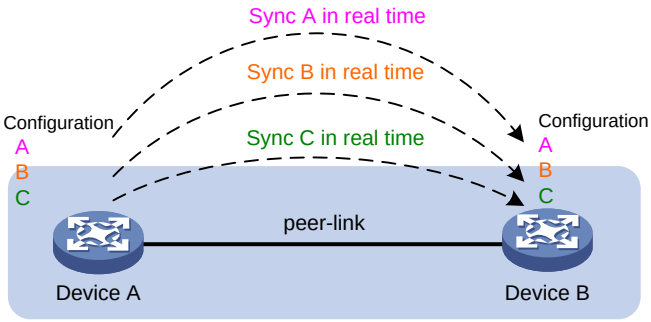
Multichassis configuration sync

About multichassis configuration sync



Multichassis configuration synchronization (sync) allows you to synchronize and back up configurations between multiple devices to simplify the configuration procedure, improve deployment efficiency, and optimize user experience. For example, after you configure one M-LAG member device, you can synchronize its configuration to the other M-LAG member device over the peer link for them to have identical configuration.

This feature is applicable only to the M-LAG system currently.

Real-time configuration sync

As shown in Figure 1, settings in multichassis configuration sync view of a member device are synchronized to its peer device in real time.

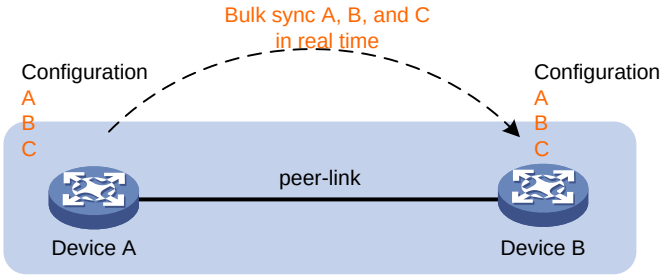


Figure 1 Real-time configuration sync

Bulk configuration sync

To fast deploy the services that are required to be consistent across the M-LAG member devices, configure the services on an M-LAG member device before M-LAG system setup. After the M-LAG system is set up and the peer link comes up, you can bulk synchronize settings on the member device to the same view for multichassis configuration sync on the M-LAG peer, as shown in Figure 2.

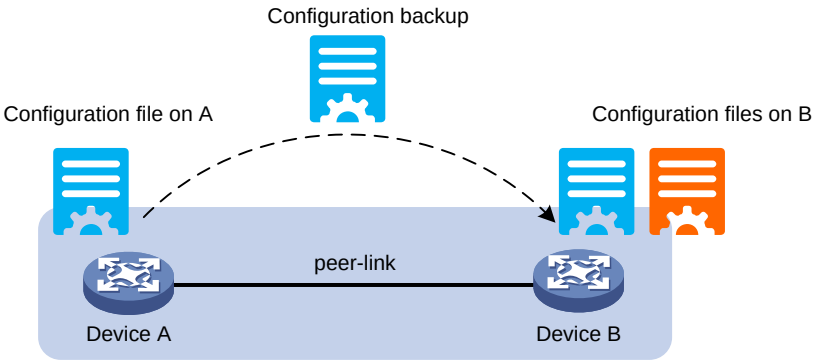

Figure 2 Bulk configuration sync

Configuration backup

If you are to update an M-LAG member device, for example, update the software version or replace the device, back up its configuration file to the M-LAG peer in advance as shown in Figure 3. After the update is completed, you can retrieve the previously saved configuration file from the peer device.

Figure 3 Configuration backup

Multichassis configuration sync tasks at a glance

To configure multichassis configuration sync, perform the following tasks:

- Synchronizing the configurations in real time
- Bulk synchronizing the configurations
- Fast configuring differential settings
- Backing up and restoring a configuration file

Restrictions and guidelines: multichassis configuration sync configuration

Only the S5200-HI-G switch series supports the multichassis configuration sync feature.

Restrictions and guidelines for multichassis configuration sync

Real-time or bulk configuration sync synchronizes only configurations required to be consistent across the M-LAG member devices.

Execute the **`mc-configure access-local enable`** command on both M-LAG member devices for them to access each another.

Before you use the multichassis configuration sync feature, verify that the M-LAG system is operating correctly and the peer link is up.

Synchronizing the configurations in real time

About this task

This feature enables commands executed in multichassis configuration sync view on an M-LAG member device to be synchronized to its M-LAG peer in real time.

Procedure

1. Enter system view.

   system-view

2. Permit the M-LAG peer to access the local device via the sync channel.

   mc-configure access-local enable

   By default, the M-LAG peer is permitted to access the local device via the sync channel.

3. Return to user view.

   quit

4. Enter multichassis configuration sync view.

   system-view mc-config

   Commands executed in any view for multichassis configuration sync will be synchronized to the M-LAG peer in real time.

Bulk synchronizing the configurations

About this task

To fast deploy the services that are required to be consistent across the M-LAG member devices, configure the services on an M-LAG member device before M-LAG system setup. After the M-LAG system is set up and the peer link comes up, you can use this feature to bulk synchronize settings on the member device to the same view for multichassis configuration sync on the M-LAG peer.

Procedure

1. Enter system view.

   system-view

2. Permit the M-LAG peer to access the local device via the sync channel.

   mc-configure access-local enable

   By default, the M-LAG peer is permitted to access the local device via the sync channel.

3. Pre-configure settings in system view and any view under system view as needed.

4. Return to user view.

   quit

5. Enter multichassis configuration sync view.

   system-view mc-config

6. Bulk synchronize the settings to the M-LAG peer.

   mc-configure batch-synchronize

   You can execute this command in any view for multichassis configuration sync.

   For example, if you execute this command in +[Sysname] view, the device will bulk synchronize the configurations in [Sysname] view and its sub-views to the peer device. If you execute this command in [Sysname1-GigabitEthernet1/0/1] view, the device will bulk synchronize the configurations in [Sysname1-GigabitEthernet1/0/1] view and its sub-views to the peer device.

Fast configuring differential settings

About this task

For settings required only on the local device, you can execute the **mc-configure switch-to-local** command in any view for multichassis configuration sync to switch to the same view of the local device and then configure the settings. To return to the original view for multichassis configuration sync after configuring the settings on the local device, execute the **mc-configure quit** command or press **Ctrl+Q**.

For the settings required only on the peer device, you can execute the **mc-configure switch-to-peer** in any view for multichassis configuration sync of the local device to switch to the same view of the peer device and then configure the settings. To return to the original view for multichassis configuration sync after configuring the settings on the peer device, execute the **mc-configure quit** command or press **Ctrl+Q**.

Configuring the differential settings on the local device

1. Enter multichassis configuration sync view.

   system-view mc-config
2. Switch to the same view of the local device.

   [@local] will be added to the commands executed in any view of the local device.

   mc-configure switch-to-local

   You can execute this command in any view for multichassis configuration sync.
3. Configure the differential commands on the local device.
4. Return to the original view for multichassis configuration sync.

   mc-configure quit

Configuring the differential settings on the M-LAG peer

1. Enter multichassis configuration sync view.

   system-view mc-config
2. Switch to the same view of the M-LAG peer.

   [@local] will be added to the commands executed in any view of the peer device.

   mc-configure switch-to-local

   You can execute this command in any view for multichassis configuration sync.
3. Configure the differential commands on the M-LAG peer.
4. Return to the original view for multichassis configuration sync.

   mc-configure quit

Backing up and restoring a configuration file

About this task

To update an M-LAG member device, for example, update the software version or replace the device, you can the **mc-configure backup-to-peer** command to back up its configuration file to the M-LAG peer in advance. After the update is completed, you can use the **mc-configure get-from-peer** command to retrieve the previously saved configuration file from the peer device and replace the configuration file on the local device.

Procedure

Execute the following command in user view to save the local configuration file to the M-LAG peer.

mc-configure backup-to-peer *local-filename*

Execute the following command in user view to retrieve the configuration file from the M-LAG peer.

mc-configure get-from-peer *filename*

Display and maintenance commands for multichassis configuration sync

Execute **display** commands in any view.

Task	Command
Display the configuration check result for multichassis configuration sync.	**display mc-configure config-check m-lag**
Display the configuration comparison result for multichassis configuration sync.	**display mc-configure config-compare** [**different** | [**interface** | **verbose**] [**by-table** [**width** *width-length*]]]
Display settings not synchronized during multichassis configuration sync.	**display mc-configure unsync-info**

Upgrading software

About software upgrade

Software upgrade enables you to upgrade a software version, add new features, and fix software bugs. This chapter describes software types and release forms, compares software upgrade methods, and provides the procedures for upgrading software from the CLI.

Software types

The following software types are available:

- **BootWare image**—Also called the Boot ROM image. This image contains a basic segment and an extended segment.
  - The basic segment is the minimum code that bootstraps the system.
  - The extended segment enables hardware initialization and provides system management menus. When the device cannot start up correctly, you can use the menus to load software and the startup configuration file or manage files.

  Typically, the BootWare image is integrated into the Boot image to avoid software compatibility errors.
- **Comware image**—Includes the following image subcategories:
  - **Boot image**—A .bin file that contains the Linux operating system kernel. It provides process management, memory management, file system management, and the emergency shell.
  - **System image**—A .bin file that contains the Comware kernel and standard features, including device management, configuration management, and routing.
  - **Feature image**—A .bin file that contains advanced or customized software features. You can purchase feature images as needed.
  - **Patch image**—A .bin file that is released for fixing bugs without rebooting the device. A patch image does not add or remove features.

    Patch images have the following types:

    - **Incremental patch images**—A new patch image can cover all, part, or none of the functions provided by an old patch image. A new patch image can coexist with an old patch image on the device only when the former covers none of the functions provided by the latter.
    - **Non-incremental patch images**—A new non-incremental patch image covers all functions provided by an old non-incremental patch image. Each boot, system, or feature image can have one non-incremental patch image, and these patch images can coexist on the device. The device uninstalls the old non-incremental patch image before installing a new non-incremental patch image.

    An incremental patch image and a non-incremental patch image can coexist on the device.

  Comware images that have been loaded are called current software images. Comware images specified to load at the next startup are called startup software images.

BootWare image, boot image, and system image are required for the device to operate.

You can install up to 32 .bin files on the device, including one boot image file, one system image file, and up to 30 feature and patch image files.

Software release forms

Software images are released in one of the following forms:

- Separate .bin files. You must verify compatibility between software images.
- As a whole in one .ipe package file. The images in an .ipe package file are compatible. The system decompresses the file automatically, loads the .bin images and sets them as startup software images.

NOTE:

Software image file names use the *model-comware version-im*age *type-release* format. This document uses **boot.bin** and **system.bin** as boot and system image file names.

Upgrade methods

Upgrade method	Software types	Remarks
Upgrading from the CLI by using the boot loader method	• BootWare image • Comware images (excluding incremental patches)	This method is disruptive. You must reboot the entire device to complete the upgrade.
Performing an ISSU from the CLI	Comware images	This method enables a software upgrade with a minimum amount of downtime. Use this method if possible. For more information about ISSU, see "Performing an ISSU."
Upgrading from the BootWare menu	• BootWare image • Comware images	Use this method when the device cannot start up correctly. To use this method, first connect to the console port and power cycle the device. Then, press **Ctrl+B** at prompt to access the BootWare menu. For more information about upgrading software from the BootWare menu, see the release notes for the software version. **IMPORTANT:** Use this method only when you do not have any other choice.

This chapter covers only upgrading software from the CLI by using the boot loader method.

Device software upgrade

Startup software images

To upgrade software, you must specify the upgrade files as the startup software images for the device to load at next startup. You can specify two lists of software images: one main and one backup. The device first loads the main startup software images. If the main startup software images are not available, the devices loads the backup startup software images.

Image loading process at startup

At startup, the device performs the following operations after loading and initializing BootWare:

1. Loads main images.
2. If any main image does not exist or is invalid, loads the backup images.
3. If any backup image does not exist or is invalid, checks the main or backup boot image.
4. If the main or backup boot image exist and is valid, enters the emergency shell.

If both the main and backup boot images do not exist or are invalid, the device cannot start up.

Handling the image loading failure

After the device enters the emergency shell, connect to the console port and load a system image so you can access the Comware system. For more information about using the emergency shell, see "Using the emergency shell."

If the device fails to load the images, connect to the console port, power cycle the device, and use the BootWare menu to load new startup images.

Application scenarios

Software upgrade

When the current software cannot meet the requirements of network operation or user services, you can upgrade the software to optimize device performance to meet the requirements.

Feature and patch package installation

To fix software defects without upgrading the software version, you can install patch packages compatible with the software version. To expand service features on the device, you can install the corresponding feature packages.

Digitally signed software images

The software images for the device are digitally signed for authenticity and integrity verification. This mechanism ensures that the software installed on the system is from a trusted source and has not been tampered with in the transfer, storage, or installation phase.

The system performs software digital signature verification for authenticity and integrity in the following situations:

- Before the system loads a software image during startup. If the digital signature verification fails, the system will not load the image and you will receive a digital signature verification failure message.
- When you specify a software image to upgrade the device from the BootWare menu. If the digital signature verification fails, the system will not set the image for upgrade and you will receive a digital signature verification failure message.
- Before the system loads a BootWare image to the Normal area of BootWare. If the digital signature verification fails, the system will not load the image and you will receive a digital signature verification failure message.
- When you specify a software image as a startup image through the boot loader. The system will verify the digital signature of the image before it updates the startup image list with the specified image. If the digital signature verification fails, the system will not update the startup image list and you will receive a digital signature verification failure message.
- When you specify startup images for an ISSU. The system verifies the digital signature of a software image for authenticity and integrity before it sets and loads that image as a main startup image. If the digital signature verification fails, the system will not set or load the image as a main startup image and you will receive a digital signature verification failure message. For more information about ISSU, see "Performing an ISSU."

- Before the system performs an ISSU. If the digital signature verification fails, the system will not perform the ISSU and you will receive a digital signature verification failure message. For more information about ISSU, see "Performing an ISSU."
- Before the system activates a feature or patch image. If the digital signature verification fails, the system will not activate the image and you will receive a digital signature verification failure message.

Restrictions and guidelines: Software upgrade

Do not execute the **`install`**, **`issu`**, or **`boot-loader`** command before the current upgrade action completes.

As a best practice, store the startup images in a fixed storage medium. If you store the startup images in a hot swappable storage medium, do not remove the hot swappable storage medium during the startup process.

Upgrading device software by using the boot loader method

Software upgrade tasks at a glance

To upgrade software, perform one of the following tasks:

1.
2. Upgrade the IRF fabric:
   a. (Optional.) Preloading the BootWare image to BootWare

      If a BootWare upgrade is required, you can perform this task to shorten the subsequent upgrade time. This task helps reduce upgrade problems caused by unexpected power failure. If you skip this task, the device upgrades the BootWare automatically when it upgrades the startup software images.

   b. Specifying startup images and completing the upgrade
3. (Optional.) Synchronizing startup images from the master device to subordinate devices

   Perform this task when the startup images on subordinate devices are not the same version as those on the master device.

Prerequisites

1. Use the **`display version`** command to verify the current BootWare image version and startup software version.
2. Use the release notes for the upgrade software version to evaluate the upgrade impact on your network and verify the following items:
   - Software and hardware compatibility.
   - Version and size of the upgrade software.
   - Compatibility of the upgrade software with the current BootWare image and startup software image.
3. Use the **`dir`** command to verify that all IRF member devices have sufficient storage space for the upgrade images. If the storage space is not sufficient on any member device, delete unused files by using the **`delete /unreserved`** command. For more information, see "Managing file systems."

4. Use FTP or TFTP to transfer the upgrade image file to the root directory of a file system. For more information about FTP and TFTP, see "Configuring FTP" or "Configuring TFTP." For more information about file systems, see "Managing file systems."

Preloading the BootWare image to BootWare

Perform the following steps in user view:

5.

6. Load the upgrade BootWare image to the Normal area of BootWare.

   bootrom update file *file* **slot** *slot-number-list*

   Specify the downloaded software image file for the *file* argument.

   The new BootWare image takes effect at a reboot.

NOTE:

The system will verify the digital signature of a BootWare image before it loads it to the Normal area of BootWare. If the digital signature verification fails, the system will not load the image and you will receive a digital signature verification failure message.

Specifying startup images and completing the upgrade

Perform the following steps in user view:

1. Specify main or backup startup images for all member devices.
   - Use an .ipe file:

     boot-loader file *ipe-filename* [**patch** *filename*&<1-16>] { **all** | **slot** *slot-number* } { **backup** | **main** }
   - Use .bin files:

     boot-loader file boot *filename* **system** *filename* [**feature** *filename*&<1-30>] [**patch** *filename*&<1-16>] { **all** | **slot** *slot-number* } { **backup** | **main** }

   As a best practice in a multichassis IRF fabric, specify the **all** keyword for the command. If you use the **slot** *slot-number* option to upgrade member devices one by one, version inconsistencies occur among the member devices during the upgrade.

NOTE:

The system will verify the digital signature of the specified images before it updates the startup image list with the specified images. If the digital signature verification fails, the system will not update the startup image list and you will receive a digital signature verification failure message.

2. Save the running configuration.

   save

   This step ensures that any configuration you have made can survive a reboot.
3. Reboot the IRF fabric.

   reboot
4. (Optional.) Verify the software image settings.

   display boot-loader [**slot** *slot-number*]

Verify that the current software images are the same as the startup software images.

Synchronizing startup images from the master device to subordinate devices

About this task

Perform this task when the startup images on subordinate devices are not the same version as those on the master device.

This task synchronizes startup images that are running on the master device to subordinate devices. If any of the startup images does not exist or is invalid, the synchronization fails.

The startup images synchronized to subordinate devices are set as main startup images, regardless of whether the source startup images are main or backup.

Restrictions and guidelines

If an ISSU or patch installation has been performed on the master device, use the **install commit** command to update the set of main startup images on the master device before software synchronization. This command ensures startup image consistency between the master and subordinate devices.

Procedure

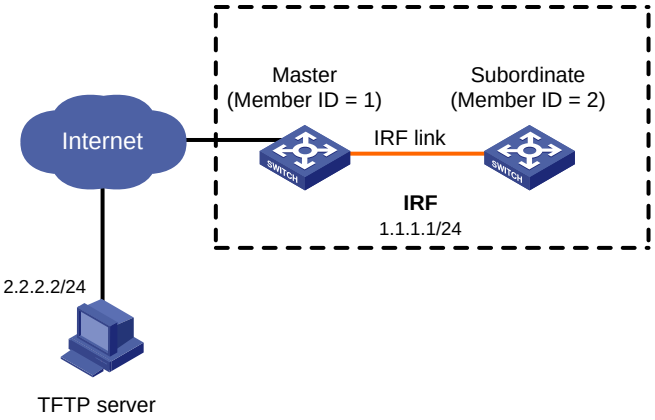
Perform the following steps in user view:

1. Synchronize startup images from the master to subordinate devices.
   boot-loader update { **all** | **slot** *slot-number* }
2. Reboot the subordinate devices.
   reboot slot *slot-number* [**force**]

Display and maintenance commands for software image settings

Execute **display** commands in any view.

Task	Command
Display current software images and startup software images.	**display boot-loader** [**slot** *slot-number*]



Software upgrade examples

Example: Upgrading device software

Network configuration

As shown in Figure 1, use the file **startup-a2105.ipe** to upgrade software images for the IRF fabric.

Figure 1 Network diagram

Procedure

Configure IP addresses and routes. Make sure the device and the TFTP server can reach each other.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ip address 1.1.1.1 24
[Sysname-GigabitEthernet1/0/1]quit
[Sysname] ip route-static 2.2.2.0 24 1.1.1.2
[Sysname] quit
```

Configure TFTP settings on both the device and the TFTP server. (Details not shown.)

Display information about the current software images.

```
<Sysname> display version
```

Back up the current software images.

```
<Sysname> copy boot.bin boot_backup.bin
<Sysname> copy system.bin system_backup.bin
```

Specify **boot_backup.bin** and **system_backup.bin** as the backup startup image files for all IRF member devices.

```
<Sysname> boot-loader file boot flash:/boot_backup.bin system flash:/system_backup.bin
slot 1 backup
<Sysname> boot-loader file boot flash:/boot_backup.bin system flash:/system_backup.bin
slot 2 backup
```

Use TFTP to download the **startup-a2105.ipe** image file from the TFTP server to the root directory of the flash memory on the master device.

```
<Sysname> tftp 2.2.2.2 get startup-a2105.ipe
```

Specify **startup-a2105.ipe** as the main startup image file for all IRF member devices.

```
<Sysname> boot-loader file flash:/startup-a2105.ipe slot 1 main
<Sysname> boot-loader file flash:/startup-a2105.ipe slot 2 main
```

Verify the startup image settings.

```
<Sysname> display boot-loader
```

Reboot the device to complete the upgrade.

```
<Sysname> reboot
```

Verify that the device is running the correct software.

```
<Sysname> display version
```

Performing an ISSU

About ISSU

The In-Service Software Upgrade (ISSU) feature upgrades the Comware software with a minimum amount of downtime.

Unless otherwise stated, the term "upgrade" refers to both software upgrade and downgrade in ISSU.

ISSU advantages

The Comware software includes the boot image, the system image, and feature images. ISSU supports upgrading the images individually.

When you use ISSU to upgrade a feature, only the related feature images are affected. Other features can continue to provide services.

ISSU supports installing patch images to fix system bugs without a system reboot.

ISSU methods

ISSU methods are determined at software release depending on the compatibility between software versions.

ISSU supports the following upgrade types:

- **Compatible upgrade**—The new software version is compatible with the running software version. This upgrade type supports the ISSU methods in Table 1.
- **Incompatible upgrade**—The new software version is incompatible with the running software version. The two versions cannot run concurrently.

  This upgrade type supports only one upgrade method (also called incompatible upgrade). This method requires a cold reboot to upgrade both control and data planes. Incompatible upgrade disrupts service if hardware redundancy is not available.

NOTE:

For the compatibility matrix, see the ISSU upgrade type matrix in the release notes.

For information about identifying the ISSU method, see "Identifying the ISSU methods."

Table 1 ISSU methods for compatible upgrade

ISSU method	Description
Incremental upgrade: • Service Upgrade • File Upgrade	Upgrades only user mode processes that have differences between the new and old software versions. Backup processes and a main/backup process switchover are required for service continuity. • **Service upgrade**—Upgrades service features. The upgrade does not affect the operation of the features that are not being upgraded. • **File upgrade**—Upgrades hidden system program files. The system can provide services during the upgrade.
Reboot	△ **CAUTION:** The Reboot method disrupts service if hardware redundancy is not available. As a best practice, schedule the downtime carefully to minimize the upgrade impact on

ISSU method	Description
	the services. Reboots member devices to complete the software upgrade. While one member device is rebooting, the other member devices can provide services.

ISSU commands

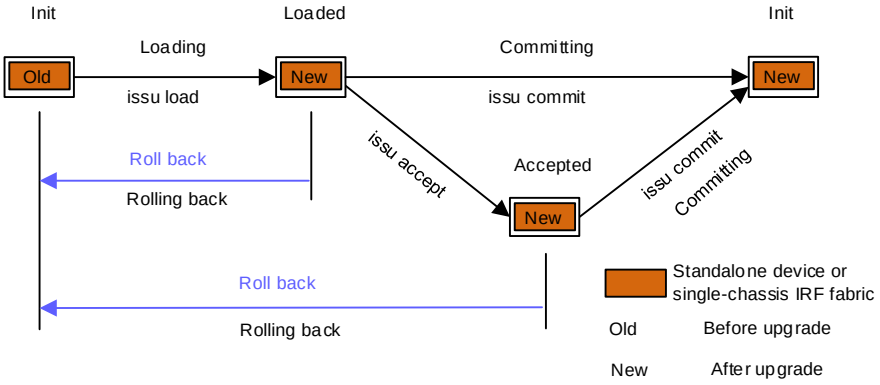
ISSU includes the **install** and **issu** command sets. After you identify the recommended ISSU method, use Table 2 to choose the command set you want to use.

Table 2 Command set comparison

Item	issu commands	install commands
Upgrade types	• Compatible. • Incompatible.	Compatible.
Impact on the system	Large.	Small.
Technical skill requirements	Low. As a best practice, use this command set.	High. Administrators must have extensive system knowledge and understand the impact of each upgrade task on the network.

Operating mechanism

Performing an incremental upgrade on a single-chassis IRF fabric



As shown in 0, the upgrade operates as follows:

1. The device is in Init state before the upgrade and enters Loading state when the **issu load** command is executed. When the upgrade completes, the device enters Loaded state.
2. The device enters Accepted state when the **issu accept** command is executed successfully to accept the upgrade to a compatible version and delete the automatic rollback timer.
3. The device enters Committing state when the **issu commit** command is executed to complete the ISSU upgrade to a compatible version, and it enters Init state when the upgrade completes.

IMPORTANT:

If a rollback is performed during the upgrade process, the system will roll back to the version before the upgrade.

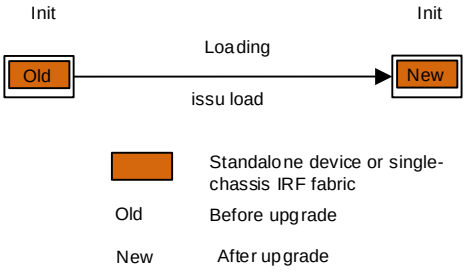


Figure 1 Performing an incremental upgrade on a standalone device or a single-chassis IRF fabric

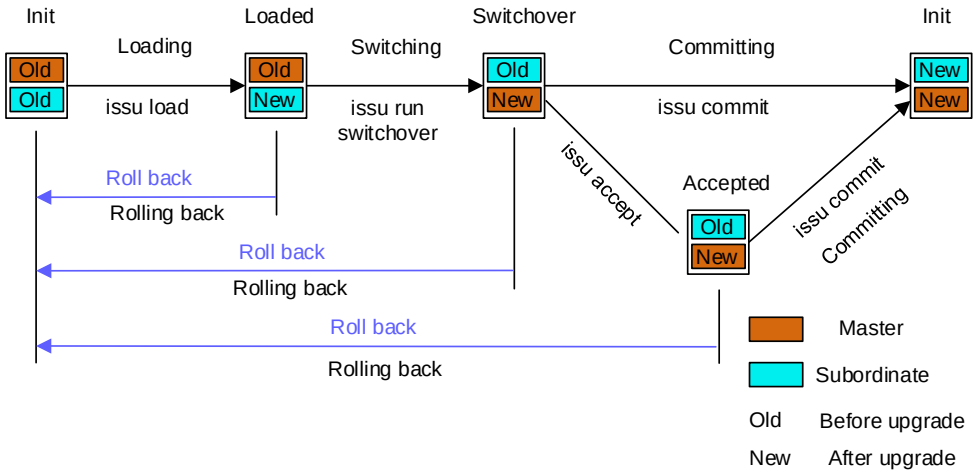
Performing an incremental upgrade on a single-chassis IRF fabric

As shown in Figure 2, the device is in Init state before the upgrade and enters Loading state when the **issu load** command is executed. When the upgrade completes, the device enters Loaded state.

Figure 2 Performing a reboot, ISSU reboot, or incompatible upgrade on a standalone device or single-chassis IRF fabric

Performing a compatible upgrade on a multichassis IRF fabric



As shown in 0, the upgrade operates as follows:

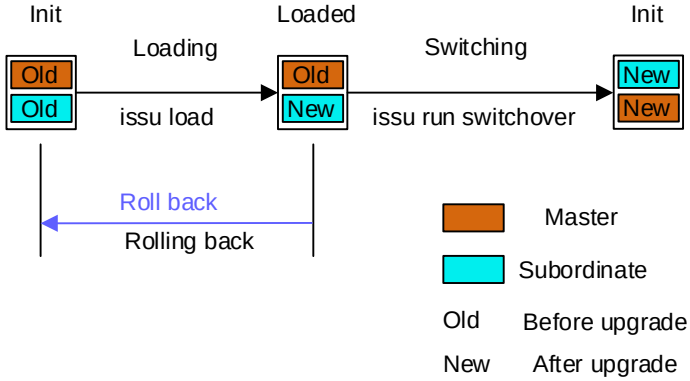
1. The device is in Init state before the upgrade and enters Loading state when the **issu load** command is executed to upgrade a subordinate device in the IRF fabric. When the upgrade completes, the device enters Loaded state.
2. The device enters Switching state when the **issu run switchover** command is executed to perform an ISSU switchover. When the switchover completes, the device enters Switchover state.
3. The device enters Accepted state when the **issu accept** command is executed successfully to accept the upgrade to a compatible version and delete the automatic rollback timer.
4. The device enters Committing state when the **issu commit** command is executed to upgrade all other member devices in the IRF fabric. When the upgrade completes, the device enters Init state.

IMPORTANT:

If a rollback is performed during the upgrade process, the system will roll back to the version before the upgrade.

Figure 3 Performing a compatible upgrade on a multichassis IRF fabric

Performing an incompatible upgrade on a multichassis IRF fabric



As shown in 0, the upgrade operates as follows:

1. The device is in Init state before the upgrade and enters Loading state when the **`issu load`** command is executed to upgrade a subordinate device in the IRF fabric. When the upgrade completes, the device enters Loaded state.
2. The device enters Switching state when the **`issu run switchover`** command is executed to perform an ISSU switchover. All the other members will be upgraded. When the switchover completes, the device enters Init state.

IMPORTANT:

If a rollback is performed during the upgrade process, the system will roll back to the version before the upgrade.

Figure 4 Performing an incompatible upgrade on a multichassis IRF fabric

Application scenarios

Traditional software upgrade methods require a device reboot, which will affect the services running on the system and communication service quality. To address this issue, you can use ISSU to upgrade the software to ensure uninterrupted services or a short service interruption period during the upgrade process.

Restrictions and guidelines: ISSU

IMPORTANT:

- For a successful ISSU, you must remove all commands that the new version does not support and save the running configuration. To identify the feature changes between the current version and the new version, read the release notes for the device.
- To ensure correct system operation, you must remove the commands configured for features to be uninstalled and save the running configuration before uninstalling the features.

During an ISSU, follow these restrictions and guidelines:

- Do not execute the **`install`**, **`issu`**, or **`boot-loader`** command before the current upgrade action completes.
- Do not perform any of the following tasks:
  - Reboot member devices.
  - Perform tasks that are irrelevant to the ISSU, such as modifying the configuration and displaying information.
  - Modify, delete, or rename image files.
- You cannot use both **`install`** and **`issu`** commands for the same ISSU.
- For better service continuity, strictly follow the recommended ISSU procedure. Make sure a step is completed before you proceed to the next step.
- Before executing the **`issu load`** command for the first time, use the **`display system stable state`** command to verify that the system is stable. If the **System State** field displays **Stable**, the system is stable.
- Before executing the following commands, use the **`display system stable state`** command to verify that the system is stable:
  - **issu commands**—**`issu load`**, **`issu run switchover`**, and **`issu commit`**.
  - **install commands**—**`install activate`** and **`install deactivate`**.

  If the **System State** field displays **Stable**, the system is stable.
- You may use **`issu`** commands to upgrade all or some of the software images. If you are upgrading only some of the images, make sure the new images are compatible with the images that are not to be upgraded. The upgrade will fail if a conflict exists.
- You can install up to 32 .bin files on the device, including one boot image file, one system image file, and up to 30 feature and patch image files.
- A patch image file can be incremental or non-incremental. You can install up to 30 incremental patch image files by using a single command. Because each boot, system, or feature image can have one non-incremental patch image file, you can install up to 16 non-incremental patch image files by using a single command. For more information about incremental and non-incremental patch image files, see "Upgrading software."

After an ISSU, you must log in to the device again before you can use the changed or added commands.

After an ISSU, use the **`display boot-loader`** command to verify that the new software images have been successfully loaded. The startup software images must always be in the flash memory and cannot be deleted. If you delete them, the device cannot restart after being rebooted.

Prerequisites for ISSU

To perform a successful ISSU, make sure all the preparation requirements are met.

Logging in to the device through the console port

Log in to the device through the console port. If you use Telnet or SSH, you might be disconnected from the device before the ISSU is completed.

In a multiuser environment, make sure no other administrators access the device while you are performing the ISSU.

Identifying availability of ISSU

Read the software release notes to identify support of the device for ISSU between the current software version and the new software version.

Verifying the device operating status

Verify the following items:

Use the **display device** command to verify that all components are operating correctly.

- Use the **display irf** command to verify that all member devices are operating correctly.
- Use the **display cpu-usage** command to verify that no CPU usage alarm exists on the device. As a best practice, verify that the CPU usage is lower than the CPU usage recovery threshold on each component.
- Use the **display memory** and **display memory-threshold** commands to verify that no memory alarm exists on the device. As a best practice, verify that the free memory is greater than the normal state threshold on each component.
- Use the **display fan** command to verify that all fans are in **Normal** state.
- Use the **display power** command to verify that all power supplies are in **Normal** state.
- Use the **display environment** command to verify that the temperature of each component is lower than the high-temperature warning threshold.
- Use the **display counters rate inbound interface** command to verify that all interfaces are forwarding packets correctly.
- Use the **display interface | include CRC** command to verify that all interfaces are forwarding packets correctly.

Preparing the upgrade images

1. Use the **dir** command to verify that every file system has sufficient free storage space for the upgrade images. If the storage space is not sufficient, delete unused files by using the **delete /unreserved** *file-url* command. If the files to be deleted will be used, back up the files before deleting them. You will be unable to restore a deleted file if the **/unreserved** keyword is used. For more information, see "Managing file systems."
2. Use FTP or TFTP to transfer upgrade image files (in .bin or .ipe) to the root directory of a file system on the master device.

Identifying the ISSU methods

1. Execute the **display version comp-matrix file** command to identify the recommended ISSU methods.

- For a compatible upgrade, check the **Upgrade Way** field to identify the recommended ISSU methods.
- For an incompatible upgrade, check the end of command output for the **Incompatible upgrade** string.

For more information about ISSU methods, see Table 1.

Verifying the device configuration

For a successful ISSU reboot or incompatible upgrade and the IRF fabric integrity during the ISSU, a set of features must have the same configuration as expected after the upgrade. The following are the features and the commands for you to change and verify feature settings:

Maximum number of ECMP routes.

`max-ecmp-num`

`display max-ecmp-num`

For more information about ECMP routes, see basic IP routing configuration in *Layer 3—IP Routing Configuration Guide*.

Verifying feature status

For service continuity during an ISSU, configure the following feature settings:

Feature	Setting requirements
GR and NSR	Enable GR or NSR for protocols including OSPF, ISIS, BGP, and FSPF. Use the **`display`** commands to verify that the system is in stable state after GR or NSR is enabled for a protocol. For example, use the **`display ospf graceful-restart`** or **`display ospf non-stop-routing status`** command to verify that the system is in stable state after GR or NSR is enabled for OSPF.
BFD	Disable BFD for protocols including OSPF, IS-IS, RIP, BGP, VRRP, and NQA.
Ethernet link aggregation	Use the long LACP timeout interval (the **`lacp period short`** command is not configured) on all member ports in dynamic aggregation groups. Make sure all member ports are Selected ports.
IRF	Before performing an incompatible upgrade for the IRF fabric, verify that IRF MAD is disabled. To use IRF MAD, enable IRF MAD after finishing the upgrade. Configure IRF bridge MAC persistence as follows: • **Compatible upgrade**—Execute the **`irf mac-address persistent timer`** or **`irf mac-address persistent always`** command. • **Incompatible upgrade**—Execute the **`irf mac-address persistent always`** command if the bridge MAC address is the MAC address of the device for which you want to execute the **`issu load`** command.

Determining the upgrade procedure

1. Use Table 2 to choose an upgrade command set, depending on the ISSU method.
2. Identify the hardware redundancy condition.

ISSU can maintain service continuity only when the following conditions are met:

- The IRF fabric has multiple members and uses the ring topology.

IMPORTANT:

If hardware redundancy is not available, service discontinuity is not avoidable during a reboot upgrade or an incompatible upgrade. Make sure you understand the impact of the upgrade on the network.

3. Choose the correct procedure from the procedures described in "Performing an ISSU step by step by using issu commands" or "Performing an ISSU by using install commands."

Adjusting and saving the running configuration

1. Remove all commands that the new software version does not support from the running configuration. To identify all feature changes between the current version and the new version, read the release notes for the device.
2. To uninstall a feature image, remove the commands configured for the feature.
3. Use the **save** command to save the running configuration.

Performing an ISSU step by step by using issu commands

Performing a compatible upgrade on a multichassis IRF fabric

Restrictions and guidelines

Upgrade a subordinate member device first. Then, upgrade the remaining member devices, including the original master.

Procedure

1. (Optional.) Configure automatic rollback:
   a. Enter system view.
      system-view
   b. Set the automatic rollback timer.
      issu rollback-timer *minutes*
      By default, the automatic rollback timer is set to 45 minutes.
      The automatic rollback timer starts when you execute the **issu run switchover** command.
   c. Return to user view.
      quit
2. Verify that the system is stable.
   display system stable state
   The system is stable if the **System State** field displays **Stable**. For a successful ISSU, you must make sure the system is stable before you proceed to the next step.
3. Load the upgrade images as startup images on a subordinate member.

- Use .bin files:

  issu load file { **boot** *filename* | **system** *filename* | **feature** *filename*&<1-30> | **patch** *filename*&<1-30> } * **slot** *slot-number*&<1-9> [**reboot**]

- Use an .ipe file:

  issu load file ipe *ipe-filename* [**patch** *filename*&<1-30>] **slot** *slot-number*&<1-9> [**reboot**]

NOTE:

The software images for the device are digitally signed. The system verifies the digital signatures of the specified software images for authenticity and integrity before it sets or loads them as main startup images. If the digital signature verification fails, the system will not set or load the specified images as main startup images and you will receive a digital signature verification failure message.

4. Verify that the system is stable.

   display system stable state

   The system is stable if the **System State** field displays **Stable**. For a successful ISSU, you must make sure the system is stable before you proceed to the next step. If the system reported an error in the previous step, verify that the system is stable and then use the **issu rollback** command to roll back the upgrade.

5. Perform an ISSU switchover.

   issu run switchover

   This command also starts the automatic rollback timer. When the timer expires, the system automatically rolls back to the original software images.

6. (Optional.) Accept the upgrade and delete the automatic rollback timer.

   issu accept

   Execute this command before the automatic rollback timer expires.

7. Verify that the system is stable.

   display system stable state

   The system is stable if the **System State** field displays **Stable**. For a successful ISSU, you must make sure the system is stable before you proceed to the next step. If the system reported an error in the previous two steps, verify that the system is stable and then use the **issu rollback** command to roll back the upgrade.

8. Upgrade the remaining members to complete the ISSU.

   issu commit slot *slot-number*

   Execute this command before the automatic rollback timer expires.

△ **CAUTION:**

Repeat the previous step and this step to upgrade the remaining member devices, including the original master device. After you execute this command for one member device, wait for the member device to start up and join the IRF fabric again before you upgrade another member device. This practice ensures a successful ISSU.

9. Verify that the ISSU is finished.

   display issu state

   If the **ISSU state** field displays **Init**, the ISSU is finished.

Performing an incompatible upgrade on a multichassis IRF fabric

Restrictions and guidelines

Upgrade one or more subordinate member devices first. Then, upgrade the remaining member devices, including the original master.

Procedure

To perform an incompatible upgrade on a multichassis IRF fabric, execute the following commands in user view:

1. Verify that the system is stable.

   display system stable state

   The system is stable if the **System State** field displays **Stable**. For a successful ISSU, you must make sure the system is stable before you proceed to the next step.

2. Load the upgrade images as startup images on subordinate members.

   - Use .bin files:

     issu load file { **boot** *filename* | **system** *filename* | **feature** *filename*&<1-30> | **patch** *filename*&<1-30> } * **slot** *slot-number*&<1-9> [**reboot**]

   - Use an .ipe file:

     issu load file ipe *ipe-filename* [**patch** *filename*&<1-30>] **slot** *slot-number*&<1-9> [**reboot**]

   As a best practice on a ring-topology IRF fabric, specify half of the subordinate members for this command to reduce service interruption. Make sure the specified subordinate members are physically connected.

   NOTE:

   The software images for the device are digitally signed. The system verifies the digital signatures of the specified software images for authenticity and integrity before it sets or loads them as main startup images. If the digital signature verification fails, the system will not set or load the specified images as main startup images and you will receive a digital signature verification failure message.

3. Verify that the system is stable.

   display system stable state

   The system is stable if the **System State** field displays **Stable**. For a successful ISSU, you must make sure the system is stable before you proceed to the next step. If the system reported an error in the previous step, verify that the system is stable and then use the **issu rollback** command to roll back the upgrade.

4. Perform an ISSU switchover to complete the ISSU process.

   issu run switchover

   This command upgrades the remaining members.

5. Verify that the ISSU is finished.

   display issu state

   If the **ISSU state** field displays **Init**, the ISSU is finished.

Performing an ISSU by using install commands

ISSU tasks at a glance

1. (Optional.) Decompressing an .ipe file
2. Installing and upgrading software images
3. (Optional.) Deactivating software images
4. (Optional.) Rolling back the running software images
5. (Optional.) Aborting a software activate or deactivate operation
6. (Optional.) Verifying software images
7. Committing software changes
8. (Optional.) Deleting inactive software images

Decompressing an .ipe file

1. (Optional.) Identify images that are included in the .ipe file.
   `display install ipe-info`
2. Decompress the .ipe file.
   `install add` *`ipe-filename filesystem`*

Installing and upgrading software images

About this task

Use this task to install new feature and patch images or upgrade the boot, system, or feature images.

Software image installation and upgrade methods

Use one of the following methods to install or upgrade software images:

- **Slot by slot**—Activate all the images on one slot, and then move to the next slot.
- **Image by image**—Activate one image on all slots before moving to another image. Before using this method, read the release notes to make sure the upgrade images are compatible with the current images. If the upgrade images are not compatible with the current images, the upgrade might fail.

Restrictions and guidelines

To install an image, you must begin with the master device. To upgrade an image, you must begin with a subordinate device.

For incremental upgrades and patch installations, the software images take effect only during the current device operation. For the software image to take effect across device reboots, you must execute the **`install commit`** command. For reboot upgrades, you do not need to execute this command, because the system has already modified the next startup software list when you execute the **`install activate`** command.

Installing or upgrading boot, system, and feature images

Execute the following commands in user view:

1. Verify that the system is stable.
   `display system stable state`

   The system is stable if the **System State** field displays **Stable**. For a successful ISSU, you must make sure the system is stable before you proceed to the next step.

2. (Optional.) Identify the recommended ISSU method and the possible impact of the upgrade.

   install activate { **boot** *filename* | **system** *filename* | **feature** *filename*&<1-30> } * **slot** *slot-number* **test**

3. Activate images.

   install activate { **boot** *filename* | **system** *filename* | **feature** *filename*&<1-30> } * **slot** *slot-number*

NOTE:

The software images for the device are digitally signed. The system will verify the digital signatures of the specified software images for authenticity and integrity before it activates them. If the digital signature verification fails, the system will not activate the specified images and you will receive a digital signature verification failure message.

Installing patch images

To install patch images, execute the following commands in user view:

Table 3 Verify that the system is stable.

display system stable state

The system is stable if the **System State** field displays **Stable**. For a successful installation, you must make sure the system is stable before you proceed to the next step.

1. Install patch images.

   install activate patch *filename* { **all** | **slot** *slot-number* }

   You can specify only one patch image file for this command at a time. However, you can execute this command multiple times to install multiple patch image files.

   The **install activate patch** *filename* **all** command installs the specified patch images on all hardware and the images can survive a reboot. You do not need to execute the **install commit** command for the installation.

NOTE:

The software images for the device are digitally signed. The system verifies the digital signature of a patch image for authenticity and integrity before it activates it. If the digital signature verification fails, the system will not activate the image and you will receive a digital signature verification failure message.

Deactivating software images

Restrictions and guidelines

You can deactivate only feature and patch images.

The deactivate operation only removes images from the current software image list. For the image changes to take effect after a reboot, you must perform a commit operation to remove the images from the main startup image list.

Deactivated images are still stored on the storage medium. To permanently delete the images, execute the **install remove** command. For more information, see "Deleting inactive software images."

Deactivating feature images

To deactivate feature images, execute the following commands in user view:

Table 4 Verify that the system is stable.

display system stable state

The system is stable if the **System State** field displays **Stable**. For a successful deactivate operation, you must make sure the system is stable before you proceed to the next step.

1. Deactivate feature images.

   install deactivate feature *filename*&<1-30> **slot** *slot-number*

Deactivating patch images

To deactivate patch images, execute the following commands in user view:

Table 5 Verify that the system is stable.

display system stable state

The system is stable if the **System State** field displays **Stable**. For a successful deactivate operation, you must make sure the system is stable before you proceed to the next step.

1. Deactivate patch images.

   install deactivate patch *filename* { **all** | **slot** *slot-number* }

   You can specify only one patch image file for this command at a time. However, you can execute this command multiple times to deactivate multiple patch image files.

   The **install deactivate patch** *filename* **all** command deactivates the specified patch images on all hardware and the image changes can survive a reboot. You do not need to execute the **install commit** command for the deactivation.

Rolling back the running software images

About this task

During an incremental upgrade, the system creates a rollback point for each activate or deactivate operation of a boot, system, or feature image. The system can maintain a maximum of 50 rollback points. If this limit has been reached when a rollback point is created, the system removes the earliest rollback point. You can roll back the software to any of the rollback points.

During a reboot upgrade, the system does not create rollback points. After a reboot upgrade, you can roll back the software only to the status before any activate or deactivate operations were performed.

Restrictions and guidelines

You can perform this task only before committing software changes. A commit operation deletes all rollback points.

For an incremental upgrade rollback to take effect after a reboot, you must perform a commit operation to update the main startup image list.

Procedure

To roll back the running software images, execute the following commands in user view:

1. (Optional.) Display available rollback points.

   display install rollback

2. Roll back the software.

   install rollback to { *point-id* | **original** }

Aborting a software activate or deactivate operation

About this task

While the system is activating or deactivating a software image for a service upgrade or file upgrade, you can abort the activate or deactivate operation. After an operation is aborted, the system runs with the software images that it was running with before the operation.

Procedure

To abort a software activate or deactivate operation, use one of the following methods:

- Execute the **install abort** [*job-id*] command in user view.
- Press **Ctrl+C**.

Committing software changes

About this task

When you activate or deactivate images for an incremental upgrade, or activate or deactivate patch images, the main startup image list does not update with the changes. The software changes are lost at reboot. For the changes to take effect after a reboot, you must commit the changes.

Procedure

To commit software changes, execute the following command in user view:

install commit

Verifying software images

About this task

Perform this task to verify the following items:

- **Integrity**—Verify that the boot, system, and feature images are integral.
- **Consistency**—Verify that the same active images are running across the entire system.
- **Software commit status**—Verify that the active images are committed as needed.

Procedure

To verify software images, execute the following commands in user view:

1. Verify software images.
   install verify
2. Activate or deactivate images as required.
   install { **activate** | **deactivate** }
3. Commit the software changes.
   install commit

Deleting inactive software images

About this task

After completing an ISSU, you can use this task to delete old image files permanently.

Restrictions and guidelines

This task deletes image files permanently. You cannot use the **install rollback to** command to revert the operation, or use the **install abort** command to abort the operation.

Procedure

To delete inactive software image files, execute the following command in user view:

install remove [**slot** *slot-number*] { *filename* | **inactive** }

Terminating the ongoing ISSU process forcibly

About this task

Use this feature to terminate the ISSU process if one of the following exceptions occurs and you cannot perform an upgrade or rollback:

- The ISSU status is not **Init** but the upgrade has stopped.
- The ISSU status is **Init** but the upgrade has not completed.

Procedure

1. Enter system view.
   system-view
2. Terminate the ongoing ISSU process forcibly.
   issu quit

Display and maintenance commands for ISSU

CAUTION:
The **reset install rollback oldest** command clears the specified rollback point and all rollback points earlier than the specified rollback point. You will be unable to roll back the configuration to the status when any of these rollback points was created.

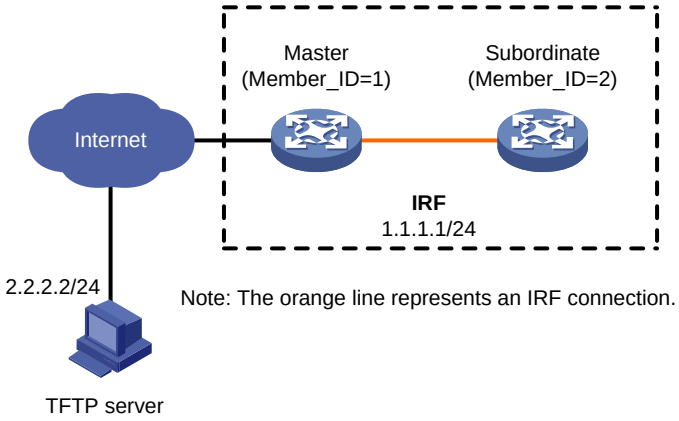
Unless otherwise stated, the **display** and **reset** commands can be used during an ISSU, regardless of whether the **install** or **issu** commands are used.

Execute **display** commands in any view and **reset** commands in user view.

Task	Command	Remarks
Display active software images.	**display install active** [**slot** *slot-number*] [**verbose**]	N/A
Display backup startup software images.	**display install backup** [**slot** *slot-number*] [**verbose**]	N/A
Display main startup software images.	**display install committed** [**slot** *slot-number*] [**verbose**]	N/A
Display inactive software images in the root	**display install inactive** [**slot** *slot-number*]	N/A

Task	Command	Remarks
directories of file systems.	[**verbose**]	
Display the software images included in an .ipe file.	**display install ipe-info** *ipe-filename*	N/A
Display ongoing ISSU activate, deactivate, and rollback operations.	**display install job**	N/A
Display ISSU log entries.	**display install log** [*log-id*] [**verbose**]	N/A
Display software image file information.	**display install package** { *filename* | **all** } [**verbose**]	N/A
Display rollback point information.	**display install rollback** [*point-id*]	The system does not record rollback points during an ISSU that uses **issu** commands.
Display the software image file that includes a specific component or file.	**display install which** { **component** *name* | **file** *filename* } [**slot** *slot-number*]	N/A
Display automatic rollback timer information.	**display issu rollback-timer**	N/A
Display ISSU status information.	**display issu state**	This command applies only to an ISSU that uses **issu** commands.
Display the ISSU methods.	**display version comp-matrix file** { **boot** *filename* | **system** *filename* | **feature** *filename*&<1-30> | **patch** *filename*&<1-30> } * **display version comp-matrix file ipe** *ipe-filename* [**patch** *filename*&<1-30>]	N/A
Clear ISSU log entries.	**reset install log-history oldest** *log-number*	N/A
Clear ISSU rollback points.	**reset install rollback oldest** *point-id*	N/A

Examples of using issu commands for ISSU



Example: Upgrading the system software to a compatible version

Network configuration

As shown in Figure 5, the IRF fabric has two members.

Upgrade the boot, system, and feature images from T0001015 to T0001016. The two versions are compatible.

Figure 5 Network diagram

Procedure

Download the upgrade image files from the TFTP server.

```
<Sysname> tftp 2.2.2.2 get boot-t0001016.bin
  % Total    % Received % Xferd  Average Speed   Time    Time     Time  Current
                                 Dload  Upload   Total   Spent    Left  Speed

  flash:/system-t0001015.bin
```

```
  flash:/feature1-t0001016.bin
```

Example: Rolling back a feature

Network configuration

As shown in Figure 8, the IRF fabric has two members. The Feature1 feature has been upgraded from T0001015 to T0001016. However, the software change has not been committed.

Roll back the Feature1 feature from T0001016 to T0001015.

Procedure

Display active software images.

```
<Sysname> display install active
Active packages on slot 1:
  flash:/boot-t0001015.bin
  flash:/system-t0001015.bin
  flash:/feature1-t0001016.bin
Active packages on slot2:
  flash:/boot-t0001015.bin
  flash:/system-t0001015.bin
  flash:/feature1-t0001016.bin
```

Display available rollback points.

```
<Sysname> display install rollback
  Install rollback information 1 on slot 1:
    Updating from flash:/feature1-t0001015.bin
             to flash:/feature1-t0001016.bin.
  Install rollback information 2 on slot 2:
    Updating from flash:/feature1-t0001015.bin
             to flash:/feature1-t0001016.bin.
```

Roll back the Feature1 feature to T0001015.

```
<Sysname> install rollback to original
This operation might take several minutes, please wait...Done.
```

Verify that the IRF members are running the old Feature1 image.

```
<Sysname> display install active

Configuring graceful insertion and removal

About graceful insertion and removal

Graceful insertion and removal (GIR) enables you to gracefully isolate the device from the network for device maintenance or upgrade. GIR minimizes service interruption by instructing the affected protocols (for example, routing protocols) to isolate the device and switch over to the redundant path. You do not need to configure graceful switchover protocol by protocol.

GIR modes

The device can operate in either of the following GIR modes:

- **Normal mode**—The device can forward traffic.
- **Maintenance mode**—The device is gracefully placed out of service for maintenance or upgrade purposes. In this mode, the device cannot forward traffic.

How GIR works

Overview

When you place the device in maintenance mode, GIR instructs each affected protocol (for example, BGP) to remove the device from the network. Then, each protocol takes action as instructed to isolate the device and switch over to the redundant path. When you change the device back to normal mode, GIR instructs the affected protocols to add the device back to the network. These protocols are called GIR-capable protocols.

To record the configuration before and after a GIR operation, GIR takes a snapshot of protocol data when the device changes to maintenance mode and when the device changes back to normal mode. You can compare the snapshots to verify configuration data consistency for each protocol.

GIR supports the following protocols: LACP, BGP, IS-IS, OSPF, and OSPFv3. For more information about how each protocol isolates the device, see its configuration guide.

Protocol isolation methods

GIR-capable protocols typically use the isolate and shutdown methods to isolate the device from the network. The following information uses OSPF for example to describe the isolation procedures.

- Isolate switching:
  a. When you place the device in maintenance mode, GIR executes the **`isolate enable`** command for OSPF to increase the link cost in the LSAs advertised by the device.
  b. Each OSPF neighbor of the device reselects an optimal route based on the LSAs and stops forwarding traffic to the device. After the device is fully isolated from the network, you can upgrade the device.
  c. When you revert the device back to normal mode, GIR executes the **`undo isolate enable`** command for OSPF to restore its original link cost and gracefully add the device back to the network.
- Shutdown method:
  d. After a process is shut down by using the **`shutdown process`** command, it sends 1-way hello packets to its neighbors

e. On receipt of the packets, the neighbors disconnect from the OSPF process and use the backup path to forward traffic.

f. The process stops receiving and sending OSPF packets.

g. The process clears its neighbor, LSDB, and OSPF route information.

Compared with the shutdown method, the isolate method uses more resources, but it can faster restore a protocol to the state before the isolation. For more information about the **`isolate enable`** and **`shutdown process`** commands for OSPF, see OSPF commands in *Layer 3—IP Routing Command Reference*.

GIR mode switching

GIR supports the following methods for you to change the device from normal mode to maintenance mode:

- **Isolate switching**—By default, GIR performs isolate switching to change the device from normal mode to maintenance mode if you do not specify shutdown or profile-based switching. With isolate switching, GIR uses the isolation commands for each GIR-capable protocol to isolate the device.
- **Shutdown switching**—GIR uses the shutdown method for each GIR-aware protocol to isolate the device when it changes the device from normal mode to maintenance mode. With this method, GIR also shuts down all interfaces except the management port.
- **Profile-based switching**—GIR executes the custom profile when it changes the system from normal mode to maintenance mode.

NOTE:

A custom profile contains a series of user-specified commands to be executed in sequence upon a mode switching. With GIR, you can configure one switch-to-maintenance profile and one switch-to-normal profile for changing to maintenance mode and normal mode, respectively.

When GIR performs an isolate or shutdown switching, it automatically writes the executed series of commands to the switch-to-maintenance custom profile if the profile is empty.

GIR supports the following methods for you to change the device from maintenance mode back to normal mode:

- **Profile-based switching**—Configure GIR to execute a custom profile for mode switching.
- **Reverse switching**—Configure GIR to perform operations in reverse to the operations performed when it changed from normal mode to maintenance mode.

When GIR performs a reverse switching, it automatically writes the executed series of commands to the switch-to-normal custom profile if the profile is empty.

GIR snapshots

A GIR snapshot records the running data of the device in NETCONF format at a point in time for system restoration or comparison of data to identify changes over time.

GIR snapshots include automatically generated snapshots and manually created snapshots.

The device automatically generates in the following situations:

- When the device enters maintenance mode, it generates a GIR snapshot named **before_maintenance** before each protocol switches traffic over to the redundant path.
- When the device returns to normal mode, it generates a GIR snapshot named **after_maintenance** after all protocols insert the device back into the traffic path and the system enters the stable state. You can use the **`display system stable state`** command to verify that the system is stable.

The device stores only the automatically generated snapshots for the most recent GIR operation.

With GIR, you can compare snapshots to identify data changes over a period of time. For example, you can identify the configuration differences of the device before and after a GIR operation by comparing the two automatically snapshots.

Restrictions: Hardware compatibility with GIR

Only the S5200-HI-G switch series supports GIR.

GIR tasks at a glance

To configure GIR, perform the following tasks:

1. Configuring a custom profile

   To perform profile-based switching, configure custom profiles.
2. Perform a mode switching operation
   a. Switching to maintenance mode
   b. Switching back to normal mode
3. Managing GIR snapshots
   - Manually creating a snapshot
   - Manually deleting snapshot
   - Including additional data in snapshots
4. Configuring advanced GIR features
   - Configuring the delay for the device to enter maintenance mode
   - Specifying a delay for after_maintenance snapshot creation

Configuring a custom profile

About this task

By default, GIR performs isolate switching to change the device from normal mode to maintenance mode. To customize the commands to execute and the interfaces to shut down for a profile-based mode switching, perform this task.

A custom profile contains a series of user-specified commands to be executed in sequence upon a mode switching.

With GIR, you can configure one switch-to-maintenance profile and one switch-to-normal profile for changing to maintenance mode and normal mode, respectively.

For more information about mode switching with GIR, see "How GIR works."

Restrictions and guidelines

CAUTION:

When you configure a custom profile, make sure you understand the impact of each command on the device and enter the commands in their correct form. Misconfiguration might cause traffic switchover failure.

When you edit a customer profile, use the following guidelines:

- You can only append commands to the end of a custom profile. You cannot remove or modify commands in a custom profile or insert a command between commands in the profile, except that you can edit the sleep instance settings.

  As a best practice, use the following steps to configure a custom profile:

  a. Add the series of commands to be executed to a text file.

  b. Verify that the commands are correct in form and order.

  c. Copy the commands to the custom profile in custom profile view.

  To modify a custom profile:

  d. Edit the command file.

  e. Delete the custom profile.

  f. Copy the commands to the custom profile in custom profile view.
- The system executes the commands in a custom profile in their configuration order. If one command depends on another, enter the prerequisite command first.
- Do not add commands in user view to custom profiles. The system can execute only commands in system view or subviews of system view.
- By default, the system executes the commands in a custom profile in system view. To execute a command in a subview of system view, you must add the command used to access that subview before you add the command to execute in that subview.
- If it takes some time for a command to take effect after it is executed, you can add the **`sleep instance`** command next to it to introduce a delay. The system will wait for the delay to expire before it executes subsequent commands. If you are not sure whether a command requires a delay, add the **`sleep instance 0`** command next to it. Then, you can change the value after you determine that a delay is required.
- If you have inadvertently entered an incorrect command, you can add its **undo** form to remove it as long as that command is reversible by simply adding the **undo** keyword before it. Then, the system will automatically delete that command and its **undo** form from the profile. You cannot use this method to remove a command if it does not have an **undo** form or if the command and its **undo** form is not symmetric.
- The system provides the following mechanisms for profile optimization:
  - **Deduplication mechanism**—If you enter the same command line multiple times, the system automatically removes the duplicate commands. You do not need to do that manually.
  - **Command grouping**—The system groups commands in the same view together and then executes them in configuration order.
- Verify the settings in the custom profiles by executing the **`display gir custom-profile`** command. If you introduce irreversible misconfiguration items in a custom profile, delete and then reconfigure that profile.
- If you need to slightly optimize the series of commands used when the system changes to maintenance or normal mode, use the following method:

  g. Make sure the switch-to-maintenance or switch-to-normal custom profile is empty.

  h. Execute an isolate or shutdown mode switching.

  The system automatically populates the custom profile with the series of commands executed on mode switching.

  i. Edit the custom profile.
- The storage space for a custom profile is limited. When the storage space is full, no commands can be entered in the custom profile. As a best practice, do not enter irrelevant commands in the custom profile.

Configuring the switch-to-maintenance profile

1. Enter system view.
   system-view
2. Enter the view of the switch-to-maintenance profile.
   gir custom-profile maintenance-mode
3. Enter isolation commands.
   For isolation commands, see the command reference for each service module.
4. End the configuration and quit the view.
   config-end

Configuring the switch-to-normal profile

1. Enter system view.
   system-view
2. Enter the view of the switch-to-normal profile.
   gir custom-profile normal-mode
3. Enter the commands to remove the isolation.
   For information about the commands, see the command reference for each service module.
4. End the configuration and quit the view.
   config-end

Switching to maintenance mode

About this task

Perform this task before you maintain or upgrade the device.

The device will return to normal mode if a service module fails in switchover. The device will display the commands that failed to be executed or generate logs, but it will not roll back the commands that have been executed.

Restrictions and guidelines

CAUTION:

To maintain configuration consistency for a feature across mode switching, do not modify its configuration after you place the device in maintenance mode. To check for configuration changes, execute the **display gir snapshot compare** command after you revert the device back to normal mode.

Prerequisites

If the device is performing a snapshot operation, you must wait for the operation to end before you can change the GIR mode. Conversely, you cannot perform a snapshot operation while the device is changing the GIR mode.

Procedure

1. Verify that the system is stable.
   display system stable state
   The system is stable if the **System State** field displays **Stable**. For a successful GIR operation, you must make sure the system is stable.
2. Enter system view.
   system-view

3. Switch to maintenance mode.

   gir system-mode maintenance [**shutdown** | **custom-profile**] [**non-interactive**]

> **CAUTION:**
>
> - Packet loss might occur during mode switching.
> - Do not restart the device or a process while GIR is switching mode. The system cannot roll back settings issued during mode switching. If you restart the device or a disruptive process, mode switching will be interrupted, with only some of the commands issued.

4. If a service module fails in switchover, use the following methods to identify and remove the issue:
   - Remove the issue based on the error message.
   - Compare the snapshots to identify configuration inconsistencies that might have caused the issue.

     Identify snapshot information:

     display gir snapshot

     Compare the snapshots:

     display gir snapshot compare *snapshot1-name snapshot2-name* [**verbose**]
5. Verify that no traffic traverses the device before you maintain or upgrade the device.

   display counters

   This command is available in any view. This step prevents the packet loss that might occur because a protocol is slow or fails in switchover.

Switching back to normal mode

Manually switching back to normal mode

About this task

Perform this task after you maintain or upgrade the device.

The device will return to maintenance mode if a service module fails in switchover. The device will display the commands that failed to be executed or generate logs, but it will not roll back the commands that have been executed.

Prerequisites

If the device is performing a snapshot operation, you must wait for the operation to end before you can change the GIR mode. Conversely, you cannot perform a snapshot operation while the device is changing the GIR mode.

Before you change the M-LAG system in an M-LAG environment back to normal mode, execute the **display m-lag mad verbose** command to verify that no network interfaces are in M-LAG MAD DOWN state. For more information about M-LAG, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

Table 1 Verify that the system is stable.

display system stable state

The system is stable if the **System State** field displays **Stable**.

1. Enter system view.

   system-view

2. Switch back to normal mode.

   undo gir system-mode maintenance [**custom-profile**] [**non-interactive**]

CAUTION:

Do not restart the device or a process while GIR is switching mode. The system cannot roll back settings issued during mode switching. If you restart the device or a disruptive process, mode switching will be interrupted, with only some of the commands issued.

3. If a service module fails in switchover, use the following methods to identify and remove the issue:
   - Remove the issue based on the error message.
   - Compare the snapshots to identify configuration inconsistencies that might cause the issue.

     Identify the snapshot names:

     display gir snapshot

     Compare the snapshots:

     display gir snapshot compare *snapshot1-name snapshot2-name* [**verbose**]

Configuring GIR to automatically switch back to normal mode

About this task

Automatic reverse switching enables the system to automatically revert back to normal mode from maintenance mode when the specified revert-delay expires.

This feature is helpful when the window of maintenance is deterministic.

Procedure

1. Enter system view.

   system-view

2. Specify the delay for the system to automatically revert to normal mode.

   gir system-mode maintenance revert-delay *value*

   By default, the system does not automatically revert to normal mode.

Managing GIR snapshots

Manually creating a snapshot

About this task

A GIR snapshot records the running data of the device in NETCONF format at a point in time for system restoration or comparison of data to identify changes over time.

Restrictions and guidelines

If the device is performing a mode switching or snapshot operation, you must wait for the operation to end before you can create a snapshot.

Procedure

1. Enter system view.

   system-view

2. Create a snapshot.

   gir snapshot create *snapshot-name description*

   The snapshot name can contain only digits, letters, and underscores (_).

Manually deleting snapshots

About this task

Perform this task to delete earliest snapshots to free up memory space.

Restrictions and guidelines

If the device is performing a mode switching or snapshot operation, you must wait for the operation to end before you can delete a snapshot.

Procedure

1. Enter system view.

   system-view

2. Delete snapshots.

   gir snapshot delete { **all** | *snapshot-name* }

Including additional data in snapshots

About this task

By default, the system does not include routing information in created snapshots, because the routing table is large in size. Perform this task to include IPv4 or IPv6 routes in created snapshots.

Procedure

1. Enter system view.

   system-view

2. Include IPv4 or IPv6 routes in snapshots.

   gir snapshot add { **ipv4routes** | **ipv6routes** }*

   By default, the system does not include routing information in created snapshots.

Configuring advanced GIR features

Configuring the delay for the device to enter maintenance mode

About this task

Execution of some commands might take some time. To ensure that all GIR applicable service modules complete traffic path switchover before you maintain the device, GIR introduces a maintenance delay for the device to enter maintenance mode.

Increase the maintenance delay if its default value is not sufficient.

Procedure

1. Enter system view.
   system-view
2. Set the maintenance delay.
   gir system-mode maintenance maintenance-delay *value*
   By default, the maintenance delay is 120 seconds.

Specifying a delay for after_maintenance snapshot creation

About this task

If the default snapshot delay value is not sufficient for a service module to restore its services, increase the delay so that GIR can take an **after_maintenance** snapshot of complete and accurate data.

Procedure

1. Enter system view.
   system-view
2. Specify a delay for **after_maintenance** snapshot creation.
   gir system-mode maintenance snapshot-delay *value*
   By default, the delay for creation of **after_maintenance** snapshots is 120 seconds.

Display and maintenance commands for GIR

Execute **display** commands in any view.

Task	Command
Display all GIR snapshots on the device.	**display gir snapshot**
Compare GIR snapshots to view their differences.	**display gir snapshot compare** *snapshot1-name snapshot2-name* [**verbose**]
Display the current GIR mode.	**display gir system-mode**
Display the GIR custom profiles.	**display gir custom-profile** [**maintenance-mode** | **normal-mode**]

GIR configuration examples

Example: Configuring GIR in an ECMP-based node redundancy environment

Network configuration

As shown in Figure 1, Device A and Device B have ECMP routes for traffic between Internet and Device C. Before upgrading Device A, use GIR to place it in maintenance mode to prevent packet losses during upgrade. Then, change Device A back to normal mode after its software is upgraded.

Figure 1 Network diagram

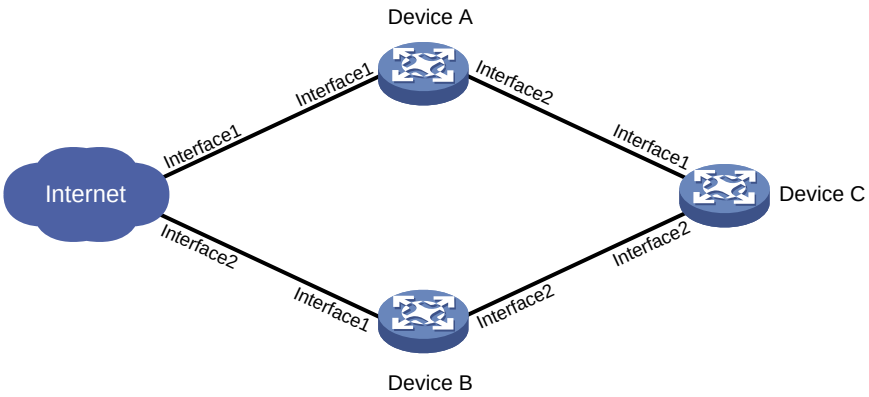

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure IP addresses and a unicast routing protocol (for example, OSPF). Make sure ECMP routes are available for traffic between the Internet and Device C to traverse Device A or Device B to reach the destination. (Details not shown.)
2. Isolate Device A from the network before you upgrade it.

   # Change Device A from the normal mode to the maintenance mode.

```
<Device A> display system stable state summary

Example: Configuring GIR on an M-LAG system

Network configuration

As shown in Figure 2, Device A and Device B form an M-LAG system.

Use the following method to upgrade the M-LAG system to prevent packet loss during the upgrade:

1. Upgrade Device B.
2. Perform a forward switching operation by using the isolate method on Device A.
3. Upgrade Device A.

Figure 2 Network diagram

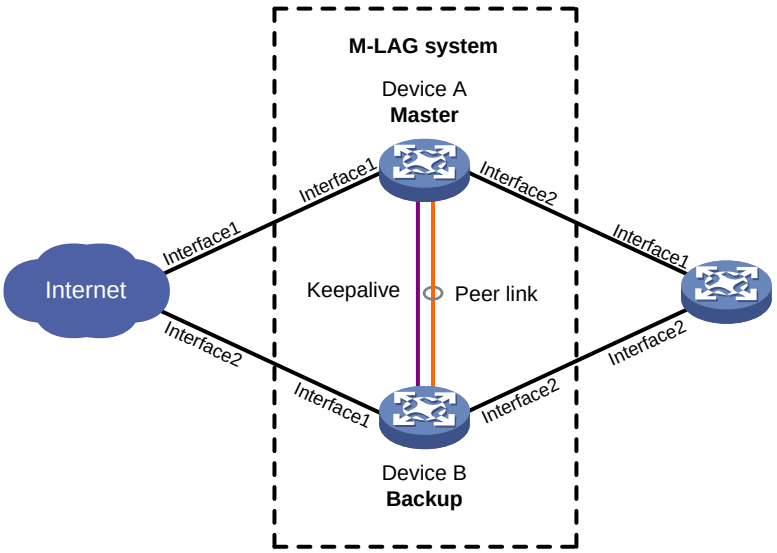

Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Using automatic configuration

About automatic configuration

When the device starts up without a valid next-startup configuration file, the device searches the root directory of its default file system for the autocfg.py, autocfg.tcl, and autocfg.cfg files. Only one of files might exist in the root directory. If any one of the files exists, the device loads the file. If none of the files exists, the device uses the automatic configuration feature to obtain a set of configuration settings.

With the automatic configuration feature, the device can automatically obtain a set of configuration settings at startup. This feature simplifies network configuration and maintenance.

Automatic configuration can be implemented by using the implementation methods in Table 1.

Table 1 Automatic configuration implementation methods

Implementation method	Configuration file location	Application scenarios
Server-based automatic configuration	File server	A number of geographically distributed devices need to be configured.
USB-based automatic configuration	USB disk	• On a small network, the devices reside near to each other, and no host can be used as a file server. • On a large network, only a few devices require automatic configuration or configuration update.

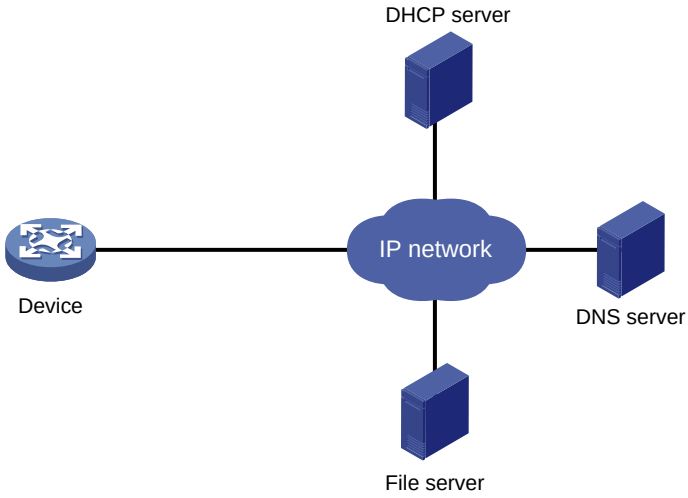
If both server-based automatic configuration and USB-based automatic configuration are available, the device prefers USB-based automatic configuration.

Using server-based automatic configuration

About server-based automatic configuration

With server-based automatic configuration, a device without a configuration file can run the DHCP client to obtain a configuration file from a file server at startup.

You can deploy server-based automatic configuration on both IPv4 and IPv6 networks by using the same method. This chapter describes the tasks for deploying server-based automatic configuration on an IPv4 network.



Typical server-based automatic configuration network

As shown in Figure 1, a typical server-based automatic configuration network consists of the following servers:

- **DHCP server**—Allocates an IP address to the device that performs server-based automatic configuration and notifies the device of the method to obtain the configuration file or script file for automatic configuration.
- **File server**—TFTP, HTTP, SFTP, or FTP server. The file server stores the configuration file or script file for automatic configuration.

- (Optional.) **DNS server**—Obtains the configuration file name or the IP address of the file server for the device.

Figure 1 Server-based automatic configuration network diagram

Host name file

A host name file stores mappings between host IP addresses and host names. To configure a host name file:

1. Create a host name file. The file name must be **network.cfg**.
2. Add each mapping entry in the **ip host** *host-name ip-address* format on a separate line. For example:

```
ip host host1 101.101.101.101
ip host host2 101.101.101.102
ip host client1 101.101.101.103
ip host client2 101.101.101.104
```

IMPORTANT:

The host name for a device must be the same as the name of the configuration file configured for the device. For example, the name of the configuration file for the device at 101.101.101.101 is **host1.cfg**.

Selecting the interface used for automatic configuration

The device uses the following steps to select the interface for automatic configuration:

1. Identifies the status of the management Ethernet interface at Layer 2. If the management Ethernet interface is up, the device uses that interface.
2. Identifies the status of Layer 2 Ethernet interfaces. If one or more Layer 2 Ethernet interfaces are in up state, the device uses the VLAN interface of the default VLAN.
3. Sorts all Layer 3 Ethernet interfaces in up state first in lexicographical order of interface types and then in ascending order of interface numbers. Uses the interface with the smallest interface number among the interfaces of the first interface type.

4. If no Layer 3 Ethernet interfaces are in up state, the device waits 30 seconds and goes to step 1 to try again.

For fast automatic device configuration, connect only the management Ethernet interface on each device to the network.

Operating mechanism

The process for server-based automatic configuration for a device is as follows:

1. The device selects the interface used to obtain the configuration file or script file for automatic configuration and sends an IP request message to the DHCP server. For more information about the interface selection order, see "Selecting the interface used for automatic configuration."
2. After the DHCP server receives the IP request message, it sends a reply message to the device. If the device does not receive any reply message within the timeout period of the request message, it selects the next interface according to the interface selection order and sends the IP request message again.
3. The device parses the reply message.
   - Obtains the IP address included in the reply message and uses it as the IP address for the selected interface to connect to the DHCP server. If the interface already has an IP address assigned, the device replaces the original IP address with the one included in the reply message. Once the automatic configuration process is complete, the device restores the original IP address to the interface.
   - Obtains the protocol information (HTTP, TFTP, SFTP, or FTP), configuration file name information, and file server address included in the reply message.
4. If no configuration file name is obtained or the obtained configuration file name does not meet the requirements, the device uses file **network.cfg** on the file server. If file **network.cfg** does not exist, the device uses file **device.cfg** on the file server. If file **device.cfg** does not exist, the device fails to obtain the configuration file or script file. In this case, the process returns to step 1.
5. The device resolves the domain name of the file server. If the file server address included in the reply message is a domain name rather than an IP address, the device uses the DNS server to resolve the domain name to an IP address.
6. The device downloads the configuration file or script file used for automatic configuration from the file server based on the obtained protocol, file server address, and configuration file name.
7. The device deploys the configuration in the configuration file or executes the script file.
8. The device automatically deletes the configuration file or script file.

Server-based automatic configuration tasks at a glance

To configure server-based automatic configuration, perform the following tasks:

1. Prepare the files for automatic configuration:
   - Preparing configuration files
   - Preparing script files
2. Configuring the file server
3. Configuring the DHCP server
4. (Optional.) Configuring the DNS server
5. (Optional.) Configuring the gateway
6. Starting and completing automatic configuration
7. (Optional.) Stopping automatic configuration

Preparing configuration files

Configuration file types

The device supports the configuration file types listed in Table 2.

Table 2 Configuration file types

Configuration file type	Application objects	File name requirements	Supported file server types
Dedicated configuration file	Devices that require different settings	*File name*.**cfg** For simple file name identification, use configuration file names that do not contain spaces.	• HTTP server • TFTP server • SFTP server • FTP server
Common configuration file	Devices that share all or some settings	*File name*.**cfg** For simple file name identification, use configuration file names that do not contain spaces.	• HTTP server • TFTP server • SFTP server • FTP server
Default configuration file	All devices. The file contains only common configurations that devices use to start up.	**device.cfg**	TFTP server

Identifying requirements for and preparing configuration files

1. Identify the requirements of the devices for configuration files.
2. For devices that require different configurations, prepare a configuration file for each of them and save the files to the file server.
3. For devices that share all or some configurations, save the common configurations to a .cfg file on the file server.
4. If a TFTP file server is used, you can save the common configurations that devices use to start up to the **device.cfg** file on the server. The file is assigned to a device only when the device does not have any other configuration file to use.

Preparing a host name file on the file server

If the DHCP server does not assign configuration file names, you can configure a host name file on the file server. The host name file contains the host name-IP address mappings of the devices to be automatically configured.

Preparing script files

About this task

Script files can be used for automatic software upgrade and automatic configuration.

The devices support Python scripts (.py files) and Tcl scripts (.tcl files). For more information about Python and Tcl scripts, see "Using Python" and "Using Tcl."

The devices support dedicated script files and common dedicated script files. They do not support using a default script file. For information about dedicated script files and common dedicated script files, see Table 2.

When script files are used, you cannot use a host name file to provide the host name-IP address mappings for devices.

Restrictions and guidelines

To use a Tcl script, make sure all commands in the script are supported and correctly configured. Any error in a command causes the automatic configuration process to quit.

When you use a Python script to automatically configure a device, make sure the script file does not contain command line errors (such as spelling mistakes, incorrect views, and unsupported commands for the device). If the script file contains command line errors, the current round of automatic configuration will fail and the device will proceed to the next round of automatic configuration.

When you use a Python script to automatically configure a device, the device is in the startup phase and the device is unstable. Therefore, do not use the **Stable** value in the **`display system stable state`** command output as the judgment condition in the Python script.

Procedure

- For devices that share all or some configurations, create a script file that contains the common configurations.
- For the other devices, create a separate script file for each of them.

Configuring the file server

For devices to obtain configuration information from an HTTP, TFTP, SFTP, or FTP server, start HTTP, TFTP, SFTP, or FTP service on the file server, respectively.

Configuring the DHCP server

About this task

The DHCP server assigns the following items to devices that need to be automatically configured:

- IP addresses.
- Paths of the configuration or script files.

When you configure the DHCP server, follow these guidelines:

- For devices for which you have prepared different configuration files, perform the following tasks for each of the devices on the DHCP server:
  - Create a DHCP address pool.
  - Configure a static address binding.
  - Specify a configuration file or script file.

  Because an address pool can use only one configuration file, you can specify only one static address binding for an address pool.
- For devices for which you have prepared the same configuration file, use either of the following methods:
  - Method 1:
    - Create a DHCP address pool for the devices.
    - Configure a static address binding for each of the devices in the address pool.
    - Specify the configuration file for the devices.
  - Method 2:
    - Create a DHCP address pool for the devices.
    - Specify the subnet for dynamic allocation.
    - Specify the TFTP server.
    - Specify the configuration file for the devices.

- If all devices on a subnet share the same configuration file or script file, perform the following tasks on the DHCP server:
  - Configure dynamic address allocation.
  - Specify the configuration file or script file for the devices.

  The configuration file can contain only the common settings for the devices. You can provide a method for the device administrators to change the configurations after their devices start up.

Restrictions and guidelines

When you specify a startup configuration file on a remote server for a DHCP client, follow these restrictions and guidelines:

- If a TFTP server is used, you must specify the file name. If the file name contains special characters, you must transcode the special characters according to the RFC specification.
- If an HTTP server is used, you must specify the URL of the file in the format of **http://***HTTP-server-IP-address***:***port-number***/***path***/***file-name*. If the path or file name in the URL contains special characters, you must transcode the special characters according to the RFC specification. If you do not specify a port number, the default port number applies.
- If an FTP server is used, you must specify the URL of the file in the format of **ftp://***username***:***password@FTP-server-IP-address***:***port-number***/***path***/***file-name*. If the username, password, path, or file name in the URL contains special characters, you must transcode the special characters according to the RFC specification. If you do not specify a port number, the default port number applies. If you do not specify a path, the root directory of the server applies.
- If an SFTP server is used, you must specify the URL of the file in the format of **sftp://***username***:***password@SFTP-server-IP-address***:***port-number***/***path***/***file-name*. If the username, password, path, or file name in the URL contains special characters, you must transcode the special characters according to the RFC specification. If you do not specify a port number, the default port number applies. If you do not specify a path, the root directory of the server applies.

Configuring the DHCP server when an HTTP file server is used

1. Enter system view.

   system-view
2. Enable DHCP.

   dhcp enable

   By default, DHCP is disabled.
3. Create a DHCP address pool and enter its view.

   dhcp server ip-pool *pool-name*
4. Configure the address pool.

   Choose the options to configure as needed:
   - Specify the primary subnet for the address pool.

     network *network-address* [*mask-length* | **mask** *mask*]

     By default, no primary subnet is specified.
   - Configure a static binding.

     static-bind ip-address *ip-address* [*mask-length* | **mask** *mask*] { **client-identifier** *client-identifier* | **hardware-address** *hardware-address* [**ethernet** | **token-ring**] }

     By default, no static binding is configured.

     You can configure multiple static bindings. However, one IP address can be bound to only one client. To change the binding for a DHCP client, you must remove the binding and reconfigure a binding.

5. Specify the URL of the configuration or script file in HTTP format.

   bootfile-name *url*

   By default, no configuration or script file URL is specified in HTTP format.

Configuring the DHCP server when a TFTP file server is used

1. Enter system view.

   system-view

2. Enable DHCP.

   dhcp enable

   By default, DHCP is disabled.

3. Create a DHCP address pool and enter its view.

   dhcp server ip-pool *pool-name*

4. Configure the address pool.

   Choose the options to configure as needed:

   - Specify the primary subnet for the address pool.

     network *network-address* [*mask-length* | **mask** *mask*]

     By default, no primary subnet is specified.

   - Configure a static binding.

     static-bind ip-address *ip-address* [*mask-length* | **mask** *mask*] { **client-identifier** *client-identifier* | **hardware-address** *hardware-address* [**ethernet** | **token-ring**] }

     By default, no static binding is configured.

     You can configure multiple static bindings. However, one IP address can be bound to only one client. To change the binding for a DHCP client, you must remove the binding and reconfigure a binding.

5. Specify a TFTP server.

   Choose one option as needed:

   - Specify the IP address of the TFTP server.

     tftp-server ip-address *ip-address*

     By default, no TFTP server IP address is specified.

   - Specify the name of the TFTP server.

     tftp-server domain-name *domain-name*

     By default, no TFTP server name is specified.

     If you specify a TFTP server by its name, a DNS server is required on the network.

6. Specify the name of the configuration or script file.

   bootfile-name *bootfile-name*

   By default, no configuration or script file name is specified.

Configuring the DHCP server when an SFTP file server is used

1. Enter system view.

   system-view

2. Enable DHCP.

   dhcp enable

   By default, DHCP is disabled.

3. Create a DHCP address pool and enter its view.

   dhcp server ip-pool *pool-name*

4. Configure the address pool.

   Choose the options to configure as needed:

   - Specify the primary subnet for the address pool.

     network *network-address* [*mask-length* | **mask** *mask*]

     By default, no primary subnet is specified.

   - Configure a static binding.

     static-bind ip-address *ip-address* [*mask-length* | **mask** *mask*] { **client-identifier** *client-identifier* | **hardware-address** *hardware-address* [**ethernet** | **token-ring**] }

     By default, no static binding is configured.

     You can configure multiple static bindings. However, one IP address can be bound to only one client. To change the binding for a DHCP client, you must remove the binding and reconfigure a binding.

5. Specify the URL of the configuration or script file in SFTP format.

   bootfile-name *url*

   By default, no configuration or script file URL in SFTP format is specified.

Configuring the DHCP server when an FTP file server is used

1. Enter system view.

   system-view

2. Enable DHCP.

   dhcp enable

   By default, DHCP is disabled.

3. Create a DHCP address pool and enter its view.

   dhcp server ip-pool *pool-name*

4. Configure the address pool.

   Choose the options to configure as needed:

   - Specify the primary subnet for the address pool.

     network *network-address* [*mask-length* | **mask** *mask*]

     By default, no primary subnet is specified.

   - Configure a static binding.

     static-bind ip-address *ip-address* [*mask-length* | **mask** *mask*] { **client-identifier** *client-identifier* | **hardware-address** *hardware-address* [**ethernet** | **token-ring**] }

     By default, no static binding is configured.

     You can configure multiple static bindings. However, one IP address can be bound to only one client. To change the binding for a DHCP client, you must remove the binding and reconfigure a binding.

5. Specify the URL of the configuration or script file in FTP format.

   bootfile-name *url*

   By default, no configuration or script file URL in FTP format is specified.

Configuring the DNS server

A DNS server is required in the following situations:

- **Obtaining the names of configuration files for automatic configuration when the TFTP server does not have a host name file**—In this situation, the devices that perform

server-based automatic configuration use the DNS server to resolve their IP addresses to their host names. Then, each device can use its host name to obtain the configuration file that has the same name as its host name from the TFTP server.

- **Obtaining the IP address of a file server**—If the devices obtain the domain name of the file server from DHCP reply messages, they can use the domain name to obtain the IP address of the file server through the DNS server.

For more information about DNS servers, see DNS configuration in *Layer 3—IP Services Configuration Guide*.

Configuring the gateway

If the devices to be automatically configured and the servers for automatic configuration reside in different network segments, you must perform the following tasks:

- Deploy a gateway and make sure the devices can communicate with the servers.
- Configure the DHCP relay agent feature on the gateway.
- Configure the UDP helper feature on the gateway.

  This task is required if devices send requests to a TFTP server by using broadcast packets. A device uses broadcast packets to send requests to a TFTP server in the following situations:

  - The DHCP reply does not contain the IP address or domain name of the TFTP server.
  - The IP address or domain name of the TFTP server is invalid.

  The UDP helper transforms a broadcast packet into a unicast packet and forwards the unicast packet to the file server. For more information about UDP helper, see *Layer 3—IP Services Configuration Guide*.

Starting and completing automatic configuration

1. Power on the devices to be automatically configured.
2. The devices enter the automatic configuration process. After a device obtains a configuration file and executes the file successfully, the automatic configuration process ends.
3. Save the running configuration.

   save

   As a best practice, save the running configuration on each device after the configuration file is executed successfully on the device.

   For more information about the **save** command, see configuration file management commands in *Fundamentals Command Reference*.

Stopping automatic configuration

If a device cannot obtain a configuration file for automatic configuration, the current automatic configuration attempt fails, and the device continues attempting automatic configuration. You can wait until the device automatically ends the automatic configuration process after it has made the maximum number of attempts. Alternatively, you can manually stop the automatic configuration process by using shortcut keys **Ctrl+C** or **Ctrl+D** based on the prompt information. After the automatic configuration process fails and ends, the device starts up with initial settings.

Using USB-based automatic configuration

About USB-based automatic configuration

When a device enters the automatic configuration process after it starts up with initial settings, it first attempts to load configuration from a USB disk. USB-based automatic configuration supports the following methods:

- Index file-based automatic configuration.
- Automatic configuration without an index file.

A device prefers index file-based automatic configuration to automatic configuration without an index file.

Configuring and using index file-based automatic configuration

Operating mechanism

Save an index file and configuration file on a USB disk. When a device starts, it automatically obtains and executes the configuration file on the USB disk based on the index file for automatic configuration.

The process for index file-based automatic configuration for a device is as follows:

1. The device detects that a USB disk is present.
2. Check whether the index file named **smart_config.ini** exists on the USB disk.
   - If the index file named **smart_config.ini** exists, the device enters step 3.
   - If the index file named **smart_config.ini** does not exist, the device performs automatic configuration without an index file. For more information, see "Configuring and using automatic configuration without an index file."
3. Check whether the format of the **smart_config.ini** index file is valid.
   - If the index file is valid, the device enters step 4.
   - If the index file is invalid, USB-based automatic configuration fails and the automatic configuration process ends. An error report is generated on the USB disk.
4. The device compares the data change time flag specified in the **smart_config.ini** index file with the time flag of the last USB-based automatic configuration recorded on the device.
   - If they are different, the device enters step 5.
   - If they are the same, USB-based automatic configuration fails and the automatic configuration process ends. An error report is generated on the USB disk.
5. The device obtains the configuration file from the USB disk according to the description information in the **smart_config.ini** index file and saves the configuration file to the default storage medium.
   - If the device obtains the configuration file successfully, it enters step 6.
   - If the device fails to obtain the configuration file, USB-based automatic configuration fails and the automatic configuration process ends. An error report is generated on the USB disk.
6. The device determines whether a reboot activation is required based on the obtained configuration file or the specified activation method.
   - If a reboot is not required, the device activates the files specified in the index file online and proceeds to step 7.
   - If a reboot is required, the device sets the files specified in the index file as the next-startup files. After a successful automatic reboot, the device proceeds to step 7.

7. After automatic configuration succeeds, the device uses the configuration in the configuration file obtained from the USB disk to overwrite the running configuration and sets the configuration as the next-startup configuration. The automatic configuration process ends.
8. Remove the USB disk from the device.

Prerequisites

Create an index file and save it to the root directory of the USB disk. Save the required files to the directory specified in the index file on the USB disk.

Creating an index file

The name of the index file must be **smart_config.ini**.

To use index file-based automatic configuration, you can edit the index file for USB-based automatic configuration on your PC as follows:

1. Create an empty .txt file.
2. Edit the file contents according to the format of the index file for USB-based automatic configuration.
3. Save the .txt file as **smart_config.ini**.
4. Copy the index file named **smart_config.ini** to the root directory of the USB disk.

The index file format is as follows:

```
BEGIN LSW
[GLOBAL CONFIG]
TIMESN=
AUTOOVERWRITEFILE=
AUTODELFILE=
ACTIVEMODE=
[DEVICE DESCRIPTION]
OPTION=
SN=
MAC=
AUTODELFILE=
ACTIVEMODE=
DEVICETYPE=
DIRECTORY=
SYSTEM-IPE=
HMAC=
SYSTEM-BOOT-BIN=
HMAC=
SYSTEM-SYSTEM-BIN=
HMAC=
SYSTEM-FEATURE-BIN=
HMAC=
SYSTEM-FEATURE-BIN=
HMAC=
SYSTEM-FEATURE-BIN=
HMAC=
SYSTEM-PATCH-BIN=
HMAC=
SYSTEM-CONFIG=
HMAC=
```

```
END LSW
```

Table 3 shows the description for parameters in the index file.

Table 3 Description for parameters in the index file

Parameter	Description
BEGIN LSW	Required. Start flag. It cannot be modified.
[GLOBAL CONFIG]	Required. Global configuration start flag. It cannot be modified.
TIMESN	Required. Data change time flag, in string format. It can contain 1 to 16 characters, and cannot contain spaces. Recommended format: year month day.hour minute second. For example, you can set TIMESN=20110628.080910 to represent 08:09:10 28 June 2011. Each TIMESN value corresponds to a device that will be upgraded. During the USB-based automatic configuration process, a device records its own TIMESN value before it reboots. If a reboot is not required for the upgrade, the device records its own TIMESN value when the upgrade is complete. This TIMESN value cannot be used in the next upgrade. When some devices fail to be upgraded, you must change their TIMESN values before performing another USB-based automatic configuration.
AUTODELFILE	Optional. Specifies whether to automatically delete the old software package after upgrade. Options include: • **YES**—Delete. • **NO**—Not delete By default, the value for the AUTODELFILE parameter is NO. If this parameter does not exist or the value for this parameter is empty or invalid, the default setting applies. AUTODELFILE parameters include two types, global and device-specific. • The parameters in the [GLOBAL CONFIG] area are global, and the parameters in the [DEVICE DESCRIPTION] area are device-specific. • If this parameter is set to YES or NO for a specific device, the device-specific configuration takes effect. If this parameter is not set or is empty for a specific device, the global configuration for this parameter takes effect on the device.
AUTOOVERWRITEFILE	Optional. Specifies whether to overwrite a configuration file on a device when a configuration file with the same name is copied from a USB disk to the device. • **YES**—Overwrite. • **NO**—Not overwrite. By default, the value for the AUTOOVERWRITEFILE parameter is YES. If this parameter does not exist or the value for this parameter is empty or invalid, the default setting applies.
ACTIVEMODE	Optional. Specifies the file activation method after a file is copied. Options include: • **DEFAULT**—Activates a file by its own default activation method. The default activation method is rebooting devices for system software. The default activation method is online activation without rebooting devices for configuration files and patch files. • **REBOOT**—Activates a file by rebooting the device. By default, the value for the ACTIVEMODE parameter is DEFAULT. If this parameter does not exist or the value for this

Parameter	Description
	parameter is empty or invalid, the default setting applies. ACTIVEMODE parameters include two types, global and device-specific. • The parameters in the [GLOBAL CONFIG] area are global, and the parameters in the [DEVICE DESCRIPTION] area are device-specific. • If this parameter is set to DEFAULT or REBOOT for a specific device, the device-specific configuration takes effect. If this parameter is not set or is empty for a specific device, the global configuration for this parameter takes effect on the device.
[DEVICE DESCRIPTION]	Required. Start flag for a device-specific configuration file. Each parameter in a device-specific configuration file cannot be repeated. If a device-specific configuration file contains repeated parameters, no device can match it. Each device can match only one device-specific configuration file. After a device matches a device-specific configuration file, it stops matching the subsequent device-specific configuration files.
OPTION	Optional. Validity flag for a device-specific configuration file, which indicates whether the device configuration file is valid. Options include: • **OK**—Valid. • **NOK**—Invalid. All information in the device-specific configuration file will not be used for device matching. By default, the value for the OPTION parameter is OK. If this parameter does not exist or the value for this parameter is empty or invalid, the default setting applies.
SN	Optional. Device serial number. If the value for the SN parameter is DEFAULT, the device SN will not be matched. Otherwise, the device SN will be matched. By default, the value for the SN parameter is DEFAULT. If this parameter does not exist or the value for this parameter is empty, the default setting applies.
MAC	Optional. Device MAC address, in the format of XXXX-XXXX-XXXX, where X is a hexadecimal digit. If the value for this parameter is DEFAULT, the device MAC address will not be matched. Otherwise, the device MAC address will be matched. By default, the value for the MAC parameter is DEFAULT. If this parameter does not exist or the value for this parameter is empty, the default setting applies.
DEVICETYPE	Optional. Matches the device type, for example, S12700. If the value for the DEVICETYPE parameter is DEFAULT, the device type will not be matched. Otherwise, the device type will be matched. By default, the value for the DEVICETYPE parameter is DEFAULT. If this parameter does not exist or the value for this parameter is empty, the default setting applies.
DIRECTORY	Optional. Directory for saving the software package and configuration file on the USB disk. • When the value for this parameter is empty or this parameter does not exist, the software package and configuration file will be saved in the root directory of the USB disk. • When DIRECTORY is set to /abc, the software package and configuration file will be saved in the abc directory in the USB

Parameter	Description
	disk. By default, the value for the DIRECTORY parameter is empty. The file directory format in the index file must be the same as that of the file system in the device. • The specified directory can contain a maximum of four levels. A directory must start with a slash (/), and different levels are separated by using slashes (/). However, a directory cannot end with a slash (/). For example, /abc/test is a valid directory, and /abc/test/ is an invalid directory. • The string in each level of a directory is 1 to 15 characters. • A directory cannot contain spaces or the following characters: ~ * / \ : ' " < > | ? [ ] %. A directory is case insensitive.
SYSTEM-IPE	Optional. IPE file name, which ends with .ipe.
HMAC=	Optional. The HMAC verification code for the .ipe system software package. If the system software package is used for initial deployment and the index file for USB-based automatic configuration has a verification password, you must specify this field.
SYSTEM-BOOT-BIN	Optional. Boot image file name, which ends with .bin.
HMAC=	Optional. The HMAC verification code for the Boot image file. If the Boot image file is used for initial deployment and the index file for USB-based automatic configuration has a verification password, you must specify this field.
SYSTEM-SYSTEM-BIN	Optional. System image file name, which ends with .bin.
HMAC=	Optional. The HMAC verification code for the system image file. If the system image file is used for initial deployment and the index file for USB-based automatic configuration has a verification password, you must specify this field.
SYSTEM-FEATURE-BIN	Optional. Feature image file name, which ends with .bin.
HMAC=	Optional. The HMAC verification code for the feature image file. If the feature image file is used for initial deployment and the index file for USB-based automatic configuration has a verification password, you must specify this field.
SYSTEM-PATCH-BIN	Optional. Patch file name, which ends with .bin.
HMAC=	Optional. The HMAC verification code for the patch file. If the patch file is used for initial deployment and the index file for USB-based automatic configuration has a verification password, you must specify this field.
SYSTEM-CONFIG	Optional. Configuration file name, which ends with .cfg.
HMAC=	Optional. The HMAC verification code for the configuration file. If the configuration file is used for initial deployment and the index file for USB-based automatic configuration has a verification password, you must specify this field.
END LSW	Required. End flag of the file.

CAUTION:

When editing an index file for USB-based automatic configuration, make sure the contents in the index file are correct. The devices to be upgraded are matched in the order of the DEVICE parameters in the index file from top to bottom. A device is matched in the following order: MAC > SN > DEVICETYPE. Once a match is found, the files in the matching DEVICE information are

loaded. If an error occurs during this process, the whole USB-based automatic configuration process is terminated, and an error report is output. The configuration will not be rolled back for devices that have been upgraded successfully.

When you use an index file for automatic configuration, the device will confirm the files to be loaded according to the index file as follows:

5. The device identifies whether an .ipe file is specified in the index file. If yes, the device confirms loading the .ipe file, skips step 6, and proceeds with 7. If not, the device skips step 5 and proceeds with step 6.
6. The device identifies whether the index file has boot, system, and feature files specified. If yes, the specified files are loaded. The boot and system files are required, and the feature file is optional. After the files to be loaded are confirmed, the device proceeds with step 7. If no boot, system, or feature file is specified in the index file, the device skips step 6 and proceeds with step 7.
7. The device identifies whether a patch file is specified in the index file. If yes, the device confirms loading the patch file, skips steps 7, and proceeds with step 8. If not, the device skips step 7 and proceeds with step 8.
8. The device identifies whether a. cfg configuration file is specified in the index file. If yes, the device confirms loading the .cfg configuration file. If not, the device skips the step of loading files.
9. The device performs either of the following operations depending on whether an index file verification password has been specified for USB-based automatic configuration:
   - If an index file verification password has been specified for USB-based automatic configuration, the device verifies the index file first by comparing the password with the HMAC verification code in the index file. If the verification succeeds, the device copies the configuration files from the USB drive to the local device to perform automatic configuration. If the verification fails, the device does not perform USB-based automatic configuration.
   - If an index file verification password has not been specified, the device starts loading the files to be loaded. If files fail to be loaded, the USB-based automatic configuration process stops.

NOTE:

- When editing an index file, you must press **Enter** after entering a line in the specified format and then editing new contents. After editing the index file, save the index file.
- If the keyword of a parameter is not matched or found, the parameter is considered as empty.
- When the value for a parameter in the GLOBAL CONFIG area is different from that in the DEVICE DESCRIPTION area for a matching device, the configuration in the DEVICE DESCRIPTION area takes effect on the device.

Procedure

1. Enable USB-based automatic configuration on the device:
   a. Enter system view.
      ```
      system-view
      ```
   b. Enable USB-based automatic configuration.
      ```
      autodeploy udisk enable
      ```
      By default, USB-based automatic configuration is enabled.
      For the enabling configuration to take effect if USB-based automatic configuration has been disabled, you must save the configuration and reboot the device.
   c. (Optional) Specify an index file verification password for USB-based automatic configuration.

autodeploy udisk file-verification password { **simple** | **cipher** } *string*

By default, no index file verification password is configured for USB-based automatic configuration.

d. Save the running configuration.

save

2. Create an index file.
3. Save the index file to the root directory of the USB disk, and save the files specified in the index file to the specified directory. By default, the directory is the root directory of the USB disk.
4. Insert the USB disk into interface USB1, namely, usba0:, on the active device. After USB-based automatic configuration ends, the standby device will automatically synchronize its configuration with the active device at startup.
5. Observe the LEDs of the device.

   If the configuration file fails to be deployed, you can view the log file named *fully qualified configuration file name***.log** in the root directory of the USB disk to locate and resolve the issue.
6. Use the **display current-configuration** command to verify that the configuration file has been loaded correctly. For more information about this command, see configuration file management in *Fundamentals Command Reference*.
7. Remove the USB disk.

Configuring and using automatic configuration without an index file

Operating mechanism

Save a configuration file on a USB disk. When a device starts, it automatically obtains and executes the configuration file from the USB disk for automatic configuration.

The process for USB-based automatic configuration without an index file is as follows:

1. The device detects that the USB disk is present.
2. Check whether the index file named **smart_config.ini** exists on the USB disk.
   - If the index file named **smart_config.ini** exists, the device performs index file-based automatic configuration. For more information, see "Configuring and using index file-based automatic configuration."
   - If the index file named **smart_config.ini** does not exist, proceed to step 3.
3. Manually reboot the device.
4. When the device starts up, it detects whether a .cfg configuration file exists on the USB disk.
   - If a .cfg file exists, the device proceeds to step 5.
   - If no .cfg file exists, the USB-based automatic configuration process ends.
5. After the device obtains a configuration file from the USB disk, it compares the content of the configuration file with the content of the current main next-startup configuration file on the device.
   - If the contents are the same, the device directly loads the main next-startup configuration file instead of the configuration file on the USB disk.
   - If the contents are different, the device copies the configuration file on the USB disk to the local storage medium and proceeds to step 6.

     If the device has a local file that uses the same name as the configuration file copied from the USB disk, it handles the local file as follows:

     – If the local file is the main next-startup configuration file, the device saves the file as *original-file-name*_**bak.cfg**.

- If the local file is not the main next-startup configuration file, the device directly uses the configuration file copied from the USB disk to overwrite the local file.

6. The device executes the configuration file copied from the USB disk.
   - If the execution succeeds, the device automatically runs the configuration in the configuration file as the running configuration and sets the configuration file as the main next-startup configuration file.
   - If the device fails to execute any command in the configuration file, it ignores all settings in the configuration file and loads settings in the original next-startup configuration file. If no next-startup configuration file is available, the device starts up with initial settings.

Prerequisites

1. Prepare a USB disk that has only one partition.
2. Display the serial number of the device.

   `display device manuinfo`

   For more information about this command, see device management commands in *Fundamentals Command Reference*.
3. Create a configuration file named *device serial number***.cfg** or **autodeploy.cfg**, and save the file to the root directory of the file system on the USB disk.

   If a configuration file named *device serial number***.cfg** coexists with configuration file **autodeploy.cfg**, the configuration file named *device serial number***.cfg** is used.

Procedure

1. Enable USB-based automatic configuration on the device:
   a. Enter system view.

      `system-view`

   b. Enable USB-based automatic configuration.

      `autodeploy udisk enable`

      By default, USB-based automatic configuration is enabled.

      For the enabling configuration to take effect if USB-based automatic configuration has been disabled, you must save the configuration and reboot the device.

   c. Save the running configuration.

      `save`
2. Insert the USB disk with the configuration file saved into interface USB1, namely, usba0:, on the active device. After USB-based automatic configuration ends, the standby device will automatically synchronize its configuration with the active device at startup.
3. Reboot the device and observe the LEDs of the device.
   - If the SYS LED flashes green quickly for 5 seconds, the automatic configuration succeeds. Proceed to step 4.
   - If the SYS LED flashes yellow quickly for 10 seconds, the automatic configuration fails. Display the log file named *fully qualified configuration file name***.log** in the root directory of the USB disk to locate and resolve the issue.

   How LED status reflects automatic configuration results depends on the device model.
4. Use the **`display current-configuration`** command to verify that the configuration file has been loaded correctly.

   For more information about this command, see configuration file management commands in *Fundamentals Command Reference*.
5. Remove the USB disk.

Display and maintenance commands for automatic configuration

Execute **display** commands in any view.

Task	Command
Display information about automatic configuration status.	**display autodeploy status**

Server-based automatic configuration examples

Example: Using a TFTP server for automatic configuration

Network configuration

As shown in Figure 2, two departments of a company are connected to the network through gateways (Switch B and Switch C). Access devices Switch D, Switch E, Switch F, and Switch G do not have a configuration file.

Configure the servers and gateways so the access devices can obtain a configuration file to complete the following configuration tasks:

- Enable administrators of access devices to Telnet to and manage their respective access devices.
- Require administrators to enter their respective usernames and passwords at login.

Figure 2 Network diagram

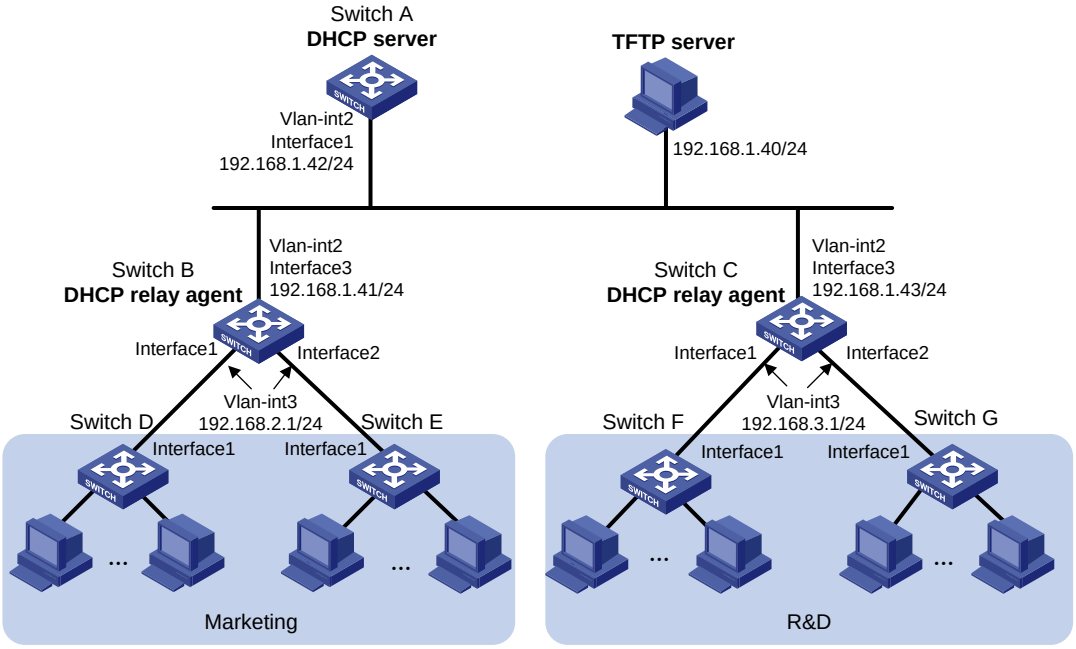


Table 4 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure Switch A:

   # Create a VLAN interface and assign an IP address to the interface.

   ```
   <Sysname> system-view
   [Sysname] sysname SwitchA
   [SwitchA] vlan 2
   [SwitchA-vlan2] port gigabitethernet 1/0/1
   [SwitchA-vlan2] quit
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ip address 192.168.1.42 24
   [SwitchA-Vlan-interface2] quit
   ```

   # Enable DHCP.

   ```
   [SwitchA] dhcp enable
   ```

   # Enable the DHCP server on VLAN-interface 2.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] dhcp select server
   [SwitchA-Vlan-interface2] quit
   ```

   # Configure address pool **market** to assign IP addresses on the 192.168.2.0/24 subnet to clients in the Marketing department. Specify the TFTP server, gateway, and configuration file name for the clients.

   ```
   [SwitchA] dhcp server ip-pool market
   [SwitchA-dhcp-pool-market] network 192.168.2.0 24
   [SwitchA-dhcp-pool-market] tftp-server ip-address 192.168.1.40
   [SwitchA-dhcp-pool-market] gateway-list 192.168.2.1
   [SwitchA-dhcp-pool-market] bootfile-name market.cfg
   [SwitchA-dhcp-pool-market] quit
   ```

   # Configure address pool **rd** to assign IP addresses on the 192.168.3.0/24 subnet to clients in the R&D department. Specify the TFTP server, gateway, and configuration file name for the clients.

   ```
   [SwitchA] dhcp server ip-pool rd
   [SwitchA-dhcp-pool-rd] network 192.168.3.0 24
   [SwitchA-dhcp-pool-rd] tftp-server ip-address 192.168.1.40
   [SwitchA-dhcp-pool-rd] gateway-list 192.168.3.1
   [SwitchA-dhcp-pool-rd] bootfile-name rd.cfg
   [SwitchA-dhcp-pool-rd] quit
   ```

   # Configure static routes to the DHCP relay agents.

   ```
   [SwitchA] ip route-static 192.168.2.0 24 192.168.1.41
   [SwitchA] ip route-static 192.168.3.0 24 192.168.1.43
   [SwitchA] quit
   ```

2. Configure the gateway Switch B:

Create VLAN interfaces and assign IP addresses to the interfaces.

```
<Sysname> system-view
[Sysname] sysname SwitchB
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/3
[SwitchB-vlan2] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 192.168.1.41 24
[SwitchB-Vlan-interface2] quit
[SwitchB] vlan 3
[SwitchB-vlan3] port gigabitethernet 1/0/1
[SwitchB-vlan3] port gigabitethernet 1/0/2
[SwitchB-vlan3] quit
[SwitchB] interface vlan-interface 3
[SwitchB-Vlan-interface3] ip address 192.168.2.1 24
[SwitchB-Vlan-interface3] quit
```

Enable DHCP.

```
[SwitchB] dhcp enable
```

Enable the DHCP relay agent on VLAN-interface 3.

```
[SwitchB] interface vlan-interface 3
[SwitchB-Vlan-interface3] dhcp select relay
```

Specify the DHCP server address.

```
[SwitchB-Vlan-interface3] dhcp relay server-address 192.168.1.42
```

3. Configure the gateway Switch C:

Create VLAN interfaces and assign IP addresses to the interfaces.

```
<Sysname> system-view
[Sysname] sysname SwitchC
[SwitchC] vlan 2
[SwitchC-vlan2] port gigabitethernet 1/0/3
[SwitchC-vlan2] quit
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] ip address 192.168.1.43 24
[SwitchC-Vlan-interface2] quit
[SwitchC] vlan 3
[SwitchC-vlan3] port gigabitethernet 1/0/1
[SwitchC-vlan3] port gigabitethernet 1/0/2
[SwitchC-vlan3] quit
[SwitchC] interface vlan-interface 3
[SwitchC-Vlan-interface3] ip address 192.168.3.1 24
[SwitchC-Vlan-interface3] quit
```

Enable DHCP.

```
[SwitchC] dhcp enable
```

Enable the DHCP relay agent on VLAN-interface 3.

```
[SwitchC] interface vlan-interface 3
[SwitchC-Vlan-interface3] dhcp select relay
```

Specify the DHCP server address.

```
[SwitchC-Vlan-interface3] dhcp relay server-address 192.168.1.42
```

4. Configure the TFTP server:

On the TFTP server, create a configuration file named **market.cfg**.

```
#
 sysname Market
#
 telnet server enable
#
vlan 3
#
local-user market
 password simple build22345
 service-type telnet
 quit
#
interface Vlan-interface3
 ip address dhcp-alloc
 quit
#
interface gigabitethernet 1/0/1
 port access vlan 3
 quit
#
user-interface vty 0 63
 authentication-mode scheme
 user-role network-admin
#
return
```

On the TFTP server, create a configuration file named **rd.cfg**.

```
#
 sysname RD
#
 telnet server enable
#
vlan 3
#
local-user rd
 password simple create22345
 service-type telnet
 quit
#
interface Vlan-interface3
 ip address dhcp-alloc
 quit
#
interface gigabitethernet 1/0/1
 port access vlan 3
 quit
#
user-interface vty 0 63
```

```
 authentication-mode scheme
 user-role network-admin
#
return
```

Start TFTP service software, and specify the folder where the two configuration files reside as the working directory. (Details not shown.)

Verify that the TFTP server and DHCP relay agents can reach each other. (Details not shown.)

Verifying the configuration

1. Power on Switch D, Switch E, Switch F, and Switch G.
2. After the access devices start up, display assigned IP addresses on Switch A.

```
<SwitchA> display dhcp server ip-in-use
IP address       Client-identifier/    Lease expiration      Type
                 Hardware address
192.168.2.2      3030-3066-2e65-3233-  May 6 05:21:25 2013   Auto(C)
                 642e-3561-6633-2d56-
                 6c61-6e2d-696e-7465-
                 7266-6163-6533
192.168.2.3      3030-3066-2e65-3230-  May 6 05:22:50 2013   Auto(C)
                 302e-3232-3033-2d56-
                 6c61-6e2d-696e-7465-
                 7266-6163-6533
192.168.3.2      3030-6530-2e66-6330-  May 6 05:23:15 2013   Auto(C)
                 302e-3335-3131-2d56-
                 6c61-6e2d-696e-7465-
                 7266-6163-6531
192.168.3.3      3030-6530-2e66-6330-  May 6 05:24:10 2013   Auto(C)
                 302e-3335-3135-2d56-
                 6c61-6e2d-696e-7465-
                 7266-6163-6532
```

3. Telnet to 192.168.2.2 from Switch A.

```
<SwitchA> telnet 192.168.2.2
```

4. Enter username **market** and password **build22345** as prompted. (Details not shown.)

   You are logged in to Switch D or Switch E.

Example: Using an HTTP server and Tcl scripts for automatic configuration

Network configuration

As shown in Figure 3, Switch A does not have a configuration file.

Configure the servers so Switch A can obtain a Tcl script to complete the following configuration tasks:

- Enable the administrator to Telnet to Switch A to manage Switch A.
- Require the administrator to enter the correct username and password at login.

Figure 3 Network diagram

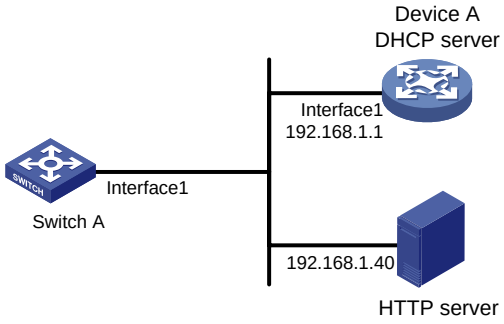

Table 5 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

1. Configure the DHCP server:

   # Enable DHCP.

   ```
   <Sysname> system-view
   [Sysname] sysname DeviceA
    [DeviceA] dhcp enable
   ```

   # Configure address pool **1** to assign IP addresses on the 192.168.1.0/24 subnet to clients.

   ```
   [DeviceA] dhcp server ip-pool 1
   [DeviceA-dhcp-pool-1] network 192.168.1.0 24
   ```

   # Specify the URL of the script file for the clients.

   ```
   [DeviceA-dhcp-pool-1] bootfile-name http://192.168.1.40/device.tcl
   [DeviceA-dhcp-pool-1] quit
   ```

   # Enable the DHCP server on GigabitEthernet1/0/1.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ip address 192.168.1.1 24
   [DeviceA-GigabitEthernet1/0/1] dhcp select server
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

2. Configure the HTTP server:

   # Create a configuration file named **device.tcl** on the HTTP server.

   ```
   system-view
   telnet server enable
   local-user user
   password simple hello22345
   service-type telnet
   quit
   user-interface vty 0 63
   authentication-mode scheme
   user-role network-admin
   quit

   interface gigabitethernet 1/0/1
   ```

```
port link-mode route
ip address dhcp-alloc
return
```

Start HTTP service software and enable HTTP service. (Details not shown.)

Verifying the configuration

1. Power on Switch A.
2. After Switch A starts up, display assigned IP addresses on Device A.

```
<DeviceA> display dhcp server ip-in-use
IP address       Client identifier/    Lease expiration      Type
                 Hardware address
192.168.1.2      0030-3030-632e-3239-  Dec 12 17:41:15 2013  Auto(C)
                 3035-2e36-3736-622d-
                 4574-6830-2f30-2f32
```

3. Telnet to 192.168.1.2 from Device A.

```
<DeviceA> telnet 192.168.1.2
```

4. Enter username **user** and password **hello22345** as prompted. (Details not shown.)

   You are logged in to Switch A.

Configuration files

```
#
 sysname DeviceA
#
 dhcp enable
#
dhcp server ip-pool 1
 network 192.168.1.0 mask 255.255.255.0
 bootfile-name http://192.168.1.40/device.tcl
#
interface GigabitEthernet1/0/1
 port link-mode route
 ip address 192.168.1.1 255.255.255.0
#
return
```

Example: Using an HTTP server and Python scripts for automatic configuration

Network configuration

As shown in Figure 4, Switch A does not have a configuration file.

Configure the servers so Switch A can obtain a Python script to complete the following configuration tasks:

- Enable the administrator to Telnet to Switch A to manage Switch A.
- Require the administrator to enter the correct username and password at login.

Figure 4 Network diagram

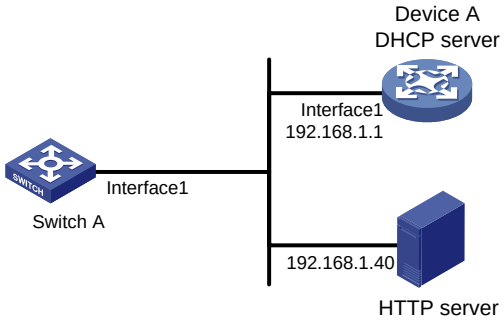

Table 6 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

1. Configure the DHCP server:

   # Enable DHCP.

   ```
   <Sysname> system-view
   [Sysname] sysname DeviceA
   [DeviceA] dhcp enable
   ```

   # Configure address pool **1** to assign IP addresses on the 192.168.1.0/24 subnet to clients.

   ```
   [DeviceA] dhcp server ip-pool 1
   [DeviceA-dhcp-pool-1] network 192.168.1.0 24
   ```

   # Specify the URL of the script file for the clients.

   ```
   [DeviceA-dhcp-pool-1] bootfile-name http://192.168.1.40/device.py
   [DeviceA-dhcp-pool-1] quit
   ```

   # Enable the DHCP server on GigabitEthernet1/0/1.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ip address 192.168.1.1 24
   [DeviceA-GigabitEthernet1/0/1] dhcp select server
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

2. Configure the HTTP server:

   # Create a configuration file named **device.py** on the HTTP server.

   ```
   #!usr/bin/python

   import platformtools
   platformtools.CLI('system-view ;telnet server enable ;local-user user ;password
   simple hello22345 ;service-type telnet ;quit ;user-interface vty 0
   63 ;authentication-mode scheme ;user-role network-admin ;quit ;interface
   gigabitethernet 1/0/1 ;port link-mode route ;ip address dhcp-alloc ;return')
   ```

   # Start HTTP service software and enable HTTP service. (Details not shown.)

Verifying the configuration

1. Power on Switch A.
2. After Switch A starts up, display assigned IP addresses on Device A.

   ```
   <DeviceA> display dhcp server ip-in-use
   ```

```
IP address       Client identifier/    Lease expiration      Type
                 Hardware address
192.168.1.2      0030-3030-632e-3239-  Dec 12 17:41:15 2013  Auto(C)
                 3035-2e36-3736-622d-
                 4574-6830-2f30-2f32
```

3. Telnet to 192.168.1.2 from Device A.

```
<DeviceA> telnet 192.168.1.2
```

4. Enter username **user** and password **hello22345** as prompted. (Details not shown.)
   You are logged in to Switch A.

Configuration files

```
#
 sysname DeviceA
#
 dhcp enable
#
dhcp server ip-pool 1
 network 192.168.1.0 mask 255.255.255.0
 bootfile-name http://192.168.1.40/device.py
#
interface GigabitEthernet1/0/1
 port link-mode route
 ip address 192.168.1.1 255.255.255.0
#
return
```

Example: Using an SFTP server for automatic configuration

Network configuration

As shown in Figure 5, Switch A automatically obtains and executes a configuration file from the SFTP server after it starts up in order to meet the following requirements:

- The network administrator can log in to and control the switch through Telnet.
- Authentication is required for switch login to enhance security.

Figure 5 Network diagram

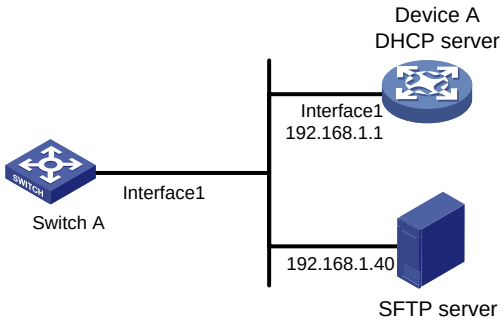

Table 7 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

1. Configure the DHCP server:

   # Enable DHCP, create DHCP address pool **1**, and specify primary subnet 192.168.1.0/24 for dynamic allocation in the address pool.

   ```
   <Sysname> system-view
   [Sysname] sysname DeviceA
   [DeviceA] dhcp enable
   [DeviceA] dhcp server ip-pool 1
   [DeviceA-dhcp-pool-1] network 192.168.1.0 24
   ```

   # Specify the URL of the configuration file. The username and password must be the same as those on the SFTP server.

   ```
   [DeviceA-dhcp-pool-1] bootfile-name sftp://user%dd:pass@192.168.1.40:22/device.cfg
   [DeviceA-dhcp-pool-1] quit
   ```

   # Enable the DHCP server on GigabitEthernet1/0/1.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ip address 192.168.1.1 24
   [DeviceA-GigabitEthernet1/0/1] dhcp select server
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

2. Configure the SFTP server to ensure that Switch A can successfully download configuration file **device.cfg** from the SFTP server:

   # Create configuration file **device.cfg** on the SFTP server. The file contents are as follows:

   ```
   #
   telnet server enable
   #
   local-user user
   password simple hello12345
   service-type telnet
   quit
   #
   user-interface vty 0 63
   authentication-mode scheme
   user-role network-admin
   quit
   #
   interface gigabitethernet 1/0/1
   port link-mode route
   ip address dhcp-alloc
   return
   ```

   # Start the SFTP management software and enable the SFTP service. (Details not shown.)

Verifying the configuration

Start up Switch A without a startup configuration file. After the switch starts up successfully, display binding information about assigned IP addresses on Device A.

```
<DeviceA> display dhcp server ip-in-use
```

```
IP address       Client identifier/    Lease expiration      Type
                 Hardware address
192.168.1.2      0030-3030-632e-3239-  Dec 12 17:41:15 2013  Auto(C)
                 3035-2e36-3736-622d-
                 4574-6830-2f30-2f32
```

On Device A, Telnet to Switch A.

```
<SwitchA> telnet 192.168.1.2
```

Enter username **user** and password **hello12345**. Verify that you can Telnet to Switch A from Device A.

Configuration files

```
#
 sysname DeviceA
#
 dhcp enable
#
dhcp server ip-pool 1
 network 192.168.1.0 mask 255.255.255.0
 bootfile-name sftp://user%dd:pass@192.168.1.40:22/device.cfg
#
interface GigabitEthernet1/0/1
 port link-mode route
 ip address 192.168.1.1 255.255.255.0
#
return
```

Example: Using an FTP server for automatic configuration

Network configuration

As shown in Figure 6, Switch A automatically obtains and executes a configuration file from the FTP server after it starts up in order to meet the following requirements:

- The network administrator can log in to and control the switch through Telnet.
- Authentication is required for switch login to enhance security.

Figure 6 Network diagram

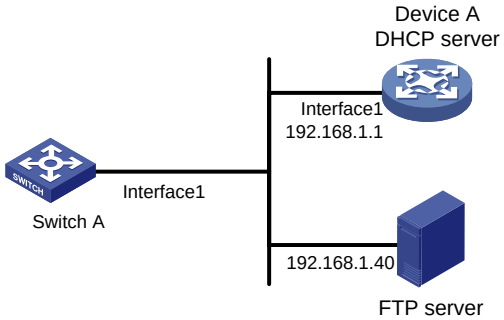

Table 8 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

1. Configure the DHCP server:

   # Enable DHCP, create DHCP address pool **1**, and specify primary subnet 192.168.1.0/24 for dynamic allocation in the address pool.

   ```
   <Sysname> system-view
   [Sysname] sysname DeviceA
    [DeviceA] dhcp enable
   [DeviceA] dhcp server ip-pool 1
   [DeviceA-dhcp-pool-1] network 192.168.1.0 24
   ```

   # Specify the URL of the configuration file. The username and password must be the same as those on the FTP server.

   ```
   [DeviceA-dhcp-pool-1] bootfile-name ftp://user:pass@192.168.1.40:22/device.cfg
   [DeviceA-dhcp-pool-1] quit
   ```

   # Enable the DHCP server on GigabitEthernet1/0/1.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ip address 192.168.1.1 24
   [DeviceA-GigabitEthernet1/0/1] dhcp select server
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

2. Configure the FTP server to ensure that Switch A can successfully download configuration file **device.cfg** from the FTP server:

   # Create configuration file **device.cfg** on the FTP server. The file contents are as follows:

   ```
   #
   telnet server enable
   #
   local-user user
   password simple hello12345
   service-type telnet
   quit
   #
   user-interface vty 0 63
   authentication-mode scheme
   user-role network-admin
   quit
   #
   interface gigabitethernet 1/0/1
   port link-mode route
   ip address dhcp-alloc
   return
   ```

   # Start the FTP management software and enable the FTP service. (Details not shown.)

Verifying the configuration

Start up Switch A without a startup configuration file. After the switch starts up successfully, display binding information about assigned IP addresses on Device A.

```
<DeviceA> display dhcp server ip-in-use
```

```
IP address       Client identifier/    Lease expiration      Type
                 Hardware address
192.168.1.2      0030-3030-632e-3239-  Dec 12 17:41:15 2013  Auto(C)
                 3035-2e36-3736-622d-
                 4574-6830-2f30-2f32
```

On Device A, Telnet to Switch A.

```
<SwitchA> telnet 192.168.1.2
```

Enter username **user** and password **hello12345**. Verify that you can Telnet to Switch A from Device A.

Configuration files

```
#
 sysname DeviceA
#
 dhcp enable
#
dhcp server ip-pool 1
 network 192.168.1.0 mask 255.255.255.0
 bootfile-name ftp://user:pass@192.168.1.40:22/device.cfg
#
interface GigabitEthernet1/0/1
 port link-mode route
 ip address 192.168.1.1 255.255.255.0
#
return
```

Example: Setting up an IRF fabric

Network configuration

As shown in Figure 7, Switch A and Switch B do not have a configuration file.

Configure the servers so the switches can obtain a Python script to complete their respective configurations and form an IRF fabric.

Figure 7 Network diagram

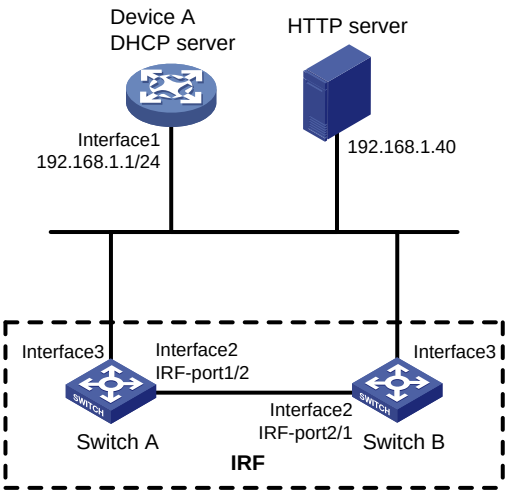

Table 9 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	Management Ethernet interface

Procedure

1. Configure Device A as the DHCP server:

   # Enable DHCP.

   ```
   <Sysname> system-view
   [Sysname] sysname DeviceA
   [DeviceA] dhcp enable
   ```

   # Configure IP pool **1** to assign IP addresses on the 192.168.1.0/24 subnet to clients.

   ```
   [DeviceA] dhcp server ip-pool 1
   [DeviceA-dhcp-pool-1] network 192.168.1.0 24
   ```

   # Specify the URL of the script file for the clients.

   ```
   [DeviceA-dhcp-pool-1] bootfile-name http://192.168.1.40/device.py
   [DeviceA-dhcp-pool-1] quit
   ```

   # Enable the DHCP server on GigabitEthernet 1/0/1.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] ip address 192.168.1.1 24
   [DeviceA-GigabitEthernet1/0/1] dhcp select server
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

2. Configure the following files on the HTTP server:

File	Content	Remarks
.cfg configuration file	Commands required for IRF setup.	You can create a configuration file by copying and modifying the configuration file of an existing IRF fabric.
sn.txt	Serial numbers of the member switches.	Each SN uniquely identifies a switch. These SNs will be used for assigning a unique IRF member ID to each member switch.
(Optional.) .ipe or .bin software image file	Software images.	If the member switches are running different software versions, you must prepare the software image file used for software upgrade.
.py Python script file	Python commands that complete the following tasks: **1.** (Optional.) Verify that the flash memory has sufficient space for the files to be downloaded. **2.** Download the configuration file and **sn.txt**.	For more information about Python script configuration, see "Using Python."

	3. (Optional.) Download the software image file and specify it as the main startup image file. **4.** Resolve **sn.txt** and assign a unique IRF member ID to each SN. **5.** Specify the configuration file as the main next-startup configuration file. **6.** Reboot the member switches.	

The specific content of the Python script is as follows (there are simple comments in the Python script, delete the comments when you use the script):

```
#!usr/bin/python

import comware
from time import strftime,gmtime,sleep
import signal
import os
import string
import commands
import hashlib

#python_config_file_mode
#'python_static'
#python_serial_number

  #after download file user can not stop script
  signal.signal(signal.SIGTERM, sig_handler_no_exit)
  if (True == installBootImage()) and (True == startupCfg()) and (True ==
stackIrfCfg()):
    doExit("success")
doExit("error")
```

3. Power on Switch A and Switch B.

   Switch A and Switch B will obtain the Python script file from the DHCP server and execute the script. After completing the IRF configuration, Switch A and Switch B reboot.

4. After Switch A and Switch B start up again, use a cable to connect Switch A and Switch B through their IRF physical ports.

   Switch A and Switch B will elect a master member. The subordinate member will reboot to join the IRF fabric.

Verifying the configuration

On Switch A, display IRF member devices. You can also use the **display irf** command on Switch B to display IRF member devices.

```
<Switch A> display irf
MemberID  Slot  Role    Priority  CPU-Mac         Description
   1      1     Standby 1         00e0-fc0f-8c02  ---
 *+2      1     Master  30        00e0-fc0f-8c14  ---
-------------------------------------------------
 * indicates the device is the master.
 + indicates the device through which the user logs in.

 The Bridge MAC of the IRF is: 000c-1000-1111
 Auto upgrade                : yes
 Mac persistent              : always
 Domain ID                   : 0
 Auto merge                  : yes
```

The output shows that the switches have formed an IRF fabric.

Configuration files

```
#

Managing the device

This chapter describes how to configure basic device parameters and manage the device.

Device management tasks at a glance

All device management tasks are optional. You can perform any of the tasks in any order.

- Configuring basic parameters
  - Configuring the device name
  - Configuring the system ID
  - Configuring the system time
  - Enabling displaying the copyright statement
  - Configuring banners
- Configuring security parameters
  - Disabling password recovery capability
- Adjusting device capacities
  - Setting the port state detection timer
- Monitoring the device
  - Monitoring CPU usage
  - Setting memory alarm thresholds
  - Monitoring DMA memory
  - Configuring resource monitoring
  - Setting the temperature alarm thresholds
  - Configuring consistency error logging for software and hardware forwarding entries
  - Configuring consistency error logging for software and hardware forwarding entries
  - Configuring consistency error logging for software and hardware forwarding entries
- Managing resources
  - Ignoring absent fans
  - Verifying and diagnosing transceiver modules
  - Configuring transceiver monitoring
  - Configuring transceiver health check
  - Enabling a lane on a transceiver module
  - Monitoring optical power of transceiver modules
    - Configuring RX and TX power thresholds for a transceiver module
    - Configuring RX and TX power change thresholds for a transceiver module
- Maintaining the device
  - Scheduling a task
  - Rebooting the device
  - Restoring the factory-default configuration

Configuring the device name

About this task

A device name (also called hostname) identifies a device in a network and is used in CLI view prompts. For example, if the device name is **Sysname**, the user view prompt is <Sysname>.

Procedure

1. Enter system view.
   system-view
2. Configure the device name.
   sysname *sysname*
   By default, the device name is **H3C**.

Configuring the system ID

About this task

You can use the system ID to indicate the position or functionality of the device or any other information.

Procedure

1. Enter system view.
   system-view
2. Configure the system ID.
   sysid *system-id*
   By default, the device does not have a system ID.

Configuring the system time

About the system time

Correct system time is essential to network management and communication. Configure the system time correctly before you run the device on the network.

The device can use one of the following methods to obtain the system time:

- Uses the locally set system time, and then uses the clock signals generated by its built-in crystal oscillator to maintain the system time.
- Periodically obtains the UTC time from an NTP source, and uses the UTC time, time zone, and daylight saving time to calculate the system time. For more information about NTP, see *Network Management and Monitoring Configuration Guide*.

The system time calculated by using the UTC time from a time source is more precise.

Restrictions and guidelines for configuring the system time

After you execute the **clock protocol none** command, the **clock datetime** command determines the system time, whether or not the time zone or daylight saving time has been configured.

If you configure or change the time zone or daylight saving time after the device obtains the system time, the device recalculates the system time. To view the system time, execute the **display clock** command.

System time configuration tasks at a glance

To configure the system time, perform the following tasks:

1. Configuring the system time

   Choose one of the following tasks:

   - Setting the system time at the CLI
   - Obtaining the UTC time through a time protocol

2. (Optional.) Setting the time zone

   Make sure each network device uses the time zone of the place where the device resides.

3. (Optional.) Setting the daylight saving time

   Make sure each network device uses the daylight saving time parameters of the place where the device resides.

Setting the system time at the CLI

1. Enter system view.

   system-view

2. Configure the device to use the local system time.

   clock protocol none

   By default, the device uses the NTP time source.

   If you execute the **clock protocol** command multiple times, the most recent configuration takes effect.

3. Return to user view.

   quit

4. Set the local system time.

   clock datetime *time date*

   By default, the system time is UTC time 00:00:00 01/01/2011.

CAUTION:

Change of the system time affects execution of system time-related features (such as scheduled tasks) and cooperative operation with other devices (such as log reporting and statistics collection). Before using this command, make sure you understand its impact on the live network.

Obtaining the UTC time through a time protocol

1. Enter system view.

   system-view

2. Specify the system time source.

   clock protocol ntp

   By default, the device uses the NTP time source.

   If you execute this command multiple times, the most recent configuration takes effect.

3. Configure time protocol parameters.

   For more information about NTP configuration, see *Network Management and Monitoring Configuration Guide*.

Setting the time zone

1. Enter system view.

   system-view
2. Set the time zone.

   clock timezone *zone-name* { **add** | **minus** } *zone-offset*

   By default, the system uses the UTC time zone.

Setting the daylight saving time

1. Enter system view.

   system-view
2. Set the daylight saving time.

   clock summer-time *name start-time start-date end-time end-date add-time*

   By default, the daylight saving time is not set.

Enabling displaying the copyright statement

About this task

This feature enables the device to display the copyright statement in the following situations:

- When a Telnet or SSH user logs in.
- When a console user quits user view. This is because the device automatically tries to restart the user session.

If you disable displaying the copyright statement, the device does not display the copyright statement in any situations.

Procedure

1. Enter system view.

   system-view
2. Enable displaying the copyright statement.

   copyright-info enable

   By default, displaying the copyright statement is enabled.

Configuring banners

About this task

Banners are messages that the system displays when a user logs in.

The system supports the following banners:

- **Legal banner**—Appears after the copyright statement.
- **Message of the Day (MOTD) banner**—Appears after the legal banner and before the login banner.

- **Login banner**—Appears only when password or scheme authentication is configured.
- **Shell banner**—Appears when the user accesses user view.
- **Shell banner**—Appears for a login user when the user accesses user view.
- **Shell banner**—Appears when the user accesses user view.
- **Shell banner**—Appears when the user accesses user view.

The system displays the banners in the following order: legal banner, MOTD banner, login banner, and shell banner.

Banner input methods

You can configure a banner by using one of the following methods:

- Input the entire command line in a single line.

  The banner cannot contain carriage returns. The entire command line, including the command keywords, the banner, and the delimiters, can have a maximum of 511 characters. The delimiters for the banner can be any printable character but must be the same. You cannot press **Enter** before you input the end delimiter.

  For example, you can configure the shell banner "Have a nice day." as follows:

  ```
  <System> system-view
  [System] header shell %Have a nice day.%
  ```

- Input the command line in multiple lines.

  The banner can contain carriage returns. A carriage return is counted as two characters.

  To input a banner configuration command line in multiple lines, use one of the following methods:

  - Press **Enter** after the final command keyword, type the banner, and end the final line with the delimiter character %. The banner plus the delimiter can have a maximum of 1999 characters.

    For example, you can configure the banner "Have a nice day." as follows:

    ```
    <System> system-view
    [System] header shell
    Please input banner content, and quit with the character '%'.
    Have a nice day.%
    ```

  - After you type the final command keyword, type any printable character as the start delimiter for the banner and press **Enter**. Then, type the banner and end the final line with the same delimiter. The banner plus the end delimiter can have a maximum of 1999 characters.

    For example, you can configure the banner "Have a nice day." as follows:

    ```
    <System> system-view
    [System] header shell A
    Please input banner content, and quit with the character 'A'.
    Have a nice day.A
    ```

  - After you type the final command keyword, type the start delimiter and part of the banner. Make sure the final character of the final string is different from the start delimiter. Then, press **Enter**, type the rest of the banner, and end the final line with the same delimiter. The banner plus the start and end delimiters can have a maximum of 2002 characters.

    For example, you can configure the banner "Have a nice day." as follows:

    ```
    <System> system-view
    [System] header shell AHave a nice day.
    Please input banner content, and quit with the character 'A'.
    A
    ```

Procedure

1. Enter system view.
   system-view
2. Configure the legal banner.
   header legal *text*
3. Configure the MOTD banner.
   header motd *text*
4. Configure the login banner.
   header login *text*
5. Configure the shell banner.
   header shell *text*

Disabling password recovery capability

About this task

Password recovery capability controls console user access to the device configuration and SDRAM from BootWare menus. For more information about BootWare menus, see the release notes.

If password recovery capability is enabled, a console user can access the device configuration without authentication to configure a new password.

If password recovery capability is disabled, console users must restore the factory-default configuration before they can configure new passwords. Restoring the factory-default configuration deletes the next-startup configuration files.

To enhance system security, disable password recovery capability.

Restrictions and guidelines

To access the device configuration without authentication, you must connect to the master device and access the BootWare menu during the device startup.

Procedure

1. Enter system view.
   system-view
2. Disable password recovery capability.
   undo password-recovery enable
   By default, password recovery capability is enabled.

Disabling USB interfaces

About this task

You can use USB interfaces to upload or download files. By default, all USB interfaces are enabled. You can disable USB interfaces as needed.

Prerequisites

Before using this command, use the **umount** command to unmount all USB partitions. For more information about this command, see *Fundamentals Command Reference*.

Procedure

1. Enter system view.

system-view

2. Disable USB interfaces.

   usb disable

   By default, all USB interfaces are enabled.

Setting the port state detection timer

About this task

On a network enabled with loopback detection or the spanning tree feature, the device starts a port status detection timer when a port is shut down by a protocol. If the port remains in down state when the timer expires, the device sets the port state to the port's real physical state.

Procedure

1. Enter system view.

   system-view

2. Set the port state detection timer.

   shutdown-interval *time*

   The default setting is 30 seconds.

Enabling MODE button press configuration

About this task

The MODE button on the front panel works in conjunction with the port LEDs to indicate the operating state of the ports from different dimensions and obtain more device information. By default, the operations that can be performed by pressing the MODE button depend on the duration of the press as follows:

- 0 to 5 seconds: Change the type of port information that the port LEDs are showing.
- More than 5 seconds: Invalid operation.

After you execute the **push-button mode enable** command, the operations that can be performed by pressing the MODE button depend on the duration of the press as follows:

- Less than 5 seconds: Change the type of port information that the port LEDs are showing, which is the same as the default setting.
- 5 to 10 seconds: Deploy the device to Cloudnet. In this case, the device attempts to set up a connection with Cloudnet. If the Cloudnet management status LED flashes at 1Hz in blue, the connection is being set up. After the connection is set up, you can add the device to Cloudnet. When the device is managed by Cloudnet successfully, the Cloudnet management status LED changes to steady blue. After the device is managed by Cloudnet, pressing the MODE button for 5 to 10 seconds will disconnect the device from Cloudnet, which changes turns off the Cloudnet management status LED.
- More than 10 seconds: No operation will be performed. To indicate that you have pressed MODE button for 10 seconds, the Cloudnet management status LED flashes once at 3Hz in blue.

Hardware and feature compatibility

This feature is available only on the S5200-EI-G switch series.

Procedure

1. Enter system view.

   system view

2. Enable MODE button press configuration.

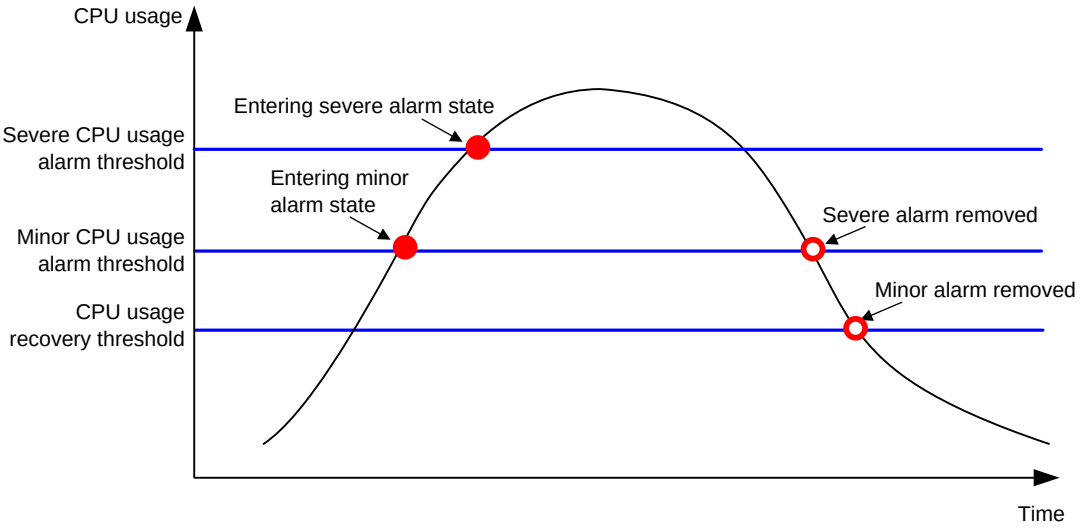
   `push-button mode enable`

   By default, MODE button press configuration is disabled.

Monitoring CPU usage

About this task

To monitor CPU usage, the device performs the following operations:



- Samples CPU usage at 1-minute intervals, and compares the samples with CPU usage thresholds to identify the CPU usage status and send alarms or notifications accordingly.
- Samples CPU core usage at 1-minute intervals, and compares the samples with CPU core usage thresholds to identify the CPU core usage status. If a sample is greater than the threshold, the device sends a log message.
- Samples and saves CPU usage at a configurable interval if CPU usage tracking is enabled. You can use the **`display cpu-usage history`** command to display the historical CPU usage statistics in a coordinate system.

The device supports the following CPU usage thresholds:

- **Minor threshold**—If the CPU usage increases to or above the minor threshold but is less than the severe threshold, the CPU usage enters minor alarm state. The device sends minor alarms periodically until the CPU usage increases above the severe threshold or the minor alarm is removed.
- **Severe threshold**—If the CPU usage increases above the severe threshold, the CPU usage enters severe alarm state. The device sends severe alarms periodically until the severe alarm is removed.
- **Recovery threshold**—If the CPU usage decreases below the recovery threshold, the CPU usage enters recovered state. The device sends a recovery notification.

CPU usage alarms and notifications can be sent to NETCONF, SNMP, and the information center to be encapsulated as NETCONF events, SNMP traps and informs, and log messages. For more information, see NETCONF, SNMP, and information center in *Network Management and Monitoring Configuration Guide*.

Figure 1 CPU alarms and alarm-removed notifications

Procedure

1. Enter system view.

   system-view

2. Set the CPU usage alarm thresholds.

   monitor cpu-usage threshold *severe-threshold* { **minor-threshold** *minor-threshold* **recovery-threshold** *recovery-threshold* [**slot** *slot-number* [**cpu** *cpu-number*]] }

   The default settings are as follows:

   - **Severe CPU usage alarm threshold**—99%.
   - **Minor CPU usage alarm threshold**—80%.
   - **CPU usage recovery threshold**—60%.

   CAUTION:

   If you set the severe CPU usage alarm threshold to a too low value, the device will reach the threshold easily. Normal service processing will be affected.

3. Set CPU usage alarm resending intervals.

   monitor resend cpu-usage { **minor-interval** *minor-interval* | **severe-interval** *severe-interval* } * [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, the minor alarm resending interval is 300 seconds and the severe alarm resending interval is 60 seconds.

4. Set the sampling interval for CPU usage tracking.

   monitor cpu-usage interval *interval* [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, the sampling interval for CPU usage tracking is 1 minute.

5. Enable CPU usage tracking.

   monitor cpu-usage enable [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, CPU usage tracking is enabled.

6. (Optional.) Enable periodic CPU usage logging.

   monitor cpu-usage logging interval *interval-time*

   By default, periodic CPU usage logging is disabled.

Setting memory alarm thresholds

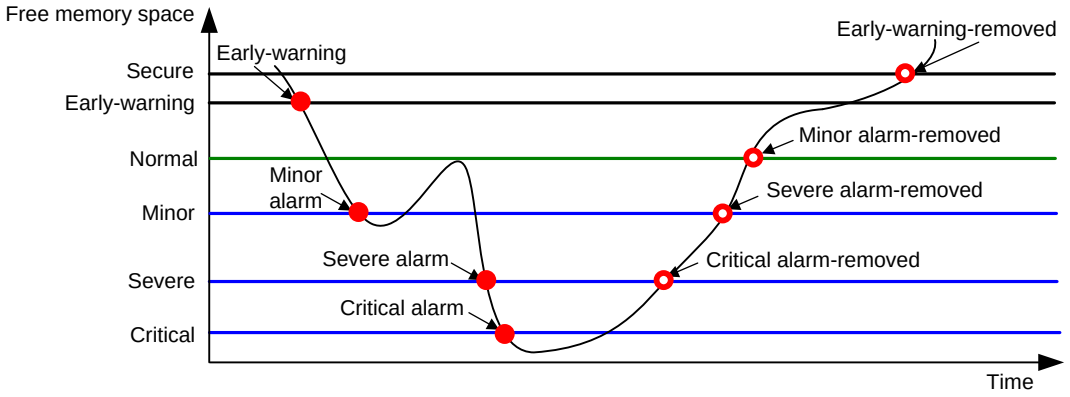
About this task

To ensure correct operation and improve memory efficiency, the system monitors the amount of free memory space in real time. If the amount of free memory space reaches the minor, severe, or critical alarm threshold, the system issues an alarm to affected service modules and processes.

The system can also issue an early warning to warn you of an approaching insufficient-memory condition.

The system monitors only the amount of free memory space. You can use the **display memory** command to display memory usage information.

The system supports these free memory thresholds:



- Sufficient-memory threshold.

- Early-warning threshold.
- Normal state threshold.
- Minor alarm threshold.
- Severe alarm threshold.
- Critical alarm threshold.

Table 1 Memory alarm notifications and memory alarm-removed notifications

Notification	Triggering condition	Remarks
Early-warning notification	The amount of free memory space decreases below the early-warning threshold.	After generating and sending an early-warning notification, the system does not generate and send any additional early-warning notifications until the early warning is removed.
Minor alarm notification	The amount of free memory space decreases below the minor alarm threshold.	After generating and sending a minor alarm notification, the system does not generate and send any additional minor alarm notifications until the minor alarm is removed.
Severe alarm notification	The amount of free memory space decreases below the severe alarm threshold.	After generating and sending a severe alarm notification, the system does not generate and send any additional severe alarm notifications until the severe alarm is removed.
Critical alarm notification	The amount of free memory space decreases below the critical alarm threshold.	After generating and sending a critical alarm notification, the system does not generate and send any additional critical alarm notifications until the critical alarm is removed.
Critical alarm-removed notification	The amount of free memory space increases above the severe alarm threshold.	N/A
Severe alarm-removed notification	The amount of free memory space increases above the minor alarm threshold.	N/A
Minor alarm-removed notification	The amount of free memory space increases above the normal state threshold.	N/A
Early-warning-removed notification	The amount of free memory space increases above the sufficient-memory threshold.	N/A

Figure 2 Memory alarm notifications and alarm-removed notifications

Hardware and feature compatibility

The early-warning-related functions are supported only on the S5200-HI-G switch series.

Restrictions and guidelines

If a memory alarm occurs, delete unused configuration items or disable some features to increase the free memory space. Because the memory space is insufficient, some configuration items might not be able to be deleted.

The system reboots the device if one of the following conditions is met:

- After a critical alarm occurs, the remaining free-memory value has been smaller than the critical alarm threshold for 30 seconds.
- The interval between two consecutive critical alarms is shorter than 30 seconds.
- The critical alarm has occurred three times within three minutes.
- After a critical alarm occurs, the system will periodically sample free memory space and predict if the free memory space will be exhausted within 30 seconds. If the prediction result indicates that the free memory space will be exhausted within 30 seconds, the system will reboot the device.

Once the free memory space reaches the early warning, minor, severe, or critical alarm threshold, the device will display the current memory usage information when you log in to the device through console or Telnet login, or execute every command.

After you configure this feature, if the amount of the free memory space reaches the minor alarm threshold, the device cannot generate an asymmetric key pair through the **public-key local create** command. For more information, see PKI configuration in *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Set the memory usage threshold.

   memory-threshold [**slot** *slot-number* [**cpu** *cpu-number*]] **usage** *memory-threshold*

   By default, the memory usage threshold is 100%.

3. Set the free-memory thresholds.

   memory-threshold [**slot** *slot-number* [**cpu** *cpu-number*]] [**ratio**] **minor** *minor-value* **severe** *severe-value* **critical** *critical-value* **normal** *normal-value* [**early-warning** *early-warning-value* **secure** *secure-value*]

   By default:

- For the S5200-HI-G switch series:
  - **Minor alarm threshold**—190 MB.
  - **Severe alarm threshold**—133 MB.
  - **Critical alarm threshold**—76 MB.
  - **Normal state threshold**—247 MB.
  - **Early-warning threshold**—304 MB.
  - **Sufficient-memory threshold**—342 MB.
- For the S5200-EI-G switch series:
  - **Minor alarm threshold**—56 MB.
  - **Severe alarm threshold**—52 MB.
  - **Critical alarm threshold**—48 MB.
  - **Normal state threshold**—64 MB.

The default settings are as follows:

- **Minor alarm threshold**—194 MB.
- **Severe alarm threshold**—136 MB.
- **Critical alarm threshold**—77 MB.
- **Normal state threshold**—252 MB.
- **Early-warning threshold**—311 MB.
- **Sufficient-memory threshold**—350 MB.

4. Set memory depletion alarm resending intervals.

   monitor resend memory-threshold { **critical-interval** *critical-interval* | **early-warning-interval** *early-warning-interval* | **minor-interval** *minor-interval* | **severe-interval** *severe-interval* } * [**slot** *slot-number* [**cpu** *cpu-number*]]

   For the S5200-HI-G switch series, the default settings are as follows:

   - **Early warning resending interval**—1 hour.
   - **Minor alarm resending interval**—12 hours.
   - **Severe alarm resending interval**—3 hours.
   - **Critical alarm resending interval**—1 hour.

   For the S5200-EI-G switch series, the default settings are as follows:

   - **Minor alarm resending interval**—12 hours.
   - **Severe alarm resending interval**—3 hours.
   - **Critical alarm resending interval**—1 hour.

5. (Optional.) Enable periodic memory usage logging.

   monitor memory-usage logging interval *interval-time*

   By default, periodic memory usage logging is disabled.

Monitoring DMA memory

About this task

To ensure correct operation of services that use Direct Memory Access (DMA) memory, the system monitors the amount of free DMA memory space regularly. If the amount of free DMA memory space decreases to or below the alarm threshold, the system generates a notification that the DMA memory space is insufficient. If the amount of free DMA memory space increases above the normal state threshold, the system generates a notification that the DMA memory space is sufficient.

DMA memory alarm notifications are sent to NETCONF, SNMP, and the information center to be encapsulated as NETCONF events, SNMP traps and informs, and log messages. For more information about NETCONF, SNMP, and information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Set the DMA memory thresholds.

   memory-threshold dma [**slot** *slot-number* [**cpu** *cpu-number*]] [**ratio**] **critical** *critical-value* **normal** *normal-value*

   The DMA memory alarm threshold is 2048 KB and the normal state threshold is 4096 KB.

3. Set the DMA memory alarm resending interval.

   monitor resend memory-threshold dma critical-interval *critical-interval* [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, the DMA memory alarm resending interval is 300 seconds.

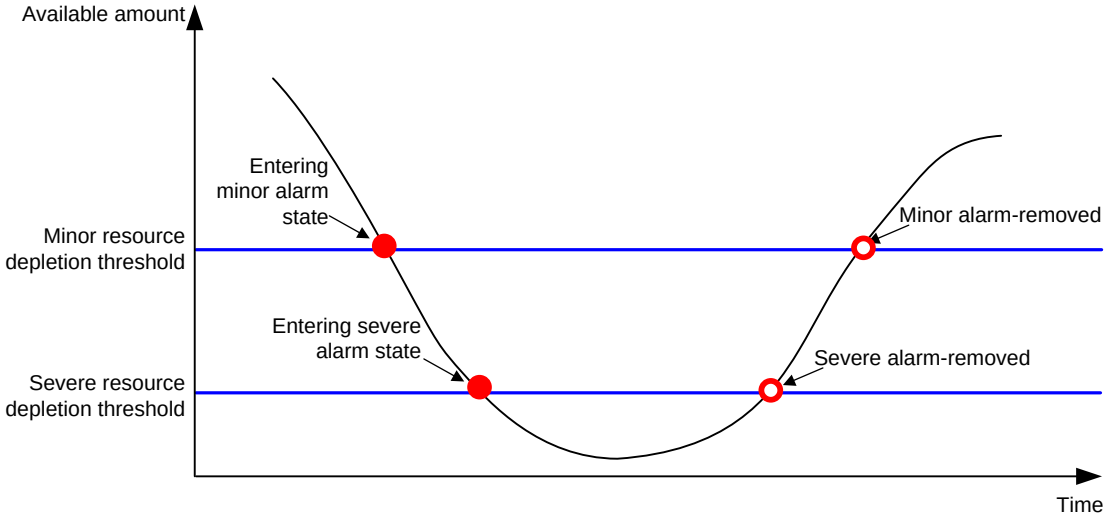
   This feature is available only for the S5200-EI-G switch series.

Configuring resource monitoring

About this task

The resource monitoring feature enables the device to monitor the available amounts of types of resources, for example, the space for ARP entries. The device samples the available amounts periodically and compares the samples with resource depletion thresholds to identify the resource depletion status.

The device supports a minor resource depletion threshold and a severe resource depletion threshold for each supported resource type.



- If the available amount is equal to or less than the minor resource depletion threshold but greater than the severe resource depletion threshold, the resource type is in minor alarm state.
- If the available amount is equal to or less than the severe resource depletion threshold, the resource type is in severe alarm state.
- If the available amount increases above the minor resource depletion threshold, the resource type is in recovered state.

When a resource type enters severe alarm state, the device issues a severe alarm. If the resource type stays in severe alarm state, the device resends severe alarms periodically.

When a resource type enters minor alarm state, the device issues a minor alarm. If the resource type stays in minor alarm state or changes from severe alarm state to minor alarm state, the device identifies whether resending of minor resource depletion alarms is enabled. If the feature is disabled, the device does not issue additional minor alarms. If the feature is enabled, the device resends minor alarms periodically.

Resource depletion alarms can be sent to NETCONF, SNMP, and the information center to be encapsulated as NETCONF events, SNMP traps and informs, and log messages. For more information, see NETCONF, SNMP, and information center in *Network Management and Monitoring Configuration Guide*.

Figure 3 Resource depletion alarms and alarm-removed notifications

Hardware and feature compatibility

This feature is supported only on the S5200-HI-G switch series.

Procedure

1. Enter system view.

   system-view

2. Set resource depletion thresholds.

   resource-monitor resource *resource-name* **slot** *slot-number* **cpu** *cpu-number* **by-percent minor-threshold** *minor-threshold* **severe-threshold** *severe-threshold*

   The default settings vary by resource type. Use the **display resource-monitor** command to display the resource depletion thresholds.

3. Specify destinations for resource depletion alarms.

   resource-monitor output { **netconf-event** | **snmp-notification** | **syslog** } *

   By default, resource depletion alarms are sent to NETCONF, SNMP, and the information center.

4. Enable resending of minor resource depletion alarms.

   resource-monitor minor resend enable

   By default, resending of minor resource depletion alarms is enabled.

Setting the temperature alarm thresholds

About this task

The device monitors its temperature based on the following thresholds:

- Low-temperature threshold.
- High-temperature warning threshold.
- High-temperature alarming threshold.

When the device temperature drops below the low-temperature threshold or reaches the high-temperature warning or alarming threshold, the device performs the following operations:

- Sends log messages and traps.
- Sets LEDs on the device panel.

Procedure

1. Enter system view.

   system-view

2. Configure the temperature alarm thresholds.

   temperature-limit slot *slot-number* **hotspot** *sensor-number lowlimit warninglimit* [*alarmlimit*]

   The defaults vary by temperature sensor model. To view the defaults, execute the **undo temperature-limit** and **display environment** commands in turn.

   The high-temperature alarming threshold must be higher than the high-temperature warning threshold, and the high-temperature warning threshold must be higher than the low-temperature threshold.

Disabling the notification of hardware resource alarms

About this task

Perform this task to disable the notification of hardware resource alarms.

Procedure

1. Enter system view.

   system-view

2. Disable the notification of hardware resource alarms.

   hardware-alarm { **syslog** | **trap** } **resource-type** { **all** | **board** | **bus** | **chip-channel** | **chip-port** | **device** | **disk** | **fan** | **interface** | **power** | **subcard** | **transceiver** | **voltage** } **disable**

   By default, the notification of all hardware resource alarms is enabled.

Configuring consistency error logging for software and hardware forwarding entries

About this task

To forward packets, the device generates hardware forwarding entries in forwarding chips and software forwarding entries in memory at the same time. The device automatically detects whether the hardware forwarding entries and the software forwarding entries are consistent.

The consistency error logging for software and hardware forwarding entries enables the device to collect statistics for consistency errors between software and hardware forwarding entries periodically. If the number of consistency errors reaches or exceeds the logging threshold, the device generates a log message.

Procedure

1. Enter system view.

   system-view

2. Set the logging threshold for consistency errors between software and hardware forwarding entries.

parity-error consistency-check threshold *value*

By default, the logging threshold is 10.

3. Set the statistics period for consistency errors between software and hardware forwarding entries.

   parity-error consistency-check period *value*

   By default, the statistics period is 3600 seconds.

4. Enable consistency error logging for software and hardware forwarding entries.

   parity-error consistency-check log enable

   By default, consistency error logging is enabled for software and hardware forwarding entries.

Configuring parity error and ECC error logging for entries on forwarding chips

About this task

The device automatically detects parity errors and ECC errors in entries on forwarding chips. The parity error and ECC error logging feature collects parity errors and ECC error statistics periodically, and generates a log message if the number of parity errors and ECC errors reaches or exceeds the logging threshold.

Procedure

1. Enter system view.

   system-view

2. Set the parity error and ECC error statistics period for entries on forwarding chips.

   parity-error monitor period *value*

   By default, the parity error and ECC error statistics period for entries on forwarding chips is 60 seconds.

3. Set the parity error and ECC error logging threshold for entries on forwarding chips.

   parity-error monitor threshold *value*

   By default, the parity error and ECC error logging threshold for entries on forwarding chips is 5000.

4. Enable parity error and ECC error logging for entries on forwarding chips.

   parity-error monitor log enable

   By default, parity error and ECC error logging is enabled for entries on forwarding chips.

Configuring uncorrectable parity error and ECC error logging for entries on forwarding chips

About this task

The device automatically detects parity errors and ECC errors in entries on forwarding chips and tries to correct the error when an error is detected. The uncorrectable parity error and ECC error logging feature enables the device to collect statistics for uncorrectable parity errors and ECC errors periodically. If the number of uncorrectable parity errors and ECC errors reaches or exceeds the logging threshold, the device generates a log message.

Uncorrectable parity errors and ECC errors in entries on forwarding chips might affect system services. To remove the errors from the entries on forwarding chips, you can enable automatic system reboot upon generation of an uncorrectable parity error and ECC error log.

Procedure

1. Enter system view.

   system-view

2. Set the statistics period for uncorrectable parity error and ECC errors for entries on forwarding chips.

   parity-error unrecoverable period *value*

   By default, the statistics period for uncorrectable parity error and ECC errors for entries on forwarding chips is 60 seconds.

3. Set the logging threshold for uncorrectable parity errors and ECC errors for entries on forwarding chips.

   parity-error unrecoverable threshold *value*

   By default, the logging threshold for uncorrectable parity errors and ECC errors for entries on forwarding chips is 1.

4. Enable uncorrectable parity error and ECC error logging for entries on forwarding chips.

   parity-error unrecoverable log enable

   By default, uncorrectable parity error and ECC error logging is enabled for entries on forwarding chips

5. (Optional.) Enable automatic system reboot upon generation of an uncorrectable parity error and ECC error log.

   parity-error unrecoverable reboot

   By default, the device reboots automatically upon generation of an uncorrectable parity error and ECC error log.

Configuring device poweroff alarming

About this task

This feature enables the device to detect a device poweroff event and issue a poweroff alarm by sending SNMP notifications or log messages.

Procedure

1. Enter system view.

   system-view

2. Specify the source interface for sending the poweroff alarm.

   dying-gasp source *interface-type interface-number*

   By default, no source interface is specified. On an IPv4 network, the device uses the primary IPv4 address of the output interface for the route to the destination host as the source address. On an IPv6 network, the device selects a source IPv6 address as defined in RFC 3484.

3. Configure SNMP notification destination host settings.

   dying-gasp host { *ip-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] **snmp-trap version**{ **v1** | **v2c** | **v3** [**authentication** | **privacy**] } **securityname** *security-string*

   By default, no SNMP notification destination host settings are configured.

   You can configure the device to send poweroff alarm SNMP notifications to multiple destination hosts.

4. Configure log message destination host settings.

   dying-gasp host { *ip-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] **syslog**

By default, no log message destination host settings are configured.

You can configure the device to send the poweroff alarm log messages to multiple destination hosts.

Ignoring absent fans

About this task

The device periodically polls the status of fans. Upon detecting an absent fan, the device sets the status of the fan to **Absent** and sends a log message and a trap. If the device has external fans and is well ventilated, you can use this command to configure the device to ignore absent fans. Then, the device does not send log messages or traps upon detecting absent fans.

Restrictions and guidelines

CAUTION:

This feature suppresses fan absence notifications and might cause device reboot and even device damage if the device is not well ventilated.

Before and after you configure this feature, make sure the device is well ventilated.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Set the fan operating mode.
   ```
   fan ignore-absent
   ```
   By default, the devices does not ignore absent fans.

Verifying and diagnosing transceiver modules

Verifying transceiver modules

About this task

You can use one of the following methods to verify the genuineness of a transceiver module:

- Display the key parameters of a transceiver module, including its transceiver type, connector type, central wavelength of the transmit laser, transfer distance, and vendor name.
- Display its electronic label. The electronic label is a profile of the transceiver module and contains the permanent configuration, including the serial number, manufacturing date, and vendor name. The data was written to the transceiver module or the device's storage component during debugging or testing of the transceiver module or device.

The device regularly checks transceiver modules for their vendor names. If a transceiver module does not have a vendor name or the vendor name is not H3C, the device repeatedly outputs traps and log messages. For information about logging rules, see *Network Management and Monitoring Configuration Guide*.

Procedure

To verify transceiver modules, execute the following commands in any view:

- Display the key parameters of transceiver modules.
  display transceiver interface [*interface-type interface-number*]
- Display the electrical label information of transceiver modules.

display transceiver manuinfo interface [*interface-type interface-number*]

Diagnosing transceiver modules

About this task

The device provides the following diagnosis functions for transceiver modules:

The device provides the alarm and digital diagnosis functions for transceiver modules. When a transceiver module fails or is not operating correctly, you can perform the following tasks:

- Display transceiver alarms. The device check the alarms that exist on transceiver modules to identify the fault source.
- Display the current values of the digital diagnosis parameters on transceiver modules, that is, digital diagnosis functions for transceiver modules. The device can examine the key parameters monitored by the digital diagnosis function, including the temperature, voltage, laser bias current, TX power, and RX power.
- Display diagnosis information in an eye diagram. This function simulates the quality of data transmission from professional testing instruments. It obtains the sampling values of received data on chips and outputs the diagnostic results of transceiver modules in an eye diagram. This facilitates users in analyzing and evaluating the data transmission quality of transceiver modules.

Procedure

To diagnose transceiver modules, execute the following commands in any view:

- Display transceiver alarms.

  display transceiver alarm interface [*interface-type interface-number*]
- Display the current values of the digital diagnosis parameters on transceiver modules.

  display transceiver diagnosis interface [*interface-type interface-number*]
- Display diagnostic information for transceiver modules in an eye diagram.

  display transceiver eyediagram-diagnosis interface [*interface-type interface-number*]

Configuring transceiver monitoring

About this task

After transceiver monitoring is enabled, the device samples the parameters of transceiver modules periodically, including the input power and output power of transceiver modules. If a sampled value reaches the alarm threshold, the device generates a log to notify users.

Hardware and feature compatibility

This feature is supported only on the S5200-HI-G switch series.

Restrictions and guidelines

Procedure

1. Enter system view.

   system-view
2. Set the transceiver monitoring interval.

   transceiver monitor interval *interval*

By default, the transceiver monitoring interval is 600 seconds.

3. Enable transceiver monitoring.

   transceiver monitor enable

   By default, transceiver monitoring is disabled.

Configuring transceiver health check

About this task

The transceiver health is calculated based on the weights of five diagnosis parameters of transceiver modules, including temperature, voltage, bias current, transmit power, and receive power.

Transceiver health check enables the device to automatically check transceiver module status, and calculate transceiver health and diagnosis parameter health based on the configured weights of diagnosis parameters.

After transceiver health check is enabled and the weights for transceiver health calculation are configured, you can use the **display transceiver health** command to view transceiver health information. A greater health value indicates a healthier status.

Hardware and feature compatibility

This feature is supported only on the S5200-HI-G switch series.

Restrictions and guidelines

The sum of the weights of temperature, voltage, bias current, transmit power, and receive power for transceiver health calculation must be 100.

Procedure

1. Enter system view.

   system-view

2. Enable transceiver health check.

   transceiver health check enable

   By default, transceiver health check is disabled.

3. Configure the weights for transceiver health calculation.

   transceiver health weight temp *temp-weight* **voltage** *voltage-weight* **bias** *bias-weight* **rxpower** *rxpower-weight* **txpower** *txpower-weight*

   The default settings are as follows:

   - Temperature weight: 15.
   - Voltage weight: 5.
   - Bias current weight: 30.
   - Receive power weight: 10.
   - Transmit power weight: 40.

Enabling a lane on a transceiver module

Restrictions and guidelines

Perform this task only to verify that a transceiver module functions correctly.

Disabling a lane on a transceiver module will stop signal transmission on the lane.

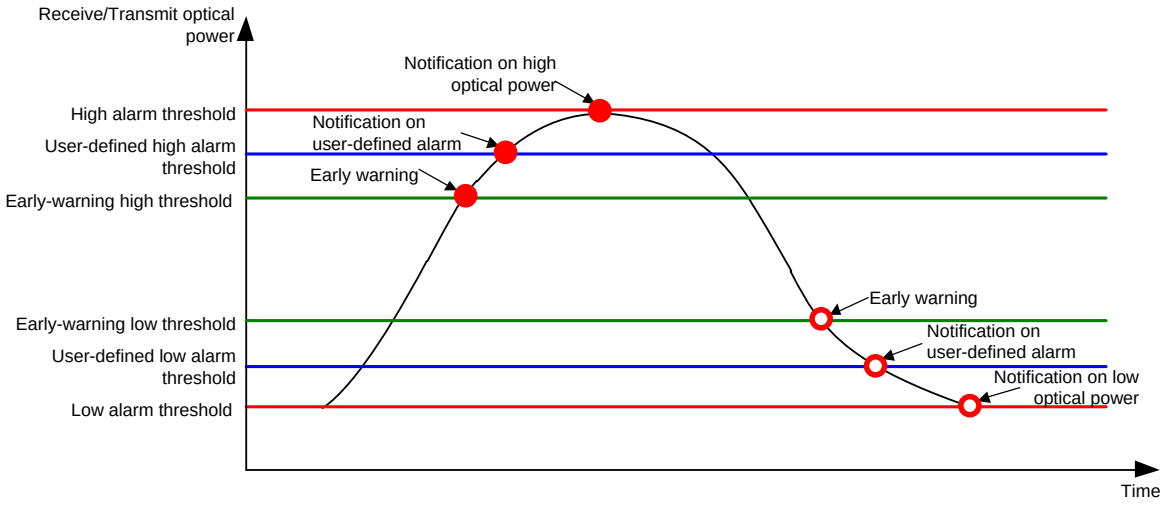
The lane enablement setting is saved in a register on the transceiver module. It is not saved to the configuration file.

This feature is supported only on an SFP transceiver module.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Enable a lane on the transceiver module.
   transceiver lane [*lane-number*] **enable**
   By default, the lanes on the transceiver module are enabled.

Monitoring optical power of transceiver modules



Configuring RX and TX power thresholds for a transceiver module

About this task

To detect optical power anomalies and take actions promptly, you can set alarm thresholds between the default early-warning thresholds and alarm thresholds for RX and TX power of transceiver modules, as shown in Figure 4. If the RX/TX power of a transceiver module exceeds or drops below a user-defined threshold, the system generates an alarm message.

You can execute the **display transceiver diagnosis** command to obtain the current RX/TX power, early-warning thresholds, user-defined thresholds, and alarm thresholds.

Figure 4 Configuring RX and TX power thresholds for a transceiver module

Restrictions and guidelines

This feature is available only for digital-diagnosis-capable the SFP, SFP+ transceiver modules. It is not available for the 400G ZR, 400G ZR+, or fiber-to-copper transceiver modules.

Procedure

1. Enter system view.
   system-view

2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. (Optional.) Set the high RX power threshold for a transceiver module.
   transceiver rx-power high-threshold *power-value*
   By default, no high RX power threshold is set for a transceiver module.
4. (Optional.) Set the low RX power threshold for a transceiver module.
   transceiver rx-power low-threshold *power-value*
   By default, no low RX power threshold is set for a transceiver module.
5. (Optional.) Set the high TX power threshold for a transceiver module.
   transceiver tx-power high-threshold *power-value*
   By default, no high TX power threshold is set for a transceiver module.
6. (Optional.) Set the low TX power threshold for a transceiver module.
   transceiver tx-power low-threshold *power-value*
   By default, no low TX power threshold is set for a transceiver module.

Configuring RX and TX power change thresholds for a transceiver module

About this task

The device sets the initial RX optical power as the baseline for a transceiver module after the transceiver module starts up and operates correctly for the first time. After you execute the **transceiver rx-power change-threshold** or **transceiver tx-power change-threshold** command, the system checks the RX/TX optical power periodically. If the RX/TX optical power changes exceed the user-defined thresholds compared to the baseline, the system identifies it as significant changes and generates alarms.

Restrictions and guidelines

This feature is available only for digital-diagnosis-capable SFP and SFP+ transceiver modules. It is not available for the 400G ZR, 400G ZR+, or fiber-to-copper transceiver modules.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. (Optional.) Configure the RX power change threshold for a transceiver module.
   transceiver rx-power change-threshold *power-value*
   By default, the RX power change threshold for a transceiver module is 5.00 dBm.
4. (Optional.) Configure the TX power change threshold for a transceiver module.
   transceiver tx-power change-threshold *power-value*
   By default, the TX power change threshold for a transceiver module is 4.00 dBm.

Scheduling a task

About task scheduling

You can schedule the device to automatically execute a command or a set of commands without administrative interference.

You can configure a periodic schedule or a non-periodic schedule. A non-periodic schedule is not saved to the configuration file and is lost when the device reboots. A periodic schedule is saved to the startup configuration file and is automatically executed periodically.

Restrictions and guidelines

- The default system time is always restored at reboot. To make sure a task schedule can be executed as expected, reconfigure the system time or configure NTP after you reboot the device. For more information about NTP, see *Network Management and Monitoring Configuration Guide*.
- To assign a command (command A) to a job, you must first assign the job the command or commands for entering the view of command A.
- Make sure all commands in a schedule are compliant to the command syntax. The system does not check the syntax when you assign a command to a job.
- A schedule cannot contain any one of these commands: **`telnet`**, **`ftp`**, **`ssh2`**, and **`monitor process`**.
- A schedule does not support user interaction. If a command requires a yes or no answer, the system always assumes that a **Y** or **Yes** is entered. If a command requires a character string input, the system assumes that either the default character string (if any) or a null string is entered.
- A schedule is executed in the background, and no output (except for logs, traps, and debug information) is displayed for the schedule.

Procedure

1. Enter system view.
   `system-view`
2. Create a job.
   `scheduler job` *`job-name`*
3. Assign a command to the job.
   `command` *`id command`*
   By default, no command is assigned to a job.
   You can assign multiple commands to a job. A command with a smaller ID is executed first.
4. Exit to system view.
   `quit`
5. Create a schedule.
   `scheduler schedule` *`schedule-name`*
6. Assign a job to the schedule.
   `job` *`job-name`*
   By default, no job is assigned to a schedule.
   You can assign multiple jobs to a schedule. The jobs will be executed concurrently.

7. Assign user roles to the schedule.

   user-role *role-name*

   By default, a schedule has the user role of the schedule creator.

   You can assign a maximum of 64 user roles to a schedule. A command in a schedule can be executed if it is permitted by one or more user roles of the schedule.

8. Specify the execution time for the schedule.

   Choose one option as needed:

   - Execute the schedule at specific points of time.

     time at *time date*

     time once at *time* [**month-date** *month-day* | **week-day** *week-day*&<1-7>]

   - Execute the schedule after a period of time.

     time once delay *time*

   - Execute the schedule at the specified time on every specified day in a month or week.

     time repeating at *time* [**month-date** [*month-day* | **last**] | **week-day** *week-day*&<1-7>]

   - Execute the schedule periodically from the specified time on.

     time repeating [**at** *time* [*date*]] **interval** *interval*

   By default, no execution time is specified for a schedule.

   The **time** commands overwrite each other. The most recently executed command takes effect.

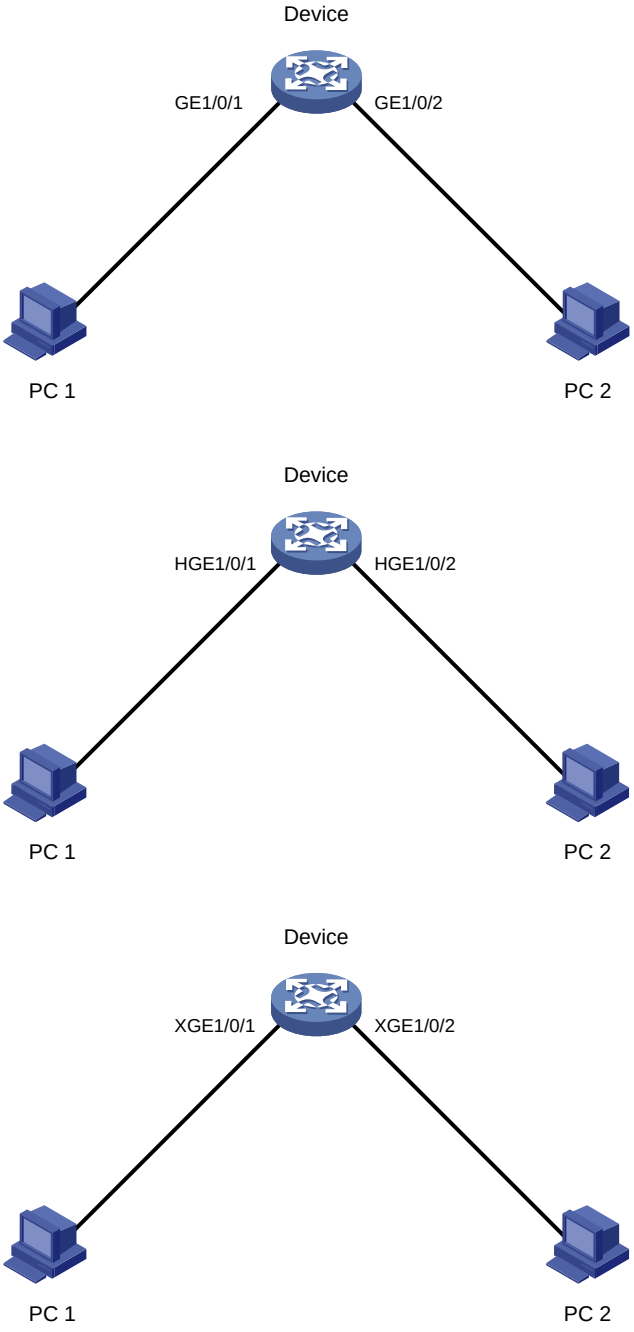
9. (Optional.) Set the schedule log file size limit.

   scheduler logfile size *value*

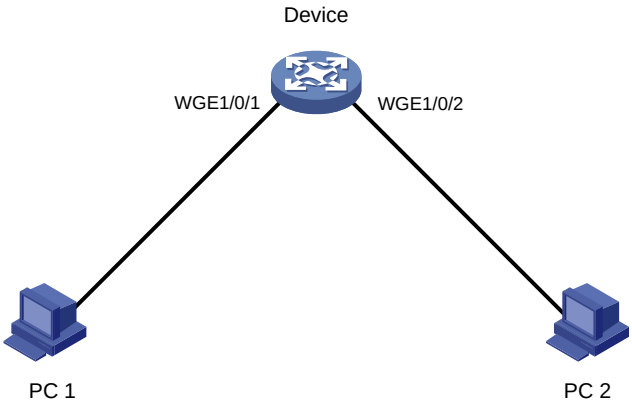
   By default, the schedule log file size limit is 16 KB.

   The schedule log file stores log messages for execution results of commands in jobs. After the limit is reached, the system deletes the oldest log messages to store the new log messages. If the remaining space of the log file is not enough for a single log message, the system truncates the message and does not store the extra part.

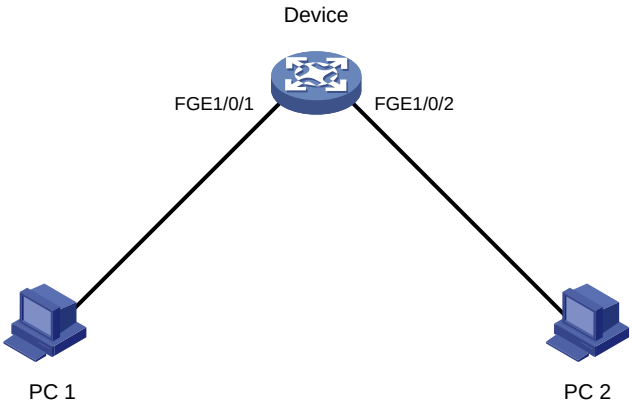
Example: Scheduling a task



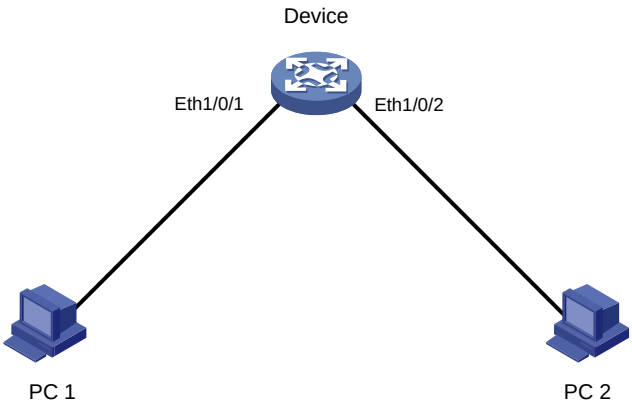
Network configuration



As shown in Figure 5, two interfaces of the device are connected to users.



To save energy, configure the device to perform the following operations:



- Enable the interfaces at 8:00 a.m. every Monday through Friday.
- Disable the interfaces at 18:00 every Monday through Friday.

[Sysname] scheduler job shutdown-GigabitEthernet1/0/1
[Sysname-job-shutdown-GigabitEthernet1/0/1] command 1 system-view
[Sysname-job-shutdown-GigabitEthernet1/0/1] command 2 interface gigabitethernet 1/0/1
[Sysname-job-shutdown-GigabitEthernet1/0/1] command 3 shutdown
[Sysname-job-shutdown-GigabitEthernet1/0/1] quit
```

Configure a job for enabling interface GigabitEthernet 1/0/1.

```
[Sysname] scheduler job start-GigabitEthernet1/0/1
[Sysname-job-start-GigabitEthernet1/0/1] command 1 system-view
[Sysname-job-start-GigabitEthernet1/0/1] command 2 interface gigabitethernet 1/0/1
[Sysname-job-start-GigabitEthernet1/0/1] command 3 undo shutdown
[Sysname-job-start-GigabitEthernet1/0/1] quit
```

Configure a job for disabling interface GigabitEthernet 1/0/2.

```
[Sysname] scheduler job shutdown-GigabitEthernet1/0/2
[Sysname-job-shutdown-GigabitEthernet1/0/2] command 1 system-view
[Sysname-job-shutdown-GigabitEthernet1/0/2] command 2 interface gigabitethernet 1/0/2
[Sysname-job-shutdown-GigabitEthernet1/0/2] command 3 shutdown
[Sysname-job-shutdown-GigabitEthernet1/0/2] quit
```

Configure a job for enabling interface GigabitEthernet 1/0/2.

```
[Sysname] scheduler job start-GigabitEthernet1/0/2
[Sysname-job-start-GigabitEthernet1/0/2] command 1 system-view
[Sysname-job-start-GigabitEthernet1/0/2] command 2 interface gigabitethernet 1/0/2
[Sysname-job-start-GigabitEthernet1/0/2] command 3 undo shutdown
[Sysname-job-start-GigabitEthernet1/0/2] quit
```

Configure a periodic schedule for enabling the interfaces at 8:00 a.m. every Monday through Friday.

```
[Sysname] scheduler schedule START-pc1/pc2
[Sysname-schedule-START-pc1/pc2] job start-GigabitEthernet1/0/1
[Sysname-schedule-START-pc1/pc2] job start-GigabitEthernet1/0/2
[Sysname-schedule-START-pc1/pc2] time repeating at 8:00 week-day mon tue wed thu fri
[Sysname-schedule-START-pc1/pc2] quit
```

Configure a periodic schedule for disabling the interfaces at 18:00 every Monday through Friday.

```
[Sysname] scheduler schedule STOP-pc1/pc2
[Sysname-schedule-STOP-pc1/pc2] job shutdown-GigabitEthernet1/0/1
[Sysname-schedule-STOP-pc1/pc2] job shutdown-GigabitEthernet1/0/2
[Sysname-schedule-STOP-pc1/pc2] time repeating at 18:00 week-day mon tue wed thu fri
[Sysname-schedule-STOP-pc1/pc2] quit
```

Verifying the configuration

Display the configuration information of all jobs.

```
[Sysname] display scheduler job
Job name: shutdown-GigabitEthernet1/0/1
 system-view
 interface gigabitethernet 1/0/1
 shutdown

Job name: shutdown-GigabitEthernet1/0/2
 system-view
 interface gigabitethernet 1/0/2
 shutdown

Job name: start-GigabitEthernet1/0/1
 system-view
 interface gigabitethernet 1/0/1
 undo shutdown

Job name: start-GigabitEthernet1/0/2
 system-view
 interface gigabitethernet 1/0/2
 undo shutdown
```

Display the schedule information.

```
[Sysname] display scheduler schedule
Schedule name        : START-pc1/pc2
Schedule type        : Run on every Mon Tue Wed Thu Fri at 08:00:00
Start time           : Wed Sep 28 08:00:00 2011
Last execution time  : Wed Sep 28 08:00:00 2011
Last completion time : Wed Sep 28 08:00:03 2011
Execution counts     : 1
----------------------------------------------------------------------

```

Locating devices

About device locating

The device provides LEDs for device locating. The **locator blink** *blink-time* command flashes the LEDs quickly for the specified period of time unless you execute the **locator blink stop** command or the specified flash duration expires.

Starting LED flashing

To start LED flashing, execute one of the following commands in user view:

locator [**slot** *slot-number*] **blink** *blink-time*

Stopping LED flashing

To stop LED flashing, execute one of the following commands in user view:

locator [**slot** *slot-number*] **blink stop**

Rebooting the device

About device reboot

The following device reboot methods are available:

- Schedule a reboot at the CLI, so the device automatically reboots at the specified time or after the specified period of time.
- Immediately reboot the device at the CLI.

  During the reboot process, the device performs the following operations:

  a. Resets all of its chips.

  b. Uses the BootWare to verify the startup software package, decompress the package, and load the images.

  c. Initializes the system.
- Power off and then power on the device. This method might cause data loss, and is the least-preferred method.

Using the CLI, you can reboot the device from a remote host.

Restrictions and guidelines for device reboot

For data security, the device does not reboot while it is performing file operations.

Rebooting the device immediately at the CLI

Prerequisites

Perform the following steps in any view:

1. Verify that the next-startup configuration file is correctly specified.

   display startup

   For more information about the **display startup** command, see *Fundamentals Command Reference*.

2. Verify that the startup image files are correctly specified.

   display boot-loader

   If one main startup image file is damaged or does not exist, you must specify another main startup image file before rebooting the device.

   For more information about the **display boot-loader** command, see *Fundamentals Command Reference*.

3. Save the running configuration to the next-startup configuration file.

   save

   To avoid configuration loss, save the running configuration before a reboot.

   For more information about the **save** command, see *Fundamentals Command Reference*.

Procedure

To reboot the device immediately at the CLI, execute one of the following commands in user view:

reboot [**slot** *slot-number*] [**force**]

CAUTION:

- A device reboot might result in a service outage. Before using this command, make sure you understand its impact on the live network.
- Use the **force** keyword to reboot the device only when the system is faulty or fails to start up normally. A forced device reboots might cause file system damage. Before using the **force** keyword to reboot the device, make sure you understand its impact.

Scheduling a device reboot

Restrictions and guidelines

The automatic reboot configuration takes effect on all member devices. It will be canceled if a master/subordinate switchover occurs.

The device supports only one device reboot schedule. If you execute the **scheduler reboot** command multiple times, the most recent configuration takes effect.

Procedure

To schedule a reboot, execute one of the following commands in user view:

- **scheduler reboot at** *time* [*date*]
- **scheduler reboot delay** *time*

By default, no device reboot time is specified.

CAUTION:

This task enables the device to reboot at a scheduled time, resulting in service interruption. Before using this command, make sure you understand its impact on the live network.

Restoring the factory-default configuration

About this task

If you want to use the device in a different scenario or you cannot troubleshoot the device by using other methods, use this task to restore the factory-default configuration.

This task does not delete **.bin** files.

Restrictions and guidelines

This feature is disruptive.

Procedure

1. Execute the following command in user view to restore the factory-default configuration for the device:

   `restore factory-default`

2. Reboot the device.

   `reboot`

CAUTION:

This command restores the device to the factory default settings. Before using this command, make sure you understand its impact on the live network.

When the command prompts you to choose whether to save the running configuration, enter **N**. If you choose to save the running configuration, the device loads the saved configuration at startup.

Display and maintenance commands for device management configuration

Execute **`display`** commands in any view. Execute the **`reset scheduler logfile`** and **`display disk-information`** commands in user view. Execute and **`reset version-update-record`** in system view.

Task	Command
Display information about active alarms.	**`display alarm active`** [**`verbose`**]
Display information about historical alarms.	**`display alarm history`** [**`verbose`**]
Display the system time, date, time zone, and daylight saving time.	**`display clock`**
Display the copyright statement.	**`display copyright`**
Display CPU usage statistics. The **`core`** keyword is mutually exclusive with the **`control-plane`** and **`data-plane`** keywords.	**`display cpu-usage [ control-plane | data-plane ]`** [**`summary`**] [**`slot`** *`slot-number`* [**`cpu`** *`cpu-number`* [**`core`** { *`core-number`* | **`all`** }]]]
Display CPU usage monitoring settings.	**`display cpu-usage configuration`** [**`slot`** *`slot-number`* [**`cpu`** *`cpu-number`*]]

Task	Command
Display the historical CPU usage statistics in a coordinate system.	**display cpu-usage history** [**job** *job-id*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display hardware information.	**display device** [**flash** | **usb**] [**slot** *slot-number* [**subslot** *subslot-number*] | **verbose**]
Display electronic label information for the device.	**display device manuinfo** [**slot** *slot-number* [**subslot** *subslot-number*]]
Display electronic label information for a fan tray.	**display device manuinfo slot** *slot-number* **fan** *fan-id*
Display electronic label information for a power module.	**display device manuinfo slot** *slot-number* **power** *power-id*
Display information about member device uptime starting from the latest startup.	**display device uptime**
Display or save diagnostic information for features and hardware modules.	**display diagnostic-information** [**hardware** | **ifmgr** | **infrastructure** | **l2** | **l3** | **service**] [**key-info**] [*filename*]
Display poweroff alarm destination host settings.	**display dying-gasp host**
Display device temperature information.	**display environment** [**slot** *slot-number*]
Display the operating states of fan trays.	**display fan** [**slot** *slot-number* [*fan-id*]] [**verbose**]
Display memory usage statistics.	**display memory** [**summary**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display memory allocation failure information in the kernel.	**display kernel memory alloc-failure** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display memory fragment statistics in the kernel.	**display kernel memory fragment free** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display DMA memory usage statistics.	**display memory dma** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display memory alarm thresholds and statistics.	**display memory-threshold** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display DMA memory alarm information.	**display memory-threshold dma** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display power module information.	**display power** [**slot** *slot-number* [*power-id* | **verbose**]]
Display resource monitoring information.	**display resource-monitor**

Task	Command
	[**resource** *resource-name*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display job configuration information.	**display scheduler job** [*job-name*]
Display job execution log information.	**display scheduler logfile**
Display the automatic reboot schedule.	**display scheduler reboot**
Display schedule information.	**display scheduler schedule** [*schedule-name*]
Display system heath status information.	**display system health** [**slot** *slot-number*]
Display historical system heath status change information.	**display system health history** [**slot** *slot-number*]
Display system stability and status information.	**display system stable state**
Display health information of transceiver modules.	**display transceiver health interface** [*interface-type interface-number*]
Display power information for transceiver modules.	**display transceiver power interface** [*interface-type interface-number*]
Display transceiver module status information. Only SFP transceiver modules support this command.	**display transceiver status interface** [*interface-type interface-number*]
Display system version information.	**display version**
Display startup software image upgrade records.	**display version-update-record**
Clear job execution log information.	**reset scheduler logfile**
Clear startup software image upgrade records.	**reset version-update-record**

Managing target configuration 1

About target configuration 1
Hardware compatibility with target configuration management 1
Enabling target configuration management 1
Committing the target configuration command lines 2
Display and maintenance commands for target configuration 3

Managing target configuration

About target configuration

Target configuration enables you to configure and verify intended settings before merging them into the running configuration.

You can configure target configuration command lines in the following views:

- Private-mode system view and its lower-level views.
- Exclusive-mode system view and its lower-level views.

Commands available for real-time configuration are all available for target configuration.

Support for command lines in private-mode system view and in exclusive-mode system view depends on the device model. In private-mode system view and in exclusive-mode system, you do not need to commit hardware-related command lines and action command lines, because they take effect immediately.

Private-mode views and exclusive-mode views have an extra tilde sign (~) in their prompts as compared to their counterpart real-time-mode views. After you execute a command that does not take effect in real time, the prompt will have a leading asterisk sign (*) to indicate that the command has not taken effect in the current mode. After the **commit** command is executed to commit the configuration, the prompt will have a leading tilde sign (~).

For more information about views, see "Using the CLI."

Hardware compatibility with target configuration management

Only the S5200-HI-G switch series supports target configuration management.

Enabling target configuration management

About this task

To save memory, you can disable target configuration management by executing the **undo commit enable** command. This can reduce unnecessary resource consumption and improve system efficiency.

Restrictions and guidelines

After you enable target configuration management, you cannot enter private-mode or exclusive-mode system view by executing the **system-view** command.

If a user already enters private-mode system view, executing the **undo commit enable** command will force that user to exit private-mode system view.

Procedure

1. Enter real-time-mode system view.

   system-view

2. Enable target configuration management.

   commit enable

   By default, target configuration management is enabled.

Committing the target configuration command lines

About this task

A commit operation commits all target configuration command lines. After a successful commit operation, the system creates a configuration rollback point.

Restrictions and guidelines

As a best practice, do not execute the **commit** command frequently. The system creates a configuration rollback point after each successful commit operation. Executing the command frequently increases device load and might cause commit failures.

To save the running configuration while committing the target configuration command lines, you can use one of the following methods:

- Specify the **save-running** *filename* option when you use the **commit** command to commit the target configuration command lines. The system saves the running configuration to the specified file while committing the target configuration command lines.
- Use the **configuration commit auto-save path** command to enable automatic saving for the target configuration command lines. This command enables the device to automatically save the running configuration to a configuration file in the specified directory each time the **commit** command is executed. The directory is specified by using the *directory* argument. The prefix for the configuration file is specified by using the **filename-prefix** *filename-prefix* option.

The automatic saving feature takes effect if you do not specify the **save-running** *filename* option when executing the **commit** command. If you specify this option when executing the **commit** command, the automatic saving feature cannot take effect. The target configuration command lines are saved to the file specified by using this option.

Procedure

1. (Optional.) Specify the maximum number of rollback points:
   a. Enter real-time-mode system view.
      system-view
   b. Set the maximum number of rollback points.
      configuration commit max-number *max-number*
      By default, the maximum number of rollback points is 100.
      To create a new rollback point when the number of rollback points reaches the maximum, the system deletes the oldest rollback point.
   c. Return to user view.
      Quit
2. (Optional.) Enable automatic saving for the target configuration command lines and configure the related parameters:
   a. Enter real-time-mode system view.
      system-view
   b. Enable automatic saving for the target configuration command lines and configure the related parameters.
      configuration commit auto-save path *directory* **filename-prefix** *filename-prefix* [**user** *user-name* [**password** { **cipher** | **simple** } *string*] | **vpn-instance** *vpn-instance-name*] *
      By default, automatic saving is disabled for the target configuration command lines.

c. Return to user view.

   abort

3. Enter private-mode system view or exclusive-mode system view.

   system-view { **exclusive** | **private** }

4. Configure features as required.

   For more information about configuring features, see the configuration guides.

5. (Optional.) Display target configuration command lines.

   display target-configuration

   Incorrect target configuration command lines will affect the operation of the network. Use this command to verify that all target configuration command lines are correct.

6. (Optional.) Refresh uncommitted target configuration.

   refresh target-configuration

7. Commit the target configuration command lines.

   commit [**best-effort**] [**force**] [**label** *labelname*] [**save-running** *filename*] [**confirmed** [*seconds* | **minutes** *minutes*]] [**show-error**] [**clear-error**] [**description** *text*]

8. (Optional.) Roll back the running configuration.

   configuration replace { **file** *filename* | **last** *number* | **commit-id** *commit-id* | **label** *labelname* }

CAUTION:

This operation will cause settings not at the rollback point to be lost, which might cause service interruption. When you perform configuration rollback, make sure you fully understand its impact on your network.

To reclaim target configuration command lines that have been committed, use this command to roll back the running configuration as required. For more information about this command, see configuration file management commands in *Fundamentals Command Reference*.

Display and maintenance commands for target configuration

Execute the following commands in private-mode system view, exclusive-mode system view, or their lower-level views:

- **display target-configuration**
- **reset target-configuration**

Task	Command
Display the target configuration command lines.	**display target-configuration** [**diff** | **failure** [**brief**] | **merge** | **success**]
Clear the target configuration command lines.	**reset target-configuration** [**command** [*text*]]

Using Tcl 1

About Tcl 1
Restrictions and guidelines: Tcl 1
Using Tcl commands to configure the device 1
Restrictions and guidelines 1
Procedure 1
Executing Comware commands in Tcl configuration view 2
About executing Comware commands in Tcl configuration view 2
Restrictions and guidelines 2
Procedure 2

Using Tcl

About Tcl

Comware 7 provides a built-in tool command language (Tcl) interpreter. From user view, you can use the **tclsh** command to enter Tcl configuration view to execute the following commands:

- Tcl 8.5 commands.
- Comware commands.

The Tcl configuration view is equivalent to the user view. You can use Comware commands in Tcl configuration view in the same way they are used in user view.

Restrictions and guidelines: Tcl

To return from a subview under Tcl configuration view to the upper-level view, use the **quit** command.

To return from a subview under Tcl configuration view to the Tcl configuration view, press **Ctrl+Z**.

Using Tcl commands to configure the device

Restrictions and guidelines

When you use Tcl to configure the device, follow these restrictions and guidelines:

- You can apply Tcl environment variables to Comware commands.
- No online help information is provided for Tcl commands.
- You cannot press **Tab** to complete an abbreviated Tcl command.
- Make sure the Tcl commands can be executed correctly.
- As a best practice, log in through Telnet or SSH. You cannot stop Tcl commands by using a shortcut key or a CLI command. If a problem occurs when the Tcl commands are being executed, you can terminate the process by closing the connection if you logged in through Telnet or SSH. If you logged in from the console port, you must perform one of the following tasks:
  - Restart the device.
  - Log in to the device by using a different method, and use the **free line** command to release the console line. For more information about the command, see *Fundamentals Command Reference*.
- You can press **Ctrl+D** to abort Tcl command **read stdin**.

Procedure

1. Enter Tcl configuration view from user view.
   tclsh
2. Execute a Tcl command.
   Tcl command
3. Return from Tcl configuration view to user view.

- **tclquit**
- **quit**

Executing Comware commands in Tcl configuration view

About executing Comware commands in Tcl configuration view

To execute a Comware command in Tcl configuration view, use one of the following methods:

- Enter the Comware command directly. If a Tcl command uses the same command string as the Comware command, the Tcl command is executed.
- Prefix the Comware command with the **cli** keyword. If a Tcl command uses the same command string as the Comware command, the Comware command is executed.

Restrictions and guidelines

Follow these restrictions and guidelines when you execute Comware commands in Tcl configuration view:

- To specify a string enclosed in quotation marks (") or braces ({ and }), you must use the escape character (\) before the quotation marks or braces. For example, to specify **"a"** as the description for an interface, you must enter **description \"a\"**. If you enter **description "a"**, the description is **a**.
- For Comware commands, you can enter **?** to obtain online help or press **Tab** to complete an abbreviated command. For more information, see "Using the CLI."
- The **cli** command is a Tcl command, so you cannot enter **?** to obtain online help or press **Tab** to complete an abbreviated command.
- Successfully executed Comware commands are saved to command history buffers. You can use the upper arrow or lower arrow key to obtain executed commands.
- To execute multiple Comware commands in one operation, use one of the following methods:
  - Enter multiple Comware commands separated by semi-colons to execute the commands in the order they are entered. For example, **vlan 2;description Tech**.
  - Specify multiple Comware commands for the **cli** command, quote them, and separate them by a space and a semicolon. For example, **cli "vlan 2 ;description Tech"**.
  - Specify one Comware command for each **cli** command and separate them by a space and a semicolon. For example, **cli vlan 2 ;cli description Tech**.

Procedure

1. Enter Tcl configuration view

   tclsh
2. Execute Comware commands.
   - Execute Comware commands directly.

     Command
   - Execute Comware commands by using the **cli** command.

     cli *command*

3. Return from Tcl configuration view to user view.
    - **`tclquit`**
    - **`quit`**

Using Python

About Python

Python is a simple and powerful programming language, with high-level data structures. It provides an easy and efficient method for object-oriented programming. Its concise syntax, support for dynamic input, and interpretive nature make it an ideal scripting language for rapid application development across many platforms and areas.

Python tasks at a glance

Python2 tasks at a glance

Comware 7 provides a built-in Python2 interpreter. You can use Python2 to perform the following tasks:

- Executing a Python2 script

  You can execute Python2 scripts to implement automatic device configuration.
- Enter Python2 shell to configure the device by using the following items:
  - Python 2.7 commands.
  - Python 2.7 standard API.
  - Extended API. For more information about the extended API, see "Comware 7 extended Python API."

  Perform the following tasks accordingly:

  a. Entering the Python2 shell

  b. Importing and using the extended Python API

  c. Exiting the Python shell

Executing a Python2 script

To execute a Python2 script, use the following command in user view:

python *filename*

Entering the Python2 shell

To enter the Python2 shell from user view, execute the following command:

python

Importing and using the extended Python API

To use the extended Python API, you must first import the API to Python.

Importing the entire extended API and using the API

Procedure

1. Import the entire extended API in the Python shell.
   `import platformtools`
2. Execute an extended API function.
   `platformtools.`*`api`*

Example

In the Python2 shell, use extended API function **`Transfer`** to download the **test.cfg** file from TFTP server 192.168.1.26.

```
<Sysname> python
>>> import platformtools
>>> platformtools.Transfer('tftp', '192.168.1.26', 'test.cfg', 'flash:/test.cfg',
user='', password='')
<platformtools.Transfer object at 0xb7eab0e0>
```

Importing an extended API function and using the function

Procedure

1. Import an extended API function in the Python shell.
   `from platformtools import` *`api-name`*
2. Execute an extended API function.
   `api-function`

Example

In the Python2 shell, use extended API function **`Transfer`** to download the **test.cfg** file from TFTP server 192.168.1.26.

```
<Sysname> python
>>> from platformtools import Transfer
>>> Transfer('tftp', '192.168.1.26', 'test.cfg', 'flash:/test.cfg', user='',
password='')
<platformtools.Transfer object at 0xb7e5e0e0>
```

Exiting the Python shell

To exit the Python shell, execute the following command in the Python shell.

`exit()`

Python usage examples

Example: Using a Python2 script for device configuration

Network configuration

Use a Python2 script to perform the following tasks:

- Download configuration files **main.cfg** and **backup.cfg** to the device.

- Configure the files as the main and backup configuration files for the next startup.

Figure 1 Network diagram

Procedure

Use a text editor on the PC to configure Python2 script **test.py** as follows:

```
#!usr/bin/python
import platformtools

platformtools.Transfer('tftp', '192.168.1.26', 'main.cfg', 'flash:/main.cfg')
platformtools.Transfer('tftp', '192.168.1.26', 'backup.cfg', 'flash:/backup.cfg')
platformtools.CLI('startup saved-configuration flash:/main.cfg main ;startup
saved-configuration flash:/backup.cfg backup')
```

Use TFTP to download the script to the device.

```
<Sysname> tftp 192.168.1.26 get test.py
```

Execute the script.

```
<Sysname> python flash:/test.py
<Sysname>startup saved-configuration flash:/main.cfg main
Please wait...... Done.
<Sysname>startup saved-configuration flash:/backup.cfg backup
Please wait...... Done.
```

Verifying the configuration

Display startup configuration files.

```
<Sysname> display startup
 Current startup saved-configuration file: flash:/startup.cfg
 Next main startup saved-configuration file: flash:/main.cfg
 Next backup startup saved-configuration file: flash:/backup.cfg
```

Comware 7 extended Python API

The Comware 7 extended Python API is compatible with the Python syntax.

This document uses Python2 shell as an example.

channel

Use **channel** to execute Comware 7 CLI commands and create channel objects.

Syntax

channel(*command*='')

Parameters

command: Specifies the commands to be executed. To enter multiple commands, use a space and a semicolon (;) as the delimiter. To enter a command in a view other than user view, you must first enter the commands used to enter the view. For example, you must enter **'system-view ;display interface brief | include UP'** to execute the **display interface brief | include UP** command.

Usage guidelines

This API function supports only Comware 7 commands. It does not support Linux, Python, or Tcl commands.

The API function is used for automated testing.

The list objects returned by the channel function might contain hexadecimal hidden characters such as 0x08. To hide the hexadecimal hidden characters, you can use the CLI function instead, or use the **for** loop to output the execution result of the channel function, for example:

```
<Sysname> python
>>> import platformtools
>>> c = platformtools.channel('display vlan')
>>> for value in c:
...  print value
...
display vlan
 Total VLANs: 13
 The VLANs include:
 1(default), 2-3, 10, 20, 30, 40, 100-101, 200-202, 300
<Sysname>
```

Returns

Output from the executed commands, in the format of a list object.

Examples

Display the VLAN inforamtion.

```
<Sysname> python
>>> import platformtools
>>> platformtools.channel('display vlan')
```

Sample output

```
['display vlan', ' Total VLANs: 13', ' The VLANs include:', ' 1(default), 2-3, 10, 2
```

```
0, 30, 40, 100-101, 200-202, 300, \x08\x08 ', '<Sysname>']
```

CLI

Use **CLI** to execute Comware 7 CLI commands and create CLI objects.

Syntax

CLI(*command*='', *do_print*=True)

Parameters

command: Specifies the commands to be executed. To enter multiple commands, use a space and a semicolon (;) as the delimiter. To enter a command in a view other than user view, you must first enter the commands used to enter the view. For example, you must enter **'system-view ;local-user test class manage'** to execute the **local-user test class manage** command.

do_print: Specifies whether to output the execution result:

- **True**—Outputs the execution result. This value is the default.
- **False**—Does not output the execution result.

Usage guidelines

This API function supports only Comware 7 commands. It does not support Linux, Python, or Tcl commands.

Returns

CLI objects

Examples

Add a local user named **test**.

```
<Sysname> python
>>> import platformtools
>>> platformtools.CLI('system-view ;local-user test class manage')
```

Sample output

```
<Sysname> system-view
System View: return to User View with Ctrl+Z.
[Sysname] local-user test class manage
New local user added.
<platformtools.CLI object at 0xb7f680a0>
```

get_error

Use **get_error** to get the error information from the download operation.

Syntax

Transfer.get_error()

Returns

Error information (if there is no error information, the return is null)

Examples

Download file **test.cfg** from TFTP server 1.1.1.1 and get the error information from the operation.

```
<Sysname> python
```

```
>>> import platformtools
>>> c = platformtools.Transfer('tftp', '1.1.1.1', 'test.cfg', 'flash:/test.cfg', user='', password='')
>>> c.get_error()
```

Sample output

```
"Couldn't connect to server"
```

get_output

Use **`get_output`** to get the output from executed commands.

Syntax

`CLI.get_output()`

Returns

Output from executed commands

Examples

Add a local user and get the output from the command.

```
<Sysname> python
>>> import platformtools
>>> c = platformtools.CLI('system-view ;local-user test class manage', False)
>>> c.get_output()
```

Sample output

```
['<Sysname>system-view', 'System View: return to User View with Ctrl+Z.',
'[Sysname]local-user test class manage', 'New local user added.']
```

get_self_slot

Use **`get_self_slot`** to get the member ID of the master device.

Syntax

`get_self_slot()`

Returns

A list object in the format of `[-1,`*slot-number*`]`. The *slot-number* indicates the member ID of the master device.

Examples

Get the member ID of the master device.

```
<Sysname> python
>>> import platformtools
>>> platformtools.get_self_slot()
```

Sample output

```
[-1,1]
```

get_slot_info

Use **`get_slot_info`** to get information about a member device.

Syntax

`get_slot_info()`

Returns

A dictionary object in the format of {'Slot': *slot-number*, 'Status': '*status*', 'Chassis': *chassis-number*, 'Role': '*role*', 'Cpu': *CPU-number* }. The *slot-number* argument indicates the member ID of the device. The *status* argument indicates the status of the member device. The *chassis-number* and *CPU-number* arguments are fixed at 0. The *role* argument indicates the role of the member device.

Examples

Get information about the device, a card, or a member device.

```
<Sysname> python
>>> import platformtools
>>> platformtools.get_slot_info(1)
```

Sample output

```
{'Slot': 1, 'Status': 'Normal', 'Chassis': 0, 'Role': 'Master', 'Cpu': 0}
```

get_slot_range

Use **`get_slot_range`** to get the supported IRF member ID range.

Syntax

`get_slot_range()`

Returns

A dictionary object in the format of {'MaxSlot': *max-slot-number*, 'MinSlot': *min-slot-number* }. The *max-slot-number* argument indicates the maximum member ID. The *min-slot-number* argument indicates the minimum member ID.

Examples

Get the supported IRF member ID range.

```
<Sysname> python
>>> import platformtools
>>> platformtools.get_slot_range()
```

Sample output

```
{'MaxSlot': 4, 'MinSlot': 1}
```

get_standby_slot

Use **`get_standby_slot`** to get the member IDs of the subordinate devices.

Syntax

`get_standby_slot()`

Returns

A list object in one of the following formats:

- [ ]—The IRF fabric does not have a subordinate device.
- [[-1,*slot-number*]]—The IRF fabric has only one subordinate device.
- [[-1,*slot-number1*], [-1,*slot-number2*],...]—The IRF fabric has multiple subordinate devices.

The *slot-number* arguments indicate the member IDs of the subordinate devices.

Examples

Get the member IDs of the subordinate devices.

```
<Sysname> python
>>> import platformtools
>>> platformtools.get_standby_slot()
```

Sample output

```
[]
```

Transfer

Use **Transfer** to download a file from a server.

Syntax

Transfer(*protocol*='', *host*='', *source*='', *dest*='', *vrf*='',*login_timeout*=10, *user*='', *password*='')

Parameters

protocol: Specifies the protocol used to download a file:

- **ftp**—Uses FTP.
- **tftp**—Uses TFTP.
- **http**—Uses HTTP.

host: Specifies the IP address of the remote server.

source: Specifies the name of the file to be downloaded from the remote server.

dest: Specifies a name for the downloaded file.

vrf: Specifies the VPN instance to which the remote server belongs. This argument represents the VPN instance name, a case-sensitive string of 1 to 31 characters. If the server belongs to the public network, do not specify this argument.

login_timeout: Specifies the timeout for the operation, in seconds. The default is 10.

user: Specifies the username for logging in to the server.

password: Specifies the login password.

Returns

Transfer object

Usage guidelines

If the IP address of the server is an IPv6 address, enclose the IP address with brackets ([]). For example:

```
Transfer("ftp","[2200::22]","0729.cfg","flash:/0729.cfg",user="abc",password="123456"
)
```

Examples

Download file **test.cfg** from TFTP server 192.168.1.26.

```
<Sysname> python
>>> import platformtools
>>> platformtools.Transfer('tftp', '192.168.1.26', 'test.cfg', 'flash:/test.cfg',
user='', password='')
```

Sample output

```
<platformtools.Transfer object at 0xb7f700e0>
```

send

Use **send** to generate and send a log message.

Syntax

SYSLOG.send(*digest*='', *info*='', *priority*='')

Parameters

digest: Specifies a mnemonic for the log message. The mnemonic is a case-sensitive string of 1 to 32 characters.

info: Specifies the contents for the log message, a case-sensitive string of 1 to 1024 characters.

priority: Specifies a priority for the log message, in the range of 0 to 4294967295.

Usage guidelines

You must use the **SYSLOG** function to create a syslog object before you can generate and send a log message for the object.

To enable the current terminal to display the generated log messages, first execute the **terminal monitor** command in user view.

Returns

None.

Examples

Enable the API to generate and send a log message for SNMP. Set the mnemonic to **Test**, the contents to **Try to send one message.**, and the priority to 1000.

```
<Sysname> terminal monitor
<Sysname> python
>>> import platformtools
>>> a = platformtools.SYSLOG('snmp')
>>> a.send('Test','Try to send one message.',1000)
```

Sample output

```
>>> %Jan  1 06:24:17:908 2019 Sysname SNMP/0/Test: Try to send one message.
```

SYSLOG

Use **SYSLOG** to create a syslog object.

Syntax

SYSLOG(*module*='')

Parameters

module: Specifies a name for the syslog object. The name is a case-insensitive string of 1 to 8 characters.

Usage guidelines

You must create a syslog object before you can send a log message for the object.

Returns

None.

Examples

Create a syslog object named **SNMP** and assign the object to variable **a**.

```
<Sysname> python
>>> import platformtools
>>> a = platformtools.SYSLOG('snmp')
>>> a
```

Sample output

```
<platformtools.SYSLOG object at 0xb7e180e0>
```

H3C S5100[S5500]-D-G&S5130S-G[-V2] Switch Series Virtual Technologies Configuration Guide

New H3C Technologies Co., Ltd.

All contents in this document, including statements, information, and recommendations, are believed to be accurate, but they are presented without warranty of any kind, express or implied. H3C shall not be liable for technical or editorial errors or omissions contained herein.

Preface

This configuration guide describes the fundamentals and configuration procedures for IRF feature.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

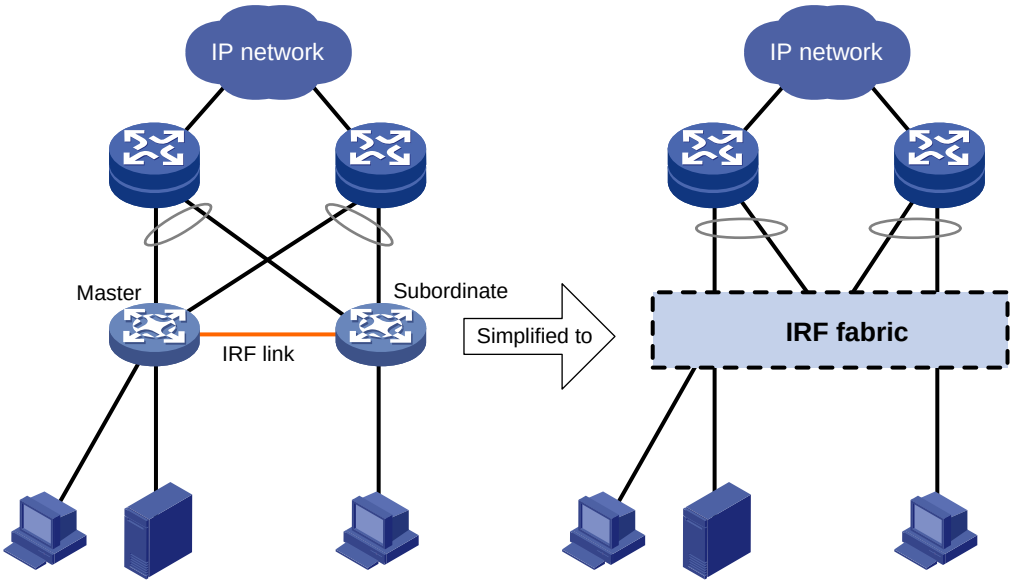
Configuring an IRF fabric



About IRF

The Intelligent Resilient Framework (IRF) technology virtualizes multiple physical devices at the same layer into one virtual fabric to provide data center class availability and scalability. IRF virtualization technology offers processing power, interaction, unified management, and uninterrupted maintenance of multiple devices.

IRF network model

Figure 1 shows an IRF fabric that has two devices, which appear as a single node to the upper-layer and lower-layer devices.

Figure 1 IRF application scenario

IRF benefits

IRF provides the following benefits:

- **Simplified topology and easy management**—An IRF fabric appears as one node and is accessible at a single IP address on the network. You can use this IP address to log in at any member device to manage all the members of the IRF fabric. In addition, you do not need to run the spanning tree feature among the IRF members.
- **1:N redundancy**—In an IRF fabric, one member acts as the master to manage and control the entire IRF fabric. All the other members process services while backing up the master. When the master fails, all the other member devices elect a new master from among them to take over without interrupting services.
- **IRF link aggregation**—You can assign several physical links between neighboring members to their IRF ports to create a load-balanced aggregate IRF connection with redundancy.
- **Multichassis link aggregation**—You can use the Ethernet link aggregation feature to aggregate the physical links between the IRF fabric and its upstream or downstream devices across the IRF members.

- **Network scalability and resiliency**—Processing capacity of an IRF fabric equals the total processing capacities of all the members. You can increase ports, network bandwidth, and processing capacity of an IRF fabric simply by adding member devices without changing the network topology.

Basic concepts

IRF member roles

IRF uses two member roles: master and standby (called subordinate throughout the documentation).

When devices form an IRF fabric, they elect a master to manage and control the IRF fabric, and all the other devices back up the master. When the master device fails, the other devices automatically elect a new master. For more information about master election, see "Master election."

IRF member ID

An IRF fabric uses member IDs to uniquely identify and manage its members. This member ID information is included as the first part of interface numbers and file paths to uniquely identify interfaces and files in an IRF fabric. Two devices cannot form an IRF fabric if they use the same member ID. A device cannot join an IRF fabric if its member ID has been used in the fabric.

Member priority

Member priority determines the possibility of a member device to be elected the master. A member with higher priority is more likely to be elected the master.

IRF port

An IRF port is a logical interface that connects IRF member devices. Every IRF-capable device has two IRF ports.

The IRF ports are named IRF-port *n*/1 and IRF-port *n*/2, where *n* is the member ID of the device. The two IRF ports are referred to as IRF-port 1 and IRF-port 2.

To use an IRF port, you must bind a minimum of one physical interface to it. The physical interfaces assigned to an IRF port automatically form an aggregate IRF link. An IRF port goes down when all its IRF physical interfaces are down.

IRF physical interface

IRF physical interfaces connect IRF member devices and must be bound to an IRF port. They forward traffic between member devices, including IRF protocol packets and data packets that must travel across IRF member devices.

IRF split

IRF split occurs when an IRF fabric breaks up into multiple IRF fabrics because of IRF link failures, as shown in Figure 2. The split IRF fabrics operate with the same IP address. IRF split causes routing and forwarding problems on the network. To quickly detect a multi-active collision, configure a minimum of one MAD mechanism (see "Configuring MAD").

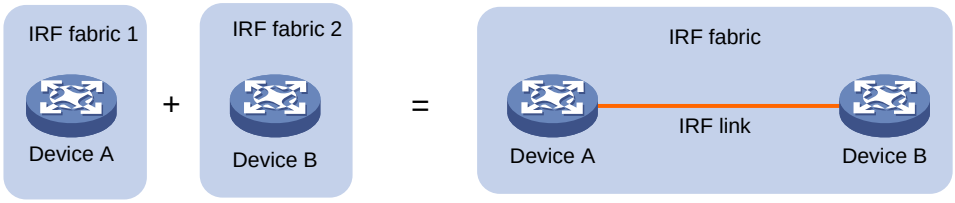


Figure 2 IRF split

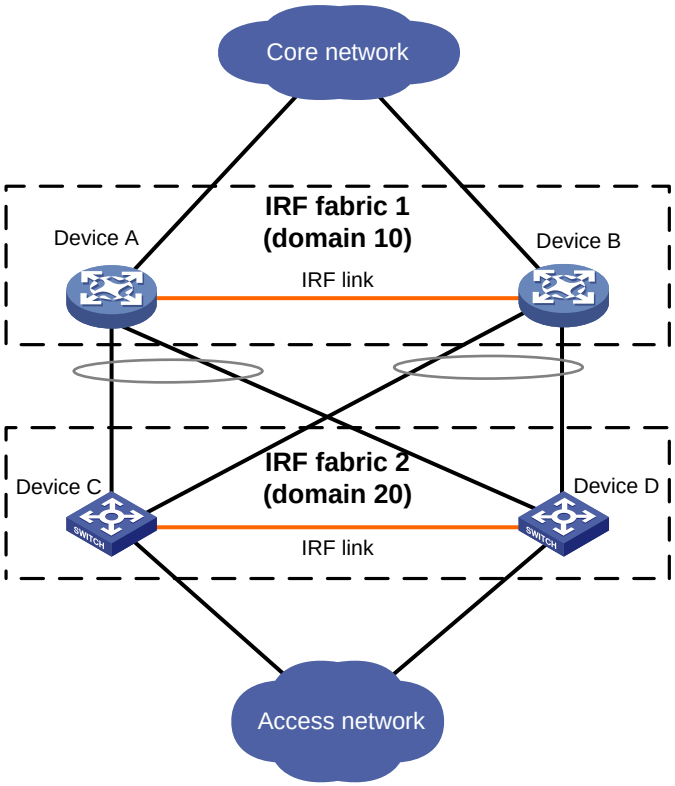
IRF merge

IRF merge occurs when two split IRF fabrics reunite or when two independent IRF fabrics are united, as shown in Figure 3.

Figure 3 IRF merge

MAD



An IRF link failure causes an IRF fabric to split in two IRF fabrics operating with the same Layer 3 settings, including the same IP address. To avoid IP address collision and network problems, IRF uses multi-active detection (MAD) mechanisms to detect the presence of multiple identical IRF fabrics, handle collisions, and recover from faults.

IRF domain ID

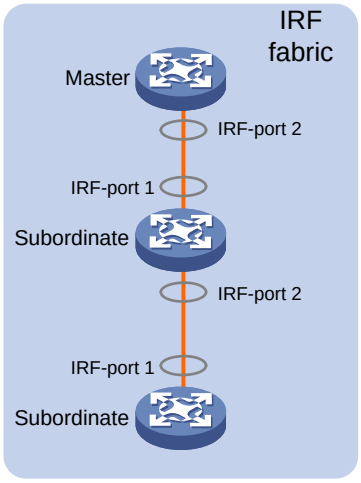
One IRF fabric forms one IRF domain. IRF uses IRF domain IDs to uniquely identify IRF fabrics and prevent IRF fabrics from interfering with one another.

As shown in Figure 4, IRF fabric 1 contains Device A and Device B, and IRF fabric 2 contains Device C and Device D. Both fabrics use the LACP aggregate links between them for MAD. When a member device receives an extended LACPDU for MAD, it checks the domain ID to determine whether the packet is from the local IRF fabric. Then, the member device can handle the packet correctly.

Figure 4 A network that contains two IRF domains

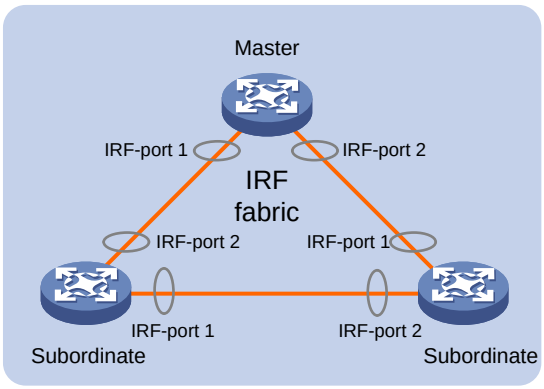
IRF network topology

IMPORTANT:



When you set up an IRF fabric, make sure the links in any of the following lists have the same bandwidth as the links in the same list:

- The bandwidth of each IRF physical link attached to the same IRF port.
- The bandwidth of each IRF aggregate link attached to the IRF ports on the same IRF member device.
- The bandwidth of each IRF aggregate link attached to the IRF ports connecting two member devices.



If the bandwidths do not meet the requirements, packet loss might occur for the traffic forwarded across member devices.

An IRF fabric can use a daisy-chain or ring topology. As shown in Figure 5, a ring topology is more reliable. In ring topology, the failure of one IRF link does not cause the IRF fabric to split as in daisy-chain topology. Rather, the IRF fabric changes to a daisy-chain topology without interrupting network services.

Figure 5 Daisy-chain topology vs. ring topology

Daisy-chain topology

Ring topology

IMPORTANT:

This switch series does not support building a two-member IRF fabric in ring topology.

Master election

Master election occurs each time the IRF fabric topology changes in the following situations:

- The IRF fabric is established.
- The master device fails or is removed.
- The IRF fabric splits.
- Independent IRF fabrics merge.

NOTE:

Master election does not occur when split IRF fabrics merge. For information about the master device of the merged IRF fabric, see "Failure recovery."

Master election selects a master in descending order:

1. Current master, even if a new member has higher priority.

   When an IRF fabric is being formed, all members consider themselves as the master. This rule is skipped.
2. Member with higher priority.
3. Member with the longest system uptime.

   Two members are considered to start up at the same time if the difference between their startup times is equal to or less than 10 minutes. For these members, the next tiebreaker applies.
4. Member with the lowest CPU MAC address.

For the setup of a new IRF fabric, the subordinate devices must reboot to complete the setup after the master election.

For an IRF merge, devices must reboot if they are in the IRF fabric that fails the master election.

Interface naming conventions

A physical interface is numbered in the *chassis-number/slot-number/interface-index* format.

- ***chassis-number***—Member ID of the device. The default value for this argument is 1. Any change to the member ID takes effect after a reboot.
- ***slot-number***—Slot number of the interface, which is fixed at 0.
- ***interface-index***—Interface index on the device. Interface index depends on the number of physical interfaces available on the device. To identify the index of a physical interface, examine its index mark on the chassis.

For example, GigabitEthernet 2/0/1 represents the first fixed physical interface on member device 2. Set its link type to trunk, as follows:

```
<Sysname> system-view
[Sysname] interface gigabitethernet 2/0/1
[Sysname-GigabitEthernet2/0/1] port link-type trunk
```

File system naming conventions

On a single-chassis fabric, you can use its storage device name to access its file system.

On a multichassis IRF fabric, you can use the storage device name to access the file system of the master. To access the file system of any other member device, use the name in the **slot***member-ID#storage-device-name* format.

For more information about storage device naming conventions, see *Fundamentals Configuration Guide*.

For example:

- To create and access the **test** folder under the root directory of the flash memory on the master switch:

  ```
  <Master> mkdir test
  Creating directory flash:/test... Done.
  <Master> cd test
  <Master> dir
  ```

```
Directory of flash:/test
The directory is empty.
2009784 KB total (1239680 KB free)
```

- To create and access the **test** folder under the root directory of the flash memory on member device 3:

```
<Master> mkdir slot3#flash:/test
Creating directory slot3#flash:/test... Done.
<Master> cd slot3#flash:/test
<Master> dir
Directory of slot3#flash:/test
The directory is empty.
2009784 KB total (1239652 KB free)
```

Configuration synchronization

IRF uses a strict running-configuration synchronization mechanism to make sure all member devices operate as if they were one device. When the master device fails, the remaining devices can still operate correctly to provide services.

The configuration synchronization mechanism has two phases: bulk sync at startup and real-time sync during operation.

1. **Bulk sync**—Occurs when a device starts up in the following situations:
   - The device reboots to join the IRF fabric as a new subordinate device.

     In this situation, the device takes the following actions:
     - Pulls and loads the running configuration from the master device.
     - Loads the IRF member description, priority, and IRF port bindings locally configured for it by using the **`irf member description, irf member priority, and irf-port commands, respectively.`**
     - Pushes its IRF member description, priority, and IRF port bindings to the master device.

     The configuration files on the device are retained, but they do not take effect.
   - The entire IRF fabric reboots.

     In this situation, all member devices in the IRF reboot simultaneously. The subordinate devices pull the startup configuration file from the master device and then extract the configuration from the file to run in memory.
2. **Real-time sync**—Occurs while the IRF fabric is operating.

   In this situation, the system takes the following actions:
   - Saves all configuration changes you make to the running configuration on the master device.
   - Pushes the configuration changes to the subordinate devices in real time.

Bulk sync and real-time sync ensure that all member devices in an IRF fabric run the same configuration. When the master device fails, the remaining member devices can still operate as configured.

To prevent configuration loss upon reboot of the IRF fabric, save configuration changes to all member devices by using the **`save all`** command while the IRF fabric is operating.

Multi-active handling procedure

The multi-active handling procedure includes detection, collision handling, and failure recovery.

Detection

IRF provides MAD mechanisms by extending LACP, BFD, ARP, and IPv6 ND to detect multi-active collisions. As a best practice, configure a minimum of one MAD mechanism on an IRF fabric. For more information about the MAD mechanisms and their application scenarios, see "MAD mechanisms."

For information about LACP, see Ethernet link aggregation in *Layer 2—LAN Switching Configuration Guide*. For information about BFD, see *High Availability Configuration Guide*. For information about ARP, see *Layer 3—IP Services Configuration Guide*. For information about ND, see IPv6 basics in *Layer 3—IP Services Configuration Guide*.

Collision handling

When detecting a multi-active collision, MAD disables all IRF fabrics except one from forwarding data traffic by placing them in Recovery state. The IRF fabrics placed in Recovery state are called inactive IRF fabrics. The IRF fabric that continues to forward traffic is called the active IRF fabric.

BFD MAD and LACP MAD use the following process to handle a multi-active collision:

1. Compare the health states of split fabrics. To view their health states, use the **`display system health`** command. For more information about this command, see device management in *Fundamentals Command Reference*.
2. Set all fabrics to the Recovery state except the healthiest one.
3. Compare the number of members in each fabric if all IRF fabrics are in the same health state.
4. Set all fabrics to the Recovery state except the one that has the most members.
5. Compare the member IDs of their masters if all IRF fabrics have the same number of members.
6. Set all fabrics to the Recovery state except the one that has the lowest numbered master.
7. Shut down all common network interfaces in the Recovery-state fabrics except for the following interfaces:
   - Interfaces automatically excluded from being shut down by the system.
   - Interfaces specified by using the **`mad exclude interface`** command.

ARP MAD and ND MAD use the following process to handle a multi-active collision:

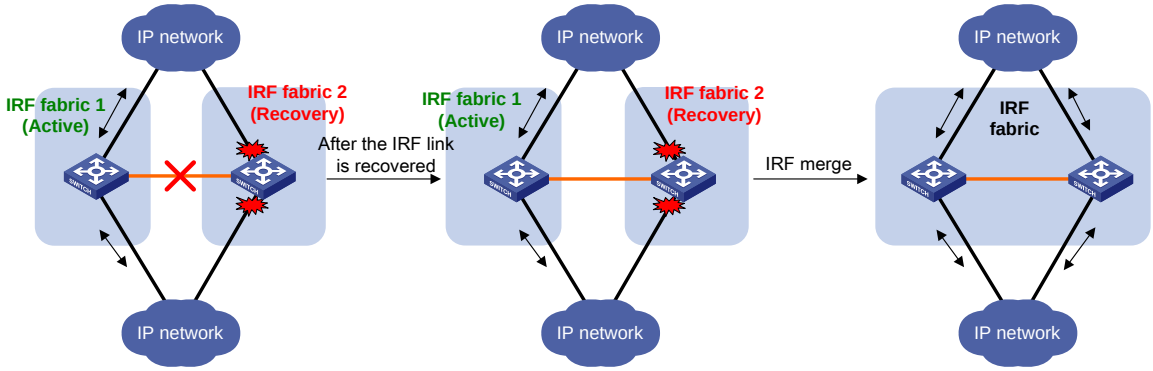
8. Compare the health states of split fabrics. To view their health states, use the **`display system health`** command. For more information about this command, see device management in *Fundamentals Command Reference*.
9. Set all fabrics to the Recovery state except the healthiest one.
10. Compare the member IDs of the masters in the IRF fabrics if all IRF fabrics have the same health state.
11. Set all fabrics to the Recovery state except the one that has the lowest numbered master.
12. Shut down all common network interfaces in the Recovery-state fabrics except for the following interfaces:
    - Interfaces automatically excluded from being shut down by the system.
    - Interfaces specified by using the **`mad exclude interface`** command.

Failure recovery

To merge two split IRF fabrics, first repair the failed IRF link and remove the IRF link failure.

When the failed IRF link between two split IRF fabrics is recovered, all member devices in the inactive IRF fabric automatically reboot to join the active IRF fabric as subordinate members. The

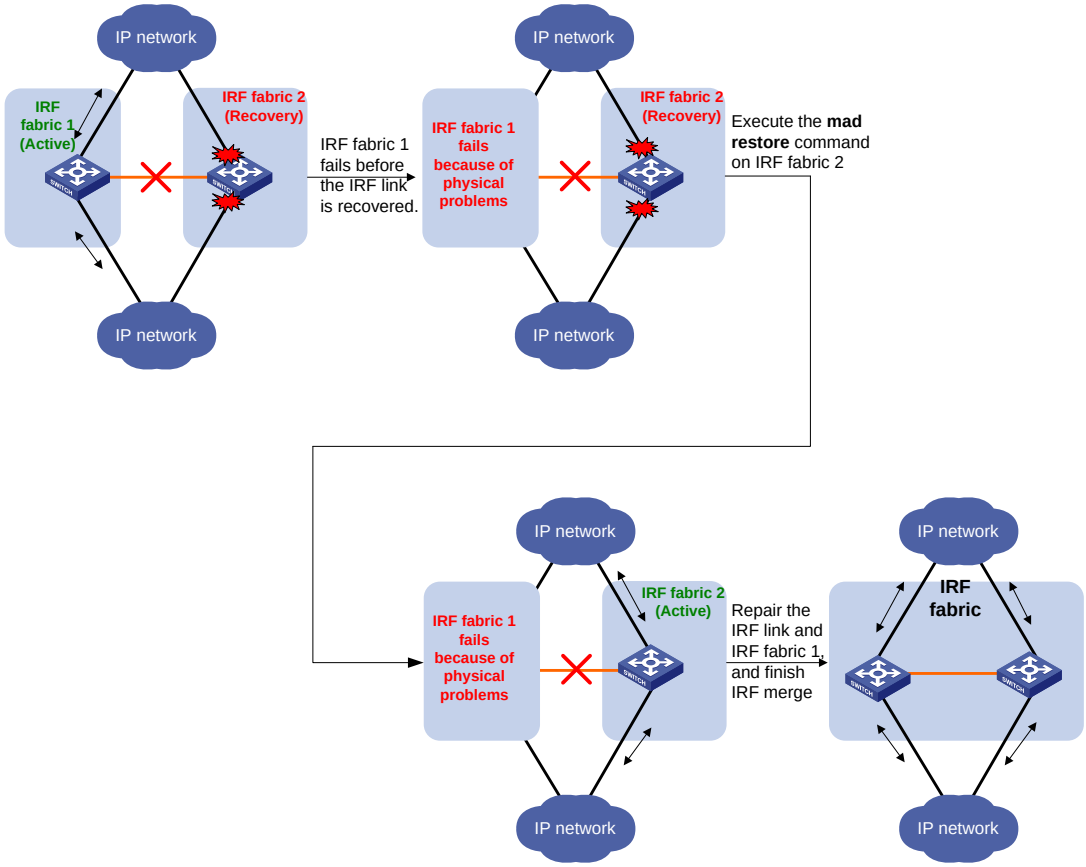
network interfaces that have been shut down by MAD automatically restore their original state, as shown in Figure 6.



CAUTION:

If you inadvertently reboot the active IRF fabric after the failed IRF link recovers, its member devices will join the inactive IRF fabric with their network interfaces being shut down by MAD. To restore the original states of the network interfaces in the merged IRF fabric, use the **mad restore** command.

NOTE:



If the IRF auto-merge feature is enabled, the inactive IRF member devices will automatically reboot after the failed IRF link recovers and a manual reboot is typically not required.

Figure 6 Recovering the IRF fabric

If the active IRF fabric fails before the IRF link is recovered (see Figure 7), use the **mad restore** command on the inactive IRF fabric to recover the inactive IRF fabric. This command brings up all network interfaces that were shut down by MAD. After the IRF link is repaired, merge the two parts into a unified IRF fabric.

Figure 7 Active IRF fabric fails before the IRF link is recovered

MAD mechanisms

IRF provides MAD mechanisms by extending LACP, BFD, ARP, and IPv6 ND.

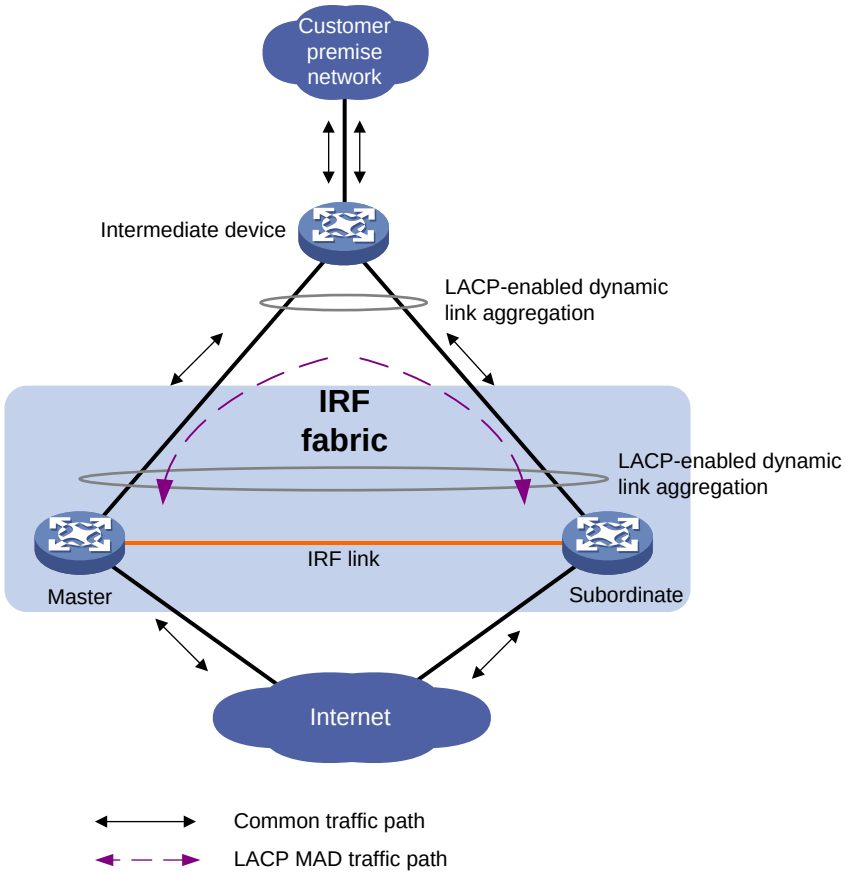
Table 1 compares the MAD mechanisms and their application scenarios.

Table 1 Comparison of MAD mechanisms

MAD mechanism	Advantages	Disadvantages	Application scenarios
LACP MAD	• Detection speed is fast. • Runs on existing aggregate links without requiring MAD-dedicated physical links or Layer 3 interfaces.	Requires an intermediate device that supports extended LACP for MAD.	Link aggregation is used between the IRF fabric and its upstream or downstream device.
BFD MAD	• Detection speed is fast. • Intermediate device, if used, can come from any vendor.	Requires MAD dedicated physical links and Layer 3 interfaces, which cannot be used for transmitting user traffic.	• No special requirements for network scenarios. • If no intermediate device is used, this mechanism is only suitable for IRF fabrics that have only two members that are geographically

MAD mechanism	Advantages	Disadvantages	Application scenarios
			close to one another.
ARP MAD	• No intermediate device is required. • Intermediate device, if used, can come from any vendor. • Does not require MAD dedicated ports.	• Detection speed is slower than BFD MAD and LACP MAD. • The spanning tree feature must be enabled if common Ethernet ports are used for ARP MAD links.	Spanning tree-enabled non-link aggregation IPv4 network scenarios if common Ethernet ports are used.
ND MAD	• No intermediate device is required. • Intermediate device, if used, can come from any vendor. • Does not require MAD dedicated ports.	• Detection speed is slower than BFD MAD and LACP MAD. • The spanning tree feature must be enabled if common Ethernet ports are used for ND MAD links.	Spanning tree-enabled non-link aggregation IPv6 network scenarios if common Ethernet ports are used.

LACP MAD



As shown in Figure 8, LACP MAD has the following requirements:

- Every IRF member must have a link with an intermediate device.
- All the links form a dynamic link aggregation group.
- The intermediate device must be a device that supports extended LACP for MAD.

The IRF member devices send extended LACPDUs that convey a domain ID and an active ID (the member ID of the master). The intermediate device transparently forwards the extended LACPDUs received from one member device to all the other member devices.

- If the domain IDs and active IDs sent by all the member devices are the same, the IRF fabric is integrated.
- If the extended LACPDUs convey the same domain ID but different active IDs, a split has occurred. LACP MAD handles this situation as described in "Collision handling."

Figure 8 LACP MAD scenario

BFD MAD

BFD MAD detects multi-active collisions by using BFD.

You can use common or management Ethernet ports for BFD MAD.

If management Ethernet ports are used, BFD MAD has the following requirements:

- Use an intermediate device and make sure each IRF member device has a BFD MAD link to the intermediate device.
- Assign each member device a MAD IP address on the master's management Ethernet port.

If common Ethernet ports are used, BFD MAD has the following requirements:

- If an intermediate device is used, each member device must have a BFD MAD link to the intermediate device. If no intermediate device is used, all member devices must have a BFD MAD link to each other.
- Assign all ports on the BFD MAD links to the same VLAN or Layer 3 aggregate interface. Assign each member device a MAD IP address on the VLAN interface or Layer 3 aggregate interface.

When you use BFD MAD, follow these restrictions and guidelines:

- As a best practice, use an intermediate device to connect IRF member devices if the IRF fabric has more than two member devices. A full mesh of IRF members might cause broadcast loops.
- As a best practice, preferentially use management Ethernet ports for BFD MAD.
- The BFD MAD links and BFD MAD VLAN (or Layer 3 aggregate interface) must be dedicated. Do not use the BFD MAD links or BFD MAD VLAN (or Layer 3 aggregate interface) for any other purposes.

- When you use a Layer 3 aggregate interface for BFD MAD, make sure its member ports do not exceed the maximum number of Selected ports allowed for an aggregation group. If the number of member ports exceeds the maximum number of Selected ports, some member ports cannot become Selected. BFD MAD will be unable to work correctly and its state will change to Faulty. For more information about setting the maximum number of Selected ports for an aggregation group, see Ethernet link aggregation in *Layer 2—LAN Switching Configuration Guide*.

NOTE:

- The MAD addresses identify the member devices and must belong to the same subnet.
- Of all management Ethernet ports on an IRF fabric, only the master's management Ethernet port is accessible.

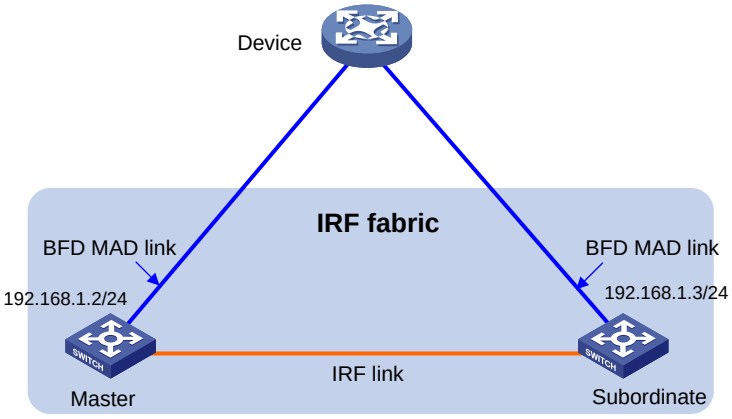
Figure 9 shows a typical BFD MAD scenario that uses an intermediate device. On the intermediate device, assign the ports on the BFD MAD links to the same VLAN.

Figure 10 shows a typical BFD MAD scenario that does not use an intermediate device.

With BFD MAD, the master attempts to establish BFD sessions with other member devices by using its MAD IP address as the source IP address.

- If the IRF fabric is integrated, only the MAD IP address of the master takes effect. The master cannot establish a BFD session with any other member. If you execute the **`display bfd session`** command, the state of the BFD sessions is **Down**.
- When the IRF fabric splits, the IP addresses of the masters in the split IRF fabrics take effect. The masters can establish a BFD session. If you execute the **`display bfd session`** command, the state of the BFD session between the two devices is **Up**.

Figure 9 BFD MAD scenario with an intermediate device



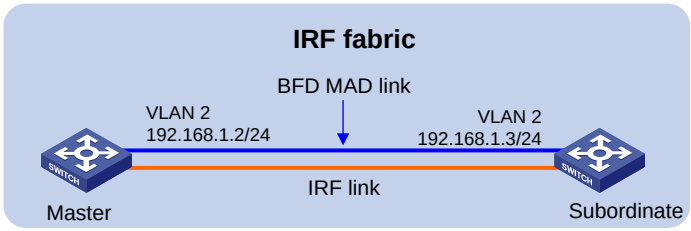


Figure 10 BFD MAD scenario without an intermediate device

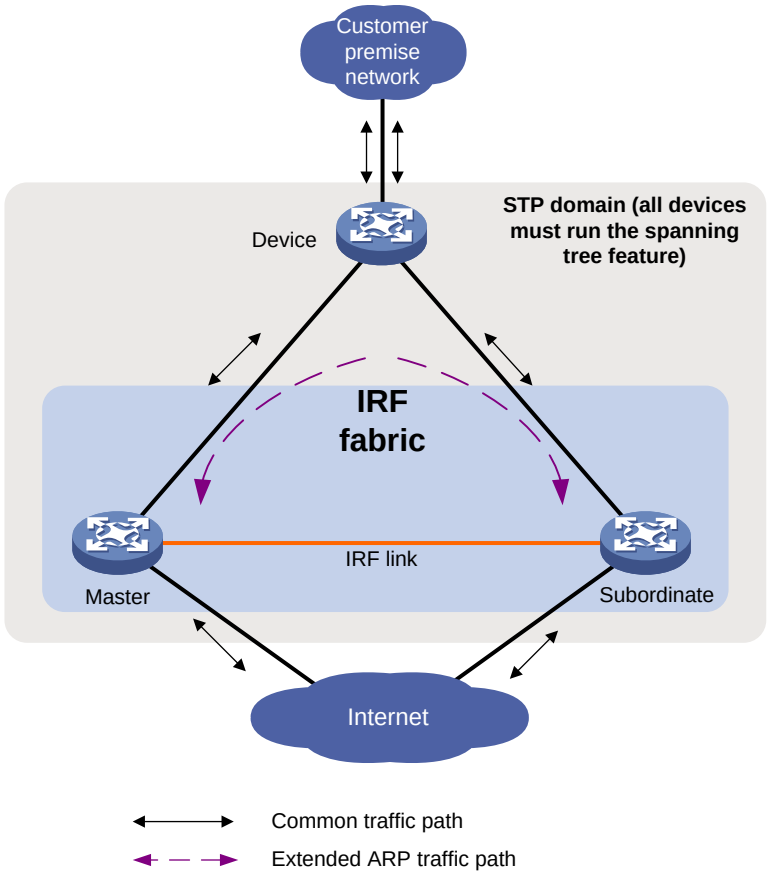
ARP MAD

ARP MAD detects multi-active collisions by using extended ARP packets that convey the IRF domain ID and the active ID.

You can use common or management Ethernet ports for ARP MAD.

If management Ethernet ports are used, ARP MAD must work with an intermediate device. Make sure the following requirements are met:

- Connect a management Ethernet port on each member device to the intermediate device.
- On the intermediate device, you must assign the ports used for ARP MAD to the same VLAN.



If common Ethernet ports are used, ARP MAD can work with or without an intermediate device. Make sure the following requirements are met:

- If an intermediate device is used, connect each IRF member device to the intermediate device, as shown in Figure 11. Run the spanning tree feature between the IRF fabric and the intermediate device. In this situation, data links can be used.
- If no intermediate device is used, connect each IRF member device to all other member devices. In this situation, IRF links cannot be used for ARP MAD.

Each IRF member compares the domain ID and the active ID (the member ID of the master) in incoming extended ARP packets with its domain ID and active ID.

- If the domain IDs are different, the extended ARP packet is from a different IRF fabric. The device does not continue to process the packet with the MAD mechanism.
- If the domain IDs are the same, the device compares the active IDs.
  - If the active IDs are different, the IRF fabric has split.
  - If the active IDs are the same, the IRF fabric is integrated.

Figure 11 ARP MAD scenario

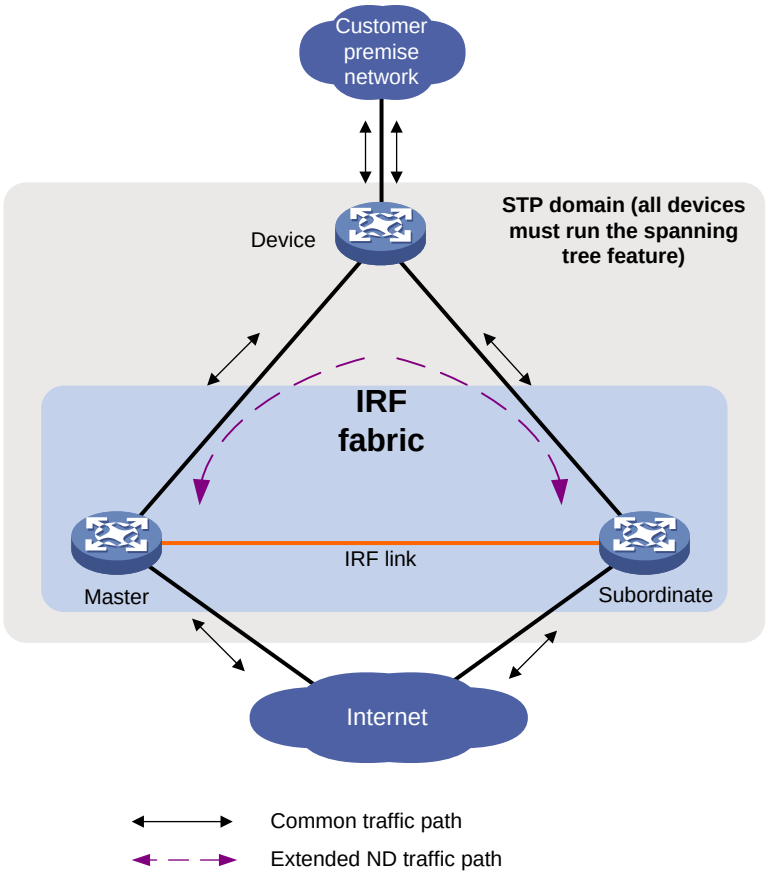
ND MAD

ND MAD detects multi-active collisions by using NS packets to transmit the IRF domain ID and the active ID.

You can use common or management Ethernet ports for ND MAD.

If management Ethernet ports are used, ND MAD must work with an intermediate device. Make sure the following requirements are met:

- Connect a management Ethernet port on each member device to the intermediate device.
- On the intermediate device, you must assign the ports used for ND MAD to the same VLAN.



If common Ethernet ports are used, ND MAD can work with or without an intermediate device. Make sure the following requirements are met:

- If an intermediate device is used, connect each IRF member device to the intermediate device, as shown in Figure 12. Run the spanning tree feature between the IRF fabric and the intermediate device. In this situation, data links can be used.
- If no intermediate device is used, connect each IRF member device to all other member devices. In this situation, IRF links cannot be used for ND MAD.

Each IRF member device compares the domain ID and the active ID (the member ID of the master) in incoming NS packets with its domain ID and active ID.

- If the domain IDs are different, the NS packet is from a different IRF fabric. The device does not continue to process the packet with the MAD mechanism.
- If the domain IDs are the same, the device compares the active IDs.
    - If the active IDs are different, the IRF fabric has split.
    - If the active IDs are the same, the IRF fabric is integrated.

Figure 12 ND MAD scenario

Restrictions and guidelines: IRF configuration

Hardware compatibility with IRF

A switch in the S5200-HI-G series can form an IRF fabric only with switches in the same series. Likewise, a switch in the S5200-EI-G series can form an IRF fabric only with switches in the same series.

Software requirements for IRF

All IRF member devices must run the same software image version. Make sure the software auto-update feature is enabled on all member devices.

IRF fabric size

An IRF fabric can contain a maximum of nine member devices.

As a best practice, use a maximum of four devices to form an IRF fabric. If an IRF fabric contains more than four member devices, do not use any network management software to manage those devices.

Candidate IRF physical interfaces

QSFP28 ports can be used as IRF physical interfaces. The 10-GE or 25-GE breakout interfaces of a QSFP28 port cannot be used as IRF physical interfaces. On the S5200-HI-G or S5200-EI-G switch series, use SFP+ ports as IRF physical interfaces.

Transceiver modules and cables selection for IRF

When you select transceiver modules and cables, follow these restrictions and guidelines:

- To connect SFP+ ports in a long distance, use SFP+ transceiver modules and fibers.
- To connect SFP+ ports in a short distance, use SFP+ cables.
- To have an SFP+ port operate at 12 Gbps as an IRF physical interface, strictly use the following procedure to set up the IRF connections:
  a. Install a trasceiver module that can uprate to 12 Gbps in the port. For more information about the available uprate-capable trasceiver modules, see *Hardware Information and Specifications* for the product.
  b. Connect the port with an SFP+ cable.
  c. Configure the IRF settings on the port.

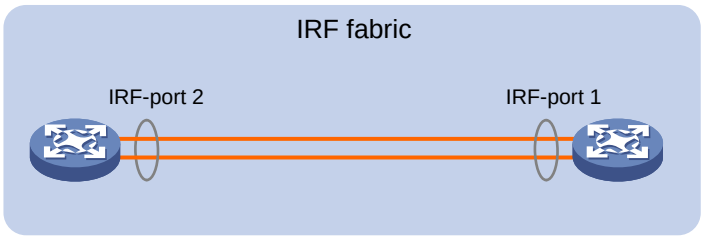
  When the system reboots to establish IRF connections, it automatically sets the port speed to 12 Gbps.

  If the port operates at a rate lower than 12 Gbps, handle the issue as follows:
  d. Make sure the transceiver module installed in the port supports uprating feature.
  e. Remove the IRF settings from the port.
  f. Remove and reinsert the SFP+ cable.
  g. Reconfigure the IRF port settings.

  Then, when the system reboots to establish IRF connections, it automatically sets the port speed to 12 Gbps.
- The transceiver modules at the two ends of an IRF link must be the same type.

For more information about the transceiver modules and DAC cables, see the device installation guide and *H3C Transceiver Modules User Guide*.

NOTE:



The transceiver modules and DAC cables available for the device are subject to change over time. For the most up-to-date list of transceiver modules and DAC cables, contact your H3C sales representative.

IRF port connection

When you connect two neighboring IRF members, follow these restrictions and guidelines:

- You must connect the physical interfaces of IRF-port 1 on one member to the physical interfaces of IRF-port 2 on the other.
- For high availability, bind multiple physical interfaces to an IRF port. You can bind a maximum of eight physical interfaces to an IRF port.

Figure 13 Connecting IRF physical interfaces

IRF physical interface configuration restrictions and guidelines

Command configuration restrictions

On a physical interface bound to an IRF port, you can execute only the following commands:

- Basic interface commands, including **shutdown** and **description**. For more information about these commands, see Ethernet interface commands in *Layer 2—LAN Switching Command Reference*.
- The **flow-interval** command, which sets the statistics polling interval on an interface. For more information about this command, see Ethernet interface commands in *Layer 2—LAN Switching Command Reference*.
- The **itu-channel** command for setting the ITU channel number for a transceiver module. For more information about this command, see device management commands in *Fundamentals Command Reference*.
- MAC address table configuration commands, including the **mac-address static source-check enable** command. For more information about these commands, see *Layer 2—LAN Switching Command Reference*.
- LLDP commands, including:
  - **lldp admin-status**.
  - **lldp check-change-interval**.
  - **lldp enable**.
  - **lldp encapsulation snap**.
  - **lldp notification remote-change enable**.
  - **lldp tlv-enable**.

  For more information about these commands, see LLDP in *Layer 2—LAN Switching Command Reference*.

Suppressing SNMP notifications of packet drops on IRF physical interfaces

Before an IRF member device forwards a packet, it examines its forwarding path in the IRF fabric for a loop. If a loop exists, the device discards the packet on the source interface of the looped path. This loop elimination mechanism will drop a large number of broadcast packets on the IRF physical interfaces.

To suppress SNMP notifications of packet drops that do not require attention, do not monitor packet forwarding on the IRF physical interfaces.

Feature compatibility and configuration restrictions with IRF

Routing settings

To form an IRF fabric, all member devices must use the same settings for the following routing features:

- Maximum number of ECMP routes (set by using the **`max-ecmp-num`** command).

For more information about the routing features, see basic IP routing in *Layer 3—IP Routing Configuration Guide*.

Configuration rollback restrictions

The configuration rollback feature cannot roll back the following IRF settings:

- Member device description (set by using the **`irf member description`** command).
- Member device priority (set by using the **`irf member priority`** command).
- IRF physical interface and IRF port bindings (set by using the **`port group interface`** command).

For more information about the configuration rollback feature, see configuration file management in *Fundamentals Configuration Guide*.

IRF tasks at a glance

To configure IRF, perform the following tasks:

1. Configuring MAD

   Configure a minimum of one MAD mechanism on an IRF fabric. For the MAD compatibility, see "MAD mechanism compatibility."

   - Configuring LACP MAD
   - Configuring BFD MAD
   - Configuring ARP MAD
   - Configuring ND MAD
   - Excluding interfaces from the shutdown action upon detection of multi-active collision

     This feature excludes an interface from the shutdown action for management or other special purposes when an IRF fabric transits to the Recovery state.
   - Recovering an IRF fabric
2. (Optional.) Optimizing IRF settings for an IRF fabric
   - Enabling IRF auto-merge

     When two IRF fabrics merge, this feature enables the IRF fabric that failed the master election to automatically reboot all its member devices to complete the merge.
   - Configuring a member device description
   - Configuring IRF bridge MAC address settings
   - Enabling software auto-update for software image synchronization

     This feature automatically synchronizes the current software images of the master to devices that are attempting to join the IRF fabric.
   - Setting the IRF link down report delay

Planning the IRF fabric setup

Consider the following items when you plan an IRF fabric:

- Hardware compatibility and restrictions.
- IRF fabric size.
- Master device.
- Member ID and priority assignment scheme.
- Fabric topology and cabling scheme.
- IRF physical interfaces.

Setting up an IRF fabric

IRF setup tasks at a glance

To set up an IRF fabric, perform the following tasks:

1. Configure member IDs, priorities, and IRF physical interfaces separately.
   a. Assigning a member ID to each IRF member device
   b. (Optional.) Specifying a priority for each member device
   c. Binding physical interfaces to IRF ports

   Skip these tasks if you configure member IDs, priorities, domain ID, and IRF physical interfaces in bulk.
2. Bulk-configuring basic IRF settings for a member device

   Skip this task if you configure member IDs, priorities, domain ID, and IRF physical interfaces separately.
3. Connecting IRF physical interfaces
4. Accessing the IRF fabric

Assigning a member ID to each IRF member device

Restrictions and guidelines

CAUTION:
An IRF member ID change can invalidate member ID-related settings and cause data loss. Make sure you fully understand its impact on your live network.

To create an IRF fabric, you must assign a unique IRF member ID to each member device.

The new member ID of a device takes effect at a reboot. After the device reboots, the settings on all member ID-related physical resources (including common physical network interfaces) are removed, regardless of whether you have saved the configuration.

Procedure

Table 2 Enter system view.

```
system-view
```

2. Assign a member ID to a member device.

   ```
   irf member member-id renumber new-member-id
   ```

   The default IRF member ID is 1.

CAUTION:

An IRF member ID change can invalidate member ID-related settings and cause data loss. Make sure you fully understand its impact on your live network.

3. (Optional.) Save the configuration.

   save

   If you have bound physical interfaces to IRF ports or assigned member priority, you must perform this step for these settings to take effect after the reboot.

4. Return to user view.

   quit

5. Reboot the device.

   reboot [**slot** *slot-number*] [**force**]

Specifying a priority for each member device

About this task

IRF member priority represents the possibility for a device to be elected the master in an IRF fabric. A larger priority value indicates a higher priority.

A change to member priority affects the election result at the next master election, but it does not cause an immediate master re-election.

Procedure

1. Enter system view.

   system-view

2. Specify a priority for the device.

   irf member *member-id* **priority** *priority*

   The default IRF member priority is 1.

Binding physical interfaces to IRF ports

Restrictions and guidelines

Select qualified physical interfaces as IRF physical interfaces as described in "Candidate IRF physical interfaces."

Make sure the IRF physical interfaces of an IRF port use the same binding mode.

After binding physical interfaces to IRF ports for the first time, you must use the **irf-port-configuration active** command to activate the settings on the IRF ports.

The system activates the IRF port settings automatically only in the following situations:

- The configuration file that the device starts with contains IRF port bindings.
- You are adding physical interfaces to an IRF port (in UP state) after an IRF fabric is formed.

Procedure

1. Enter system view.

   system-view

2. Enter interface view or interface range view.
   - Enter interface view.

interface *interface-type interface-number*

- Enter interface range view. Choose one of the following commands:

  interface range { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>

  interface range name *name* [**interface** { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>]

To shut down a range of IRF physical interfaces, enter interface range view.

To shut down one IRF physical interface, enter its interface view.

3. Shut down the physical interfaces.

   shutdown

   By default, interfaces on the device are disabled (in **ADM** or **Administratively Down** state).

   You must always shut down a physical interface before binding it to an IRF port or removing the binding. If the system prevents you from shutting down an interface, follow the system instructions to disable its peer interface.

4. Return to system view.

   quit

5. Enter IRF port view.

   irf-port *member-id/irf-port-number*

6. Bind each physical interface to the IRF port.

   port group interface *interface-type interface-number* [**mode enhanced**]

   By default, no physical interfaces are bound to an IRF port.

   Repeat this step to assign multiple physical interfaces to the IRF port.

7. Return to system view.

   quit

8. Enter interface view or interface range view.

   - Enter interface view.

     interface *interface-type interface-number*

   - Enter interface range view. Choose one of the following commands:

     interface range { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>

     interface range name *name* [**interface** { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>]

9. Bring up the physical interfaces.

   undo shutdown

10. Return to system view.

    quit

11. Save the configuration.

    save

    Activating IRF port configurations causes IRF merge and reboot. To avoid data loss, save the running configuration to the startup configuration file before you perform the operation.

12. Activate the IRF port settings.

    irf-port-configuration active

Bulk-configuring basic IRF settings for a member device

About this task

Use the easy IRF feature to bulk-configure basic IRF settings for a member device, including the member ID, domain ID, priority, and IRF port bindings.

The easy IRF feature provides the following configuration methods:

- **Interactive method**—Enter the **easy-irf** command without parameters. The system will guide you to set the parameters step by step.
- **Non-interactive method**—Enter the **easy-irf** command with parameters.

As a best practice, use the interactive method if you are new to IRF.

Restrictions and guidelines

CAUTION:

- Use caution when you change the member ID of an IRF member device. An IRF member ID uniquely identifies a device in an IRF fabric. An IRF member ID change can invalidate member ID-related settings, including interface and file path settings, and cause data loss. Make sure you fully understand its impact on the live network.
- The member device reboots immediately after you specify a new member ID for it. Make sure you are aware of the impact of this operation on the network.

If you execute the **easy-irf** command multiple times, the following settings take effect:

- The most recent settings for the member ID, domain ID, and priority.
- IRF port bindings added through repeated executions of the command. To remove an IRF physical interface from an IRF port, you must use the **undo port group interface** command in IRF port view.

If you specify IRF physical interfaces by using the interactive method, you must also follow these restrictions and guidelines:

- Do not enter spaces between the interface type and interface number.
- Use a comma (,) to separate two physical interfaces. No spaces are allowed between interfaces.

Procedure

1. Enter system view.

   system-view

2. Bulk-configure basic IRF settings for the device.

   easy-irf [**member** *member-id* [**renumber** *new-member-id*] **domain** *domain-id* [**priority** *priority*] [**irf-port1** *interface-list1*] [**irf-port2** *interface-list2*]]

   Make sure the new member ID is unique in the IRF fabric to which the device will be added.

Connecting IRF physical interfaces

Follow the restrictions in "IRF port connection" to connect IRF physical interfaces as well as based on the topology and cabling scheme. The devices perform master election. The member devices that fail the master election automatically reboot to form an IRF fabric with the master device.

Accessing the IRF fabric

The IRF fabric appears as one device after it is formed. You configure and manage all IRF members at the CLI of the master. All settings you have made are automatically propagated to the IRF members.

The following methods are available for accessing an IRF fabric:

- **Local login**—Log in through the console port of any member device.
- **Remote login**—Log in at a Layer 3 interface on any member device by using methods including Telnet and SNMP.

When you log in to an IRF fabric, you are placed at the CLI of the master, regardless of at which member device you are logged in.

For more information, see login configuration in *Fundamentals Configuration Guide*.

Configuring MAD

Restrictions and guidelines for MAD configuration

MAD mechanism compatibility

As a best practice, configure a minimum of one MAD mechanism on an IRF fabric for prompt IRF split detection. Because MAD mechanisms use different collision handling processes, follow these restrictions and guidelines when you configure multiple MAD mechanisms on an IRF fabric:

- Do not configure LACP MAD together with ARP MAD or ND MAD.
- Do not configure BFD MAD together with ARP MAD or ND MAD.

Assigning IRF domain IDs

An IRF fabric has only one IRF domain ID. You can change the IRF domain ID by using the following commands: **irf domain**, **mad enable**, **mad arp enable**, or **mad nd enable**. The IRF domain IDs configured by using these commands overwrite each other.

If LACP MAD, ARP MAD, or ND MAD runs between two IRF fabrics, assign each fabric a unique IRF domain ID. (For BFD MAD, this task is optional.)

Actions on interfaces shut down by MAD

To prevent a multi-active collision from causing network issues, avoid using the **undo shutdown** command to bring up the interfaces shut down by a MAD mechanism on a Recovery-state IRF fabric.

Configuring LACP MAD

1. Enter system view.
   system-view
2. Assign a domain ID to the IRF fabric.
   irf domain *domain-id*
   The default IRF domain ID is 0.

CAUTION:

Changing the IRF domain ID of an IRF member device will remove that member device from the IRF fabric. This member device will be unable to exchange IRF protocol packets with the

remaining member devices in the IRF fabric.

3. Create an aggregate interface and enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.
     interface route-aggregation *interface-number*

   Perform this step also on the intermediate device.
4. Configure the aggregation group to operate in dynamic aggregation mode.
   link-aggregation mode dynamic

   By default, an aggregation group operates in static aggregation mode.

   LACP MAD takes effect only on dynamic aggregate interfaces.

   Perform this step also on the intermediate device.
5. Enable LACP MAD.
   mad enable

   By default, LACP MAD is disabled.
6. Return to system view.
   quit
7. Enter Ethernet interface view or interface range view.
   - Enter Ethernet interface view.
     interface *interface-type interface-number*
   - Enter interface range view. Choose one of the following commands:
     interface range { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>

     interface range name *name* [**interface** { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>]

   To assign a range of ports to the aggregation group, enter interface range view.

   To assign one port to the aggregation group, enter Ethernet interface view.
8. Assign the Ethernet port or the range of Ethernet ports to the specified aggregation group.
   port link-aggregation group *group-id*

   Multichassis link aggregation is allowed.

   Perform this step also on the intermediate device.

Configuring BFD MAD

Restrictions and guidelines for configuring BFD MAD

As a best practice, use the following procedure to set up BFD MAD:

1. Choose a BFD MAD link scheme as described in "BFD MAD."
2. Configure BFD MAD.
3. Connect the BFD MAD links.

When you configure BFD MAD on a VLAN interface, follow these restrictions and guidelines:

Category	Restrictions and guidelines
BFD MAD VLAN	• Do not enable BFD MAD on VLAN-interface 1. • If you are using an intermediate device, perform the following tasks: ○ On the IRF fabric and the intermediate device, create a VLAN for BFD MAD. ○ On the IRF fabric and the intermediate device, assign the ports of BFD MAD links to the BFD MAD VLAN. ○ On the IRF fabric, create a VLAN interface for the BFD MAD VLAN. • Make sure the IRF fabrics on the network use different BFD MAD VLANs. • Make sure the BFD MAD VLAN contains only ports on the BFD MAD links. Exclude a port from the BFD MAD VLAN if that port is not on a BFD MAD link. If you have assigned that port to all VLANs by using the **`port trunk permit vlan all`** command, use the **`undo port trunk permit`** command to exclude that port from the BFD MAD VLAN. • After an IRF fabric split, the system handles the BFD MAD VLAN and its interface in the IRF fabric that lost the master election as follows: ○ Retains the BFD MAD VLAN interface. ○ Shuts down all Layer 2 Ethernet interfaces in the BFD MAD VLAN except one on the master device for BFD MAD detection. The interfaces that shut down are placed in MAD down state.
BFD MAD VLAN and feature compatibility	Do not use the BFD MAD VLAN and its member ports for any purpose other than BFD MAD. • Use only the **`mad bfd enable`** and **`mad ip address`** commands on the BFD MAD-enabled VLAN interface. If you configure other features, both BFD MAD and other features on the interface might run incorrectly. • Disable the spanning tree feature on any Layer 2 Ethernet ports in the BFD MAD VLAN. The MAD feature is mutually exclusive with the spanning tree feature. • You can use multiple Layer 2 Ethernet ports to establish BFD MAD links directly between the member devices or across a relay device, for redundancy. To avoid loops in this situation, take the following actions: ○ Create one Layer 2 aggregate interface for each member device. ○ Assign all the ports used on each member device for BFD MAD to one of those aggregate interfaces. ○ Make sure each aggregate interface contains only ports on the same member device. ○ Assign the aggregate interfaces to the BFD MAD VLAN.
MAD IP address	• To avoid network issues, only use the **`mad ip address`** command to configure IP addresses on the BFD MAD-enabled VLAN interface. Do not configure an IP address by using the **`ip address`** command or configure a VRRP virtual address on the BFD MAD-enabled VLAN interface. • Make sure all the MAD IP addresses are on the same subnet. • To make sure BFD MAD can operate correctly, do not use the BFD MAD IP address to create BFD sessions for other services.

When you configure BFD MAD on a Layer 3 aggregate interface, follow these restrictions and guidelines:

Category	Restrictions and guidelines
BFD MAD-enabled Layer 3 aggregate interface	• Make sure the Layer 3 aggregate interface operates in static aggregation mode. • Make sure the member ports in the aggregation group do not exceed the

Category	Restrictions and guidelines
	maximum number of Selected ports allowed for an aggregation group. If the number of member ports exceeds the maximum number of Selected ports, some member ports cannot become Selected. BFD MAD will be unable to work correctly and its state will change to Faulty.
BFD MAD VLAN	If a switch is used as the intermediate device, use a VLAN as the BFD MAD VLAN on the intermediate device. • If the intermediate device acts as a BFD MAD intermediate device for multiple IRF fabrics, assign different BFD MAD VLANs to the IRF fabrics. • Assign the ports on the BFD MAD links for the same IRF fabric to the same VLAN. Do not assign the ports to an aggregate interface. If the ports are hybrid ports, make sure these ports are untagged members of their PVIDs. • Do not use the BFD MAD VLAN on the intermediate device for any purposes other than BFD MAD. • Make sure the BFD MAD VLAN on the intermediate device contains only ports on the BFD MAD links. Exclude a port from the BFD MAD VLAN if that port is not on a BFD MAD link. If you have assigned that port to all VLANs by using the **port trunk permit vlan all** command, use the **undo port trunk permit** command to exclude that port from the BFD MAD VLAN.
BFD MAD-enabled Layer 3 aggregate interface and feature compatibility	Use only the **mad bfd enable** and **mad ip address** commands on the BFD MAD-enabled interface. If you configure other features, both BFD MAD and other features on the interface might run incorrectly.
MAD IP address	• To avoid network issues, only use the **mad ip address** command to configure IP addresses on the BFD MAD-enabled interface. Do not configure an IP address by using the **ip address** command or configure a VRRP virtual address on the BFD MAD-enabled interface. • Make sure all the MAD IP addresses are on the same subnet. • To make sure BFD MAD can operate correctly, do not use the BFD MAD IP address to create BFD sessions for other services.

When you configure BFD MAD on a management Ethernet port, follow these restrictions and guidelines:

Category	Restrictions and guidelines
Management Ethernet ports for BFD MAD	Connect a management Ethernet port on each IRF member device to the common Ethernet ports on the intermediate device.
BFD MAD VLAN	• On the intermediate device (if any), create a VLAN for BFD MAD, and assign the ports used for BFD MAD to the VLAN. On the IRF fabric, you do not need to assign the management Ethernet ports to the VLAN. • Make sure the IRF fabrics on the network use different BFD MAD VLANs. • Make sure the BFD MAD VLAN on the intermediate device contains only ports on the BFD MAD links.
MAD IP address	• Use the **mad ip address** command instead of the **ip address** command to configure MAD IP addresses on the BFD MAD-enabled management Ethernet ports. • Make sure all the MAD IP addresses are on the same subnet. • To make sure BFD MAD can operate correctly, do not use the BFD MAD IP address to create BFD sessions for other services.

Configuring BFD MAD on a VLAN interface

1. Enter system view.

system-view

2. (Optional.) Assign a domain ID to the IRF fabric.

   irf domain *domain-id*

   By default, the domain ID of an IRF fabric is 0.

CAUTION:

Changing the IRF domain ID of an IRF member device will remove that member device from the IRF fabric. This member device will be unable to exchange IRF protocol packets with the remaining member devices in the IRF fabric.

3. Create a VLAN dedicated to BFD MAD.

   vlan *vlan-id*

   By default, only VLAN 1 exists.

   Do not enable BFD MAD on VLAN-interface 1.

   Perform this step also on the intermediate device (if any).

4. Return to system view.

   quit

5. Enter Ethernet interface view or interface range view.

   - Enter Ethernet interface view.

     interface *interface-type interface-number*

   - Enter interface range view. Choose one of the following commands:

     interface range { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>

     interface range name *name* [**interface** { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>]

   To assign a range of ports to the BFD MAD VLAN, enter interface range view.

   To assign one port to the BFD MAD VLAN, enter Ethernet interface view.

6. Assign the port or the range of ports to the BFD MAD VLAN.

   - Assign the ports to the VLAN as access ports.

     port access vlan *vlan-id*

   - Assign the ports to the VLAN as trunk ports.

     port trunk permit vlan *vlan-id*

   - Assign the ports to the VLAN as hybrid ports.

     port hybrid vlan *vlan-id* { **tagged** | **untagged** }

   The link type of BFD MAD ports can be access, trunk, or hybrid.

   The default link type of a port is access.

   Perform this step also on the intermediate device (if any).

7. Return to system view.

   quit

8. Enter VLAN interface view.

   interface vlan-interface *vlan-interface-id*

9. Enable BFD MAD.

   mad bfd enable

   By default, BFD MAD is disabled.

10. Assign a MAD IP address to a member device on the VLAN interface.

mad ip address *ip-address* { *mask* | *mask-length* } **member** *member-id*

By default, no MAD IP addresses are configured on any VLAN interfaces.

Repeat this step to assign a MAD IP address to each member device on the VLAN interface.

Configuring BFD MAD on a Layer 3 aggregate interface

1. Enter system view.

   system-view

2. (Optional.) Assign a domain ID to the IRF fabric.

   irf domain *domain-id*

   By default, the domain ID of an IRF fabric is 0.

CAUTION:

Changing the IRF domain ID of an IRF member device will remove that member device from the IRF fabric. This member device will be unable to exchange IRF protocol packets with the remaining member devices in the IRF fabric.

3. Create a Layer 3 aggregate interface for BFD MAD.

   interface route-aggregation *interface-number*

4. Return to system view.

   quit

5. Enter interface view or interface range view.

   - Enter Ethernet interface view.

     interface *interface-type interface-number*

   - Enter interface range view. Choose one of the following commands:

     interface range { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>

     interface range name *name* [**interface** { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>]

   To assign a range of ports to the aggregation group for the aggregate interface, enter interface range view.

   To assign one port to the aggregation group for the aggregate interface, enter Ethernet interface view.

6. Assign the port or the range of ports to the aggregation group for the aggregate interface.

   port link-aggregation group *number*

7. Return to system view.

   quit

8. Enter Layer 3 aggregate interface view.

   interface route-aggregation *interface-number*

9. Enable BFD MAD.

   mad bfd enable

   By default, BFD MAD is disabled.

10. Assign a MAD IP address to a member device on the Layer 3 aggregate interface.

    mad ip address *ip-address* { *mask* | *mask-length* } **member** *member-id*

    By default, no MAD IP addresses are configured on aggregate interfaces.

    Repeat this step to assign a MAD IP address to each member device on the aggregate interface.

Configuring BFD MAD on a management Ethernet port

1. Enter system view.
   system-view
2. (Optional.) Assign a domain ID to the IRF fabric.
   irf domain *domain-id*
   By default, the domain ID of an IRF fabric is 0.

CAUTION:
Changing the IRF domain ID of an IRF member device will remove that member device from the IRF fabric. This member device will be unable to exchange IRF protocol packets with the remaining member devices in the IRF fabric.

3. Enter management Ethernet interface view.
   interface m-gigabitethernet *interface-number*
   Of all management Ethernet ports on an IRF fabric, only the master's management Ethernet port is accessible.
4. Enable BFD MAD.
   mad bfd enable
   By default, BFD MAD is disabled.
5. Assign a MAD IP address to each member device.
   mad ip address *ip-address* { *mask* | *mask-length* } **member** *member-id*
   By default, no MAD IP addresses are configured.

Configuring ARP MAD

Restrictions and guidelines for configuring ARP MAD

As a best practice, use the following procedure to set up ARP MAD:

1. Choose an ARP MAD link scheme as described in "ARP MAD."
2. Configure ARP MAD.
3. Connect the ARP MAD links.

When you configure ARP MAD on a VLAN interface, follow these restrictions and guidelines:

Category	Restrictions and guidelines
ARP MAD VLAN	• Do not enable ARP MAD on VLAN-interface 1. • If you are using an intermediate device, perform the following tasks: ○ On the IRF fabric and the intermediate device, create a VLAN for ARP MAD. ○ On the IRF fabric and the intermediate device, assign the ports of ARP MAD links to the ARP MAD VLAN. ○ On the IRF fabric, create a VLAN interface for the ARP MAD VLAN. • Do not use the ARP MAD VLAN for any other purposes.
ARP MAD and feature configuration	If an intermediate device is used, make sure the following requirements are met: • Run the spanning tree feature between the IRF fabric and the intermediate device to ensure that there is only one ARP MAD link in forwarding state. For more information about the spanning tree feature

Category	Restrictions and guidelines
	and its configuration, see *Layer 2—LAN Switching Configuration Guide*. • Enable the IRF fabric to change its bridge MAC address as soon as the address owner leaves. • If the intermediate device is also an IRF fabric, assign the two IRF fabrics different domain IDs for correct split detection.

When you configure ARP MAD on a management Ethernet port, follow these restrictions and guidelines:

Category	Restrictions and guidelines
Management Ethernet ports for ARP MAD	Connect a management Ethernet port on each member device to the common Ethernet ports on the intermediate device.
ARP MAD VLAN	On the intermediate device, create a VLAN for ARP MAD, and assign the ports used for ARP MAD to the VLAN. On the IRF fabric, you do not need to assign the management Ethernet ports to the VLAN.
ARP MAD and feature configuration	• Enable the IRF fabric to change its bridge MAC address as soon as the address owner leaves. • If the intermediate device is also an IRF fabric, assign the two IRF fabrics different domain IDs for correct split detection.

Configuring ARP MAD on a VLAN interface

1. Enter system view.

   system-view
2. Assign a domain ID to the IRF fabric.

   irf domain *domain-id*

   The default IRF domain ID is 0.

   CAUTION:

   Changing the IRF domain ID of an IRF member device will remove that member device from the IRF fabric. This member device will be unable to exchange IRF protocol packets with the remaining member devices in the IRF fabric.
3. Configure the IRF bridge MAC address to change as soon as the address owner leaves.

   undo irf mac-address persistent

   By default, the IRF bridge MAC address does not change after the address owner leaves.

   CAUTION:

   IRF bridge MAC address change will cause transient traffic disruption.
4. Create a VLAN dedicated to ARP MAD.

   vlan *vlan-id*

   By default, only VLAN 1 exists.

   Do not configure ARP MAD on VLAN-interface 1.

   Perform this task also on the intermediate device (if any).
5. Return to system view.

   quit
6. Enter Ethernet interface view or interface range view.
   - Enter Ethernet interface view.

interface *interface-type interface-number*

- Enter interface range view. Choose one of the following commands:

  interface range { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>

  interface range name *name* [**interface** { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>]

To assign a range of ports to the ARP MAD VLAN, enter interface range view.

To assign one port to the ARP MAD VLAN, enter Ethernet interface view.

7. Assign the port or the range of ports to the ARP MAD VLAN.
   - Assign the ports to the VLAN as access ports.

     port access vlan *vlan-id*
   - Assign the ports to the VLAN as trunk ports.

     port trunk permit vlan *vlan-id*
   - Assign the ports to the VLAN as hybrid ports.

     port hybrid vlan *vlan-id* { **tagged** | **untagged** }

   The link type of ARP MAD ports can be access, trunk, or hybrid.

   The default link type of a port is access.

   Perform this task also on the intermediate device (if any).
8. Return to system view.

   quit
9. Enter VLAN interface view.

   interface vlan-interface *vlan-interface-id*
10. Assign the interface an IP address.

    ip address *ip-address* { *mask* | *mask-length* }

    By default, no IP addresses are assigned to any VLAN interfaces.
11. Enable ARP MAD.

    mad arp enable

    By default, ARP MAD is disabled.

Configuring ARP MAD on a management Ethernet port

1. Enter system view.

   system-view
2. Assign a domain ID to the IRF fabric.

   irf domain *domain-id*

   The default IRF domain ID is 0.

CAUTION:

Changing the IRF domain ID of an IRF member device will remove that member device from the IRF fabric. This member device will be unable to exchange IRF protocol packets with the remaining member devices in the IRF fabric.

3. Configure the IRF bridge MAC address to change as soon as the address owner leaves.

   undo irf mac-address persistent

   By default, the IRF bridge MAC address does not change after the address owner leaves.

CAUTION:

IRF bridge MAC address change will cause transient traffic disruption.

4. Enter management Ethernet interface view.
   interface m-gigabitethernet *interface-number*
   Of all management Ethernet ports on an IRF fabric, only the master's management Ethernet port is accessible.
5. Assign an IP address to the management Ethernet port.
   ip address ip-address { *mask* | *mask-length* }
   By default, no IP addresses are configured.
6. Enable ARP MAD.
   mad arp enable
   By default, ARP MAD is disabled.

Configuring ND MAD

Restrictions and guidelines for configuring ND MAD

As a best practice, use the following procedure to set up ND MAD:

1. Choose an ND MAD link scheme as described in "ND MAD."
2. Configure ND MAD.
3. Connect the ND MAD links.

When you configure ND MAD on a VLAN interface, follow these restrictions and guidelines:

Category	Restrictions and guidelines
ND MAD VLAN	• Do not enable ND MAD on VLAN-interface 1. • If you are using an intermediate device, perform the following tasks: ○ On the IRF fabric and the intermediate device, create a VLAN for ND MAD. ○ On the IRF fabric and the intermediate device, assign the ports of ND MAD links to the ND MAD VLAN. ○ On the IRF fabric, create a VLAN interface for the ND MAD VLAN. • Do not use the ND MAD VLAN for any other purposes.
ND MAD and feature configuration	If an intermediate device is used, make sure the following requirements are met: • Run the spanning tree feature between the IRF fabric and the intermediate device to ensure that there is only one ND MAD link in forwarding state. For more information about the spanning tree feature and its configuration, see *Layer 2—LAN Switching Configuration Guide*. • Enable the IRF fabric to change its bridge MAC address as soon as the address owner leaves. • If the intermediate device is also an IRF fabric, assign the two IRF fabrics different domain IDs for correct split detection.

When you configure ND MAD on a management Ethernet port, follow these restrictions and guidelines:

Category	Restrictions and guidelines
Management Ethernet ports for ND MAD	Connect a management Ethernet port on each member device to the common Ethernet ports on the intermediate device.
ND MAD VLAN	On the intermediate device, create a VLAN for ND MAD, and assign the ports

Category	Restrictions and guidelines
	used for ND MAD to the VLAN. On the IRF fabric, you do not need to assign the management Ethernet ports to the VLAN.
ND MAD and feature configuration	• Enable the IRF fabric to change its bridge MAC address as soon as the address owner leaves. • If the intermediate device is also an IRF fabric, assign the two IRF fabrics different domain IDs for correct split detection.

Configuring ND MAD on a VLAN interface

1. Enter system view.
   system-view
2. Assign a domain ID to the IRF fabric.
   irf domain *domain-id*
   The default IRF domain ID is 0.

CAUTION:
Changing the IRF domain ID of an IRF member device will remove that member device from the IRF fabric. This member device will be unable to exchange IRF protocol packets with the remaining member devices in the IRF fabric.

3. Configure the IRF bridge MAC address to change as soon as the address owner leaves.
   undo irf mac-address persistent
   By default, the IRF bridge MAC address does not change after the address owner leaves.

CAUTION:
IRF bridge MAC address change will cause transient traffic disruption.

4. Create a VLAN dedicated to ND MAD.
   vlan *vlan-id*
   By default, only VLAN 1 exists.
   Do not configure ND MAD on VLAN-interface 1.
   Perform this task also on the intermediate device (if any).
5. Return to system view.
   quit
6. Enter Ethernet interface view or interface range view.
   - Enter Ethernet interface view.
     interface *interface-type interface-number*
   - Enter interface range view. Choose one of the following commands:
     interface range { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>
     interface range name *name* [**interface** { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>]

   To assign a range of ports to the ND MAD VLAN, enter interface range view.
   To assign one port to the ND MAD VLAN, enter Ethernet interface view.
7. Assign the port or the range of ports to the ND MAD VLAN.
   - Assign the ports to the VLAN as access ports.
     port access vlan *vlan-id*

- Assign the ports to the VLAN as trunk ports.
  port trunk permit vlan *vlan-id*
- Assign the ports to the VLAN as hybrid ports.
  port hybrid vlan *vlan-id* { **tagged** | **untagged** }

The link type of ND MAD ports can be access, trunk, or hybrid.

The default link type of a port is access.

Perform this task also on the intermediate device (if any).

8. Return to system view.
   quit
9. Enter VLAN interface view.
   interface vlan-interface *interface-number*
10. Assign the interface an IPv6 address.
    ipv6 address { *ipv6-address/prefix-length* | *ipv6-address prefix-length* }

    By default, no IPv6 addresses are assigned to a VLAN interface.
11. Enable ND MAD.
    mad nd enable

    By default, ND MAD is disabled.

Configuring ND MAD on a management Ethernet port

1. Enter system view.
   system-view
2. Assign a domain ID to the IRF fabric.
   irf domain *domain-id*

   The default IRF domain ID is 0.

CAUTION:
Changing the IRF domain ID of an IRF member device will remove that member device from the IRF fabric. This member device will be unable to exchange IRF protocol packets with the remaining member devices in the IRF fabric.

3. Configure the IRF bridge MAC address to change as soon as the address owner leaves.
   undo irf mac-address persistent

   By default, the IRF bridge MAC address does not change after the address owner leaves.

CAUTION:
IRF bridge MAC address change will cause transient traffic disruption.

4. Enter management Ethernet interface view.
   interface m-gigabitethernet *interface-number*

   Of all management Ethernet ports on an IRF fabric, only the master's management Ethernet port is accessible.
5. Assign an IPv6 address to the management Ethernet port.
   ipv6 address { *ipv6-address/pre-length* | *ipv6 address pre-length* }

   By default, no IPv6 addresses are assigned to a management Ethernet port.
6. Enable ND MAD.
   mad nd enable

By default, ND MAD is disabled.

Excluding interfaces from the shutdown action upon detection of multi-active collision

About this task

When an IRF fabric transits to the Recovery state, the system automatically excludes the following network interfaces from being shut down:

- IRF physical interfaces.
- Interfaces used for BFD MAD.
- Member interfaces of an aggregate interface if the aggregate interface is excluded from being shut down.

You can exclude an interface from the shutdown action for management or other special purposes. For example:

- Exclude a port from the shutdown action so you can Telnet to the port for managing the device.
- Exclude a VLAN interface and its Layer 2 ports from the shutdown action so you can log in through the VLAN interface.

Restrictions and guidelines

When you exclude a logical interface from the shutdown action, you must also exclude its associated physical interfaces. If you fail to do so, the logical interface will be unable to forward packets when the device is placed in Recovery state and the associated physical interfaces are shut down. For example, if a VLAN interface is used for remote login, you must exclude the VLAN interface and its associated physical interfaces from the shutdown action.

Procedure

1. Enter system view.

   system-view

2. Configure an interface to not shut down when the IRF fabric transits to the Recovery state.

   mad exclude interface *interface-type interface-number*

   By default, all network interfaces on a Recovery-state IRF fabric are shut down, except for the network interfaces automatically excluded by the system.

Recovering an IRF fabric

About this task

If the active IRF fabric fails before the IRF link is recovered, perform this task on the inactive IRF fabric to recover the inactive IRF fabric for traffic forwarding. The manual recovery operation brings up all interfaces that were shut down by MAD on the inactive IRF fabric.

Procedure

1. Enter system view.

   system-view

2. Recover the inactive IRF fabric.

   mad restore

Optimizing IRF settings for an IRF fabric

Enabling IRF auto-merge

About this task

When two IRF fabrics merge, you must reboot the member devices in the IRF fabric that fails in the master election. The auto-merge feature enables the IRF fabric to automatically reboot all its member devices to complete the merge.

If this feature is disabled, you must manually reboot the devices that failed the master election to complete the merge.

Procedure

1. Enter system view.
   `system-view`
2. Enable IRF auto-merge.
   `irf auto-merge enable`
   By default, this feature is enabled.

Configuring a member device description

1. Enter system view.
   `system-view`
2. Configure a description for a member device.
   `irf member` *`member-id`* **`description`** *`text`*
   By default, no member device description is configured.

Configuring IRF bridge MAC address settings

About this task

The bridge MAC address of a system must be unique on a switched LAN. IRF bridge MAC address identifies an IRF fabric by Layer 2 protocols (for example, LACP) on a switched LAN.

By default, an IRF fabric uses the bridge MAC address of the master as the IRF bridge MAC address. After the master leaves, the IRF bridge MAC address persists for a period of time or permanently depending on the IRF bridge MAC persistence setting. When the IRF bridge MAC persistence timer expires, the IRF fabric uses the bridge MAC address of the current master as the IRF bridge MAC address.

In special occasions that require a fixed special IRF bridge MAC address, you can specify that MAC address as the IRF bridge MAC address. For example, when you replace an IRF fabric as a whole, you can configure the new IRF fabric with the IRF bridge MAC address of the existing IRF fabric before the replacement to minimize service interruption.

The IRF bridge MAC persistence setting does not take effect on the manually specified IRF bridge MAC address.

If IRF fabric merge occurs, IRF determines the IRF bridge MAC address of the merged IRF fabric as follows:

1. When IRF fabrics merge, IRF ignores the IRF bridge MAC addresses and checks the bridge MAC address of each member device in the IRF fabrics. IRF merge fails if any two member devices have the same bridge MAC address.

2. After IRF fabrics merge, the merged IRF fabric uses the bridge MAC address of the merging IRF fabric that won the master election as the IRF bridge MAC address.

Restrictions and guidelines for IRF bridge MAC address configuration

CAUTION:
Bridge MAC address change will cause transient traffic disruption.

When you configure IRF bridge MAC persistence, follow these restrictions and guidelines:

- If ARP MAD or ND MAD is used with the spanning tree feature, you must disable IRF bridge MAC persistence by using the **`undo irf mac-address persistent`** command. In addition, do not specify a MAC address as the IRF bridge MAC address.
- If the IRF fabric has multichassis aggregate links, do not use the **`undo irf mac-address persistent`** command. Use of this command might cause traffic disruption.

Configuring IRF bridge MAC persistence

1. Enter system view.
   `system-view`
2. Configure IRF bridge MAC persistence.
   - Retain the bridge MAC address permanently even if the address owner has left the fabric.
     `irf mac-address persistent always`
   - Retain the bridge MAC address for 6 minutes after the address owner leaves the fabric.
     `irf mac-address persistent timer`
   - Change the bridge MAC address as soon as the address owner leaves the fabric.
     `undo irf mac-address persistent`

   By default, the IRF bridge MAC address does not change after the address owner leaves.

   The **`irf mac-address persistent timer`** command avoids unnecessary bridge MAC address changes caused by device reboot, transient link failure, or purposeful link disconnection.

Specifying a MAC address as the IRF bridge MAC address

1. Enter system view.
   `system-view`
2. Specify a MAC address as the IRF bridge MAC address.
   `irf mac-address` *`mac-address`*

   By default, an IRF fabric uses the bridge MAC address of the master as the IRF bridge MAC address.

CAUTION:
IRF bridge MAC address change will cause transient traffic disruption.

If an IRF fabric splits after you configure the IRF bridge MAC address, both the split IRF fabrics use the configured bridge MAC address as the IRF bridge MAC address.

Enabling software auto-update for software image synchronization

About this task

The software auto-update feature automatically synchronizes the current software images of the master to devices that are attempting to join the IRF fabric.

To join an IRF fabric, a device must use the same software images as the master in the fabric.

When you add a device to the IRF fabric, software auto-update compares the startup software images of the device with the current software images of the IRF master. If the two sets of images are different, the device automatically performs the following operations:

1. Downloads the current software images of the master.
2. Sets the downloaded images as its main startup software images.
3. Reboots with the new software images to rejoin the IRF fabric.

You must manually update the new device with the software images running on the IRF fabric if software auto-update is disabled.

Restrictions and guidelines

To ensure a successful software auto-update in a multi-user environment, prevent anyone from rebooting member devices during the auto-update process. To inform administrators of the auto-update status, configure the information center to output the status messages to configuration terminals (see *Network Management and Monitoring Configuration Guide*).

Make sure the device you are adding to the IRF fabric has sufficient storage space for the new software images.

If sufficient storage space is not available, the device automatically deletes the current software images. If the reclaimed space is still insufficient, the device cannot complete the auto-update. You must reboot the device, and then access the Boot menu to delete files.

Procedure

1. Enter system view.

   `system-view`
2. Enable software auto-update.

   `irf auto-update enable`

   By default, software auto-update is enabled.

Setting the IRF link down report delay

About this task

To prevent frequent IRF splits and merges during link flapping, configure the IRF ports to delay reporting link down events.

An IRF port does not report a link down event to the IRF fabric immediately after its link changes from up to down. If the IRF link state is still down when the delay is reached, the port reports the change to the IRF fabric.

IRF ports do not delay link up events. They report the link up event immediately after the IRF link comes up.

Restrictions and guidelines

Make sure the IRF link down report delay is shorter than the heartbeat or hello timeout settings of upper-layer protocols (for example, OSPF). If the report delay is longer than the timeout setting of a protocol, unnecessary recalculations might occur.

Set the delay to 0 seconds in the following situations:

- The IRF fabric requires a fast master/subordinate or IRF link switchover.
- The RRPP, BFD, or GR feature is used.
- You want to shut down an IRF physical interface or reboot an IRF member device. (After you complete the operation, reconfigure the delay depending on the network condition.)

Procedure

1. Enter system view.
   system-view
2. Set the IRF link down report delay.
   irf link-delay *interval*
   The default IRF link down report delay is 4000 milliseconds (4 seconds).

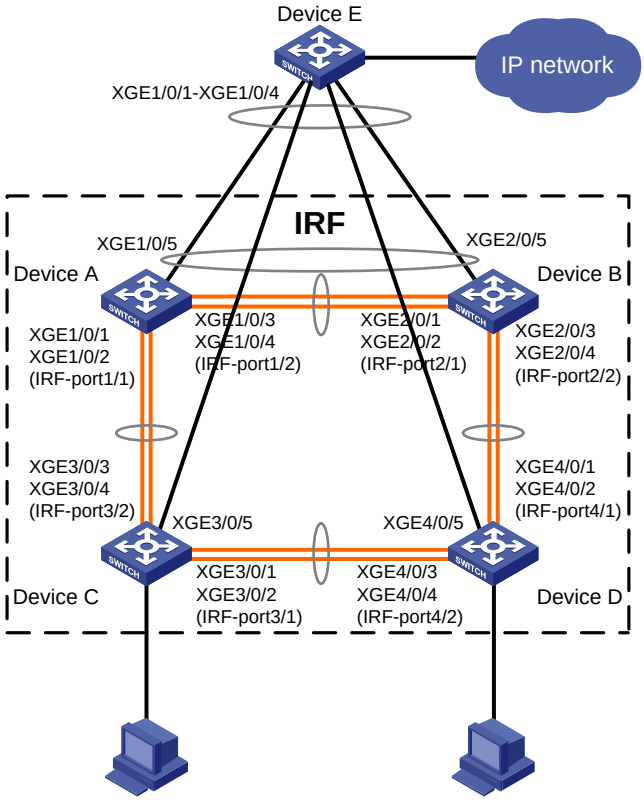
Display and maintenance commands for IRF

Execute **display** commands in any view.

Task	Command
Display information about all IRF members.	**display irf**
Display the IRF fabric topology.	**display irf topology**
Display IRF link information.	**display irf link**
Display IRF configuration.	**display irf configuration**
Display MAD configuration.	**display mad** [**verbose**]

IRF configuration examples

The IRF configuration examples show how to set up IRF fabrics that use different MAD mechanisms.



Example: Configuring an IRF fabric with LACP MAD enabled on an aggregate interface

Network configuration

As shown in Figure 14, set up a four-chassis IRF fabric at the access layer of the enterprise network.

Configure LACP MAD on the multichassis aggregation to Device E, which supports extended LACP.

Figure 14 Network diagram

Procedure

1. Configure settings for IRF setup on Device A:

   # Shut down the physical interfaces used for IRF links. In this example, the physical interfaces are shut down in batch. For more information, see *Layer 2—LAN Switching Configuration Guide*.

   ```
   <Sysname> system-view
   [Sysname] interface range ten-gigabitethernet 1/0/1 to ten-gigabitethernet 1/0/4
   [Sysname-if-range] shutdown
   [Sysname-if-range] quit
   ```

   # Bind Ten-GigabitEthernet 1/0/1 and Ten-GigabitEthernet 1/0/2 to IRF-port 1/1.

   ```
   [Sysname] irf-port 1/1
   [Sysname-irf-port1/1] port group interface ten-gigabitethernet 1/0/1
   [Sysname-irf-port1/1] port group interface ten-gigabitethernet 1/0/2
   [Sysname-irf-port1/1] quit
   ```

   # Bind Ten-GigabitEthernet 1/0/3 and Ten-GigabitEthernet 1/0/4 to IRF-port 1/2.

   ```
   [Sysname] irf-port 1/2
   [Sysname-irf-port1/2] port group interface ten-gigabitethernet 1/0/3
   [Sysname-irf-port1/2] port group interface ten-gigabitethernet 1/0/4
   [Sysname-irf-port1/2] quit
   ```

   # Bring up the physical interfaces and save the configuration.

   ```
   [Sysname] interface range ten-gigabitethernet 1/0/1 to ten-gigabitethernet 1/0/4
   [Sysname-if-range] undo shutdown
   [Sysname-if-range] quit
   [Sysname] save
   ```

Activate the IRF port configuration.

```
[Sysname] irf-port-configuration active
```

2. Configure settings for IRF setup on Device B:

Change the member ID of Device B to 2 and reboot the device to have the change take effect.

```
<Sysname> system-view
[Sysname] irf member 1 renumber 2
Renumbering the member ID may result in configuration change or loss. Continue? [Y/N]:y
[Sysname] quit
<Sysname> reboot
```

Connect Device B to Device A as shown in Figure 14, and log in to Device B. (Details not shown.)

Shut down the physical interfaces for IRF links.

```
<Sysname> system-view
[Sysname] interface range ten-gigabitethernet 2/0/1 to ten-gigabitethernet 2/0/4
[Sysname-if-range] shutdown
[Sysname-if-range] quit
```

Bind Ten-GigabitEthernet 2/0/1 and Ten-GigabitEthernet 2/0/2 to IRF-port 2/1.

```
[Sysname] irf-port 2/1
[Sysname-irf-port2/1] port group interface ten-gigabitethernet 2/0/1
[Sysname-irf-port2/1] port group interface ten-gigabitethernet 2/0/2
[Sysname-irf-port2/1] quit
```

Bind Ten-GigabitEthernet 2/0/3 and Ten-GigabitEthernet 2/0/4 to IRF-port 2/2.

```
[Sysname] irf-port 2/2
[Sysname-irf-port2/2] port group interface ten-gigabitethernet 2/0/3
[Sysname-irf-port2/2] port group interface ten-gigabitethernet 2/0/4
[Sysname-irf-port2/2] quit
```

Bring up the physical interfaces and save the configuration.

```
[Sysname] interface range ten-gigabitethernet 2/0/1 to ten-gigabitethernet 2/0/4
[Sysname-if-range] undo shutdown
[Sysname-if-range] quit
[Sysname] save
```

Activate the IRF port configuration.

```
[Sysname] irf-port-configuration active
```

The two devices perform master election, and the one that has lost the election reboots to form an IRF fabric with the master.

3. Configure settings for IRF setup on Device C:

Change the member ID of Device C to 3 and reboot the device to have the change take effect.

```
<Sysname> system-view
[Sysname] irf member 1 renumber 3
Renumbering the member ID may result in configuration change or loss. Continue? [Y/N]:y
[Sysname] quit
<Sysname> reboot
```

Connect Device C to Device A as shown in Figure 14, and log in to Device C. (Details not shown.)

Shut down the physical interfaces for IRF links.

```
<Sysname> system-view
[Sysname] interface range ten-gigabitethernet 3/0/1 to ten-gigabitethernet 3/0/4
[Sysname-if-range] shutdown
```

```
[Sysname-if-range] quit
```

Bind Ten-GigabitEthernet 3/0/1 and Ten-GigabitEthernet 3/0/2 to IRF-port 3/1.

```
[Sysname] irf-port 3/1
[Sysname-irf-port3/1] port group interface ten-gigabitethernet 3/0/1
[Sysname-irf-port3/1] port group interface ten-gigabitethernet 3/0/2
[Sysname-irf-port3/1] quit
```

Bind Ten-GigabitEthernet 3/0/3 and Ten-GigabitEthernet 3/0/4 to IRF-port 3/2.

```
[Sysname] irf-port 3/2
[Sysname-irf-port3/2] port group interface ten-gigabitethernet 3/0/3
[Sysname-irf-port3/2] port group interface ten-gigabitethernet 3/0/4
[Sysname-irf-port3/2] quit
```

Bring up the physical interfaces and save the configuration.

```
[Sysname] interface range ten-gigabitethernet 3/0/1 to ten-gigabitethernet 3/0/4
[Sysname-if-range] undo shutdown
[Sysname-if-range] quit
[Sysname] save
```

Activate the IRF port configuration.

```
[Sysname] irf-port-configuration active
```

Device C reboots to join the IRF fabric.

4. Configure settings for IRF setup on Device D:

Change the member ID of Device D to 4 and reboot the device to have the change take effect.

```
<Sysname> system-view
[Sysname] irf member 1 renumber 4
Renumbering the member ID may result in configuration change or loss. Continue? [Y/N]:y
[Sysname] quit
<Sysname> reboot
```

Connect Device D to Device B and Device C as shown in Figure 14, and log in to Device D. (Details not shown.)

Shut down the physical interfaces.

```
<Sysname> system-view
[Sysname] interface range ten-gigabitethernet 4/0/1 to ten-gigabitethernet 4/0/4
[Sysname-if-range] shutdown
[Sysname-if-range] quit
```

Bind Ten-GigabitEthernet 4/0/1 and Ten-GigabitEthernet 4/0/2 to IRF-port 4/1.

```
[Sysname] irf-port 4/1
[Sysname-irf-port4/1] port group interface ten-gigabitethernet 4/0/1
[Sysname-irf-port4/1] port group interface ten-gigabitethernet 4/0/2
[Sysname-irf-port4/1] quit
```

Bind Ten-GigabitEthernet 4/0/3 and Ten-GigabitEthernet 4/0/4 to IRF-port 4/2.

```
[Sysname] irf-port 4/2
[Sysname-irf-port4/2] port group interface ten-gigabitethernet 4/0/3
[Sysname-irf-port4/2] port group interface ten-gigabitethernet 4/0/4
[Sysname-irf-port4/2] quit
```

Bring up the physical interfaces and save the configuration.

```
[Sysname] interface range ten-gigabitethernet 4/0/1 to ten-gigabitethernet 4/0/4
[Sysname-if-range] undo shutdown
[Sysname-if-range] quit
```

```
[Sysname] save
```

Activate the IRF port configuration.

```
[Sysname] irf-port-configuration active
```

Device D reboots to join the IRF fabric. A four-chassis IRF fabric is formed.

5. Configure LACP MAD on the IRF fabric:

Set the domain ID of the IRF fabric to 1.

```
<Sysname> system-view
[Sysname] irf domain 1
```

Create a dynamic aggregate interface and enable LACP MAD.

```
[Sysname] interface bridge-aggregation 2
[Sysname-Bridge-Aggregation2] link-aggregation mode dynamic
[Sysname-Bridge-Aggregation2] mad enable
You need to assign a domain ID (range: 0-4294967295)
[Current domain ID is: 1]:
The assigned domain ID is: 1
[Sysname-Bridge-Aggregation2] quit
```

Assign Ten-GigabitEthernet 1/0/5, Ten-GigabitEthernet 2/0/5, Ten-GigabitEthernet 3/0/5, and Ten-GigabitEthernet 4/0/5 to the aggregate interface.

```
[Sysname] interface range ten-gigabitethernet 1/0/5 ten-gigabitethernet 2/0/5
ten-gigabitethernet 3/0/5 ten-gigabitethernet 4/0/5
[Sysname-if-range] port link-aggregation group 2
[Sysname-if-range] quit
```

6. Configure Device E as the intermediate device for LACP MAD:

CAUTION:

If the intermediate device is also an IRF fabric, assign the two IRF fabrics different domain IDs for correct split detection. False detection causes IRF split.

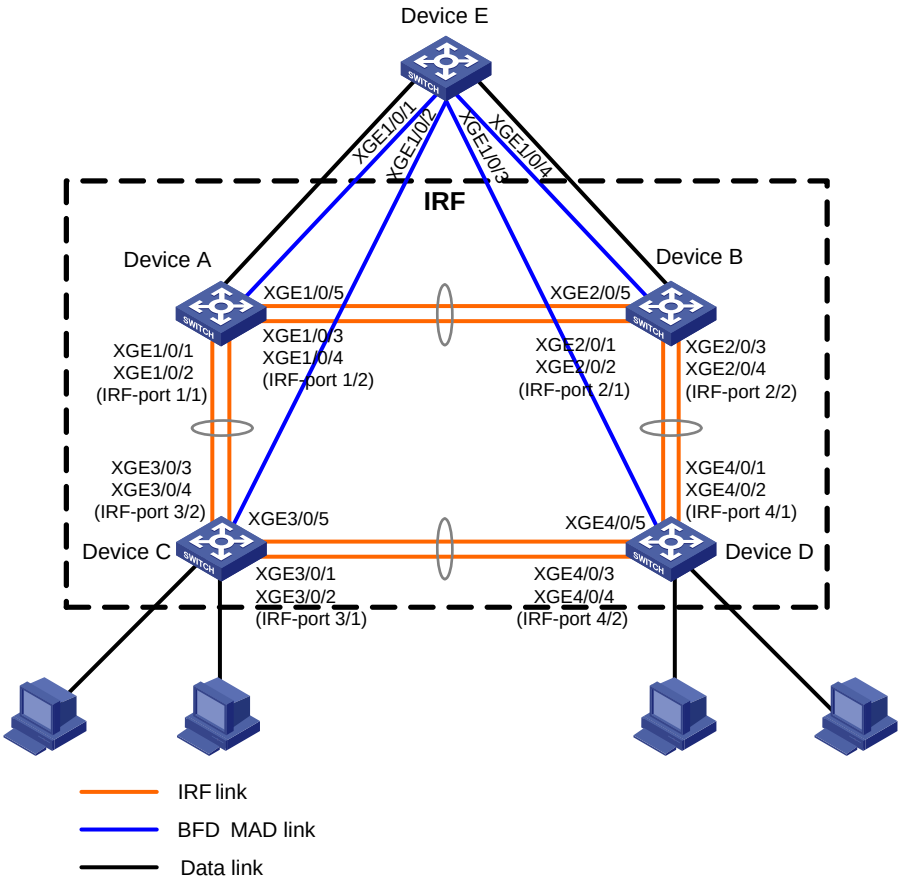
Create a dynamic aggregate interface.

```
<Sysname> system-view
[Sysname] interface bridge-aggregation 2
[Sysname-Bridge-Aggregation2] link-aggregation mode dynamic
[Sysname-Bridge-Aggregation2] quit
```

Assign Ten-GigabitEthernet 1/0/1, Ten-GigabitEthernet 1/0/2, Ten-GigabitEthernet 1/0/3, and Ten-GigabitEthernet 1/0/4 to the aggregate interface.

```
[Sysname] interface range ten-gigabitethernet 1/0/1 to ten-gigabitethernet 1/0/4
[Sysname-if-range] port link-aggregation group 2
[Sysname-if-range] quit
```

Example: Configuring an IRF fabric with BFD MAD enabled on a VLAN interface



Network configuration

As shown in Figure 15, set up a four-chassis IRF fabric at the distribution layer of the enterprise network.

- Configure BFD MAD on the IRF fabric and set up BFD MAD links between each member device and the intermediate device.

- Disable the spanning tree feature on the ports used for BFD MAD, because the two features conflict with each other.

Figure 15 Network diagram

Procedure

1. Configure settings for IRF setup on Device A:

   # Shut down the physical interfaces used for IRF links.

   ```
   <Sysname> system-view
   [Sysname] interface range ten-gigabitethernet 1/0/1 to ten-gigabitethernet 1/0/4
   [Sysname-if-range] shutdown
   [Sysname-if-range] quit
   ```

   # Bind Ten-GigabitEthernet 1/0/1 and Ten-GigabitEthernet 1/0/2 to IRF-port 1/1.

   ```
   [Sysname] irf-port 1/1
   [Sysname-irf-port1/1] port group interface ten-gigabitethernet 1/0/1
   [Sysname-irf-port1/1] port group interface ten-gigabitethernet 1/0/2
   [Sysname-irf-port1/1] quit
   ```

   # Bind Ten-GigabitEthernet 1/0/3 and Ten-GigabitEthernet 1/0/4 to IRF-port 1/2.

   ```
   [Sysname] irf-port 1/2
   [Sysname-irf-port1/2] port group interface ten-gigabitethernet 1/0/3
   [Sysname-irf-port1/2] port group interface ten-gigabitethernet 1/0/4
   [Sysname-irf-port1/2] quit
   ```

   # Bring up the physical interfaces and save the configuration.

   ```
   [Sysname] interface range ten-gigabitethernet 1/0/1 to ten-gigabitethernet 1/0/4
   ```

```
[Sysname-if-range] undo shutdown
[Sysname-if-range] quit
[Sysname] save
```

Activate the IRF port configuration.

```
[Sysname] irf-port-configuration active
```

2. Configure settings for IRF setup on Device B:

Change the member ID of Device B to 2 and reboot the device to have the change take effect.

```
<Sysname> system-view
[Sysname] irf member 1 renumber 2
Renumbering the member ID may result in configuration change or loss. Continue? [Y/N]:y
[Sysname] quit
<Sysname> reboot
```

Connect Device B to Device A as shown in Figure 15, and log in to Device B. (Details not shown.)

Shut down the physical interfaces used for IRF links.

```
<Sysname> system-view
[Sysname] interface range ten-gigabitethernet 2/0/1 to ten-gigabitethernet 2/0/4
[Sysname-if-range] shutdown
[Sysname-if-range] quit
```

Bind Ten-GigabitEthernet 2/0/1 and Ten-GigabitEthernet 2/0/2 to IRF-port 2/1.

```
[Sysname] irf-port 2/1
[Sysname-irf-port2/1] port group interface ten-gigabitethernet 2/0/1
[Sysname-irf-port2/1] port group interface ten-gigabitethernet 2/0/2
[Sysname-irf-port2/1] quit
```

Bind Ten-GigabitEthernet 2/0/3 and Ten-GigabitEthernet 2/0/4 to IRF-port 2/2.

```
[Sysname] irf-port 2/2
[Sysname-irf-port2/2] port group interface ten-gigabitethernet 2/0/3
[Sysname-irf-port2/2] port group interface ten-gigabitethernet 2/0/4
[Sysname-irf-port2/2] quit
```

Bring up the physical interfaces and save the configuration.

```
[Sysname] interface range ten-gigabitethernet 2/0/1 to ten-gigabitethernet 2/0/4
[Sysname-if-range] undo shutdown
[Sysname-if-range] quit
[Sysname] save
```

Activate the IRF port configuration.

```
[Sysname] irf-port-configuration active
```

The two devices perform master election, and the one that has lost the election reboots to form an IRF fabric with the master.

3. Configure settings for IRF setup on Device C:

Change the member ID of Device C to 3 and reboot the device to have the change take effect.

```
<Sysname> system-view
[Sysname] irf member 1 renumber 3
Renumbering the member ID may result in configuration change or loss. Continue? [Y/N]:y
[Sysname] quit
<Sysname> reboot
```

Connect Device C to Device A as shown in Figure 15, and log in to Device C. (Details not shown.)

Shut down the physical interfaces used for IRF links.

```
<Sysname> system-view
[Sysname] interface range ten-gigabitethernet 3/0/1 to ten-gigabitethernet 3/0/4
[Sysname-if-range] shutdown
[Sysname-if-range] quit
```

Bind Ten-GigabitEthernet 3/0/1 and Ten-GigabitEthernet 3/0/2 to IRF-port 3/1.

```
[Sysname] irf-port 3/1
[Sysname-irf-port3/1] port group interface ten-gigabitethernet 3/0/1
[Sysname-irf-port3/1] port group interface ten-gigabitethernet 3/0/2
[Sysname-irf-port3/1] quit
```

Bind Ten-GigabitEthernet 3/0/3 and Ten-GigabitEthernet 3/0/4 to IRF-port 3/2.

```
[Sysname] irf-port 3/2
[Sysname-irf-port3/2] port group interface ten-gigabitethernet 3/0/3
[Sysname-irf-port3/2] port group interface ten-gigabitethernet 3/0/4
[Sysname-irf-port3/2] quit
```

Bring up the physical interfaces and save the configuration.

```
[Sysname] interface range ten-gigabitethernet 3/0/1 to ten-gigabitethernet 3/0/4
[Sysname-if-range] undo shutdown
[Sysname-if-range] quit
[Sysname] save
```

Activate the IRF port configuration.

```
[Sysname] irf-port-configuration active
```

Device C reboots to join the IRF fabric.

4. Configure settings for IRF setup on Device D:

Change the member ID of Device D to 4 and reboot the device to have the change take effect.

```
<Sysname> system-view
[Sysname] irf member 1 renumber 4
Renumbering the member ID may result in configuration change or loss. Continue? [Y/N]:y
[Sysname] quit
<Sysname> reboot
```

Connect Device D to Device B and Device C as shown in Figure 15, and log in to Device D. (Details not shown.)

Shut down the physical interfaces used for IRF links.

```
<Sysname> system-view
[Sysname] interface range ten-gigabitethernet 4/0/1 to ten-gigabitethernet 4/0/4
[Sysname-if-range] shutdown
[Sysname-if-range] quit
```

Bind Ten-GigabitEthernet 4/0/1 and Ten-GigabitEthernet 4/0/2 to IRF-port 4/1.

```
[Sysname] irf-port 4/1
[Sysname-irf-port4/1] port group interface ten-gigabitethernet 4/0/1
[Sysname-irf-port4/1] port group interface ten-gigabitethernet 4/0/2
[Sysname-irf-port4/1] quit
```

Bind Ten-GigabitEthernet 4/0/3 and Ten-GigabitEthernet 4/0/4 to IRF-port 4/2.

```
[Sysname] irf-port 4/2
[Sysname-irf-port4/2] port group interface ten-gigabitethernet 4/0/3
[Sysname-irf-port4/2] port group interface ten-gigabitethernet 4/0/4
[Sysname-irf-port4/2] quit
```

Bring up the physical interfaces and save the configuration.

```
[Sysname] interface range ten-gigabitethernet 4/0/1 to ten-gigabitethernet 4/0/4
[Sysname-if-range] undo shutdown
[Sysname-if-range] quit
[Sysname] save
```

Activate the IRF port configuration.

```
[Sysname] irf-port-configuration active
```

Device D reboots to join the IRF fabric. A four-chassis IRF fabric is formed.

5. Configure BFD MAD on the IRF fabric:

Create VLAN 3, and add Ten-GigabitEthernet 1/0/5, Ten-GigabitEthernet 2/0/5, Ten-GigabitEthernet 3/0/5, and Ten-GigabitEthernet 4/0/5 to VLAN 3.

```
[Sysname] vlan 3
[Sysname-vlan3] port ten-gigabitethernet 1/0/5 ten-gigabitethernet 2/0/5
ten-gigabitethernet 3/0/5 ten-gigabitethernet 4/0/5
[Sysname-vlan3] quit
```

Create VLAN-interface 3, and configure a MAD IP address for each member device on the VLAN interface.

```
[Sysname] interface vlan-interface 3
[Sysname-Vlan-interface3] mad bfd enable
[Sysname-Vlan-interface3] mad ip address 192.168.2.1 24 member 1
[Sysname-Vlan-interface3] mad ip address 192.168.2.2 24 member 2
[Sysname-Vlan-interface3] mad ip address 192.168.2.3 24 member 3
[Sysname-Vlan-interface3] mad ip address 192.168.2.4 24 member 4
[Sysname-Vlan-interface3] quit
```

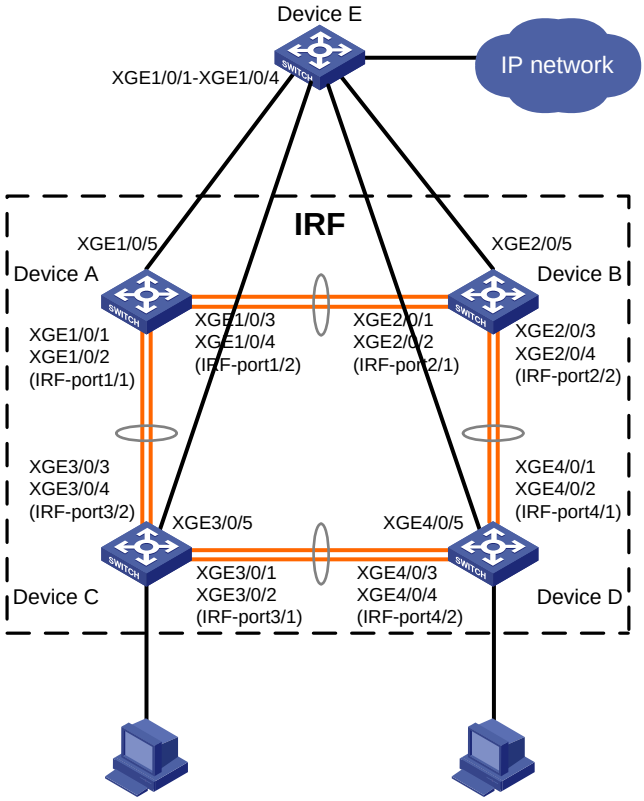
Disable the spanning tree feature on Ten-GigabitEthernet 1/0/5, Ten-GigabitEthernet 2/0/5, Ten-GigabitEthernet 3/0/5, and Ten-GigabitEthernet 4/0/5.

```
[Sysname] interface range ten-gigabitethernet 1/0/5 ten-gigabitethernet 2/0/5
ten-gigabitethernet 3/0/5 ten-gigabitethernet 4/0/5
[Sysname-if-range] undo stp enable
[Sysname-if-range] quit
```

6. Configure Device E as the intermediate device for BFD MAD:

Create VLAN 3, and assign Ten-GigabitEthernet 1/0/1, Ten-GigabitEthernet 1/0/2, Ten-GigabitEthernet 1/0/3, and Ten-GigabitEthernet 1/0/4 to VLAN 3 for forwarding BFD MAD packets.

```
<DeviceE> system-view
[DeviceE] vlan 3
[DeviceE-vlan3] port ten-gigabitethernet 1/0/1 to ten-gigabitethernet 1/0/4
[DeviceE-vlan3] quit
```



Example: Configuring an IRF fabric with ARP MAD enabled on a VLAN interface

Network configuration

As shown in Figure 16, set up a four-chassis IRF fabric in the enterprise network.

- Configure ARP MAD on the IRF fabric and use the links connected to Device E for transmitting ARP MAD packets.
- To prevent loops, run the spanning tree feature between Device E and the IRF fabric.

Figure 16 Network diagram

Procedure

1. Configure settings for IRF setup on Device A:

   # Shut down the physical interfaces used for IRF links.

   ```
   <Sysname> system-view
   [Sysname] interface range ten-gigabitethernet 1/0/1 to ten-gigabitethernet 1/0/4
   [Sysname-if-range] shutdown
   [Sysname-if-range] quit
   ```

   # Bind Ten-GigabitEthernet 1/0/1 and Ten-GigabitEthernet 1/0/2 to IRF-port 1/1.

   ```
   [Sysname] irf-port 1/1
   [Sysname-irf-port1/1] port group interface ten-gigabitethernet 1/0/1
   [Sysname-irf-port1/1] port group interface ten-gigabitethernet 1/0/2
   [Sysname-irf-port1/1] quit
   ```

   # Bind Ten-GigabitEthernet 1/0/3 and Ten-GigabitEthernet 1/0/4 to IRF-port 1/2.

   ```
   [Sysname] irf-port 1/2
   [Sysname-irf-port1/2] port group interface ten-gigabitethernet 1/0/3
   [Sysname-irf-port1/2] port group interface ten-gigabitethernet 1/0/4
   [Sysname-irf-port1/2] quit
   ```

   # Bring up the physical interfaces and save the configuration.

   ```
   [Sysname] interface range ten-gigabitethernet 1/0/1 to ten-gigabitethernet 1/0/4
   [Sysname-if-range] undo shutdown
   [Sysname-if-range] quit
   [Sysname] save
   ```

   # Activate the IRF port configuration.

   ```
   [Sysname] irf-port-configuration active
   ```

2. Configure settings for IRF setup on Device B:

   # Change the member ID of Device B to 2 and reboot the device to have the change take effect.

```
<Sysname> system-view
[Sysname] irf member 1 renumber 2
Renumbering the member ID may result in configuration change or loss. Continue? [Y/N]:y
[Sysname] quit
<Sysname> reboot
```

   # Connect Device B to Device A as shown in Figure 16, and log in to Device B. (Details not shown.)

   # Shut down the physical interfaces used for IRF links.

```
<Sysname> system-view
[Sysname] interface range ten-gigabitethernet 2/0/1 to ten-gigabitethernet 2/0/4
[Sysname-if-range] shutdown
[Sysname-if-range] quit
```

   # Bind Ten-GigabitEthernet 2/0/1 and Ten-GigabitEthernet 2/0/2 to IRF-port 2/1.

```
[Sysname] irf-port 2/1
[Sysname-irf-port2/1] port group interface ten-gigabitethernet 2/0/1
[Sysname-irf-port2/1] port group interface ten-gigabitethernet 2/0/2
[Sysname-irf-port2/1] quit
```

   # Bind Ten-GigabitEthernet 2/0/3 and Ten-GigabitEthernet 2/0/4 to IRF-port 2/2.

```
[Sysname] irf-port 2/2
[Sysname-irf-port2/2] port group interface ten-gigabitethernet 2/0/3
[Sysname-irf-port2/2] port group interface ten-gigabitethernet 2/0/4
[Sysname-irf-port2/2] quit
```

   # Bring up the physical interfaces and save the configuration.

```
[Sysname] interface range ten-gigabitethernet 2/0/1 to ten-gigabitethernet 2/0/4
[Sysname-if-range] undo shutdown
[Sysname-if-range] quit
[Sysname] save
```

   # Activate the IRF port configuration.

```
[Sysname] irf-port-configuration active
```

   The two devices perform master election, and the one that has lost the election reboots to form an IRF fabric with the master.

3. Configure settings for IRF setup on Device C:

   # Change the member ID of Device C to 3 and reboot the device to have the change take effect.

```
<Sysname> system-view
[Sysname] irf member 1 renumber 3
Renumbering the member ID may result in configuration change or loss. Continue? [Y/N]:y
[Sysname] quit
<Sysname> reboot
```

   # Connect Device C to Device A as shown in Figure 16, and log in to Device C. (Details not shown.)

   # Shut down the physical interfaces used for IRF links.

```
<Sysname> system-view
[Sysname] interface range ten-gigabitethernet 3/0/1 to ten-gigabitethernet 3/0/4
[Sysname-if-range] shutdown
[Sysname-if-range] quit
```

   # Bind Ten-GigabitEthernet 3/0/1 and Ten-GigabitEthernet 3/0/2 to IRF-port 3/1.

```
[Sysname] irf-port 3/1
[Sysname-irf-port3/1] port group interface ten-gigabitethernet 3/0/1
[Sysname-irf-port3/1] port group interface ten-gigabitethernet 3/0/2
[Sysname-irf-port3/1] quit
```

Bind Ten-GigabitEthernet 3/0/3 and Ten-GigabitEthernet 3/0/4 to IRF-port 3/2.

```
[Sysname] irf-port 3/2
[Sysname-irf-port3/2] port group interface ten-gigabitethernet 3/0/3
[Sysname-irf-port3/2] port group interface ten-gigabitethernet 3/0/4
[Sysname-irf-port3/2] quit
```

Bring up the physical interfaces and save the configuration.

```
[Sysname] interface range ten-gigabitethernet 3/0/1 to ten-gigabitethernet 3/0/4
[Sysname-if-range] undo shutdown
[Sysname-if-range] quit
[Sysname] save
```

Activate the IRF port configuration.

```
[Sysname] irf-port-configuration active
```

Device C reboots to join the IRF fabric.

4. Configure settings for IRF setup on Device D:

Change the member ID of Device D to 4 and reboot the device to have the change take effect.

```
<Sysname> system-view
[Sysname] irf member 1 renumber 4
Renumbering the member ID may result in configuration change or loss. Continue? [Y/N]:y
[Sysname] quit
<Sysname> reboot
```

Connect Device D to Device B and Device C as shown in Figure 16, and log in to Device D. (Details not shown.)

Shut down the physical interfaces used for IRF links.

```
<Sysname> system-view
[Sysname] interface range ten-gigabitethernet 4/0/1 to ten-gigabitethernet 4/0/4
[Sysname-if-range] shutdown
[Sysname-if-range] quit
```

Bind Ten-GigabitEthernet 4/0/1 and Ten-GigabitEthernet 4/0/2 to IRF-port 4/1.

```
[Sysname] irf-port 4/1
[Sysname-irf-port4/1] port group interface ten-gigabitethernet 4/0/1
[Sysname-irf-port4/1] port group interface ten-gigabitethernet 4/0/2
[Sysname-irf-port4/1] quit
```

Bind Ten-GigabitEthernet 4/0/3 and Ten-GigabitEthernet 4/0/4 to IRF-port 4/2.

```
[Sysname] irf-port 4/2
[Sysname-irf-port4/2] port group interface ten-gigabitethernet 4/0/3
[Sysname-irf-port4/2] port group interface ten-gigabitethernet 4/0/4
[Sysname-irf-port4/2] quit
```

Bring up the physical interfaces and save the configuration.

```
[Sysname] interface range ten-gigabitethernet 4/0/1 to ten-gigabitethernet 4/0/4
[Sysname-if-range] undo shutdown
[Sysname-if-range] quit
[Sysname] save
```

Activate the IRF port configuration.

```
[Sysname] irf-port-configuration active
```

Device D reboots to join the IRF fabric. A four-chassis IRF fabric is formed.

5. Configure ARP MAD on the IRF fabric:

Enable the spanning tree feature globally. Map the ARP MAD VLAN to MSTI 1 in the MST region.

```
<Sysname> system-view
[Sysname] stp global enable
[Sysname] stp region-configuration
[Sysname-mst-region] region-name arpmad
[Sysname-mst-region] instance 1 vlan 3
[Sysname-mst-region] active region-configuration
[Sysname-mst-region] quit
```

Configure the IRF fabric to change its bridge MAC address as soon as the address owner leaves.

```
[Sysname] undo irf mac-address persistent
```

Set the domain ID of the IRF fabric to 1.

```
[Sysname] irf domain 1
```

Create VLAN 3, and assign Ten-GigabitEthernet 1/0/5, Ten-GigabitEthernet 2/0/5, Ten-GigabitEthernet 3/0/5, and Ten-GigabitEthernet 4/0/5 to VLAN 3.

```
[Sysname] vlan 3
[Sysname-vlan3] port ten-gigabitethernet 1/0/5 ten-gigabitethernet 2/0/5
ten-gigabitethernet 3/0/5 ten-gigabitethernet 4/0/5
[Sysname-vlan3] quit
```

Create VLAN-interface 3, assign it an IP address, and enable ARP MAD on the interface.

```
[Sysname] interface vlan-interface 3
[Sysname-Vlan-interface3] ip address 192.168.2.1 24
[Sysname-Vlan-interface3] mad arp enable
You need to assign a domain ID (range: 0-4294967295)
[Current domain ID is: 1]:
The assigned domain ID is: 1
```

6. Configure Device E as the intermediate device for ARP MAD:

CAUTION:

If the intermediate device is also in an IRF fabric, assign the two IRF fabrics different domain IDs for correct split detection. False detection causes IRF split.

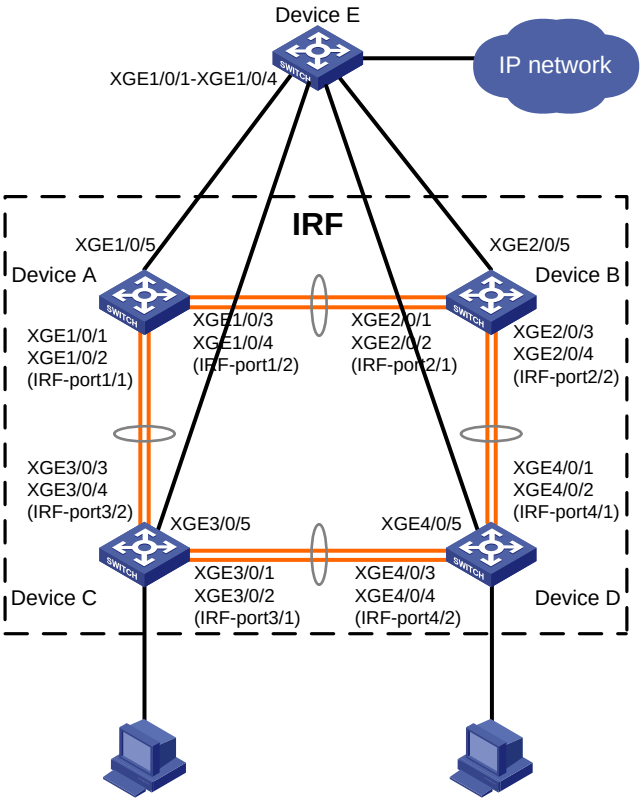
Enable the spanning tree feature globally. Map the ARP MAD VLAN to MSTI 1 in the MST region.

```
<DeviceE> system-view
[DeviceE] stp global enable
[DeviceE] stp region-configuration
[DeviceE-mst-region] region-name arpmad
[DeviceE-mst-region] instance 1 vlan 3
[DeviceE-mst-region] active region-configuration
[DeviceE-mst-region] quit
```

Create VLAN 3, and assign Ten-GigabitEthernet 1/0/1, Ten-GigabitEthernet 1/0/2, Ten-GigabitEthernet 1/0/3, and Ten-GigabitEthernet 1/0/4 to VLAN 3 for forwarding ARP MAD packets.

```
[DeviceE] vlan 3
```

```
[DeviceE-vlan3] port ten-gigabitethernet 1/0/1 to ten-gigabitethernet 1/0/4
[DeviceE-vlan3] quit
```



Example: Configuring an IRF fabric with ND MAD enabled on a VLAN interface

Network configuration

As shown in Figure 17, set up a four-chassis IRF fabric in the IPv6 enterprise network.

- Configure ND MAD on the IRF fabric and use the links connected to Device E for transmitting ND MAD packets.
- To prevent loops, run the spanning tree feature between Device E and the IRF fabric.

Figure 17 Network diagram

Procedure

1. Configure settings for IRF setup on Device A:

   # Shut down the physical interfaces used for IRF links.

   ```
   <Sysname> system-view
   [Sysname] interface range ten-gigabitethernet 1/0/1 to ten-gigabitethernet 1/0/4
   [Sysname-if-range] shutdown
   [Sysname-if-range] quit
   ```

   # Bind Ten-GigabitEthernet 1/0/1 and Ten-GigabitEthernet 1/0/2 to IRF-port 1/1.

   ```
   [Sysname] irf-port 1/1
   [Sysname-irf-port1/1] port group interface ten-gigabitethernet 1/0/1
   [Sysname-irf-port1/1] port group interface ten-gigabitethernet 1/0/2
   ```

```
[Sysname-irf-port1/1] quit
```

Bind Ten-GigabitEthernet 1/0/3 and Ten-GigabitEthernet 1/0/4 to IRF-port 1/2.

```
[Sysname] irf-port 1/2
[Sysname-irf-port1/2] port group interface ten-gigabitethernet 1/0/3
[Sysname-irf-port1/2] port group interface ten-gigabitethernet 1/0/4
[Sysname-irf-port1/2] quit
```

Bring up the physical interfaces and save the configuration.

```
[Sysname] interface range ten-gigabitethernet 1/0/1 to ten-gigabitethernet 1/0/4
[Sysname-if-range] undo shutdown
[Sysname-if-range] quit
[Sysname] save
```

Activate the IRF port configuration.

```
[Sysname] irf-port-configuration active
```

2. Configure settings for IRF setup on Device B:

Change the member ID of Device B to 2 and reboot the device to have the change take effect.

```
<Sysname> system-view
[Sysname] irf member 1 renumber 2
Renumbering the member ID may result in configuration change or loss. Continue? [Y/N]:y
[Sysname] quit
<Sysname> reboot
```

Connect Device B to Device A as shown in Figure 17, and log in to Device B. (Details not shown.)

Shut down the physical interfaces used for IRF links.

```
<Sysname> system-view
[Sysname] interface range ten-gigabitethernet 2/0/1 to ten-gigabitethernet 2/0/4
[Sysname-if-range] shutdown
[Sysname-if-range] quit
```

Bind Ten-GigabitEthernet 2/0/1 and Ten-GigabitEthernet 2/0/2 to IRF-port 2/1.

```
[Sysname] irf-port 2/1
[Sysname-irf-port2/1] port group interface ten-gigabitethernet 2/0/1
[Sysname-irf-port2/1] port group interface ten-gigabitethernet 2/0/2
[Sysname-irf-port2/1] quit
```

Bind Ten-GigabitEthernet 2/0/3 and Ten-GigabitEthernet 2/0/4 to IRF-port 2/2.

```
[Sysname] irf-port 2/2
[Sysname-irf-port2/2] port group interface ten-gigabitethernet 2/0/3
[Sysname-irf-port2/2] port group interface ten-gigabitethernet 2/0/4
[Sysname-irf-port2/2] quit
```

Bring up the physical interfaces and save the configuration.

```
[Sysname] interface range ten-gigabitethernet 2/0/1 to ten-gigabitethernet 2/0/4
[Sysname-if-range] undo shutdown
[Sysname-if-range] quit
[Sysname] save
```

Activate the IRF port configuration.

```
[Sysname] irf-port-configuration active
```

The two devices perform master election, and the one that has lost the election reboots to form an IRF fabric with the master.

3. Configure settings for IRF setup on Device C:

Change the member ID of Device C to 3 and reboot the device to have the change take effect.

```
<Sysname> system-view
[Sysname] irf member 1 renumber 3
Renumbering the member ID may result in configuration change or loss. Continue? [Y/N]:y
[Sysname] quit
<Sysname> reboot
```

Connect Device C to Device A as shown in Figure 17, and log in to Device C. (Details not shown.)

Shut down the physical interfaces used for IRF links.

```
<Sysname> system-view
[Sysname] interface range ten-gigabitethernet 3/0/1 to ten-gigabitethernet 3/0/4
[Sysname-if-range] shutdown
[Sysname-if-range] quit
```

Bind Ten-GigabitEthernet 3/0/1 and Ten-GigabitEthernet 3/0/2 to IRF-port 3/1.

```
[Sysname] irf-port 3/1
[Sysname-irf-port3/1] port group interface ten-gigabitethernet 3/0/1
[Sysname-irf-port3/1] port group interface ten-gigabitethernet 3/0/2
[Sysname-irf-port3/1] quit
```

Bind Ten-GigabitEthernet 3/0/3 and Ten-GigabitEthernet 3/0/4 to IRF-port 3/2.

```
[Sysname] irf-port 3/2
[Sysname-irf-port3/2] port group interface ten-gigabitethernet 3/0/3
[Sysname-irf-port3/2] port group interface ten-gigabitethernet 3/0/4
[Sysname-irf-port3/2] quit
```

Bring up the physical interfaces and save the configuration.

```
[Sysname] interface range ten-gigabitethernet 3/0/1 to ten-gigabitethernet 3/0/4
[Sysname-if-range] undo shutdown
[Sysname-if-range] quit
[Sysname] save
```

Activate the IRF port configuration.

```
[Sysname] irf-port-configuration active
```

Device C reboots to join the IRF fabric.

4. Configure settings for IRF setup on Device D:

Change the member ID of Device D to 4 and reboot the device to have the change take effect.

```
<Sysname> system-view
[Sysname] irf member 1 renumber 4
Renumbering the member ID may result in configuration change or loss. Continue? [Y/N]:y
[Sysname] quit
<Sysname> reboot
```

Connect Device D to Device B and Device C as shown in Figure 17, and log in to Device D. (Details not shown.)

Shut down the physical interfaces used for IRF links.

```
<Sysname> system-view
[Sysname] interface range ten-gigabitethernet 4/0/1 to ten-gigabitethernet 4/0/4
[Sysname-if-range] shutdown
[Sysname-if-range] quit
```

Bind Ten-GigabitEthernet 4/0/1 and Ten-GigabitEthernet 4/0/2 to IRF-port 4/1.

```
[Sysname] irf-port 4/1
[Sysname-irf-port4/1] port group interface ten-gigabitethernet 4/0/1
```

```
[Sysname-irf-port4/1] port group interface ten-gigabitethernet 4/0/2
[Sysname-irf-port4/1] quit
```

Bind Ten-GigabitEthernet 4/0/3 and Ten-GigabitEthernet 4/0/4 to IRF-port 4/2.

```
[Sysname] irf-port 4/2
[Sysname-irf-port4/2] port group interface ten-gigabitethernet 4/0/3
[Sysname-irf-port4/2] port group interface ten-gigabitethernet 4/0/4
[Sysname-irf-port4/2] quit
```

Bring up the physical interfaces and save the configuration.

```
[Sysname] interface range ten-gigabitethernet 4/0/1 to ten-gigabitethernet 4/0/4
[Sysname-if-range] undo shutdown
[Sysname-if-range] quit
[Sysname] save
```

Activate the IRF port configuration.

```
[Sysname] irf-port-configuration active
```

Device D reboots to join the IRF fabric. A four-chassis IRF fabric is formed.

5. Configure ND MAD on the IRF fabric:

Enable the spanning tree feature globally. Map the ND MAD VLAN to MSTI 1 in the MST region.

```
<Sysname> system-view
[Sysname] stp global enable
[Sysname] stp region-configuration
[Sysname-mst-region] region-name ndmad
[Sysname-mst-region] instance 1 vlan 3
[Sysname-mst-region] active region-configuration
[Sysname-mst-region] quit
```

Configure the IRF fabric to change its bridge MAC address as soon as the address owner leaves.

```
[Sysname] undo irf mac-address persistent
```

Set the domain ID of the IRF fabric to 1.

```
[Sysname] irf domain 1
```

Create VLAN 3, and add Ten-GigabitEthernet 1/0/5, Ten-GigabitEthernet 2/0/5, Ten-GigabitEthernet 3/0/5, and Ten-GigabitEthernet 4/0/5 to VLAN 3.

```
[Sysname] vlan 3
[Sysname-vlan3] port ten-gigabitethernet 1/0/5 ten-gigabitethernet 2/0/5
ten-gigabitethernet 3/0/5 ten-gigabitethernet 4/0/5
[Sysname-vlan3] quit
```

Create VLAN-interface 3, assign it an IPv6 address, and enable ND MAD on the interface.

```
[Sysname] interface vlan-interface 3
[Sysname-Vlan-interface3] ipv6 address 2001::1 64
[Sysname-Vlan-interface3] mad nd enable
You need to assign a domain ID (range: 0-4294967295)
[Current domain ID is: 1]:
The assigned domain ID is: 1
```

6. Configure Device E as the intermediate device for ND MAD:

CAUTION:

If the intermediate device is also in an IRF fabric, assign the two IRF fabrics different domain IDs for correct split detection. False detection causes IRF split.

Enable the spanning tree feature globally. Map the ND MAD VLAN to MSTI 1 in the MST region.

```
<DeviceE> system-view
[DeviceE] stp global enable
[DeviceE] stp region-configuration
[DeviceE-mst-region] region-name ndmad
[DeviceE-mst-region] instance 1 vlan 3
[DeviceE-mst-region] active region-configuration
[DeviceE-mst-region] quit
```

Create VLAN 3, and add Ten-GigabitEthernet 1/0/1, Ten-GigabitEthernet 1/0/2, Ten-GigabitEthernet 1/0/3, and Ten-GigabitEthernet 1/0/4 to VLAN 3 for forwarding ND MAD packets.

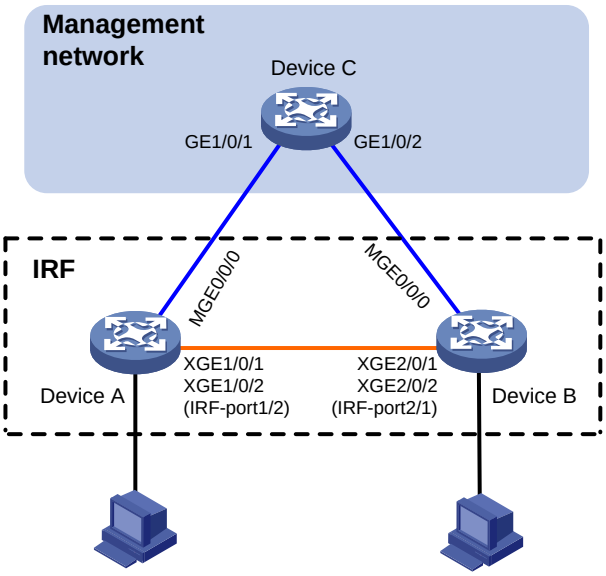
```
[DeviceE] vlan 3
[DeviceE-vlan3] port ten-gigabitethernet 1/0/1 to ten-gigabitethernet 1/0/4
[DeviceE-vlan3] quit
```

Example: Configuring an IRF fabric with ARP MAD and management IP configured on the same management Ethernet port

IMPORTANT:

This example is also applicable to a two-chassis IRF fabric running ND MAD, except that you must configure ND MAD rather than ARP MAD.

Network configuration



As shown in Figure 18, use Device A and Device B to set up a two-chassis IRF fabric.

Use management Ethernet port M-GigabitEthernet 0/0/0 to perform ARP MAD for IRF split detection and to provide device access for management purposes.

Configure management IP addresses for the IRF fabric and each member device on the management port to meet the following requirements:

- The administrator can use the same management IP address to access the IRF fabric before and after an active/subordinate switchover.
- The administrator can access each member device for failure recovery through their respective management IP addresses after the IRF fabric splits.

Figure 18 Network diagram

Restrictions and guidelines

When you configure management IP addresses, follow these restrictions and guidelines:

- To make sure you can access the IRF fabric at the same IP address after a master/subordinate switchover, use the **ip address** *ip-address* { *mask-length* | *mask* } command to configure a management IP address on the management port, in this example, on M-GigabitEthernet 0/0/0. You can use this address to access the IRF fabric as long as the fabric has not split. This address might be inaccesible for an IP conflict after the IRF fabric splits, because it exists on all member devices. In the context of IRF, this address is called a global management IP address.
- To access each member device for failure recovery after the IRF fabric splits, use the **ip address** *ip-address* { *mask-length* | *mask* } **irf-member** *member-id* command to configure a management IP address for each member device on the management port, in this example, on M-GigabitEthernet 0/0/0. In the context of IRF, this address is called a member-specific management IP address.
- Make sure the management IP addresses assigned to all IRF member devices on the same management Ethernet port belong to the same subnet. Make sure the management IP addresses assigned to an IRF member device on different management Ethernet ports belong to different subnets.
- You must manually make sure the management IP addresses configured on the subordinate devices will not cause IP address conflicts on the network. When the IRF fabric is running correctly, only the IP addresses of the management Ethernet ports on the master device take effect. The management IP addresses of the management Ethernet ports on the subordinate devices do not take effect. If a management IP address on a subordinate device conflicts with an IP address in the network, the system cannot detect the IP conflict, causing network issues after an IRF split.

NOTE:

When the IRF fabric is integrated, you can access the IRF fabric by using either the global management IP address or the management IP address specific to the master device. As a best practice to prevent the management IP address from changing upon a master/subordinate switchover, use the global management IP address as long as the IRF fabric is integrated.

When you configure ARP MAD on a management Ethernet port, follow the restrictions and guidelines in "Configuring ARP MAD."

Setting up the IRF fabric

1. Configure settings for IRF setup on Device A:

   # Shut down the physical interfaces used for IRF connection. This example uses Ten-GigabitEthernet 1/0/1 and Ten-GigabitEthernet 1/0/2 for IRF connection.

   ```
   <Sysname> system-view
   [Sysname] interface range ten-gigabitethernet 1/0/1 to ten-gigabitethernet 1/0/2
   [Sysname-if-range] shutdown
   [Sysname-if-range] quit
   ```

   # Bind Ten-GigabitEthernet 1/0/1 and Ten-GigabitEthernet 1/0/2 to IRF-port 1/2.

   ```
   [Sysname] irf-port 1/2
   [Sysname-irf-port1/2] port group interface ten-gigabitethernet 1/0/1
   [Sysname-irf-port1/2] port group interface ten-gigabitethernet 1/0/2
   [Sysname-irf-port1/2] quit
   ```

   # Bring up the physical interfaces.

   ```
   [Sysname] interface range ten-gigabitethernet 1/0/1 to ten-gigabitethernet 1/0/2
   [Sysname-if-range] undo shutdown
   [Sysname-if-range] quit
   ```

   # Save the running configuration to the next-startup configuration file.

   ```
   [Sysname] save
   ```

   # Activate the IRF port configuration.

   ```
   [Sysname] irf-port-configuration active
   ```

2. Configure settings for IRF setup on Device B:

   # Assign member ID 2 to Device B, and reboot the device to have the change take effect.

   ```
   <Sysname> system-view
   [Sysname] irf member 1 renumber 2
   Renumbering the member ID may result in configuration change or loss. Continue? [Y/N]:y
   [Sysname] quit
   <Sysname> reboot
   ```

   # Shut down the physical interfaces used for IRF connection. This example uses Ten-GigabitEthernet 2/0/1 and Ten-GigabitEthernet 2/0/2 for IRF connection.

   ```
   <Sysname> system-view
   [Sysname] interface range ten-gigabitethernet 2/0/1 to ten-gigabitethernet 2/0/2
   [Sysname-if-range] shutdown
   [Sysname-if-range] quit
   ```

   # Bind Ten-GigabitEthernet 2/0/1 and Ten-GigabitEthernet 2/0/2 to IRF-port 2/1.

   ```
   [Sysname] irf-port 2/1
   [Sysname-irf-port2/1] port group interface ten-gigabitethernet 2/0/1
   [Sysname-irf-port2/1] port group interface ten-gigabitethernet 2/0/2
   [Sysname-irf-port2/1] quit
   ```

   # Bring up the physical interfaces.

   ```
   [Sysname] interface range ten-gigabitethernet 2/0/1 to ten-gigabitethernet 2/0/2
   [Sysname-if-range] undo shutdown
   [Sysname-if-range] quit
   ```

   # Save the running configuration to the next-startup configuration file.

   ```
   [Sysname] save
   ```

Connect Device B to Device A, as shown in Figure 18.

Activate the IRF port configuration.

```
[Sysname] irf-port-configuration active
```

Device A and Device B perform master election. The device that has failed master election automatically reboots to form an IRF fabric with the other device. A two-chassis IRF fabric is formed.

Configuring management IP addresses

Assign IP address 192.168.1.1/24 to the IRF fabric on management Ethernet port M-GigabitEthernet 0/0/0.

```
<Sysname> system-view
[Sysname] interface m-gigabitethernet 0/0/0
[Sysname-M-GigabitEthernet0/0/0] ip address 192.168.1.1 24
```

On management Ethernet port M-GigabitEthernet 0/0/0, assign IP addresses 192.168.1.101/24 and 192.168.1.102/24 to IRF member device 1 (Device A) and IRF member device 2 (Device B), respectively. After the IRF fabric splits, the administrator can use IP addresses 192.168.1.101/24 and 192.168.1.102/24 to log in to Device A and Device B, respectively.

```
[Sysname-M-GigabitEthernet0/0/0] ip address 192.168.1.101 24 irf-member 1
[Sysname-M-GigabitEthernet0/0/0] ip address 192.168.1.102 24 irf-member 2
[Sysname-M-GigabitEthernet0/0/0] quit
```

Exclude management Ethernet port M-GigabitEthernet 0/0/0 from being shut down by MAD upon detection of multi-active collisions.

```
[Sysname] mad exclude interface m-gigabitethernet 0/0/0
```

Configuring ARP MAD

1. Configure the IRF fabric:

Configure the IRF fabric to change its bridge MAC address as soon as the address owner leaves.

```
[Sysname] undo irf mac-address persistent
```

Set the domain ID of the IRF fabric to 1.

```
[Sysname] irf domain 1
```

Enable ARP MAD on management Ethernet port M-GigabitEthernet 0/0/0.

```
[Sysname] interface m-gigabitethernet 0/0/0
[Sysname-M-GigabitEthernet0/0/0] mad arp enable
You need to assign a domain ID (range: 0-4294967295)
[Current domain ID is: 1]:
The assigned domain ID is: 1
[Sysname-M-GigabitEthernet0/0/0] quit
```

Save the running configuration to the next-startup configuration file.

```
[Sysname] save
```

2. Configure Device C (a switch that supports ARP) as the intermediate device for ARP MAD:

CAUTION:

If the intermediate device is also in an IRF fabric, assign the two IRF fabrics different domain IDs for correct split detection. False detection causes IRF split.

Create VLAN 100.

```
<DeviceC> system-view
[DeviceC] vlan 100
```

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to VLAN 100 for forwarding ARP MAD packets.

```
[DeviceC-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/2
[DeviceC-vlan100] quit
```

Verifying the configuration

Disconnect the IRF links between Device A and Device B. Verify that you can use 192.168.1.101 and 192.168.1.102 to log in to Device A and Device B, respectively. (Details not shown.)

Execute the **`display mad verbose`** command on Device A and Device B to verify that MAD is correctly functioning, as follows:

- The **Multi-active recovery state** field displays **Yes** on one device and displays **No** on the other device.
- On each device, the IRF physical interfaces and management Ethernet port M-GigabitEthernet 0/0/0 are excluded from being shut down by MAD.

Execute the **`display interface brief`** command on Device A and Device B to verify that the MAD shutdown action is performed correctly, as follows:

- On the device in Recovery state, all network interfaces have been shut down by MAD except the IRF physical interfaces and management Ethernet port M-GigabitEthernet 0/0/0.
- On the device not in Recovery state, no network interfaces are shut down by MAD.

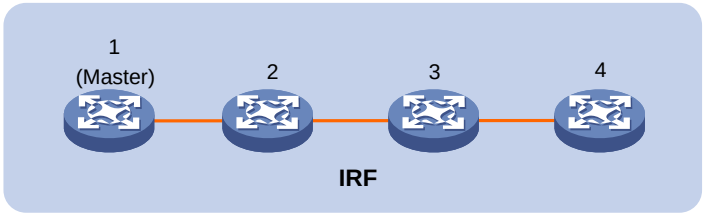
Example: Removing member devices from an IRF fabric without MAD in place

Network configuration

As shown in Figure 19 or Figure 20, an IRF fabric is in daisy-chain or ring topology. The IRF fabric contains four member devices, in which member 1 is the master device. MAD is not configured on the IRF fabric.

Remove member devices 3 and 4 from the IRF fabric.

Figure 19 Network diagram (daisy-chain topology)



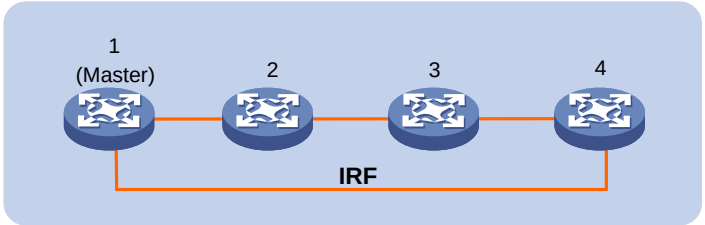


Figure 20 Network diagram (ring topology)

Procedure

1. Enable the IRF fabric to change its bridge MAC address as soon as the address owner leaves the fabric.

```
<System> system-view
[System] undo irf mac-address persistent
```

2. Shut down the network interfaces that connect member devices 3 and 4 to the upstream and downstream devices. (Details not shown.)
3. Use one of the following methods to split the IRF fabric into two IRF fabrics (IRF 1 and IRF 2):
   - Disconnect the physical IRF links between IRF 1 and IRF 2, as shown in Figure 21 or Figure 22.

     Figure 21 Disconnecting physical IRF links (daisy-chain topology)

     Figure 22 Disconnecting physical IRF links (ring topology)

   - Shut down the IRF physical interfaces that connect IRF 1 and IRF 2, as shown in Figure 21 or Figure 22. (Details not shown.)

   The IRF fabric splits into IRF 1 and IRF 2. Because MAD is not configured, both IRF 1 and IRF 2 are active. The member devices in IRF 2 automatically elect a master on split.
4. Handle IRF 2:
   - To retain IRF 2 in the network, log in to IRF 2, modify the IP addresses that conflict with those on IRF 1 and change its domain ID. (Details not shown.)
   - To remove IRF 2 from the network, disconnect all physical network connections from the IRF fabric and remove IRF configuration from all member devices in the IRF fabric. (Details not shown.)
5. Bring up the network interfaces that have been shut down on the removed member devices. (Details not shown.)
6. Remove IRF port bindings from unused IRF physical interfaces on IRF 1. (Details not shown.)

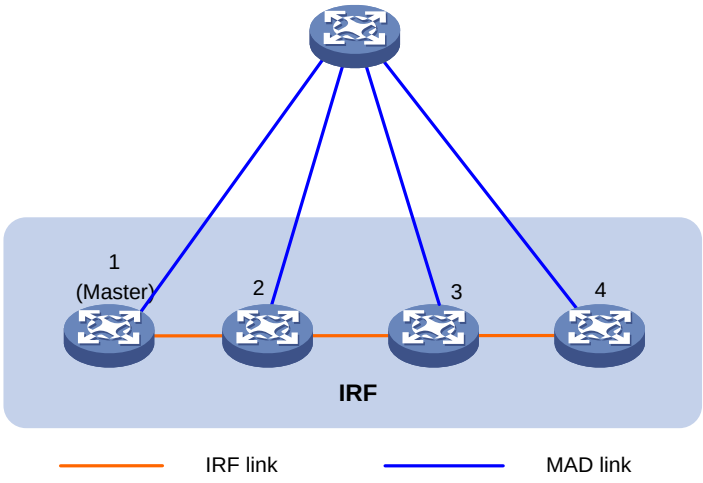
Example: Removing member devices from an IRF fabric with MAD in place

Network configuration

As shown in Figure 23 or Figure 24, an IRF fabric is in daisy-chain or ring topology. The IRF fabric contains four member devices, in which member 1 is the master device. MAD is configured on the IRF fabric.

Remove member devices 3 and 4 from the IRF fabric.

Figure 23 Network diagram (daisy-chain topology)



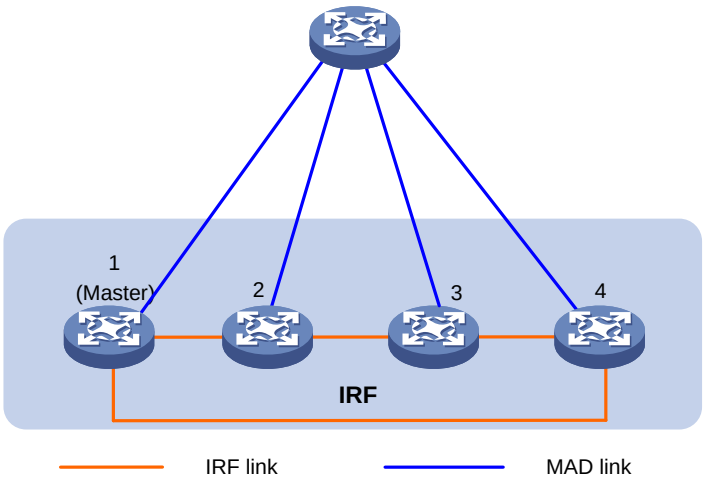


Figure 24 Network diagram (ring topology)

Procedure

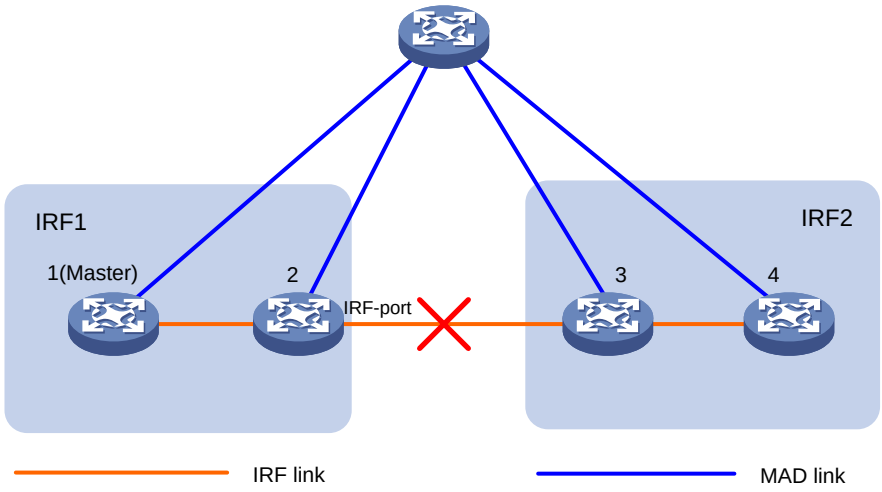
1. Enable the IRF fabric to change its bridge MAC address as soon as the address owner leaves the fabric.

   ```
   <System> system-view
   [System] undo irf mac-address persistent
   ```

2. Shut down the network interfaces that connect member devices 3 and 4 to the upstream and downstream devices. (Details not shown.)
3. Use one of the following methods to split the IRF fabric into two IRF fabrics (IRF 1 and IRF 2):

- Disconnect the physical IRF links between IRF 1 and IRF 2, as shown in Figure 25 or Figure 26.

Figure 25 Disconnecting physical IRF links (daisy-chain topology)



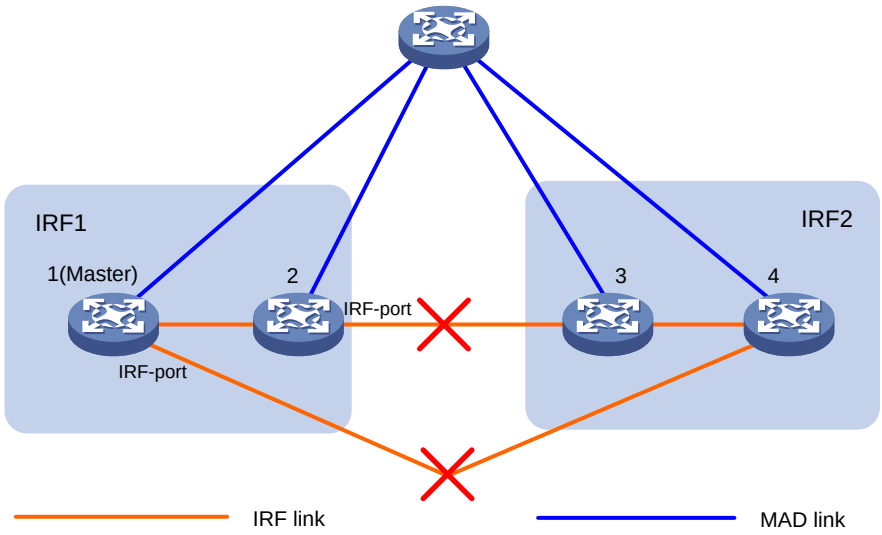


Figure 26 Disconnecting physical IRF links (ring topology)

- Shut down the IRF physical interfaces that connect IRF 1 and IRF 2, as shown in Figure 25 or Figure 26. (Details not shown.)

The IRF fabric splits into IRF 1 and IRF 2. Because MAD is configured, IRF 1 remains active and IRF 2 is placed in Recovery state and becomes inactive.

4. Handle IRF 2:
   - To retain IRF 2 in the network, log in to IRF 2, modify the IP addresses that conflict with those on IRF 1, change its domain ID, and recover IRF 2.

     ```
     <System> system-view
     [System] irf domain 2
     [System] mad restore
     ```

   - To remove IRF 2 from the network, disconnect all physical network connections from the IRF fabric and remove IRF configuration from all member devices in the IRF fabric. (Details not shown.)

5. Bring up the network interfaces that have been shut down on the removed member devices. (Details not shown.)
6. Remove IRF port bindings from unused IRF physical interfaces on IRF 1. (Details not shown.)

Preface

This configuration guide describes LAN switching fundamentals and configuration procedures. It describes how to configure a Layer 2 network.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

Configuring the MAC address table

About the MAC address table

An Ethernet device uses a MAC address table to forward frames. A MAC address entry includes a destination MAC address, an outgoing interface, and a VLAN ID. When the device receives a frame, it uses the destination MAC address of the frame to look for a match in the MAC address table.

- The device forwards the frame out of the outgoing interface in the matching entry if a match is found.
- The device floods the frame in the VLAN of the frame if no match is found.

How a MAC address entry is created

The entries in the MAC address table include entries automatically learned by the device and entries manually added.

MAC address learning

The device can automatically populate its MAC address table by learning the source MAC addresses of incoming frames on each interface.

The device performs the following operations to learn the source MAC address of incoming packets:

1. Checks the source MAC address (for example, MAC-SOURCE) of the frame.
2. Looks up the source MAC address in the MAC address table.
    - The device updates the entry if an entry is found.
    - The device adds an entry for MAC-SOURCE and the incoming port if no entry is found.

When the device receives a frame destined for MAC-SOURCE after learning this source MAC address, the device performs the following operations:

3. Finds the MAC-SOURCE entry in the MAC address table.
4. Forwards the frame out of the port in the entry.

The device performs the learning process for each incoming frame with an unknown source MAC address until the table is fully populated.

Manually configuring MAC address entries

Dynamic MAC address learning does not distinguish between illegitimate and legitimate frames, which can invite security hazards. When Host A is connected to Port A, a MAC address entry will be learned for the MAC address of Host A (for example, MAC A). When an illegal user sends frames with MAC A as the source MAC address to Port B, the device performs the following operations:

1. Learns a new MAC address entry with Port B as the outgoing interface and overwrites the old entry for MAC A.
2. Forwards frames destined for MAC A out of Port B to the illegal user.

As a result, the illegal user obtains the data of Host A. To improve the security for Host A, manually configure a static entry to bind Host A to Port A. Then, the frames destined for Host A are always sent out of Port A. Other hosts using the forged MAC address of Host A cannot obtain the frames destined for Host A.

Types of MAC address entries

A MAC address table can contain the following types of entries:

- **Static entries**—A static entry is manually added to forward frames with a specific destination MAC address out of the associated interface, and it never ages out. A static entry has higher priority than a dynamically learned one.
- **Dynamic entries**—A dynamic entry can be manually configured or dynamically learned to forward frames with a specific destination MAC address out of the associated interface. A dynamic entry might age out. A manually configured dynamic entry has the same priority as a dynamically learned one.
- **Blackhole entries**—A blackhole entry is manually configured and never ages out. A blackhole entry is configured for filtering out frames with a specific source or destination MAC address. For example, to block all frames destined for or sourced from a user, you can configure the MAC address of the user as a blackhole MAC address entry. A blackhole entry has higher priority than a dynamically learned one.
- **Multiport unicast entries**—A multiport unicast entry is manually added to send frames with a specific unicast destination MAC address out of multiple ports, and it never ages out. A multiport unicast entry has higher priority than a dynamically learned one.

A static or blackhole MAC address entry can overwrite a dynamic MAC address entry. A dynamic MAC address entry cannot overwrite a static, dynamic, blackhole, or multiport unicast MAC address entry. A static entry, a blackhole entry, and a multiport unicast entry cannot overwrite one another.

A multiport unicast MAC address entry does not affect learning the corresponding dynamic MAC address entry. For the same MAC address, a multiport unicast MAC address entry and a dynamic MAC address entry can coexist, and the multiport unicast MAC address takes priority.

This document does not cover the configuration of static multicast MAC address entries. For more information about configuring static multicast MAC address entries, see IGMP snooping in *IP Multicast Configuration Guide*.

MAC address table tasks at a glance

All MAC address table configuration tasks are optional.

To configure the MAC address table, perform the following tasks:

- Configuring MAC address entries
  - Adding or modifying a static or dynamic MAC address entry
  - Adding or modifying a blackhole MAC address entry
  - Adding or modifying a multiport unicast MAC address entry
- Setting the aging timer for dynamic MAC address entries
- Configuring MAC address learning
  - Disabling MAC address learning
  - Setting the MAC learning limit
  - Configuring the unknown frame forwarding rule after the MAC learning limit is reached
- Configuring MAC address move notifications and suppression
- Disabling static source check
- Enabling SNMP notifications for the MAC address table

Configuring MAC address entries

About MAC address entry-based frame forwarding

A frame whose source MAC address matches different types of MAC address entries is processed differently.

Type	Description
Static MAC address entry	By default, if the interface in the entry is different from the frame's ingress interface, the device drops the packet. If the interface in the entry is the same as the frame's ingress interface, the device forwards the frame according to the destination MAC address. With the static source check disabled, the device forwards the frame according to the destination MAC address regardless of whether the frame's ingress interface is the same as that in the entry.
Multiport unicast MAC address entry	Learns the source MAC address of the frame, generates a dynamic MAC address entry for that MAC address, and forwards the frame. The multiport unicast MAC address entry has higher priority than the dynamic MAC address entry in traffic forwarding. Learns the source MAC address of the frame, generates a dynamic MAC address entry for that MAC address, and forwards the frame. The multiport unicast MAC address entry has higher priority than the dynamic MAC address entry in traffic forwarding.
Blackhole MAC address entry	Drops the frame.
Dynamic MAC address entry	• Learns the MAC address of the frames received on a different interface from that in the entry and overwrites the original entry. • Forwards the frame received on the same interface as that in the entry and updates the aging timer for the entry.

Restrictions and guidelines for MAC address entry configuration

The manually configured static, blackhole, and multiport unicast MAC address entries cannot survive a reboot if you do not save the configuration. The manually configured dynamic MAC address entries are lost upon reboot whether or not you save the configuration.

Do not configure the following MAC addresses as static, dynamic, blackhole, or multiport unicast MAC addresses:

- Reserved MAC addresses of the device.
- MAC addresses of Layer 3 Ethernet interfaces.
- MAC addresses of Layer 3 aggregate interfaces.

The reserved MAC addresses are the bridge MAC address and its subsequent higher 37 MAC addresses. For information about bridge MAC addresses, see IRF in *Virtual Technologies Configuration Guide*.

You cannot add or modify dynamic MAC address entries for interfaces in the down state.

Prerequisites for MAC address entry configuration

Before manually configuring a MAC address entry for an interface, make sure the VLAN in the entry has been created.

Adding or modifying a static or dynamic MAC address entry

Adding or modifying a static or dynamic MAC address entry globally

1. Enter system view.

system-view

2. Add or modify a static or dynamic MAC address entry.

   mac-address { **dynamic** | **static** } *mac-address* **interface** *interface-type interface-number* **vlan** *vlan-id*

   By default, no MAC address entry is configured globally.

   Make sure you have assigned the interface to the VLAN.

Adding or modifying a static or dynamic MAC address entry on an interface

1. Enter system view.

   system-view

2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.

     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.

     interface bridge-aggregation *interface-number*

3. Add or modify a static or dynamic MAC address entry.

   mac-address { **dynamic** | **static** } *mac-address* **vlan** *vlan-id*

   By default, no MAC address entry is configured on an interface.

   Make sure you have assigned the interface to the VLAN.

Adding or modifying a blackhole MAC address entry

1. Enter system view.

   system-view

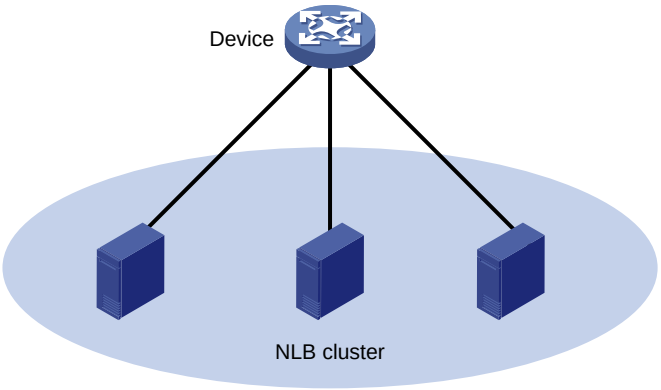
2. Add or modify a blackhole MAC address entry.

   mac-address blackhole *mac-address* **vlan** *vlan-id*

   By default, no blackhole MAC address entry is configured.

Adding or modifying a multiport unicast MAC address entry

About this task



You can configure a multiport unicast MAC address entry to associate a unicast destination MAC address with multiple ports. The frame with a destination MAC address matching the entry is sent out of multiple ports.

For example, in NLB unicast mode (see Figure 1):

- All servers within a cluster uses the cluster's MAC address as their own address.
- Frames destined for the cluster are forwarded to every server in the group.

In this case, you can configure a multiport unicast MAC address entry on the device connected to the server group. Then, the device forwards the frame destined for the server group to every server through all ports connected to the servers within the cluster.

Figure 1 NLB cluster

You can configure a multiport unicast MAC address entry globally or on an interface.

Configuring a multiport unicast MAC address entry globally

1. Enter system view.
   system-view
2. Add or modify a multiport unicast MAC address entry.
   mac-address multiport *mac-address* **interface** *interface-list* **vlan** *vlan-id*
   By default, no multiport unicast MAC address entry is configured globally.
   Make sure you have assigned the interface to the VLAN.

Configuring a multiport unicast MAC address entry on an interface

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
3. Add the interface to a multiport unicast MAC address entry.
   mac-address multiport *mac-address* **vlan** *vlan-id*
   By default, no multiport unicast MAC address entry is configured on an interface.
   Make sure you have assigned the interface to the VLAN.

Setting the aging timer for dynamic MAC address entries

About this task

For security and efficient use of table space, the MAC address table uses an aging timer for each dynamic MAC address entry. If a dynamic MAC address entry is not updated before the aging timer expires, the device deletes the entry. This aging mechanism ensures that the MAC address table can promptly update to accommodate latest network topology changes.

A stable network requires a longer aging interval, and an unstable network requires a shorter aging interval.

An aging interval that is too long might cause the MAC address table to retain outdated entries. As a result, the MAC address table resources might be exhausted, and the MAC address table might fail to update its entries to accommodate the latest network changes.

An interval that is too short might result in removal of valid entries, which would cause unnecessary floods and possibly affect the device performance.

To reduce floods on a stable network, set a long aging timer or disable the timer to prevent dynamic entries from unnecessarily aging out. Reducing floods improves the network performance. Reducing flooding also improves the security because it reduces the chances for a data frame to reach unintended destinations.

Procedure

1. Enter system view.
   system-view
2. Set the aging timer for dynamic MAC address entries.
   mac-address timer { **aging** *seconds* | **no-aging** }
   By default, the aging timer is 300 seconds for dynamic MAC address entries.

Disabling MAC address learning

About disabling MAC address learning

MAC address learning is enabled by default. To prevent the MAC address table from being saturated when the device is experiencing attacks, disable MAC address learning. For example, you can disable MAC address learning to prevent the device from being attacked by a large amount of frames with different source MAC addresses.

After MAC address learning is disabled, the device immediately deletes existing dynamic MAC address entries.

After MAC address learning is disabled, the device immediately deletes existing dynamic MAC address entries.

Disabling MAC address learning on an interface

About this task

When global MAC address learning is enabled, you can disable MAC address learning on a single interface.

Restrictions and guidelines

The **mac-address mac-learning enable** command and its **undo** form do not take effect on a Layer 2 aggregate interface acting as an M-LAG peer-link interface, because MAC address learning is always disabled on that interface. For more information about peer-link interfaces, see "Configuring M-LAG."

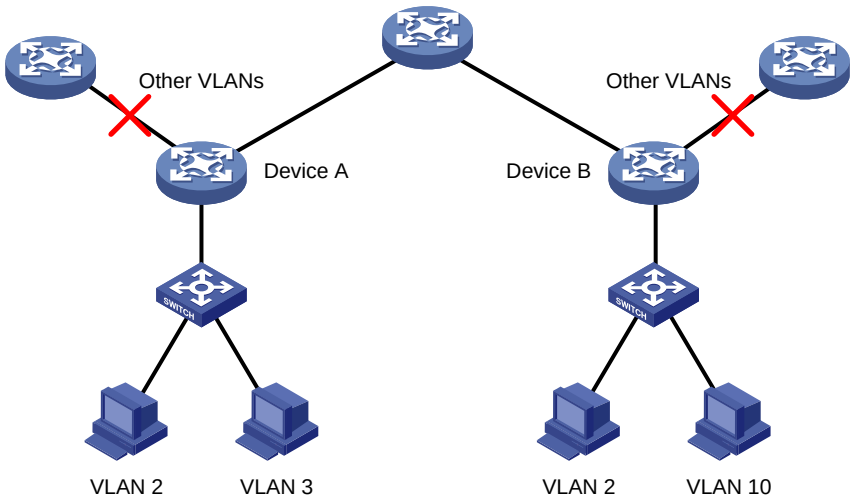
M-LAG is not supported on the S5200-EI-G switch series.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*

- Enter Layer 2 aggregate interface view.
  interface bridge-aggregation *interface-number*

3. Disable MAC address learning on the interface.
   undo mac-address mac-learning enable
   By default, MAC address learning is enabled on an interface.



Disabling MAC address learning on a VLAN

About this task

When global MAC address learning is enabled, you can disable MAC address learning on a per-VLAN basis.

As shown in Figure 2, VLAN 2, VLAN 3, and VLAN 10 are configured on the network to isolate users from different departments. To save MAC address entry resources on the core device and deny external access to these VLANs, you can disable MAC address learning for the VLANs other than VLAN 2, VLAN 3, and VLAN 10 on Device A and Device B.

Figure 2 Network diagram

Procedure

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Disable MAC address learning on the VLAN.
   undo mac-address mac-learning enable
   By default, MAC address learning on the VLAN is enabled.

Setting the MAC learning limit

Setting the MAC learning limit on interfaces

About this task

This feature limits the MAC address table size. A large MAC address table will degrade forwarding performance.

Restrictions and guidelines

The MAC learning limit does not control the number of MAC addresses learned in voice VLANs. For more information, see "Configuring voice VLANs."

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
3. Set the MAC learning limit on the interface.
   mac-address max-mac-count *count*

   By default, no MAC learning limit is configured on an interface.

Setting the MAC learning limit for a VLAN

About this task

You can limit the number of MAC addresses that can be learned for a VLAN. A large MAC address table will degrade forwarding performance.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Set the MAC leaning limit for the VLAN.
   mac-address max-mac-count *count*

   By default, no MAC address learning limit is set for a VLAN.

Configuring the unknown frame forwarding rule after the MAC learning limit is reached

In this document, unknown frames refer to frames whose source MAC addresses are not in the MAC address table.

About unknown frame forwarding rule configuration

You can enable or disable forwarding of unknown frames after the MAC learning limit is reached.

Configuring the device to forward unknown frames after the MAC learning limit on an interface is reached

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
3. Configure the device to forward unknown frames received on the interface after the MAC learning limit on the interface is reached.
   mac-address max-mac-count enable-forwarding

   By default, the device can forward unknown frames received on an interface after the MAC learning limit on the interface is reached.

Configuring the device to forward unknown frames after the MAC learning limit for a VLAN is reached

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Configure the device to forward unknown frames received on interfaces in the VLAN after the MAC learning limit for the VLAN is reached.
   mac-address max-mac-count enable-forwarding

   By default, the device can forward unknown frames received on interfaces in a VLAN after the MAC learning limit for the VLAN is reached.

Configuring MAC address move notifications and suppression

About this task

The outgoing interface for a MAC address entry learned on interface A is changed to interface B when the following conditions exist:

- Interface B receives a packet with the MAC address as the source MAC address.
- Interface B belongs to the same VLAN as interface A.

In this case, the MAC address is moved from interface A to interface B, and a MAC address move occurs.

The MAC address move notifications feature enables the device to output MAC address move logs when MAC address moves are detected.

If a MAC address is continuously moved between the two interfaces, Layer 2 loops might occur. To detect and locate loops, you can view the MAC address move information. To display the MAC address move records after the device is started, use the **display mac-address mac-move** command.

If the system detects that MAC address moves occur frequently on an interface, you can configure MAC address move suppression to shut the interface down. The interface automatically goes up after a suppression interval. Or, you can manually bring up the interface.

Restrictions and guidelines

After you configure MAC address move notifications, the system sends only log messages to the information center module. If the device is also configured with the **snmp-agent trap enable mac-address** command, the system also sends SNMP notifications to the SNMP module.

Procedure

1. Enter system view.
   system-view
2. Enable MAC address move notifications and optionally specify a MAC move detection interval.
   mac-address notification mac-move [**interval** *interval*]
   By default, MAC address move notifications are disabled.
3. (Optional.) Set MAC address move suppression parameters.
   mac-address notification mac-move suppression { **interval** *interval* | **threshold** *threshold* }
   By default, the suppression interval is 30 seconds, and the suppression threshold is 3.
   For the MAC address move suppression parameters to take effect, enable the MAC address move suppression on a port.
4. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
5. Enable MAC address move suppression.
   mac-address notification mac-move suppression
   By default, MAC address move suppression is disabled.

Disabling static source check

About this task

By default, the static source check feature is enabled on an interface. The check identifies whether a received frame meets the following conditions:

- The source MAC address of the frame matches a static MAC address entry.
- The incoming interface of the frame is different from the outgoing interface in the entry.

If the frame meets both conditions, the device drops the frame.

When this feature is disabled, the device does not perform the check for a received frame. It can forward the frame whether or not the frame meets the conditions.

Disabling static source check on an interface

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.
     interface route-aggregation { *interface-number* | *interface-number.subnumber* }
   - Enter IRF physical interface view.
     interface *interface-type interface-number*
3. Disable the static source check feature on the interface.
   undo mac-address static source-check enable
   By default, the static source check feature is enabled on an interface.

Enabling SNMP notifications for the MAC address table

About this task

To report critical MAC address move events to an NMS, enable SNMP notifications for the MAC address table. For MAC address move event notifications to be sent correctly, you must also configure SNMP on the device.

When SNMP notifications are disabled for the MAC address table, the device sends the generated logs to the information center. To display the logs, configure the log destination and output rule configuration in the information center.

For more information about SNMP and information center configuration, see the network management and monitoring configuration guide for the device.

Procedure

1. Enter system view.
   system-view
2. Enable SNMP notifications for the MAC address table.
   snmp-agent trap enable mac-address [**mac-move**]
   By default, SNMP notifications are enabled for the MAC address table.
   If you execute this command without specifying any keywords, the command enables all types of SNMP notifications for the MAC address table. If you specify a keyword, the command enables only the specified type of SNMP notifications for the MAC address table.

Display and maintenance commands for MAC address table

Execute **display** commands in any view.

Task	Command
Display MAC address table information.	**display mac-address** [*mac-address* [**vlan** *vlan-id*] | [[**dynamic** | **static**] [**interface** *interface-type interface-number*] | **blackhole** | **multiport**] [**vlan** *vlan-id*] [**count**]]
Display the aging timer for dynamic MAC address entries.	**display mac-address aging-time**
Display the system or interface MAC address learning state.	**display mac-address mac-learning** [**interface** *interface-type interface-number*]
Display the MAC address move records.	**display mac-address mac-move** [**slot** *slot-number*]
Display MAC address statistics.	**display mac-address statistics**
Clear the MAC address move records for all VLANs after the device is started.	**reset mac-address mac-move**

MAC address table configuration examples

Example: Configuring the MAC address table

Network configuration

As shown in Figure 3:

- Host A at MAC address 000f-e235-dc71 is connected to GigabitEthernet 1/0/1 of Device and belongs to VLAN 10.
- Host B at MAC address 000f-e235-abcd, which behaved suspiciously on the network, also belongs to VLAN 10.

Configure the MAC address table as follows:

- To prevent MAC address spoofing, add a static entry for Host A in the MAC address table of Device.
- To drop all frames destined for Host B, add a blackhole MAC address entry for Host B.
- Set the aging timer to 500 seconds for dynamic MAC address entries.

Figure 3 Network diagram

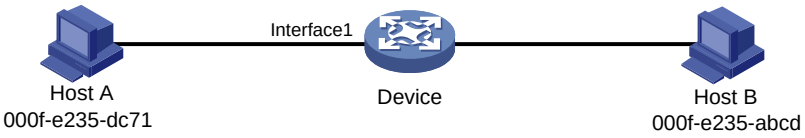


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

Create VLAN-interface 10, and assign an IP address and subnet mask to the interface.

```
<Device> system-view
[Device] vlan 10
[Device-vlan10] quit

Bulk configuring interfaces 1
About interface bulk configuration 1
Restrictions and guidelines: Bulk interface configuration 1
Procedure 2
Display and maintenance commands for bulk interface configuration 2

Bulk configuring interfaces

About interface bulk configuration

You can enter interface range view to bulk configure multiple interfaces with the same feature instead of configuring them one by one. For example, you can execute the **shutdown** command in interface range view to shut down a range of interfaces.

To configure interfaces in bulk, you must configure an interface range and enter its view by using the **interface range** or **interface range name** command.

The interface range created by using the **interface range** command is not saved to the running configuration. You cannot use the interface range repeatedly. To create an interface range that can be used repeatedly, use the **interface range name** command.

Restrictions and guidelines: Bulk interface configuration

When you bulk configure interfaces in interface range view, follow these restrictions and guidelines:

- In interface range view, only the commands supported by the first interface in the specified interface list (alphabetically sorted) are available for configuration.
- Before you configure an interface as the first interface in an interface range, make sure you can enter the view of the interface by using the **interface** *interface-type* { *interface-number* | *interface-number.subnumber* } command.
- Do not assign both an aggregate interface and any of its member interfaces to an interface range. Some commands, after being executed on both an aggregate interface and its member interfaces, can break up the aggregation.
- Understand that the more interfaces you specify, the longer the command execution time.
- To guarantee bulk interface configuration performance, configure fewer than 1000 interface range names.

The device does not output prompt or alarm messages during the bulk interface configuration process. Make sure you are fully aware of the support and impacts of bulk interface configuration.

- After a command is executed in interface range view, one of the following situations might occur:
  - The system displays an error message and stays in interface range view. This means that the execution failed on one or multiple member interfaces.
    - If the execution failed on the first member interface, the command is not executed on any member interfaces.
    - If the execution failed on a non-first member interface, the command takes effect on the remaining member interfaces.
  - The system returns to system view. This means that:
    - The command is supported in both system view and interface view.
    - The execution failed on a member interface in interface range view and succeeded in system view.
    - The command is not executed on the subsequent member interfaces.

You can use the **display this** command to verify the configuration in interface view of each member interface. In addition, if the configuration in system view is not needed, use the **undo** form of the command to remove the configuration.

Procedure

1. Enter system view.

   system-view
2. Create an interface range and enter interface range view.
   - **Create an interface range without specifying a name.**

     interface range { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>
   - **Create a named interface range.**

     interface range name *name* [**interface** { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>]
   - **Add or delete interfaces for an existing interface range.**

     interface range name *name* [**add** | **delete**] **interface** { *interface-type interface-number* [**to** *interface-type interface-number*] } &<1-24>]
3. (Optional.) Display commands available for the first interface in the interface range.

   Enter a question mark (?) at the interface range prompt.
4. Use available commands to configure the interfaces.

   Available commands depend on the interface.
5. (Optional.) Verify the configuration.

   display this

Display and maintenance commands for bulk interface configuration

Execute the **display** command in any view.

Task	Command
Display information about the interface ranges created by using the **interface range name** command.	**display interface range** [**name** *name*]

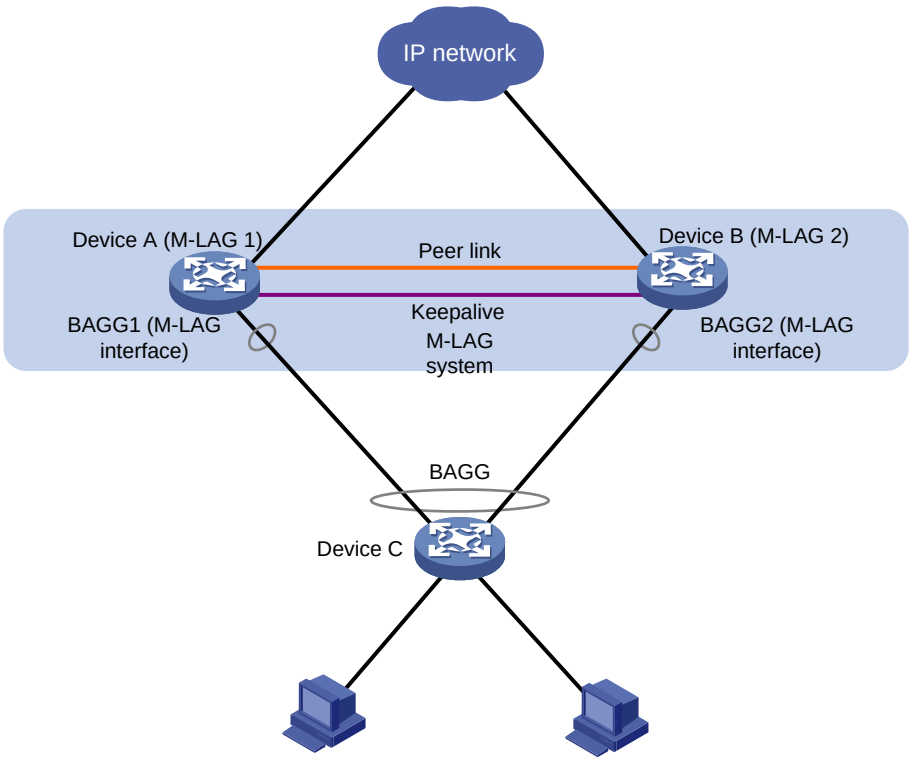
M-LAG overview



About M-LAG

Multichassis Link Aggregation (M-LAG) virtualizes two physical devices into one system through multichassis link aggregation.

M-LAG network model

As shown in Figure 1, M-LAG virtualizes two devices into an M-LAG system, which connects to the remote aggregation system through a multichassis aggregate link. To the remote aggregation system, the M-LAG system is one device.

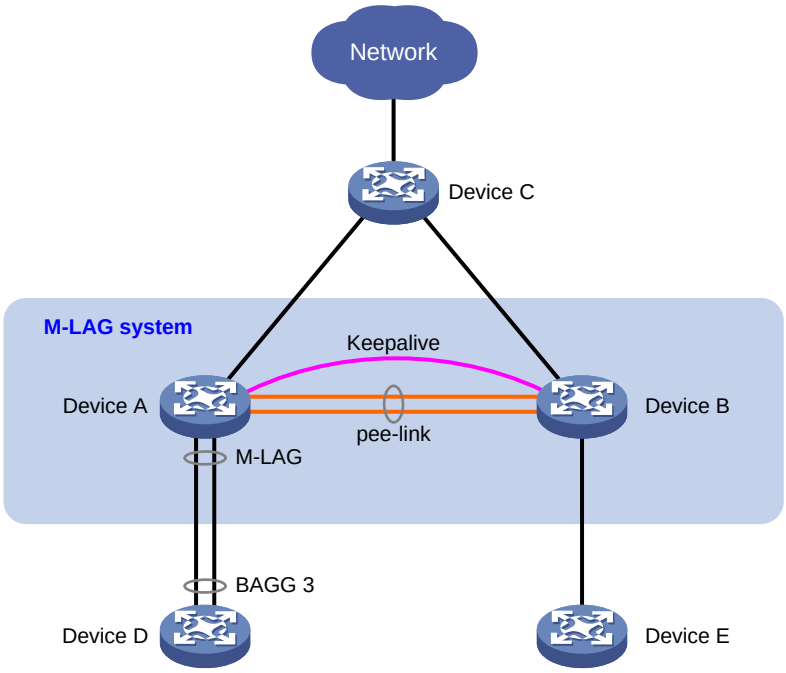
Figure 1 M-LAG network model

The M-LAG member devices are M-LAG peers to each other. For features that require centralized traffic processing (for example, spanning tree), an M-LAG member device is assigned the primary or secondary role based on its M-LAG role priority. The secondary M-LAG member device passes the traffic of those features to the primary M-LAG member device for processing. If the M-LAG member devices in an M-LAG system have the same M-LAG role priority, the device with the lower bridge MAC address is assigned the primary role.

M-LAG defines the following interface roles for each M-LAG member device:

- **M-LAG interface**—Layer 2 aggregate interface connected to the remote aggregation system. M-LAG interfaces connected to the same remote aggregation system belong to one M-LAG group. In Figure 1, Bridge-Aggregation 1 on Device A and Bridge-Aggregation 2 on Device B belong to the same M-LAG group. M-LAG interfaces in an M-LAG group form a multichassis aggregate link.

- **Peer-link interface**—Interface connected to the M-LAG peer for internal control. Each M-LAG member device has only one peer-link interface. The peer-link interfaces of the M-LAG member devices transmit M-LAG protocol packets and data packets through the peer link established between them. An M-LAG system has only one peer link.



M-LAG member devices use a keepalive link to monitor each other's state. For more information about the keepalive mechanism, see "Keepalive and failover mechanism."

If a device is attached to only one of the M-LAG member devices in an M-LAG system, that device is a single-homed device. Single-homed access includes the following types:

- **M-LAG single-homed access**—Connects to one of the M-LAG member devices through an M-LAG interface.
- **Non-M-LAG single-homed access**—Connects to one of the M-LAG member devices through a non-M-LAG interface.

As shown in Figure 2, Device D connects to the M-LAG system in M-LAG single-homed mode, while Device E connects to the M-LAG system in non-M-LAG single-homed mode. Device D and Device E connect to the M-LAG system in single-homed mode. The MAC address entries and ARP/ND entries of Device D and E are backed up between the M-LAG member devices. This provides a backup path for north-south traffic, enhancing reliability.

Figure 2 Connecting to an M-LAG network in single-homed access mode

M-LAG benefits

Traditional aggregate links rely on interoperation between single devices. If a link or peer device fails, normal communication with the peer device might fail. The M-LAG technology addresses this issue by aggregating ports from different devices in the system into one logical interface, effectively preventing single point failures from affecting the overall link and ensuring reliable data flow transmission. Additionally, the M-LAG system features a loop-free Layer 2 topology, allowing for more efficient use of links. Two M-LAG member devices can be upgraded independently, reducing service interruption time.

M-LAG setup mechanism

M-LAG system setup process

As shown in Figure 3, two devices perform the following operations to form an M-LAG system:

1. Send DRCPDUs over the peer link to each other and compare the DRCPDUs to determine the M-LAG system stackability and device roles:
   a. Compare the M-LAG system settings. The devices can form an M-LAG system if they have consistent M-LAG system settings.
   b. Determine the device roles as described in "Device role calculation."
   c. Perform configuration consistency check. For more information, see "Configuration consistency check."
2. Send keepalive packets over the keepalive link after primary M-LAG member election to verify that the peer system is operating correctly.
3. Synchronize configuration data by sending DRCPDUs over the peer link. The configuration data includes MAC address entries and ARP entries.

Figure 3 M-LAG system setup process

DRCP

M-LAG uses H3C proprietary Distributed Relay Control Protocol (DRCP) for multichassis link aggregation. DRCP runs on the peer link and uses distributed relay control protocol data units (DRCPDUs) to advertise the M-LAG configuration out of peer-link interfaces and M-LAG interfaces.

DRCP operating mechanism

M-LAG-enabled devices use DRCPDUs for the following purposes:

- Exchange DRCPDUs through M-LAG interfaces to determine whether they can form an M-LAG system.
- Exchange DRCPDUs through peer-link interfaces to negotiate the peer link state.

DRCP timeout timers

DRCP uses a timeout mechanism to specify the amount of time that a peer-link interface or M-LAG interface must wait to receive DRCPDUs before it determines that the peer interface is down. This timeout mechanism provides the following timer options:

- Short DRCP timeout timer, which is fixed at 3 seconds. If this timer is used, the peer interface sends one DRCPDU every second.
- Long DRCP timeout timer, which is fixed at 90 seconds. If this timer is used, the peer interface sends one DRCPDU every 30 seconds.

Short DRCP timeout timer enables the M-LAG member devices to detect a peer interface down event more quickly than the long DRCP timeout timer. However this benefit is at the expense of bandwidth and system resources.

Device role calculation

As shown in Figure 4, the role of an M-LAG member device can be primary, secondary, or none after role calculation.

Figure 4 M-LAG role calculation process

Role calculation rules

M-LAG calculates the roles of the M-LAG member devices according to the following rules:

- The M-LAG roles are determined upon M-LAG system initialization triggered by M-LAG system setup or reboot of an M-LAG member device.
- If the peer link is up, the M-LAG member devices exchange DRCPDUs over the peer link to determine which of them to take the primary role.
- If the peer link is down while the keepalive link is up, the M-LAG member devices exchange keepalive packets over the link to determine their roles.
- If both the peer link and the keepalive link are down, an M-LAG member device takes the primary role if it has available uplink interfaces or M-LAG interfaces.

Factors in role calculation

When the peer link or keepalive link is up, the M-LAG member devices exchange the following information to determine which of them takes the primary role:

1. (Applicable only when the peer link fails but the keepalive link is operating correctly.) When both M-LAG member devices have configured uplink interfaces, the one with the uplink interface that comes up first is preferred. If both devices do not have uplink interfaces configured, skip this comparison factor.
2. Status of M-LAG interfaces. An M-LAG member device takes the primary role if it has available M-LAG interfaces. This status is skipped if role calculation is performed over the peer link.
3. Device roles before calculation. If one device already has the primary role, the primary device retains its role.
4. M-LAG MAD DOWN state. If one device has not placed any network interfaces in M-LAG MAD DOWN state, it becomes the primary device.
5. Health state. The healthier device takes the primary role.

   To view the health state of the device, execute the **`display system health`** command. The smaller the health state value, the healthier the device is. The health state value is 0 if the device is running without faults. For more information about the **`display system health`** command, see device management commands in *Fundamentals Command Reference*.
6. M-LAG role priority. The device with higher M-LAG role priority takes the primary role.
7. Bridge MAC address. The device with a lower bridge MAC address takes the primary role.

The device that has failed the election takes the secondary role.

Configuration consistency check

During M-LAG system setup, M-LAG member devices exchange the configuration and perform configuration consistency check to verify their consistency in the following configurations:

- **Type 1 configuration**—Settings that affect traffic forwarding of the M-LAG system. If an inconsistency in type 1 configuration is detected, the secondary M-LAG member device shuts down its M-LAG interfaces.
- **Type 2 configuration**—Settings that affect only service features. If an inconsistency in type 2 configuration is detected, the secondary M-LAG member device disables the affected service features, but it does not shut down its M-LAG interfaces.

To prevent interface flapping, the M-LAG system performs configuration consistency check when half the data restoration interval elapses.

NOTE:

The data restoration interval specifies the maximum amount of time for the secondary M-LAG member device to synchronize data with the primary M-LAG member device during M-LAG system setup. For more information, see "Setting the data restoration interval."

Type 1 configuration

Type 1 configuration consistency check is performed both globally and on M-LAG interfaces. Table 1 and Table 2 show settings that type 1 configuration contains.

Table 1 Global type 1 configuration

Setting	Details
Peer-link interface link type	Peer-link interface link type, including access, hybrid, and trunk.
PVID on the peer-link interface	PVID on the peer-link interface.
Spanning tree state	• Global spanning tree state. • VLAN-specific spanning tree state. M-LAG checks the VLAN-specific spanning tree state only when PVST is enabled.
Spanning tree mode	Spanning tree mode, including STP, RSTP, PVST, and MSTP.
MST region settings	• MST region name. • MST region revision level. • VLAN-to-MSTI mappings.

Table 2 M-LAG interface type 1 configuration

Setting	Details
Aggregation mode	Aggregation mode, including static and dynamic.
Spanning tree state	Interface-specific spanning tree state.
Link type	Interface link type, including access, hybrid, and trunk.
PVID	Interface PVID.

Type 2 configuration

Type 2 configuration consistency check is performed both globally and on M-LAG interfaces. Table 3 and Table 4 show settings that type 2 configuration contains.

Table 3 Global type 2 configuration

Setting	Details
VLANs permitted by the peer-link interface	VLANs permitted by the peer-link interface. The M-LAG system compares tagged VLANs prior to untagged VLANs.
VLAN interfaces	Up VLAN interfaces of which the VLANs contain the peer-link interface.
VLAN interface status	Whether a VLAN interface is in administratively down state.
IPv4 address of a VLAN interface	IPv4 address assigned to a VLAN interface.
IPv6 address of a VLAN interface	IPv6 address assigned to a VLAN interface.
Virtual IPv4 address of the VRRP	Virtual IPv4 address of the VRRP group configured on a VLAN

Setting	Details
group on a VLAN interface	interface on the VRRP master.
Global BPDU guard	Global status of BPDU guard.
MAC aging timer	Aging timer for dynamic MAC address entries.
Global state of port security.	Whether port security is enabled globally.
Authentication load sharing mode for users on port security-enabled M-LAG interfaces	Authentication load sharing mode for users on port security-enabled M-LAG interfaces: • **Centralized**—The primary M-LAG member device authenticates users. • **Local**—Each M-LAG member device authenticates their local users. • **Odd-MAC**—The local M-LAG member device authenticates odd-MAC users on all M-LAG interfaces of the M-LAG system. • **Even-MAC**—The local M-LAG member device authenticates even-MAC users on all M-LAG interfaces of the M-LAG system.
MAC move	Status of the MAC move feature.
MAC move mode	Port security MAC move mode: • **Port**—Allows an authenticated online user to move between ports on the device. • **VLAN**—Allows an authenticated online user to move between VLANs on a trunk or hybrid port. • **All**—Allows an authenticated online user to move between ports on the device or VLANs on a trunk or hybrid port.
State of traffic statistics for 802.1X and MAC authentication users	Whether traffic statistics collection is enabled globally for 802.1X and MAC authentication users.
Global state of 802.1X authentication	Whether 802.1X authentication is enabled globally.
802.1X authentication method	802.1X authentication method: • **Chap**—Performs EAP termination and uses CHAP to communicate with the RADIUS server. • **Eap**—Relays EAP packets and supports any of the EAP authentication methods to communicate with the RADIUS server. • **Pap**—Performs EAP termination and uses PAP to communicate with the RADIUS server.
EAD rule timer of 802.1X authentication	EAD rule timer value for 802.1X authentication.
Handshake timer of 802.1X authentication	Handshake timer value for 802.1X authentication.
Offline detection timer of 802.1X authentication	Offline detection timer value for 802.1X authentication.
Quiet timer of 802.1X authentication	Quiet timer value for 802.1X authentication.
Periodic reauthentication timer of 802.1X authentication	Periodic reauthentication timer value for 802.1X authentication.
Server timeout timer of 802.1X authentication	Server timeout timer value for 802.1X authentication.
Client timeout timer of 802.1X authentication	Client timeout timer value for 802.1X authentication.
Username request timeout timer of	Username request timeout timer value for 802.1X authentication.

Setting	Details
802.1X authentication	
Aging timer for users in Auth-Fail VLANs of 802.1X authentication	Aging timer value for users in Auth-Fail VLANs of 802.1X authentication.
Aging timer for users in critical VLANs of 802.1X authentication	Aging timer value for users in critical VLANs of 802.1X authentication.
Aging timer for users in guest VLANs of 802.1X authentication	Aging timer value for users in guest VLANs of 802.1X authentication.
Global state of MAC authentication	Whether MAC authentication is enabled globally.
MAC authentication method	MAC authentication method: • **Chap**—CHAP authentication. • **Pap**—PAP authentication.
Offline detection timer of MAC authentication	Offline detection timer value for MAC authentication.
Quiet timer of MAC authentication	Quiet timer value for MAC authentication.
Periodic reauthentication timer of MAC authentication	Periodic reauthentication timer value for MAC authentication.
Server timeout timer of MAC authentication	Server timeout timer value for MAC authentication.
Aging timer for temporary MAC authentication users	Aging timer value for temporary MAC authentication users.
Aging timer for users in critical VLANs of MAC authentication	Aging timer value for users in critical VLANs of MAC authentication.
Aging timer for users in guest VLANs of MAC authentication	Aging timer value for users in guest VLANs of MAC authentication.
Aging timer for MAC address entries created for temporary MAC authentication users	Aging timer value for MAC address entries created for temporary MAC authentication users.

The device displays the following global type 2 settings only when VLAN or VLAN interface configuration inconsistency exists:

- VLAN interface status.
- IPv4 address of a VLAN interface.
- IPv6 address of a VLAN interface.
- Virtual IPv4 address of the VRRP group on a VLAN interface.

Table 4 M-LAG interface type 2 configuration

Setting	Details
VLANs permitted by an M-LAG interface	VLANs permitted by an M-LAG interface. The M-LAG system compares tagged VLANs prior to untagged VLANs.
Using port speed as the prioritized criterion for reference port selection	Whether an M-LAG interface uses port speed as the prioritized criterion for reference port selection.
Ignoring port speed in setting the aggregation states of member ports	Whether an M-LAG interface ignores port speed in setting the aggregation states of member ports.

Setting	Details
Root guard status	Status of root guard.
Port security mode	Port security mode: • Autolearn. • Mac-authentication. • Mac-and-userlogin-secure-ext. • Mac-else-userlogin-secure. • Mac-else-userlogin-secure-ext. • Secure. • Userlogin. • Userlogin-secure. • Userlogin-secure-ext. • Userlogin-secure-or-mac. • Userlogin-secure-or-mac-ext. • Userlogin-withoui.
Secure MAC address aging type	Secure MAC address aging type: • **Inactivity**—Inactivity aging feature together with the aging timer. • **Periodical**—Timer aging only.
State of 802.1X authentication on an interface	Whether 802.1X authentication is enabled on an interface.
802.1X online user handshake	Status of the 802.1X online user handshake feature.
802.1X multicast trigger	Status of the 802.1X multicast trigger feature.
802.1X unicast trigger	Status of the 802.1X unicast trigger feature.
802.1X authentication offline detection	State of 802.1X authentication offline detection on an M-LAG interface: • **Enabled**. • **Disabled**.
Periodic reauthentication timer of 802.1X authentication	Periodic reauthentication timer of 802.1X authentication.
802.1X authentication critical profile	802.1X authentication critical profile.
802.1X critical VLAN	802.1X critical VLAN which an M-LAG interface is assigned to.
802.1X packet detection	State of 802.1X packet detection.
802.1X packet detection retries	Number of 802.1X packet detection retries.
State of MAC authentication on an interface	Whether MAC authentication is enabled on an interface.
Parallel processing of MAC authentication and 802.1X authentication on a port	Status of parallel processing of MAC authentication and 802.1X authentication on a port.
MAC authentication offline detection	State of MAC authentication offline detection on an M-LAG interface: • **Enabled**. • **Disabled**.
MAC authentication VLAN mode for users moving from one VLAN to another	MAC authentication VLAN mode for users moving from one VLAN to another on an M-LAG interface: • **Single VLAN**—Single-VLAN mode. • **Multiple VLAN**—Multi-VLAN mode.

Setting	Details
MAC authentication delay timer	MAC authentication delay timer value.
Periodic reauthentication timer of MAC authentication	Periodic reauthentication timer value for MAC authentication.
MAC authentication critical profile	MAC authentication critical profile name.
Critical VLAN of MAC authentication	Critical VLAN of MAC authentication.
MAC authentication packet detection	State of MAC authentication packet detection.
MAC authentication packet detection retries	Number of MAC authentication packet detection retries.
Online detection interval of Web authentication	Online detection interval of Web authentication.

Keepalive and failover mechanism

H3C provides proprietary keepalive mechanism to detect the availability of the M-LAG member devices.

In normal conditions, an M-LAG system can have only one primary device, which is responsible for processing control messages and distributing data-plane traffic for load sharing. When a failure occurs in the M-LAG system, both M-LAG member devices might consider the peer device unavailable and both attempt to become the primary device, a situation known as a dual-primary conflict. A dual-primary conflict can lead to issues such as loops, failure of traffic load sharing, and flapping of forwarding entries. To prevent dual-primary conflicts, M-LAG implements a dual-primary detection mechanism that uses the keepalive mechanism to ensure that only one device operates as the primary device.

For the secondary M-LAG member device to monitor the state of the primary device, you must establish a Layer 3 keepalive link between the M-LAG member devices.

The M-LAG member devices periodically send keepalive packets over the keepalive link. If an M-LAG member device has not received keepalive packets from the peer when the keepalive timeout timer expires, it determines that the keepalive link is down. When both the keepalive link and the peer link are down, an M-LAG member device acts depending on its role.

- When the local device is the primary device and has uplink interfaces configured, it remains as the primary device if any uplink interface is in up state. If no uplink interface in up state exists, the local device's role changes to None.
- When the local device is the primary device and no uplink interface is configured on it, the local device remains as the primary device if an M-LAG interface in up state exists. If no M-LAG interface in up state exists, the local device's role changes to None.
- When the local device is a secondary device, it becomes the primary device. If the local device is configured with uplink interfaces, it will remain as the primary device as long as an uplink interface in up state exists on the local device. If no uplink interface in up state exists, the local device's role will change to None.
- When the local device is a secondary device, it becomes the primary device. If the local device does not have an uplink interface configured, it will remain as the primary device as long as an M-LAG interface in up state exists on the device. If no M-LAG interface in up state exists, the local device's role will change to None.

A device with the None role cannot send or receive keepalive packets. Its keepalive link stays in the down state.

If the keepalive link is down while the peer link is up, the M-LAG member devices prompt you to check for keepalive link issues.

If the keepalive link is up while the peer link is down, the M-LAG member devices elect a primary device based on the information in the keepalive packets.

MAD mechanism

M-LAG MAD

A multi-active collision occurs if the peer link goes down while the keepalive link is up. To avoid network issues, M-LAG MAD shuts down all network interfaces on the secondary M-LAG member device except those manually or automatically excluded.

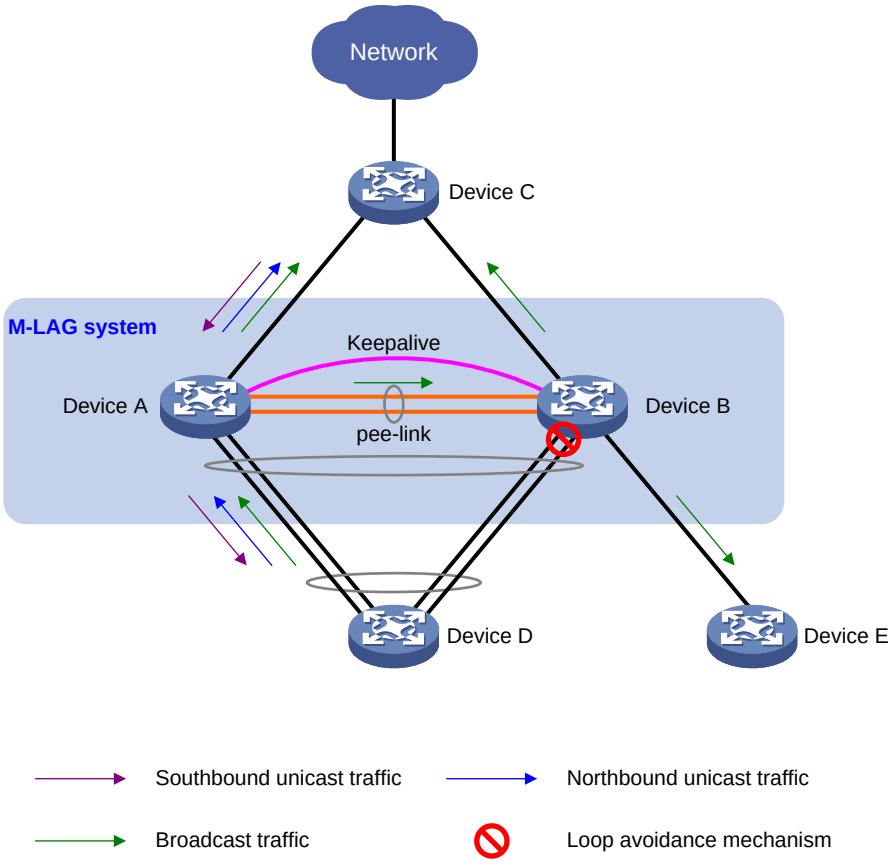
When the peer link comes up, the secondary M-LAG member device starts a delay timer and begins to restore table entries (including MAC address entries and ARP entries) from the primary M-LAG member device. When the delay timer expires, the secondary M-LAG member device brings up all network interfaces placed in M-LAG MAD DOWN state.

M-LAG MAD DOWN state persistence

Both of the M-LAG member devices might take the primary role if both of them have M-LAG interfaces in up state after the following series of events occur:

1. The peer link goes down while the keepalive link is up. Then, M-LAG MAD shuts down all network interfaces on the secondary M-LAG member device except those excluded from the shutdown action by M-LAG MAD.
2. The keepalive link also goes down. Then, the secondary M-LAG member device brings up the network interfaces in M-LAG MAD DOWN state and sets its role to primary.

M-LAG MAD DOWN state persistence helps avoid the forwarding issues that might occur in the multi-active situation that occurs because the keepalive link goes down while the peer link is down.



To prevent packet loss after the peer link recovers from a link fault, the secondary member device should try to synchronize entries (such as the MAC address entries and ARP entries) within the data restoration interval. Subsequently, interfaces in M-LAG MAD DOWN state on the device will restore to up.

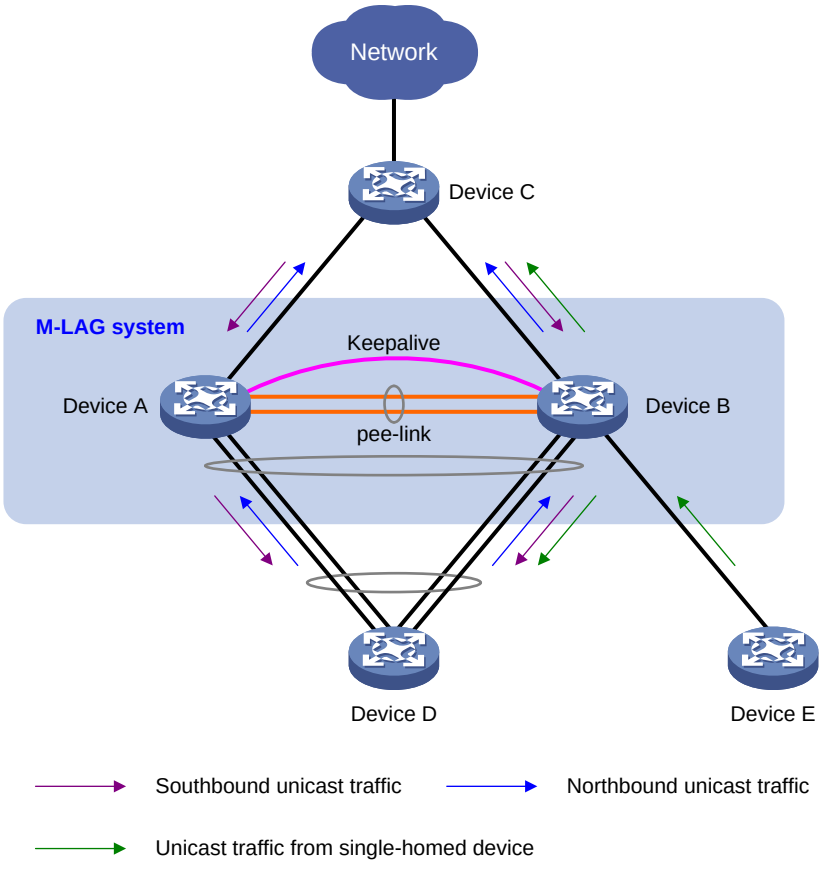
M-LAG traffic forwarding

M-LAG loop avoidance mechanism

An M-LAG system is a loop-free network. As shown in Figure 5, when north-south unicast traffic reaches the M-LAG system, it is preferentially forwarded directly locally. Typically, the peer link does not forward data traffic. Only BUM traffic is forwarded to the peer M-LAG member device through the peer link. The M-LAG device does not forward traffic received from the peer link out through the local M-LAG interface, thus preventing loops. This is the loop avoidance mechanism of M-LAG.

Figure 5 Schematic diagram for the M-LAG loop avoidance mechanism

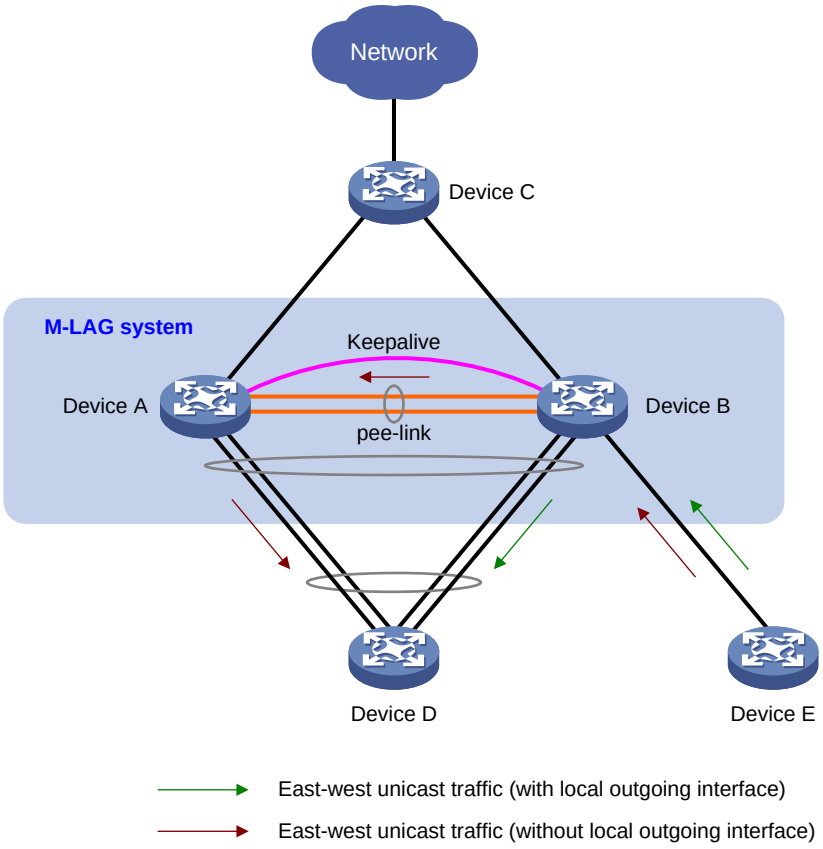
NOTE:



The preceding loop avoidance mechanism takes effect on dual-homed devices but does not take effect on single-homed devices. Single-homed devices will still receive traffic forwarded from the M-LAG peer link.

Unicast traffic forwarding

As shown in Figure 6, Device D and Device E connect to the M-LAG system. The known unicast traffic is forwarded as follows:



- For north-south unicast traffic, the M-LAG system preferentially forwards the traffic directly upon receiving the traffic, instead of sending it to the peer through the peer link.
- For east-west unicast traffic (traffic forwarded between access devices), the traffic is preferentially forwarded locally on the M-LAG member devices.

Figure 6 Schematic diagram for unicast traffic forwarding

As shown in Figure 7, for east-west traffic, if the traffic is received and no local outgoing interface is available, the traffic will traverse through the peer link and be forwarded by the peer M-LAG member device.

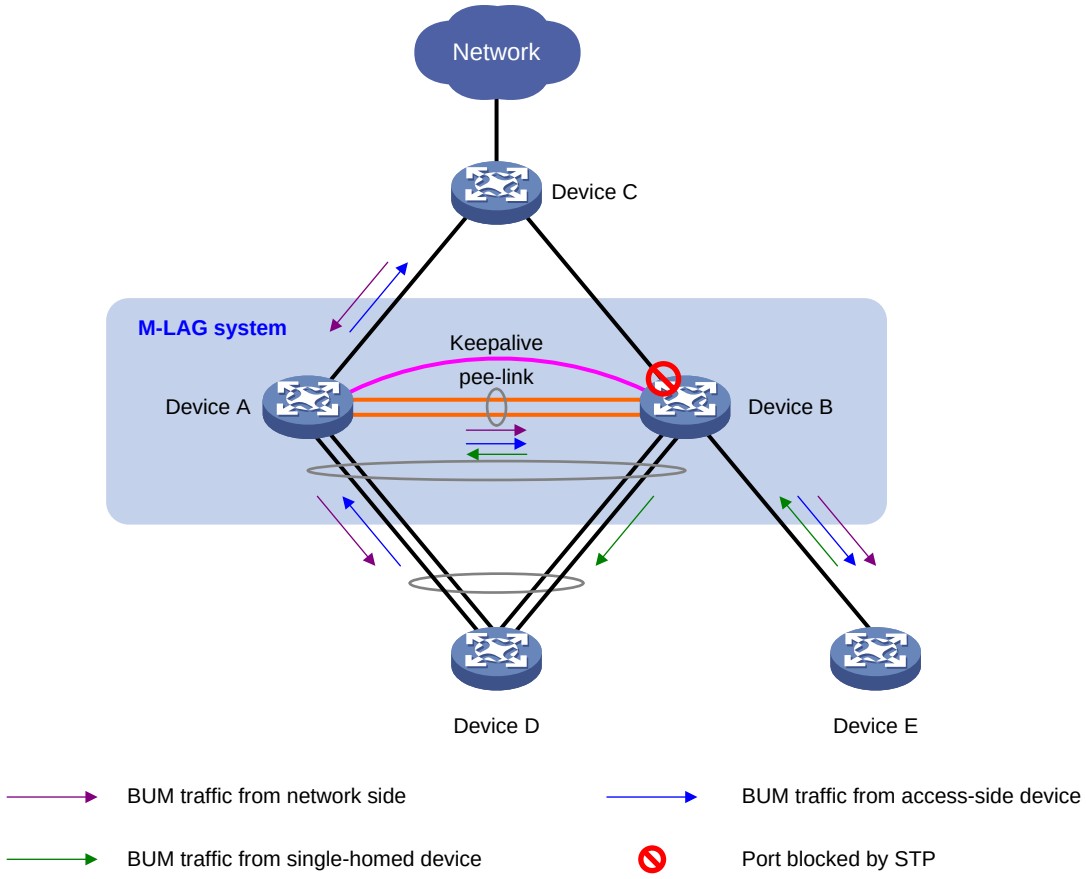


Figure 7 Schematic diagram east-west traffic forwarding

BUM traffic forwarding

As shown in Figure 8, BUM traffic will be forwarded through the peer link, but the loop avoidance mechanism prevents an access device from receiving its own BUM traffic.

Figure 8 Schematic diagram for BUM traffic forwarding

M-LAG failure handling

M-LAG standalone mode

The M-LAG member devices might both operate with the primary role to forward traffic if they have M-LAG interfaces in up state after the M-LAG system splits. M-LAG standalone mode helps avoid traffic forwarding issues in this multi-active situation by allowing only the member ports in the M-LAG interfaces on one member device to forward traffic.

The following information describes the operating mechanism of this feature.

The M-LAG member devices change to M-LAG standalone mode when they detect that both the peer link and the keepalive link are down. In addition, the secondary M-LAG member device changes its role to primary.

In M-LAG standalone mode, the LACPDUs sent out of an M-LAG interface by each M-LAG member device contain the interface-specific LACP system MAC address and LACP system priority.

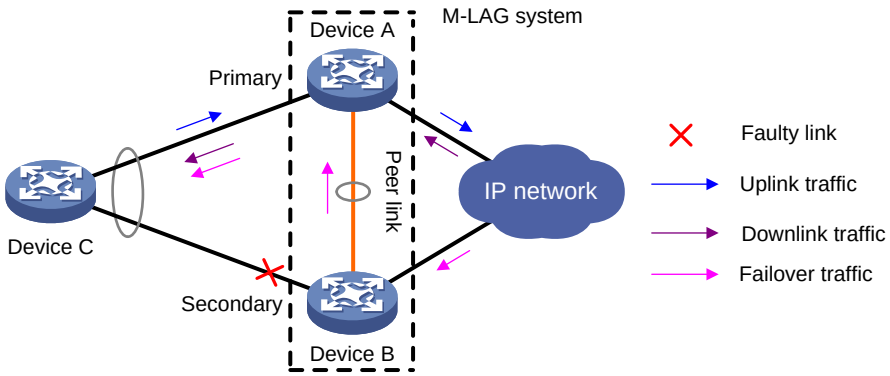
The Selected state of the member ports in the M-LAG interfaces in an M-LAG group depends on their LACP system MAC address and LACP system priority. If an M-LAG interface has a lower LACP system priority value or LACP system MAC address, the member ports in that M-LAG interface become Selected to forward traffic. If those Selected ports fail, the member ports in the M-LAG interface on the other M-LAG member device become Selected to forward traffic.

NOTE:

An M-LAG member device changes to M-LAG standalone mode only when it detects that both the peer link and the keepalive link are down. It does not change to M-LAG standalone mode when the peer M-LAG member device reboots.

M-LAG failure handling mechanisms

M-LAG interface failure handling mechanism



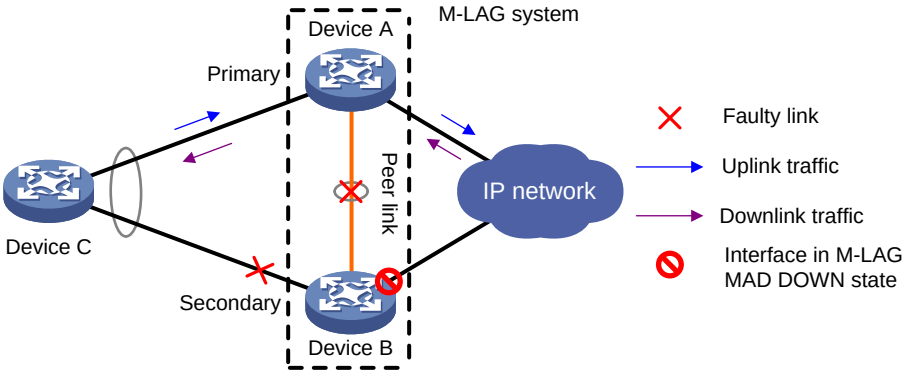
When the M-LAG interface of one M-LAG member device fails, the M-LAG system forwards traffic through the other M-LAG member device.

As shown in Figure 9, Device A and Device B form an M-LAG system, to which Device C is attached through a multichassis aggregation. If traffic to Device C arrives at Device B after the M-LAG interface connected Device B to Device C has failed, the M-LAG system forwards the traffic as follows:

1. Device B sends the traffic to Device A over the peer link.
2. Device A forwards the downlink traffic received from the peer link to Device C.

After the faulty M-LAG interface comes up, Device B forwards traffic to Device C through the M-LAG interface.

Figure 9 M-LAG interface failure handling mechanism



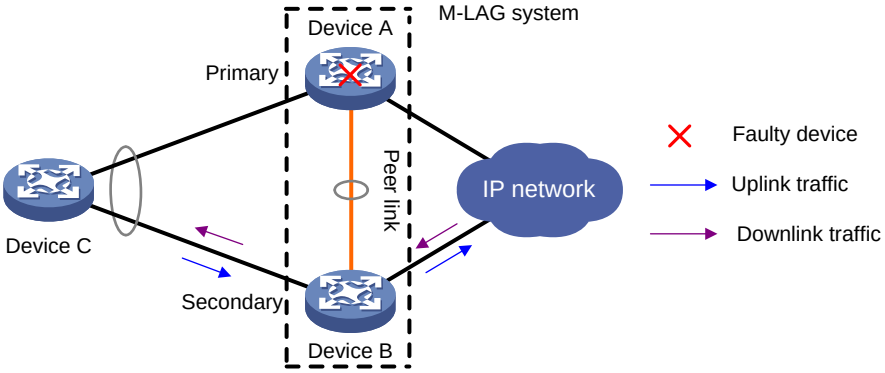
Peer link failure handling mechanism

As shown in Figure 10, multi-active collision occurs if the the peer link goes down while the keepalive link is up. To avoid network issues, the secondary M-LAG device sets all network interfaces to M-LAG MAD DOWN state, except for the interfaces excluded from the shutdown action by M-LAG MAD.

In this situation, the primary M-LAG member device forwards all traffic for the M-LAG system.

When the peer-link interface comes up, the secondary M-LAG member device does not bring up the network interfaces immediately. Instead, it starts a delay timer and begins to recover data from the primary M-LAG member device. When the delay timer expires, the secondary M-LAG member device brings up all network interfaces.

Figure 10 Peer link failure handling mechanism

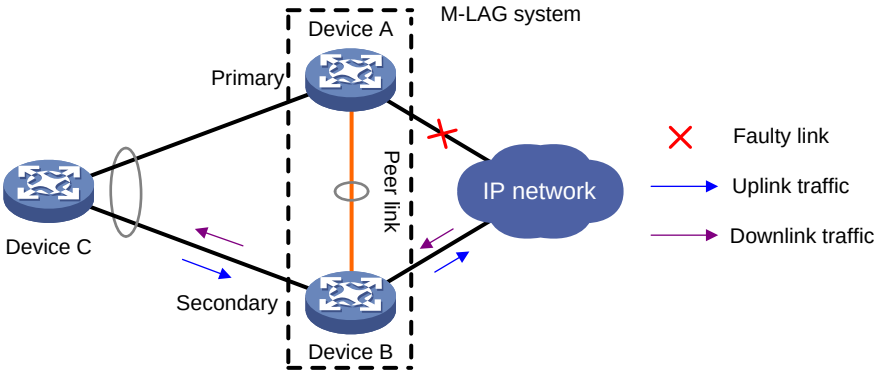


Device failure handling mechanism

As shown in Figure 11, when the primary M-LAG member device fails, the secondary M-LAG member device takes over the primary role to forward all traffic for the M-LAG system. When the faulty device recovers, it becomes the secondary M-LAG member device.

When the secondary M-LAG member device fails, the primary M-LAG member device forwards all traffic for the M-LAG system.

Figure 11 Device failure handling mechanism



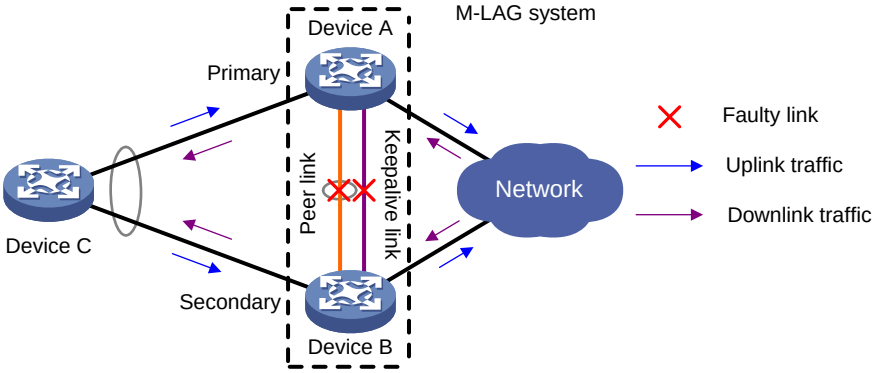
Uplink failure handling mechanism

Uplink failure does not interrupt traffic forwarding of the M-LAG system. As shown in Figure 12, when the uplink of Device A fails, Device A passes traffic destined for the IP network to Device B for forwarding.

To enable faster traffic switchover in response to an uplink failure and minimize traffic losses, configure Monitor Link to associate the M-LAG interfaces with the uplink interfaces. When the uplink interface of an M-LAG member device fails, that device shuts down its M-LAG interface for the other M-LAG member device to forward all traffic of Device C. For more information about Monitor Link, see *High Availability Configuration Guide*.

Figure 12 Uplink failure handling mechanism

Mechanisms to handle concurrent peer link and keepalive link failures



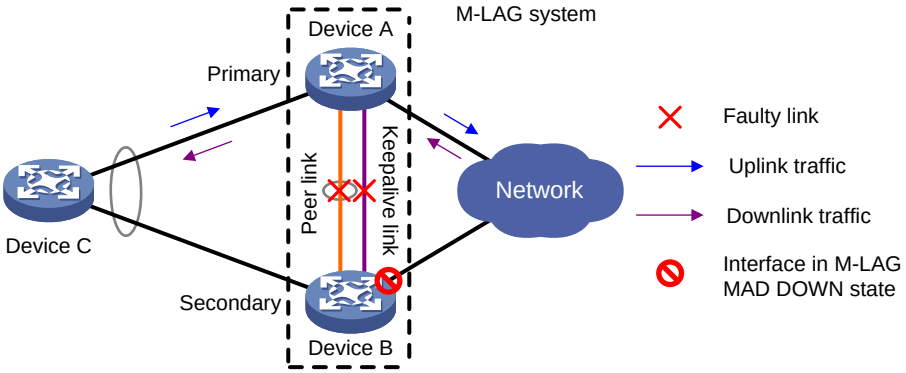
When both the peer link and the keepalive link are down, the M-LAG member devices handle this situation depending on your configuration.

Default failure handling mechanism

Figure 13 shows the default mechanism to handle peer link and keepalive link failures when the M-LAG standalone mode and M-LAG MAD DOWN state persistency features are not configured.

- If the peer link goes down while the keepalive link is up, the M-LAG member devices negotiate their roles over the keepalive link. M-LAG MAD shuts down all network interfaces on the secondary M-LAG member device except those excluded from the shutdown action by M-LAG MAD.
- If the keepalive link goes down while the peer link is down, the secondary M-LAG member device sets its role to primary and brings up the network interfaces in M-LAG MAD DOWN state to forward traffic. In this situation, both of the M-LAG member devices might operate with the primary role to forward traffic. Forwarding errors might occur because the M-LAG member devices cannot synchronize MAC address entries over the peer link.
- If the keepalive link is down before the peer link goes down, M-LAG MAD will not place network interfaces in M-LAG MAD DOWN state. Both M-LAG member devices can operate with the primary role to forward traffic.

Figure 13 Default failure handling mechanism



Failure handling mechanism with M-LAG MAD DOWN state persistence

Figure 14 shows the mechanism to handle peer link and keepalive link failures when the M-LAG MAD DOWN state persistence feature is configured.

- If the peer link goes down while the keepalive link is up, the M-LAG member devices negotiate their roles over the keepalive link. M-LAG MAD shuts down all network interfaces on the secondary M-LAG member device except those excluded from the shutdown action by M-LAG MAD.
- If the keepalive link goes down while the peer link is down, the secondary M-LAG member device sets its role to primary, but it does not bring up the network interfaces in M-LAG MAD DOWN state. Only the original primary member device can forward traffic.
- If the keepalive link is down before the peer link goes down, M-LAG MAD will not place network interfaces in M-LAG MAD DOWN state. Both M-LAG member devices can operate with the primary role to forward traffic.

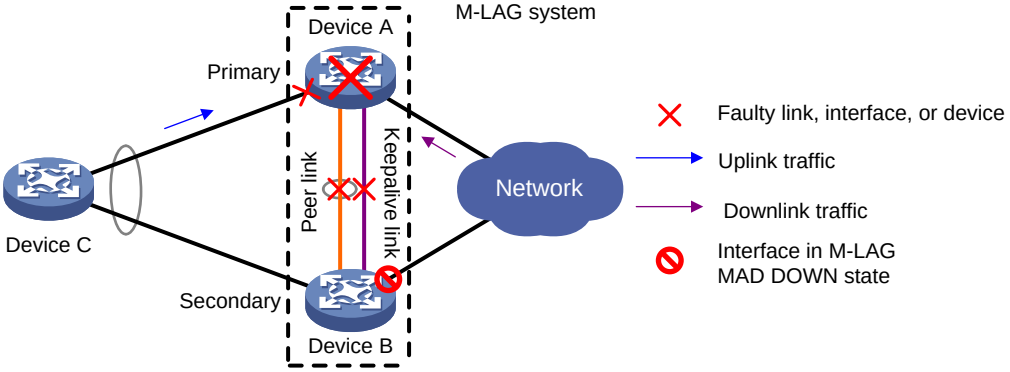


Figure 14 Failure handling mechanism with M-LAG MAD DOWN state persistence

As shown in Figure 15, you can bring up the interfaces in M-LAG MAD DOWN state on the secondary M-LAG member device for it to forward traffic if the following conditions exist:

- Both the peer link and the keepalive link are down.
- The primary M-LAG member device fails or its M-LAG interface fails.

Figure 15 Bringing up the interfaces in M-LAG MAD DOWN state

Failure handling mechanism with M-LAG standalone mode

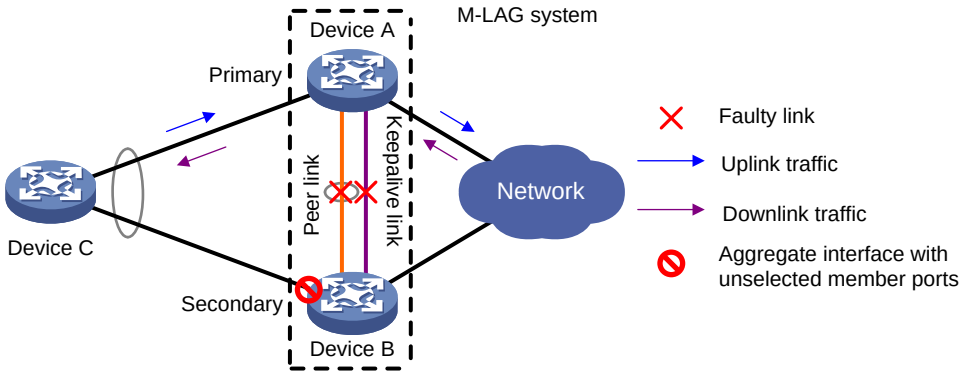

Figure 16 shows the mechanism to handle peer link and keepalive link failures when the M-LAG standalone mode feature is configured.

- If the peer link goes down while the keepalive link is up, the M-LAG member devices negotiate their roles over the keepalive link. M-LAG MAD shuts down all network interfaces on the

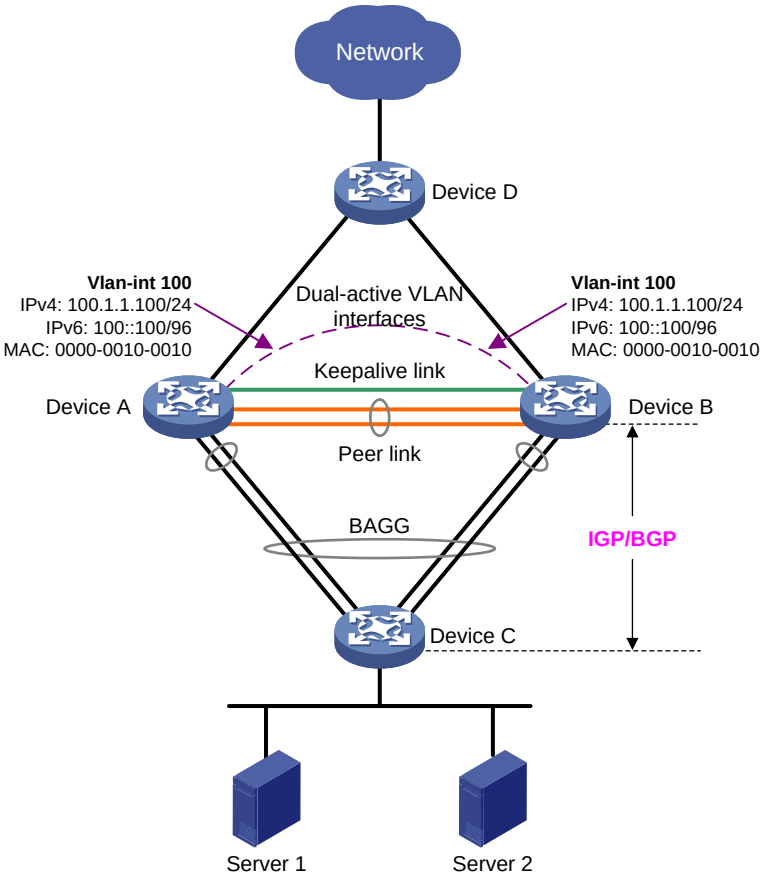
secondary M-LAG member device except those excluded from the shutdown action by M-LAG MAD.

- If the keepalive link goes down while the peer link is down, both M-LAG member devices change to M-LAG standalone mode. The secondary M-LAG member device sets its role to primary and brings up its network interfaces in M-LAG MAD DOWN state. In M-LAG standalone mode, only the aggregation member ports on one M-LAG member device can become Selected to forward traffic. For more information about how M-LAG standalone mode operates, see "M-LAG standalone mode."
- If the keepalive link is down before the peer link goes down, both M-LAG member devices change to M-LAG standalone mode.

Figure 16 Failure handling mechanism with M-LAG standalone mode

Extended M-LAG features

Dual-active gateways on an M-LAG system



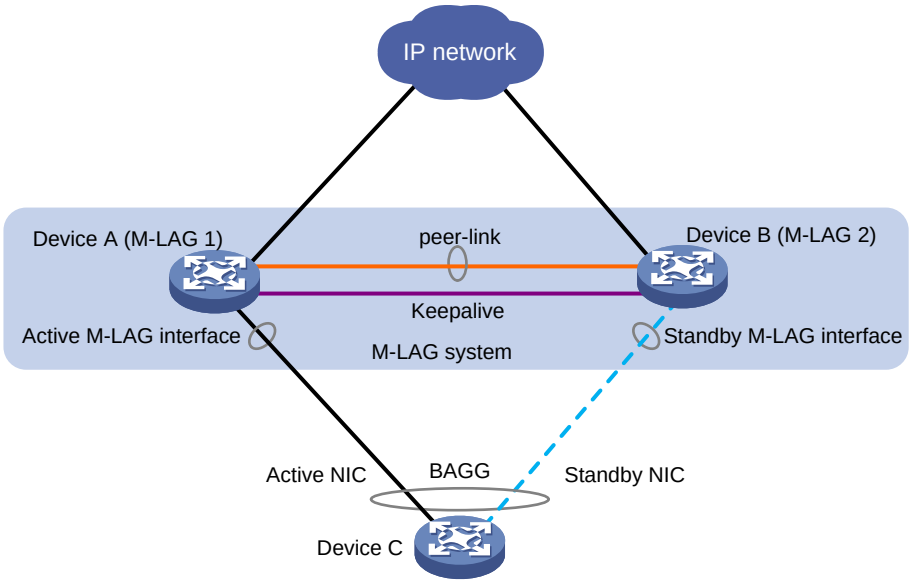
When a Layer 3 network is dualhomed to an M-LAG system, each M-LAG member device uses a logical interface as the gateway interface for the Layer 3 network. Both logical interfaces are active to perform Layer 3 forwarding, and they use the same IP address and MAC address. When both links to the M-LAG system are operating correctly, the links load share traffic to balance bandwidth usage. When one of the links fails, the M-LAG system switches the traffic on the failed link to the other link to ensure high availability.

Typically, dual-active gateways are deployed if downstream devices run a dynamic routing protocol to communicate with the M-LAG system. As shown in Figure 17, IGP or BGP runs between Device C and the M-LAG system. To configure dual-active VLAN interfaces, perform the following tasks on Device A and Device B:

1. Create VLAN interfaces for the same VLAN, VLAN-interface 100 for example, assign the same IPv4, IPv6, and MAC addresses to the VLAN interfaces, and assign the M-LAG interfaces to that VLAN.
2. Assign different M-LAG VIPs to the VLAN interfaces.

Device A and Device B use their M-LAG VIPs to set up IGP or BGP peer relationships with Device C and with each other.

Figure 17 Layer 3 access to an M-LAG system through dynamic routing protocols

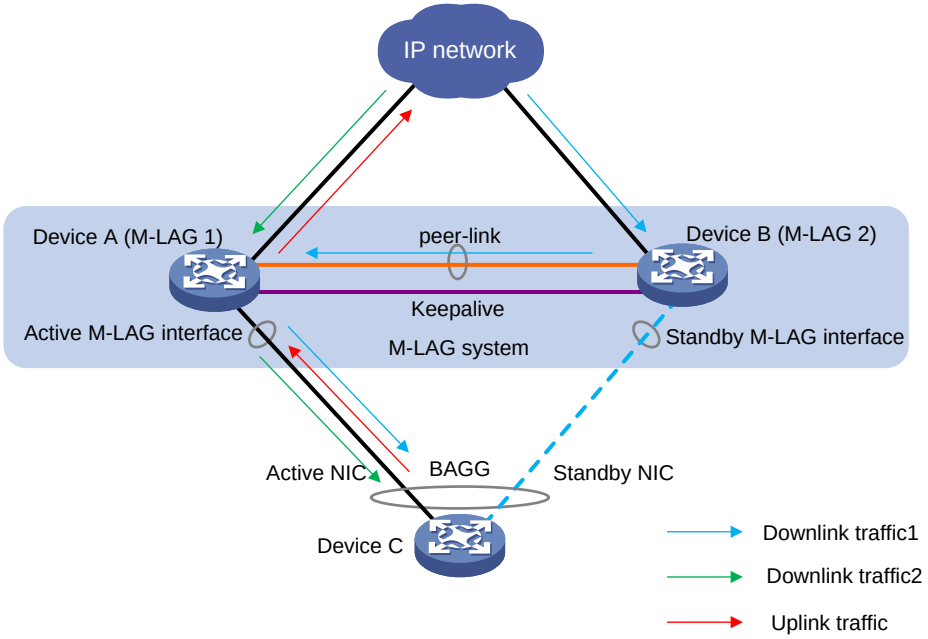


M-LAG active/standby mode

About M-LAG active/standby mode

By default, M-LAG interfaces on two M-LAG member devices forward traffic for load sharing. However, when a device with active and standby NICs connects to the M-LAG system, only the active NIC can send, receive, and process traffic. As a result, the dual-active mode of M-LAG interfaces for load sharing is not applicable. In this scenario, configure the M-LAG interfaces to operate in active/standby mode. Then, only the M-LAG interface connected to the active NIC can forward traffic.

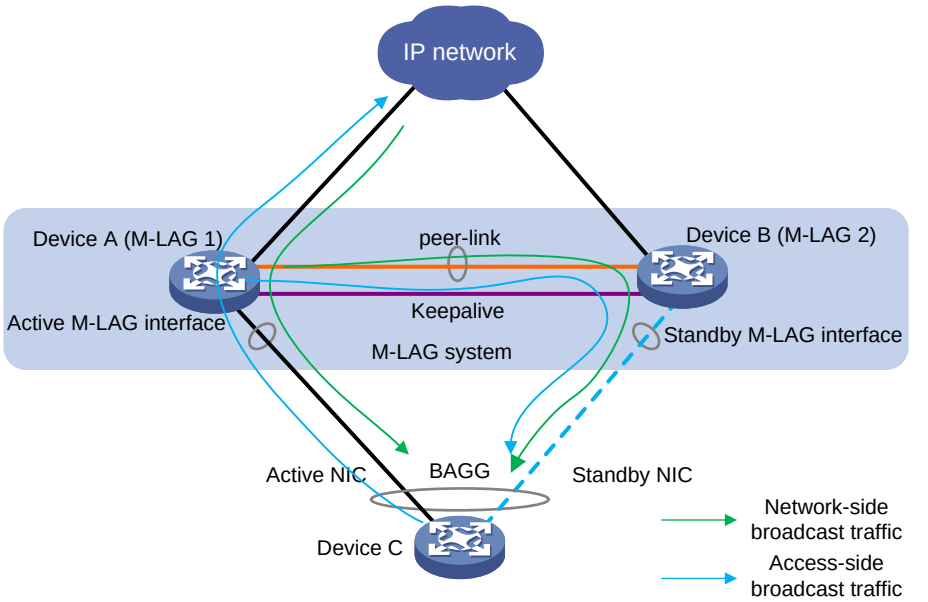
Figure 18 M-LAG active/standby mode network model



As shown in Figure 18, in active/standby mode, only the M-LAG interface connected to the active NIC sends and receives traffic in normal conditions, and this M-LAG interface is called the active M-LAG interface. The M-LAG interface connected to the standby NIC acts as a backup and does not send or receive traffic, and this M-LAG interface is called the standby M-LAG interface. When the active M-LAG interface fails, the standby M-LAG interface takes over to forward traffic.

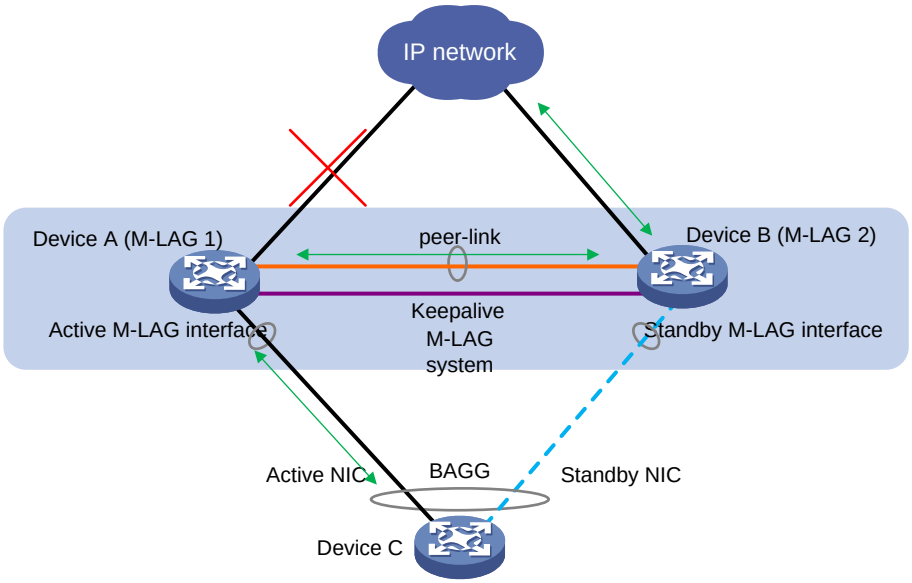
In an M-LAG system, the active and standby M-LAG interfaces are elected based on protocol packets sent by the active NIC. The M-LAG interface that receives protocol packets from the active NIC becomes the active M-LAG interface, while the M-LAG interface on the other end becomes the standby M-LAG interface. The roles of the active/standby M-LAG interfaces do not change or restore proactively. If an active/standby NIC switchover occurs on the device connected to M-LAG interfaces, the M-LAG interface that receives the protocol packets for election changes to trigger a re-election. Then, the roles of the active/standby M-LAG interfaces change.

In the current software version, the following types of protocol packets are supported for election: ARP, DHCP, IGMP, MLD, and ND.



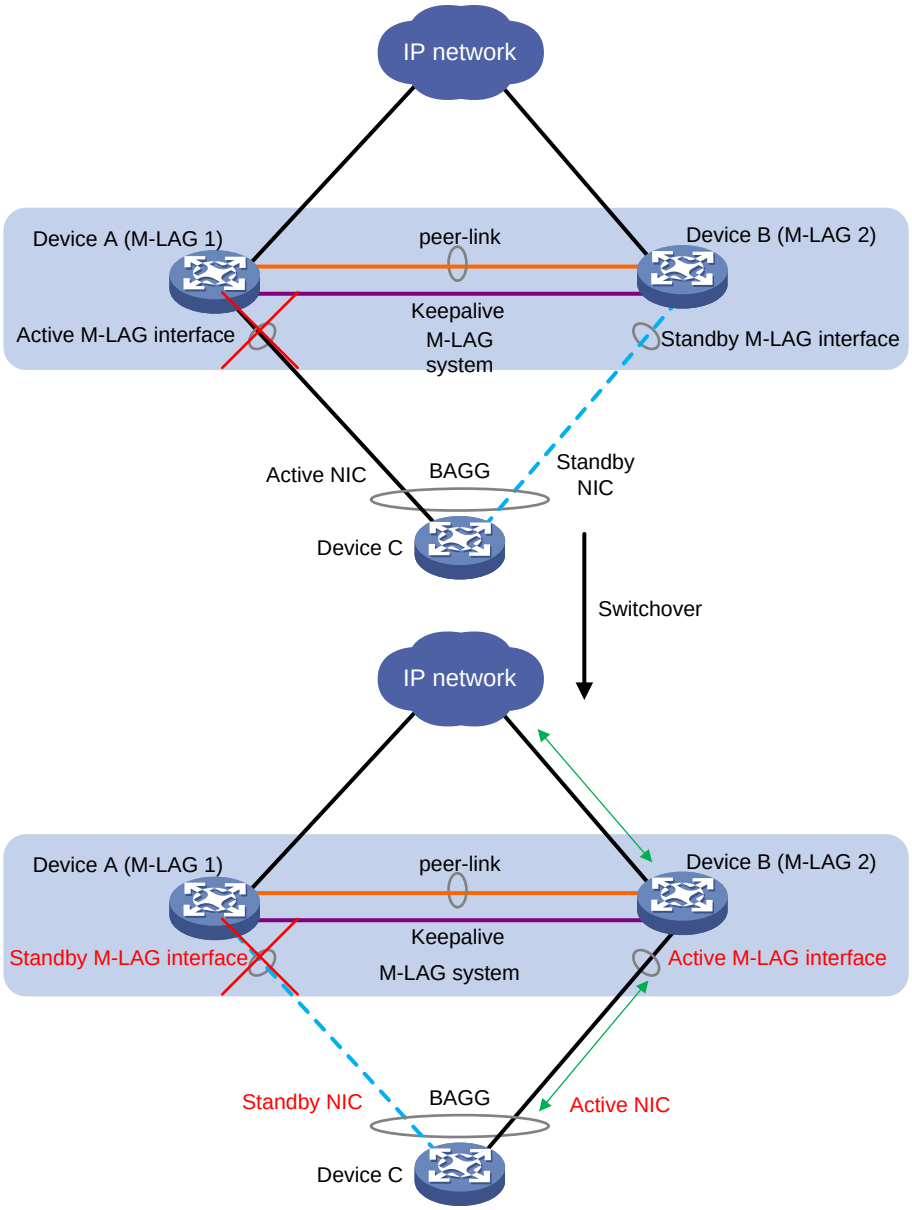
Traffic forwarding mechanism in M-LAG active/standby mode

Figure 19 M-LAG unicast and multicast traffic forwarding mechanism in normal state



As shown in Figure 19, in normal state, the access device only sends uplink unicast and multicast traffic out the active NIC. After the active M-LAG interface receives the traffic, the M-LAG interface directly forwards the traffic out the uplink interface of the local M-LAG member device. For downlink unicast and multicast traffic, if the network-side traffic is sent to the device with the active M-LAG interface, the device forwards the traffic directly out the active M-LAG interface to the access device. If the network-side traffic is sent to the device with the standby M-LAG interface, the device must reroute the traffic through the peer link to the device with the active M-LAG interface. Then, the device with the active M-LAG interface forwards the traffic out the active M-LAG interface to the access device.

Figure 20 Broadcast traffic forwarding mechanism in normal state



As shown in Figure 20, in normal state, whether the broadcast traffic comes from the network side or the access side, the device with the active M-LAG interface forwards the received broadcast traffic to all interfaces. The peer M-LAG device also forwards the received broadcast traffic to the access device through the M-LAG interface. Therefore, the access device will receive the broadcast traffic that it sends out. However, no loop will occur because the standby NIC does not process traffic.

Figure 21 Traffic forwarding mechanism when the uplink fails but the active M-LAG interface is normal

As shown in Figure 21, when the uplink of the device with the active M-LAG interface fails but the active M-LAG interface is normal, both uplink and downlink traffic need to bypass the device with the standby M-LAG interface for forwarding. The access device still receives traffic through the active NIC.

Figure 22 Traffic forwarding mechanism when the active M-LAG interface is unavailable

As shown in Figure 22, the active M-LAG interface becomes unavailable when a downlink fault or device fault occurs on the device with the active M-LAG interface. When the active NIC of the access device detects the link fault, the access device performs an active/standby NIC switchover. After the original standby M-LAG interface receives protocol packets sent by the new active NIC, it triggers a re-election and becomes the active M-LAG interface. Subsequently, the new active M-LAG interface sends and receives traffic to and from the access device.

M-LAG sequence number check

M-LAG sequence number check protects M-LAG member devices from replay attacks.

With this feature enabled, the M-LAG member devices insert a sequence number into each outgoing DRCPDU or keepalive packet and the sequence number increases by 1 for each sent packet. When receiving a DRCPDU or keepalive packet, the M-LAG member devices check its sequence number and drop the packet if the check result is either of the following:

- The sequence number of the packet is the same as that of a previously received packet.

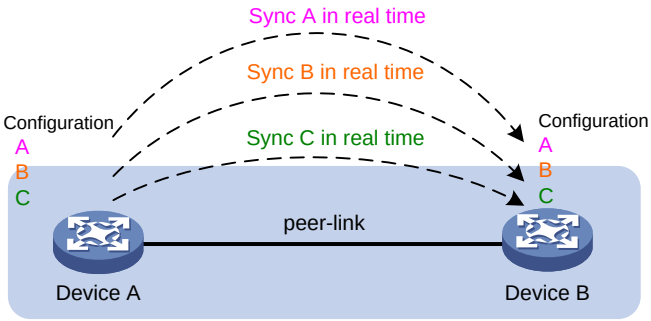
- The sequence number of the packet is smaller than that of the most recently received packet.

M-LAG packet authentication

M-LAG packet authentication prevents DRCPDU and keepalive packet tampering from causing link flapping.

With this feature enabled, the M-LAG member devices compute a message digest by using an authentication key for each outgoing DRCPDU or keepalive packet and insert the message digest into the packet. When receiving a DRCPDU or keepalive packet, an M-LAG member device computes a message digest and compares it with the message digest in the packet. If the message digests match, the packet passes authentication. If the message digests do not match, the device drops the packet.

Multichassis configuration synchronization



Multichassis configuration synchronization (sync) allows you to synchronize and back up configurations between multiple devices to simplify the configuration procedure, improve deployment efficiency, and optimize user experience. For example, after you configure one M-LAG member device, you can synchronize its configuration to the other M-LAG member device over the peer link for them to have identical configuration.

This feature is applicable only to an M-LAG system currently.

Real-time configuration sync

As shown in Figure 23, settings in multichassis configuration sync view of a member device are synchronized to its peer device in real time.

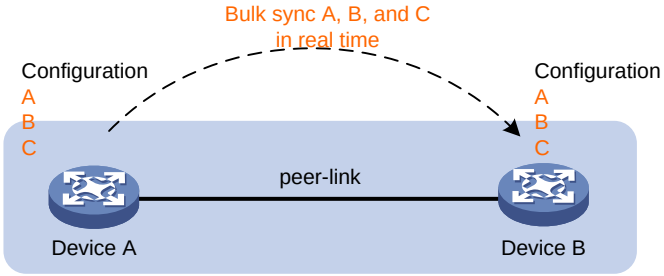


Figure 23 Real-time configuration sync

Bulk configuration sync

To fast deploy the services that are required to be consistent across the M-LAG member devices, configure the services on an M-LAG member device before M-LAG system setup. After the M-LAG system is set up and the peer link comes up, you can bulk synchronize settings on the member device to the same view for multichassis configuration sync on the M-LAG peer, as shown in Figure 24.

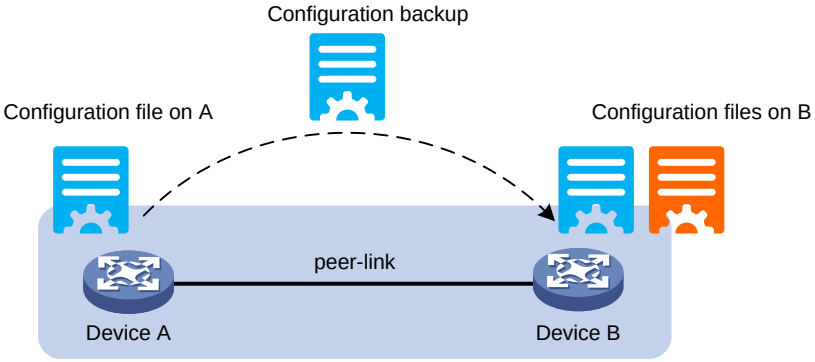

Figure 24 Bulk configuration sync

Configuration backup

If you are to update an M-LAG member device, for example, update the software version or replace the device, back up its configuration file to the M-LAG peer in advance as shown in Figure 25. After the update is completed, you can retrieve the previously saved configuration file from the peer device.

Figure 25 Configuration backup

Protocols and standards

IEEE P802.1AX-REV™/D4.4c, *Draft Standard for Local and Metropolitan Area Networks*

Configuring M-LAG

Feature and hardware compatibility

The S5200-EI-G switch series does not support M-LAG.

Restrictions and guidelines: M-LAG configuration

Software version requirements

The M-LAG member devices in an M-LAG system must use the same software version.

During an upgrade, the CLI of the peer M-LAG member device is locked after the local M-LAG member device is upgraded and rebooted. You cannot operate the CLI of the peer M-LAG member

device. To unlock the CLI of the peer M-LAG member device, perform a primary/secondary role switchover or restart the M-LAG process of the device.

M-LAG configuration

For the M-LAG member devices to be identified as one M-LAG system, you must configure the same M-LAG system MAC address and M-LAG system priority on them. You must assign different M-LAG system numbers to the M-LAG member devices.

The M-LAG interfaces in the same M-LAG group must use different LACP system MAC addresses.

To ensure correct forwarding, delete M-LAG configuration from an M-LAG member device if it leaves its M-LAG system.

As a best practice to reduce the impact of interface flapping on upper-layer services, use the **link-delay** command to configure the same link delay settings on the peer-link interfaces.

In an M-LAG system, two peer-link interfaces must have the same configuration for the maximum jumbo frame length.

As a best practice, establish a directly connected physical link between the M-LAG member devices as the keepalive link and use this link for the sole purpose of keepalive detection. When the keepalive link uses the IP address of a VLAN interface, do not assign the peer-link interface to the VLAN corresponding to the VLAN-interface. If you do that, the keepalive mechanism might fail.

To configure dual-active gateways for an M-LAG system, first set up the M-LAG system.

Compatibility with other features

An M-LAG member device does not support the following service features. Do not configure these service features on an M-LAG system.

- MVRP.
- IPsec.
- DNS.

For correct traffic forwarding, make sure the M-LAG member devices are consistent in service feature settings.

GIR

Before you change an M-LAG system back to normal mode by using the **undo gir system-mode maintenance** command, execute the **display m-lag mad verbose** command to verify that no network interfaces are in M-LAG MAD DOWN state. For information about GIR, see *Fundamentals Configuration Guide*.

IRF

M-LAG cannot work correctly on an IRF fabric. Do not configure M-LAG on an IRF fabric. For more information about IRF, see *Virtual Technologies Configuration Guide*.

MAC address table

If the M-LAG system has a large number of MAC address entries, set the MAC aging timer to a higher value than 20 minutes as a best practice. To set the MAC aging timer, use the **mac-address timer** command.

To ensure correct Layer 3 unicast forwarding, disable static source check on aggregate interfaces acting as peer-link interfaces by using the **undo mac-address static source-check enable** command.

The MAC address learning feature is disabled on the peer-link interface.

For more information about the MAC address table, see "Configuring the MAC address table."

Ethernet link aggregation

Do not configure automatic link aggregation on an M-LAG system.

The aggregate interfaces in an S-MLAG group cannot be used as M-LAG interfaces or peer-link interfaces.

You cannot configure link aggregation management subnets on an M-LAG system.

When you configure an M-LAG interface, follow these restrictions and guidelines:

- The **link-aggregation selected-port minimum** command does not take effect on an M-LAG interface.
- If you execute the **display link-aggregation verbose** command for an M-LAG interface, the displayed system ID contains the M-LAG system MAC address and the M-LAG system priority.
- If the reference port is a member port of an M-LAG interface, the **display link-aggregation verbose** command displays the reference port on both M-LAG member devices.

For more information about Ethernet link aggregation, see "Configuring Ethernet link aggregation."

Port isolation

Do not assign peer-link interfaces to a port isolation group. For more information about port isolation, see "Configuring port isolation."

Loop detection

Member devices in an M-LAG system must have the same loop detection configuration. For information about loop detection, see "Configuring loop detection."

Spanning tree

When the spanning tree protocol is enabled for an M-LAG system, follow these restrictions and guidelines:

- Make sure the M-LAG member devices have the same spanning tree configuration. Violation of this rule might cause network flapping. The configuration includes:
  - Global spanning tree configuration.
  - Spanning tree configuration on the peer-link interface.
  - Spanning tree configuration on M-LAG interfaces.
- Peer-link interfaces of the M-LAG system do not participate in spanning tree calculation.
- The M-LAG member devices still use the M-LAG system MAC address after the M-LAG system splits, which will cause spanning tree calculation issues. To avoid the issues, enable M-LAG standalone mode on the M-LAG member devices before the M-LAG system splits.

For more information about spanning tree, see "Configuring spanning tree."

ICMP

An M-LAG system does not support sending ICMPv4 or ICMPv6 redirect messages. These features are configurable with the **ip redirects enable** and **ipv6 redirects enable** commands.

DHCP snooping

Do not use DHCP snooping and QinQ together on an M-LAG system. DHCP snooping cannot operate correctly when QinQ is configured.

AAA

On an M-LAG system, you must specify a virtual IP address as the source IP address of outgoing RADIUS packets.

When RADIUS DAS is enabled, an M-LAG system does not support shutting down or rebooting the access ports for 802.1X authentication users or reauthenticating the users through CoA messages.

For more information about AAA, see *Security Configuration Guide*.

Portal

Before you configure portal authentication to support M-LAG, you must complete the following tasks on both the primary and secondary M-LAG member devices:

- Enable portal authentication.
- Configure IPv4 portal authentication or IPv6 portal authentication.
- Set the portal authentication mode.
- Enable or disable MAC-based quick portal authentication.
- Set the free-traffic threshold.
- Enable portal fail-permit for a portal authentication server.
- Configure the URL of the portal Web server.
- Configure portal user roaming.
- Enable or disable portal authentication to support IPv4/IPv6 dual stack.

Make sure the above configuration on both the primary and secondary M-LAG member devices is the same.

For information about portal configuration, see *Security Configuration Guide*.

Port security

In an M-LAG system, the M-LAG member devices exchange configuration information with each other to detect whether configuration conflicts exist. The detection does not affect packet forwarding on the M-LAG member devices. If configuration conflicts exist, the M-LAG member devices do not allow new users to come online.

For information about port security configuration, see *Security Configuration Guide*.

Mirroring

For a mirroring group, do not assign the source port to an aggregation group other than the one that accommodates the destination port, egress port, or reflector port. If the source port is in a different aggregation group than the other ports, mirrored LACPDUs will be transmitted between the aggregation groups and cause aggregate interface flapping.

Support for DRNI commands

The M-LAG feature was named DRNI in earlier software versions. For compatibility with earlier software versions, the device supports both M-LAG and DRNI commands.

Table 5 Difference between M-LAG and DRNI commands

Feature name	Keywords	Example
M-LAG	**m-lag**, **mlag**, **peer-link**	**m-lag system-number** *system-number* As a best practice, use M-LAG commands.
DRNI	**drni**, **drmac**, **ipp**	**drni system-number** *system-number* To use configuration files created from an earlier software version, use DRNI commands. The system recognizes only the complete syntaxes of DRNI commands. It does not support displaying available

		keywords and arguments in response to a question mark (?) or automatically completing the last keyword or argument in response to the Tab key. If you execute a DRNI command, the system converts it into the corresponding M-LAG command and saves the M-LAG command in the configuration file.

M-LAG and DRNI commands do not differ in the configuration method or functionality. For more information about the keyword differences, see "Comparison between M-LAG and DRNI commands."

M-LAG tasks at a glance

To configure M-LAG, perform the following tasks:

1. Configuring multichassis configuration sync
2. Configuring M-LAG system settings
   - Configuring the M-LAG system MAC address
   - Setting the M-LAG system number
   - Setting the M-LAG system priority
3. Setting the M-LAG role priority of the device
4. (Optional.) Enabling M-LAG standalone mode on an M-LAG member device
5. Configuring M-LAG keepalive settings
   - Configuring M-LAG keepalive packet parameters
   - Setting the M-LAG keepalive interval and timeout timer
   - Associating the keepalive link with a track entry
6. Configuring M-LAG MAD
   - Configuring the default M-LAG MAD action on network interfaces
   - Excluding an interface from the shutdown action by M-LAG MAD
   - Excluding all logical interfaces from the shutdown action by M-LAG MAD
   - Specifying interfaces to be shut down by M-LAG MAD when the M-LAG system splits
   - Enabling M-LAG MAD DOWN state persistence
7. Configuring interfaces on the M-LAG system
   - Configuring an M-LAG interface
   - Configuring an M-LAG uplink interface
   - Configuring the flapping detection interval for M-LAG uplink interfaces
   - Setting up a peer link
   - (Optional.) Enabling the short DRCP timeout timer on the peer-link interface or an M-LAG interface
   - (Optional.) Configuring the M-LAG active/standby mode
8. (Optional.) Enabling the peer-link interface to retain MAC address entries for down single-homed devices
9. (Optional.) Assigning a M-LAG virtual IP address to an interface

   Configure M-LAG VIPs for devices to communicate with the M-LAG system by using dynamic routing protocols.
10. (Optional.) Configuring M-LAG extra VLANs
11. (Optional.) Configuring configuration consistency check
    - Setting the mode of configuration consistency check

- (Optional.) Disabling configuration consistency check

  Configuration consistency check might fail when you upgrade the M-LAG member devices in an M-LAG system. To prevent the M-LAG system from falsely shutting down M-LAG interfaces, temporarily disable configuration consistency check.

12. Configuring M-LAG timers
    - (Optional.) Setting the keepalive hold timer for identifying the cause of peer link down events
    - Configuring M-LAG system auto-recovery
    - (Optional.) Setting the data restoration interval
13. (Optional.) Configuring M-LAG security features
    - Enabling M-LAG sequence number check
    - Enabling M-LAG packet authentication

Configuring multichassis configuration sync

Restrictions and guidelines for multichassis configuration sync

Real-time or bulk configuration sync synchronizes only configurations required to be consistent across the M-LAG member devices.

Execute the **mc-configure access-local enable** command on both M-LAG member devices for them to access each another.

Before you use the multichassis configuration sync feature, verify that the M-LAG system is operating correctly and the peer link is up.

For more information about the multichassis configuration sync commands, see *Fundamentals Command Reference*.

Synchronizing the configurations in real time

About this task

This feature enables commands executed in multichassis configuration sync view on an M-LAG member device to be synchronized to its M-LAG peer in real time.

Procedure

1. Enter system view.

   system-view
2. Permit the M-LAG peer to access the local device via the sync channel.

   mc-configure access-local enable

   By default, the M-LAG peer is permitted to access the local device via the sync channel.
3. Return to user view.

   quit
4. Enter multichassis configuration sync view.

   system-view mc-config

   Commands executed in any view for multichassis configuration sync will be synchronized to the M-LAG peer in real time.

Bulk synchronizing the configurations

About this task

To fast deploy the services that are required to be consistent across the M-LAG member devices, configure the services on an M-LAG member device before M-LAG system setup. After the M-LAG system is set up and the peer link comes up, you can use this feature to bulk synchronize settings on the member device to the same view for multichassis configuration sync on the M-LAG peer.

Procedure

1. Enter system view.
   `system-view`
2. Permit the M-LAG peer to access the local device via the sync channel.
   `mc-configure access-local enable`
   By default, the M-LAG peer is permitted to access the local device via the sync channel.
3. Configure required settings in system view or any view under system view.
4. Return to user view.
   `quit`
5. Enter multichassis configuration sync view.
   `system-view mc-config`
6. Bulk synchronize the settings to the M-LAG peer.
   `mc-configure batch-synchronize`
   You can execute this command in any view for multichassis configuration sync.

Fast configuring differential settings

About this task

For settings required only on the local device, you can execute the **`mc-configure switch-to-local`** command in any view for multichassis configuration sync to switch to the same view of the local device and then configure the settings. To return to the original view for multichassis configuration sync after configuring the settings on the local device, execute the **`mc-configure quit`** command or press **Ctrl+Q**.

For the settings required only on the peer device, you can execute the **`mc-configure switch-to-peer`** in any view for multichassis configuration sync of the local device to switch to the same view of the peer device and then configure the settings. To return to the original view for multichassis configuration sync after configuring the settings on the peer device, execute the **`mc-configure quit`** command or press **Ctrl+Q**.

Configuring the differential settings on the local device

1. Enter multichassis configuration sync view.
   `system-view mc-config`
2. Switch to the same view of the local device.
   [@local] will be added to the commands executed in any view of the local device.
   `mc-configure switch-to-local`
   You can execute this command in any view for multichassis configuration sync.
3. Configure the differential commands on the local device.
4. Return to the original view for multichassis configuration sync.
   `mc-configure quit`

Configuring the differential settings on the M-LAG peer

1. Enter multichassis configuration sync view.
   system-view mc-config
2. Switch to the same view of the M-LAG peer.
   [@peer] will be added to the commands executed in any view of the peer device.
   mc-configure switch-to-local
   You can execute this command in any view for multichassis configuration sync.
3. Configure the differential commands on the M-LAG peer.
4. Return to the original view for multichassis configuration sync.
   mc-configure quit

Backing up and restoring a configuration file

About this task

To update an M-LAG member device, for example, update the software version or replace the device, you can the **mc-configure backup-to-peer** command to back up its configuration file to the M-LAG peer in advance. After the update is completed, you can use the **mc-configure get-from-peer** command to retrieve the previously saved configuration file from the peer device and replace the configuration file on the local device.

Procedure

Execute the following command in user view to save the local configuration file to the M-LAG peer.

mc-configure backup-to-peer *local-filename*

Execute the following command in user view to retrieve the configuration file from the M-LAG peer.

mc-configure get-from-peer *filename*

Configuring M-LAG system settings

Configuring the M-LAG system MAC address

Restrictions and guidelines

On an M-LAG system, M-LAG interfaces in the same M-LAG group must use the same LACP system MAC address. As a best practice, use the bridge MAC address of one M-LAG member device as the M-LAG system MAC address.

Changing the M-LAG system MAC address causes M-LAG system split. When you perform this task on a live network, make sure you are fully aware of its impact.

You can configure the M-LAG system MAC address on an aggregate interface only after it is configured as an M-LAG interface.

You can configure the M-LAG system MAC address globally and in aggregate interface view. The global M-LAG system MAC address takes effect on all aggregation groups. On an aggregate interface, the interface-specific M-LAG system MAC address takes precedence over the global M-LAG system MAC address.

Procedure

1. Enter system view.
   system-view
2. Configure the M-LAG system MAC address.

m-lag system-mac { *bridge-address* | *mac-address* }

By default, the M-LAG system MAC address is not configured.

3. Enter Layer 2 aggregate interface view.

   interface bridge-aggregation *interface-number*

4. Set the M-LAG system MAC address on the aggregate interface.

   port m-lag system-mac *mac-address*

   By default, the M-LAG system MAC address is not configured.

Setting the M-LAG system number

Restrictions and guidelines

Changing the M-LAG system number causes M-LAG system split. When you perform this task on a live network, make sure you are fully aware of its impact.

You must assign different M-LAG system numbers to the M-LAG member devices in an M-LAG system.

Procedure

1. Enter system view.

   system-view

2. Set the M-LAG system number.

   m-lag system-number *system-number*

   By default, the M-LAG system number is not set.

Setting the M-LAG system priority

About this task

An M-LAG system uses its M-LAG system priority as the system LACP priority to communicate with the remote aggregation system.

Restrictions and guidelines

Changing the M-LAG system priority in system view causes M-LAG system split. When you perform this task on a live network, make sure you are fully aware of its impact.

You must configure the same M-LAG system priority for the M-LAG interfaces in the same M-LAG group.

You can configure the M-LAG system priority on an aggregate interface only after it is configured as an M-LAG interface.

You can configure the M-LAG system priority globally and in aggregate interface view. The global M-LAG system priority takes effect on all aggregation groups. On an aggregate interface, the interface-specific M-LAG system priority takes precedence over the global M-LAG system priority.

Procedure

1. Enter system view.

   system-view

2. Set the M-LAG system priority.

   m-lag system-priority *system-priority*

   By default, the M-LAG system priority is 32768.

3. Enter Layer 2 aggregate interface view.

   interface bridge-aggregation *interface-number*

4. Set the M-LAG system priority on the aggregate interface.

   port m-lag system-priority *priority*

   By default, the M-LAG system priority is 32768.

Setting the M-LAG role priority of the device

About this task

M-LAG assigns the primary or secondary role to an M-LAG member device based on its M-LAG role priority. The smaller the priority value, the higher the priority. If the M-LAG member devices in an M-LAG system use the same M-LAG role priority, the device with the lower bridge MAC address is assigned the primary role.

Restrictions and guidelines

To prevent a primary/secondary role switchover from causing network flapping, avoid changing the M-LAG priority assignment after the M-LAG system is established.

Procedure

1. Enter system view.

   system-view

2. Set the M-LAG role priority of the device.

   m-lag role priority *priority-value*

   By default, the M-LAG role priority of the device is 32768.

Enabling M-LAG standalone mode on an M-LAG member device

About this task

Perform this task to avoid forwarding issues in the multi-active situation that might occur after both the peer link and the keepalive link are down.

M-LAG standalone mode helps avoid traffic forwarding issues in this multi-active situation by allowing only the member ports in the M-LAG interfaces on one member device to forward traffic. For more information about this mode, see "M-LAG standalone mode."

When you configure this feature, you can configure a delay to prevent an unnecessary mode change because of transient link down issues.

Restrictions and guidelines

An M-LAG member device changes to M-LAG standalone mode only when it detects that both the peer link and the keepalive link are down. It does not change to M-LAG standalone mode when the peer M-LAG member device reboots. As a best practice, set the delay that the device must wait before changing to M-LAG standalone mode based on the cause of simultaneous failure of the peer link and keepalive link:

- If the cause is device poweroff, set the delay to be longer than the time required to finish a device reboot.
- For any other causes, reduce the delay to speed up transition to M-LAG standalone mode.

As a best practice, enable M-LAG standalone mode on both M-LAG member devices.

If the MAC address of an M-LAG system does not correspond to any actual MAC address on any M-LAG member device, and the M-LAG interface contains multiple aggregation member ports, enabling the M-LAG standalone mode might cause the aggregation member ports of the M-LAG

interface to flap. Make sure you are fully aware of the impact of this feature when you use it on a live network.

In a single-level M-LAG network, before you enable M-LAG standalone mode on an M-LAG member device, make sure its LACP system priority is higher than that of the remote aggregation system. This restriction ensures that the reference port is on the remote aggregation system and prevents the interfaces attached to the M-LAG system from flapping.

Procedure

1. Enter system view.

   system-view

2. Enable M-LAG standalone mode.

   m-lag standalone enable [**delay** *delay-time*]

   By default, M-LAG standalone mode is disabled.

Configuring M-LAG keepalive settings

Restrictions and guidelines for configuring M-LAG keepalive settings

As a best practice, establish a direct physical link between the M-LAG member devices as the keepalive link and use that link only for keepalive detection purposes. Make sure the link has both Layer 2 and Layer 3 connectivity.

Make sure the two ends use the same keepalive settings. M-LAG member devices check the peer keepalive settings for consistency. If an inconsistency is found, the device will prompt for configuration revision.

Configuring M-LAG keepalive packet parameters

About this task

Perform this task to specify the parameters for sending M-LAG keepalive packets, such as its source and destination IP addresses.

The device accepts only keepalive packets that are sourced from the specified destination IP address. The keepalive link goes down if the device receives keepalive packets sourced from any other IP address. To improve reliability, use both the **m-lag keepalive** { **ip** | **ipv6** } and **m-lag keepalive standby** { **ip** | **ipv6** } commands to configure the primary and standby keepalive links.

In normal conditions, the primary keepalive link is used to transmit keepalive packets. When the primary keepalive link does not receive keepalive packets within a certain time, the standby link is used to transmit keepalive packets.

If the primary and standby keepalive links both fail to receive keepalive packets within a certain time, they are both considered DOWN, and the system detects a keepalive link fault.

Restrictions and guidelines

Make sure the source and destination IP addresses of M-LAG keepalive packets have Layer 3 connectivity.

If you do not specify the **source** keyword, the keepalive interface might fail to be excluded from the shutdown action by M-LAG MAD. For the keepalive interface to be excluded from the shutdown action by M-LAG MAD, you must specify the **source** keyword.

Make sure the M-LAG member devices in an M-LAG system use the same keepalive destination UDP port.

The standby keepalive link uses the same UDP port as the primary link, so you do not need to configure the UDP port.

Procedure

1. Enter system view.

   system-view

2. Configure the primary keepalive link.

   m-lag keepalive { **ip** | **ipv6** } **destination** { *ipv4-address* | *ipv6-address* } [**source** { *ipv4-address* | *ipv6-address* } | **udp-port** *udp-number* | **vpn-instance** *vpn-instance-name*] *

   By default, no primary keepalive link is configured. If you do not specify a source IP address or destination UDP port when you execute this command, the IP address of the outgoing interface and UDP port 6400 are used, respectively.

3. (Optional.) Configure the standby keepalive link.

   m-lag keepalive standby { **ip** | **ipv6** } **destination** { *ipv4-address* | *ipv6-address* } [**source** { *ipv4-address* | *ipv6-address* } | **vpn-instance** *vpn-instance-name*] *

   By default, no standby keepalive link is configured for M-LAG.

Setting the M-LAG keepalive interval and timeout timer

About this task

The device sends keepalive packets at the specified interval to its M-LAG peer. If the device has not received a keepalive packet from the M-LAG peer before the keepalive timeout timer expires, the device determines that the keepalive link is down.

Restrictions and guidelines

The local M-LAG keepalive timeout timer must be two times the M-LAG keepalive interval of the peer at minimum.

Configure the same M-LAG keepalive interval on the M-LAG member devices in the M-LAG system.

Procedure

1. Enter system view.

   system-view

2. Set the M-LAG keepalive interval and timeout timer.

   m-lag keepalive interval *interval* [**timeout** *timeout*]

   By default, the M-LAG keepalive interval is 1000 milliseconds, and the M-LAG keepalive timeout timer is 5 seconds.

Associating the keepalive link with a track entry

About this task

Associate a track entry with the keepalive link to fast detect state changes of the keepalive link. For more information about track entries, see Track configuration in *High Availability Configuration Guide*.

Restrictions and guidelines

As a best practice, do not specify the track entry associated with M-LAG MAD when executing **m-lag keepalive track** command. If you do that, the M-LAG system state might flap.

Procedure

1. Enter system view.
   system-view
2. Associate the keepalive link with a track entry.
   m-lag keepalive track *track-entry-number*
   By default, no track entry is associated with the keepalive link.

Configuring M-LAG MAD

About this task

M-LAG MAD configuration methods

When you configure M-LAG MAD, use either of the following methods:

- To shut down all network interfaces on the secondary M-LAG member device except a few special-purpose interfaces that must be retained in up state:
  - Set the default M-LAG MAD action to M-LAG MAD DOWN. For more information, see "Configuring the default M-LAG MAD action on network interfaces."
  - Exclude interfaces from being shut down by M-LAG MAD. For more information, see "Excluding an interface from the shutdown action by M-LAG MAD."

  This method is applicable to most network environments.
- To have the secondary M-LAG member device retain a large number of interfaces in up state and shut down the remaining interfaces:
  - Set the default M-LAG MAD action to NONE. For more information, see "Configuring the default M-LAG MAD action on network interfaces."
  - Specify network interfaces that must be shut down by M-LAG MAD. For more information, see "Specifying interfaces to be shut down by M-LAG MAD when the M-LAG system splits."

  Use this method if you must retain a large number of logical interfaces (for example, VLAN, aggregate, loopback, and tunnel interfaces) in up state.

List of automatically included interfaces

M-LAG MAD will always shut down the ports in the system-configured included port list if the device acts as the secondary M-LAG member device when the M-LAG system splits.

This list contains aggregation member ports of M-LAG interfaces. To identify system-configured included ports, execute the **display m-lag mad verbose** command.

List of automatically excluded interfaces

M-LAG MAD will not shut down the ports in the following list when the M-LAG system splits:

- System-configured excluded port list in M-LAG MAD:
  - Peer-link interface.
  - Aggregation member interfaces if a Layer 2 aggregate interface is used as the peer-link interface.
  - M-LAG interfaces.
  - Keepalive interfaces, interfaces used for setting up the keepalive link.
  - VLAN interfaces.

- Management interfaces.

  To identify these interfaces, execute the **display m-lag mad verbose** command.

- Network interfaces used for special purposes, including:
  - Interfaces placed in a loopback test by using the **loopback** command. For more information about this command, see Ethernet interface commands in *Layer 2—LAN Switching Command Reference*.
  - Interfaces in a mirroring group.
  - Interfaces forced to stay up by using the **port-up mode** command. For more information about this command, see Ethernet interface commands in *Layer 2—LAN Switching Command Reference.*

Restrictions and guidelines for M-LAG MAD

When the M-LAG system splits, M-LAG MAD takes the same action on an aggregate interface and its member ports. For example, if M-LAG MAD shuts down an aggregate interface, it also shuts down the member ports of the aggregate interface.

If you specify an aggregation member port in the **m-lag mad include interface** or **m-lag mad exclude interface** command, the configuration takes precedence over the M-LAG MAD action on the aggregate interface.

Configuring the default M-LAG MAD action on network interfaces

About this task

You can configure M-LAG MAD to take either of the following default actions on network interfaces if the device acts as the secondary M-LAG member device when the M-LAG system splits:

- **M-LAG MAD DOWN**—M-LAG MAD will shut down all network interfaces on the secondary M-LAG member device when the M-LAG system splits, except the interfaces excluded manually or by the system.
- **NONE**—M-LAG MAD will not shut down any network interfaces when the M-LAG system splits, except the interfaces configured manually or by the system to be shut down by M-LAG MAD.

Restrictions and guidelines

The M-LAG MAD DOWN action will not take effect on the interfaces listed in "List of automatically excluded interfaces."

The M-LAG MAD DOWN action will always take on the interfaces listed in "List of automatically included interfaces," even if the default M-LAG MAD action is NONE.

Procedure

1. Enter system view.

   system-view

2. Configure the default M-LAG MAD action to take on network interfaces on the secondary M-LAG member device when the M-LAG system splits.

   m-lag mad default-action { down | none }

   By default, M-LAG MAD shuts down network interfaces on the secondary M-LAG member device.

Excluding an interface from the shutdown action by M-LAG MAD

About this task

By default, M-LAG MAD automatically excludes the interfaces listed in "List of automatically excluded interfaces" when it shuts down network interfaces on the secondary M-LAG member device.

To specify additional interfaces that cannot be shut down, perform this task.

You typically perform this task when the default M-LAG MAD action is set to M-LAG MAD DOWN.

Restrictions and guidelines

The M-LAG MAD DOWN action is always taken on interfaces listed in "List of automatically included interfaces." You cannot disable the action by excluding those interfaces.

To view interfaces excluded from the MAD shutdown action, see the **Excluded ports (user-configured)** field in the output from the **`display m-lag mad verbose`** command.

If you exclude an interface that is already in M-LAG MAD DOWN state from the MAD shutdown action, the interface stays in that state. It will not come up automatically.

Peer-link interface, member ports in the Layer 2 aggregation group of the peer-link interface, M-LAG interfaces, management Ethernet interface, keepalive interfaces, and VLAN interfaces are excluded by the system from the MAD shutdown action.

When an M-LAG member device reboots, its keepalive interface might remain in the MAD DOWN state after recovery. This prevents the M-LAG system from being established correctly. Resolve this issue in either of the following methods:

- Use the **`m-lag mad exclude interface`** command to manually exclude the keepalive interface from the shutdown action by M-LAG MAD.
- Specify the **`source`** keyword when you use the **`m-lag keepalive`** { **`ip`** | **`ipv6`** } or **`m-lag keepalive standby`** { **`ip`** | **`ipv6`** } command to configure the M-LAG keepalive link.

As a best practice, when you exclude a logical interface from the shutdown action by M-LAG MAD, also exclude its bound physical interfaces from the shutdown action.

Procedure

1. Enter system view.

   `system-view`
2. Exclude an interface from the shutdown action by M-LAG MAD.

   `m-lag mad exclude interface` *`interface-type interface-number`*

   By default, M-LAG MAD shuts down all network interfaces when detecting a multi-active collision, except for the network interfaces set by the system to not shut down.

Excluding all logical interfaces from the shutdown action by M-LAG MAD

About this task

To retain a large number of logical interfaces (for example, aggregate, loopback, and tunnel interfaces, and aggregation member ports) in up state, you can exclude all logical interfaces from the shutdown action by M-LAG MAD.

Peer-link interface, member ports in the Layer 2 aggregation group of the peer-link interface, M-LAG interfaces, management Ethernet interface, keepalive interfaces, and VLAN interfaces are excluded by the system from the MAD shutdown action.

Peer-link interface, member ports in the Layer 2 aggregation group of the peer-link interface, M-LAG interfaces, management Ethernet interface, keepalive interfaces, VLAN interfaces, and VSI interfaces are excluded by the system from the MAD shutdown action.

Restrictions and guidelines

The **m-lag mad exclude interface** and **m-lag mad include interface** commands take precedence over the **m-lag mad exclude logical-interfaces** command.

Procedure

1. Enter system view.

   system-view

2. Exclude all logical interfaces from the shutdown action by M-LAG MAD.

   m-lag mad exclude logical-interfaces

   By default, M-LAG MAD shuts down all network interfaces when it detects a multi-active collision, except for the network interfaces set by the system to not shut down.

Specifying interfaces to be shut down by M-LAG MAD when the M-LAG system splits

About this task

By default, M-LAG MAD automatically shuts down the interfaces listed in "List of automatically included interfaces" if the device is the secondary M-LAG member device when the M-LAG system splits.

To specify additional interfaces to be shut down by M-LAG MAD, perform this task.

You typically perform this task when the default M-LAG MAD action is set to NONE.

Restrictions and guidelines

The M-LAG MAD DOWN action will not take effect on the interfaces listed in "List of automatically excluded interfaces."

Procedure

1. Enter system view.

   system-view

2. Specify interfaces to be shut down by M-LAG MAD when the M-LAG system splits.

   m-lag mad include interface *interface-type interface-number*

   By default, the user-configured included port list does not contain any ports.

Enabling M-LAG MAD DOWN state persistence

About this task

M-LAG MAD DOWN state persistence helps avoid the multi-active situation by preventing the secondary M-LAG member device from bringing up the network interfaces in M-LAG MAD DOWN state. For more information about this feature, see "M-LAG MAD DOWN state persistence" and "Failure handling mechanism with M-LAG MAD DOWN state persistence."

You can bring up the interfaces in M-LAG MAD DOWN state on the secondary M-LAG member device for it to forward traffic if the following conditions exist:

- The primary M-LAG member device fails while the peer link is down.
- The M-LAG MAD DOWN state persists on the secondary M-LAG member device.

To prevent packet loss after the peer link recovers from a link fault, the secondary member device should try to synchronize entries (such as the MAC address entries and ARP entries) within the data restoration interval. Subsequently, interfaces in M-LAG MAD DOWN state on the device will restore to up.

Procedure

1. Enter system view.

   `system-view`
2. Enable M-LAG MAD DOWN state persistence.

   `m-lag mad persistent`

   By default, the secondary M-LAG member device brings up interfaces in M-LAG MAD DOWN state when its role changes to primary.
3. (Optional.) Bring up the interfaces in M-LAG MAD DOWN state.

   `m-lag mad restore`

   Execute this command only when both the peer link and the keepalive link are down.

Configuring an M-LAG interface

About this task

If an M-LAG group contains only one M-LAG interface, that interface is called a single-homed M-LAG interface. By default, M-LAG does not allow access through single-homed M-LAG interfaces, which means M-LAG MAD shuts down an M-LAG interface if it is the only member in its M-LAG group.

To ensure traffic forwarding for a device single-homed to an M-LAG interface, allow the M-LAG interface to be the single member in its M-LAG group. M-LAG MAD will not shut down the single-homed M-LAG interface, and the device will not perform configuration consistency check on the interface.

Restrictions and guidelines

Specify the **`allow-single-member`** keyword only when the network is managed by a controller. For example, Device A and Device B form an M-LAG system, and they separately set up OpenFlow channels with the controller. If the OpenFlow channel of Device A is disconnected, the controller will notify Device B of this event. Then, Device B will permit access of single-homed peer devices on the M-LAG interfaces with the **`allow-single-member`** keyword configured. Those M-LAG interfaces will not be shut down by M-LAG MAD.

The device can have multiple M-LAG interfaces. However, you can assign a Layer 2 aggregate interface to only one M-LAG group.

A Layer 2 aggregate interface cannot operate as both peer-link interface and M-LAG interface.

To improve forwarding efficiency, exclude the M-LAG interface on the secondary M-LAG member device from the shutdown action by M-LAG MAD. This action enables the M-LAG interface to forward traffic immediately after a multi-active collision is removed without having to wait for the secondary M-LAG member device to complete entry restoration.

If you execute the **`port m-lag group`** command multiple times, the most recent configuration takes effect.

To prevent loops when you assign a single-homed aggregate interface to an M-LAG group, use the following procedure:

1. Assign the aggregate interface to the M-LAG group.
2. Assign ports to the aggregation group of the aggregate interface.

When you remove a single-homed M-LAG interface from its M-LAG group, use the following procedure:

3. Remove the member ports from the aggregation group of the M-LAG interface.
4. Remove the M-LAG interface from the M-LAG group.

Procedure

1. Enter system view.

   system-view
2. Enter Layer 2 aggregate interface view.

   interface bridge-aggregation *interface-number*
3. Assign the aggregate interface to an M-LAG group.

   port m-lag group *group-id* [**allow-single-member**]

   As a best practice, specify the **allow-single-member** keyword for a dynamic aggregate interface.

Configuring an M-LAG uplink interface

About this task

Use this feature to configure the interface that connects the M-LAG device to the uplink network and determine the role election for the M-LAG system based on the interface state.

When the peer link of an M-LAG system is down but can still receive keepalive packets, the M-LAG member device whose uplink interface comes up first becomes the primary device if both M-LAG member devices have configured uplink interfaces. All user traffic between the users and the uplink network is then forwarded solely through the primary device.

If the local M-LAG member device does not receive the keepalive packets transmitted by the peer M-LAG member device within the specified time and the peer link is down, the local M-LAG member device considers the peer M-LAG device as down.

- When the local device is the primary device and has uplink interfaces configured, it remains as the primary device if any uplink interface is in up state. If no uplink interface in up state exists, the local device's role changes to None.
- When the local device is the primary device and no uplink interface is configured on it, the local device remains as the primary device if an M-LAG interface in up state exists. If no M-LAG interface in up state exists, the local device's role changes to None.
- When the local device is a secondary device, it becomes the primary device. If the local device is configured with uplink interfaces, it will remain as the primary device as long as an uplink interface in up state exists on the local device. If no uplink interface in up state exists, the local device's role will change to None.
- When the local device is a secondary device, it becomes the primary device. If the local device does not have an uplink interface configured, it will remain as the primary device as long as an M-LAG interface in up state exists on the device. If no M-LAG interface in up state exists, the local device's role will change to None.

When the device is of the None role, it cannot send or receive keepalive packets, and the keepalive link is down.

Restrictions and guidelines

You cannot configure aggregation member ports or peer-link interfaces as uplink interfaces by using this feature.

To configure an M-LAG uplink interface, configure it on both M-LAG member devices. This prevents abnormal M-LAG device role elections.

Procedure

1. Enter system view.

   system-view

2. Enter the Layer 2 Ethernet interface view, Layer 3 Ethernet interface view, Layer 2 aggregate interface view, or Layer 3 aggregate interface view.

   interface *interface-type interface-number*

3. Configure the interface as an M-LAG uplink interface.

   m-lag uplink-port enable

   By default, no M-LAG uplink interface is configured.

Configuring the flapping detection interval for M-LAG uplink interfaces

About this task

M-LAG uplink interfaces are used to elect the primary and secondary M-LAG member devices when the peer link is down but the keepalive link remains up. If an uplink interface on the local M-LAG member device comes up first, that M-LAG member device is elected as the primary device. Then, all traffic is forwarded through the primary device. However, the uplink interfaces on an M-LAG member device might frequently flap, which can cause packet loss for traffic on the primary device. To prevent packet loss caused by uplink interface flapping, configure the flapping detection interval for M-LAG uplink interfaces on both M-LAG member devices. The system elects the device with less frequent or no flappings within the detection interval as the primary device.

Within the flapping detection interval, each M-LAG member device counts the flapping frequency of its uplink interfaces. The system calculates the flapping frequency through dividing the number of flaps by the detection interval. A higher flapping frequency gives a lower priority in primary/secondary device election. The two M-LAG member devices notify each other through keepalive packets and elect the M-LAG member device with the best uplink quality as the primary device based on flapping frequency.

Restrictions and guidelines

For this feature to take effect, configure M-LAG uplink interfaces and the flapping detection interval on both M-LAG member devices.

If you configure multiple interfaces as M-LAG uplink interfaces, the system calculates the flapping frequency for those M-LAG uplink interfaces through dividing the total flaps of all M-LAG uplink interfaces by the detection interval.

Procedure

1. Enter system view.

   system-view

2. Configure the flapping detection interval for M-LAG uplink interfaces.

   m-lag uplink-port flapping-detection timer *value*

   By default, an M-LAG member device does not perform flapping detection for M-LAG uplink interfaces, and no flapping detection interval is configured.

Setting up a peer link

Specifying a Layer 2 aggregate interface or VXLAN tunnel interface as the peer-link interface

About this task

On a peer-link interface, you can specify the **auto-negotiate** keyword to enable M-LAG system parameter autonegotiation. The M-LAG member devices will negotiate the M-LAG system parameters not manually configured as follows:

- **M-LAG system MAC address**—The M-LAG member devices compare their bridge MAC addresses and use the lower value as the M-LAG system MAC address.
- **M-LAG system number**—The M-LAG system number is 1 for the M-LAG member device with the lower bridge MAC address and 2 for the other M-LAG member device.
- **M-LAG system priority**—The default M-LAG system priority is used by both M-LAG member devices.

Restrictions and guidelines

A Layer 2 aggregate interface cannot operate as both peer-link interface and M-LAG interface. Make sure the bandwidth of the peer-link interface is higher than that of an M-LAG interface.

An M-LAG member device can have only one peer-link interface.

If you specify an aggregate interface as a peer-link interface, the following rules apply:

- If the aggregate interface uses the default VLAN settings, the system changes the link type of the aggregate interface to trunk, configures the interface to permit all VLANs, and sets the PVID to 4094.
- If the link type of the aggregate interface is trunk, the system configures the interface to also permit VLAN 4094 and changes the PVID to 4094.
- In any other cases, the system does not change the VLAN settings.

The device does not change the VLAN settings of an aggregate interface when you remove its peer-link interface role.

As a best practice to reduce the impact of interface flapping on upper-layer services, execute the **link-delay** command on the peer-link interface. For more information about this command, see Ethernet link aggregation commands in *Layer 2—LAN Switching Command Reference*.

By default, MAC address learning is enabled on the peer-link interface. This feature is not configurable on the peer-link interface. For more information about the MAC address learning feature, see "Configuring the MAC address table."

To prevent data synchronization failure, you must set the same maximum jumbo frame length on the peer-link interfaces of the M-LAG member devices. For more information about jumbo frames, see "Configuring Ethernet link aggregation."

You must use the **shutdown** command to shut down an interface before you remove it from the peer-link interface's aggregation group.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*

3. Specify the interface as the peer-link interface.
   port m-lag peer-link *port-number* [**auto-negotiate**]

Reserving VLANs for the peer link

About this task

Reserved VLANs enable Layer 3 multicast traffic to fail over via the peer link between the M-LAG member devices in an M-LAG system with Layer 3 multicast forwarding configured. After you reserve VLANs for the peer link, the peer-link interfaces will be assigned to the reserved VLANs and thus act as traffic outgoing interfaces of multicast forwarding entries.

For more information about configuring Layer 3 multicast forwarding on an M-LAG system, see PIM configuration and IPv6 PIM configuration in *IP Multicast Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Reserve the VLAN for the peer link.
   m-lag peer-link reserved

   By default, a VLAN is not reserved for the peer link.

Enabling the short DRCP timeout timer on the peer-link interface or an M-LAG interface

About this task

By default, the peer-link interface or an M-LAG interface uses the 90-second long DRCP timeout timer. To detect peer interface down events more quickly, enable the 3-second short DRCP timeout timer on the interface.

Restrictions and guidelines

To avoid traffic interruption during an ISSU or M-LAG process restart, disable the short DRCP timeout timer before you perform an ISSU or M-LAG process restart. For more information about ISSU, see *Fundamentals Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
3. Enable the short DRCP timeout timer.
   m-lag drcp period short

   By default, an interface uses the long DRCP timeout timer (90 seconds).

Enabling the peer-link interface to retain MAC address entries for down single-homed devices

About this task

When an M-LAG member device detects that the link to a single-homed device goes down, the peer-link interface takes the following actions:

- Deletes the MAC address entries for the single-homed device.
- Sends a message to the peer peer-link interface for it to delete the affected MAC address entries.

If the link to a single-homed device flaps constantly, the peer-link interface repeatedly deletes and adds MAC address entries for the device. This situation increases floods of unicast traffic destined for the single-homed device.

To reduce flood traffic, enable the peer-link interface to retain MAC address entries for single-homed devices. After the links to single-homed devices go down, the affected MAC address entries age out on expiration of the MAC aging timer instead of being deleted immediately. The timer is set by using the **mac-address timer** command. For more information about this command, see MAC address table commands in *Layer 2—LAN Switching Command Reference*.

Procedure

1. Enter system view.

   system-view
2. Enable the peer-link interface to retain MAC address entries for single-homed devices.

   m-lag peer-link mac-address hold

   By default, the peer-link interface does not retain MAC address entries for single-homed devices when the devices go down.

Configuring the M-LAG active/standby mode

Restrictions and guidelines

If you configure the M-LAG interface on one end to operate in active/standby mode, you must also configure the peer M-LAG interface numbered the same to operate in active/standby mode and use the same type of protocol packets for election.

The M-LAG active/standby mode is applicable only when the following conditions exist:

- Active/standby NICs are connected to an M-LAG interface.
- The Layer 2 aggregation group of the M-LAG interface operates in static aggregation mode.

Procedure

1. Enter system view.

   system-view
2. Enter Layer 2 aggregate interface view.

   interface bridge-aggregation *interface-number*
3. Assign the Layer 2 aggregate interface to an M-LAG group in active/standby mode.

   port m-lag group *group-id* **active-standby**

   By default, a Layer 2 aggregate interface is not assigned to an M-LAG group.
4. Configure the type of protocol packets used for active/standby M-LAG interface election.

port m-lag active-standby election { **arp** | **dhcp** | **igmp** | **mld** | **nd** } *

By default, the type of protocol packets used for active/standby M-LAG interface election is not specified, and the active/standby mode does not take effect.

Assigning a M-LAG virtual IP address to an interface

About this task

M-LAG virtual IP addresses (VIPs) allow devices to communicate with the M-LAG system by using dynamic routing protocols.

To ensure correct traffic forwarding, assign M-LAG virtual IP addresses to the following interfaces on the M-LAG system:

- VLAN interfaces that act as dual-active gateways for the same VLAN.
- Loopback interfaces that offer AAA and 802.1X authentication services. For more information, see AAA configuration in *Security Configuration Guide*.

When both M-LAG member devices act as gateways for dualhomed user-side devices, the gateway interfaces (VLAN interfaces) on the M-LAG member devices use the same IP address and MAC address. In this scenario, the M-LAG member devices cannot set up neighbor relationships with the user-side devices. To resolve this issue, assign VIPs to the gateway interfaces and configure routing protocols such as BGP, OSPF, and OSPFv3 to use the VIPs for neighbor relationship setup.

When dual-active gateways exist on the M-LAG system, you must assign unique VIPs to the gateway interfaces on the M-LAG member devices and configure both VIPs to be active. When you assign a virtual MAC address to a VLAN interface, make sure the virtual MAC address is identical to the MAC address assigned to the VLAN interface by using the **mac-address** command.

Restrictions and guidelines

When you assign multiple M-LAG VIPs to an interface, follow these restrictions and guidelines:

- You can assign a maximum of two virtual IPv4 or IPv6 addresses to an interface.
- If you configure different virtual MAC addresses for a virtual IPv4 or IPv6 address, the most recent configuration takes effect.
- You cannot configure the same virtual MAC address for multiple virtual IPv4 or IPv6 addresses.
- When you assign a virtual IPv4 or IPv6 address to VLAN interfaces, you must configure the same virtual MAC address for the virtual IPv4 or IPv6 address on both M-LAG member devices.
- To assign a virtual IPv6 address to an interface, specify the **link-local** keyword only if the address is used for OSPFv3 peer relationship setup.

If you assign both virtual IPv4 and IPv6 addresses to VLAN interfaces, make sure the virtual IPv4 and IPv6 addresses that use the same virtual MAC address are in the same state on the M-LAG member devices.

Assigning M-LAG VIPs to a VLAN interface

1. Enter system view.

   system-view
2. Enter VLAN interface view.

   interface vlan-interface *interface-number*
3. Assign a virtual IPv4 address to the VLAN interface.

   port m-lag virtual-ip *ipv4-address* { *mask-length* | *mask* } [**active** | **standby**] [**virtual-mac** *mac-address*]

By default, no virtual IPv4 addresses are assigned to interfaces.

4. Assign a virtual IPv6 address to the VLAN interface.

   port m-lag ipv6 virtual-ip *ipv6-address* { *prefix-length* [**active** | **standby**] [**virtual-mac** *mac-address*] | **link-local** }

   By default, no virtual IPv6 addresses are assigned to interfaces.

Assigning M-LAG VIPs to a loopback interface

1. Enter system view.

   system-view

2. Enter loopback interface view.

   interface loopback *interface-number*

3. Assign a virtual IPv4 address to the loopback interface.

   port m-lag virtual-ip *ipv4-address* { *mask-length* | *mask* } [**active** | **standby**]

   By default, no virtual IPv4 addresses are assigned to interfaces.

4. Assign a virtual IPv6 address to the loopback interface.

   port m-lag ipv6 virtual-ip *ipv6-address* { *prefix-length* [**active** | **standby**] | **link-local** }

   By default, no virtual IPv6 addresses are assigned to interfaces.

Configuring M-LAG extra VLANs

About this task

For VLANs permitted only on non-M-LAG interfaces, the device processes traffic locally. For the device to synchronize forwarding entries for such VLANs, configure them as extra VLANs. The device will synchronize forwarding entries for the extra VLANs (such as ARP entries) even though they are not permitted on M-LAG interfaces, as shown in Figure 26. When the uplink of one M-LAG member device fails, traffic of the extra VLANs can fail over to the other M-LAG member device through the peer link.

Figure 26 M-LAG extra VLANs

Procedure

1. Enter system view.
   `system-view`
2. Configure M-LAG extra VLANs.
   `m-lag extra-vlan` *`vlan-id-list`*
   By default, no M-LAG extra VLANs are configured.

Setting the mode of configuration consistency check

About this task

The device handles configuration inconsistency depending on the mode of configuration consistency check.

- For type 1 configuration inconsistency:
  - The device generates log messages if loose mode is enabled.
  - The device shuts down M-LAG interfaces and generates log messages if strict mode is enabled.
- For type 2 configuration inconsistency, the device only generates log messages, whether strict or loose mode is enabled.

Procedure

1. Enter system view.
   `system-view`
2. Set the mode of configuration consistency check.

m-lag consistency-check mode { **loose** | **strict** }

By default, configuration consistency check uses strict mode.

Disabling configuration consistency check

About this task

To ensure that the M-LAG system can operate correctly, M-LAG by default performs configuration consistency check when the M-LAG system is set up.

Configuration consistency check might fail when you upgrade the M-LAG member devices in an M-LAG system. To prevent the M-LAG system from falsely shutting down M-LAG interfaces, you can temporarily disable configuration consistency check.

Restrictions and guidelines

Make sure the M-LAG member devices use the same setting for configuration consistency check.

Procedure

1. Enter system view.

   system-view
2. Disable configuration consistency check.

   m-lag consistency-check disable

   By default, configuration consistency check is enabled.

Setting the keepalive hold timer for identifying the cause of peer link down events

About this task

The keepalive hold timer starts when the peer link goes down. The keepalive hold timer specifies the amount of time that the device uses to identify the cause of a peer link down event.

- If the device receives keepalive packets from the M-LAG peer before the timer expires, the peer link is down because the peer link fails.
- If the device does not receive keepalive packets from the M-LAG peer before the timer expires, the peer link is down because the peer M-LAG member device fails.

Procedure

1. Enter system view.

   system-view
2. Set the keepalive hold timer.

   m-lag keepalive hold-time *value*

   By default, the keepalive hold timer is 3 seconds.

Configuring M-LAG system auto-recovery

About this task

If only one M-LAG member device recovers after the entire M-LAG system reboots, auto-recovery enables that member device to remove its M-LAG interfaces from the M-LAG DOWN interface list.

- If an uplink interface is configured on the device, an uplink interface in up state must exist for the device to become the primary device and forward user traffic normally. If no uplink interface in

up state exists on the device, the device will remain in the None role, and user traffic cannot be forwarded.

- If no uplink interface is configured on the device, an M-LAG interface in up state must exist for the device to become the primary device and forward user traffic normally. If no M-LAG interface in up state exists on the device, the device will remain in the None role, and user traffic cannot be forwarded.

If auto-recovery is disabled, that M-LAG member device will be stuck in the None role with all its M-LAG interfaces being M-LAG DOWN after it recovers.

Restrictions and guidelines

Both member M-LAG devices in an M-LAG system become primary devices if the following conditions exist:

- Both primary and secondary member devices restart due to a fault.
- Neither device receives DRCP or keepalive packets and both devices have M-LAG or uplink interfaces in up state (consider only uplink interfaces if they exist, and consider M-LAG interfaces otherwise) before the automatic recovery timer expires.

In this case, you must check the peer link and keepalive link and resolve any faults.

To avoid incorrect role preemption, make sure the reload delay timer is longer than the amount of time required for the device to restart.

If you execute both the **m-lag default-auto-recovery enable** and **m-lag auto-recovery reload-delay** commands, the **m-lag auto-recovery reload-delay** command takes effect.

Procedure

1. Enter system view.

   system-view

2. Set the M-LAG system reload delay timer.

   m-lag auto-recovery reload-delay *delay-value*

   By default, the device does not automatically recover.

Setting the data restoration interval

About this task

The data restoration interval specifies the maximum amount of time for the secondary M-LAG device to synchronize data with the primary M-LAG device during M-LAG system setup. Within the data restoration interval, the secondary M-LAG device sets all network interfaces to M-LAG MAD DOWN state, except for the interfaces excluded from the shutdown action by M-LAG MAD.

When the data restoration interval expires, the secondary M-LAG member device brings up all network interfaces.

Restrictions and guidelines

Increase the data restoration interval as needed for the following purposes:

- Avoid packet loss and forwarding failure that might occur when the amount of data is large or when you perform an ISSU between the M-LAG member devices.
- Avoid M-LAG interface flapping that might occur if type 1 configuration consistency check fails after the M-LAG interfaces come up upon expiration of the data restoration interval.

Procedure

1. Enter system view.

   system-view

2. Set the data restoration interval.

   m-lag restore-delay *value*

   By default, the data restoration interval is 300 seconds.

Enabling M-LAG sequence number check

Restrictions and guidelines

As a best practice to improve security, use M-LAG sequence number check together with M-LAG packet authentication.

After one M-LAG member device reboots, the other M-LAG member device might receive and accept the packets that were intercepted by an attacker before the reboot. As a best practice, change the authentication key after an M-LAG member device reboots.

Procedure

1. Enter system view.

   system-view

2. Enable M-LAG sequence number check.

   m-lag sequence enable

   By default, M-LAG sequence number check is disabled.

Enabling M-LAG packet authentication

Restrictions and guidelines

For successful authentication, configure the same authentication key for the M-LAG member devices.

Procedure

1. Enter system view.

   system-view

2. Enable M-LAG packet authentication and configure an authentication key.

   m-lag authentication key { **simple** | **cipher** } *string*

   By default, M-LAG packet authentication is disabled.

Displaying and maintaining M-LAG

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display information about the configuration consistency check done by M-LAG.	**display m-lag consistency** { **type1** | **type2** } { **global** | **interface** *interface-type interface-number* }
Display the status of configuration consistency check.	**display m-lag consistency-check status**
Display DRCPDU statistics.	**display m-lag drcp statistics** [**interface** *interface-type interface-number*]
Display M-LAG keepalive packet	**display m-lag keepalive**

Task	Command
statistics.	
Display detailed M-LAG MAD information.	**display m-lag mad verbose**
Display M-LAG role information.	**display m-lag role**
Display brief information about the peer-link interface and M-LAG interfaces.	**display m-lag summary**
Display the M-LAG system settings.	**display m-lag system**
Display detailed information about the peer-link interface and M-LAG interfaces.	**display m-lag verbose** [**interface bridge-aggregation** *interface-number*]
Display M-LAG troubleshooting information.	**display m-lag troubleshooting** [**m-lag-interface** | **peer-link** | **keepalive**] [**history**] [*count*]

Clear M-LAG troubleshooting records.	**reset m-lag troubleshooting history**

M-LAG configuration examples

Example: Configuring basic M-LAG functions

Network configuration

As shown in Figure 27, configure M-LAG on Device A and Device B to establish a multichassis aggregate link with Device C.

Figure 27 Network diagram

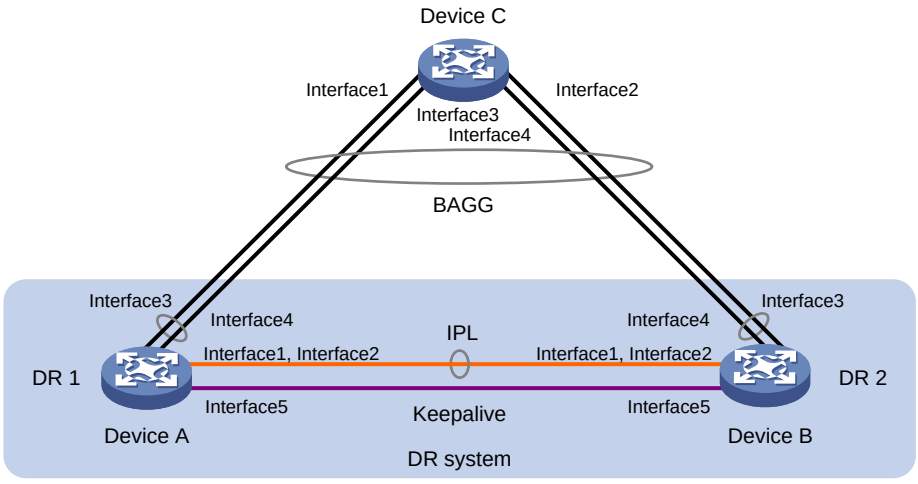

Table 6 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4
Interface5	GigabitEthernet1/0/5

Procedure

1. Configure Device A:

Configure M-LAG system settings.

```
<Sysname> system-view
[Sysname] sysname DeviceA
[DeviceA] m-lag system-mac 1-1-1
[DeviceA] m-lag system-number 1
[DeviceA] m-lag system-priority 123
```

Configure M-LAG keepalive packet parameters.

```
[DeviceA] m-lag keepalive ip destination 1.1.1.1 source 1.1.1.2
```

Set the link mode of GigabitEthernet 1/0/5 to Layer 3, and assign the interface an IP address. The IP address will be used as the source IP address of keepalive packets.

```
[DeviceA] interface gigabitethernet 1/0/5
[DeviceA-GigabitEthernet1/0/5] port link-mode route
[DeviceA-GigabitEthernet1/0/5] ip address 1.1.1.2 24
[DeviceA-GigabitEthernet1/0/5] quit
```

Exclude the interface used for M-LAG keepalive detection (GigabitEthernet 1/0/5) from the shutdown action by M-LAG MAD.

```
[DeviceA] m-lag mad exclude interface gigabitethernet 1/0/5
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 3.

```
[DeviceA] interface bridge-aggregation 3
[DeviceA-Bridge-Aggregation3] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation3] quit
```

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to aggregation group 3.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-aggregation group 3
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-aggregation group 3
[DeviceA-GigabitEthernet1/0/2] quit
```

Specify Bridge-Aggregation 3 as the peer-link interface.

```
[DeviceA] interface bridge-aggregation 3
[DeviceA-Bridge-Aggregation3] port m-lag peer-link 1
[DeviceA-Bridge-Aggregation3] undo mac-address static source-check enable
[DeviceA-Bridge-Aggregation3] quit
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 4.

```
[DeviceA] interface bridge-aggregation 4
```

```
[DeviceA-Bridge-Aggregation4] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation4] quit
```

Assign GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 to aggregation group 4.

```
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] port link-aggregation group 4
[DeviceA-GigabitEthernet1/0/3] quit
[DeviceA] interface gigabitethernet 1/0/4
[DeviceA-GigabitEthernet1/0/4] port link-aggregation group 4
[DeviceA-GigabitEthernet1/0/4] quit
```

Assign Bridge-Aggregation 4 to M-LAG group 4.

```
[DeviceA] interface bridge-aggregation 4
[DeviceA-Bridge-Aggregation4] port m-lag group 4
[DeviceA-Bridge-Aggregation4] quit
```

2. Configure Device B:

Configure M-LAG system settings.

```
<Sysname> system-view
[Sysname] sysname DeviceB
[DeviceB] m-lag system-mac 1-1-1
[DeviceB] m-lag system-number 2
[DeviceB] m-lag system-priority 123
```

Configure M-LAG keepalive packet parameters.

```
[DeviceB] m-lag keepalive ip destination 1.1.1.2 source 1.1.1.1
```

Set the link mode of GigabitEthernet 1/0/5 to Layer 3, and assign the interface an IP address. The IP address will be used as the source IP address of keepalive packets.

```
[DeviceB] interface gigabitethernet 1/0/5
[DeviceB-GigabitEthernet1/0/5] port link-mode route
[DeviceB-GigabitEthernet1/0/5] ip address 1.1.1.1 24
[DeviceB-GigabitEthernet1/0/5] quit
```

Exclude the interface used for M-LAG keepalive detection (GigabitEthernet 1/0/5) from the shutdown action by M-LAG MAD.

```
[DeviceB] m-lag mad exclude interface gigabitethernet 1/0/5
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 3.

```
[DeviceB] interface bridge-aggregation 3
[DeviceB-Bridge-Aggregation3] link-aggregation mode dynamic
[DeviceB-Bridge-Aggregation3] quit
```

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to aggregation group 3.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-aggregation group 3
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-aggregation group 3
[DeviceB-GigabitEthernet1/0/2] quit
```

Specify Bridge-Aggregation 3 as the peer-link interface.

```
[DeviceB] interface bridge-aggregation 3
[DeviceB-Bridge-Aggregation3] port m-lag peer-link 1
[DeviceB-Bridge-Aggregation3] undo mac-address static source-check enable
[DeviceB-Bridge-Aggregation3] quit
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 4.

```
[DeviceB] interface bridge-aggregation 4
[DeviceB-Bridge-Aggregation4] link-aggregation mode dynamic
[DeviceB-Bridge-Aggregation4] quit
```

Assign GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 to aggregation group 4.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-aggregation group 4
[DeviceB-GigabitEthernet1/0/3] quit
[DeviceB] interface gigabitethernet 1/0/4
[DeviceB-GigabitEthernet1/0/4] port link-aggregation group 4
[DeviceB-GigabitEthernet1/0/4] quit
```

Assign Bridge-Aggregation 4 to M-LAG group 4.

```
[DeviceB] interface bridge-aggregation 4
[DeviceB-Bridge-Aggregation4] port m-lag group 4
[DeviceB-Bridge-Aggregation4] quit
```

3. Configure Device C:

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 4.

```
<Sysname> system-view
[Sysname] sysname DeviceC
[DeviceC] interface bridge-aggregation 4
[DeviceC-Bridge-Aggregation4] link-aggregation mode dynamic
[DeviceC-Bridge-Aggregation4] quit
```

Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to aggregation group 4.

```
[DeviceC] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/4
[DeviceC-if-range] port link-aggregation group 4
[DeviceC-if-range] quit
```

Verifying the configuration

Verify that the keepalive link is working correctly on Device A.

```
[DeviceA] display m-lag keepalive
Neighbor keepalive link status (cause): Up
Neighbor is alive for: 104 s, 16 ms
Keepalive packet transmission status:
  Sent: Successful
  Received: Successful
Last received keepalive packet information:
  Source IP address: 1.1.1.1
  Time: 2019/09/11 09:21:51
  Action: Accept

M-LAG keepalive parameters:
Destination IP address: 1.1.1.1
Source IP address: 1.1.1.2
Keepalive UDP port : 6400
Keepalive VPN name : N/A
Keepalive interval : 1000 ms
Keepalive timeout  : 5 sec
Keepalive hold time: 3 sec
```

Verify that the peer-link interface and the M-LAG interface are working correctly on Device A.

```
[DeviceA] display m-lag summary
Flags: A -- Aggregate interface down, B -- No peer M-LAG interface configured
       C -- Configuration consistency check failed

Example: Configuring Layer 3 gateways on an M-LAG system

Network configuration

As shown in Figure 28:

- Configure Device A and Device B as an M-LAG system to establish one multichassis aggregate link with Device C and one with Device D.
- Set up a keepalive link between GigabitEthernet 1/0/5 of Device A and GigabitEthernet 1/0/5 of Device B, and exclude the interfaces from the shutdown action by M-LAG MAD.
- Configure two VRRP groups on Device A and Device B to provide gateway services for VLAN 100 and VLAN 200. Configure Device A as the master of the VRRP groups.

Figure 28 Network diagram

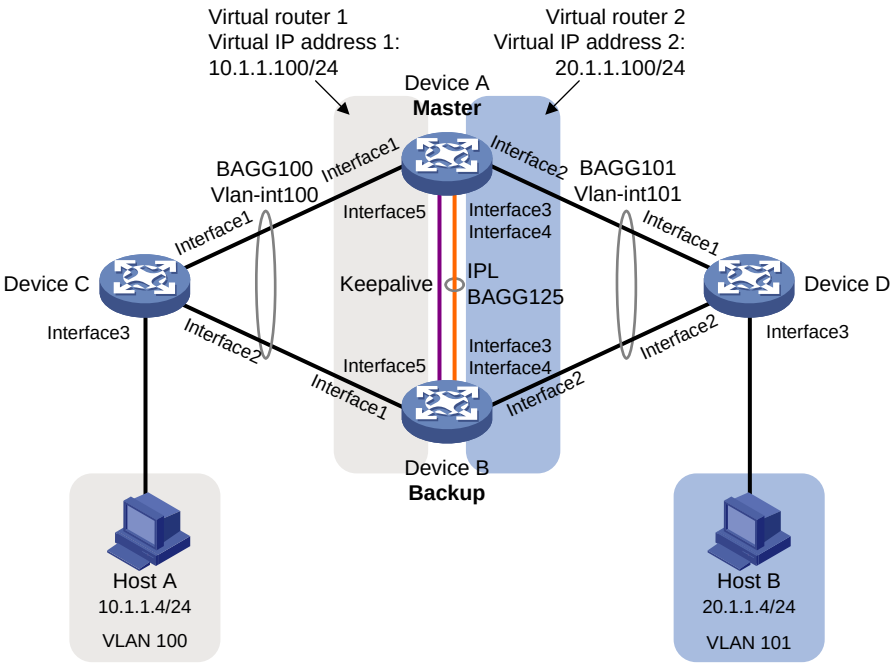

Table 7 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4
Interface5	GigabitEthernet1/0/5

Procedure

1. Configure Device A:

Configure M-LAG system settings.

```
<Sysname> system-view
[Sysname] sysname DeviceA
[DeviceA] m-lag system-mac 1-1-1
[DeviceA] m-lag system-number 1
[DeviceA] m-lag system-priority 123
```

Configure M-LAG keepalive parameters.

```
[DeviceA] m-lag keepalive ip destination 1.1.1.2 source 1.1.1.1
```

Set the link mode of GigabitEthernet 1/0/5 to Layer 3, and assign the interface an IP address. The IP address will be used as the source IP address of keepalive packets.

```
[DeviceA] interface gigabitethernet 1/0/5
[DeviceA-GigabitEthernet1/0/5] port link-mode route
[DeviceA-GigabitEthernet1/0/5] ip address 1.1.1.1 24
[DeviceA-GigabitEthernet1/0/5] quit
```

Exclude the interface used for M-LAG keepalive detection (GigabitEthernet 1/0/5) from the shutdown action by M-LAG MAD.

```
[DeviceA] m-lag mad exclude interface gigabitethernet 1/0/5
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 125.

```
[DeviceA] interface bridge-aggregation 125
[DeviceA-Bridge-Aggregation125] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation125] quit
```

Assign GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 to aggregation group 125.

```
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] port link-aggregation group 125
[DeviceA-GigabitEthernet1/0/3] quit
[DeviceA] interface GigabitEthernet 1/0/4
[DeviceA-GigabitEthernet1/0/4] port link-aggregation group 125
[DeviceA-GigabitEthernet1/0/4] quit
```

Specify Bridge-Aggregation 125 as the peer-link interface.

```
[DeviceA] interface bridge-aggregation 125
[DeviceA-Bridge-Aggregation125] port m-lag peer-link 1
[DeviceA-Bridge-Aggregation125] undo mac-address static source-check enable
[DeviceA-Bridge-Aggregation125] quit
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 100, and assign it to M-LAG group 1.

```
[DeviceA] interface bridge-aggregation 100
```

```
[DeviceA-Bridge-Aggregation100] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation100] port m-lag group 1
[DeviceA-Bridge-Aggregation100] quit
```

Assign GigabitEthernet 1/0/1 to aggregation group 100.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-aggregation group 100
[DeviceA-GigabitEthernet1/0/1] quit
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 101, and assign it to M-LAG group 2.

```
[DeviceA] interface bridge-aggregation 101
[DeviceA-Bridge-Aggregation101] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation101] port m-lag group 2
[DeviceA-Bridge-Aggregation101] quit
```

Assign GigabitEthernet 1/0/2 to aggregation group 101.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-aggregation group 101
[DeviceA-GigabitEthernet1/0/2] quit
```

Create VLAN 100 and VLAN 101.

```
[DeviceA] vlan 100
[DeviceA-vlan100] quit
[DeviceA] vlan 101
[DeviceA-vlan101] quit
```

Set the link type of Bridge-Aggregation 100 to trunk, and assign it to VLAN 100.

```
[DeviceA] interface bridge-aggregation 100
[DeviceA-Bridge-Aggregation100] port link-type trunk
[DeviceA-Bridge-Aggregation100] port trunk permit vlan 100
[DeviceA-Bridge-Aggregation100] quit
```

Set the link type of Bridge-Aggregation 101 to trunk, and assign it to VLAN 101.

```
[DeviceA] interface bridge-aggregation 101
[DeviceA-Bridge-Aggregation101] port link-type trunk
[DeviceA-Bridge-Aggregation101] port trunk permit vlan 101
[DeviceA-Bridge-Aggregation101] quit
```

Create VLAN-interface 100 and VLAN-interface 101, and assign IP addresses to them.

```
[DeviceA] interface vlan-interface 100
[DeviceA-vlan-interface100] ip address 10.1.1.1 24
[DeviceA-vlan-interface100] quit
[DeviceA] interface vlan-interface 101
[DeviceA-vlan-interface101] ip address 20.1.1.1 24
[DeviceA-vlan-interface101] quit
```

Exclude VLAN-interface 100 and VLAN-interface 101 from the shutdown action by M-LAG MAD.

```
[DeviceA] m-lag mad exclude interface vlan-interface 100
[DeviceA] m-lag mad exclude interface vlan-interface 101
```

Configure OSPF.

```
[DeviceA] ospf
[DeviceA-ospf-1] import-route direct
[DeviceA-ospf-1] area 0
[DeviceA-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
```

```
[DeviceA-ospf-1-area-0.0.0.0] network 20.1.1.0 0.0.0.255
[DeviceA-ospf-1-area-0.0.0.0] quit
[DeviceA-ospf-1] quit
```

Create VRRP group 1 on VLAN-interface 100 and set its virtual IP address to 10.1.1.100.

```
[DeviceA] interface vlan-interface 100
[DeviceA-Vlan-interface100] vrrp vrid 1 virtual-ip 10.1.1.100
```

Set the priority of Device A (primary M-LAG member device) to 200 for it to become the master in VRRP group 1.

```
[DeviceA-Vlan-interface100] vrrp vrid 1 priority 200
[DeviceA-Vlan-interface100] quit
```

Create VRRP group 2 on VLAN-interface 101 and set its virtual IP address to 20.1.1.100.

```
[DeviceA] interface vlan-interface 101
[DeviceA-Vlan-interface101] vrrp vrid 2 virtual-ip 20.1.1.100
```

Set the priority of Device A (primary M-LAG member device) to 200 for it to become the master in VRRP group 2.

```
[DeviceA-Vlan-interface101] vrrp vrid 2 priority 200
[DeviceA-Vlan-interface101] quit
```

2. Configure Device B:

Configure M-LAG system settings.

```
<Sysname> system-view
[Sysname] sysname DeviceB
[DeviceB] m-lag system-mac 1-1-1
[DeviceB] m-lag system-number 2
[DeviceB] m-lag system-priority 123
```

Configure M-LAG keepalive parameters.

```
[DeviceB] m-lag keepalive ip destination 1.1.1.1 source 1.1.1.2
```

Set the link mode of GigabitEthernet 1/0/5 to Layer 3, and assign the interface an IP address. The IP address will be used as the source IP address of keepalive packets.

```
[DeviceB] interface gigabitethernet 1/0/5
[DeviceB-GigabitEthernet1/0/5] port link-mode route
[DeviceB-GigabitEthernet1/0/5] ip address 1.1.1.2 24
[DeviceB-GigabitEthernet1/0/5] quit
```

Exclude the interface used for M-LAG keepalive detection (GigabitEthernet 1/0/5) from the shutdown action by M-LAG MAD.

```
[DeviceB] m-lag mad exclude interface gigabitethernet 1/0/5
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 125.

```
[DeviceB] interface bridge-aggregation 125
[DeviceB-Bridge-Aggregation125] link-aggregation mode dynamic
[DeviceB-Bridge-Aggregation125] quit
```

Assign GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 to aggregation group 125.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-aggregation group 125
[DeviceB-GigabitEthernet1/0/3] quit
[DeviceB] interface gigabitethernet 1/0/4
[DeviceB-GigabitEthernet1/0/4] port link-aggregation group 125
[DeviceB-GigabitEthernet1/0/4] quit
```

Specify Bridge-Aggregation 125 as the peer-link interface.

```
[DeviceB] interface bridge-aggregation 125
```

```
[DeviceB-Bridge-Aggregation125] port m-lag peer-link 1
[DeviceB-Bridge-Aggregation125] undo mac-address static source-check enable
[DeviceB-Bridge-Aggregation125] quit
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 100, and assign it to M-LAG group 1.

```
[DeviceB] interface bridge-aggregation 100
[DeviceB-Bridge-Aggregation100] link-aggregation mode dynamic
[DeviceB-Bridge-Aggregation100] port m-lag group 1
[DeviceB-Bridge-Aggregation100] quit
```

Assign GigabitEthernet 1/0/1 to aggregation group 100.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-aggregation group 100
[DeviceB-GigabitEthernet1/0/1] quit
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 101, and assign it to M-LAG group 2.

```
[DeviceB] interface bridge-aggregation 101
[DeviceB-Bridge-Aggregation101] link-aggregation mode dynamic
[DeviceB-Bridge-Aggregation101] port m-lag group 2
[DeviceB-Bridge-Aggregation101] quit
```

Assign GigabitEthernet 1/0/2 to aggregation group 101.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-aggregation group 101
[DeviceB-GigabitEthernet1/0/2] quit
```

Create VLAN 100 and VLAN 101.

```
[DeviceB] vlan 100
[DeviceB-vlan100] quit
[DeviceB] vlan 101
[DeviceB-vlan101] quit
```

Set the link type of Bridge-Aggregation 100 to trunk, and assign it to VLAN 100.

```
[DeviceB] interface bridge-aggregation 100
[DeviceB-Bridge-Aggregation100] port link-type trunk
[DeviceB-Bridge-Aggregation100] port trunk permit vlan 100
[DeviceB-Bridge-Aggregation100] quit
```

Set the link type of Bridge-Aggregation 101 to trunk, and assign it to VLAN 101.

```
[DeviceB] interface bridge-aggregation 101
[DeviceB-Bridge-Aggregation101] port link-type trunk
[DeviceB-Bridge-Aggregation101] port trunk permit vlan 101
[DeviceB-Bridge-Aggregation101] quit
```

Create VLAN-interface 100 and VLAN-interface 101, and assign IP addresses to them.

```
[DeviceB] interface vlan-interface 100
[DeviceB-vlan-interface100] ip address 10.1.1.2 24
[DeviceB-vlan-interface100] quit
[DeviceB] interface vlan-interface 101
[DeviceB-vlan-interface101] ip address 20.1.1.2 24
[DeviceB-vlan-interface101] quit
```

Exclude VLAN-interface 100 and VLAN-interface 101 from the shutdown action by M-LAG MAD.

```
[DeviceB] m-lag mad exclude interface vlan-interface 100
```

```
[DeviceB] m-lag mad exclude interface vlan-interface 101
```

Configure OSPF.

```
[DeviceB] ospf
[DeviceB-ospf-1] import-route direct
[DeviceB-ospf-1] area 0
[DeviceB-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[DeviceB-ospf-1-area-0.0.0.0] network 20.1.1.0 0.0.0.255
[DeviceB-ospf-1-area-0.0.0.0] quit
[DeviceB-ospf-1] quit
```

Create VRRP group 1 on VLAN-interface 100 and set its virtual IP address to 10.1.1.100.

```
[DeviceB] interface vlan-interface 100
[DeviceB-Vlan-interface100] vrrp vrid 1 virtual-ip 10.1.1.100
[DeviceB-Vlan-interface100] quit
```

Create VRRP group 2 on VLAN-interface 101 and set its virtual IP address to 20.1.1.100.

```
[DeviceB] interface vlan-interface 101
[DeviceB-Vlan-interface101] vrrp vrid 2 virtual-ip 20.1.1.100
[DeviceB-Vlan-interface101] quit
```

3. Configure Device C:

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 100.

```
<Sysname> system-view
[Sysname] sysname DeviceC
[DeviceC] interface bridge-aggregation 100
[DeviceC-Bridge-Aggregation100] link-aggregation mode dynamic
[DeviceC-Bridge-Aggregation100] quit
```

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to aggregation group 100.

```
[DeviceC] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/2
[DeviceC-if-range] port link-aggregation group 100
[DeviceC-if-range] quit
```

Create VLAN 100.

```
[DeviceC] vlan 100
[DeviceC-vlan100] quit
```

Set the link type of Bridge-Aggregation 100 to trunk, and assign it to VLAN 100.

```
[DeviceC] interface bridge-aggregation 100
[DeviceC-Bridge-Aggregation100] port link-type trunk
[DeviceC-Bridge-Aggregation100] port trunk permit vlan 100
[DeviceC-Bridge-Aggregation100] quit
```

Set the link type of GigabitEthernet 1/0/3 to trunk, and assign it to VLAN 100.

```
[DeviceC] interface gigabitethernet 1/0/3
[DeviceC-GigabitEthernet1/0/3] port link-type trunk
[DeviceC-GigabitEthernet1/0/3] port trunk permit vlan 100
[DeviceC-GigabitEthernet1/0/3] quit
```

Create VLAN-interface 100, and assign it an IP address.

```
[DeviceC] interface vlan-interface 100
[DeviceC-vlan-interface100] ip address 10.1.1.3 24
[DeviceC-vlan-interface100] quit
```

Configure OSPF.

```
[DeviceC] ospf
```

```
[DeviceC-ospf-1] import-route direct
[DeviceC-ospf-1] area 0
[DeviceC-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[DeviceC-ospf-1-area-0.0.0.0] quit
[DeviceC-ospf-1] quit
```

4. Configure Device D:

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 101.

```
<Sysname> system-view
[Sysname] sysname DeviceD
[DeviceD] interface bridge-aggregation 101
[DeviceD-Bridge-Aggregation101] link-aggregation mode dynamic
[DeviceD-Bridge-Aggregation101] quit
```

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to aggregation group 101.

```
[DeviceD] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/2
[DeviceD-if-range] port link-aggregation group 101
[DeviceD-if-range] quit
```

Create VLAN 101.

```
[DeviceD] vlan 101
[DeviceD-vlan101] quit
```

Set the link type of Bridge-Aggregation 101 to trunk, and assign it to VLAN 101.

```
[DeviceD] interface bridge-aggregation 101
[DeviceD-Bridge-Aggregation101] port link-type trunk
[DeviceD-Bridge-Aggregation101] port trunk permit vlan 101
[DeviceD-Bridge-Aggregation101] quit
```

Set the link type of GigabitEthernet 1/0/3 to trunk, and assign it to VLAN 101.

```
[DeviceD] interface gigabitethernet 1/0/3
[DeviceD-GigabitEthernet1/0/3] port link-type trunk
[DeviceD-GigabitEthernet1/0/3] port trunk permit vlan 101
[DeviceD-GigabitEthernet1/0/3] quit
```

Create VLAN-interface 101, and assign it an IP address.

```
[DeviceD] interface vlan-interface 101
[DeviceD-vlan-interface101] ip address 20.1.1.3 24
[DeviceD-vlan-interface101] quit
```

Configure OSPF.

```
[DeviceD] ospf
[DeviceD-ospf-1] import-route direct
[DeviceD-ospf-1] area 0
[DeviceD-ospf-1-area-0.0.0.0] network 20.1.1.0 0.0.0.255
[DeviceD-ospf-1-area-0.0.0.0] quit
[DeviceD-ospf-1] quit
```

Verifying the configuration

Verify that Device A has formed an M-LAG system with Device B.

```
[DeviceA] display m-lag summary
Flags: A -- Aggregate interface down, B -- No peer M-LAG interface configured
       C -- Configuration consistency check failed

Peer-link interface: BAGG125
```

```
Peer-link interface state (cause): UP

Example: Configure dual-active gateways on an M-LAG system

Network configuration

As shown in Figure 29, set up an M-LAG system with Device A and Device B and configure dual-active gateways for the servers on Device A and Device B.

Figure 29 Network diagram

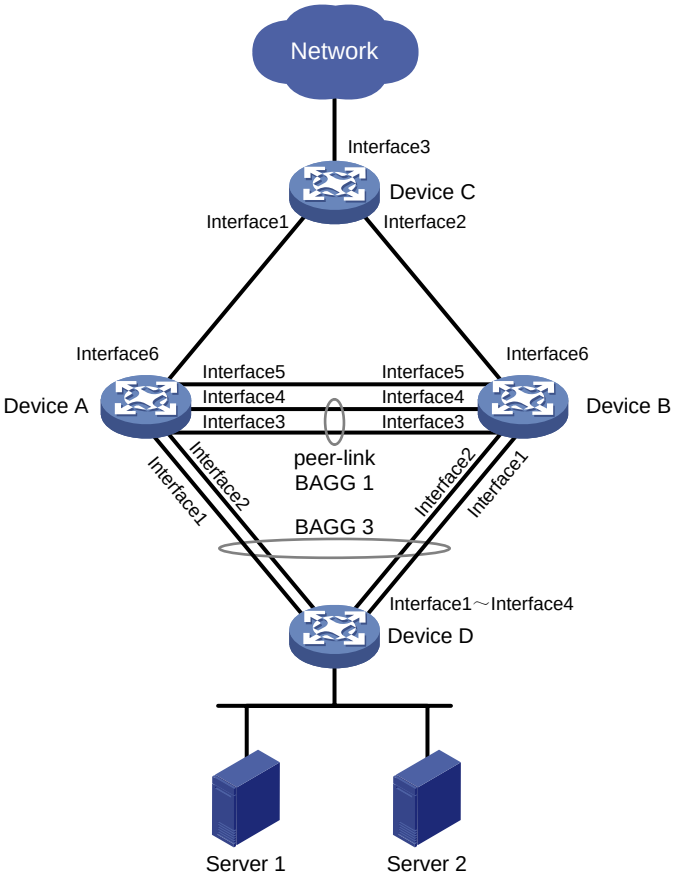

Table 8 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4
Interface5	GigabitEthernet1/0/5
Interface6	GigabitEthernet1/0/6

Restrictions and guidelines

In this example, all devices use the factory default settings. When you apply this configuration example to a live environment, make sure the existing configurations do not conflict with the configurations in this example.

You must configure the same M-LAG system MAC address on the M-LAG member devices in the same M-LAG system. You must assign unique M-LAG system MAC addresses to different M-LAG systems.

To avoid loops, do not configure local proxy ARP or ND on the downstream VLAN interfaces of the M-LAG member devices. For more information about local proxy ARP or ND, see proxy ARP configuration and IPv6 neighbor discovery in *Layer 3—IP Services Configuration Guide*.

Procedure

1. Configure Device A to form an M-LAG system:

Configure M-LAG system settings.

```
<Sysname> system-view
[Sysname] sysname DeviceA
[DeviceA] m-lag system-mac 2-2-2
[DeviceA] m-lag system-number 1
[DeviceA] m-lag system-priority 123
```

Configure M-LAG keepalive parameters.

```
[DeviceA] m-lag keepalive ip destination 21.1.1.2 source 21.1.1.1
```

Set the link mode of GigabitEthernet 1/0/5 to Layer 3, and assign the interface IPv4 and IPv6 addresses. The IPv4 address will be used as the source IP address of keepalive packets.

```
[DeviceA] interface gigabitethernet 1/0/5
[DeviceA-GigabitEthernet1/0/5] port link-mode route
[DeviceA-GigabitEthernet1/0/5] ip address 21.1.1.1 24
[DeviceA-GigabitEthernet1/0/5] ipv6 address 21::1 64
[DeviceA-GigabitEthernet1/0/5] quit
```

Exclude the interface used for M-LAG keepalive detection (GigabitEthernet 1/0/5) from the shutdown action by M-LAG MAD.

```
[DeviceA] m-lag mad exclude interface gigabitethernet 1/0/5
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 1.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation1] quit
```

Assign GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 to aggregation group 1.

```
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/3] quit
[DeviceA] interface gigabitethernet 1/0/4
[DeviceA-GigabitEthernet1/0/4] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/4] quit
```

Configure Bridge-Aggregation 1 as the peer-link interface.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] port m-lag peer-link 1
[DeviceA-Bridge-Aggregation1] undo mac-address static source-check enable
[DeviceA-Bridge-Aggregation1] quit
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 3, and assign it to M-LAG group 1.

```
[DeviceA] interface bridge-aggregation 3
[DeviceA-Bridge-Aggregation3] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation3] port m-lag group 1
[DeviceA-Bridge-Aggregation3] quit
```

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to aggregation group 3.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-aggregation group 3
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-aggregation group 3
[DeviceA-GigabitEthernet1/0/2] quit
```

Create VLAN 102 and VLAN 103.

```
[DeviceA] vlan 102 103
```

Set the link type of Bridge-Aggregation 3 to trunk, and assign it to VLAN 102 and VLAN 103.

```
[DeviceA] interface bridge-aggregation 3
[DeviceA-Bridge-Aggregation3] port link-type trunk
[DeviceA-Bridge-Aggregation3] port trunk permit vlan 102 103
[DeviceA-Bridge-Aggregation3] quit
```

2. Configure Device B to form an M-LAG system:

Configure M-LAG system settings.

```
<Sysname> system-view
[Sysname] sysname DeviceB
[DeviceB] m-lag system-mac 2-2-2
[DeviceB] m-lag system-number 2
[DeviceB] m-lag system-priority 123
```

Configure M-LAG keepalive parameters.

```
[DeviceB] m-lag keepalive ip destination 21.1.1.1 source 21.1.1.2
```

Set the link mode of GigabitEthernet 1/0/5 to Layer 3, and assign the interface IPv4 and IPv6 addresses. The IPv4 address will be used as the source IP address of keepalive packets.

```
[DeviceB] interface gigabitethernet 1/0/5
[DeviceB-GigabitEthernet1/0/5] port link-mode route
[DeviceB-GigabitEthernet1/0/5] ip address 21.1.1.2 255.255.255.0
[DeviceB-GigabitEthernet1/0/5] ipv6 address 21::2 64
[DeviceB-GigabitEthernet1/0/5] quit
```

Exclude the interface used for M-LAG keepalive detection (GigabitEthernet 1/0/5) from the shutdown action by M-LAG MAD.

```
[DeviceB] m-lag mad exclude interface gigabitethernet 1/0/5
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 1.

```
[DeviceB] interface bridge-aggregation 1
[DeviceB-Bridge-Aggregation1] link-aggregation mode dynamic
[DeviceB-Bridge-Aggregation1] quit
```

Assign GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 to aggregation group 1.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-aggregation group 1
[DeviceB-GigabitEthernet1/0/3] quit
[DeviceB] interface gigabitethernet 1/0/4
```

```
[DeviceB-GigabitEthernet1/0/4] port link-aggregation group 1
[DeviceB-GigabitEthernet1/0/4] quit
```

Configure Bridge-Aggregation 1 as the peer-link interface.

```
[DeviceB] interface bridge-aggregation 1
[DeviceB-Bridge-Aggregation1] port m-lag peer-link 1
[DeviceB-Bridge-Aggregation1] undo mac-address static source-check enable
[DeviceB-Bridge-Aggregation1] quit
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 3, and assign it to M-LAG group 1.

```
[DeviceB] interface bridge-aggregation 3
[DeviceB-Bridge-Aggregation3] link-aggregation mode dynamic
[DeviceB-Bridge-Aggregation3] port m-lag group 1
[DeviceB-Bridge-Aggregation3] quit
```

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to aggregation group 3.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-aggregation group 3
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-aggregation group 3
[DeviceB-GigabitEthernet1/0/2] quit
```

Create VLAN 102 and VLAN 103.

```
[DeviceB] vlan 102 103
```

Set the link type of Bridge-Aggregation 3 to trunk, and assign it to VLAN 102 and VLAN 103.

```
[DeviceB] interface bridge-aggregation 3
[DeviceB-Bridge-Aggregation3] port link-type trunk
[DeviceB-Bridge-Aggregation3] port trunk permit vlan 102 103
[DeviceB-Bridge-Aggregation3] quit
```

3. Configure dual-active gateways on Device A after the M-LAG system is set up:

Create VLAN-interface 102 and assign it an IPv4 address and an IPv6 address for the interface to act as an IPv4 and IPv6 gateway.

```
[DeviceA] interface vlan-interface 102
[DeviceA-Vlan-interface102] ip address 10.102.0.1 255.255.255.0
[DeviceA-Vlan-interface102] ipv6 address 10:102::1 64
```

Assign M-LAG virtual IPv4 and IPv6 addresses to VLAN-interface 102 for Device A to establish OSPF and OSPFv3 neighbor relationships with Device D.

```
[DeviceA-Vlan-interface102] port m-lag virtual-ip 10.102.0.3 24 active
[DeviceA-Vlan-interface102] port m-lag ipv6 virtual-ip FE80::2 link-local
```

Assign a MAC address to VLAN-interface 102.

```
[DeviceA-Vlan-interface102] mac-address 3-3-3
[DeviceA-Vlan-interface102] quit
```

Exclude VLAN-interface 102 from the shutdown action by M-LAG MAD.

```
[DeviceA] m-lag mad exclude interface vlan-interface 102
```

Create VLAN-interface 103 and assign it an IPv4 address and an IPv6 address for the interface to act as an IPv4 and IPv6 gateway.

```
[DeviceA] interface vlan-interface 103
[DeviceA-Vlan-interface103] ip address 10.103.0.1 24
[DeviceA-Vlan-interface103] ipv6 address 10:103::1 64
```

Assign M-LAG virtual IPv4 and IPv6 addresses to VLAN-interface 103 for Device A to establish BGP and BGP4+ peer relationships with Device D.

```
[DeviceA-Vlan-interface103] port m-lag virtual-ip 10.103.0.3 24 active
[DeviceA-Vlan-interface103] port m-lag ipv6 virtual-ip 10:103::3 64 active
```

Assign a MAC address to VLAN-interface 103.

```
[DeviceA-Vlan-interface103] mac-address 4-4-4
[DeviceA-Vlan-interface103] quit
```

Exclude VLAN-interface 103 from the shutdown action by M-LAG MAD.

```
[DeviceA] m-lag mad exclude interface vlan-interface 103
```

Assign an IPv4 address and an IPv6 address to uplink interface GigabitEthernet 1/0/6.

```
[DeviceA] interface gigabitethernet 1/0/6
[DeviceA-GigabitEthernet1/0/6] port link-mode route
[DeviceA-GigabitEthernet1/0/6] ip address 32.1.1.1 24
[DeviceA-GigabitEthernet1/0/6] ipv6 address 32:1::1 64
[DeviceA-GigabitEthernet1/0/6] quit
```

Configure OSPF.

```
[DeviceA] ospf 1 router-id 11.1.1.1
[DeviceA-ospf-1] area 0
[DeviceA-ospf-1-area-0.0.0.0] quit
[DeviceA-ospf-1] quit
[DeviceA] interface vlan-interface 102
[DeviceA-Vlan-interface102] ospf 1 area 0
[DeviceA-Vlan-interface102] ospf peer sub-address enable 10.102.0.3
[DeviceA-Vlan-interface102] quit
[DeviceA] interface gigabitethernet 1/0/6
[DeviceA-GigabitEthernet1/0/6] ospf 1 area 0
[DeviceA-GigabitEthernet1/0/6] quit
```

Configure OSPFv3.

```
[DeviceA] ospfv3 1
[DeviceA-ospfv3-1] router-id 10.1.1.1
[DeviceA-ospfv3-1] area 0
[DeviceA-ospfv3-1-area-0.0.0.0] quit
[DeviceA-ospfv3-1] quit
[DeviceA] interface vlan-interface 102
[DeviceA-Vlan-interface102] ospfv3 1 area 0
[DeviceA-Vlan-interface102] quit
[DeviceA] interface gigabitethernet 1/0/6
[DeviceA-GigabitEthernet1/0/6] ospfv3 1 area 0
[DeviceA-GigabitEthernet1/0/6] quit
```

Configure BGP.

```
[DeviceA] bgp 100
[DeviceA-bgp-default] router-id 12.1.1.1
[DeviceA-bgp-default] peer 32.1.1.2 as-number 100
[DeviceA-bgp-default] peer 10.103.0.2 as-number 100
[DeviceA-bgp-default] peer 10.103.0.2 source-address 10.103.0.3
[DeviceA-bgp-default] address-family ipv4
[DeviceA-bgp-default-ipv4] peer 10.103.0.2 enable
[DeviceA-bgp-default-ipv4] network 10.103.0.0  255.255.255.0
```

```
[DeviceA-bgp-default-ipv4] peer 32.1.1.2 enable
[DeviceA-bgp-default-ipv4] network 32.1.1.0 255.255.255.0
[DeviceA-bgp-default-ipv4] quit
```

Configure BGP4+.

```
[DeviceA-bgp-default] peer 32:1::2 as-number 100
[DeviceA-bgp-default] peer 10:103::2 as-number 100
[DeviceA-bgp-default] peer 10:103::2 source-address 10:103::3
[DeviceA-bgp-default] address-family ipv6
[DeviceA-bgp-default-ipv6] peer 10:103::2 enable
[DeviceA-bgp-default-ipv6] network 10:103::2  64
[DeviceA-bgp-default-ipv6] peer 32:1::2 enable
[DeviceA-bgp-default-ipv6] network  32:1::2 64
[DeviceA-bgp-default-ipv6] quit
[DeviceA-bgp-default] quit
```

4. Configure dual-active gateways on Device B after the M-LAG system is set up:

Create VLAN-interface 102 and assign it an IPv4 address and an IPv6 address for the interface to act as an IPv4 and IPv6 gateway.

```
[DeviceB] interface vlan-interface 102
[DeviceB-Vlan-interface102] ip address 10.102.0.1 24
[DeviceB-Vlan-interface102] ipv6 address 10:102::1 64
```

Assign M-LAG virtual IPv4 and IPv6 addresses to VLAN-interface 102 for Device A to establish OSPF and OSPFv3 neighbor relationships with Device D.

```
[DeviceB-Vlan-interface102] port m-lag virtual-ip 10.102.0.4 24 active
[DeviceB-Vlan-interface102] port m-lag ipv6 virtual-ip FE80::4 link-local
```

Assign a MAC address to VLAN-interface 102.

```
[DeviceB-Vlan-interface102] mac-address 3-3-3
[DeviceB-Vlan-interface102] quit
```

Exclude VLAN-interface 102 from the shutdown action by M-LAG MAD.

```
[DeviceB] m-lag mad exclude interface vlan-interface 102
```

Create VLAN-interface 103 and assign it an IPv4 address and an IPv6 address for the interface to act as an IPv4 and IPv6 gateway.

```
[DeviceB] interface vlan-interface 103
[DeviceB-Vlan-interface103] ip address 10.103.0.1 24
[DeviceB-Vlan-interface103] ipv6 address 10:103::1 64
```

Assign M-LAG virtual IPv4 and IPv6 addresses to VLAN-interface 103 for Device A to establish BGP and BGP4+ peer relationships with Device D.

```
[DeviceB-Vlan-interface103] port m-lag virtual-ip 10.103.0.4 24 active
[DeviceB-Vlan-interface103] port m-lag ipv6 virtual-ip 10:103::4 64 active
```

Assign a MAC address to VLAN-interface 103.

```
[DeviceB-Vlan-interface103] mac-address 4-4-4
[DeviceB-Vlan-interface103] quit
```

Exclude VLAN-interface 103 from the shutdown action by M-LAG MAD.

```
[DeviceB] m-lag mad exclude interface vlan-interface 103
```

Assign an IPv4 address and an IPv6 address to uplink interface GigabitEthernet 1/0/6.

```
[DeviceB] interface gigabitethernet 1/0/6
[DeviceB-GigabitEthernet1/0/6] port link-mode route
[DeviceB-GigabitEthernet1/0/6] ip address 33.1.1.1 24
[DeviceB-GigabitEthernet1/0/6] ipv6 address 33:1::1 64
```

```
[DeviceB-GigabitEthernet1/0/6] quit
```

Configure OSPF.

```
[DeviceB] ospf 1 router-id 11.1.1.2
[DeviceB-ospf-1] area 0
[DeviceB-ospf-1-area-0.0.0.0] quit
[DeviceB-ospf-1] quit
[DeviceB] interface vlan-interface 102
[DeviceB-Vlan-interface102] ospf 1 area 0
[DeviceB-Vlan-interface102] ospf peer sub-address enable 10.102.0.4
[DeviceB-Vlan-interface102] quit
[DeviceB] interface gigabitethernet 1/0/6
[DeviceB-GigabitEthernet1/0/6] ospf 1 area 0
[DeviceB-GigabitEthernet1/0/6] quit
```

Configure OSPFv3.

```
[DeviceB] ospfv3 1
[DeviceB-ospfv3-1] router-id 10.1.1.2
[DeviceB-ospfv3-1] area 0
[DeviceB-ospfv3-1-area-0.0.0.0] quit
[DeviceB-ospfv3-1] quit
[DeviceB] interface vlan-interface 102
[DeviceB-Vlan-interface102] ospfv3 1 area 0
[DeviceB-Vlan-interface102] quit
[DeviceB] interface gigabitethernet 1/0/6
[DeviceB-GigabitEthernet1/0/6] ospfv3 1 area 0
[DeviceB-GigabitEthernet1/0/6] quit
```

Configure BGP.

```
[DeviceB] bgp 100
[DeviceB-bgp-default] router-id 12.1.1.2
[DeviceB-bgp-default] peer 33.1.1.2 as-number 100
[DeviceB-bgp-default] peer 10.103.0.2 as-number 100
[DeviceB-bgp-default] peer 10.103.0.2 source-address 10.103.0.4
[DeviceB-bgp-default] address-family ipv4
[DeviceB-bgp-default-ipv4] peer 10.103.0.2 enable

[DeviceC-bgp-default-ipv6] network 33:1:: 64
[DeviceC-bgp-default-ipv6] quit
[DeviceC-bgp-default] quit
```

6. Configure Device D:

Create VLAN 102 and VLAN 103.

```
<Sysname> system-view
[Sysname] sysname DeviceD
[DeviceD] vlan 102 103
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 3.

```
[DeviceD] interface bridge-aggregation 3
[DeviceD-Bridge-Aggregation3] link-aggregation mode dynamic
[DeviceD-Bridge-Aggregation3] quit
```

Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to aggregation group 3.

```
[DeviceD] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/4
[DeviceD-if-range] port link-aggregation group 3
[DeviceD-if-range] quit
```

Configure Bridge-Aggregation 3 as a trunk port, and assign it to VLAN 102 and VLAN 103.

```
[DeviceD] interface bridge-aggregation 3
[DeviceD-Bridge-Aggregation3] port link-type trunk
[DeviceD-Bridge-Aggregation3] port trunk permit vlan 102 103
[DeviceD-Bridge-Aggregation3] quit
```

Create VLAN-interface102 and assign IPv4 and IPv6 addresses to it.

```
[DeviceD] interface vlan-interface 102
[DeviceD-Vlan-interface102] ip address 10.102.0.2 24
[DeviceD-Vlan-interface102] ipv6 address 10:102::2 64
[DeviceD-Vlan-interface102] quit
```

Create VLAN-interface103 and assign IPv4 and IPv6 addresses to it.

```
[DeviceD] interface vlan-interface 103
[DeviceD-Vlan-interface103] ip address 10.103.0.2 24
[DeviceD-Vlan-interface103] ipv6 address 10:103::2 64
[DeviceD-Vlan-interface103] quit
```

Configure OSPF.

```
[DeviceD] ospf 1 router-id 11.1.1.4
[DeviceD-ospf-1] area 0
[DeviceD-ospf-1-area-0.0.0.0] quit
[DeviceD-ospf-1] quit
[DeviceD] interface vlan-interface 102
[DeviceD-Vlan-interface102] ospf 1 area 0
[DeviceD-Vlan-interface102] quit
[DeviceD] interface vlan-interface 103
[DeviceD-Vlan-interface103] ospf 1 area 0
```

```
[DeviceD-Vlan-interface103] quit
```

Configure OSPFv3.

```
[DeviceD] ospfv3 1
[DeviceD-ospfv3-1] router-id 10.1.1.4
[DeviceD-ospfv3-1] area 0
[DeviceD-ospfv3-1-area-0.0.0.0] quit
[DeviceD-ospfv3-1] quit
[DeviceD] interface vlan-interface 102
[DeviceD-Vlan-interface102] ospfv3 1 area 0
[DeviceD-Vlan-interface102] quit
[DeviceD] interface vlan-interface 103
[DeviceD-Vlan-interface103] ospfv3 1 area 0
[DeviceD-Vlan-interface103] quit
```

Configure BGP.

```
[DeviceD] bgp 100
[DeviceD-bgp-default] router-id 12.1.1.4
[DeviceD-bgp-default] peer 10.103.0.3 as-number 100
[DeviceD-bgp-default] peer 10.103.0.4 as-number 100
[DeviceD-bgp-default] address-family ipv4
[DeviceD-bgp-default-ipv4] peer 10.103.0.3 enable
[DeviceD-bgp-default-ipv4] peer 10.103.0.4 enable
[DeviceD-bgp-default-ipv4] network 10.103.0.3  255.255.255.0
[DeviceD-bgp-default-ipv4] quit
```

Configure BGP4+.

```
[DeviceD-bgp-default] peer 10:103::3 as-number 100
[DeviceD-bgp-default] peer 10:103::4 as-number 100
[DeviceD-bgp-default] address-family ipv6
[DeviceD-bgp-default-ipv6] peer 10:103::3  enable
[DeviceD-bgp-default-ipv6] peer 10:103::4 enable
[DeviceD-bgp-default-ipv6] network 10:103::3 64
[DeviceD-bgp-default-ipv6] quit
[DeviceD-bgp-default] quit
```

Verifying the configuration

The following tasks use Device A as an example.

Verify that Device A has formed an M-LAG system with Device B.

```
[DeviceA] display m-lag summary
Flags: A -- Aggregate interface down, B -- No peer M-LAG interface configured
       C -- Configuration consistency check failed

Peer-link interface: BAGG1
Peer-link interface state (cause): UP
Keepalive link state (cause): UP

                    M-LAG interface information
M-LAG IF      M-LAG group  Local state (cause)  Peer state  Remaining down time(s)
BAGG3         1            UP                   UP          -
[DeviceA] display m-lag verbose
```

```
Flags: A -- Home_Gateway, B -- Neighbor_Gateway, C -- Other_Gateway,
       D -- PeerLink_Activity, E -- DRCP_Timeout, F -- Gateway_Sync,
       G -- Port_Sync, H -- Expired

Peer-link interface/Peer-link interface ID: BAGG1/1
State: UP
Cause: -
Local DRCP flags/Peer DRCP flags: ABDFG/ABDFG
Local Selected ports (index): GE1/0/3 (260), GE1/0/4 (261)
Peer Selected ports indexes: 260, 261

M-LAG interface/M-LAG group ID: BAGG3/1
Local M-LAG interface state: UP
Peer M-LAG interface state: UP
M-LAG group state: UP
Local M-LAG interface down cause: -
Remaining M-LAG DOWN time: -
Local M-LAG interface LACP MAC: Config=N/A, Effective=0002-0002-0002
Peer M-LAG interface LACP MAC: Config=N/A, Effective=0002-0002-0002
Local M-LAG interface LACP priority: Config=32768, Effective=123
Peer M-LAG interface LACP priority: Config=32768, Effective=123
Local DRCP flags/Peer DRCP flags: ABDFG/ABDFG
Local Selected ports (index): GE1/0/1 (258), GE1/0/2 (259)
Peer Selected ports indexes: 258, 259
```

Verify that Device A have established OSPF neighbor relationships.

```
[DeviceA] display ospf peer

         OSPF Process 1 with Router ID 11.1.1.1
               Neighbor Brief Information

 Area: 0.0.0.0

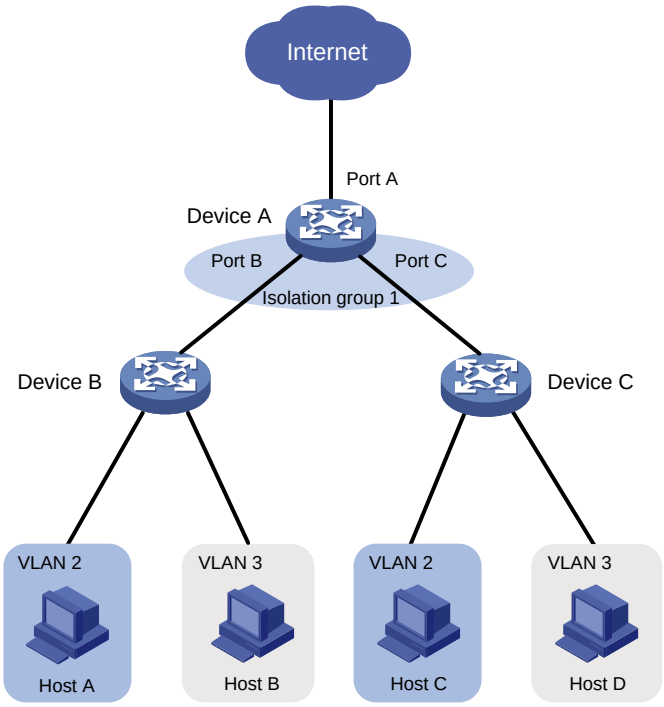
Configuring port isolation

About port isolation

The port isolation feature isolates Layer 2 traffic for data privacy and security without using VLANs.



Ports in an isolation group cannot communicate with each other. However, they can communicate with ports outside the isolation group.

You can configure community VLANs in an isolation group. Ports in an isolation group can communicate with each other if they belong to a community VLAN.

As shown in Figure 1:

- To isolate Host A from Host C, and Host B from Host D, assign Port B and Port C on Device A to isolation group 1.
- To enable Layer 2 communication between Host B and Host D, specify VLAN 3 as a community VLAN in isolation group 1. Host B and Host D belong to VLAN 3.

Figure 1 Community VLANs in an isolation group

Assigning a port to an isolation group

About this task

The device supports multiple isolation groups, which can be configured manually. The number of ports assigned to an isolation group is not limited.

Restrictions and guidelines

- You can assign a port to only one isolation group.
- The configuration in Layer 2 Ethernet interface view applies only to the interface.

- The configuration in Layer 2 aggregate interface view applies to the Layer 2 aggregate interface and its aggregation member ports. If the device fails to apply the configuration to the aggregate interface, it does not assign any aggregation member port to the isolation group. If the failure occurs on an aggregation member port, the device skips the port and continues to assign other aggregation member ports to the isolation group.
- Port isolation is not supported on an IRF fabric in the current software version.

Procedure

1. Enter system view.
   system-view
2. Create an isolation group.
   port-isolate group *group-id* [**peer-link**]
3. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
4. Assign the port to the isolation group.
   port-isolate enable group *group-id*
   By default, the port is not in any isolation group.

Display and maintenance commands for port isolation

Execute **display** commands in any view.

Task	Command
Display isolation group information.	**display port-isolate group** [*group-id*]

Port isolation configuration examples

Example: Configuring port isolation

Network configuration

As shown in Figure 2:

- LAN users Host A, Host B, and Host C are connected to GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 on the device, respectively.
- The device connects to the Internet through GigabitEthernet 1/0/4.

Configure the device to provide Internet access for the hosts, and isolate them from one another at Layer 2.

Figure 2 Network diagram

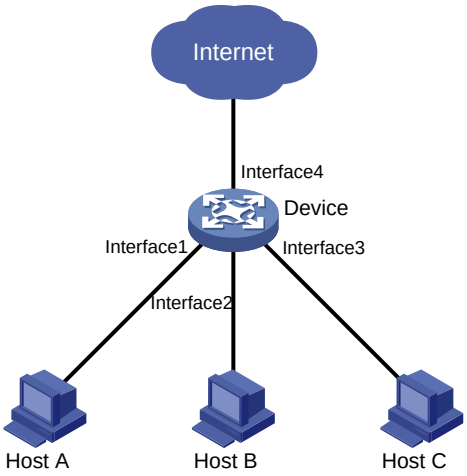


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4

Procedure

Create isolation group 2.

```
<Device> system-view
[Device] port-isolate group 2
```

Assign GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 to isolation group 2.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] port-isolate enable group 2
[Device-GigabitEthernet1/0/1] quit
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] port-isolate enable group 2
[Device-GigabitEthernet1/0/2] quit
[Device] interface gigabitethernet 1/0/3
[Device-GigabitEthernet1/0/3] port-isolate enable group 2
[Device-GigabitEthernet1/0/3] quit
```

Verifying the configuration

Display information about isolation group 2.

```
[Device] display port-isolate group 2
 Port isolation group information:
 Group ID: 2
 Group members:
    GigabitEthernet1/0/1          GigabitEthernet1/0/2
    GigabitEthernet1/0/3
```

The output shows that GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 are assigned to isolation group 2. As a result, Host A, Host B, and Host C are isolated from one another at layer 2.

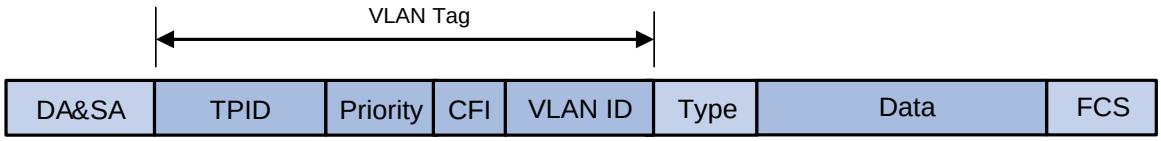
Configuring VLANs

About VLANs



The Virtual Local Area Network (VLAN) technology divides a physical LAN into multiple logical LANs. It has the following benefits:

- **Security**—Hosts in the same VLAN can communicate with one another at Layer 2, but they are isolated from hosts in other VLANs at Layer 2.
- **Broadcast traffic isolation**—Each VLAN is a broadcast domain that limits the transmission of broadcast packets.
- **Flexibility**—A VLAN can be logically divided on a workgroup basis. Hosts in the same workgroup can be assigned to the same VLAN, regardless of their physical locations.

VLAN frame encapsulation

To identify Ethernet frames from different VLANs, IEEE 802.1Q inserts a four-byte VLAN tag between the destination and source MAC address (DA&SA) field and the Type field.

Figure 1 VLAN tag placement and format

A VLAN tag includes the following fields:

- **TPID**—16-bit tag protocol identifier that indicates whether a frame is VLAN-tagged. By default, the hexadecimal TPID value 8100 identifies a VLAN-tagged frame. A device vendor can set the TPID to a different value. For compatibility with a neighbor device, set the TPID value on the device to be the same as the neighbor device.For more information about setting the TPID value, see QinQ commands in Layer 2—*LAN Switching Command Reference*.
- **Priority**—3-bit long, identifies the 802.1p priority of the frame. For more information, see *ACL and QoS Configuration Guide*.
- **CFI**—1-bit long canonical format indicator that indicates whether the MAC addresses are encapsulated in the standard format when packets are transmitted across different media. Available values include:
  - **0 (default)**—The MAC addresses are encapsulated in the standard format.
  - **1**—The MAC addresses are encapsulated in a non-standard format.

  This field is always set to 0 for Ethernet.
- **VLAN ID**—12-bit long, identifies the VLAN to which the frame belongs. The VLAN ID range is 0 to 4095. VLAN IDs 0 and 4095 are reserved, and VLAN IDs 1 to 4094 are user configurable.

The way a network device handles an incoming frame depends on whether the frame has a VLAN tag and the value of the VLAN tag (if any).

Ethernet supports encapsulation formats Ethernet II, 802.3/802.2 LLC, 802.3/802.2 SNAP, and 802.3 raw. The Ethernet II encapsulation format is used here. For information about the VLAN tag fields in other frame encapsulation formats, see related protocols and standards.

For a frame that has multiple VLAN tags, the device handles it according to its outermost VLAN tag and transmits its inner VLAN tags as the payload.

VLAN types

The following VLAN types are available:

- Port-based VLAN.
- MAC-based VLAN.
- IP subnet-based VLAN.
- Protocol-based VLAN.

If all these types of VLANs are configured on a port, the port processes packets in the following descending order of priority by default:

- MAC-based VLAN.
- IP subnet-based VLAN.
- Protocol-based VLAN.
- Port-based VLAN.

Port-based VLANs

Port-based VLANs group VLAN members by port. A port forwards packets from a VLAN only after it is assigned to the VLAN.

Port link type

You can set the link type of a port to access, trunk, or hybrid. The port link type determines whether the port can be assigned to multiple VLANs. The link types use the following VLAN tag handling methods:

- **Access**—An access port can forward packets only from one VLAN and send these packets untagged. An access port is typically used in the following conditions:
  - Connecting to a terminal device that does not support VLAN packets.
  - In scenarios that do not distinguish VLANs.
- **Trunk**—A trunk port can forward packets from multiple VLANs. Except packets from the port VLAN ID (PVID), packets sent out of a trunk port are VLAN-tagged. Ports connecting network devices are typically configured as trunk ports.
- **Hybrid**—A hybrid port can forward packets from multiple VLANs. The tagging status of the packets forwarded by a hybrid port depends on the port configuration.

PVID

The PVID identifies the default VLAN of a port. Untagged packets received on a port are considered as the packets from the port PVID.

An access port can join only one VLAN. The VLAN to which the access port belongs is the PVID of the port. A trunk or hybrid port supports multiple VLANs and the PVID configuration.

How ports of different link types handle frames

Actions	Access	Trunk	Hybrid
In the inbound direction for an untagged frame	Tags the frame with the PVID tag.	• If the PVID is permitted on the port, tags the frame with the PVID tag. • If not, drops the frame.	
In the inbound direction for a tagged frame	• Receives the frame if its VLAN ID is the same as the PVID. • Drops the frame if	• Receives the frame if its VLAN is permitted on the port. • Drops the frame if its VLAN is not permitted on the port.	

Actions	Access	Trunk	Hybrid
	its VLAN ID is different from the PVID.		
In the outbound direction	Removes the VLAN tag and sends the frame.	• Removes the tag and sends the frame if the frame carries the PVID tag and the port belongs to the PVID. • Sends the frame without removing the tag if its VLAN is carried on the port but is different from the PVID.	Sends the frame if its VLAN is permitted on the port. The tagging status of the frame depends on the **`port hybrid vlan`** command configuration.

MAC-based VLANs

The MAC-based VLAN feature assigns hosts to a VLAN based on their MAC addresses. This feature is also called user-based VLAN because VLAN configuration remains the same regardless of a user's physical location.

Static MAC-based VLAN assignment

Use static MAC-based VLAN assignment in networks that have a small number of VLAN users. To configure static MAC-based VLAN assignment on a port, perform the following tasks:

1. Create MAC-to-VLAN entries.
2. Enable the MAC-based VLAN feature on the port.
3. Assign the port to the MAC-based VLAN.

A port configured with static MAC-based VLAN assignment processes a received frame as follows before sending the frame out:

- For an untagged frame, the port determines its VLAN ID in the following workflow:
  a. The port first performs a fuzzy match as follows:
     - Searches for the MAC-to-VLAN entries whose masks are not all Fs.
     - Performs a logical AND operation on the source MAC address and each of these masks.

       If an AND operation result matches the MAC address in a MAC-to-VLAN entry, the port tags the frame with the VLAN ID specific to this entry.

  b. If the fuzzy match fails, the port performs an exact match. It searches for MAC-to-VLAN entries whose masks are all Fs. If the source MAC address of the frame exactly matches the MAC address of a MAC-to-VLAN entry, the port tags the frame with the VLAN ID specific to this entry.

  c. If no matching VLAN ID is found, the port determines the VLAN for the packet by using the following matching order:
     - IP subnet-based VLAN.
     - Protocol-based VLAN.
     - Port-based VLAN.

     When a match is found, the port tags the packet with the matching VLAN ID.
- For a tagged frame, the port determines whether the VLAN ID of the frame is permitted on the port.

- If the VLAN ID of the frame is permitted on the port, the port forwards the frame.
- If the VLAN ID of the frame is not permitted on the port, the port drops the frame.

Dynamic MAC-based VLAN assignment

When you cannot determine the target MAC-based VLANs of a port, use dynamic MAC-based VLAN assignment on the port. To use dynamic MAC-based VLAN assignment, perform the following tasks:

1. Create MAC-to-VLAN entries.
2. Enable the MAC-based VLAN feature on the port.
3. Enable dynamic MAC-based VLAN assignment on the port.

Dynamic MAC-based VLAN assignment uses the following workflow, as shown in Figure 2:

1. When a port receives a frame, it first determines whether the frame is tagged.
   - If the frame is tagged, the port gets the source MAC address of the frame.
   - If the frame is untagged, the port selects a VLAN for the frame by using the following matching order:
     - MAC-based VLAN (fuzzy and exact MAC address match).
     - IP subnet-based VLAN.
     - Protocol-based VLAN.
     - Port-based VLAN.

     After tagging the frame with the selected VLAN, the port gets the source MAC address of the frame.
2. The port uses the source MAC address and VLAN of the frame to match the MAC-to VLAN entries.
   - If the source MAC address of the frame exactly matches the MAC address in a MAC-to-VLAN entry, the port checks whether the VLAN ID of the frame matches the VLAN in the entry.
     - If the two VLAN IDs match, the port joins the VLAN and forwards the frame.
     - If the two VLAN IDs do not match, the port drops the frame.
   - If the source MAC address of the frame does not exactly match any MAC addresses in MAC-to-VLAN entries, the port checks whether the VLAN ID of the frame is its PVID.
     - If the VLAN ID of the frame is the PVID of the port, the port determines whether it allows the PVID.

       If the PVID is allowed, the port generates a dynamic MAC address entry with the source MAC address of the packet as the destination MAC address, and forwards the frame within the PVID. If the PVID is not allowed, the port drops the frame.

IMPORTANT:

If the device has generated a dynamic MAC address entry, packets whose source MAC address is the destination MAC address in the dynamic MAC address entry can still be forwarded by the port, even if the PVID configuration of the port is changed and the VLAN ID of the packet no longer meets the above conditions. The port drops the frame only when the generated dynamic MAC address entry ages out and the frame no longer meets the above conditions.

     - If the VLAN ID of the frame is not the PVID of the port, the port determines whether the VLAN ID is the primary VLAN ID and the port PVID is a secondary VLAN ID. If yes, the port forwards the frame. Otherwise, the port drops the frame.

Figure 2 Flowchart for processing a frame in dynamic MAC-based VLAN assignment

Server-assigned MAC-based VLAN

Use this feature with access authentication, such as MAC-based 802.1X authentication, to implement secure and flexible terminal access.

To implement server-assigned MAC-based VLAN, perform the following tasks:

1. Configure the server-assigned MAC-based VLAN feature on the access device.
2. Configure username-to-VLAN entries on the access authentication server.

When a user passes authentication of the access authentication server, the server assigns the authorization VLAN information for the user to the device. The device then performs the following operations:

1. Generates a MAC-to-VLAN entry by using the source MAC address of the user packet and the authorization VLAN information. The authorization VLAN is a MAC-based VLAN.

   The generated MAC-to-VLAN entry cannot conflict with the existing static MAC-to-VLAN entries. If a confliction exists, the dynamic MAC-to-VLAN entry cannot be generated.
2. Assigns the port that connects the user to the MAC-based VLAN.

When the user goes offline, the device automatically deletes the MAC-to-VLAN entry and removes the port from the MAC-based VLAN. For more information about 802.1X and MAC authentication, see *Security Configuration Guide*.

IP subnet-based VLANs

The IP subnet-based VLAN feature assigns untagged packets to VLANs based on their source IP addresses and subnet masks.

Use this feature when untagged packets from an IP subnet or IP address must be transmitted in a VLAN.

Protocol-based VLANs

The protocol-based VLAN feature assigns inbound packets to different VLANs based on their protocol types and encapsulation formats. The protocols available for VLAN assignment include IP, IPX, and AT. The encapsulation formats include Ethernet II, 802.3 raw, 802.2 LLC, and 802.2 SNAP.

This feature associates the available network service types with VLANs and facilitates network management and maintenance.

Layer 3 communication between VLANs

Hosts of different VLANs use VLAN interfaces to communicate at Layer 3. VLAN interfaces are virtual interfaces that do not exist as physical entities on devices. For each VLAN, you can create one VLAN interface and assign an IP address to it. The VLAN interface acts as the gateway of the VLAN to forward packets at Layer 3. When the IP addresses of multiple VLAN interfaces are on different subnets, you must configure IP routing protocols to enable Layer 3 communication between these IP addresses. Then, the devices can forward packets at Layer 3 across subnets between different VLANs. For more information about IP routing protocols, see *Layer 3—IP Routing Configuration Guide*.

Protocols and standards

IEEE 802.1Q, *IEEE Standard for Local and Metropolitan Area Networks: Virtual Bridged Local Area Networks*

Configuring a VLAN

Restrictions and guidelines

- As the system default VLAN, VLAN 1 cannot be created or deleted.
- Before you delete a dynamic VLAN or a VLAN locked by an application, you must first remove the configuration from the VLAN.

VLAN configuration tasks at a glance

To configure VLANs, perform the following tasks:

1. Creating VLANs
2. (Optional.) Enabling packet statistics for the VLAN

Creating VLANs

1. Enter system view.
   system-view
2. Create one or multiple VLANs.
   - Create a VLAN and enter its view.
     vlan *vlan-id*
   - Create multiple VLANs and enter VLAN view.
     Create VLANs.
     vlan { *vlan-id-list* | **all** }

Enter VLAN view.

vlan *vlan-id*

By default, only the system default VLAN (VLAN 1) exists.

3. (Optional.) Set a name for the VLAN.

   name *text*

   By default, the name of a VLAN is **VLAN** *vlan-id.* The *vlan-id* argument specifies the VLAN ID in a four-digit format. If the VLAN ID has fewer than four digits, leading zeros are added. For example, the name of VLAN 100 is **VLAN 0100**.

4. (Optional.) Configure the description for the VLAN.

   description *text*

   By default, the description of a VLAN is **VLAN** *vlan-id.* The *vlan-id* argument specifies the VLAN ID in a four-digit format. If the VLAN ID has fewer than four digits, leading zeros are added. For example, the default description of VLAN 100 is **VLAN 0100**.

Enabling packet statistics for the VLAN

About this task

When you need to examine or troubleshoot the network, you can enable packet statistics for a VLAN to monitor the statistics of packets in the VLAN. The VLAN packet statistics include statistics on unicast, multicast, and broadcast packets.

Restrictions and guidelines

Disable packet statistics for a VLAN to save system resources when you do not need this feature.

The system does not automatically clear the packet statistics for VLANs. To clear the packet statistics for a VLAN, use the **reset vlan statistics** command.

Procedure

1. Enter system view.

   system-view

2. Enter VLAN view.

   vlan *vlan-id*

3. Enable packet statistics for the VLAN.

   statistics enable

   By default, packet statistics is disabled for a VLAN.

Configuring port-based VLANs

Restrictions and guidelines for port-based VLANs

- When you use the **undo vlan** command to delete the PVID of a port, either of the following events occurs depending on the port link type:
  - For an access port, the PVID of the port changes to VLAN 1.
  - For a hybrid or trunk port, the PVID setting of the port does not change.

  You can use a nonexistent VLAN as the PVID for a hybrid or trunk port, but not for an access port.
- As a best practice, set the same PVID for a local port and its peer.

- To prevent a port from dropping untagged packets or PVID-tagged packets, assign the port to its PVID.

Assigning an access port to a VLAN

About this task

You can assign an access port to a VLAN in VLAN view or interface view.

Assigning one or multiple access ports to a VLAN in VLAN view

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Assign one or multiple access ports to the VLAN.
   port *interface-list*
   By default, all ports belong to VLAN 1.

Assigning an access port to a VLAN in interface view

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
3. Set the port link type to access.
   port link-type access
   By default, all ports are access ports.
4. Assign the access port to a VLAN.
   port access vlan *vlan-id*
   By default, all access ports belong to VLAN 1.

Assigning a trunk port to a VLAN

About this task

A trunk port supports multiple VLANs. You can assign it to a VLAN in interface view.

Restrictions and guidelines

To change the link type of a port from trunk to hybrid, set the link type to access first.

To enable a trunk port to transmit packets from its PVID, you must assign the trunk port to the PVID by using the **port trunk permit vlan** command.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.

interface *interface-type interface-number*

- Enter Layer 2 aggregate interface view.
  interface bridge-aggregation *interface-number*

3. Set the port link type to trunk.
   port link-type trunk
   By default, all ports are access ports.
4. Assign the trunk port to the specified VLANs.
   port trunk permit vlan { *vlan-id-list* | **all** }
   By default, a trunk port permits only VLAN 1.
5. (Optional.) Set the PVID for the trunk port.
   port trunk pvid vlan *vlan-id*
   The default setting is VLAN 1.

Assigning a hybrid port to a VLAN

About this task

A hybrid port supports multiple VLANs. You can assign it to the specified VLANs in interface view. Make sure the VLANs have been created.

Restrictions and guidelines

To change the link type of a port from trunk to hybrid, set the link type to access first.

To enable a hybrid port to transmit packets from its PVID, you must assign the hybrid port to the PVID by using the **port hybrid vlan** command.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
3. Set the port link type to hybrid.
   port link-type hybrid
   By default, all ports are access ports.
4. Assign the hybrid port to the specified VLANs.
   port hybrid vlan *vlan-id-list* { **tagged** | **untagged** }
   By default, the hybrid port is an untagged member of the VLAN to which the port belongs when its link type is **access**.
5. (Optional.) Set the PVID for the hybrid port.
   port hybrid pvid vlan *vlan-id*
   By default, the PVID of a hybrid port is the ID of the VLAN to which the port belongs when its link type is **access**.

Configuring MAC-based VLANs

Restrictions and guidelines for MAC-based VLANs

- MAC-based VLANs are available only on hybrid ports.
- Do not configure a VLAN as both a super VLAN and a MAC-based VLAN.
- The MAC-based VLAN feature is mainly configured on downlink ports of user access devices. Do not use this feature with link aggregation.

Configuring static MAC-based VLAN assignment

1. Enter system view.

   system-view
2. Create a MAC-to-VLAN entry.

   mac-vlan mac-address *mac-address* [**mask** *mac-mask*] **vlan** *vlan-id* [**dot1p** *priority*]

   By default, no MAC-to-VLAN entries exist.
3. Enter interface view.
   - Enter Layer 2 Ethernet interface view.

     interface *interface-type interface-number*
4. Set the port link type to hybrid.

   port link-type hybrid

   By default, all ports are access ports.
5. Assign the hybrid port to the MAC-based VLANs.

   port hybrid vlan *vlan-id-list* { **tagged** | **untagged** }

   By default, a hybrid port is an untagged member of the VLAN to which the port belongs when its link type is **access**.
6. Enable the MAC-based VLAN feature.

   mac-vlan enable

   By default, this feature is disabled.
7. (Optional.) Configure the interface to assign VLANs based on the MAC address preferentially.

   vlan precedence mac-vlan

   By default, the system assigns VLANs based on the MAC address preferentially when both the MAC-based VLAN and IP subnet-based VLAN are configured on a port.

Configuring dynamic MAC-based VLAN assignment

About this task

For successful dynamic MAC-based VLAN assignment, use static VLANs when you create MAC-to-VLAN entries.

When a port joins a VLAN specified in the MAC-to-VLAN entry, one of the following events occurs depending on the port configuration:

- If the port has not been configured to allow packets from the VLAN to pass through, the port joins the VLAN as an untagged member.

- If the port has been configured to allow packets from the VLAN to pass through, the port configuration remains the same.

The 802.1p priority of the VLAN in a MAC-to-VLAN entry determines the transmission priority of the matching packets.

Restrictions and guidelines

- If you configure both static and dynamic MAC-based VLAN assignments on a port, dynamic MAC-based VLAN assignment takes effect.
- As a best practice to ensure correct operation of 802.1X and MAC authentication, do not use dynamic MAC-based VLAN assignment with 802.1X or MAC authentication.
- As a best practice, do not both configure dynamic MAC-based VLAN assignment and disable MAC address learning on a port. If the two features are configured together on a port, the port forwards only packets exactly matching the MAC-to-VLAN entries and drops inexactly matching packets.
- As a best practice, do not configure both dynamic MAC-based VLAN assignment and the MAC learning limit on a port.

  If the two features are configured together on a port and the port learns the configured maximum number of MAC address entries, the port processes packets as follows:
  - Forwards only packets matching the MAC address entries learnt by the port.
  - Drops unmatching packets.
- As a best practice, do not use dynamic MAC-based VLAN assignment with MSTP. In MSTP mode, if a port is blocked in the MSTI of its target VLAN, the port drops the received packets instead of delivering them to the CPU. As a result, the port will not be dynamically assigned to the target VLAN.
- As a best practice, do not use dynamic MAC-based VLAN assignment with PVST. In PVST mode, if the target VLAN of a port is not permitted on the port, the port is placed in blocked state. The port drops the received packets instead of delivering them to the CPU. As a result, the port will not be dynamically assigned to the target VLAN.
- As a best practice, do not configure both dynamic MAC-based VLAN assignment and automatic voice VLAN assignment mode on a port. They can have a negative impact on each other.

Procedure

1. Enter system view.

   system-view
2. Create a MAC-to-VLAN entry.

   mac-vlan mac-address *mac-address* **vlan** *vlan-id* [**dot1p** *priority*]

   By default, no MAC-to-VLAN entries exist.
3. Enter interface view.
   - Enter Layer 2 Ethernet interface view.

     interface *interface-type interface-number*
4. Set the port link type to hybrid.

   port link-type hybrid

   By default, all ports are access ports.
5. Enable the MAC-based VLAN feature.

   mac-vlan enable

   By default, MAC-based VLAN is disabled.
6. Enable dynamic MAC-based VLAN assignment.

   mac-vlan trigger enable

   By default, dynamic MAC-based VLAN assignment is disabled.

The VLAN assignment for a port is triggered only when the source MAC address of its receiving packet exactly matches the MAC address in a MAC-to-VLAN entry.

7. (Optional.) Configure the system to assign VLANs based on the MAC address preferentially.

   vlan precedence mac-vlan

   By default, the system assigns VLANs based on the MAC address preferentially when both the MAC-based VLAN and IP subnet-based VLAN are configured on a port.

8. (Optional.) Disable the port from forwarding packets that fail the exact MAC address match in its PVID.

   port pvid forbidden

   By default, when a port receives packets whose source MAC addresses fail the exact match, the port forwards them in its PVID.

Configuring server-assigned MAC-based VLAN

1. Enter system view.

   system-view

2. Enter interface view.

   - Enter Layer 2 Ethernet interface view.

     interface *interface-type interface-number*

3. Set the port link type to hybrid.

   port link-type hybrid

   By default, all ports are access ports.

4. Assign the hybrid port to the MAC-based VLANs.

   port hybrid vlan *vlan-id-list* { **tagged** | **untagged** }

   By default, a hybrid port is an untagged member of the VLAN to which the port belongs when its link type is **access**.

5. Enable the MAC-based VLAN feature.

   mac-vlan enable

   By default, MAC-based VLAN is disabled.

6. (Optional.) Configure the interface to assign VLANs based on the MAC address preferentially.

   vlan precedence mac-vlan

   By default, the system assigns VLANs based on the MAC address preferentially when both the MAC-based VLAN and IP subnet-based VLAN are configured on a port.

7. Configure 802.1X or MAC authentication.

   For more information, see *Security Command Reference*.

Enabling ARP flood suppression

About this task

Excessive ARP packets in the network lead to increased CPU load on the device, affecting normal processing of other user operations. To resolve this issue, you can enable ARP flood suppression on the device to reduce the flood of ARP packets and ensure normal network communication.

With this feature enabled, the device can monitor the ARP packets passing through it. When other devices initiate ARP resolution again, the device can responce to the ARP requests to suppress the network flood caused by ARP resolution.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable ARP flood suppression.
   arp suppression enable
   By default, ARP flood suppression is disabled.

Configuring IP subnet-based VLANs

Restrictions and guidelines

This feature is available only on hybrid ports, and it processes only untagged packets.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Associate the VLAN with an IP subnet or IP address.
   ip-subnet-vlan [*ip-subnet-index*] **ip** *ip-address* [*mask*]
   By default, a VLAN is not associated with an IP subnet or IP address.
   A multicast subnet or a multicast address cannot be associated with a VLAN.
4. Return to system view.
   quit
5. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
6. Set the port link type to hybrid.
   port link-type hybrid
   By default, all ports are access ports.
7. Assign the hybrid port to the specified IP subnet-based VLANs.
   port hybrid vlan *vlan-id-list* { **tagged** | **untagged** }
   By default, a hybrid port is an untagged member of the VLAN to which the port belongs when its link type is **access**.
8. Associate the hybrid port with the specified IP subnet-based VLAN.
   port hybrid ip-subnet-vlan vlan *vlan-id*
   By default, a hybrid port is not associated with a subnet-based VLAN.

Configuring protocol-based VLANs

About this task

A protocol-based VLAN has one or multiple protocol templates. A protocol template defines a protocol type and an encapsulation format as the match criteria to match inbound packets. Each protocol template has a unique index in the protocol-based VLAN. All protocol templates in a protocol-based VLAN have the same VLAN ID.

For a port to assign inbound packets to protocol-based VLANs, perform the following tasks:

- Assign the port to the protocol-based VLANs.
- Associate the port with the protocol templates of the protocol-based VLANs.

When an untagged packet arrives at the port, the port processes the packet as follows:

- If the protocol type and encapsulation format in the packet match a protocol template, the port tags the packet with the VLAN tag specific to the protocol template.
- If no protocol templates are matched, the port tags the packet with its PVID.

Restrictions and guidelines

The voice VLAN in automatic mode processes only tagged voice traffic. Do not configure a VLAN as both a protocol-based VLAN and a voice VLAN.

Procedure

1. Enter system view.

   system-view

2. Enter VLAN view.

   vlan *vlan-id*

3. Associate the VLAN with a protocol template.

   protocol-vlan [*protocol-index*] { **at** | **ipv4** | **ipv6** | **ipx** { **ethernetii** | **llc** | **raw** | **snap** } | **mode** { **ethernetii etype** *etype-id* | **llc** { **dsap** *dsap-id* [**ssap** *ssap-id*] | **ssap** *ssap-id* } | **snap etype** *etype-id* } }

   By default, a VLAN is not associated with a protocol template.

4. Exit VLAN view.

   quit

5. Enter interface view.
   - Enter Layer 2 Ethernet interface view.

     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.

     interface bridge-aggregation *interface-number*

6. Set the port link type to hybrid.

   port link-type hybrid

   By default, all ports are access ports.

7. Assign the hybrid port to the specified protocol-based VLANs.

   port hybrid vlan *vlan-id-list* { **tagged** | **untagged** }

   By default, a hybrid port is an untagged member of the VLAN to which the port belongs when its link type is **access**.

8. Associate the hybrid port with the specified protocol-based VLAN.

   port hybrid protocol-vlan vlan *vlan-id* { *protocol-index* [**to** *protocol-end*] | **all** }

By default, a hybrid port is not associated with a protocol-based VLAN.

Configuring a VLAN group

About this task

A VLAN group includes a set of VLANs.

On an authentication server, a VLAN group name represents a group of authorization VLANs. When an 802.1X or MAC authentication user passes authentication, the authentication server assigns a VLAN group name to the device. The device then uses the received VLAN group name to match the locally configured VLAN group names. If a match is found, the device selects a VLAN from the group and assigns the VLAN to the user. For more information about 802.1X and MAC authentication, see *Security Configuration Guide*.

Procedure

1. Enter system view.
   `system-view`
2. Create a VLAN group and enter its view.
   `vlan-group` *`group-name`*
3. Add VLANs to the VLAN group.
   `vlan-list` *`vlan-id-list`*
   By default, no VLANs exist in a VLAN group.
   You can add multiple VLAN lists to a VLAN group.

Configuring VLAN interfaces

Restrictions and guidelines

- You cannot create VLAN interfaces for sub-VLANs. For more information about sub-VLANs, see "Configuring super VLANs."
- You cannot create VLAN interfaces for secondary VLANs that have the following characteristics:
  - Associated with the same primary VLAN.
  - Enabled with Layer 3 communication in VLAN interface view of the primary VLAN interface.

  For more information about secondary VLANs, see "Configuring private VLAN."
- A VLAN interface can come up only when one or more Ethernet interfaces in the corresponding VLAN are up.

VLAN interfaces configuration tasks at a glance

To configure VLAN interfaces, perform the following tasks:

1. Creating a VLAN interface
2. Restoring the default settings for the VLAN interface

Prerequisites

Before you create a VLAN interface for a VLAN, create the VLAN first.

Creating a VLAN interface

1. Enter system view.
   system-view
2. Create a VLAN interface and enter its view.
   interface vlan-interface *interface-number*
3. Assign an IP address to the VLAN interface.
   ip address *ip-address* { *mask* | *mask-length* } [**sub**]
   By default, no IP address is assigned to a VLAN interface.
4. (Optional.) Configure the description for the VLAN interface.
   description *text*
   The default setting is the VLAN interface name. For example, **Vlan-interface1 Interface**.
5. (Optional.) Set the MTU for the VLAN interface.
   mtu *size*
   By default, the MTU of a VLAN interface is 1500 bytes.
6. (Optional.) Set a MAC address for the VLAN interface.
   mac-address *mac-address*
   By default, no MAC address is set for a VLAN interface.
7. (Optional.) Set the expected bandwidth for the interface.
   bandwidth *bandwidth-value*
   By default, the expected bandwidth (in kbps) is the interface baud rate divided by 1000.
8. Bring up the VLAN interface.
   undo shutdown
   By default, a VLAN interface is not manually shut down.

Restoring the default settings for the VLAN interface

Restrictions and guidelines

This feature might fail to restore the default settings for some commands for reasons such as command dependencies or system restrictions. Use the **display this** command in interface view to identify these commands, and then use their **undo** forms or follow the command reference to restore their default settings. If your restoration attempt still fails, follow the error message instructions to resolve the problem.

Procedure

1. Enter system view.
   system-view
2. Enter a VLAN interface view.
   interface vlan-interface *interface-number*
3. Restore the default settings for the VLAN interface.
   default

△ **CAUTION:**

This feature might interrupt ongoing network services. Make sure you are fully aware of the impact of this feature when you use it on a live network.

Enabling the function of setting VLAN tags for sent protocol packets on an interface

About this task

With this feature enabled on an interface, the interface records all layers of VLAN tags of received LACP or BFD protocol packets. When the interface sends the same protocol packets, the interface adds the recorded VLAN tags to the sent protocol packets, regardless of whether the link type of the interface allows these packets to carry these VLAN tags. For more information about LACP, see Ethernet link aggregation configuration in *Layer 2—LAN Switching Configuration Guide*. For more information about BFD, see BFD configuration in *High Availability Configuration Guide*.

Hardware and feature compatibility

This feature is not supported on the S5200-EI-G switch series.

Restrictions and guidelines

Executing the **port outbound-vlan-tag enable** command and then its **undo** form on an interface will cause BFD sessions on the interface to go down. Perform this operation with caution.

Executing this command on an aggregation group member port does not affect the other member ports in the same aggregation group or affect the Selected state of aggregation group member ports. To ensure configuration consistency within an aggregation group, manually execute this command on all aggregation group member ports.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view.
   interface *interface-type interface-number*
3. Enable the function of setting VLAN tags for sent protocol packets on the interface.
   port outbound-vlan-tag enable

Configuring the 802.1p priority for control packets sent by a device

About this task

By default, the 802.1p priority is 6 for control packets sent by a device. However, some devices will drop or not process packets with 802.1p priority 6, which affects the operation of protocols in the network. To resolve this problem, configure the 802.1p priority for control packets sent by a device.

Restrictions and guidelines

This feature configures the 802.1p priority for packets of the following protocols: ARP, NTP, OSPF, PIM, SSH, and Telnet.

Procedure

1. Enter system view.
   system-view
2. Configure the 802.1p priority for control packets sent by the device
   control-packet dot1p *priority*

By default, the 802.1p priority is 6 for control packets sent by a device.

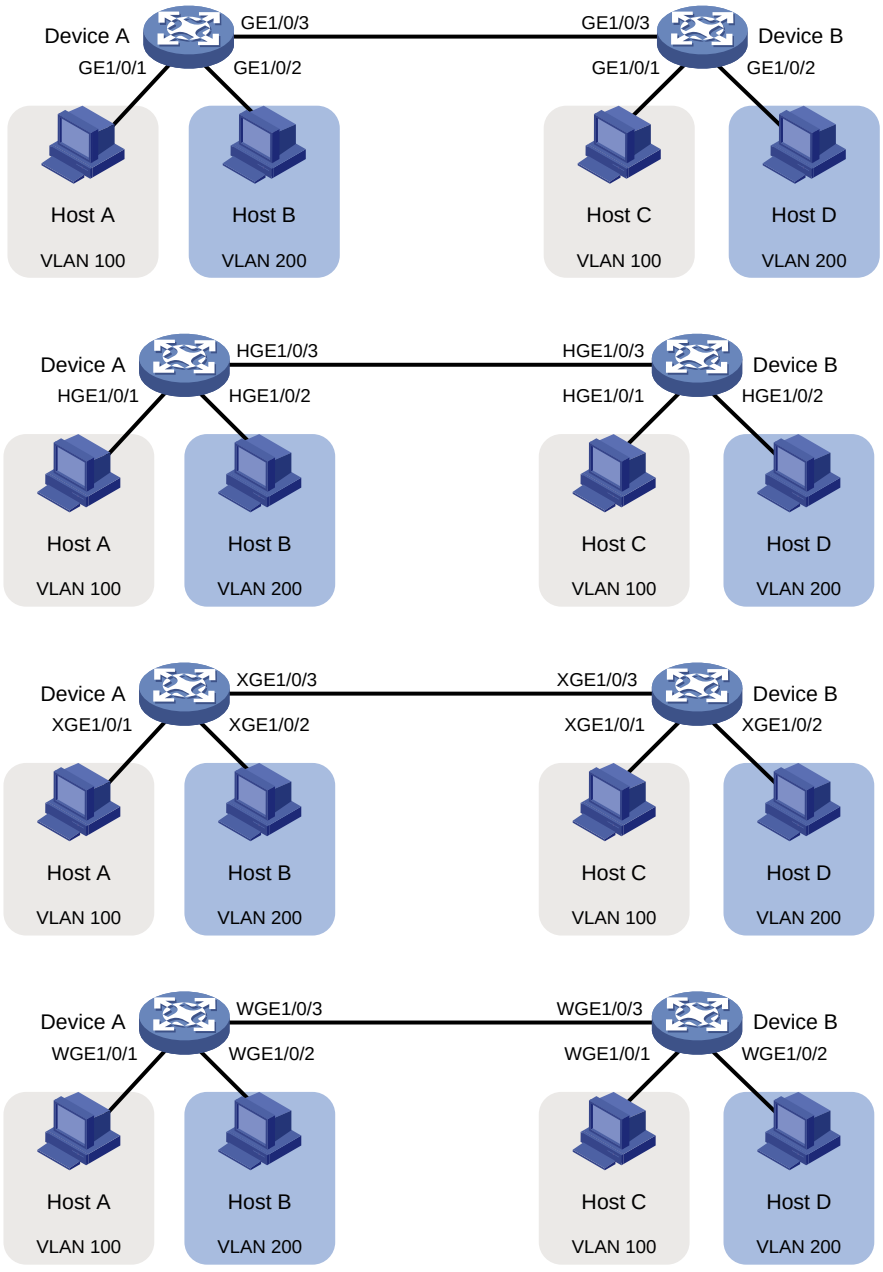
Display and maintenance commands for VLANs

Execute **display** commands in any view and **reset** commands in user view.

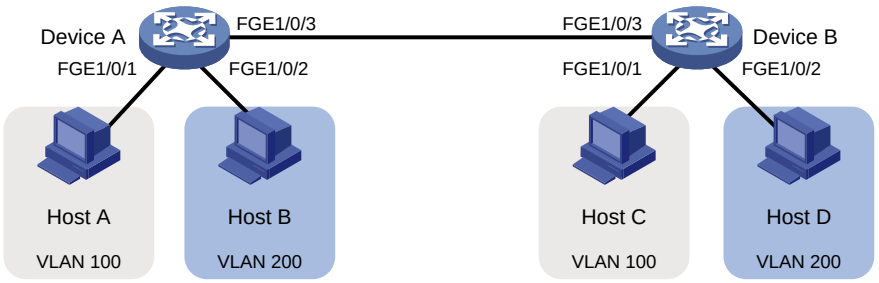
Task	Command
Display ARP suppression entries.	**display arp suppression vlan** [*vlan-id*] [**slot** *slot-number*] [**count**] **display arp suppression vlan** *vlan-id* **ip** *ip-address* [**slot** *slot-number*]
Display VLAN interface information.	**display interface** [**vlan-interface** [*interface-number*]] [**brief** [**description** | **down**]]
Display information about IP subnet-based VLANs that are associated with the specified ports.	**display ip-subnet-vlan interface** { *interface-type interface-number1* [**to** *interface-type interface-number2*] | **all** }
Display information about IP subnet-based VLANs.	**display ip-subnet-vlan vlan** { *vlan-id1* [**to** *vlan-id2*] | **all** }
Display hybrid ports or trunk ports on the device.	**display port** { **hybrid** | **trunk** }
Display information about protocol-based VLANs that are associated with the specified ports.	**display protocol-vlan interface** { *interface-type interface-number1* [**to** *interface-type interface-number2*] | **all** }
Display information about protocol-based VLANs.	**display protocol-vlan vlan** { *vlan-id1* [**to** *vlan-id2*] | **all** }
Display VLAN information.	**display vlan** [*vlan-id1* [**to** *vlan-id2*] | **all** | **dynamic** | **reserved** | **static**]
Display brief VLAN information.	**display vlan brief**
Display packet statistics for a VLAN.	**display vlan** *vlan-id* **statistics** [**slot** *slot-number*]
Display VLAN group information.	**display vlan-group** [*group-name*]
Clear ARP flood suppression entries on VSIs	**reset arp suppression vlan** [*vlan-id* **ip** *ip-address* | *vlan-id*]
Clear statistics on a VLAN interface.	**reset counters interface** [**vlan-interface** [*interface-number*]]
Clear packet statistics for a VLAN.	**reset vlan** *vlan-id* **statistics** [**slot** *slot-number*]
Display MAC-to-VLAN entries.	**display mac-vlan** { **all** | **dynamic** | **mac-address** *mac-address* [**mask** *mac-mask*] | **static** | **vlan** *vlan-id* }
Display all ports that are enabled with the MAC-based VLAN feature.	**display mac-vlan interface**

VLAN configuration examples

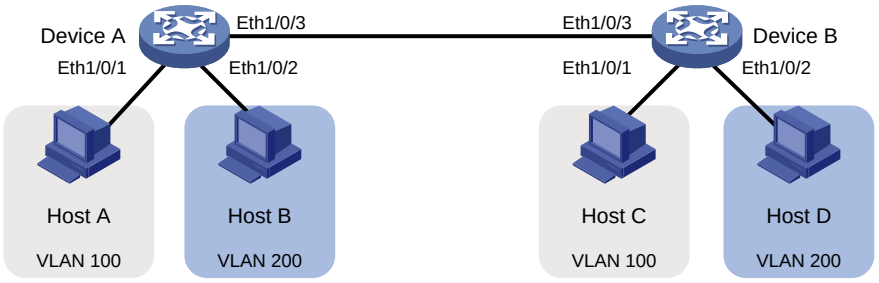
Example: Configuring port-based VLANs



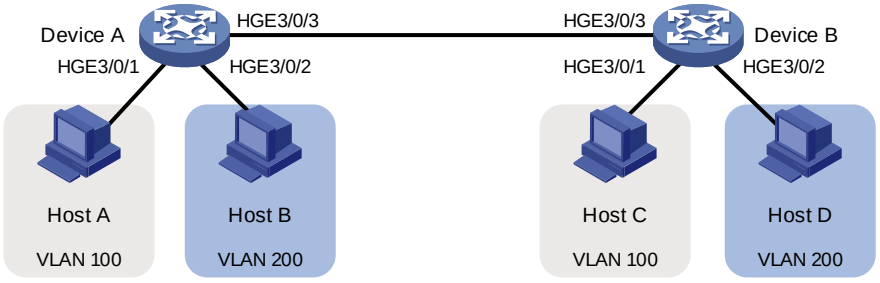
Network configuration



As shown in Figure 3:



- Host A and Host C belong to Department A. VLAN 100 is assigned to Department A.
- Host B and Host D belong to Department B. VLAN 200 is assigned to Department B.



Configure port-based VLANs so that only hosts in the same department can communicate with each other.

XGE1/1/1
XGE1/1/2
Host A
VLAN 100
Host B
VLAN 200
Host C
VLAN 100
Host D
VLAN 200

Procedure

1. Configure Device A:

   # Create VLAN 100, and assign GigabitEthernet 1/0/1 to VLAN 100.

   ```
   <DeviceA> system-view
   [DeviceA] vlan 100
   [DeviceA-vlan100] port gigabitethernet 1/0/1
   [DeviceA-vlan100] quit
   ```

   # Create VLAN 200, and assign GigabitEthernet 1/0/2 to VLAN 200.

   ```
   [DeviceA] vlan 200
   [DeviceA-vlan200] port gigabitethernet 1/0/2
   [DeviceA-vlan200] quit
   ```

   # Configure GigabitEthernet 1/0/3 as a trunk port, and assign the port to VLANs 100 and 200.

   ```
   [DeviceA] interface gigabitethernet 1/0/3
   [DeviceA-GigabitEthernet1/0/3] port link-type trunk
   [DeviceA-GigabitEthernet1/0/3] port trunk permit vlan 100 200
   Please wait... Done.
   ```

2. Configure Device B in the same way Device A is configured. (Details not shown.)
3. Configure hosts:
   a. Configure Host A and Host C to be on the same IP subnet. For example, 192.168.100.0/24.
   b. Configure Host B and Host D to be on the same IP subnet. For example, 192.168.200.0/24.

Verifying the configuration

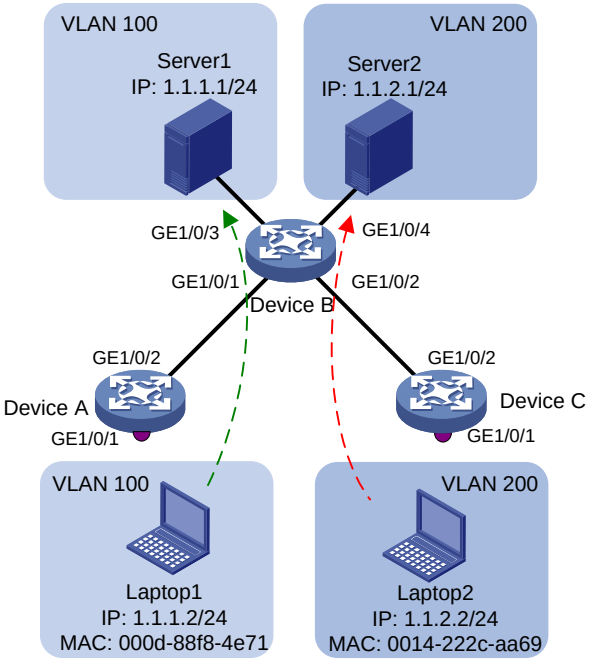
Verify that Host A and Host C can ping each other, but they both fail to ping Host B and Host D. (Details not shown.)

Verify that Host B and Host D can ping each other, but they both fail to ping Host A and Host C. (Details not shown.)

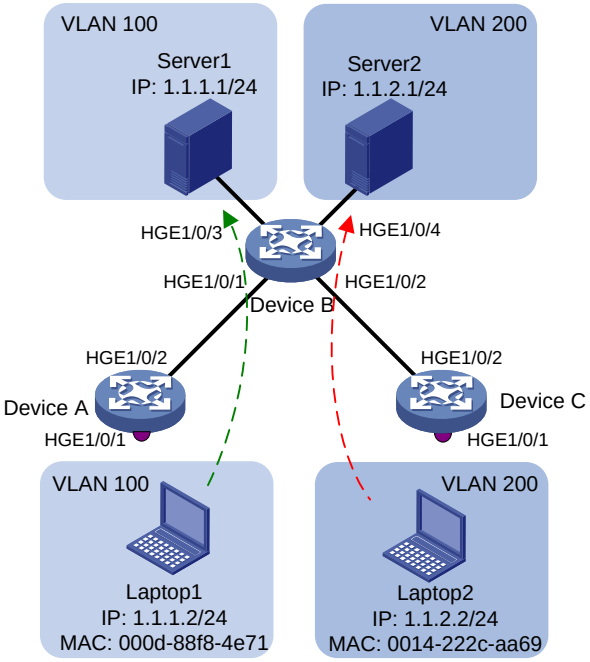
Verify that VLANs 100 and 200 are correctly configured on Device A.

```
[DeviceA-GigabitEthernet1/0/3] display vlan 100
 VLAN ID: 100
 VLAN type: Static
 Route interface: Not configured
 Description: VLAN 0100
 Name: VLAN 0100
 Tagged ports:
    GigabitEthernet1/0/3(U)
 Untagged ports:
    GigabitEthernet1/0/1(U)
[DeviceA-GigabitEthernet1/0/3] display vlan 200
 VLAN ID: 200
 VLAN type: Static
 Route interface: Not configured
 Description: VLAN 0200
 Name: VLAN 0200
 Tagged ports:
    GigabitEthernet1/0/3(U)
 Untagged ports:
    GigabitEthernet1/0/2(U)
```

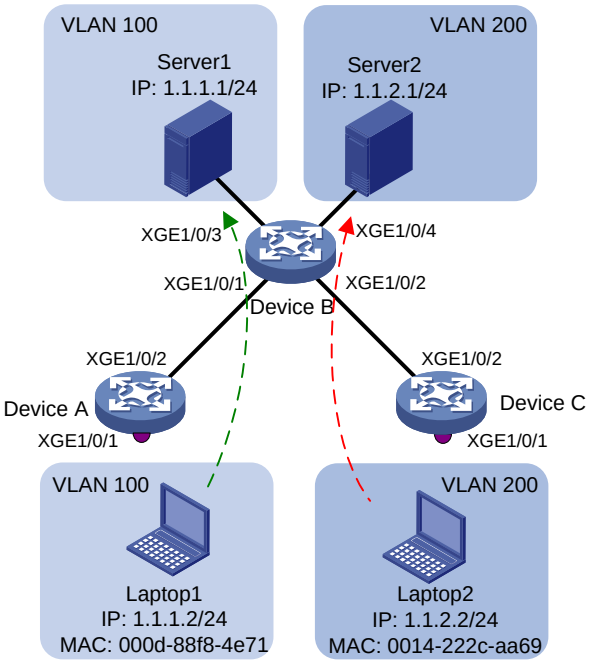
Example: Configuring MAC-based VLANs



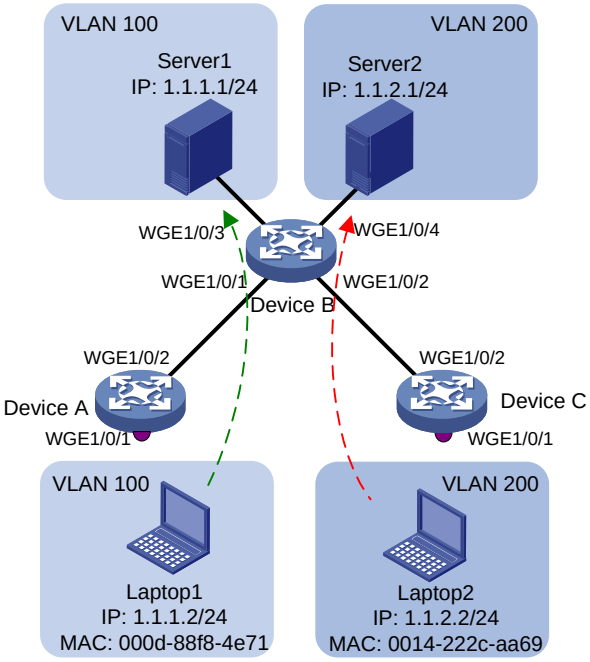
Network configuration



As shown in Figure 4:



- GigabitEthernet 1/0/1 of Device A and Device C are each connected to a meeting room. Laptop 1 and Laptop 2 are used for meetings and might be used in either of the two meeting rooms.
- One department uses VLAN 100 and owns Laptop 1. The other department uses VLAN 200 and owns Laptop 2.



Configure MAC-based VLANs, so that Laptop 1 and Laptop 2 can access Server 1 and Server 2, respectively, no matter which meeting room they are used in.

IP: 1.1.2.2/24
MAC: 0014-222c-aa69

Procedure

1. Configure Device A:

   # Create VLANs 100 and 200.

   ```
   <DeviceA> system-view
   [DeviceA] vlan 100
   [DeviceA-vlan100] quit
   [DeviceA] vlan 200
   [DeviceA-vlan200] quit
   ```

   # Associate the MAC addresses of Laptop 1 and Laptop 2 with VLANs 100 and 200, respectively.

   ```
   [DeviceA] mac-vlan mac-address 000d-88f8-4e71 vlan 100
   [DeviceA] mac-vlan mac-address 0014-222c-aa69 vlan 200
   ```

   # Configure GigabitEthernet 1/0/1 as a hybrid port, and assign it to VLANs 100 and 200 as an untagged VLAN member.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] port link-type hybrid
   [DeviceA-GigabitEthernet1/0/1] port hybrid vlan 100 200 untagged
   ```

   # Enable the MAC-based VLAN feature on GigabitEthernet 1/0/1.

   ```
   [DeviceA-GigabitEthernet1/0/1] mac-vlan enable
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Configure the uplink port (GigabitEthernet 1/0/2) as a trunk port, and assign it to VLANs 100 and 200.

   ```
   [DeviceA] interface gigabitethernet 1/0/2
   [DeviceA-GigabitEthernet1/0/2] port link-type trunk
   [DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 100 200
   [DeviceA-GigabitEthernet1/0/2] quit
   ```

2. Configure Device B:

   # Create VLAN 100, and assign GigabitEthernet 1/0/3 to VLAN 100.

   ```
   <DeviceB> system-view
   ```

```
[DeviceB] vlan 100
[DeviceB-vlan100] port gigabitethernet 1/0/3
[DeviceB-vlan100] quit
```

Create VLAN 200 and assign GigabitEthernet 1/0/4 to VLAN 200.

```
[DeviceB] vlan 200
[DeviceB-vlan200] port gigabitethernet 1/0/4
[DeviceB-vlan200] quit
```

Configure GigabitEthernet 1/0/1 as a trunk port, and assign the port to VLANs 100 and 200.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 100 200
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port, and assign the port to VLANs 100 and 200.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 100 200
[DeviceB-GigabitEthernet1/0/2] quit
```

3. Configure Device C in the same way as the Device A is configured. (Details not shown.)

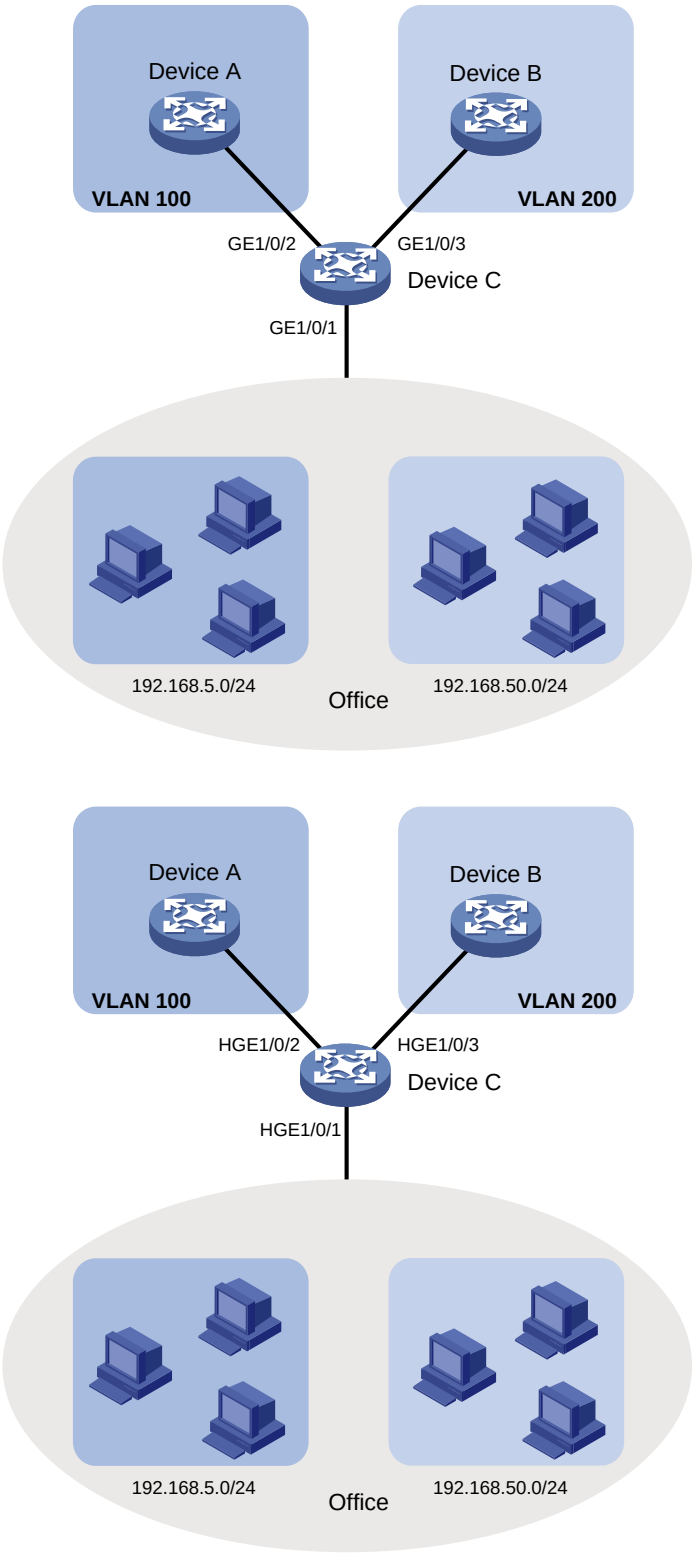
Verifying the configuration

Verify that Laptop 1 can access only Server 1, and Laptop 2 can access only Server 2. (Details not shown.)

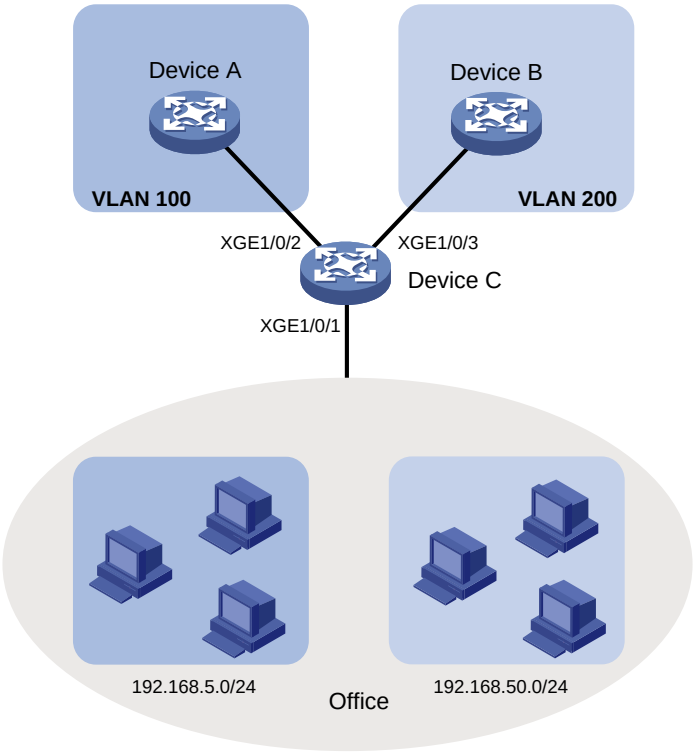
Verify the MAC-to-VLAN entries on Device A and Device C, for example, on Device A.

```
[DeviceA] display mac-vlan all
  The following MAC VLAN addresses exist:
  S:Static  D:Dynamic
  MAC address      Mask             VLAN ID   Dot1p      State
  000d-88f8-4e71   ffff-ffff-ffff   100       0          S
  0014-222c-aa69   ffff-ffff-ffff   200       0          S

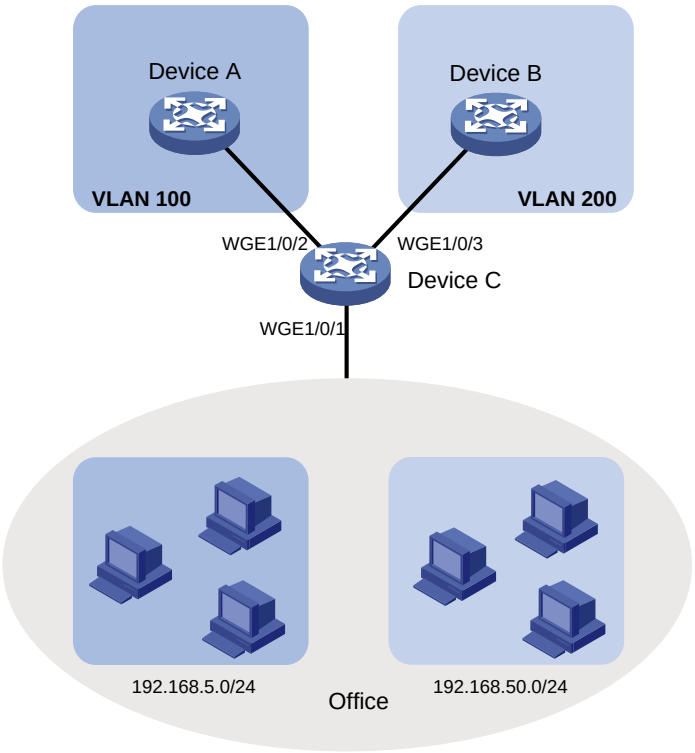
  Total MAC VLAN address count: 2
```



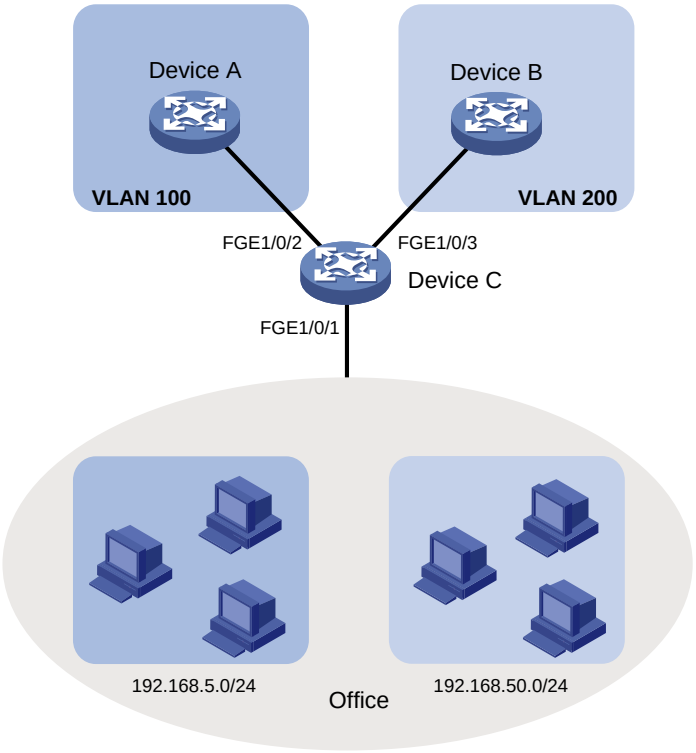
Example: Configuring IP subnet-based VLANs



Network configuration



As shown in Figure 5, the hosts in the office belong to different IP subnets.



Configure Device C to transmit packets from 192.168.5.0/24 and 192.168.50.0/24 in VLANs 100 and 200, respectively.

Procedure

1. Configure Device C:

   # Associate IP subnet 192.168.5.0/24 with VLAN 100.

   ```
   <DeviceC> system-view
   [DeviceC] vlan 100
   [DeviceC-vlan100] ip-subnet-vlan ip 192.168.5.0 255.255.255.0
   [DeviceC-vlan100] quit
   ```

   # Associate IP subnet 192.168.50.0/24 with VLAN 200.

   ```
   [DeviceC] vlan 200
   [DeviceC-vlan200] ip-subnet-vlan ip 192.168.50.0 255.255.255.0
   [DeviceC-vlan200] quit
   ```

   # Configure GigabitEthernet 1/0/2 as a hybrid port, and assign it to VLAN 100 as a tagged VLAN member.

   ```
   [DeviceC] interface gigabitethernet 1/0/2
   [DeviceC-GigabitEthernet1/0/2] port link-type hybrid
   [DeviceC-GigabitEthernet1/0/2] port hybrid vlan 100 tagged
   [DeviceC-GigabitEthernet1/0/2] quit
   ```

   # Configure GigabitEthernet 1/0/3 as a hybrid port, and assign it to VLAN 200 as a tagged VLAN member.

   ```
   [DeviceC] interface gigabitethernet 1/0/3
   [DeviceC-GigabitEthernet1/0/3] port link-type hybrid
   [DeviceC-GigabitEthernet1/0/3] port hybrid vlan 200 tagged
   [DeviceC-GigabitEthernet1/0/3] quit
   ```

   # Configure GigabitEthernet 1/0/1 as a hybrid port, and assign it to VLANs 100 and 200 as an untagged VLAN member.

   ```
   [DeviceC] interface gigabitethernet 1/0/1
   [DeviceC-GigabitEthernet1/0/1] port link-type hybrid
   ```

```
[DeviceC-GigabitEthernet1/0/1] port hybrid vlan 100 200 untagged
```

Associate GigabitEthernet 1/0/1 with the IP subnet-based VLANs 100 and 200.

```
[DeviceC-GigabitEthernet1/0/1] port hybrid ip-subnet-vlan vlan 100
[DeviceC-GigabitEthernet1/0/1] port hybrid ip-subnet-vlan vlan 200
[DeviceC-GigabitEthernet1/0/1] quit
```

2. Configure Device A and Device B to forward packets from VLANs 100 and 200, respectively. (Details not shown.)

Verifying the configuration

Verify the IP subnet-based VLAN configuration on Device C.

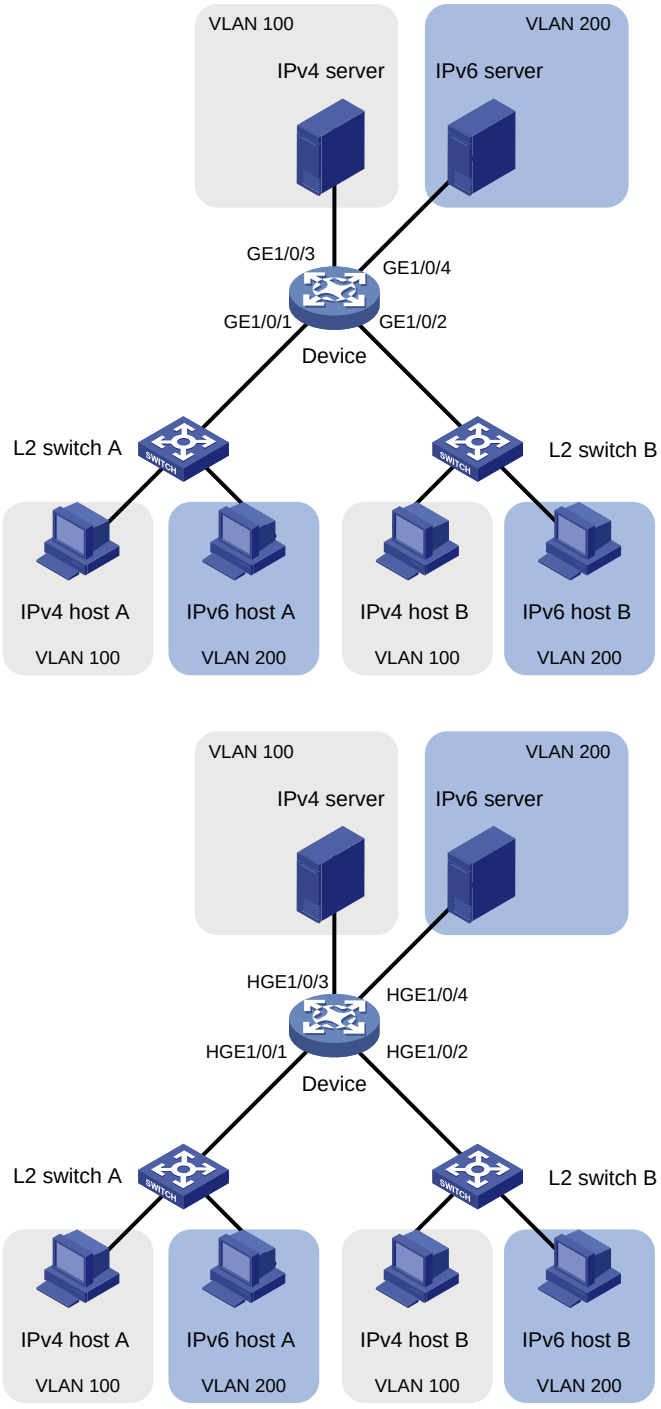
```
[DeviceC] display ip-subnet-vlan vlan all
 VLAN ID: 100
  Subnet index      IP address      Subnet mask
  0                 192.168.5.0     255.255.255.0

 VLAN ID: 200
  Subnet index      IP address      Subnet mask
  0                 192.168.50.0    255.255.255.0
```

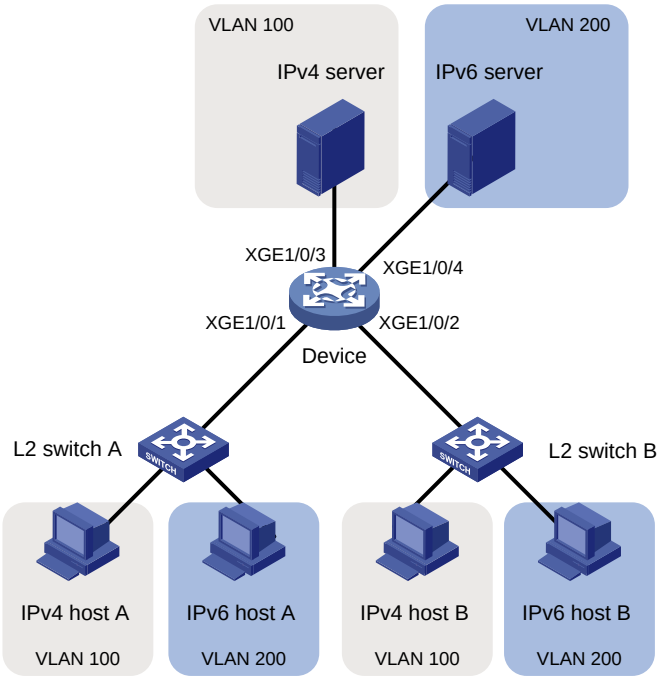
Verify the IP subnet-based VLAN configuration on GigabitEthernet 1/0/1 of Device C.

```
[DeviceC] display ip-subnet-vlan interface gigabitethernet 1/0/1
 Interface: GigabitEthernet1/0/1
  VLAN ID   Subnet index    IP address       Subnet mask       Status
  100       0               192.168.5.0      255.255.255.0     Active
  200       0               192.168.50.0     255.255.255.0     Active
```

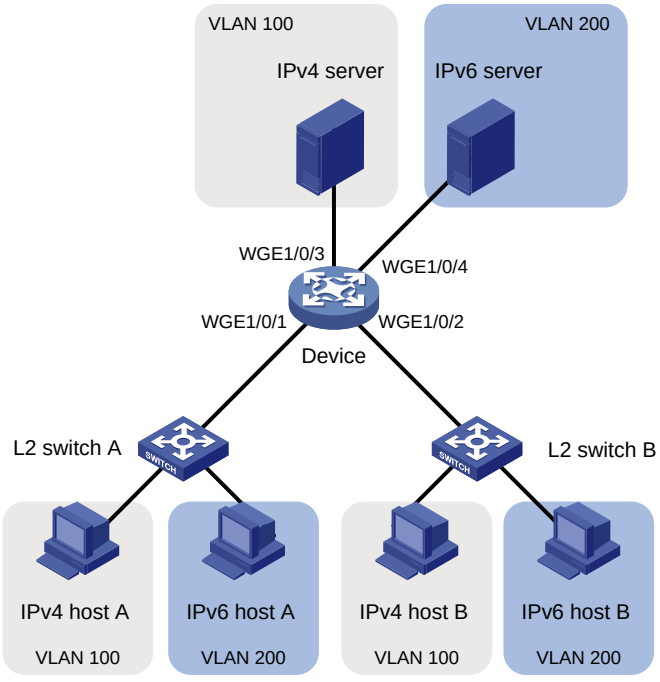
Example: Configuring protocol-based VLANs



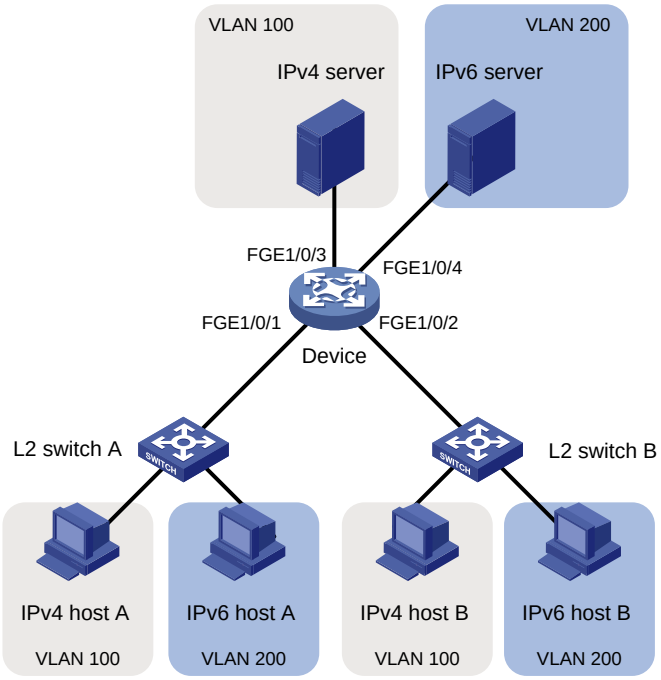
Network configuration



As shown in Figure 6:



- The majority of hosts in a lab environment run the IPv4 protocol.
- The other hosts run the IPv6 protocol for teaching purposes.



To isolate IPv4 and IPv6 traffic at Layer 2, configure protocol-based VLANs to associate the IPv4 and ARP protocols with VLAN 100, and associate the IPv6 protocol with VLAN 200.

Procedure

In this example, L2 Switch A and L2 Switch B use the factory configuration.

1. Configure Device:

   # Create VLAN 100, and configure the description for VLAN 100 as **protocol VLAN for IPv4**.

   ```
   <Device> system-view
   [Device] vlan 100
   [Device-vlan100] description protocol VLAN for IPv4
   ```

   # Assign GigabitEthernet 1/0/3 to VLAN 100.

   ```
   [Device-vlan100] port gigabitethernet 1/0/3
   [Device-vlan100] quit
   ```

   # Create VLAN 200, and configure the description for VLAN 200 as **protocol VLAN for IPv6**.

   ```
   [Device] vlan 200
   [Device-vlan200] description protocol VLAN for IPv6
   ```

   # Assign GigabitEthernet 1/0/4 to VLAN 200.

   ```
   [Device-vlan200] port gigabitethernet 1/0/4
   ```

   # Configure VLAN 200 as a protocol-based VLAN, and create an IPv6 protocol template with the index 1 for VLAN 200.

   ```
   [Device-vlan200] protocol-vlan 1 ipv6
   [Device-vlan200] quit
   ```

   # Configure VLAN 100 as a protocol-based VLAN. Create an IPv4 protocol template with the index 1, and create an ARP protocol template with the index 2. (In Ethernet II encapsulation, the protocol type ID for ARP is 0806 in hexadecimal notation.)

   ```
   [Device] vlan 100
   [Device-vlan100] protocol-vlan 1 ipv4
   [Device-vlan100] protocol-vlan 2 mode ethernetii etype 0806
   [Device-vlan100] quit
   ```

   # Configure GigabitEthernet 1/0/1 as a hybrid port, and assign it to VLANs 100 and 200 as an untagged VLAN member.

   ```
   [Device] interface gigabitethernet 1/0/1
   ```

```
[Device-GigabitEthernet1/0/1] port link-type hybrid
[Device-GigabitEthernet1/0/1] port hybrid vlan 100 200 untagged
```

Associate GigabitEthernet 1/0/1 with the IPv4 and ARP protocol templates of VLAN 100 and the IPv6 protocol template of VLAN 200.

```
[Device-GigabitEthernet1/0/1] port hybrid protocol-vlan vlan 100 1 to 2
[Device-GigabitEthernet1/0/1] port hybrid protocol-vlan vlan 200 1
[Device-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a hybrid port, and assign it to VLANs 100 and 200 as an untagged VLAN member.

```
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] port link-type hybrid
[Device-GigabitEthernet1/0/2] port hybrid vlan 100 200 untagged
```

Associate GigabitEthernet 1/0/2 with the IPv4 and ARP protocol templates of VLAN 100 and the IPv6 protocol template of VLAN 200.

```
[Device-GigabitEthernet1/0/2] port hybrid protocol-vlan vlan 100 1 to 2
[Device-GigabitEthernet1/0/2] port hybrid protocol-vlan vlan 200 1
[Device-GigabitEthernet1/0/2] quit
```

2. Configure hosts and servers:
   a. Configure IPv4 Host A, IPv4 Host B, and IPv4 server to be on the same network segment (192.168.100.0/24, for example). (Details not shown.)
   b. Configure IPv6 Host A, IPv6 Host B, and IPv6 server to be on the same network segment (2001::1/64, for example). (Details not shown.)

Verifying the configuration

1. Verify the following:
   - The hosts and the server in VLAN 100 can successfully ping one another. (Details not shown.)
   - The hosts and the server in VLAN 200 can successfully ping one another. (Details not shown.)
   - The hosts or the server in VLAN 100 cannot ping the hosts or server in VLAN 200. (Details not shown.)
2. Verify the protocol-based VLAN configuration:

Display protocol-based VLANs on Device.

```
[Device] display protocol-vlan vlan all
 VLAN ID: 100
  Protocol index  Protocol type
  1               IPv4
  2               Ethernet II Etype 0x0806

 VLAN ID: 200
  Protocol index  Protocol type
  1               IPv6
```

Display protocol-based VLANs on the ports of Device.

```
[Device] display protocol-vlan interface all
 Interface: GigabitEthernet1/0/1
  VLAN ID  Protocol index  Protocol type             Status
  100      1               IPv4                     Active
  100      2               Ethernet II Etype 0x0806  Active
  200      1               IPv6                     Active
```

```
Interface: GigabitEthernet 1/0/2
 VLAN ID  Protocol index  Protocol type             Status
 100      1              IPv4                      Active
 100      2              Ethernet II Etype 0x0806  Active
 200      1              IPv6                      Active
```

Configuring super VLANs

About super VLANs

Hosts in a VLAN typically use IP addresses in the same subnet. For Layer 3 interoperability with other VLANs, you can create a VLAN interface for the VLAN and assign an IP address to it. This requires a large number of IP addresses.

The super VLAN feature was introduced to save IP addresses. A super VLAN is associated with multiple sub-VLANs. These sub-VLANs use the VLAN interface of the super VLAN (also known as a super VLAN interface) as the gateway for Layer 3 communication.

You can create a VLAN interface for a super VLAN and assign an IP address to it. However, you cannot create a VLAN interface for a sub-VLAN. You can assign a physical port to a sub-VLAN, but you cannot assign a physical port to a super VLAN. Sub-VLANs are isolated at Layer 2.

To enable Layer 3 communication between sub-VLANs, perform the following tasks:

1. Create a super VLAN and the VLAN interface for the super VLAN.
2. Enable local proxy ARP or ND on the super VLAN interface as follows:
   - In an IPv4 network, enable local proxy ARP on the super VLAN interface. The super VLAN can then process ARP requests and replies sent from the sub-VLANs.
   - In an IPv6 network, enable local proxy ND on the super VLAN interface. The super VLAN can then process the NS and NA messages sent from the sub-VLANs.

Restrictions and guidelines: Super VLAN configuration

- The VLAN of a MAC address-to-VLAN entry cannot be configured as a super VLAN.
- A VLAN cannot be configured as both a super VLAN and a guest VLAN, Auth-Fail VLAN, or critical VLAN. For more information about guest VLANs, Auth-Fail VLANs, and critical VLANs, see *Security Configuration Guide*.
- A VLAN cannot be configured as both a super VLAN and a sub-VLAN.
- Layer 2 multicast configuration for super VLANs does not take effect because they do not have physical ports.

Super VLAN tasks at a glance

To configure a super VLAN, perform the following tasks:

1. Creating a sub-VLAN
2. Configuring a super VLAN
3. Configuring a super VLAN interface

Creating a sub-VLAN

1. Enter system view.

   `system-view`
2. Create a sub-VLAN.

vlan *vlan-id-list*

By default, only the system default VLAN (VLAN 1) exists.

Configuring a super VLAN

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Configure the VLAN as a super VLAN.
   supervlan
   By default, a VLAN is not a super VLAN.
4. Associate the super VLAN with the sub-VLANs.
   subvlan *vlan-id-list*
   Make sure the sub-VLANs already exist before associating them with a super VLAN.

Configuring a super VLAN interface

Restrictions and guidelines

As a best practice, do not configure VRRP for a super VLAN interface because the configuration affects network performance. For more information about VRRP, see *High Availability Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Create a VLAN interface and enter its view.
   interface vlan-interface *interface-number*
   The value for the *interface-number* argument must be the super VLAN ID.
3. Configure an IP address for the super VLAN interface.
   IPv4:
   ip address *ip-address* { *mask-length* | *mask* } [**sub**]
   IPv6:
   ipv6 address { *ipv6-address prefix-length* | *ipv6-address*/*prefix-length* }
   By default, no IP address is configured for a VLAN interface.
4. Configure Layer 3 communication between sub-VLANs by enabling local proxy ARP or ND.
   IPv4:
   local-proxy-arp enable
   By default:
   - Sub-VLANs cannot communicate with each other at Layer 3.
   - Local proxy ARP is disabled.

   For more information about local proxy ARP, see *Layer 3—IP Services Configuration Guide*.
   IPv6:
   local-proxy-nd enable
   By default:

- Sub-VLANs cannot communicate with each other at Layer 3.
- Local proxy ND is disabled.

For more information about local proxy ND, see *Layer 3—IP Services Configuration Guide*.

Display and maintenance commands for super VLANs

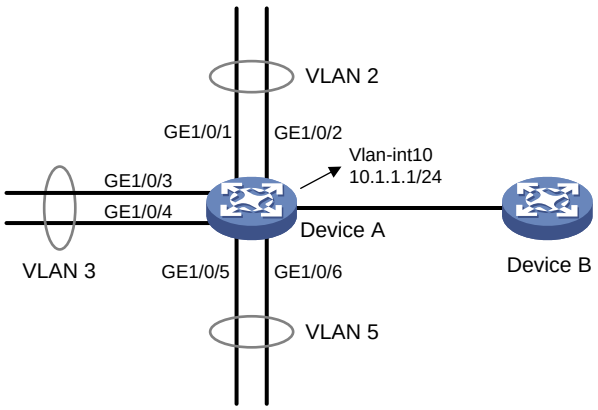
Execute **display** commands in any view.

Task	Command
Display information about super VLANs and their associated sub-VLANs.	**display supervlan** [*supervlan-id*]

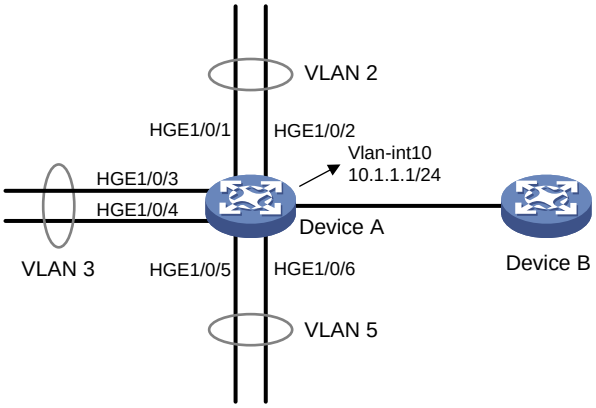
Super VLAN configuration examples

Example: Configuring a super VLAN

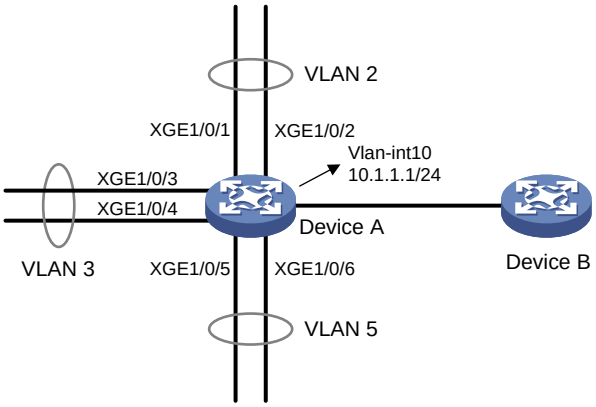
Network configuration



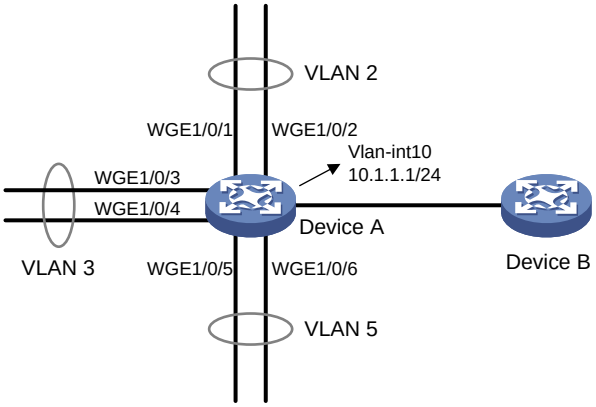
As shown in Figure 7:



- GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are in VLAN 2.
- GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 are in VLAN 3.
- GigabitEthernet 1/0/5 and GigabitEthernet 1/0/6 are in VLAN 5.



To save IP addresses and enable sub-VLANs to be isolated at Layer 2 but interoperable at Layer 3, perform the following tasks:



- Create a super VLAN and assign an IP address to its VLAN interface.
- Associate the super VLAN with VLANs 2, 3, and 5.

HGE1/1/6
VLAN 5

Procedure

Create VLAN 10.

```
<DeviceA> system-view
[DeviceA] vlan 10
[DeviceA-vlan10] quit
```

Create VLAN-interface 10, and assign IP address 10.1.1.1/24 to it.

```
[DeviceA] interface vlan-interface 10
[DeviceA-Vlan-interface10] ip address 10.1.1.1 255.255.255.0
```

Enable local proxy ARP.

```
[DeviceA-Vlan-interface10] local-proxy-arp enable
[DeviceA-Vlan-interface10] quit
```

Create VLAN 2, and assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to the VLAN.

```
[DeviceA] vlan 2
[DeviceA-vlan2] port gigabitethernet 1/0/1 gigabitethernet 1/0/2
[DeviceA-vlan2] quit
```

Create VLAN 3, and assign GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 to the VLAN.

```
[DeviceA] vlan 3
[DeviceA-vlan3] port gigabitethernet 1/0/3 gigabitethernet 1/0/4
[DeviceA-vlan3] quit
```

Create VLAN 5, and assign GigabitEthernet 1/0/5 and GigabitEthernet 1/0/6 to the VLAN.

```
[DeviceA] vlan 5
[DeviceA-vlan5] port gigabitethernet 1/0/5 gigabitethernet 1/0/6
[DeviceA-vlan5] quit
```

Configure VLAN 10 as a super VLAN, and associate sub-VLANs 2, 3, and 5 with the super VLAN.

```
[DeviceA] vlan 10
[DeviceA-vlan10] supervlan
[DeviceA-vlan10] subvlan 2 3 5
[DeviceA-vlan10] quit
[DeviceA] quit
```

Verifying the configuration

Display information about super VLAN 10 and its associated sub-VLANs.

```
<DeviceA> display supervlan
 Super VLAN ID: 10
 Sub-VLAN ID: 2-3 5
```

```
VLAN ID: 10
VLAN type: Static
It is a super VLAN.

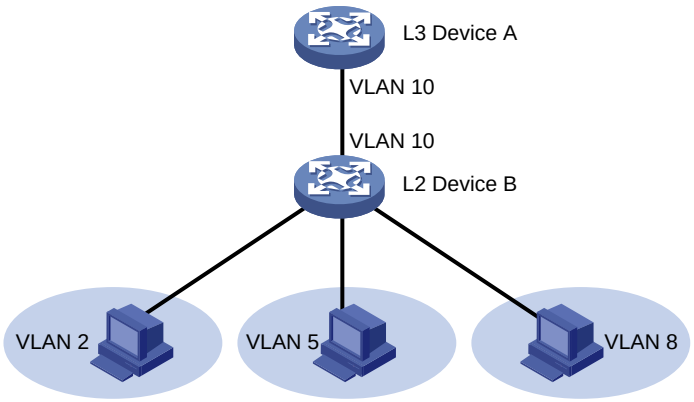
```

Configuring private VLAN

About private VLAN



VLAN technology provides a method for isolating traffic from customers. At the access layer of a network, customer traffic must be isolated for security or accounting purposes. If VLANs are assigned on a per-user basis, a large number of VLANs will be required.

The private VLAN feature saves VLAN resources. It uses a two-tier VLAN structure as follows:

- **Primary VLAN**—Used for connecting the upstream device. A primary VLAN can be associated with multiple secondary VLANs. The upstream device identifies only the primary VLAN.
- **Secondary VLANs**—Used for connecting users. Secondary VLANs are isolated at Layer 2.

As shown in Figure 8, the private VLAN feature is enabled on L2 Device B. VLAN 10 is the primary VLAN. VLANs 2, 5, and 8 are secondary VLANs that are associated with VLAN 10. L3 Device A is only aware of VLAN 10.

Figure 8 Private VLAN example

If the private VLAN feature is configured on a Layer 3 device, use one of the following methods on the Layer 3 device to enable Layer 3 communication. Layer 3 communication might be required between secondary VLANs that are associated with the same primary VLAN, or between secondary VLANs and other networks.

- Method 1:
  - **a.** Create VLAN interfaces for the secondary VLANs.
  - **b.** Assign IP addresses to the secondary VLAN interfaces.
- Method 2:
  - **c.** Enable Layer 3 communication between the secondary VLANs that are associated with the primary VLAN.
  - **d.** Create the VLAN interface for the primary VLAN and assign an IP address to it. (Do not create secondary VLAN interfaces if you use this method.)
  - **e.** Enable local proxy ARP or ND on the primary VLAN interface.

Restrictions and guidelines: Private VLAN configuration

- Make sure the following requirements are met:

    - For a promiscuous port:
        - The primary VLAN is the PVID of the port.
        - The port is an untagged member of the primary VLAN and secondary VLANs.
    - For a host port:
        - The PVID of the port is a secondary VLAN.
        - The port is an untagged member of the primary VLAN and the secondary VLAN.
    - A trunk promiscuous or trunk secondary port must be a tagged member of the primary VLANs and the secondary VLANs.
- After you configure a primary VLAN, the system automatically synchronizes the dynamic MAC address entries of the primary VLAN with the dynamic MAC address entries of the secondary VLANs. After you configure Layer 2 isolation for ports in a secondary VLAN, a port with the following configuration permits all VLAN packets in the inbound direction and forwards them according to VLAN-related configurations in the outbound orientation.
    - The port operates in trunk secondary mode in that VLAN.
    - The port operates in host mode and has the PVID as that VLAN.
- VLAN 1 (system default VLAN) does not support the private VLAN configuration.

Private VLAN tasks at a glance

To configure a private VLAN, perform the following tasks:

1. Creating a primary VLAN
2. Creating secondary VLANs
3. Associating the primary VLAN with secondary VLANs
4. Configuring the uplink port
5. Configuring a downlink port
6. (Optional.) Configuring Layer 3 communication for secondary VLANs

Creating a primary VLAN

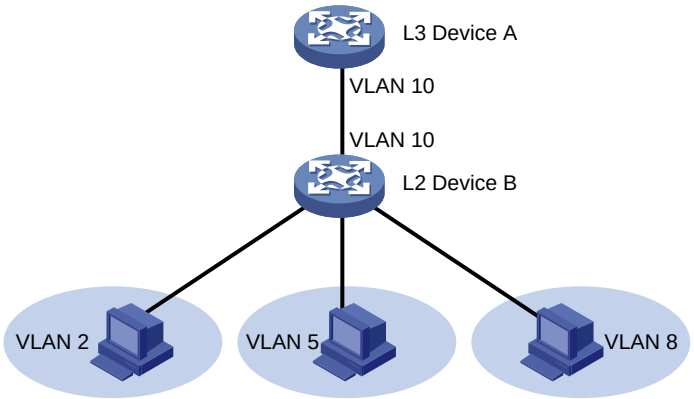
1. Enter system view.
   system-view
2. Create a VLAN and enter VLAN view.
   vlan *vlan-id*
3. Configure the VLAN as a primary VLAN.
   private-vlan primary
   By default, a VLAN is not a primary VLAN.

Creating secondary VLANs

1. Enter system view.
   system-view
2. Create one or multiple secondary VLANs.
   vlan { *vlan-id-list* | **all** }

Associating the primary VLAN with secondary VLANs

1. Enter system view.
   system-view
2. Create enter VLAN view of the primary VLAN.
   vlan *vlan-id*
3. Associate the primary VLAN with the secondary VLANs.
   private-vlan secondary *vlan-id-list*
   By default, a primary VLAN is not associated with any secondary VLANs.



Configuring the uplink port

About this task

Configure the uplink port (for example, the port connecting L2 Device B to L3 Device A in Figure 9) as follows:

- If the port allows only one primary VLAN, configure the port as a promiscuous port of the primary VLAN. The promiscuous port can be automatically assigned to the primary VLAN and its associated secondary VLANs.
- If the port allows multiple primary VLANs, configure the port as a trunk promiscuous port of the primary VLANs. The trunk promiscuous port can be automatically assigned to the primary VLANs and their associated secondary VLANs.

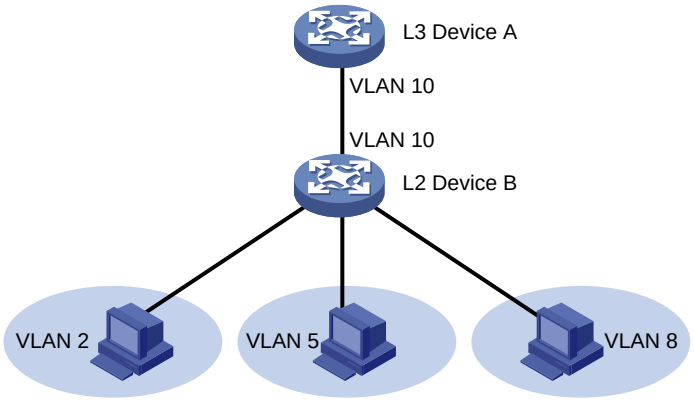
Figure 9 Private VLAN example

Procedure

1. Enter system view.
   system-view
2. Enter interface view of the uplink port.
   interface *interface-type interface-number*
3. Configure the uplink port as a promiscuous or trunk promiscuous port of the specified VLANs.
   - Configure the uplink port as a promiscuous port of the specified VLAN.
     port private-vlan *vlan-id* **promiscuous**
   - Configure the uplink port as a trunk promiscuous port of the specified VLANs.

port private-vlan *vlan-id-list* **trunk promiscuous**

By default, a port is not a promiscuous or trunk promiscuous port of any VLANs.



Configuring a downlink port

About this task

Configure a downlink port as follows:

- If a downlink port allows only one secondary VLAN (for example, the port connecting L2 Device B to a host in Figure 10), configure the port as a host port. The host port can be automatically assigned to the secondary VLAN and its associated primary VLAN.
- If a downlink port allows multiple secondary VLANs, configure the port as a trunk secondary port. The trunk secondary port can be automatically assigned to the secondary VLANs and their associated primary VLANs.

Figure 10 Private VLAN example

Procedure

1. Enter system view.
   system-view
2. Enter interface view of the downlink port.
   interface *interface-type interface-number*
3. Assign the downlink port to secondary VLANs.
   a. Set the link type of the port.
      port link-type { **access** | **hybrid** | **trunk** }
   b. Assign the access port to the specified VLAN.
      port access vlan *vlan-id*
   c. Assign the trunk port to the specified VLANs.
      port trunk permit vlan { *vlan-id-list* | **all** }
   d. Assign the hybrid port to the specified VLANs.
      port hybrid vlan *vlan-id-list* { **tagged** | **untagged** }

   Select substep b, c, or d depending on the port link type.
4. Configure the downlink port as a host or trunk secondary port.
   - Configure the downlink port as a host port.
     port private-vlan host
   - Configure the downlink port as a trunk secondary port of the specified VLANs.

port private-vlan *vlan-id-list* **trunk secondary**

By default, a port is not a host or trunk secondary port.

5. Return to system view.

   quit

6. Enter VLAN view of a secondary VLAN.

   vlan *vlan-id*

7. (Optional.) Enable Layer 2 communication for ports in the same secondary VLAN. Choose one command as needed:

   undo private-vlan isolated

   private-vlan community

   By default, ports in the same secondary VLAN can communicate with each other at Layer 2.

Configuring Layer 3 communication for secondary VLANs

Restrictions and guidelines

When the downlink port is operating in trunk secondary mode, it does not support Layer 3 communication between the specified secondary VLANs in the same primary VLAN.

Procedure

1. Enter system view.

   system-view

2. Enter VLAN interface view of the primary VLAN interface.

   interface vlan-interface *interface-number*

3. Enable Layer 3 communication between secondary VLANs that are associated with the primary VLAN.

   private-vlan secondary *vlan-id-list*

   By default, secondary VLANs cannot communicate with each other at Layer 3.

4. Assign an IP address to the primary VLAN interface.

   IPv4:

   ip address *ip-address* { *mask-length* | *mask* } [**sub**]

   IPv6:

   ipv6 address { *ipv6-address prefix-length* | *ipv6-address*/*prefix-length* }

   By default, no IP address is configured for a VLAN interface.

5. Enable local proxy ARP or ND.

   IPv4:

   local-proxy-arp enable

   By default, local proxy ARP is disabled.

   For more information about local proxy ARP, see *Layer 3—IP Services Configuration Guide*.

   IPv6:

   local-proxy-nd enable

   By default, local proxy ND is disabled.

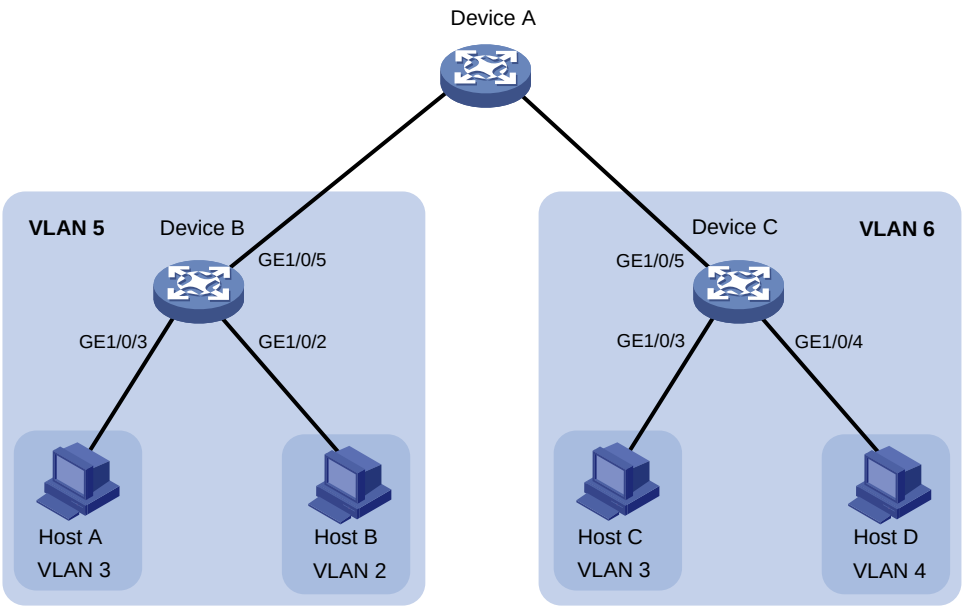
   For more information about local proxy ND, see *Layer 3—IP Services Configuration Guide*.

Display and maintenance commands for the private VLAN

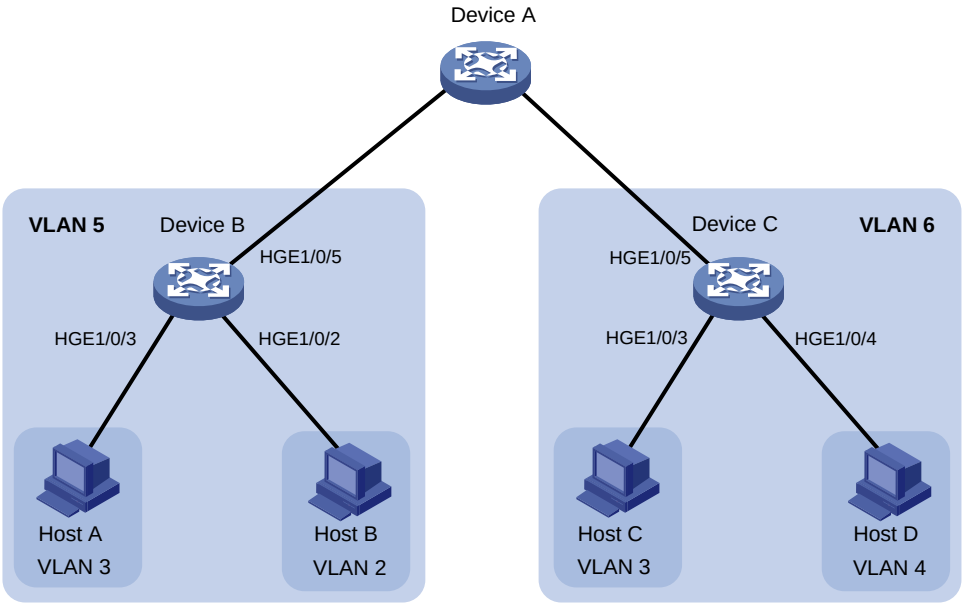
Execute **display** commands in any view.

Task	Command
Display information about primary VLANs and the secondary VLANs associated with each primary VLAN.	**display private-vlan** [*primary-vlan-id*]

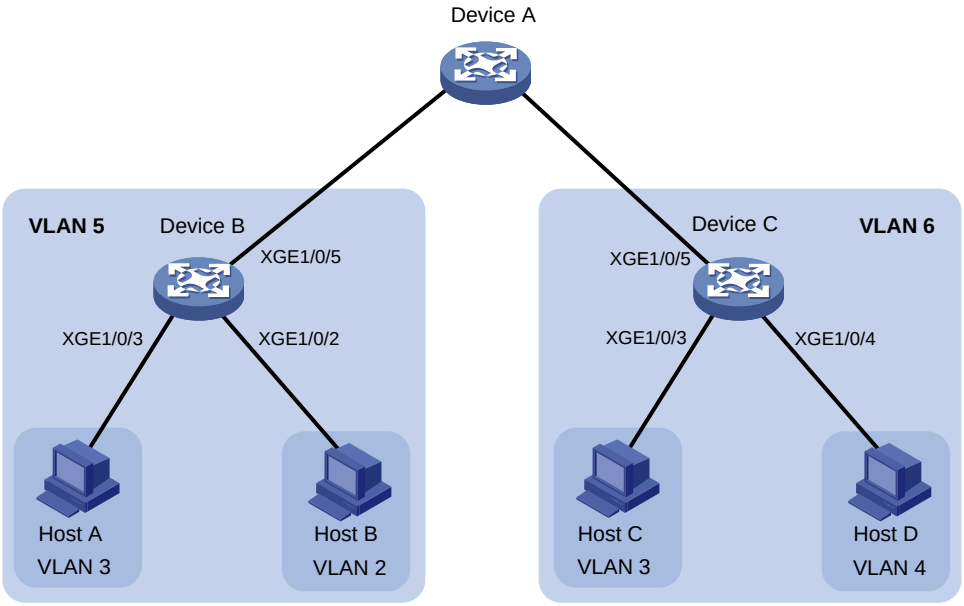
Private VLAN configuration examples



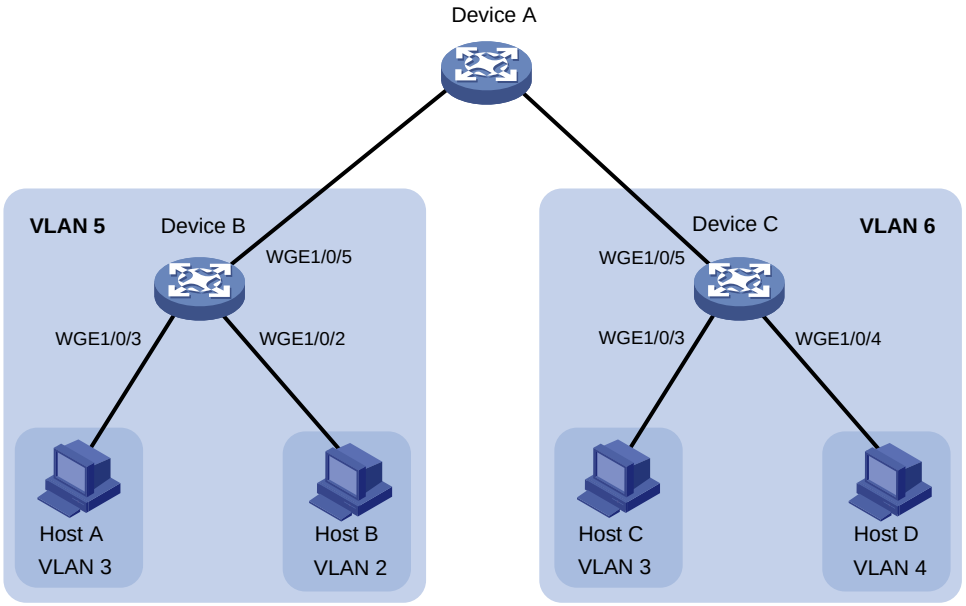
Example: Configuring promiscuous ports



Network configuration



As shown in Figure 11, configure the private VLAN feature to meet the following requirements:



- On Device B, VLAN 5 is a primary VLAN that is associated with secondary VLANs 2 and 3. GigabitEthernet 1/0/5 is in VLAN 5. GigabitEthernet 1/0/2 is in VLAN 2. GigabitEthernet 1/0/3 is in VLAN 3.
- On Device C, VLAN 6 is a primary VLAN that is associated with secondary VLANs 3 and 4. GigabitEthernet 1/0/5 is in VLAN 6. GigabitEthernet 1/0/3 is in VLAN 3. GigabitEthernet 1/0/4 is in VLAN 4.
- Device A is aware of only VLAN 5 on Device B and VLAN 6 on Device C.

Procedure

This example describes the configurations on Device B and Device C.

1. Configure Device B:

Configure VLAN 5 as a primary VLAN.

```
<DeviceB> system-view
[DeviceB] vlan 5
[DeviceB-vlan5] private-vlan primary
[DeviceB-vlan5] quit
```

Create VLANs 2 and 3.

```
[DeviceB] vlan 2 to 3
```

Associate secondary VLANs 2 and 3 with primary VLAN 5.

```
[DeviceB] vlan 5
```

```
[DeviceB-vlan5] private-vlan secondary 2 to 3
[DeviceB-vlan5] quit
```

Configure the uplink port (GigabitEthernet 1/0/5) as a promiscuous port of VLAN 5.

```
[DeviceB] interface gigabitethernet 1/0/5
[DeviceB-GigabitEthernet1/0/5] port private-vlan 5 promiscuous
[DeviceB-GigabitEthernet1/0/5] quit
```

Assign downlink port GigabitEthernet 1/0/2 to VLAN 2, and configure the port as a host port.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port access vlan 2
[DeviceB-GigabitEthernet1/0/2] port private-vlan host
[DeviceB-GigabitEthernet1/0/2] quit
```

Assign downlink port GigabitEthernet 1/0/3 to VLAN 3, and configure the port as a host port.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port access vlan 3
[DeviceB-GigabitEthernet1/0/3] port private-vlan host
[DeviceB-GigabitEthernet1/0/3] quit
```

2. Configure Device C:

Configure VLAN 6 as a primary VLAN.

```
<DeviceC> system-view
[DeviceC] vlan 6
[DeviceC–vlan6] private-vlan primary
[DeviceC–vlan6] quit
```

Create VLANs 3 and 4.

```
[DeviceC] vlan 3 to 4
```

Associate secondary VLANs 3 and 4 with primary VLAN 6.

```
[DeviceC] vlan 6
[DeviceC-vlan6] private-vlan secondary 3 to 4
[DeviceC-vlan6] quit
```

Configure the uplink port (GigabitEthernet 1/0/5) as a promiscuous port of VLAN 6.

```
[DeviceC] interface gigabitethernet 1/0/5
[DeviceC-GigabitEthernet1/0/5] port private-vlan 6 promiscuous
[DeviceC-GigabitEthernet1/0/5] quit
```

Assign downlink port GigabitEthernet 1/0/3 to VLAN 3, and configure the port as a host port.

```
[DeviceC] interface gigabitethernet 1/0/3
[DeviceC-GigabitEthernet1/0/3] port access vlan 3
[DeviceC-GigabitEthernet1/0/3] port private-vlan host
[DeviceC-GigabitEthernet1/0/3] quit
```

Assign downlink port GigabitEthernet 1/0/4 to VLAN 4, and configure the port as a host port.

```
[DeviceC] interface gigabitethernet 1/0/4
[DeviceC-GigabitEthernet1/0/4] port access vlan 4
[DeviceC-GigabitEthernet1/0/4] port private-vlan host
[DeviceC-GigabitEthernet1/0/4] quit
```

Verifying the configuration

Verify the private VLAN configurations on the devices, for example, on Device B.

```
[DeviceB] display private-vlan
 Primary VLAN ID: 5
 Secondary VLAN ID: 2-3
```

```
VLAN ID: 5
VLAN type: Static
Private VLAN type: Primary
Route interface: Not configured
Description: VLAN 0005
Name: VLAN 0005
Tagged ports:   None
Untagged ports:
    GigabitEthernet1/0/2
    GigabitEthernet1/0/3
    GigabitEthernet1/0/5

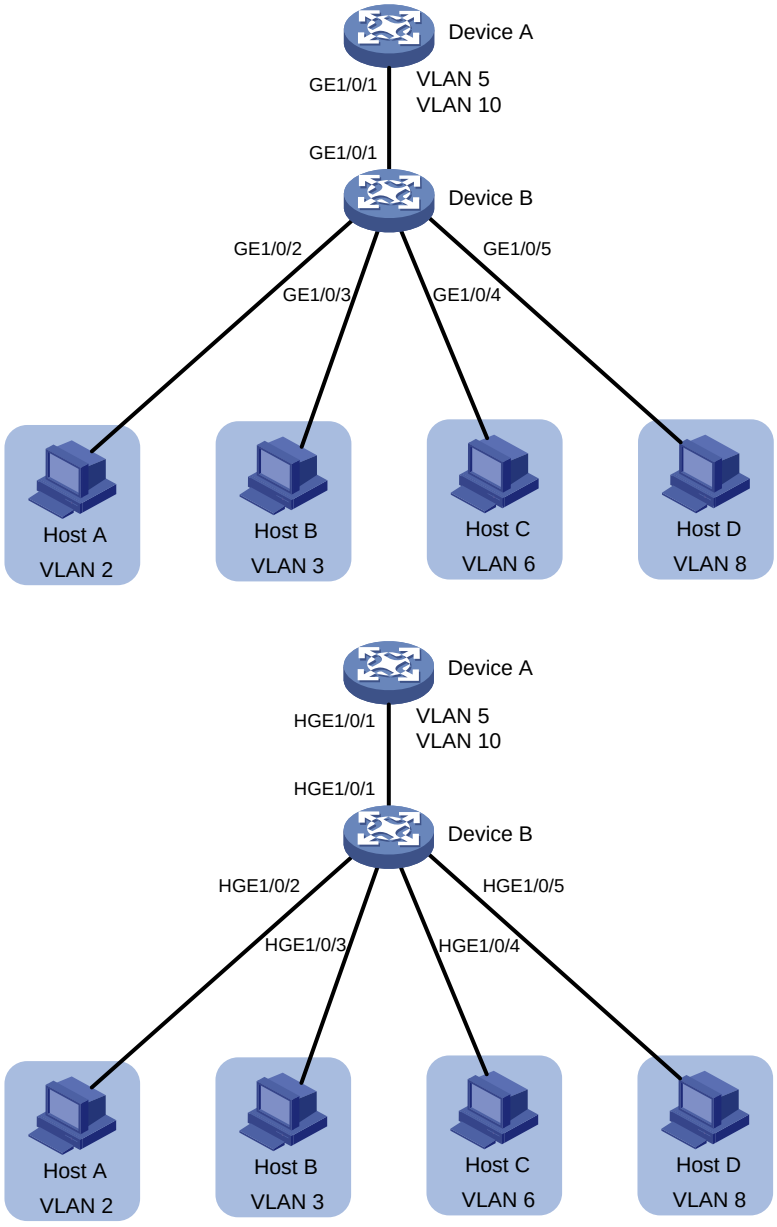
VLAN ID: 2
VLAN type: Static
Private VLAN type: Secondary
Route interface: Not configured
Description: VLAN 0002
Name: VLAN 0002
Tagged ports:   None
Untagged ports:
    GigabitEthernet1/0/2
    GigabitEthernet1/0/5

VLAN ID: 3
VLAN type: Static
Private VLAN type: Secondary
Route interface: Not configured
Description: VLAN 0003
Name: VLAN 0003
Tagged Ports:   None
Untagged Ports:
    GigabitEthernet1/0/3
    GigabitEthernet1/0/5
```

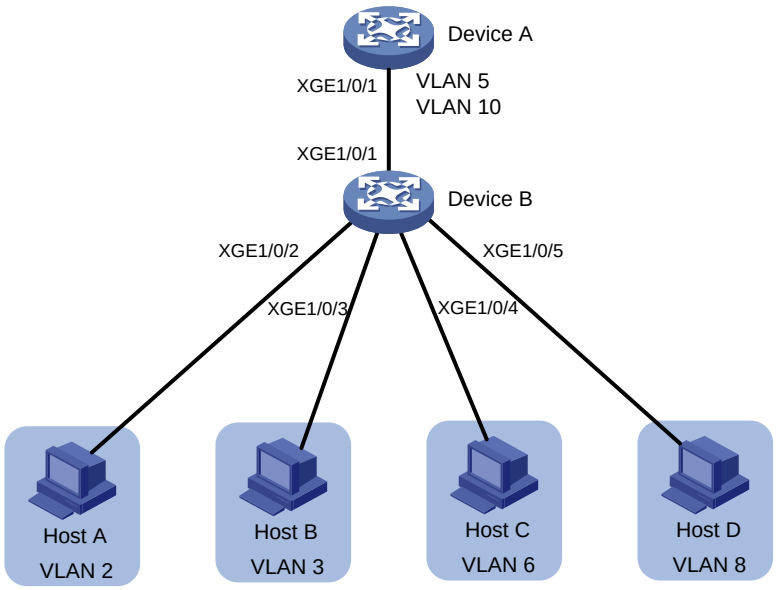
The output shows that:

- The promiscuous port (GigabitEthernet 1/0/5) is an untagged member of primary VLAN 5 and secondary VLANs 2 and 3.
- Host port GigabitEthernet 1/0/2 is an untagged member of primary VLAN 5 and secondary VLAN 2.
- Host port GigabitEthernet 1/0/3 is an untagged member of primary VLAN 5 and secondary VLAN 3.

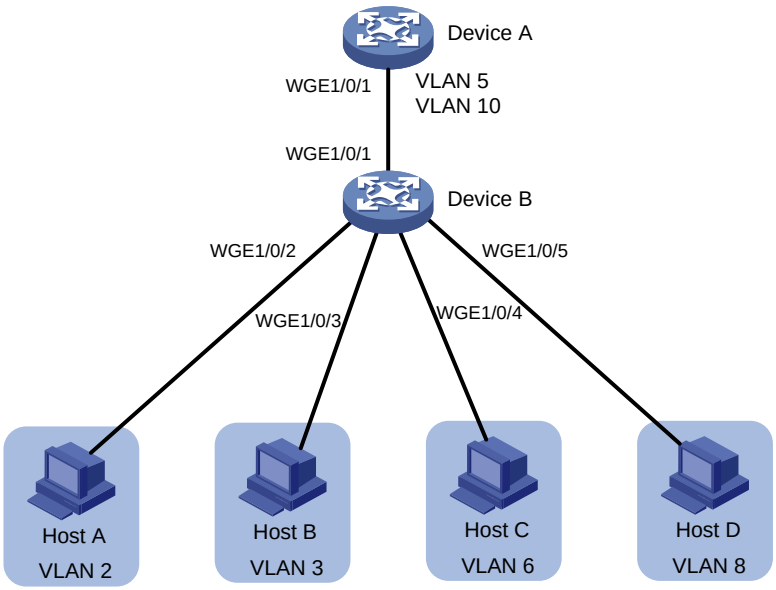
Example: Configuring trunk promiscuous ports



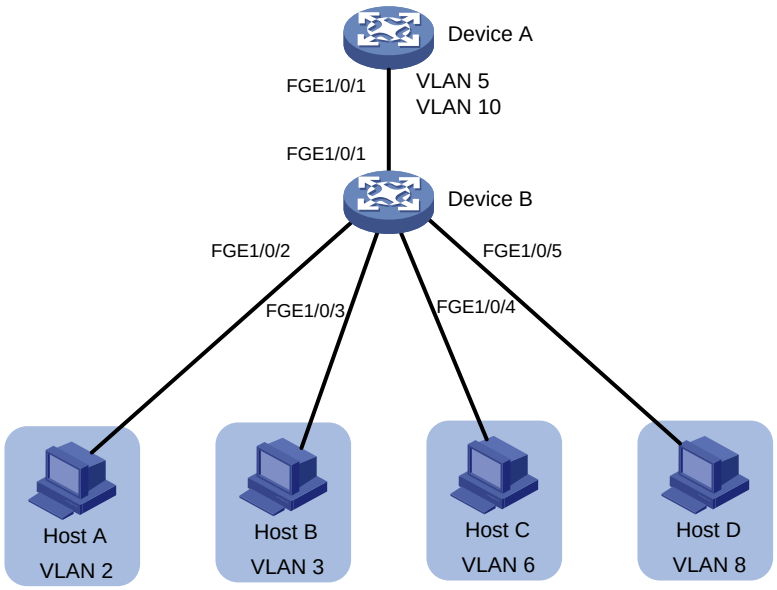
Network configuration



As shown in Figure 12, configure the private VLAN feature to meet the following requirements:



- VLANs 5 and 10 are primary VLANs on Device B. The uplink port (GigabitEthernet 1/0/1) on Device B permits the packets from VLANs 5 and 10 to pass through tagged.



- On Device B, downlink port GigabitEthernet 1/0/2 permits secondary VLAN 2. Downlink port GigabitEthernet 1/0/3 permits secondary VLAN 3. Secondary VLANs 2 and 3 are associated with primary VLAN 5.
- On Device B, downlink port GigabitEthernet 1/0/4 permits secondary VLAN 6. Downlink port GigabitEthernet 1/0/5 permits secondary VLAN 8. Secondary VLANs 6 and 8 are associated with primary VLAN 10.
- Device A is aware of only VLANs 5 and 10 on Device B.

Procedure

1. Configure Device B:

   # Configure VLANs 5 and 10 as primary VLANs.

```
<DeviceB> system-view
[DeviceB] vlan 5
[DeviceB-vlan5] private-vlan primary
[DeviceB-vlan5] quit
[DeviceB] vlan 10
[DeviceB-vlan10] private-vlan primary
[DeviceB-vlan10] quit
```

   # Create VLANs 2, 3, 6, and 8.

```
[DeviceB] vlan 2 to 3
[DeviceB] vlan 6
[DeviceB-vlan6] quit
[DeviceB] vlan 8
[DeviceB-vlan8] quit
```

   # Associate secondary VLANs 2 and 3 with primary VLAN 5.

```
[DeviceB] vlan 5
[DeviceB-vlan5] private-vlan secondary 2 to 3
[DeviceB-vlan5] quit
```

   # Associate secondary VLANs 6 and 8 with primary VLAN 10.

```
[DeviceB] vlan 10
[DeviceB-vlan10] private-vlan secondary 6 8
[DeviceB-vlan10] quit
```

   # Configure the uplink port (GigabitEthernet 1/0/1) as a trunk promiscuous port of VLANs 5 and 10.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port private-vlan 5 10 trunk promiscuous
[DeviceB-GigabitEthernet1/0/1] quit
```

   # Assign downlink port GigabitEthernet 1/0/2 to VLAN 2, and configure the port as a host port.

```
[DeviceB] interface gigabitethernet 1/0/2
```

```
[DeviceB-GigabitEthernet1/0/2] port access vlan 2
[DeviceB-GigabitEthernet1/0/2] port private-vlan host
[DeviceB-GigabitEthernet1/0/2] quit
```

Assign downlink port GigabitEthernet 1/0/3 to VLAN 3, and configure the port as a host port.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port access vlan 3
[DeviceB-GigabitEthernet1/0/3] port private-vlan host
[DeviceB-GigabitEthernet1/0/3] quit
```

Assign downlink port GigabitEthernet 1/0/4 to VLAN 6, and configure the port as a host port.

```
[DeviceB] interface gigabitethernet 1/0/4
[DeviceB-GigabitEthernet1/0/4] port access vlan 6
[DeviceB-GigabitEthernet1/0/4] port private-vlan host
[DeviceB-GigabitEthernet1/0/4] quit
```

Assign downlink port GigabitEthernet 1/0/5 to VLAN 8, and configure the port as a host port.

```
[DeviceB] interface gigabitethernet 1/0/5
[DeviceB-GigabitEthernet1/0/5] port access vlan 8
[DeviceB-GigabitEthernet1/0/5] port private-vlan host
[DeviceB-GigabitEthernet1/0/5] quit
```

2. Configure Device A:

Create VLANs 5 and 10.

```
[DeviceA] vlan 5
[DeviceA-vlan5] quit
[DeviceA] vlan 10
[DeviceA-vlan10] quit
```

Configure GigabitEthernet 1/0/1 as a hybrid port, and assign it to VLANs 5 and 10 as a tagged VLAN member.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-type hybrid
[DeviceA-GigabitEthernet1/0/1] port hybrid vlan 5 10 tagged
[DeviceA-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Verify the primary VLAN configurations on Device B. The following output uses primary VLAN 5 as an example.

```
[DeviceB] display private-vlan 5
 Primary VLAN ID: 5
 Secondary VLAN ID: 2-3

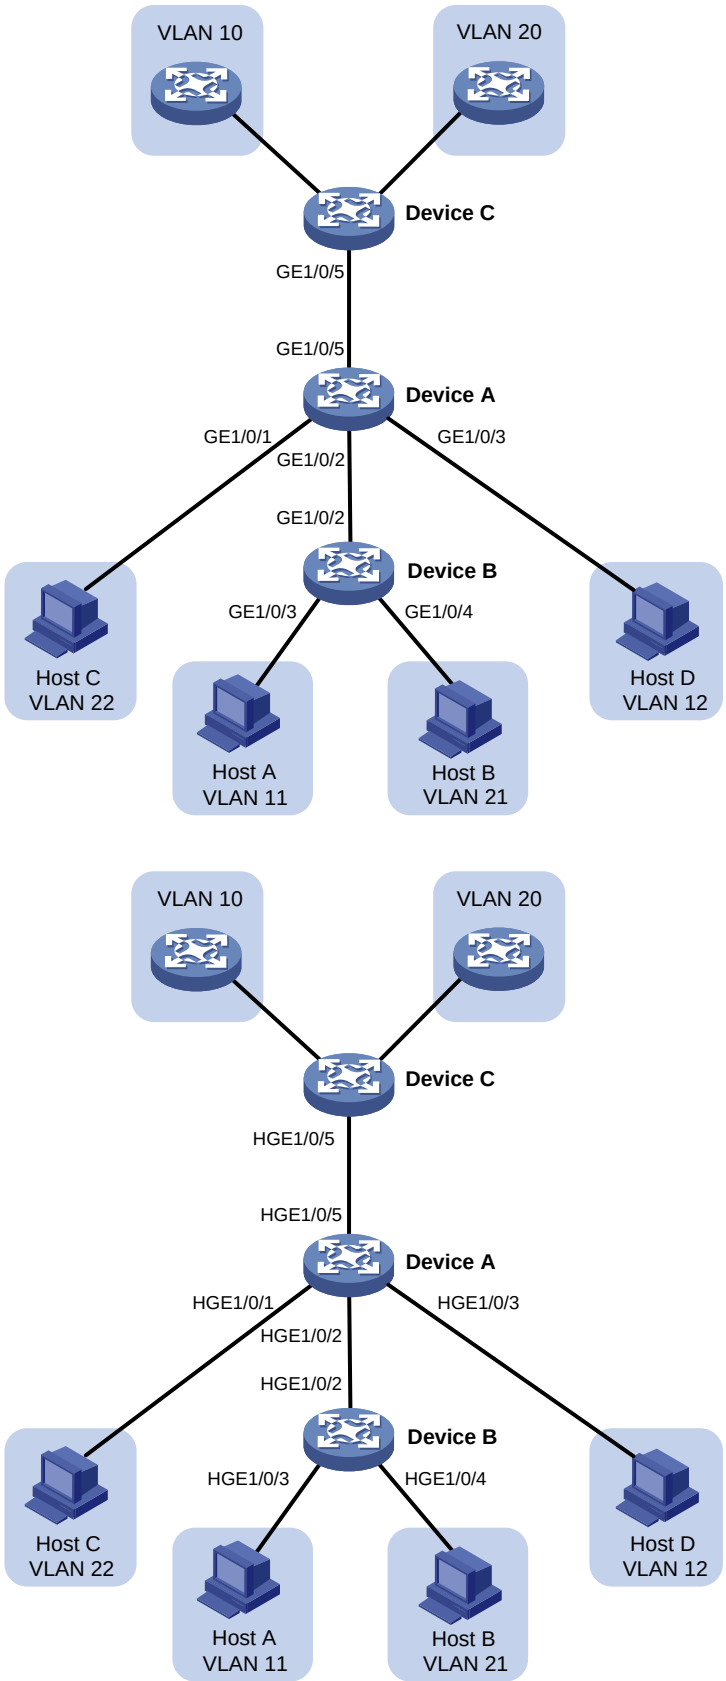
 VLAN ID: 5
 VLAN type: Static
 Private VLAN type: Primary
 Route interface: Not configured
 Description: VLAN 0005
 Name: VLAN 0005
 Tagged ports:
     GigabitEthernet1/0/1
 Untagged ports:
     GigabitEthernet1/0/2
     GigabitEthernet1/0/3
```

```
VLAN ID: 2
VLAN type: Static
Private VLAN type: Secondary
Route interface: Not configured
Description: VLAN 0002
Name: VLAN 0002
 Tagged ports:
    GigabitEthernet1/0/1
 Untagged ports:
    GigabitEthernet1/0/2

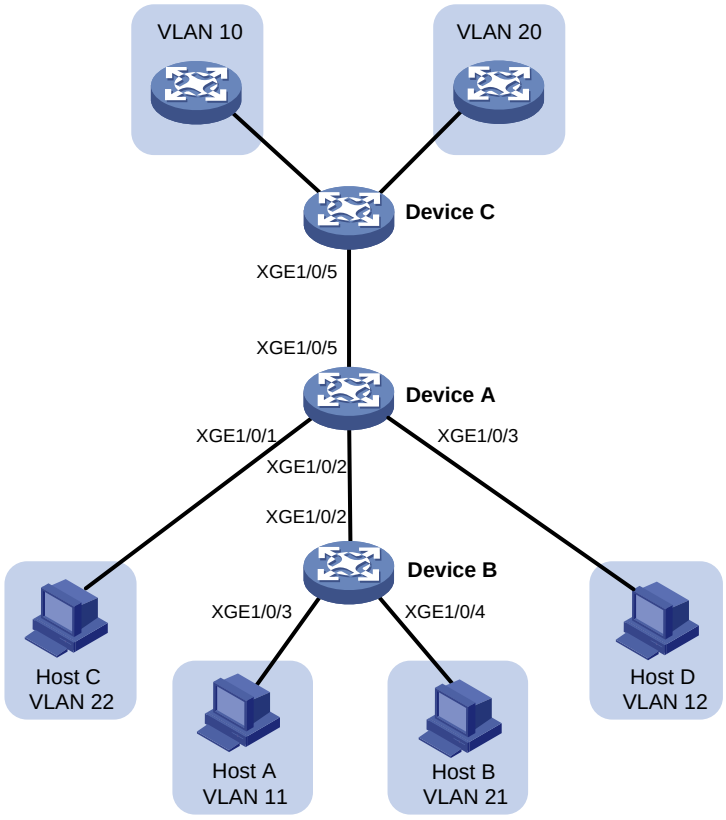
VLAN ID: 3
VLAN type: Static
Private VLAN type: Secondary
Route interface: Not configured
Description: VLAN 0003
Name: VLAN 0003
 Tagged ports:
    GigabitEthernet1/0/1
 Untagged ports:
    GigabitEthernet1/0/3
```

The output shows that:

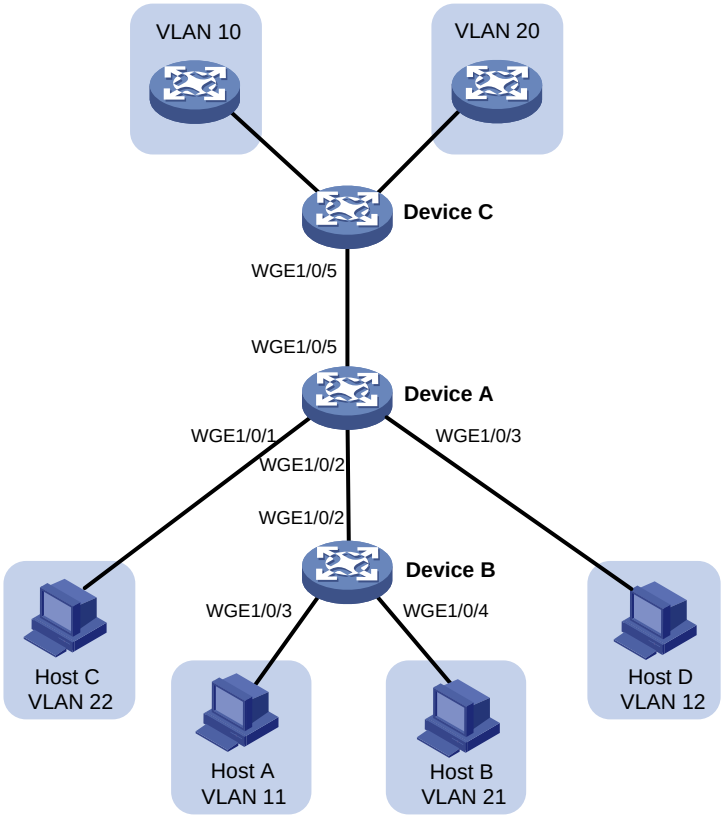
- The trunk promiscuous port (GigabitEthernet 1/0/1) is a tagged member of primary VLAN 5 and secondary VLANs 2 and 3.
- Host port GigabitEthernet 1/0/2 is an untagged member of primary VLAN 5 and secondary VLAN 2.
- Host port GigabitEthernet 1/0/3 is an untagged member of primary VLAN 5 and secondary VLAN 3.



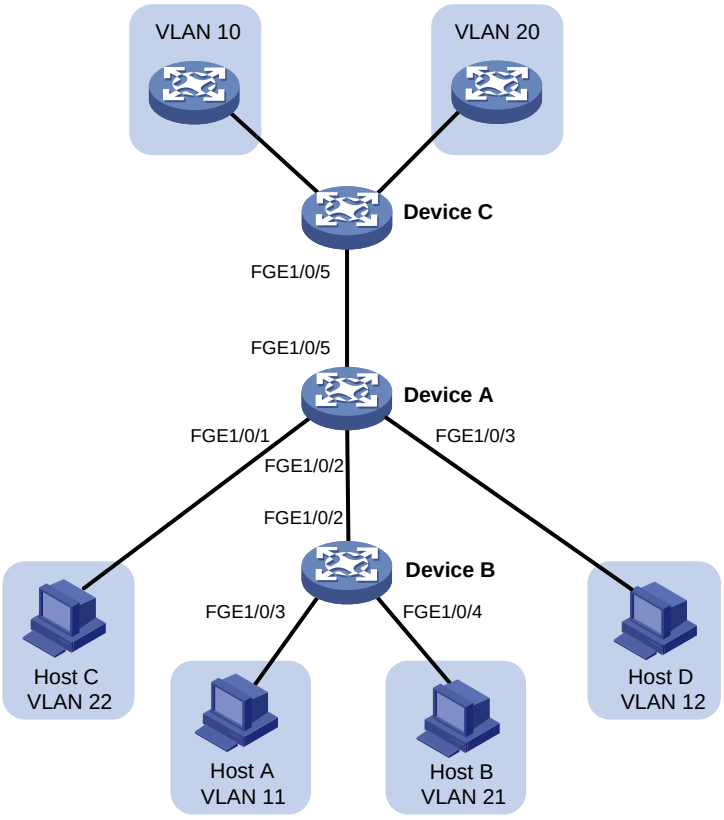
Example: Configuring trunk promiscuous and trunk secondary ports



Network configuration



As shown in Figure 13, configure the private VLAN feature to meet the following requirements:



- VLANs 10 and 20 are primary VLANs on Device A. The uplink port (GigabitEthernet 1/0/5) on Device A permits the packets from VLANs 10 and 20 to pass through tagged.
- VLANs 11, 12, 21, and 22 are secondary VLANs on Device A.
  - Downlink port GigabitEthernet 1/0/2 permits the packets from secondary VLANs 11 and 21 to pass through tagged.
  - Downlink port GigabitEthernet 1/0/1 permits secondary VLAN 22.
  - Downlink port GigabitEthernet 1/0/3 permits secondary VLAN 12.
- Secondary VLANs 11 and 12 are associated with primary VLAN 10.
- Secondary VLANs 21 and 22 are associated with primary VLAN 20.

Procedure

1. Configure Device A:

Configure VLANs 10 and 20 as primary VLANs.

```
<DeviceA> system-view
[DeviceA] vlan 10
[DeviceA-vlan10] private-vlan primary
[DeviceA-vlan10] quit
[DeviceA] vlan 20
[DeviceA-vlan20] private-vlan primary
[DeviceA-vlan20] quit
```

Create VLANs 11, 12, 21, and 22.

```
[DeviceA] vlan 11 to 12
[DeviceA] vlan 21 to 22
```

Associate secondary VLANs 11 and 12 with primary VLAN 10.

```
[DeviceA] vlan 10
[DeviceA-vlan10] private-vlan secondary 11 12
[DeviceA-vlan10] quit
```

Associate secondary VLANs 21 and 22 with primary VLAN 20.

```
[DeviceA] vlan 20
[DeviceA-vlan20] private-vlan secondary 21 22
[DeviceA-vlan20] quit
```

Configure the uplink port (GigabitEthernet 1/0/5) as a trunk promiscuous port of VLANs 10 and 20.

```
[DeviceA] interface gigabitethernet 1/0/5
```

```
[DeviceA-GigabitEthernet1/0/5] port private-vlan 10 20 trunk promiscuous
[DeviceA-GigabitEthernet1/0/5] quit
```

Assign downlink port GigabitEthernet 1/0/1 to VLAN 22 and configure the port as a host port.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port access vlan 22
[DeviceA-GigabitEthernet1/0/1] port private-vlan host
[DeviceA-GigabitEthernet1/0/1] quit
```

Assign downlink port GigabitEthernet 1/0/3 to VLAN 12 and configure the port as a host port.

```
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] port access vlan 12
[DeviceA-GigabitEthernet1/0/3] port private-vlan host
[DeviceA-GigabitEthernet1/0/3] quit
```

Configure downlink port GigabitEthernet 1/0/2 as a trunk secondary port of VLANs 11 and 21.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port private-vlan 11 21 trunk secondary
[DeviceA-GigabitEthernet1/0/2] quit
```

2. Configure Device B:

Create VLANs 11 and 21.

```
<DeviceB> system-view
[DeviceB] vlan 11
[DeviceB-vlan11] quit
[DeviceB] vlan 21
[DeviceB-vlan21] quit
```

Configure GigabitEthernet 1/0/2 as a hybrid port, and assign it to VLANs 11 and 21 as a tagged VLAN member.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type hybrid
[DeviceB-GigabitEthernet1/0/2] port hybrid vlan 11 21 tagged
[DeviceB-GigabitEthernet1/0/2] quit
```

Assign GigabitEthernet 1/0/3 to VLAN 11.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port access vlan 11
[DeviceB-GigabitEthernet1/0/3] quit
```

Assign GigabitEthernet 1/0/4 to VLAN 21.

```
[DeviceB] interface gigabitethernet 1/0/4
[DeviceB-GigabitEthernet1/0/4] port access vlan 21
[DeviceB-GigabitEthernet1/0/4] quit
```

3. Configure Device C:

Create VLANs 10 and 20.

```
<DeviceC> system-view
[DeviceC] vlan 10
[DeviceC-vlan10] quit
[DeviceC] vlan 20
[DeviceC-vlan20] quit
```

Configure GigabitEthernet 1/0/5 as a hybrid port, and assign it to VLANs 10 and 20 as a tagged VLAN member.

```
[DeviceC] interface gigabitethernet 1/0/5
[DeviceC-GigabitEthernet1/0/5] port link-type hybrid
```

```
[DeviceC-GigabitEthernet1/0/5] port hybrid vlan 10 20 tagged
[DeviceC-GigabitEthernet1/0/5] quit
```

Verifying the configuration

Verify the primary VLAN configurations on Device A. The following output uses primary VLAN 10 as an example.

```
[DeviceA] display private-vlan 10
 Primary VLAN ID: 10
 Secondary VLAN ID: 11-12

 VLAN ID: 10
 VLAN type: Static
 Private-vlan type: Primary
 Route interface: Not configured
 Description: VLAN 0010
 Name: VLAN 0010
 Tagged ports:
    GigabitEthernet1/0/2
    GigabitEthernet1/0/5
 Untagged ports:
    GigabitEthernet1/0/3

 VLAN ID: 11
 VLAN type: Static
 Private-vlan type: Secondary
 Route interface: Not configured
 Description: VLAN 0011
 Name: VLAN 0011
 Tagged ports:
    GigabitEthernet1/0/2
    GigabitEthernet1/0/5
 Untagged ports: None

 VLAN ID: 12
 VLAN type: Static
 Private-vlan type: Secondary
 Route interface: Not configured
 Description: VLAN 0012
 Name: VLAN 0012
 Tagged ports:
    GigabitEthernet1/0/5
 Untagged ports:
    GigabitEthernet1/0/3
```

The output shows that:

- The trunk promiscuous port (GigabitEthernet 1/0/5) is a tagged member of primary VLAN 10 and secondary VLANs 11 and 12.
- The trunk secondary port (GigabitEthernet 1/0/2) is a tagged member of primary VLAN 10 and secondary VLAN 11.

- The host port (GigabitEthernet 1/0/3) is an untagged member of primary VLAN 10 and secondary VLAN 12.

Configuring voice VLANs

About voice VLANs

A voice VLAN is used for transmitting voice traffic. The device can configure QoS parameters for voice packets to ensure higher transmission priority of the voice packets.

Common voice devices include IP phones and integrated access devices (IADs). This chapter uses IP phones as an example.

Working mechanism

When an IP phone accesses a device, the device performs the following operations:

1. Identifies the IP phone in the network and obtains the MAC address of the IP phone.
2. Advertises the voice VLAN information to the IP phone.

After receiving the voice VLAN information, the IP phone performs automatic configuration. Voice packets sent from the IP phone can then be transmitted within the voice VLAN.

Methods of identifying IP phones

Devices can use the OUI addresses or LLDP to identify IP phones.

Identifying IP phones through OUI addresses

A device identifies voice packets based on their source MAC addresses. A packet whose source MAC address complies with an Organizationally Unique Identifier (OUI) address of the device is regarded as a voice packet.

You can use system default OUI addresses (see Table 1) or configure OUI addresses for the device. You cannot delete the system default OUI addresses.

Table 1 Default OUI addresses

Number	OUI address	Vendor
1	0001-e300-0000	Siemens phone
2	0003-6b00-0000	Cisco phone
3	0004-0d00-0000	Avaya phone
4	000f-e200-0000	H3C Aolynk phone
5	0060-b900-0000	Philips/NEC phone
6	00d0-1e00-0000	Pingtel phone
7	00e0-7500-0000	Polycom phone
8	00e0-bb00-0000	3Com phone

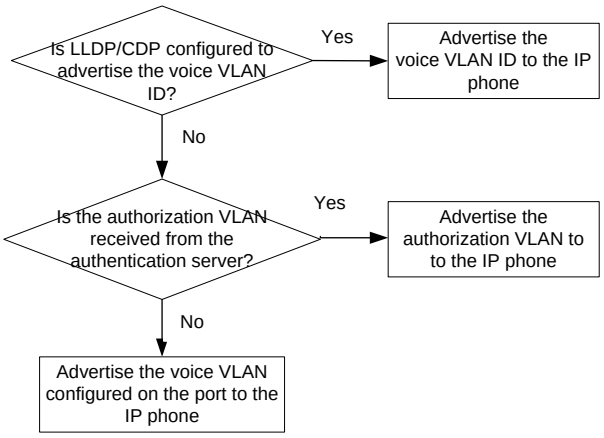
Typically, an OUI address refers to the first 24 bits of a MAC address (in binary notation) and is a globally unique identifier that IEEE assigns to a vendor. However, OUI addresses in this chapter are addresses that the system uses to identify voice packets. They are the logical AND results of the *mac-address* and *oui-mask* arguments in the **voice-vlan mac-address** command.

Automatically identifying IP phones through LLDP

If IP phones support LLDP, configure LLDP for automatic IP phone discovery on the device. The device can then automatically discover the peer through LLDP, and exchange LLDP TLVs with the peer.

If the LLDP System Capabilities TLV received on a port indicates that the peer can act as a telephone, the device performs the following operations:

1. Sends an LLDP TLV with the voice VLAN configuration to the peer.
2. Assigns the receiving port to the voice VLAN.
3. Increases the transmission priority of the voice packets sent from the IP phone.
4. Adds the MAC address of the IP phone to the MAC address table to ensure that the IP phone can pass authentication.



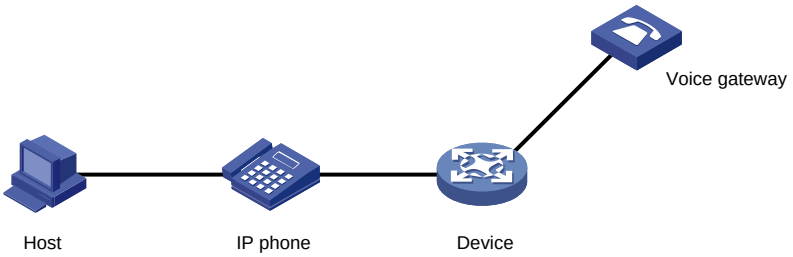
Use LLDP instead of the OUI list to identify IP phones if the network has more IP phone categories than the maximum number of OUI addresses supported on the device. LLDP has higher priority than the OUI list.

For more information about LLDP, see "Configuring LLDP."

Advertising the voice VLAN information to IP phones

Figure 14 shows the workflow of advertising the voice VLAN information to IP phones.

Figure 14 Workflow of advertising the voice VLAN information to IP phones



IP phone access methods

Connecting the host and the IP phone in series

As shown in Figure 15, the host is connected to the IP phone, and the IP phone is connected to the device. In this scenario, the following requirements must be met:

- The host and the IP phone use different VLANs.
- The IP phone is able to send out VLAN-tagged packets, so that the device can differentiate traffic from the host and the IP phone.
- The port connecting to the IP phone forwards packets from the voice VLAN and the PVID.

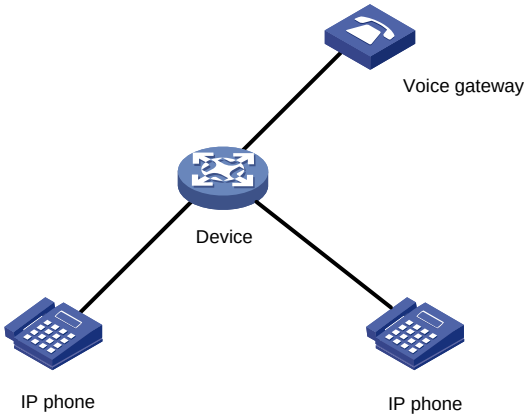


Figure 15 Connecting the host and IP phone in series

Connecting the IP phone to the device

As shown in Figure 16, IP phones are connected to the device without the presence of the host. Use this connection method when IP phones sends out untagged voice packets. In this scenario, you must configure the voice VLAN as the PVID of the access port of the IP phone, and configure the port to forward the packets from the PVID.

Figure 16 Connecting the IP phone to the device

Voice VLAN assignment modes

A port can be assigned to a voice VLAN automatically or manually.

Automatic mode

Use automatic mode when PCs and IP phones are connected in series to access the network through the device, as shown in the diagram for connecting the host and IP phone in series in "Connecting the host and the IP phone in series." Ports on the device transmit both voice traffic and data traffic.

When an IP phone is powered on, it sends out protocol packets. After receiving these protocol packets, the device uses the source MAC address of the protocol packets to match its OUI addresses. If the match succeeds, the device performs the following operations:

- Assigns the receiving port of the protocol packets to the voice VLAN.
- Issues ACL rules to set the packet precedence.
- Starts the voice VLAN aging timer.

If no voice packet is received from the port before the aging timer expires, the device will remove the port from the voice VLAN. The aging timer is also configurable.

When the IP phone reboots, the port is reassigned to the voice VLAN to ensure the correct operation of the existing voice connections. The reassignment occurs automatically without being triggered by voice traffic as long as the voice VLAN operates correctly.

Manual mode

Use manual mode when only IP phones access the network through the device, as shown in the diagram for connecting the IP phone to the device in "Connecting the IP phone to the device." In this mode, ports are assigned to a voice VLAN that transmits voice traffic exclusively. No data traffic affects the voice traffic transmission.

You must manually assign the port that connects to the IP phone to a voice VLAN. The device uses the source MAC address of the received voice packets to match its OUI addresses. If the match succeeds, the device issues ACL rules to set the packet precedence.

To remove the port from the voice VLAN, you must manually remove it.

Cooperation of voice VLAN assignment modes and IP phones

Some IP phones send out VLAN-tagged packets, and others send out only untagged packets. For correct packet processing, ports of different link types must meet specific configuration requirements in different voice VLAN assignment modes.

If an IP phone sends out tagged voice traffic, and its access port is configured with 802.1X authentication, guest VLAN, Auth-Fail VLAN, or critical VLAN, VLAN IDs must be different for the following VLANs:

- Voice VLAN.
- PVID of the access port.
- 802.1X guest, Auth-Fail, or critical VLAN.

If an IP phone sends out untagged voice traffic, the PVID of the access port must be the voice VLAN. In this scenario, 802.1X authentication is not supported.

Access ports do not transmit tagged packets.

Configuration requirements for transmitting tagged voice traffic

Port link type	Voice VLAN assignment mode	Configuration requirements
Trunk	Automatic	The PVID of the port cannot be the voice VLAN.
	Manual	The PVID of the port cannot be the voice VLAN. The port must forward packets from the voice VLAN.
Hybrid	Automatic	The PVID of the port cannot be the voice VLAN.
	Manual	The PVID of the port cannot be the voice VLAN. The port must forward packets from the voice VLAN with VLAN tags.

Configuration requirements for transmitting untagged voice traffic

When IP phones send out untagged packets, you must set the voice VLAN assignment mode to manual.

Table 2 Configuration requirements for ports in manual mode to support untagged voice traffic

Port link type	Configuration requirements
Access	The voice VLAN must be the PVID of the port.

Port link type	Configuration requirements
Trunk	The voice VLAN must be the PVID of the port. The port must forward packets from the voice VLAN.
Hybrid	The voice VLAN must be the PVID of the port. The port must forward packets from the voice VLAN without VLAN tags.

Security mode and normal mode of voice VLANs

Depending on the filtering mechanisms to incoming packets, a voice VLAN-enabled port can operate in one of the following modes:

- **Normal mode**—The port receives voice-VLAN-tagged packets and forwards them in the voice VLAN without examining their MAC addresses. If the PVID of the port is the voice VLAN and the port operates in manual VLAN assignment mode, the port forwards all the received untagged packets in the voice VLAN.

  In this mode, voice VLANs are vulnerable to traffic attacks. Malicious users might send a large number of forged voice-VLAN-tagged or untagged packets to affect voice communication.
- **Security mode**—The port uses the source MAC addresses of voice packets to match the OUI addresses of the device. Packets that fail the match will be dropped.

In a safe network, you can configure the voice VLANs to operate in normal mode. This mode reduces system resource consumption in source MAC address checking.

In either mode, the device modifies the transmission priority only for voice VLAN packets whose source MAC addresses match OUI addresses of the device.

As a best practice, do not transmit both voice traffic and non-voice traffic in a voice VLAN. If you must transmit different traffic in a voice VLAN, make sure the voice VLAN security mode is disabled.

Table 3 Packet processing on a voice VLAN-enabled port in normal or security mode

Voice VLAN mode	Packet type	Packet processing
Normal	• Untagged packets • Packets with the voice VLAN tags	The port does not examine their source MAC addresses. The device forwards voice packets and non-voice packets in the voice VLAN and modifies the priority settings for packets with source MAC addresses matching OUI addresses.
	Packets with other VLAN tags	The port forwards or drops them depending on whether the port permits packets from these VLANs to pass through.
Security	• Untagged packets • Packets with the voice VLAN tags	• If the source MAC address of a packet matches an OUI address on the device, the device modifies the priority settings for the packet as configured, and forwards the packet in the voice VLAN. • If the source MAC address of a packet does not match an OUI address on the device, the packet is dropped.
	Packets with other VLAN tags	The port forwards or drops them depending on whether the port permits packets from these VLANs to pass through.

Restrictions and guidelines: Voice VLAN configuration

The aging timer of a voice VLAN starts only when the dynamic MAC address entry of the voice VLAN ages out. The aging period for the voice VLAN equals the sum of the voice VLAN aging timer and the aging timer for its dynamic MAC address entry. For more information about the aging timer for dynamic MAC address entries, see "Configuring the MAC address table."

As a best practice, do not both configure voice VLAN and disable MAC address learning on a port. If the two features are configured together on a port, the port forwards only packets exactly matching the OUI addresses and drops inexactly matching packets.

As a best practice, do not configure both voice VLAN and the MAC learning limit on a port. If the two features are configured together on a port and the port learns the configured maximum number of MAC address entries, the port processes packets as follows:

- Forwards only packets matching the MAC address entries learnt by the port and OUI addresses.
- Drops unmatching packets.

Voice VLAN tasks at a glance

To configure a voice VLAN, perform the following tasks:

1. Configuring the QoS priority settings for voice traffic
2. (Optional.) Configuring the ACL resource occupation mode of voice VLAN
3. Use one of the following methods:
   - Configuring a port to operate in automatic voice VLAN assignment mode
   - Configuring a port to operate in manual voice VLAN assignment mode
4. (Optional.) Enabling LLDP for automatic IP phone discovery
5. (Optional.) Use one of the following methods:
   - Configuring LLDP to advertise a voice VLAN
   - Configuring CDP to advertise a voice VLAN

Configuring the QoS priority settings for voice traffic

About this task

You can configure the device to modify the QoS priority settings for voice traffic.

The QoS priority settings carried in voice traffic include the CoS and DSCP values.

- **CoS priority**—Class of service priority defined by 802.1p, a 3-bit priority field in an 802.1Q frame. When the network is congested, a device preferentially sends packets with high 802.1p priority values.
- **DSCP priority**—Differentiated Services Codepoint priority. It is a 6-bit field in the ToS field of an IPv4 packet. On a DiffServ network, a device executes a forwarding action for a packet according to its DSCP priority value.

Restrictions and guidelines

You cannot configure the QoS priority settings on a voice VLAN-enabled port. Before you configure the QoS priority settings for voice traffic on a port, you must disable the voice VLAN feature on it.

If you execute the **voice-vlan qos** and **voice-vlan qos trust** commands multiple times, the most recent configuration takes effect.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view.
   interface *interface-type interface-number*
3. Configure QoS priority settings for incoming voice VLAN packets.
   - Configure the port to trust the QoS priority settings and not to modify the priority settings for packets.
     voice-vlan qos trust
   - Configure the port to modify the CoS and DSCP values.
     voice-vlan qos *cos-value dscp-value*

   By default, a port modifies the CoS and DSCP values for voice VLAN packets to 6 and 46, respectively.

   If a port trusts the QoS priority settings in incoming voice VLAN packets, the port does not modify their CoS and DSCP values.

Configuring the ACL resource occupation mode of voice VLAN

About this task

With voice VLAN enabled on ports, you can configure the ACL resource occupation mode of voice VLAN as the global mode or the port mode.

- In global mode, ports in the same voice VLAN share one ACL resource. The global mode sharply saves ACL resources.
- In port mode, each port uses its dedicated ACL resource.

Restrictions and guidelines

Before switching the ACL resource occupation mode of voice VLAN from global mode to port mode, make sure the remaining ACL resource are sufficient. If you cannot do that, the system will prompt that the resources are insufficient and not allow the switching.

For the ACL resource occupation mode of voice VLAN to take effect, save the configuration on the device and restart the device. Before restarting the device, as a best practice, do not configure the voice VLAN related features. If you do that, the voice VLAN feature might have defects.

Software version and feature compatibility

This feature is supported only in Release 8307P08 and later.

Procedure

1. Enter system view.
   system-view
2. Configure the ACL resource occupation mode of voice VLAN.
   voice-vlan acl-resource-mode { **global** | **port** }
   By default, the ACL resource occupation mode of voice VLAN is not set.

Configuring voice VLAN assignment modes for a port

Configuring a port to operate in automatic voice VLAN assignment mode

Restrictions and guidelines

- Do not configure a VLAN as both a voice VLAN and a protocol-based VLAN.
  - A voice VLAN in automatic mode on a hybrid port processes only tagged incoming voice traffic.
  - A protocol-based VLAN on a hybrid port processes only untagged incoming packets. For more information about protocol-based VLANs, see "Configuring protocol-based VLANs."
- As a best practice, do not use this mode with MSTP. In MSTP mode, if a port is blocked in the MSTI of the target voice VLAN, the port drops the received packets instead of delivering them to the CPU. As a result, the port will not be dynamically assigned to the voice VLAN.
- As a best practice, do not use this mode with PVST. In PVST mode, if the target voice VLAN is not permitted on a port, the port is placed in blocked state. The port drops the received packets instead of delivering them to the CPU. As a result, the port will not be dynamically assigned to the voice VLAN.
- As a best practice, do not configure both dynamic MAC-based VLAN assignment and automatic voice VLAN assignment mode on a port. They can have a negative impact on each other.

Procedure

1. Enter system view.

   system-view
2. (Optional.) Set the voice VLAN aging timer.

   voice-vlan aging *minutes*

   By default, the aging timer of a voice VLAN is 1440 minutes.

   The voice VLAN aging timer takes effect only on ports in automatic voice VLAN assignment mode.
3. (Optional.) Enable the voice VLAN security mode.

   voice-vlan security enable

   By default, the voice VLAN security mode is enabled.
4. (Optional.) Add an OUI address for voice packet identification.

   voice-vlan mac-address *oui* **mask** *oui-mask* [**description** *text*]

   By default, system default OUI addresses exist. For more information, see the default OUI addresses table in "Identifying IP phones through OUI addresses."
5. Enter Layer 2 Ethernet interface view.

   interface *interface-type interface-number*
6. Configure the link type of the port.
   - **port link-type trunk**
   - **port link-type hybrid**
7. Configure the port to operate in automatic voice VLAN assignment mode.

   voice-vlan mode auto

   By default, the automatic voice VLAN assignment mode is enabled.

8. Enable the voice VLAN feature on the port.

   voice-vlan *vlan-id* **enable**

   By default, the voice VLAN feature is disabled.

   Before you execute this command, make sure the specified VLAN already exists.

Configuring a port to operate in manual voice VLAN assignment mode

Restrictions and guidelines

- You can configure different voice VLANs for different ports on the same device. Make sure the following requirements are met:
  - One port can be configured with only one voice VLAN.
  - Voice VLANs must be existing static VLANs.
- Do not enable voice VLAN on the member ports of a link aggregation group. For more information about link aggregation, see "Configuring Ethernet link aggregation."
- To make a voice VLAN take effect on a port operating in manual mode, you must manually assign the port to the voice VLAN.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Enable the voice VLAN security mode.

   voice-vlan security enable

   By default, the voice VLAN security mode is enabled.

3. (Optional.) Add an OUI address for voice packet identification.

   voice-vlan mac-address *oui* **mask** *oui-mask* [**description** *text*]

   By default, system default OUI addresses exist. For more information, see the default OUI addresses table in "Identifying IP phones through OUI addresses."

4. Enter Layer 2 Ethernet interface view.

   interface *interface-type interface-number*

5. Configure the port to operate in manual voice VLAN assignment mode.

   undo voice-vlan mode auto

   By default, a port operates in automatic voice VLAN assignment mode.

6. Assign the access, trunk, or hybrid port to the voice VLAN.
   - For the access port, see "Assigning an access port to a VLAN."
   - For the trunk port, see "Assigning a trunk port to a VLAN."
   - For the hybrid port, see "Assigning a hybrid port to a VLAN."

   After you assign an access port to the voice VLAN, the voice VLAN becomes the PVID of the port.

7. (Optional.) Configure the voice VLAN as the PVID of the trunk or hybrid port.
   - For the trunk port, see "Assigning a trunk port to a VLAN."
   - For the hybrid port, see "Assigning a hybrid port to a VLAN."

   This step is required for untagged incoming voice traffic and prohibited for tagged incoming voice traffic.

8. Enable the voice VLAN feature on the port.

   voice-vlan *vlan-id* **enable**

By default, the voice VLAN feature is disabled.

Before you execute this command, make sure the specified VLAN already exists.

Enabling LLDP for automatic IP phone discovery

Restrictions and guidelines

- Before you enable this feature, enable LLDP both globally and on access ports.

Procedure

1. Enter system view.
   `system-view`
2. Enable LLDP for automatic IP phone discovery.
   `voice-vlan track lldp`
   By default, this feature is disabled.

Configuring LLDP or CDP to advertise a voice VLAN

Configuring LLDP to advertise a voice VLAN

About this task

For IP phones that support LLDP, the device advertises the voice VLAN information to the IP phones through the LLDP-MED TLVs.

Prerequisites

Before you configure this feature, enable LLDP both globally and on access ports.

Procedure

1. Enter system view.
   `system-view`
2. Enter Layer 2 Ethernet interface view.
   `interface` *`interface-type interface-number`*
3. Configure an advertised voice VLAN ID.
   `lldp tlv-enable med-tlv network-policy` *`vlan-id`*
   By default, no advertised voice VLAN ID is configured.
   For more information about the command, see *Layer 2—LAN Switching Command Reference*.
4. (Optional.) Display the voice VLAN advertised by LLDP.
   `display lldp local-information`
   For more information about the command, see *Layer 2—LAN Switching Command Reference*.

Configuring CDP to advertise a voice VLAN

About this task

If an IP phone supports CDP but does not support LLDP, it will send out CDP packets to the device to request the voice VLAN ID. If the IP phone does not receive the voice VLAN ID within a time period,

it will send out untagged packets. The device cannot differentiate untagged voice packets from other types of packets.

You can configure CDP compatibility on the device to enable it to perform the following operations:

- Receive and identify CDP packets from the IP phone.
- Send CDP packets to the IP phone. The voice VLAN information is carried in the CDP packets.

After receiving the advertised VLAN information, the IP phone performs automatic voice VLAN configuration. Packets from the IP phone will be transmitted in the dedicated voice VLAN.

LLDP packets sent from the device carry the priority information. CDP packets sent from the device do not carry the priority information.

Prerequisites

Before you configure this feature, enable LLDP globally and on access ports.

Procedure

1. Enter system view.
   `system-view`
2. Enable CDP compatibility.
   `lldp compliance cdp`
   By default, CDP compatibility is disabled.
3. Enter Layer 2 Ethernet interface view.
   `interface` *`interface-type interface-number`*
4. Configure CDP-compatible LLDP to operate in TxRx mode.
   `lldp compliance admin-status cdp txrx`
   By default, CDP-compatible LLDP operates in Disable mode.
5. Configure an advertised voice VLAN ID.
   `cdp voice-vlan` *`vlan-id`*
   By default, no advertised voice VLAN ID is configured.
   For more information about the command, see *Layer 2—LAN Switching Command Reference*.

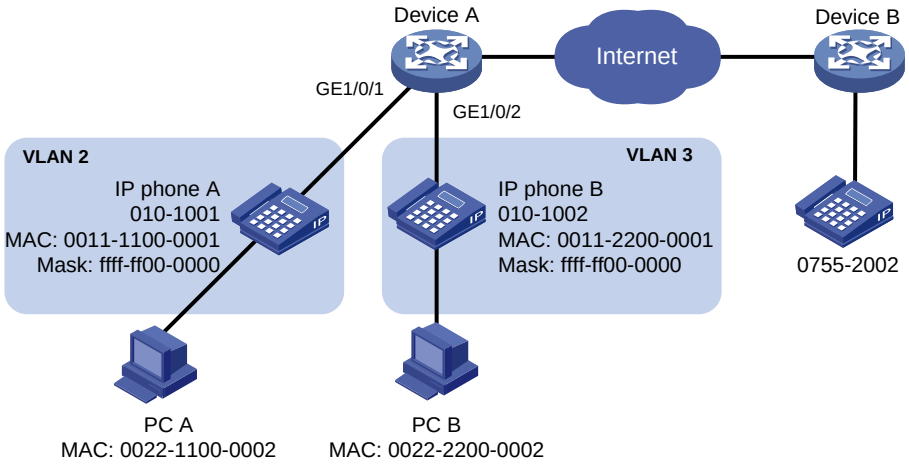
Display and maintenance commands for voice VLANs

Execute **`display`** commands in any view.

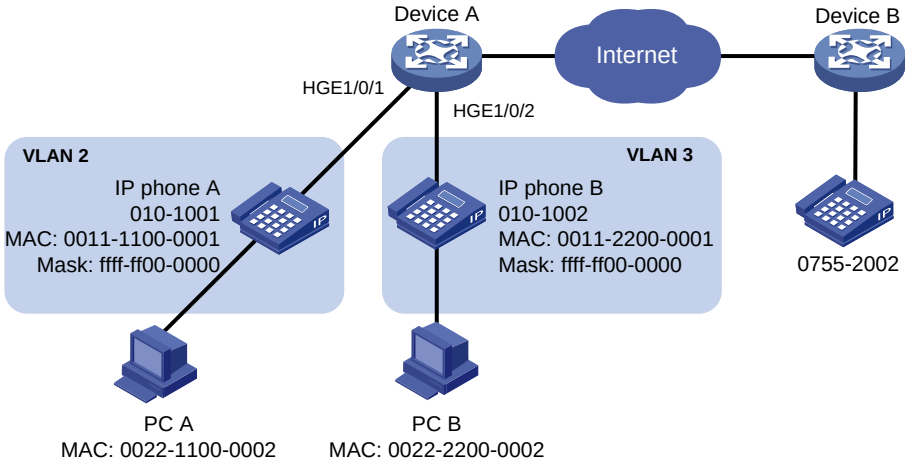
Task	Command
Display OUI addresses on a device.	**`display voice-vlan mac-address`**
Display the voice VLAN state.	**`display voice-vlan state`**

Voice VLAN configuration examples

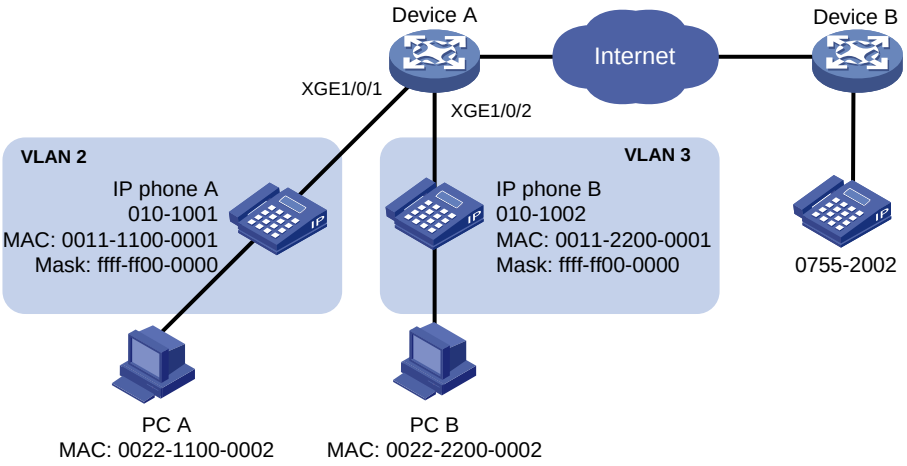
Example: Configuring automatic voice VLAN assignment mode



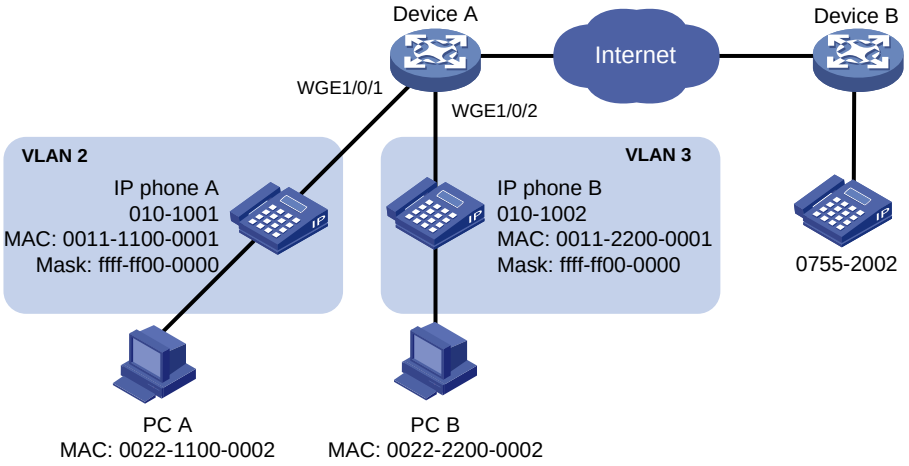
Network configuration



As shown in Figure 17, Device A transmits traffic from IP phones and hosts.



For correct voice traffic transmission, perform the following tasks on Device A:



- Configure voice VLANs 2 and 3 to transmit voice packets from IP phone A and IP phone B, respectively.
- Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to operate in automatic voice VLAN assignment mode.
- Add MAC addresses of IP phones A and B to the device for voice packet identification. The mask of the two MAC addresses is FFFF-FF00-0000.
- Set an aging timer for voice VLANs.

Procedure

1. Configure voice VLANs:

   # Create VLANs 2 and 3.

   ```
   <DeviceA> system-view
   [DeviceA] vlan 2 to 3
   ```

   # Set the voice VLAN aging timer to 30 minutes.

```
[DeviceA] voice-vlan aging 30
```

Enable security mode for voice VLANs.

```
[DeviceA] voice-vlan security enable
```

Add MAC addresses of IP phones A and B to the device with mask FFFF-FF00-0000.

```
[DeviceA] voice-vlan mac-address 0011-1100-0001 mask ffff-ff00-0000 description IP
phone A
[DeviceA] voice-vlan mac-address 0011-2200-0001 mask ffff-ff00-0000 description IP
phone B
```

2. Configure GigabitEthernet 1/0/1:

Configure GigabitEthernet 1/0/1 as a hybrid port.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-type hybrid
```

Configure GigabitEthernet 1/0/1 to operate in automatic voice VLAN assignment mode.

```
[DeviceA-GigabitEthernet1/0/1] voice-vlan mode auto
```

Enable voice VLAN on GigabitEthernet 1/0/1 and configure VLAN 2 as the voice VLAN for it.

```
[DeviceA-GigabitEthernet1/0/1] voice-vlan 2 enable
[DeviceA-GigabitEthernet1/0/1] quit
```

3. Configure GigabitEthernet 1/0/2:

Configure GigabitEthernet 1/0/2 as a hybrid port.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type hybrid
```

Configure GigabitEthernet 1/0/2 to operate in automatic voice VLAN assignment mode.

```
[DeviceA-GigabitEthernet1/0/2] voice-vlan mode auto
```

Enable voice VLAN on GigabitEthernet 1/0/2 and configure VLAN 3 as the voice VLAN for it.

```
[DeviceA-GigabitEthernet1/0/2] voice-vlan 3 enable
[DeviceA-GigabitEthernet1/0/2] quit
```

Verifying the configuration

Display the OUI addresses supported on Device A.

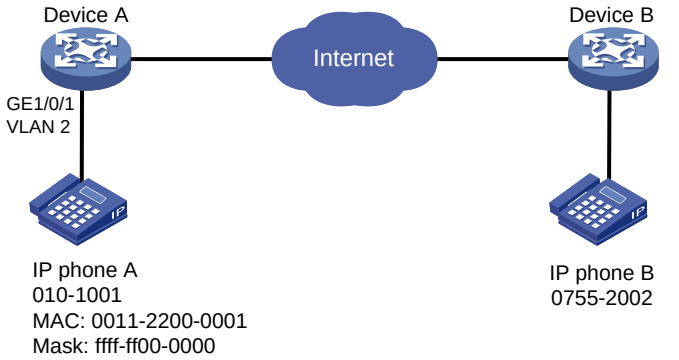
```
[DeviceA] display voice-vlan mac-address
OUI Address     Mask            Description
0001-e300-0000  ffff-ff00-0000  Siemens phone
0003-6b00-0000  ffff-ff00-0000  Cisco phone
0004-0d00-0000  ffff-ff00-0000  Avaya phone
000f-e200-0000  ffff-ff00-0000  H3C Aolynk phone
0011-1100-0000  ffff-ff00-0000  IP phone A
0011-2200-0000  ffff-ff00-0000  IP phone B
0060-b900-0000  ffff-ff00-0000  Philips/NEC phone
00d0-1e00-0000  ffff-ff00-0000  Pingtel phone
00e0-7500-0000  ffff-ff00-0000  Polycom phone
00e0-bb00-0000  ffff-ff00-0000  3Com phone
```

Display the voice VLAN state.

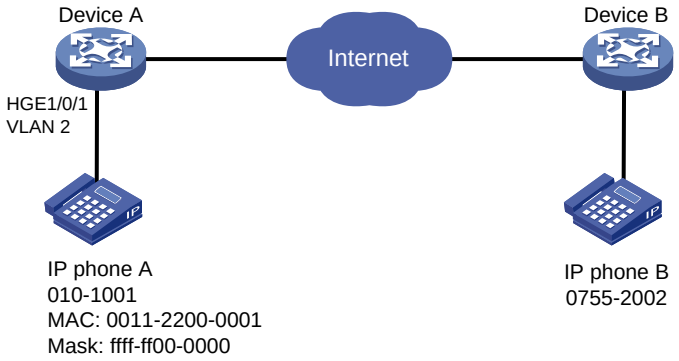
```
[DeviceA] display voice-vlan state
 Current voice VLANs: 2
 Voice VLAN security mode: Security
 Voice VLAN aging time: 30 minutes
 Voice VLAN enabled ports and their modes:
 Port                        VLAN        Mode        CoS        DSCP
```

GE1/0/1	2	Auto	6	46
GE1/0/2	3	Auto	6	46

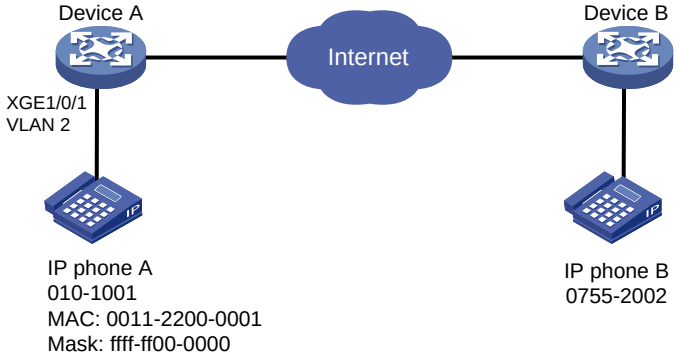
Example: Configuring manual voice VLAN assignment mode



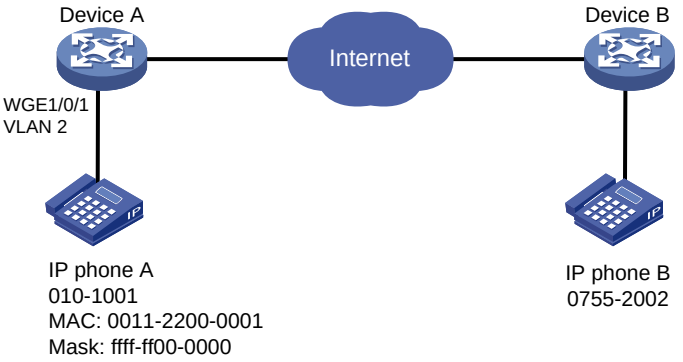
Network configuration



As shown in Figure 18, IP phone A send untagged voice traffic.



To enable GigabitEthernet 1/0/1 to transmit only voice packets, perform the following tasks on Device A:



- Create VLAN 2. This VLAN will be used as a voice VLAN.
- Configure GigabitEthernet 1/0/1 to operate in manual voice VLAN assignment mode and add it to VLAN 2.
- Add the OUI address of IP phone A to the OUI list of Device A.

Procedure

Enable security mode for voice VLANs.

```
<DeviceA> system-view
[DeviceA] voice-vlan security enable
```

Add MAC address 0011-2200-0001 with mask FFFF-FF00-0000.

```
[DeviceA] voice-vlan mac-address 0011-2200-0001 mask ffff-ff00-0000 description test
```

Create VLAN 2.

```
[DeviceA] vlan 2
[DeviceA-vlan2] quit
```

Configure GigabitEthernet 1/0/1 to operate in manual voice VLAN assignment mode.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] undo voice-vlan mode auto
```

Configure GigabitEthernet 1/0/1 as a hybrid port.

```
[DeviceA-GigabitEthernet1/0/1] port link-type hybrid
```

Set the PVID of GigabitEthernet 1/0/1 to VLAN 2.

```
[DeviceA-GigabitEthernet1/0/1] port hybrid pvid vlan 2
```

Assign GigabitEthernet 1/0/1 to VLAN 2 as an untagged VLAN member.

```
[DeviceA-GigabitEthernet1/0/1] port hybrid vlan 2 untagged
```

Enable voice VLAN and configure VLAN 2 as the voice VLAN on GigabitEthernet 1/0/1.

```
[DeviceA-GigabitEthernet1/0/1] voice-vlan 2 enable
[DeviceA-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Display the OUI addresses supported on Device A.

```
[DeviceA] display voice-vlan mac-address
OUI Address     Mask            Description
0001-e300-0000  ffff-ff00-0000  Siemens phone
0003-6b00-0000  ffff-ff00-0000  Cisco phone
0004-0d00-0000  ffff-ff00-0000  Avaya phone
000f-e200-0000  ffff-ff00-0000  H3C Aolynk phone
0011-2200-0000  ffff-ff00-0000  test
0060-b900-0000  ffff-ff00-0000  Philips/NEC phone
00d0-1e00-0000  ffff-ff00-0000  Pingtel phone
00e0-7500-0000  ffff-ff00-0000  Polycom phone
00e0-bb00-0000  ffff-ff00-0000  3Com phone
```

Display the voice VLAN state.

```
[DeviceA] display voice-vlan state
 Current voice VLANs: 1
 Voice VLAN security mode: Security
 Voice VLAN aging time: 1440 minutes
 Voice VLAN enabled ports and their modes:
 Port                        VLAN        Mode        CoS         DSCP

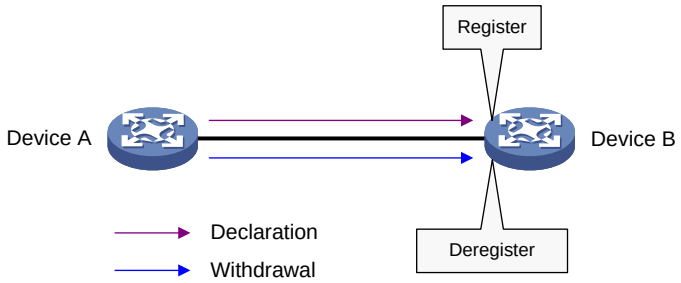
Configuring MVRP

About MVRP



Multiple Registration Protocol (MRP) is an attribute registration protocol used to transmit attribute values. Multiple VLAN Registration Protocol (MVRP) is a typical MRP application. It synchronizes VLAN information among devices and greatly reduces the workload of network administrators.

MRP implementation

An MRP-enabled port is called an MRP participant. An MVRP-enabled port is called an MVRP participant.

As shown in Figure 1, an MRP participant sends declarations and withdrawals to notify other participants to register and deregister its attribute values. It also registers and deregisters the attribute values of other participants according to the received declarations and withdrawals. MRP rapidly propagates the configuration information of an MRP participant throughout the LAN.

Figure 1 MRP implementation

For example, MRP registers and deregisters VLAN attributes as follows:

- When a port receives a declaration for a VLAN, the port registers the VLAN and joins the VLAN.
- When a port receives a withdrawal for a VLAN, the port deregisters the VLAN and leaves the VLAN.

MRP allows devices in the same LAN to transmit attribute values on a per MSTI basis. Figure 1 shows a simple MRP implementation on an MSTI. In a network with multiple MSTIs, MRP performs attribute registration and deregistration on a per MSTI basis. For more information about MSTIs, see "Configuring spanning tree protocols."

MRP messages

MRP messages include the following types:

- **Declaration**—Includes Join and New messages.
- **Withdrawal**—Includes Leave and LeaveAll messages.

Join message

An MRP participant sends a Join message to request the peer participant to register attributes in the Join message.

When receiving a Join message from the peer participant, an MRP participant performs the following tasks:

- Registers the attributes in the Join message.

- Propagates the Join message to all other participants on the device.

After receiving the Join message, other participants send the Join message to their respective peer participants.

Join messages sent from a local participant to its peer participant include the following types:

- **JoinEmpty**—Declares an unregistered attribute. For example, when an MRP participant joins an unregistered static VLAN, it sends a JoinEmpty message.

  VLANs created manually and locally are called static VLANs. VLANs learned through MRP are called dynamic VLANs.
- **JoinIn**—Declares a registered attribute. A JoinIn message is used in one of the following situations:
  - An MRP participant joins an existing static VLAN and sends a JoinIn message after registering the VLAN.
  - The MRP participant receives a Join message propagated by another participant on the device and sends a JoinIn message after registering the VLAN.

New message

Similar to a Join message, a New message enables MRP participants to register attributes.

When the MSTP topology changes, an MRP participant sends a New message to the peer participant to declare the topology change.

Upon receiving a New message from the peer participant, an MRP participant performs the following tasks:

- Registers the attributes in the message.
- Propagates the New message to all other participants on the device.

After receiving the New message, other participants send the New message to their respective peer participants.

Leave message

An MRP participant sends a Leave message to the peer participant when it wants the peer participant to deregister attributes that it has deregistered.

When the peer participant receives the Leave message, it performs the following tasks:

- Deregisters the attribute in the Leave message.
- Propagates the Leave message to all other participants on the device.

After a participant on the device receives the Leave message, it determines whether to send the Leave message to its peer participant depending on the attribute status on the device.

- If the VLAN in the Leave message is a dynamic VLAN not registered by any participants on the device, both of the following events occur:
  - The VLAN is deleted on the device.
  - The participant sends the Leave message to its peer participant.
- If the VLAN in the Leave message is a static VLAN, the participant will not send the Leave message to its peer participant.

LeaveAll message

Each MRP participant starts its LeaveAll timer when starting up. When the timer expires, the MRP participant sends LeaveAll messages to the peer participant.

Upon sending or receiving a LeaveAll message, the local participant starts the Leave timer. The local participant determines whether to send a Join message depending on its attribute status. A participant can re-register the attributes in the received Join message before the Leave timer expires.

When the Leave timer expires, a participant deregisters all attributes that have not been re-registered to periodically clear useless attributes in the network.

MRP timers

MRP uses the following timers to control message transmission.

Periodic timer

The Periodic timer controls the transmission of MRP messages. An MRP participant starts its own Periodic timer upon startup, and stores MRP messages to be sent before the Periodic timer expires. When the Periodic timer expires, MRP sends stored MRP messages in as few MRP frames as possible and restarts the Periodic timer. This mechanism reduces the number of MRP frames sent.

You can enable or disable the Periodic timer. When the Periodic timer is disabled, MRP does not periodically send MRP messages. Instead, an MRP participant sends MRP messages when the LeaveAll timer expires or the participant receives a LeaveAll message from the peer participant.

Join timer

The Join timer controls the transmission of Join messages. An MRP participant starts the Join timer after sending a Join message to the peer participant. Before the Join timer expires, the participant does not resend the Join message when the following conditions exist:

- The participant receives a JoinIn message from the peer participant.
- The received JoinIn message has the same attributes as the sent Join message.

When both the Join timer and the Periodic timer expire, the participant resends the Join message.

Leave timer

The Leave timer controls the deregistration of attributes.

An MRP participant starts the Leave timer in one of the following conditions:

- The participant receives a Leave message from its peer participant.
- The participant receives or sends a LeaveAll message.

The MRP participant does not deregister the attributes in the Leave or LeaveAll message if the following conditions exist:

- The participant receives a Join message before the Leave timer expires.
- The Join message includes the attributes that have been encapsulated in the Leave or LeaveAll message.

If the participant does not receive a Join message for these attributes before the Leave timer expires, MRP deregisters the attributes.

LeaveAll timer

After startup, an MRP participant starts its own LeaveAll timer. When the LeaveAll timer expires, the MRP participant sends out a LeaveAll message and restarts the LeaveAll timer.

Upon receiving the LeaveAll message, other participants restart their LeaveAll timer. The value of the LeaveAll timer is randomly selected between the LeaveAll timer and 1.5 times the LeaveAll timer. This mechanism provides the following benefits:

- Effectively reduces the number of LeaveAll messages in the network.
- Prevents the LeaveAll timer of a particular participant from always expiring first.

MVRP registration modes

VLAN information propagated by MVRP includes dynamic VLAN information from other devices and local static VLAN information.

Based on how an MVRP participant handles registration of dynamic VLANs, MVRP has the following registration modes:

- **Normal**—An MVRP participant in normal registration mode registers and deregisters dynamic VLANs.
- **Fixed**—An MVRP participant in fixed registration mode disables deregistering dynamic VLANs and drops received MVRP frames. The MVRP participant does not deregister dynamic VLANs or register new dynamic VLANs.
- **Forbidden**—An MVRP participant in forbidden registration mode disables registering dynamic VLANs and drops received MVRP frames. When you set the forbidden registration mode for a port, VLAN 1 of the port retains and all dynamically registered VLANs of the port will be deleted.

Protocols and standards

IEEE 802.1ak, *IEEE Standard for Local and Metropolitan Area Networks: Virtual Bridged Local Area Networks – Amendment 07: Multiple Registration Protocol*

Restrictions: Hardware compatibility with MVRP

MVRP is not supported on the S5200-EI-G switch series.

Restrictions and guidelines: MVRP configuration

When you configure MVRP, follow these restrictions and guidelines:

- MVRP can work with STP, RSTP, or MSTP. Ports blocked by STP, RSTP, or MSTP can receive and send MVRP frames. Do not configure MVRP with other link layer topology protocols (such as PVST, RRPP, and Smart Link) on the same port.

  For more information about STP, RSTP, MSTP, and PVST, see "Configuring spanning tree protocols." For more information about RRPP and Smart Link, see *High Availability Configuration Guide*.
- Do not configure both MVRP and remote port mirroring on a port. Otherwise, MVRP might register the remote probe VLAN with incorrect ports, which would cause the monitor port to receive undesired copies. For more information about port mirroring, see *Network Management and Monitoring Configuration Guide*.
- Enabling MVRP on a Layer 2 aggregate interface takes effect on the aggregate interface and all Selected member ports in the link aggregation group.
- MVRP configuration made on an aggregation group member port takes effect only after the port is removed from the aggregation group.

MVRP tasks at a glance

To configure MVRP, perform the following tasks:

1. Enabling MVRP
2. Setting an MVRP registration mode
3. (Optional.) Setting MRP timers
4. (Optional.) Enabling GVRP compatibility

Prerequisites

Before you configure MVRP, complete the following tasks:

- Map each MSTI used by MVRP to an existing VLAN on each device in the network.
- Set the port link type of MVRP participants to trunk because MVRP takes effect only on trunk ports. For more information about trunk ports, see "Configuring VLANs."

Enabling MVRP

1. Enter system view.
   system-view
2. Enable MVRP globally.
   mvrp global enable
   By default, MVRP is globally disabled.
   For MVRP to take effect on a port, enable MVRP both on the port and globally.
3. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
4. Configure the port as a trunk port.
   port link-type trunk
   By default, each port is an access port. For more information about the **port link-type trunk** command, see *Layer 2—LAN Switching Command Reference*.
5. Configure the trunk port to permit the specified VLANs.
   port trunk permit vlan { *vlan-id-list* | **all** }
   By default, a trunk port permits only VLAN 1.
   Make sure the trunk port permits all registered VLANs.
   For more information about the **port trunk permit vlan** command, see *Layer 2—LAN Switching Command Reference*.
6. Enable MVRP on the port.
   mvrp enable
   By default, MVRP is disabled on a port.

Setting an MVRP registration mode

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. Set an MVRP registration mode for the port.
   mvrp registration { **fixed** | **forbidden** | **normal** }
   The default setting is normal registration mode.

Setting MRP timers

Restrictions and guidelines

When you set MVRP timers, follow these restrictions and guidelines:

- Follow the value range requirements for Join, Leave, and LeaveAll timers and their dependencies as described in Table 1. If you set a timer to a value beyond the allowed value range, your configuration fails. You can set a timer by tuning the value of any other timer. The value of each timer must be an integer multiple of 20 centiseconds.

  Table 1 Dependencies of the Join, Leave, and LeaveAll timers

Timer	Lower limit	Upper limit
Join	20 centiseconds	Half the Leave timer
Leave	Twice the Join timer	LeaveAll timer
LeaveAll	Leave timer on each port	32760 centiseconds

- To avoid frequent VLAN registrations and deregistrations, use the same MRP timers throughout the network.
- Each port maintains its own Periodic, Join, and LeaveAll timers, and each attribute of a port maintains a Leave timer.
- As a best practice, restore the timers in the order of Join, Leave, and LeaveAll when you restore these timers to their default values.
- You can restore the Periodic timer to its default value at any time.

Procedure

1. Enter system view.

   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.

   interface *interface-type interface-number*
3. Set the LeaveAll timer.

   mrp timer leaveall *timer-value*

   The default setting is 1000 centiseconds.
4. Set the Join timer.

   mrp timer join *timer-value*

   The default setting is 20 centiseconds.
5. Set the Leave timer.

   mrp timer leave *timer-value*

   The default setting is 60 centiseconds.
6. Set the Periodic timer.

   mrp timer periodic *timer-value*

   The default setting is 100 centiseconds.

Enabling GVRP compatibility

About this task

Perform this task to enable the device to receive and send both MVRP and GVRP frames when the peer device supports GVRP. For more information about GVRP, see the IEEE 802.1Q standard.

Restrictions and guidelines

When you enable GVRP compatibility, follow these restrictions and guidelines:

- GVRP compatibility enables MVRP to work with STP or RSTP, but not MSTP.
- When the system is busy, disable the Period timer to prevent the participant from frequently registering or deregistering attributes.

Procedure

1. Enter system view.
   `system-view`
2. Enable GVRP compatibility.
   `mvrp gvrp-compliance enable`
   By default, GVRP compatibility is disabled.

Display and maintenance commands for MVRP

Execute **`display`** commands in any view and **`reset`** commands in user view.

Task	Command
Display MVRP running status.	**`display mvrp running-status`** [**`interface`** *`interface-list`*]
Display the MVRP state of a port in a VLAN.	**`display mvrp state interface`** *`interface-type interface-number`* **`vlan`** *`vlan-id`*
Display MVRP statistics.	**`display mvrp statistics`** [**`interface`** *`interface-list`*]
Clear MVRP statistics.	**`reset mvrp statistics`** [**`interface`** *`interface-list`*]

MVRP configuration examples

Example: Configuring basic MVRP functions

Network configuration

As shown in Figure 2:

- Create VLAN 10 on Device A and VLAN 20 on Device B.
- Configure MSTP, map VLAN 10 to MSTI 1, map VLAN 20 to MSTI 2, and map the other VLANs to MSTI 0 (VLAN 40 as an exmaple). Thus, Host A can reach Host C, and Host B can reach Host D.

Configure MVRP on Device A, Device B, Device C, and Device D to meet the following requirements:

- The devices can register and deregister dynamic VLANs.
- The devices can keep identical VLAN configurations for each MSTI.

Figure 2 Network diagram

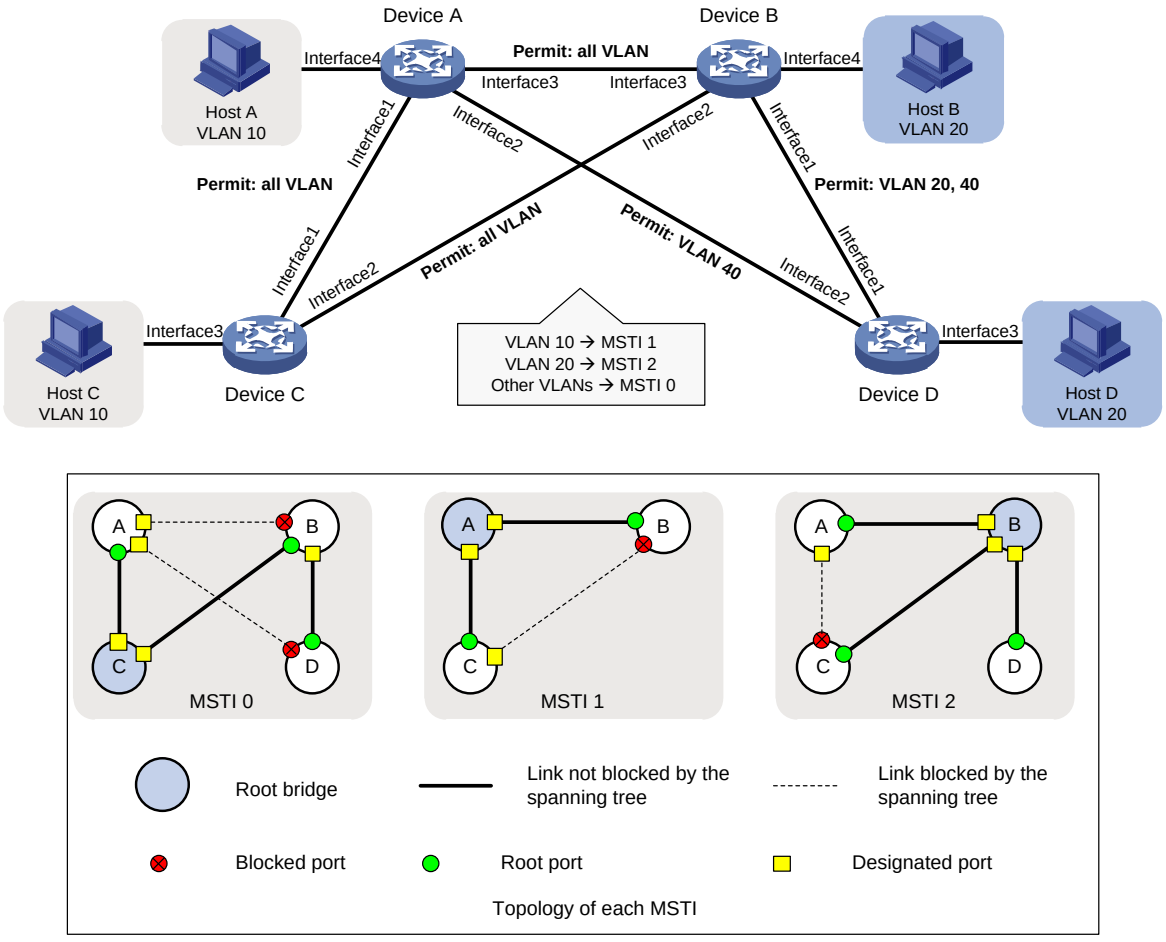


Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4

Procedure

1. Configure Device A:
   - Configure port-based VLAN assignment.

     # Configure GigabitEthernet1/0/1 as a trunk port, and configure it to permit all VLANs.

     ```
     <DeviceA> system-view
     [DeviceA] interface gigabitethernet 1/0/1
     [DeviceA-GigabitEthernet1/0/1] port link-type trunk
     [DeviceA-GigabitEthernet1/0/1] port trunk permit vlan all
     [DeviceA-GigabitEthernet1/0/1] quit
     ```

Configure GigabitEthernet 1/0/2 as a trunk port, and configure it to permit VLAN 40.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 40
[DeviceA-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 as a trunk port, and configure it to permit all VLANs.

```
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] port link-type trunk
[DeviceA-GigabitEthernet1/0/3] port trunk permit vlan all
[DeviceA-GigabitEthernet1/0/3] quit
```

Configure GigabitEthernet 1/0/4 as a trunk port, configure it to permit VLAN 10, and set the default port VLAN ID to 10.

```
[DeviceA] interface gigabitethernet 1/0/4
[DeviceA-GigabitEthernet1/0/4] port link-type trunk
[DeviceA-GigabitEthernet1/0/4] port trunk permit vlan 10
[DeviceA-GigabitEthernet1/0/4] port trunk pvid vlan 10
[DeviceA-GigabitEthernet1/0/4] quit
```

- Configure MSTP.

  # Enter MST region view.

  ```
  [DeviceA] stp region-configuration
  ```

  # Configure the MST region name, VLAN-to-instance mappings, and revision level.

  ```
  [DeviceA-mst-region] region-name example
  [DeviceA-mst-region] instance 1 vlan 10
  [DeviceA-mst-region] instance 2 vlan 20
  [DeviceA-mst-region] revision-level 0
  ```

  # Manually activate the MST region configuration.

  ```
  [DeviceA-mst-region] active region-configuration
  [DeviceA-mst-region] quit
  ```

  # Configure Device A as the primary root bridge of MSTI 1.

  ```
  [DeviceA] stp instance 1 root primary
  ```

  # Globally enable the spanning tree feature.

  ```
  [DeviceA] stp global enable
  ```

- Configure MVRP.

  # Globally enable MVRP.

  ```
  [DeviceA] mvrp global enable
  ```

  # Enable MVRP on ports GigabitEthernet1/0/1 through GigabitEthernet 1/0/4.

  ```
  [DeviceA] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/4
  [DeviceA-if-range] mvrp enable
  [DeviceA-if-range] quit
  ```

  # Create VLAN 10.

  ```
  [DeviceA] vlan 10
  [DeviceA-vlan10] quit
  ```

2. Configure Device B:

- Configure port-based VLAN assignment.

  # Configure GigabitEthernet1/0/1 as a trunk port, and configure it to permit VLAN 20 and VLAN 40.

  ```
  <DeviceB> system-view
  ```

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 20 40
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port, and configure it to permit all VLANs.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan all
[DeviceB-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 as a trunk port, and configure it to permit all VLANs.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan all
[DeviceB-GigabitEthernet1/0/3] quit
```

Configure GigabitEthernet 1/0/4 as a trunk port, configure it to permit VLAN 20, and set the default port VLAN ID to 20.

```
[DeviceB] interface gigabitethernet 1/0/4
[DeviceB-GigabitEthernet1/0/4] port link-type trunk
[DeviceB-GigabitEthernet1/0/4] port trunk permit vlan 20
[DeviceB-GigabitEthernet1/0/4] port trunk pvid vlan 20
[DeviceB-GigabitEthernet1/0/4] quit
```

- Configure MSTP.

  # Enter MST region view.

  ```
  [DeviceB] stp region-configuration
  ```

  # Configure the MST region name, VLAN-to-instance mappings, and revision level.

  ```
  [DeviceB-mst-region] region-name example
  [DeviceB-mst-region] instance 1 vlan 10
  [DeviceB-mst-region] instance 2 vlan 20
  [DeviceB-mst-region] revision-level 0
  ```

  # Manually activate the MST region configuration.

  ```
  [DeviceB-mst-region] active region-configuration
  [DeviceB-mst-region] quit
  ```

  # Configure Device B as the primary root bridge of MSTI 2.

  ```
  [DeviceB] stp instance 2 root primary
  ```

  # Globally enable the spanning tree feature.

  ```
  [DeviceB] stp global enable
  ```

- Configure MVRP.

  # Globally enable MVRP.

  ```
  [DeviceB] mvrp global enable
  ```

  # Enable MVRP on GigabitEthernet1/0/1 through GigabitEthernet 1/0/4.

  ```
  [DeviceB] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/4
  [DeviceB-if-range] mvrp enable
  [DeviceB-if-range] quit
  ```

  # Create VLAN 20.

  ```
  [DeviceB] vlan 20
  [DeviceB-vlan20] quit
  ```

3. Configure Device C:

- Configure port-based VLAN assginment.

  # Configure GigabitEthernet1/0/1 as a trunk port, and configure it to permit all VLANs.

  ```
  <DeviceC> system-view
  [DeviceC] interface gigabitethernet 1/0/1
  [DeviceC-GigabitEthernet1/0/1] port link-type trunk
  [DeviceC-GigabitEthernet1/0/1] port trunk permit vlan all
  [DeviceC-GigabitEthernet1/0/1] quit
  ```

  # Configure GigabitEthernet 1/0/2 as a trunk port, and configure it to permit all VLANs.

  ```
  [DeviceC] interface gigabitethernet 1/0/2
  [DeviceC-GigabitEthernet1/0/2] port link-type trunk
  [DeviceC-GigabitEthernet1/0/2] port trunk permit vlan all
  [DeviceC-GigabitEthernet1/0/2] quit
  ```

  # Configure GigabitEthernet 1/0/3 as a trunk port, configure it to permit VLAN 10, and set the default port VLAN ID to 10.

  ```
  [DeviceC] interface gigabitethernet 1/0/3
  [DeviceC-GigabitEthernet1/0/3] port link-type trunk
  [DeviceC-GigabitEthernet1/0/3] port trunk permit vlan 10
  [DeviceC-GigabitEthernet1/0/3] port trunk pvid vlan 10
  [DeviceC-GigabitEthernet1/0/3] quit
  ```

- Configure MSTP.

  # Enter MST region view.

  ```
  [DeviceC] stp region-configuration
  ```

  # Configure the MST region name, VLAN-to-instance mappings, and revision level.

  ```
  [DeviceC-mst-region] region-name example
  [DeviceC-mst-region] instance 1 vlan 10
  [DeviceC-mst-region] instance 2 vlan 20
  [DeviceC-mst-region] revision-level 0
  ```

  # Manually activate the MST region configuration.

  ```
  [DeviceC-mst-region] active region-configuration
  [DeviceC-mst-region] quit
  ```

  # Configure Device C as the root bridge of MSTI 0.

  ```
  [DeviceC] stp instance 0 root primary
  ```

  # Globally enable the spanning tree feature.

  ```
  [DeviceC] stp global enable
  ```

- Configure MVRP.

  # Globally enable MVRP.

  ```
  [DeviceC] mvrp global enable
  ```

  # Enable MVRP on GigabitEthernet1/0/1 through GigabitEthernet 1/0/3.

  ```
  [DeviceC] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/3
  [DeviceC-if-range] mvrp enable
  [DeviceC-if-range] quit
  ```

  # Create VLAN 40.

  ```
  [DeviceC] vlan 40
  [DeviceC-vlan40] quit
  ```

4. Configure Device D:

- Configure port-based VLAN assignment.

Configure GigabitEthernet1/0/1 as a trunk port, and configure it to permit VLAN 20 and VLAN 40.

```
<DeviceD> system-view
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 20 40
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port, and configure it to permit VLAN 40.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 40
[DeviceD-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 as a trunk port, configure it to permit VLAN 20, and set the default port VLAN ID to 20.

```
[DeviceD] interface gigabitethernet 1/0/3
[DeviceD-GigabitEthernet1/0/3] port link-type trunk
[DeviceD-GigabitEthernet1/0/3] port trunk permit vlan 20
[DeviceD-GigabitEthernet1/0/3] port trunk pvid vlan 20
[DeviceD-GigabitEthernet1/0/3] quit
```

- Configure MSTP.

  # Enter MST region view.

  ```
  [DeviceD] stp region-configuration
  ```

  # Configure the MST region name, VLAN-to-instance mappings, and revision level.

  ```
  [DeviceD-mst-region] region-name example
  [DeviceD-mst-region] instance 1 vlan 10
  [DeviceD-mst-region] instance 2 vlan 20
  [DeviceD-mst-region] revision-level 0
  ```

  # Manually activate the MST region configuration.

  ```
  [DeviceD-mst-region] active region-configuration
  [DeviceD-mst-region] quit
  ```

  # Globally enable the spanning tree feature.

  ```
  [DeviceD] stp global enable
  ```

- Configure MVRP.

  # Globally enable MVRP.

  ```
  [DeviceD] mvrp global enable
  ```

  # Enable MVRP on GigabitEthernet1/0/1 through GigabitEthernet 1/0/3.

  ```
  [DeviceD] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/3
  [DeviceD-if-range] mvrp enable
  [DeviceD-if-range] quit
  ```

5. Configure Host A, Host B, Host C, and Host D.

   Make sure the IP addresses of Host A and Host C are on 192.168.10.0/24, while the IP addresses of Host B and Host D are on 192.168.20.0/24.

Verifying the configuration

1. Use the **ping** command to verify the configuration.

   Verify that Host A and Host C can ping each other, and Host B and Host D can ping each other.

2. Verify the normal registration mode configuration.

   # Display local VLAN information on Device A.

```
[DeviceA] display mvrp running-status
 -------[MVRP Global Info]-------

 Registration Type              : Normal
 Registered VLANs :
  None
 Declared VLANs :
  1(default), 20
 Propagated VLANs :
  None
```

The output shows that the following events have occurred:

- GigabitEthernet 1/0/1 has registered and propagated VLAN 10, VLAN 20, and VLAN 40, and has not declared any VLANs.
- GigabitEthernet 1/0/2 has registered and propagated VLAN 1 and VLAN 40, and declared VLAN 1.
- GigabitEthernet 1/0/3 has not registered or propagated VLANs, and has declared VLAN 1 and VLAN 20.

3. Verify the configuration after changing the registration mode.

When the network is stable, set the MVRP registration mode to **fixed** on the port of Device B connected to Device A. Then, verify that dynamic VLANs on the port will not be deregistered.

Set the MVRP registration mode to **fixed** on GigabitEthernet 1/0/3 of Device B.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] mvrp registration fixed
[DeviceB-GigabitEthernet1/0/3] quit
[DeviceB] commit
```

Display local MVRP VLAN information on GigabitEthernet 1/0/3.

```
[DeviceB] display mvrp running-status interface gigabitethernet 1/0/3
 -------[MVRP Global Info]-------
 Global Status     : Enabled
 Compliance-GVRP   : False

 ----[GigabitEthernet1/0/3]----
 Config  Status                 : Enabled
 Running Status                 : Enabled
 Join Timer                     : 20 (centiseconds)
 Leave Timer                    : 60 (centiseconds)
 Periodic Timer                 : 100 (centiseconds)
 LeaveAll Timer                 : 1000 (centiseconds)
 Registration Type              : Fixed
 Registered VLANs :
  1(default), 10, 40
 Declared VLANs :
  20
 Propagated VLANs :
  10
```

The output shows that VLAN information on GigabitEthernet 1/0/3 is not changed after you set its MVRP registration mode to **fixed**.

Delete VLAN 10 on Device A.

```
[DeviceA] undo vlan 10
[DeviceA] commit
```

Display local MVRP VLAN information on GigabitEthernet 1/0/3 of Device B.

```
[DeviceB] display mvrp running-status interface gigabitethernet 1/0/3
 -------[MVRP Global Info]-------
 Global Status     : Enabled
 Compliance-GVRP   : False

 ----[GigabitEthernet1/0/3]----
 Config  Status                 : Enabled
 Running Status                 : Enabled
 Join Timer                     : 20 (centiseconds)
 Leave Timer                    : 60 (centiseconds)
 Periodic Timer                 : 100 (centiseconds)
 LeaveAll Timer                 : 1000 (centiseconds)
 Registration Type              : Fixed
 Registered VLANs :
  1(default), 10, 40
 Declared VLANs :
  20
 Propagated VLANs :
  10
```

The output shows that dynamic VLAN information on GigabitEthernet 1/0/3 is not changed after you set its MVRP registration mode to **fixed**.

Configuring loopback, null, and inloopback interfaces

This chapter describes how to configure a loopback interface, a null interface, and an inloopback interface.

About loopback, null, and inloopback interfaces

About loopback interfaces

A loopback interface is a virtual interface. The physical layer state of a loopback interface is always up unless the loopback interface is manually shut down. Because of this benefit, loopback interfaces are widely used in the following scenarios:

- **Configuring a loopback interface address as the source address of the IP packets that the device generates**—Because loopback interface addresses are stable unicast addresses, they are usually used as device identifications.

  When you configure a rule on an authentication or security server, you can configure it to permit or deny packets carrying the loopback interface address of a device. This simplifies your configuration and achieves the effect of permitting or denying packets that the device generates. To use a loopback interface address as the source address of IP packets, make sure the loopback interface is reachable from the peer by performing routing configuration. All data packets sent to the loopback interface are considered packets sent to the device itself, so the device does not forward these packets.
- **Using a loopback interface in dynamic routing protocols**—With no router ID configured for a dynamic routing protocol, the system selects the highest loopback interface IP address as the router ID. In BGP, to avoid interruption of BGP sessions due to physical port failure, you can use a loopback interface as the source interface of BGP packets.

About null interfaces

A null interface is a virtual interface and is always up, but you cannot use it to forward data packets or configure it with an IP address or link layer protocol. The null interface provides a simpler way to filter packets than ACL. You can filter undesired traffic by transmitting it to a null interface instead of applying an ACL. For example, if you specify a null interface as the next hop of a static route to a network segment, any packets routed to the network segment are dropped.

About inloopback interfaces

An inloopback interface is a virtual interface created by the system, which cannot be configured or deleted. The physical layer and link layer protocol states of an inloopback interface are always up. All IP packets sent to an inloopback interface are considered packets sent to the device itself and are not forwarded.

Configuring a loopback interface

1. Enter system view.

   ```
   system-view
   ```
2. Create a loopback interface and enter loopback interface view.

interface loopback *interface-number*

3. Configure the interface description.

   description *text*

   The default setting is *interface name* **Interface** (for example, **LoopBack1 Interface**).

4. Configure the expected bandwidth of the loopback interface.

   bandwidth *bandwidth-value*

   By default, the expected bandwidth of a loopback interface is 0 kbps.

5. Bring up the loopback interface.

   undo shutdown

   By default, a loopback interface is up.

Configuring a null interface

1. Enter system view.

   system-view

2. Enter null interface view.

   interface null 0

   Interface Null 0 is the default null interface on the device and cannot be manually created or removed.

   Only one null interface, Null 0, is supported on the device. The null interface number is always 0.

3. Configure the interface description.

   description *text*

   The default setting is NULL0 Interface.

Restoring the default settings for an interface

Restrictions and guidelines

CAUTION:

This feature might interrupt ongoing network services. Make sure you are fully aware of the impact of this feature when you use it on a live network.

This feature might fail to restore the default settings for some commands because of command dependencies or system restrictions. You can use the **display this** command in interface view to check for these commands and perform their **undo** forms or follow the command reference to restore their default settings. If your restoration attempt still fails, follow the error message to resolve the problem.

Procedure

1. Enter system view.

   system-view

2. Enter loopback interface view or null interface view.
   - **interface loopback** *interface-number*
   - **interface null 0**

3. Restore the default settings for the interface.

   default

Display and maintenance commands for loopback, null, and inloopback interfaces

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display information about the inloopback interface.	**display interface** [**inloopback** [**0**]] [**brief** [**description** | **down**]]
Display information about the specified or all loopback interfaces.	**display interface** [**loopback** [*interface-number*]] [**brief** [**description** | **down**]]
Display information about the null interface.	**display interface** [**null** [**0**]] [**brief** [**description** | **down**]]
Clear the statistics on the specified or all loopback interfaces.	**reset counters interface** [**loopback** [*interface-number*]]
Clear the statistics on the null interface.	**reset counters interface** [**null** [**0**]]

Configuring QinQ

This document uses the following terms:

- **CVLAN**—Customer network VLANs, also called inner VLANs, refer to VLANs that a customer uses on the private network.
- **SVLAN**—Service provider network VLANs, also called outer VLANs, refer to VLANs that a service provider uses to transmit VLAN tagged traffic for customers.

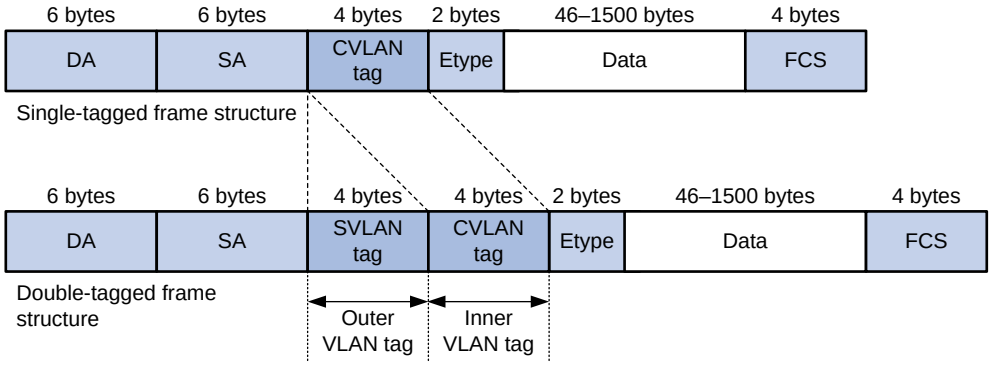
About QinQ

802.1Q-in-802.1Q (QinQ) adds an 802.1Q tag to 802.1Q tagged customer traffic. It enables a service provider to extend Layer 2 connections across an Ethernet network between customer sites.

QinQ benefits

QinQ provides the following benefits:

- Enables a service provider to use a single SVLAN to convey multiple CVLANs for a customer.
- Enables customers to plan CVLANs without conflicting with SVLANs.
- Enables customers to keep their VLAN assignment schemes unchanged when the service provider changes its VLAN assignment scheme.
- Allows different customers to use overlapping CVLAN IDs. Devices in the service provider network make forwarding decisions based on SVLAN IDs instead of CVLAN IDs.



How QinQ works

As shown in Figure 1, a QinQ frame transmitted over the service provider network carries the following tags:

- **CVLAN tag**—Identifies the VLAN to which the frame belongs when it is transmitted in the customer network.
- **SVLAN tag**—Identifies the VLAN to which the QinQ frame belongs when it is transmitted in the service provider network. The service provider allocates the SVLAN tag to the customer.

The devices in the service provider network forward a tagged frame according to its SVLAN tag only. The CVLAN tag is transmitted as part of the frame's payload.

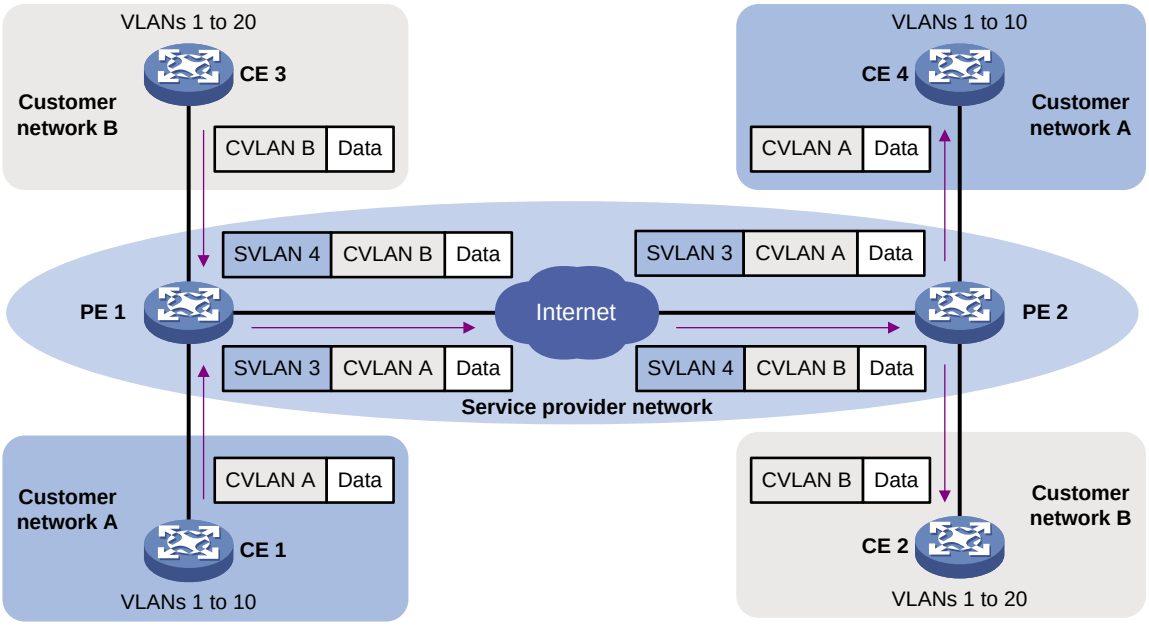


Figure 1 Single-tagged Ethernet frame header and double-tagged Ethernet frame header

As shown in Figure 2, customer A has remote sites CE 1 and CE 4. Customer B has remote sites CE 2 and CE 3. The CVLANs of the two customers overlap. The service provider assigns SVLANs 3 and 4 to customers A and B, respectively.

When a tagged Ethernet frame from CE 1 arrives at PE 1, the PE tags the frame with SVLAN 3. The double-tagged Ethernet frame travels over the service provider network until it arrives at PE 2. PE 2 removes the SVLAN tag of the frame, and then sends the frame to CE 4.

Figure 2 Typical QinQ application scenario

QinQ implementations

QinQ is enabled on a per-port basis. The link type of a QinQ-enabled port can be access, hybrid, or trunk. The QinQ tagging behaviors are the same across these types of ports.

A QinQ-enabled port tags all incoming frames (tagged or untagged) with the PVID tag.

- If an incoming frame already has one tag, it becomes a double-tagged frame.
- If the frame does not have any 802.1Q tags, it becomes a frame tagged with the PVID.

QinQ provides the most basic VLAN manipulation method to tag all incoming frames (tagged or untagged) with the PVID tag. To perform advanced VLAN manipulations, use VLAN mappings or QoS policies as follows:

- To add different SVLANs for different CVLAN tags, use one-to-two VLAN mappings.
- To replace the SVLAN ID, CVLAN ID, or both IDs for an incoming double-tagged frame, use two-to-two VLAN mappings.
- To use criteria other than the CVLAN ID to match packets for SVLAN tagging, use the QoS nest action. The QoS nest action can also be used with other actions in the same traffic behavior.
- To set the 802.1p priority in SVLAN tags, use the priority marking action as described in "Setting the 802.1p priority in SVLAN tags."

For more information about VLAN mappings, see "Configuring VLAN mapping." For more information about QoS, see *ACL and QoS Configuration Guide*.

Protocols and standards

- IEEE 802.1Q, *IEEE Standard for Local and Metropolitan Area Networks-Virtual Bridged Local Area Networks*
- IEEE 802.1ad, *IEEE Standard for Local and Metropolitan Area Networks-Virtual Bridged Local Area Networks-Amendment 4: Provider Bridges*

Restrictions and guidelines: QinQ configuration

When you configure QinQ, follow these restrictions and guidelines:

- The inner 802.1Q tag of QinQ frames is treated as part of the payload. As a best practice to ensure correct transmission of QinQ frames, set the MTU to a minimum of 1504 bytes for each port on their forwarding path. This value is the sum of the default Ethernet interface MTU (1500 bytes) and the length (4 bytes) of a VLAN tag.
- You can use a VLAN mapping and QinQ on a port for VLAN tag manipulation. If their settings conflict, the VLAN mapping takes precedence over QinQ.
- QinQ and two-to-two mappings are mutually exclusive. The device does not support adding an SVLAN tag on a QinQ-enabled port and then modifying the CVLAN and SVLAN IDs.
- For QinQ and QoS nest action to take effect, do not configure both features on the same port.

Enabling QinQ

About this task

Enable QinQ on customer-side ports of PEs. A QinQ-enabled port tags an incoming frame with its PVID.

Restrictions and guidelines

Before you enable or disable QinQ on a port, you must remove any VLAN mappings on the port. For more information about VLAN mapping, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.

   interface *interface-type interface-number*
3. Set the port link type.

   port link-type { **access** | **hybrid** | **trunk** }

   By default, the link type of a port is **access**.
4. Configure the port to allow packets from its PVID to pass through.
   - Assign the access port to the specified VLAN.

     port access vlan *vlan-id*

     By default, all access ports belong to VLAN 1.

     The PVID of an access port is the VLAN to which the port belongs. The port sends packets from the VLAN untagged.
   - Configure the hybrid port to send packets from its PVID untagged.

     port hybrid vlan *vlan-id-list* **untagged**

By default, the hybrid port is an untagged member of the VLAN to which the port belongs when its link type is access.

- Configure trunk port to allow packets from its PVID to pass through.

  port trunk permit vlan { *vlan-id-list* | **all** }

  By default, a trunk port allows packets only from VLAN 1 to pass through.

5. Enable QinQ on the port.

   qinq enable

   By default, QinQ is disabled on the port.

Configuring transmission for transparent VLANs

About this task

You can exclude a VLAN (for example, the management VLAN) from the QinQ tagging action on a customer-side port. This VLAN is called a transparent VLAN.

Restrictions and guidelines

- Make sure all ports on the traffic path permit the transparent VLAN to pass through.
- Do not configure any other VLAN manipulation actions for the transparent VLAN on the port.
- If you use both transparent VLANs and VLAN mappings on an interface, the transparent VLANs cannot be the following VLANs:
  - Original or translated VLANs of one-to-one, one-to-two, and many-to-one VLAN mappings.
  - Original or translated VLANs in two-to-one VLAN mappings.
  - Original or translated outer VLANs of two-to-two VLAN mappings.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.

   interface *interface-type interface-number*

3. Set the port link type.

   port link-type { **hybrid** | **trunk** }

   By default, the link type of a port is **access**.

4. Configure the port to allow packets from the transparent VLANs to pass through.
   - Configure the hybrid port to allow packets from the transparent VLANs to pass through.

     port hybrid vlan *vlan-id-list* { **tagged** | **untagged** }

     By default, a hybrid port is an untagged member of the VLAN to which the port belongs when its link type is **access**.
   - Configure the trunk port to allow packets from the transparent VLANs to pass through.

     port trunk permit vlan { *vlan-id-list* | **all** }

     By default, a trunk port allows packets only from VLAN 1 to pass through.

5. Specify transparent VLANs for the port.

   qinq transparent-vlan *vlan-id-list*

   By default, transparent transmission is not configured for any VLANs.

Configuring the TPID for VLAN tags

About TPID

TPID identifies a frame as an 802.1Q tagged frame. The TPID value varies by vendor. On an H3C device, the TPID in the 802.1Q tag added on a QinQ-enabled port is 0x8100 by default, in compliance with IEEE 802.1Q. In a multi-vendor network, make sure the TPID setting is the same between directly connected devices so 802.1Q tagged frames can be identified correctly.

TPID settings include CVLAN TPID and SVLAN TPID.

The TPID field is at the same position as the EtherType field in an untagged Ethernet frame. To ensure correct packet type identification, do not set the TPID value to any of the values listed in Table 1.

Table 1 Reserved EtherType values

Protocol type	Value
ARP	0x0806
PUP	0x0200
RARP	0x8035
IP	0x0800
IPv6	0x86dd
PPPoE	0x8863/0x8864
MPLS	0x8847/0x8848
IPX/SPX	0x8137
IS-IS	0x8000
LACP	0x8809
LLDP	0x88cc
802.1X	0x888e
802.1ag	0x8902
Cluster	0x88a7
Reserved	0xfffd/0xfffe/0xffff

Restrictions and guidelines

When a QinQ-enabled port adds VLAN tags to frames, the VLAN tags contain the TPID value specified in the **qinq ethernet-type service-tag** command.

Configuring the TPID for CVLAN tags

1. Enter system view.
   system-view
2. Set the TPID for CVLAN tags.
   qinq ethernet-type customer-tag *hex-value*
   By default, the TPID is 0x8100 for CVLAN tags.

Configuring the TPID for SVLAN tags

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. Set the TPID for SVLAN tags.
   qinq ethernet-type service-tag *hex-value*
   By default, the TPID is 0x8100 for SVLAN tags.

Setting the 802.1p priority in SVLAN tags

About the 802.1p priority in SVLAN tags

By default, the 802.1p priority in the SVLAN tag added by a QinQ-enabled port depends on the priority trust mode on the port.

- If the 802.1p priority in frames is trusted, the device copies the 802.1p priority in the CVLAN tag to the SVLAN tag.
- If port priority is trusted, the port priority (0 by default) is used as the 802.1p priority in the SVLAN tag.

You can configure a QoS policy to modify the 802.1p priority in the SVLAN tag based on the 802.1p priority in the CVLAN tag or the CVLAN ID.

For more information about QoS policies and priority trust mode, see *ACL and QoS Configuration Guide*.

Prerequisites for setting the 802.1p priority in SVLAN tags

1. Enable QinQ. For more information, see "Enabling QinQ."
   To use the CVLAN ID or 802.1p priority of the CVLAN tag to set the 802.1p priority of the SVLAN tag, you must first enable QinQ on the port.
2. Use the **qos trust dot1p** command to configure the port to trust the 802.1p priority in incoming frames. For more information, see *ACL and QoS Configuration Guide*.
   This setting is required if the **remark dot1p** command is configured.

Tasks at a glance

To use QoS policies to set the 802.1p priority in SVLAN tags, perform the following tasks:

1. Creating a traffic class and configuring CVLAN match criteria
2. Creating a traffic behavior and configuring a priority marking action for SVLAN tags
3. Creating a QoS policy
4. Applying the QoS policy

Creating a traffic class and configuring CVLAN match criteria

1. Enter system view.
   system-view

2. Create a traffic class and enter its view.
   traffic classifier *classifier-name* [**operator** { **and** | **or** }]
3. Configure CVLAN match criteria.
   Choose one option as needed:
   - Match CVLAN IDs.
     if-match customer-vlan-id *vlan-id-list*
   - Match 802.1p priority.
     if-match customer-dot1p *dot1p-value*&<1-8>

Creating a traffic behavior and configuring a priority marking action for SVLAN tags

1. Enter system view.
   system-view
2. Create a traffic behavior and enter its view.
   traffic behavior *behavior-name*
3. Configure a priority marking action for SVLAN tags.
   remark dot1p *dot1p-value*

Creating a QoS policy

1. Enter system view.
   system-view
2. Create a QoS policy and enter its view.
   qos policy *policy-name*
3. Specify the traffic behavior for the traffic class in the QoS policy.
   classifier *classifier-name* **behavior** *behavior-name*

Applying the QoS policy

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view.
   interface *interface-type interface-number*
3. Apply the QoS policy to the inbound direction of the port.
   qos apply policy *policy-name* **inbound**

Display and maintenance commands for QinQ

Execute **display** commands in any view.

Task	Command
Display QinQ-enabled ports.	**display qinq** [**interface** *interface-type interface-number*]

QinQ configuration examples

Example: Configuring VLAN transparent transmission

Network configuration

As shown in Figure 3:

- The service provider assigns VLAN 100 to a company's VLANs 10 through 50.
- VLAN 3000 is the dedicated VLAN of the company on the service provider network.

Configure QinQ on PE 1 and PE 2 to provide Layer 2 connectivity for CVLANs 10 through 50 over the service provider network.

Configure VLAN transparent transmission for VLAN 3000 on PE 1 and PE 2 to enable the hosts in VLAN 3000 to communicate without using an SVLAN.

Figure 3 Network diagram

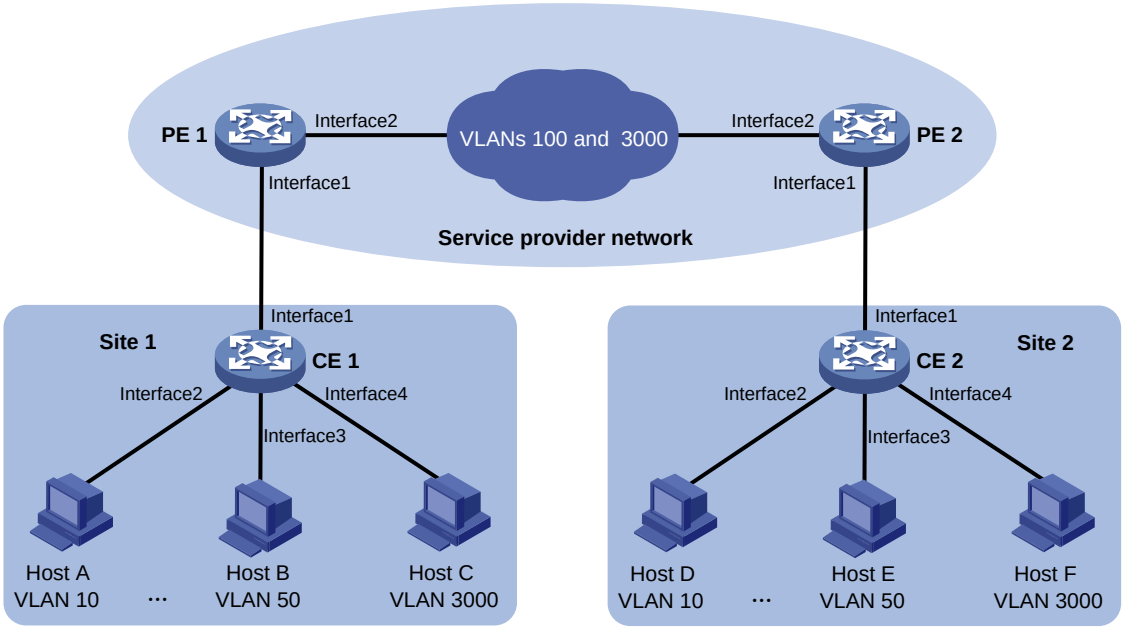

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4

Procedure

1. Configure PE 1:

   # Create VLANs 10 through 50, VLAN 100, and VLAN 3000.

   ```
   <PE1> system-view
   [PE1] vlan 10 to 50
   [PE1] vlan 100
   ```

```
[PE1-vlan100] quit
[PE1] vlan 3000
[PE1-vlan3000] quit
```

Configure GigabitEthernet1/0/1 as a trunk port, and assign it to VLAN 100, VLAN 3000, and VLANs 10 through 50.

```
[PE1] interface gigabitethernet 1/0/1
[PE1-GigabitEthernet1/0/1] port link-type trunk
[PE1-GigabitEthernet1/0/1] port trunk permit vlan 100 3000 10 to 50
```

Set the PVID of GigabitEthernet1/0/1 to VLAN 100.

```
[PE1-GigabitEthernet1/0/1] port trunk pvid vlan 100
```

Enable QinQ on GigabitEthernet1/0/1.

```
[PE1-GigabitEthernet1/0/1] qinq enable
```

Enable transparent transmission for VLAN 3000 on GigabitEthernet1/0/1.

```
[PE1-GigabitEthernet1/0/1] qinq transparent-vlan 3000
[PE1-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet1/0/2 as a trunk port, and assign it to VLANs 100 and 3000.

```
[PE1] interface gigabitethernet 1/0/2
[PE1-GigabitEthernet1/0/2] port link-type trunk
[PE1-GigabitEthernet1/0/2] port trunk permit vlan 100 3000
[PE1-GigabitEthernet1/0/2] quit
```

2. Configure PE 2:

Create VLANs 10 through 50, VLAN 100, and VLAN 3000.

```
<PE2> system-view
[PE2] vlan 10 to 50
[PE2] vlan 100
[PE2-vlan100] quit
[PE2] vlan 3000
[PE2-vlan3000] quit
```

Configure GigabitEthernet1/0/1 as a trunk port, and assign it to VLAN 100, VLANs 10 through 50, and VLAN 3000.

```
[PE2] interface gigabitethernet 1/0/1
[PE2-GigabitEthernet1/0/1] port link-type trunk
[PE2-GigabitEthernet1/0/1] port trunk permit vlan 100 3000 10 to 50
```

Set the PVID of GigabitEthernet1/0/1 to VLAN 100.

```
[PE2-GigabitEthernet1/0/1] port trunk pvid vlan 100
```

Enable QinQ on GigabitEthernet1/0/1.

```
[PE2-GigabitEthernet1/0/1] qinq enable
```

Enable transparent transmission for VLAN 3000 on GigabitEthernet1/0/1.

```
[PE2-GigabitEthernet1/0/1] qinq transparent-vlan 3000
[PE2-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet1/0/2 as a trunk port, and assign it to VLANs 100 and 3000.

```
[PE2] interface gigabitethernet 1/0/2
[PE2-GigabitEthernet1/0/2] port link-type trunk
[PE2-GigabitEthernet1/0/2] port trunk permit vlan 100 3000
[PE2-GigabitEthernet1/0/2] quit
```

3. Configure CE 1:

Create VLANs 10 through 50.

```
<CE1> system-view
[CE1] vlan 10 to 50
```

Configure GigabitEthernet1/0/2 as an access port, and assign it to VLAN 10.

```
[CE1] interface gigabitethernet 1/0/2
[CE1-GigabitEthernet1/0/2] port link-type access
[CE1-GigabitEthernet1/0/2] port access vlan 10
[CE1-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet1/0/3 as an access port, and assign it to VLAN 50.

```
[CE1] interface gigabitethernet 1/0/3
[CE1-GigabitEthernet1/0/3] port link-type access
[CE1-GigabitEthernet1/0/3] port access vlan 50
[CE1-GigabitEthernet1/0/3] quit
```

Configure GigabitEthernet1/0/4 as an access port, and assign it to VLAN 3000.

```
[CE1] interface gigabitethernet 1/0/4
[CE1-GigabitEthernet1/0/4] port link-type access
[CE1-GigabitEthernet1/0/4] port access vlan 3000
[CE1-GigabitEthernet1/0/4] quit
```

Configure GigabitEthernet1/0/1 as a trunk port, and assign it to VLANs 10 through 50 and VLAN 3000.

```
[CE1] interface gigabitethernet 1/0/1
[CE1-GigabitEthernet1/0/1] port link-type trunk
[CE1-GigabitEthernet1/0/1] port trunk permit vlan 3000 10 to 50
[CE1-GigabitEthernet1/0/1] quit
```

4. Configure CE 2:

Create VLANs 10 through 50.

```
<CE2> system-view
[CE2] vlan 10 to 50
```

Configure GigabitEthernet1/0/2 as an access port, and assign it to VLAN 10.

```
[CE2] interface gigabitethernet 1/0/2
[CE2-GigabitEthernet1/0/2] port link-type access
[CE2-GigabitEthernet1/0/2] port access vlan 10
[CE2-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet1/0/3 as an access port, and assign it to VLAN 50.

```
[CE2] interface gigabitethernet 1/0/3
[CE2-GigabitEthernet1/0/3] port link-type access
[CE2-GigabitEthernet1/0/3] port access vlan 50
[CE2-GigabitEthernet1/0/3] quit
```

Configure GigabitEthernet1/0/4 as an access port, and assign it to VLAN 3000.

```
[CE2] interface gigabitethernet 1/0/4
[CE2-GigabitEthernet1/0/4] port link-type access
[CE2-GigabitEthernet1/0/4] port access vlan 3000
[CE2-GigabitEthernet1/0/4] quit
```

Configure GigabitEthernet1/0/1 as a trunk port, and assign it to VLANs 10 through 50 and VLAN 3000.

```
[CE2] interface gigabitethernet 1/0/1
[CE2-GigabitEthernet1/0/1] port link-type trunk
[CE2-GigabitEthernet1/0/1] port trunk permit vlan 3000 10 to 50
[CE2-GigabitEthernet1/0/1] quit
```

5. Configure the devices between PE 1 and PE 2:

   # Set the MTU to a minimum of 1504 bytes for each port on the path of QinQ frames. (Details not shown.)

   # Configure all ports on the forwarding path to allow frames from VLANs 100 and 3000 to pass through without removing the VLAN tag. (Details not shown.)

6. Configure Host A through Host F:

   # Configure the IP addresses of the hosts in the same VLAN to be on the same subnet, for example, configure the IP addresses of Host A and Host D to be on subnet 192.168.1.0/24.

Verifying the configuration

- Execute the **ping** command to verify the following information:

  At Site 1 and Site 2, hosts that belong to the same VLAN can ping each other successfully and learn the MAC address of each other. For example, Host A and Host D can communicate with each other.

- Execute the **display mac-address** command (Host A and Host D, and Host C and Host F ping each other).

  # Display MAC address entries on PE 1.

```
<PE1> display mac-address
MAC Address      VLAN ID    State           Port/Nickname           Aging
7e43-5b0a-0502   100        Learned         GE1/0/1                 Y
7e42-da03-0200   3000       Learned         GE1/0/1                 Y
7e43-5d90-0602   100        Learned         GE1/0/2                 Y
7e42-df16-0400   3000       Learned         GE1/0/2                 Y
```

  The output shows that PE 1 has learned the MAC addresses of Host A and Host C through GigabitEthernet1/0/1 and those of Host D and Host F through GigabitEthernet1/0/2, respectively. The MAC addresses of Host A and Host D belong to VLAN 100 and those of Host C and Host F belong to VLAN 3000.

  # Display MAC address entries on CE 1.

```
<CE1>display mac-address
MAC Address      VLAN ID    State           Port/Nickname           Aging
7e43-5d90-0602   10         Learned         GE1/0/1                 Y
7e42-df16-0400   3000       Learned         GE1/0/1                 Y
7e43-5b0a-0502   10         Learned         GE1/0/2                 Y
7e42-da03-0200   3000       Learned         GE1/0/4                 Y
```

  The output shows that CE 1 has learned the MAC addresses of Host D and Host F through GigabitEthernet1/0/1, the MAC address of Host A through GigabitEthernet1/0/2, and the MAC address of Host C through GigabitEthernet1/0/4. The MAC addresses of Host A and Host D belong to VLAN 10 and those of Host C and Host F belong to VLAN 3000.

Example: Configuring basic QinQ

Network configuration

As shown in Figure 4:

- The service provider assigns VLAN 100 to Company A's VLANs 10 through 70.
- The service provider assigns VLAN 200 to Company B's VLANs 30 through 90.
- The devices between PE 1 and PE 2 in the service provider network use a TPID value of 0x8200.

Configure QinQ on PE 1 and PE 2 to transmit traffic in VLANs 100 and 200 for Company A and Company B, respectively.

For the QinQ frames to be identified correctly, set the SVLAN TPID to 0x8200 on the service provider-side ports of PE 1 and PE 2.

Figure 4 Network diagram

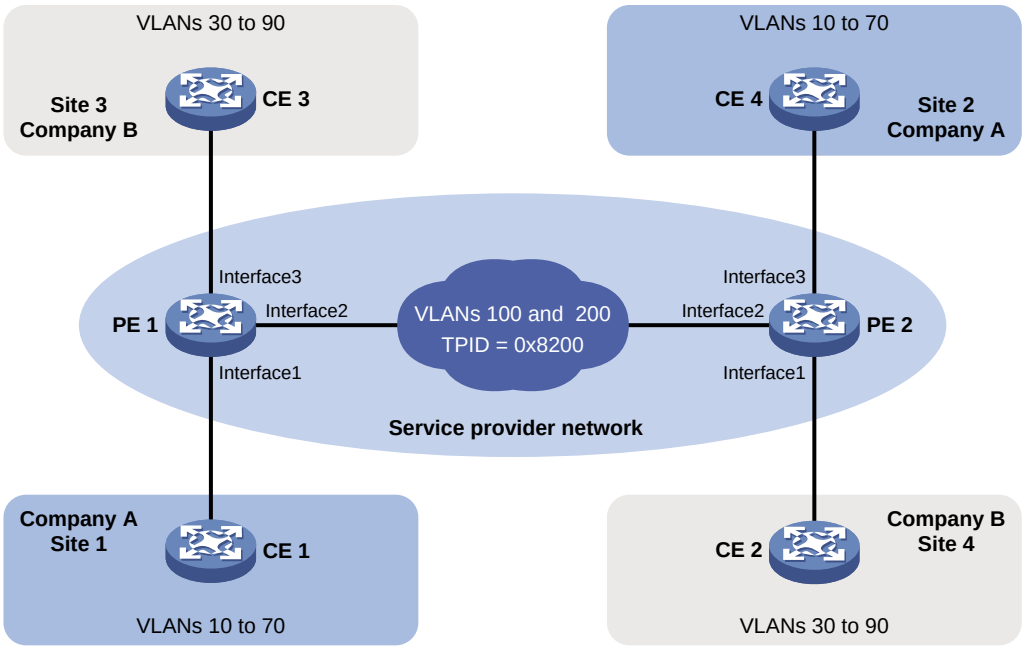

Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure PE 1:

Configure GigabitEthernet 1/0/1 as a trunk port, and assign it to VLAN 100.

```
<PE1> system-view
[PE1] interface gigabitethernet 1/0/1
[PE1-GigabitEthernet1/0/1] port link-type trunk
[PE1-GigabitEthernet1/0/1] port trunk permit vlan 100
```

Set the PVID of GigabitEthernet 1/0/1 to VLAN 100.

```
[PE1-GigabitEthernet1/0/1] port trunk pvid vlan 100
```

Enable QinQ on GigabitEthernet 1/0/1.

```
[PE1-GigabitEthernet1/0/1] qinq enable
[PE1-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port, and assign it to VLANs 100 and 200.

```
[PE1] interface gigabitethernet 1/0/2
[PE1-GigabitEthernet1/0/2] port link-type trunk
[PE1-GigabitEthernet1/0/2] port trunk permit vlan 100 200
```

Set the TPID value in the SVLAN tags to 0x8200 on GigabitEthernet 1/0/2.

```
[PE1-GigabitEthernet1/0/2] qinq ethernet-type service-tag 8200
[PE1-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 as a trunk port, and assign it to VLAN 200.

```
[PE1] interface gigabitethernet 1/0/3
[PE1-GigabitEthernet1/0/3] port link-type trunk
[PE1-GigabitEthernet1/0/3] port trunk permit vlan 200
```

Set the PVID of GigabitEthernet 1/0/3 to VLAN 200.

```
[PE1-GigabitEthernet1/0/3] port trunk pvid vlan 200
```

Enable QinQ on GigabitEthernet 1/0/3.

```
[PE1-GigabitEthernet1/0/3] qinq enable
[PE1-GigabitEthernet1/0/3] quit
```

2. Configure PE 2:

Configure GigabitEthernet 1/0/1 as a trunk port, and assign it to VLAN 200.

```
<PE2> system-view
[PE2] interface gigabitethernet 1/0/1
[PE2-GigabitEthernet1/0/1] port link-type trunk
[PE2-GigabitEthernet1/0/1] port trunk permit vlan 200
```

Set the PVID of GigabitEthernet 1/0/1 to VLAN 200.

```
[PE2-GigabitEthernet1/0/1] port trunk pvid vlan 200
```

Enable QinQ on GigabitEthernet 1/0/1.

```
[PE2-GigabitEthernet1/0/1] qinq enable
[PE2-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port, and assign it to VLANs 100 and 200.

```
[PE2] interface gigabitethernet 1/0/2
[PE2-GigabitEthernet1/0/2] port link-type trunk
[PE2-GigabitEthernet1/0/2] port trunk permit vlan 100 200
```

Set the TPID value in the SVLAN tags to 0x8200 on GigabitEthernet 1/0/2.

```
[PE2-GigabitEthernet1/0/2] qinq ethernet-type service-tag 8200
[PE2-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 as a trunk port, and assign it to VLAN 100.

```
[PE2] interface gigabitethernet 1/0/3
[PE2-GigabitEthernet1/0/3] port link-type trunk
[PE2-GigabitEthernet1/0/3] port trunk permit vlan 100
```

Set the PVID of GigabitEthernet 1/0/3 to VLAN 100.

```
[PE2-GigabitEthernet1/0/3] port trunk pvid vlan 100
```

Enable QinQ on GigabitEthernet 1/0/3.

```
[PE2-GigabitEthernet1/0/3] qinq enable
[PE2-GigabitEthernet1/0/3] quit
```

3. Configure the devices between PE 1 and PE 2:

Set the MTU to a minimum of 1504 bytes for each port on the path of QinQ frames. (Details not shown.)

Configure all ports on the forwarding path to allow frames from VLANs 100 and 200 to pass through without removing the VLAN tag. (Details not shown.)

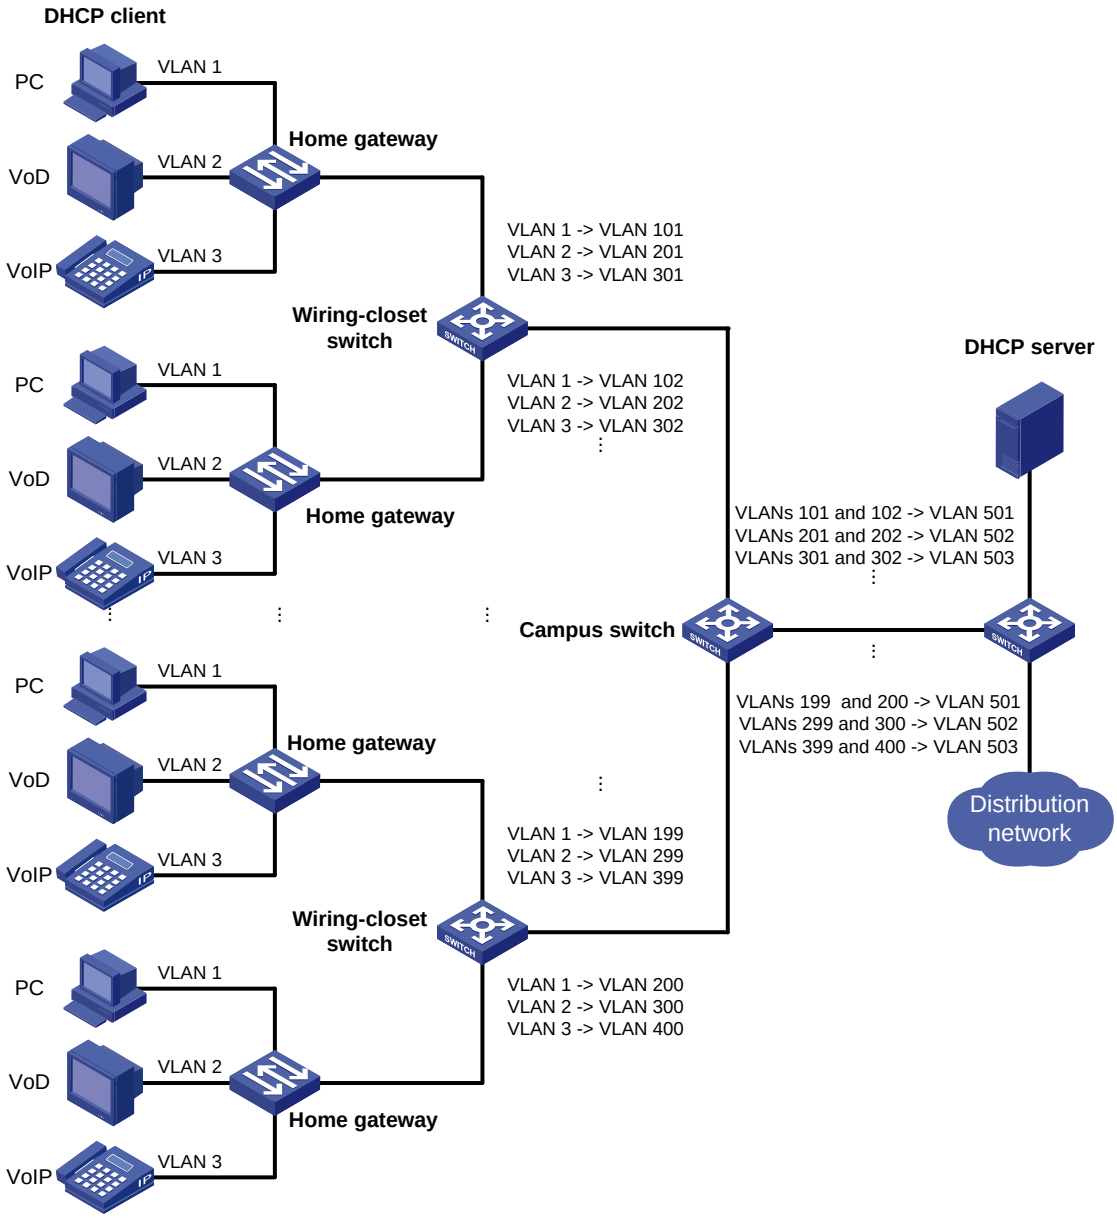
Configuring VLAN mapping

About VLAN mapping

VLAN mapping re-marks VLAN traffic with new VLAN IDs.

VLAN mapping types

H3C provides the following types of VLAN mapping:



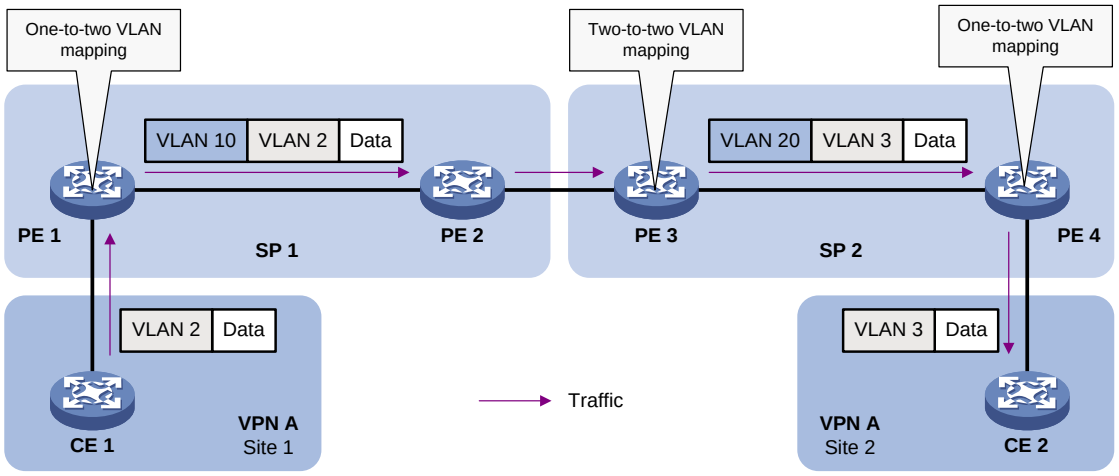
- **One-to-one VLAN mapping**—Replaces one VLAN tag with another.
- **Many-to-one VLAN mapping**—Replaces multiple VLAN tags with the same VLAN tag.
- **One-to-two VLAN mapping**—Tags single-tagged packets with an outer VLAN tag.
- **Zero-to-two VLAN mapping**—Adds double VLAN tags to untagged packets.
- **Two-to-one VLAN mapping**—Removes VLAN tags from double-tagged packets and adds a new VLAN tag to them.
- **Two-to-two VLAN mapping**—Replaces the outer and inner VLAN IDs of double tagged traffic with a new pair of VLAN IDs.

VLAN mapping application scenarios

One-to-one and many-to-one VLAN mapping

One-to-one and many-to-one VLAN mapping are typically used by a community for broadband Internet access, as shown in Figure 1.

Figure 1 Application scenario of one-to-one and many-to-one VLAN mapping



As shown in Figure 1, the network is implemented as follows:

- Each home gateway uses different VLANs to transmit the PC, VoD, and VoIP services.
- To further subclassify each type of traffic by customer, configure one-to-one VLAN mapping on the wiring-closet switches. This feature assigns a separate VLAN to each type of traffic from each customer. The required total number of VLANs in the network can be very large.
- To prevent the maximum number of VLANs from being exceeded on the distribution layer device, configure many-to-one VLAN mapping on the campus switch. This feature assigns the same VLAN to the same type of traffic from different customers.

One-to-two and two-to-two VLAN mapping

One-to-two and two-to-two VLAN mapping are typically used to implement communication across different SP networks, as shown in Figure 2.

Figure 2 Application scenario of one-to-two and two-to-two VLAN mapping

As shown in Figure 2:

Site 1 and Site 2 of VPN A are in VLAN 2 and VLAN 3, respectively. The SP 1 network assigns SVLAN 10 to Site 1. The SP 2 network assigns SVLAN 20 to Site 2. When the packet from Site 1 arrives at PE 1, PE 1 tags the packet with SVLAN 10 by using one-to-two VLAN mapping.

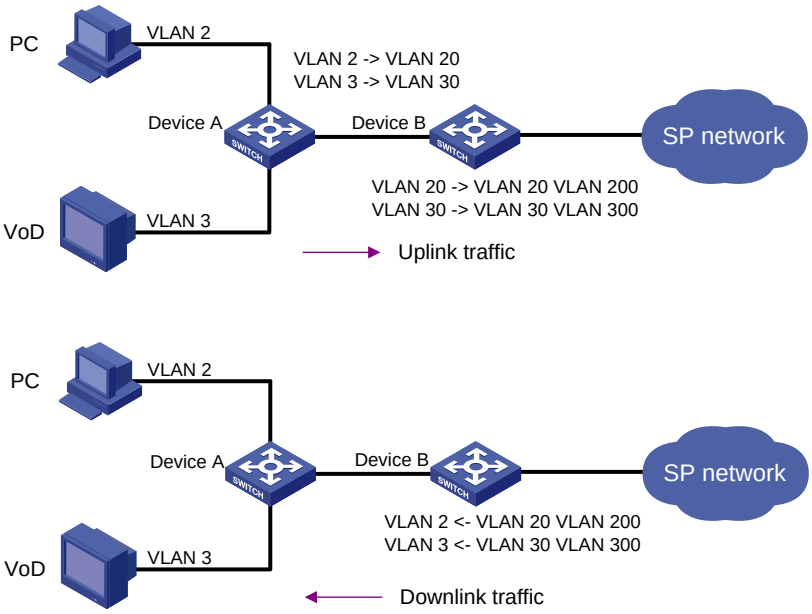
One-to-two VLAN mapping provides the following benefits:

- Enables a customer network to plan its CVLAN assignment without conflicting with SVLANs.
- Adds a VLAN tag to a tagged packet and expands the number of available VLANs to 4094 × 4094.
- Reduces the stress on the SVLAN resources, which were 4094 VLANs in the SP network before the mapping process was initiated.

When the double-tagged packet from the SP 1 network arrives at the SP 2 network interface, PE 3 processes the packet as follows:

- Replaces SVLAN tag 10 with SVLAN tag 20.
- Replaces CVLAN tag 2 with CVLAN tag 3.

Zero-to-two VLAN mapping



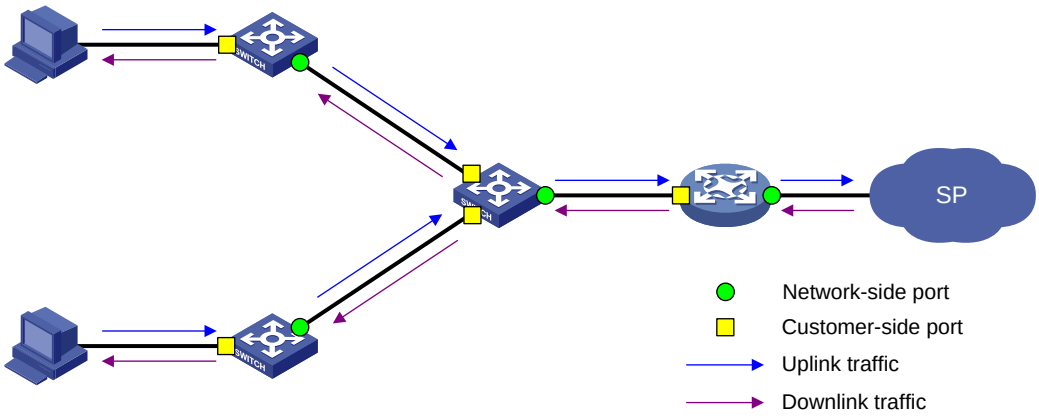
The application scenario of zero-to-two VLAN mapping is similar to the scenario of one-to-two VLAN mapping. Zero-to-two VLAN mapping is used on the customer-side port of a PE to add double tags to untagged packets.

Two-to-one VLAN mapping

As shown in Figure 3, configure VLANs and VLAN mappings to isolate traffic of different services and ensure the communication between the user network and the service provider network:

- On Device A, assign different types of service traffic to different VLANs.
- On Device B, configure one-to-one VLAN mappings and one-to-two VLAN mappings for uplink traffic.
- On Device B, configure two-to-one VLAN mappings for the downlink traffic. After receiving double-tagged reply packets, Device B removes their double VLAN tags and adds the original VLAN tags to them.

Figure 3 Application scenario of two-to-one VLAN mapping



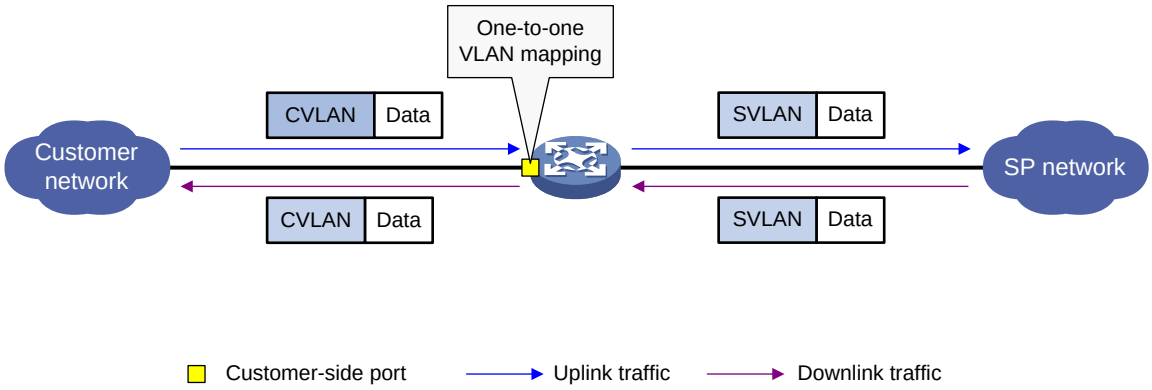
VLAN mapping implementations

Figure 4 shows a simplified network that illustrates basic VLAN mapping terms.

Basic VLAN mapping terms include the following:

- **Uplink traffic**—Traffic transmitted from the customer network to the service provider network.
- **Downlink traffic**—Traffic transmitted from the service provider network to the customer network.
- **Network-side port**—A port connected to or closer to the service provider network.
- **Customer-side port**—A port connected to or closer to the customer network.

Figure 4 Basic VLAN mapping terms



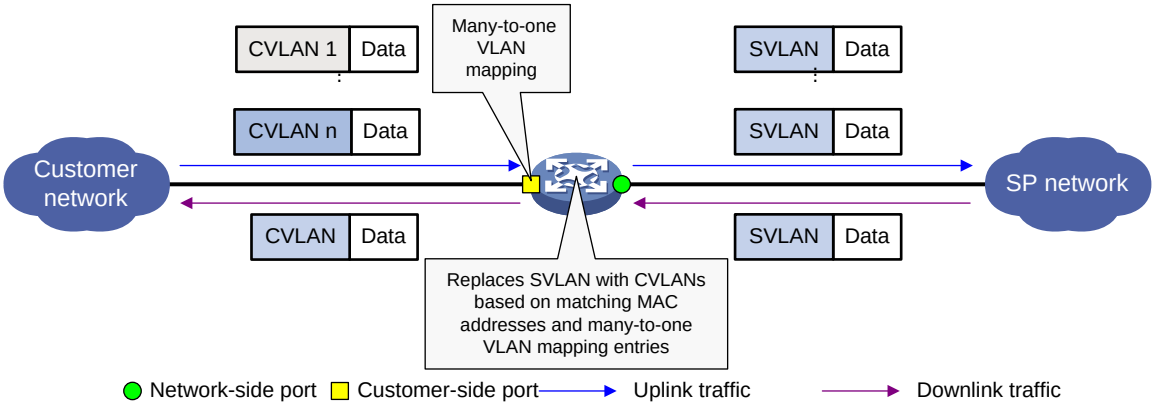
One-to-one VLAN mapping

As shown in Figure 5, one-to-one VLAN mapping is implemented on the customer-side port and replaces VLAN tags as follows:

- Replaces the CVLAN with the SVLAN for the uplink traffic.
- Replaces the SVLAN with the CVLAN for the downlink traffic.

Figure 5 One-to-one VLAN mapping implementation

Many-to-one VLAN mapping



As shown in Figure 6, many-to-one VLAN mapping is implemented on both the customer-side and network-side ports as follows:

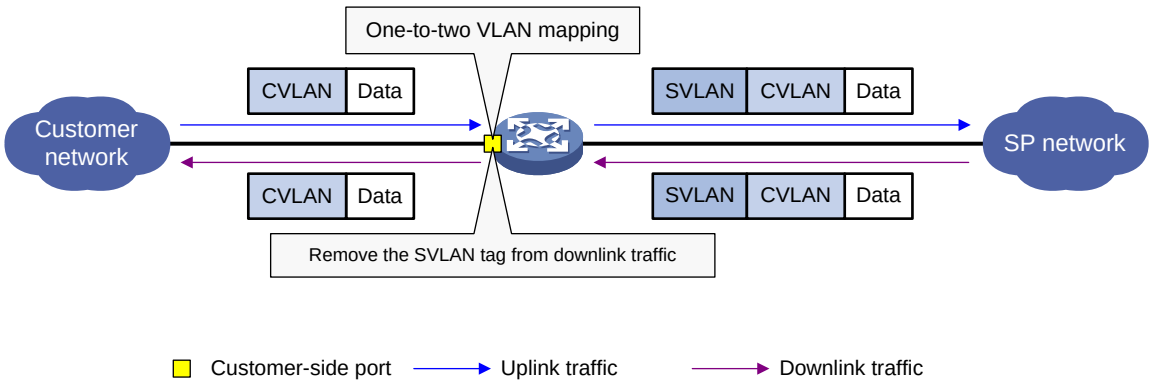
- For the uplink traffic, the customer-side many-to-one VLAN mapping replaces multiple CVLANs with the same SVLAN.
- For the downlink traffic, the device performs the following operations:
  a. Searches the MAC address table for an entry that matches the destination MAC address of the downlink packets.
  b. Replaces the SVLAN tag with a CVLAN tag based on the matching many-to-one mapping entry.

  The maximum number of the matching many-to-one mapping entries supported on the device is 170.

For more information about the MAC address table, see "Configuring the MAC address table."

Figure 6 Many-to-one VLAN mapping implementation (IPv4)

One-to-two VLAN mapping



As shown in Figure 7, one-to-two VLAN mapping is implemented on the customer-side port to add the SVLAN tag for the uplink traffic.

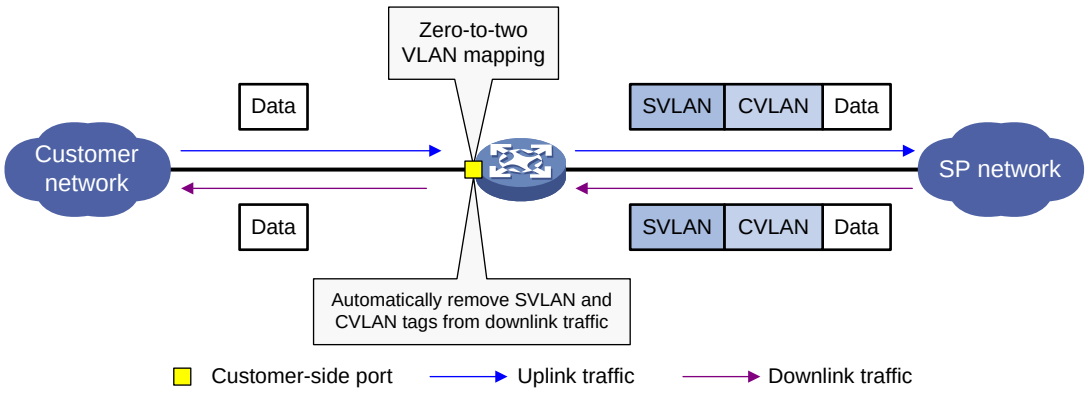
For the downlink traffic to be correctly sent to the customer network, make sure the SVLAN tag is removed on the customer-side port before transmission. Use one of the following methods to remove the SVLAN tag from the downlink traffic:

- Configure the customer-side port as a hybrid port and assign the port to the SVLAN as an untagged member.

- Configure the customer-side port as a trunk port and set the port PVID to the SVLAN.

Figure 7 One-to-two VLAN mapping implementation

Zero-to-two VLAN mapping



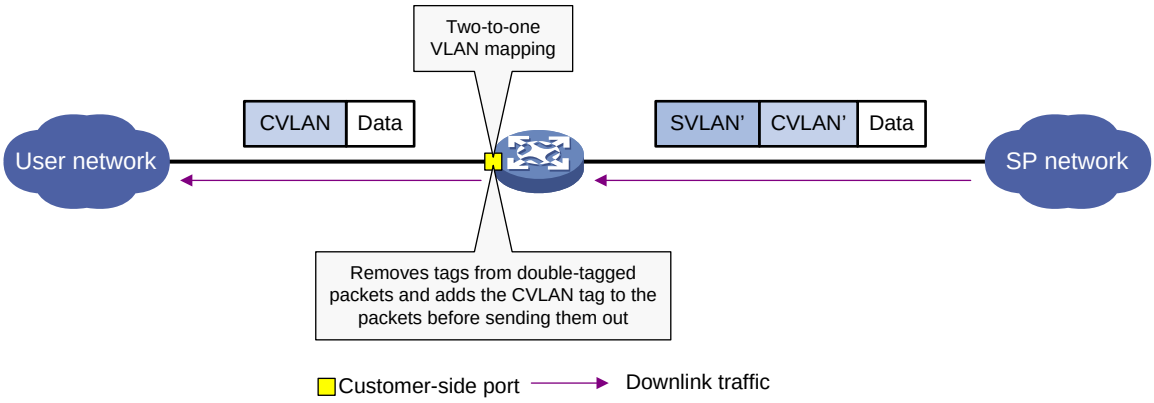
As shown in Figure 8, zero-to-two VLAN mapping is implemented on the customer-side port to add double tags to untagged uplink traffic. For zero-to-two VLAN mapping to take effect, the port PVID must be VLAN 1.

For correct downlink traffic transmission, the downlink traffic must be double-tagged. Then, the customer-side port removes both SVLAN and CVLAN tags from the traffic.

Use one of the following methods to ensure that the downlink traffic contains double tags on the customer-side port:

- Configure the port as a trunk port and assign it to the SVLAN, which must be different from the port PVID (VLAN 1).
- Configure the port as a hybrid port and assign it to the SVLAN as a tagged member.

Figure 8 Zero-to-two VLAN mapping implementation

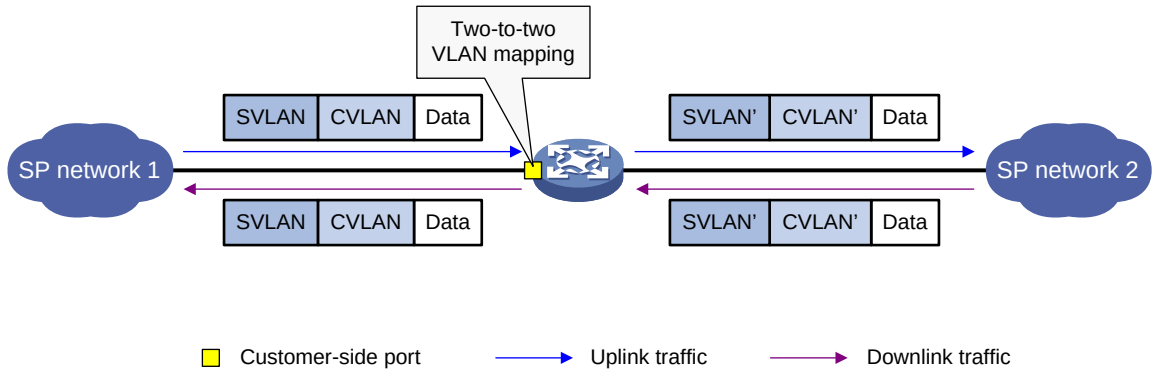


Two-to-one VLAN mapping

As shown in Figure 9, configure two-to-one VLAN mapping on the customer-side port to remove double VLAN tags from downstream packets and add the CVLAN tag to them.

Two-to-one VLAN mapping takes effect only on the outgoing downstream packets of the customer-side port and does not affect the incoming packets of the port.

Figure 9 Two-to-one VLAN mapping implementation



Two-to-two VLAN mapping

As shown in Figure 10, two-to-two VLAN mapping is implemented on the customer-side port and replaces VLAN tags as follows:

- Replaces the CVLAN and the SVLAN with the CVLAN' and the SVLAN' for the uplink traffic.
- Replaces the SVLAN' and CVLAN' with the SVLAN and the CVLAN for the downlink traffic.

Figure 10 Two-to-two VLAN mapping implementation

Restrictions and guidelines: VLAN mapping configuration

You cannot use VLAN mapping and Layer 3 forwarding together.

To add VLAN tags to packets, you can configure both VLAN mapping and QinQ. VLAN mapping takes effect if a configuration conflict occurs. For more information about QinQ, see "Configuring QinQ."

To add or replace VLAN tags for packets, you can configure both VLAN mapping and a QoS policy. The QoS policy takes effect if a configuration conflict occurs. For information about QoS policies, see *ACL and QoS Configuration Guide*.

VLAN mapping tasks at a glance

Use the appropriate VLAN mapping methods for the devices in the network.

To configure VLAN mapping, perform the following tasks:

- Configuring one-to-one VLAN mapping
- Configure one-to-one VLAN mapping on the wiring-closet switch, as shown in the network diagram in "One-to-one and many-to-one VLAN mapping."
- Configuring many-to-one VLAN mapping

  Configure many-to-one VLAN mapping on the campus switch, as shown in the network diagram in "One-to-one and many-to-one VLAN mapping."
- Configuring one-to-two VLAN mapping

  Configure one-to-two VLAN mapping on PE 1 and PE 4, as shown in the network diagram in "One-to-two and two-to-two VLAN mapping," through which traffic from customer networks enters the service provider networks.
- Configuring zero-to-two VLAN mapping

  Configure zero-to-two VLAN mapping on PE 1 and PE 4, as shown in the network diagram in "One-to-two and two-to-two VLAN mapping," through which traffic from customer networks enters the service provider networks.
- Configuring two-to-one VLAN mapping

  Configure two-to-one VLAN mapping on the customer-side port of Device B, as shown in the network diagram in "Two-to-one VLAN mapping."
- Configuring two-to-two VLAN mapping

  Configure two-to-two VLAN mapping on PE 3, as shown in the network diagram in "One-to-two and two-to-two VLAN mapping," which is an edge device of the SP 2 network.

Prerequisites

Before you configure VLAN mapping, create original and translated VLANs.

Configuring one-to-one VLAN mapping

About this task

Configure one-to-one VLAN mapping on the customer-side ports of wiring-closet switches (see the network diagram in "One-to-one and many-to-one VLAN mapping") to isolate traffic of the same service type from different homes.

Restrictions and guidelines

You cannot use one-to-one VLAN mapping together with zero-to-two, two-to-one, or two-to-two VLAN mapping.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.

     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.

     interface bridge-aggregation *interface-number*
3. Set the link type of the port.

   port link-type { **hybrid** | **trunk** }

   By default, the link type of a port is **access**.
4. Assign the port to the original VLAN and the translated VLAN.

- Assign the trunk port to the original VLAN and the translated VLAN.

  port trunk permit vlan *vlan-id-list*

  By default, a trunk port is assigned to VLAN 1.
- Assign the hybrid port to the original VLAN and the translated VLAN as a tagged member.

  port hybrid vlan *vlan-id-list* **tagged**

  By default, a hybrid port is an untagged member of the VLAN to which the port belongs when its link type is access.

5. Configure a one-to-one VLAN mapping.

   vlan mapping *vlan-id* **translated-vlan** *vlan-id*

   By default, no VLAN mapping is configured on an interface.

Configuring many-to-one VLAN mapping

About this task

Configure many-to-one VLAN mapping on campus switches (see the network diagram in "One-to-one and many-to-one VLAN mapping") to transmit the same type of traffic from different users in one VLAN.

Restrictions and guidelines for many-to-one VLAN mapping

- The device supports a maximum of 170 many-to-one mapping entries.
- When you configure both many-to-one VLAN mapping and other types of mappings on an interface, only the many-to-one VLAN mapping takes effect.
- You cannot use many-to-one VLAN mapping together with zero-to-two, two-to-one, or two-to-two VLAN mapping.
- After you configure an interface as the network-side interface of many-to-one VLAN mapping, do not configure the other types of VLAN mapping on the interface
- You can configure only one many-to-one VLAN mapping on the same interface. To modify the many-to-one VLAN mapping, perform the following tasks:
  a. Execute the **undo vlan mapping** command to delete the existing many-to-one VLAN mapping.
  b. Configure another many-to-one VLAN mapping.
- To ensure correct traffic forwarding from the service provider network to the customer network, do not configure many-to-one VLAN mapping together with the following features:
  - uRPF.
  - Disabling MAC address learning.
  - Setting the MAC learning limit.

  For more information about uRPF, see *Security Configuration Guide*. For more information about MAC address learning, see "Configuring the MAC address table."

Many-to-one VLAN mapping tasks at a glance

To configure many-to-one VLAN mapping in dynamic IP address assignment environment, perform the following tasks:

1. Configuring the customer-side port
2. Configuring the network-side port

Configuring the customer-side port

1. Enter system view.

   system-view

2. Enter Layer 2 Ethernet interface view.
   interface *interface-type interface-number*
3. Set the link type of the port.
   port link-type { **hybrid** | **trunk** }
   By default, the link type of a port is **access**.
4. Assign the port to the original VLANs.
   - Assign the trunk port to the original VLANs
     port trunk permit vlan *vlan-id-list*
     By default, a trunk port is assigned to VLAN 1.
   - Assign the hybrid port to the original VLANs as a tagged member.
     port hybrid vlan *vlan-id-list* **tagged**
     By default, a hybrid port is an untagged member of the VLAN to which the port belongs when its link type is access.
5. Configure a many-to-one VLAN mapping.
   vlan mapping uni { **range** *vlan-range-list* | **single** *vlan-id-list* } **translated-vlan** *vlan-id*
   By default, no VLAN mapping is configured on an interface.

Configuring the network-side port

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view.
   interface *interface-type interface-number*
3. Set the link type of the port.
   port link-type { **hybrid** | **trunk** }
   By default, the link type of a port is **access**.
4. Assign the port to the translated VLAN.
   - Assign the trunk port to the translated VLAN.
     port trunk permit vlan *vlan-id-list*
     By default, a trunk port is assigned to VLAN 1.
   - Assign the hybrid port to the translated VLAN as a tagged member.
     port hybrid vlan *vlan-id-list* **tagged**
     By default, a hybrid port is an untagged member of the VLAN to which the port belongs when its link type is access.

Configuring one-to-two VLAN mapping

About this task

Configure one-to-two VLAN mapping on the customer-side ports of edge devices from which customer traffic enters SP networks, for example, on PEs 1 and 4 in the network diagram in "One-to-two and two-to-two VLAN mapping." One-to-two VLAN mapping enables the edge devices to add an SVLAN tag to each incoming packet.

Restrictions and guidelines

Only one SVLAN tag can be added to packets from the same CVLAN. To add different SVLAN tags to different CVLAN packets on a port, set the port link type to hybrid and configure multiple one-to-two VLAN mappings.

The MTU of an interface is 1500 bytes by default. After a VLAN tag is added to a packet, the packet length is added by 4 bytes. As a best practice, set the MTU to a minimum of 1504 bytes for ports on the forwarding path of the packet in the service provider network.

Do not use one-to-two VLAN mapping together with zero-to-two, two-to-one, or two-to-two VLAN mapping.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
3. Set the link type of the port.
   port link-type { **hybrid** | **trunk** }
   By default, the link type of a port is **access**.
4. Configure the port to allow packets from the SVLAN to pass through untagged.
   - Configure the SVLAN as the PVID of the trunk port and assign the trunk port to the SVLAN.
     port trunk pvid vlan *vlan-id*
     port trunk permit vlan { *vlan-id-list* | **all** }
   - Assign the hybrid port to the SVLAN as an untagged member.
     port hybrid vlan *vlan-id-list* **untagged**
5. Configure a one-to-two VLAN mapping.
   vlan mapping nest { **range** *vlan-range-list* | **single** *vlan-id-list* } **nested-vlan** *vlan-id*
   By default, no VLAN mapping is configured on an interface.

Configuring zero-to-two VLAN mapping

About this task

Configure zero-to-two VLAN mapping on PE 1 and PE 4, as shown in the network diagram in "One-to-two and two-to-two VLAN mapping," through which traffic from customer networks enters the service provider networks.

Configuration restrictions and guidelines

As a best practice, set the MTU to a minimum of 1504 bytes for ports on the forwarding path of the double-tagged packet in the service provider network.

Do not use zero-to-two VLAN mapping together with one-to-one, one-to-two, or many-to-one VLAN mapping.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*

- Enter Layer 2 aggregate interface view.
  interface bridge-aggregation *interface-number*
- Enter ONU subinterface service profile view.
  onu service-profile *profile-name*
- Execute the following commands in sequence to enter ONU line profile subinterface view.
  onu line-profile *profile-name*
  subinterface *subnumber*

3. Set the link type of the port.
   port link-type { **hybrid** | **trunk** }
   By default, the link type of a port is **access**.
4. Set the port PVID to VLAN 1.
   - Set the PVID to VLAN 1 for the trunk port.
     port trunk pvid vlan 1
   - Set the PVID to VLAN 1 for the hybrid port.
     port hybrid pvid vlan 1
5. Assign the port to the SVLAN and the port PVID (VLAN 1).
   - Assign the trunk port to the SVLAN and the port PVID (VLAN 1).
     port trunk permit vlan *vlan-id-list*
     By default, a trunk port is assigned to VLAN 1.
     The SVLAN of the trunk port must be different from the port PVID (VLAN 1).
   - Assign the hybrid port to the SVLAN and the port PVID (VLAN 1) as a tagged member.
     port hybrid vlan *vlan-id-list* **tagged**
     By default, a hybrid port is an untagged member of the VLAN to which the port belongs when its link type is access.
6. Configure a zero-to-two VLAN mapping.
   vlan mapping untagged nested-outer-vlan *outer-vlan-id* **nested-inner-vlan** *inner-vlan-id*
   By default, no VLAN mapping is configured on an interface.

Configuring two-to-one VLAN mapping

About this task

Configure two-to-one VLAN mapping on the customer-side port of Device B, as shown in the network diagram in "Two-to-one VLAN mapping." Device B will remove VLAN tags from double-tagged packets and add the CVLAN tag to them. When packets arrives Device A, Device A removes the CVLAN tag.

Restrictions and guidelines

On an interface, the original CVLAN and SVLAN of a two-to-one VLAN mapping cannot be the same as the translated CVLAN and SVLAN of a two-to-two or zero-to-two VLAN mapping.

You cannot specify multiple translated VLANs for the same original CVLAN and SVLAN on an interface. To modify an existing two-to-one VLAN mapping on an interface, you must execute the **undo vlan mapping egress** command to remove it first and then configure a new mapping.

Do not use two-to-one VLAN mapping together with one-to-one, one-to-two, or many-to-one VLAN mapping.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
3. Set the port link type to hybrid or trunk.
   port link-type { **hybrid** | **trunk** }
   By default, the link type of a port is **access**.
4. Assign the port to the translated VLAN.
   - Assign the trunk port to the translated VLAN.
     port trunk permit vlan *vlan-id-list*
     By default, a trunk port is assigned to VLAN 1.
   - Assign the hybrid port to the translated VLAN.
     port hybrid vlan *vlan-id-list* **tagged**
     By default, a hybrid port is an untagged member of the VLAN to which the port belongs when its link type is access.
5. Configure a two-to-one VLAN mapping.
   vlan mapping egress outer-vlan *outer-vlan-id* **inner-vlan** *inner-vlan-id* **translated-vlan** *vlan-id*
   By default, no VLAN mapping is configured on an interface.

Configuring two-to-two VLAN mapping

About this task

Configure two-to-two VLAN mapping on the customer-side port of an edge device that connects two SP networks, for example, on PE 3 in the network diagram in "One-to-two and two-to-two VLAN mapping." Two-to-two VLAN mapping enables two sites in different VLANs to communicate at Layer 2 across two service provider networks that use different VLAN assignment schemes.

Restrictions and guidelines

Do not use two-to-two VLAN mapping together with one-to-one, one-to-two, or many-to-one VLAN mapping.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
3. Set the link type of the port.
   port link-type { **hybrid** | **trunk** }

By default, the link type of a port is **access**.

4. Assign the port to the original VLANs and the translated VLANs.
   - Assign the trunk port to the original VLANs and the translated VLANs.

     port trunk permit vlan *vlan-id-list*

     By default, a trunk port is assigned to VLAN 1.
   - Assign the hybrid port to the original VLANs and the translated VLANs as a tagged member.

     port hybrid vlan *vlan-id-list* **tagged**

     By default, a hybrid port is an untagged member of the VLAN to which the port belongs when its link type is access.
5. Configure a two-to-two VLAN mapping.

   vlan mapping tunnel *outer-vlan-id inner-vlan-id* **translated-vlan** *outer-vlan-id inner-vlan-id*

   By default, no VLAN mapping is configured on an interface.

Display and maintenance commands for VLAN mapping

Execute **display** commands in any view.

Task	Command
Display VLAN mapping information.	**display vlan mapping** [**interface** *interface-type interface-number*]

VLAN mapping configuration examples

Example: Configuring one-to-one VLAN mapping

Network configuration

As shown in Figure 11:

- Each household subscribes to PC, VoD, and VoIP services.
- On the home gateways, VLANs 1, 2, and 3 are assigned to PC, VoD, and VoIP traffic, respectively.

To isolate traffic of the same service type from different households, configure one-to-one VLAN mappings on the wiring-closet switches. This feature assigns one VLAN to each type of traffic from each household.

Figure 11 Network diagram

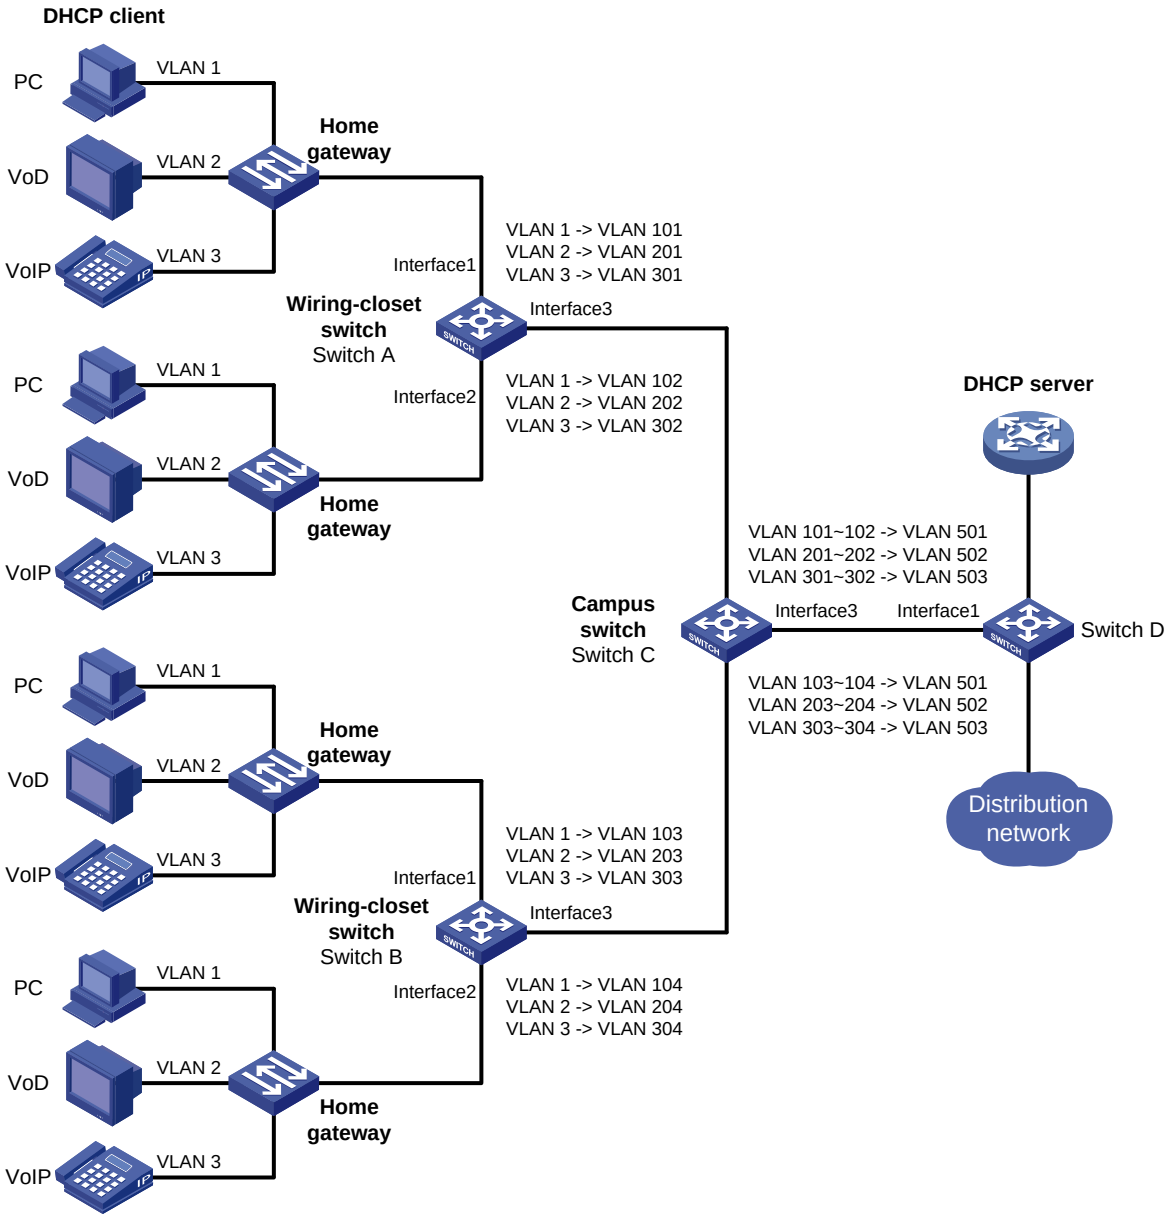


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure Switch A:

   # Create the original VLANs.

   ```
   <SwitchA> system-view
   [SwitchA] vlan 2 to 3
   ```

   # Create the translated VLANs.

```
[SwitchA] vlan 101 to 102
[SwitchA] vlan 201 to 202
[SwitchA] vlan 301 to 302
```

Configure customer-side port GigabitEthernet 1/0/1 as a trunk port.

```
<SwitchA> system-view
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] port link-type trunk
```

Assign GigabitEthernet 1/0/1 to all original VLANs and translated VLANs.

```
[SwitchA-GigabitEthernet1/0/1] port trunk permit vlan 1 2 3 101 201 301
```

Configure one-to-one VLAN mappings on GigabitEthernet 1/0/1 to map VLANs 1, 2, and 3 to VLANs 101, 201, and 301, respectively.

```
[SwitchA-GigabitEthernet1/0/1] vlan mapping 1 translated-vlan 101
[SwitchA-GigabitEthernet1/0/1] vlan mapping 2 translated-vlan 201
[SwitchA-GigabitEthernet1/0/1] vlan mapping 3 translated-vlan 301
[SwitchA-GigabitEthernet1/0/1] quit
```

Configure customer-side port GigabitEthernet 1/0/2 as a trunk port.

```
[SwitchA] interface gigabitethernet 1/0/2
[SwitchA-GigabitEthernet1/0/2] port link-type trunk
```

Assign GigabitEthernet 1/0/2 to all original VLANs and translated VLANs.

```
[SwitchA-GigabitEthernet1/0/2] port trunk permit vlan 1 2 3 102 202 302
```

Configure one-to-one VLAN mappings on GigabitEthernet 1/0/2 to map VLANs 1, 2, and 3 to VLANs 102, 202, and 302, respectively.

```
[SwitchA-GigabitEthernet1/0/2] vlan mapping 1 translated-vlan 102
[SwitchA-GigabitEthernet1/0/2] vlan mapping 2 translated-vlan 202
[SwitchA-GigabitEthernet1/0/2] vlan mapping 3 translated-vlan 302
[SwitchA-GigabitEthernet1/0/2] quit
```

Configure the network-side port (GigabitEthernet 1/0/3) as a trunk port.

```
[SwitchA] interface gigabitethernet 1/0/3
[SwitchA-GigabitEthernet1/0/3] port link-type trunk
```

Assign GigabitEthernet 1/0/3 to the translated VLANs.

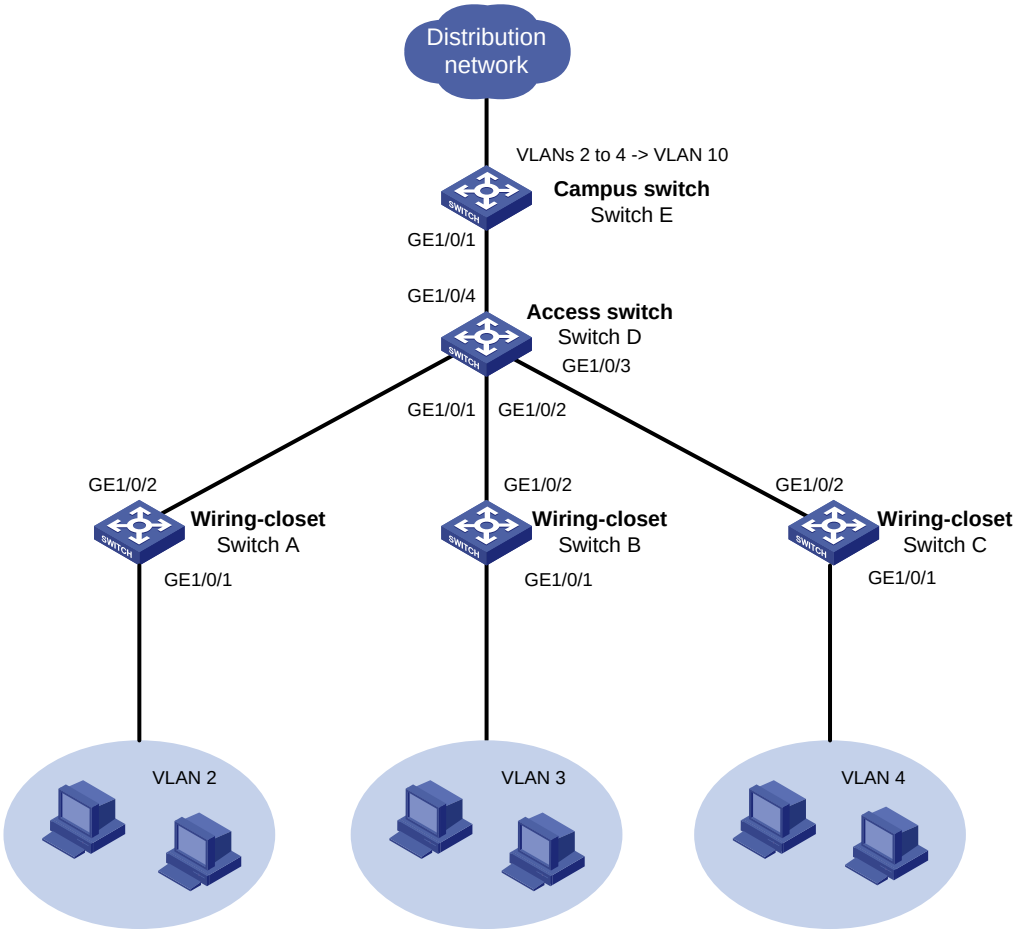
```
[SwitchA-GigabitEthernet1/0/3] port trunk permit vlan 101 201 301 102 202 302
[SwitchA-GigabitEthernet1/0/3] quit
```

2. Configure Switch B in the same way Switch A is configured. (Details not shown.)

Verifying the configuration

Verify VLAN mapping information on the wiring-closet switches, for example, Switch A.

```
[SwitchA] display vlan mapping
Interface GigabitEthernet1/0/1:
  Outer VLAN    Inner VLAN    Translated Outer VLAN    Translated Inner VLAN
  1             N/A           101                      N/A
  2             N/A           201                      N/A
  3             N/A           301                      N/A
Interface GigabitEthernet1/0/2:
  Outer VLAN    Inner VLAN    Translated Outer VLAN    Translated Inner VLAN
  1             N/A           102                      N/A
  2             N/A           202                      N/A
  3             N/A           302                      N/A
```



Example: Configuring many-to-one VLAN mapping

Network configuration

As shown in Figure 12:

- Create VLAN 2, VLAN 3, and VLAN 4 on the wiring-closet switches to isolate traffic of the same service type from different households.
- Configure many-to-one VLAN mappings on the campus switch. This feature assigns one VLAN to each type of traffic from different households.

Figure 12 Network diagram

Procedure

1. Configure Switch A:

   # Create VLAN 2 as an original VLAN.

   ```
   <SwitchA> system-view
   [SwitchA] vlan 2
   [SwitchA-vlan2] quit
   ```

   # Assign ports GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to VLAN 2.

   ```
   [SwitchA] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/2
   [SwitchA-if-range] port access vlan 2
   [SwitchA-if-range] quit
   ```

2. Configure Switch B and Switch C in the same way Switch A is configured. (Details not shown.)

3. Configure Switch D:

   # Create VLANs 2, 3, and 4 as original VLANs.

```
<SwitchD> system-view
[SwitchD] vlan 2 to 4
```

   # Assign ports GigabitEthernet 1/0/1 to VLAN 2, GigabitEthernet 1/0/2 to VLAN 3, and GigabitEthernet 1/0/3 to VLAN 4.

```
[SwitchD] interface gigabitethernet 1/0/1
[SwitchD-GigabitEthernet1/0/1] port access vlan 2
[SwitchD-GigabitEthernet1/0/1] quit
[SwitchD] interface gigabitethernet 1/0/2
[SwitchD-GigabitEthernet1/0/2] port access vlan 3
[SwitchD-GigabitEthernet1/0/2] quit
[SwitchD] interface gigabitethernet 1/0/3
[SwitchD-GigabitEthernet1/0/3] port access vlan 4
[SwitchD-GigabitEthernet1/0/3] quit
```

   # Configure port GigabitEthernet 1/0/4 as a trunk port.

```
[SwitchD] interface gigabitethernet 1/0/4
[SwitchD-GigabitEthernet1/0/4] port link-type trunk
```

   # Assign GigabitEthernet 1/0/4 to the original VLANs.

```
[SwitchD-GigabitEthernet1/0/4] port trunk permit vlan 2 to 4
[SwitchD-GigabitEthernet1/0/4] quit
```

4. Configure Switch E:

   # Create VLANs 2, 3, and 4 as original VLANs.

```
<SwitchE> system-view
[SwitchE] vlan 2 to 4
```

   # Configure the customer-side port (GigabitEthernet 1/0/1) as a trunk port.

```
<SwitchE> system-view
[SwitchE] interface gigabitethernet 1/0/1
[SwitchE-GigabitEthernet1/0/1] port link-type trunk
```

   # Assign GigabitEthernet 1/0/1 to the original VLANs.

```
[SwitchE-GigabitEthernet1/0/1] port trunk permit vlan 2 to 4
```

   # Configure many-to-one VLAN mapping on GigabitEthernet 1/0/1, which replaces VLAN tag 2 through VLAN tag 4 with VLAN tag 10.

```
[SwitchE-GigabitEthernet1/0/1] vlan mapping uni range 2 to 4 translated-vlan 10
[SwitchE-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Verify VLAN mapping information on Switch E.

```
[SwitchE] display vlan mapping
Interface GigabitEthernet1/0/1:
  Outer VLAN    Inner VLAN    Translated Outer VLAN    Translated Inner VLAN
  2-4           N/A           10                       N/A
```

Example: Configuring one-to-two and two-to-two VLAN mapping

Network configuration

As shown in Figure 13:

- Two VPN A branches, Site 1 and Site 2, are in VLAN 5 and VLAN 6, respectively.
- The two sites use different VPN access services from different service providers, SP 1 and SP 2.
- SP 1 assigns VLAN 100 to Site 1 and Site 2. SP 2 assigns VLAN 200 to Site 1 and Site 2.

Configure one-to-two VLAN mappings and two-to-two VLAN mappings to enable the two branches to communicate across networks SP 1 and SP 2.

Figure 13 Network diagram

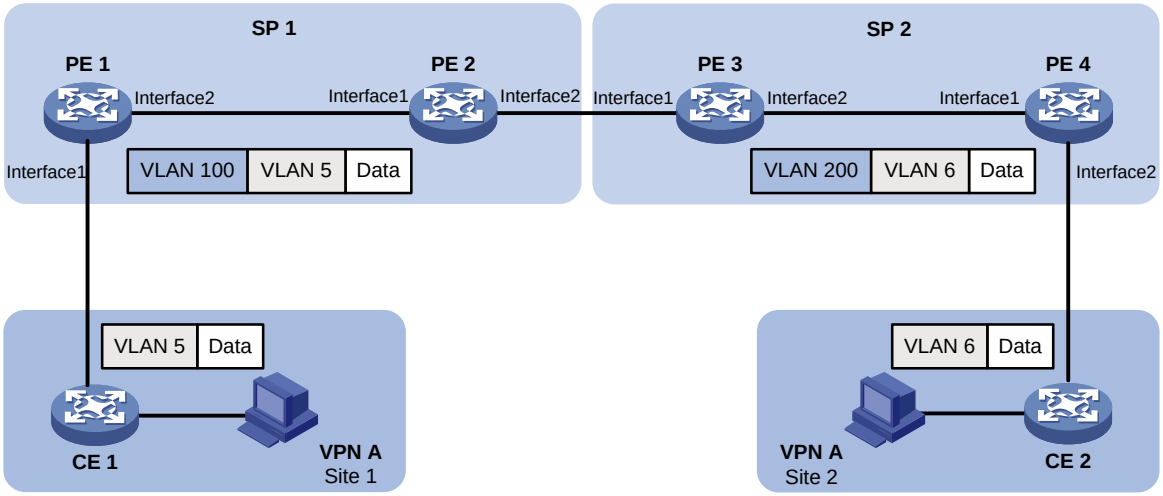


Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure PE 1:

   # Create VLANs 5 and 100.

   ```
   <PE1> system-view
   [PE1] vlan 5
   [PE1-vlan5] quit
   [PE1] vlan 100
   [PE1-vlan100] quit
   ```

   # Configure a one-to-two VLAN mapping on the customer-side port (GigabitEthernet 1/0/1) to add SVLAN tag 100 to packets from VLAN 5.

   ```
   [PE1] interface gigabitethernet 1/0/1
   [PE1-GigabitEthernet1/0/1] vlan mapping nest single 5 nested-vlan 100
   ```

   # Configure GigabitEthernet 1/0/1 as a hybrid port.

   ```
   [PE1-GigabitEthernet1/0/1] port link-type hybrid
   ```

Assign GigabitEthernet 1/0/1 to VLAN 100 as an untagged member.

```
[PE1-GigabitEthernet1/0/1] port hybrid vlan 100 untagged
[PE1-GigabitEthernet1/0/1] quit
```

Configure the network-side port (GigabitEthernet 1/0/2) as a trunk port.

```
[PE1] interface gigabitethernet 1/0/2
[PE1-GigabitEthernet1/0/2] port link-type trunk
```

Assign GigabitEthernet 1/0/2 to VLAN 100.

```
[PE1-GigabitEthernet1/0/2] port trunk permit vlan 100
[PE1-GigabitEthernet1/0/2] quit
```

2. Configure PE 2:

Create VLAN 100.

```
<PE2> system-view
[PE2] vlan 100
[PE2-vlan100] quit
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[PE2] interface gigabitethernet 1/0/1
[PE2-GigabitEthernet1/0/1] port link-type trunk
```

Assign GigabitEthernet 1/0/1 to VLAN 100.

```
[PE2-GigabitEthernet1/0/1] port trunk permit vlan 100
[PE2-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[PE2] interface gigabitethernet 1/0/2
[PE2-GigabitEthernet1/0/2] port link-type trunk
```

Assign GigabitEthernet 1/0/2 to VLAN 100.

```
[PE2-GigabitEthernet1/0/2] port trunk permit vlan 100
[PE2-GigabitEthernet1/0/2] quit
```

3. Configure PE 3:

Create VLANs 5, 6, 100, and 200.

```
<PE3> system-view
[PE3] vlan 5 to 6
[PE3] vlan 100
[PE3-vlan100] quit
[PE3] vlan 200
[PE3-vlan200] quit
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[PE3] interface gigabitethernet 1/0/1
[PE3-GigabitEthernet1/0/1] port link-type trunk
```

Assign GigabitEthernet 1/0/1 to VLANs 100 and 200.

```
[PE3-GigabitEthernet1/0/1] port trunk permit vlan 100 200
```

Configure a two-to-two VLAN mapping on GigabitEthernet 1/0/1 to map SVLAN 100 and CVLAN 5 to SVLAN 200 and CVLAN 6.

```
[PE3-GigabitEthernet1/0/1] vlan mapping tunnel 100 5 translated-vlan 200 6
[PE3-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[PE3] interface gigabitethernet 1/0/2
[PE3-GigabitEthernet1/0/2] port link-type trunk
```

Assign GigabitEthernet 1/0/2 to VLAN 200.

```
[PE3-GigabitEthernet1/0/2] port trunk permit vlan 200
[PE3-GigabitEthernet1/0/2] quit
```

4. Configure PE 4:

Create VLANs 6 and 200.

```
<PE4> system-view
[PE4] vlan 6
[PE4-vlan6] quit
[PE4] vlan 200
[PE4-vlan200] quit
```

Configure the network-side port (GigabitEthernet 1/0/1) as a trunk port.

```
[PE4] interface gigabitethernet 1/0/1
[PE4-GigabitEthernet1/0/1] port link-type trunk
```

Assign GigabitEthernet 1/0/1 to VLAN 200.

```
[PE4-GigabitEthernet1/0/1] port trunk permit vlan 200
[PE4-GigabitEthernet1/0/1] quit
```

Configure the customer-side port (GigabitEthernet 1/0/2) as a hybrid port.

```
[PE4] interface gigabitethernet 1/0/2
[PE4-GigabitEthernet1/0/2] port link-type hybrid
```

Assign GigabitEthernet 1/0/2 to VLAN 200 as an untagged member.

```
[PE4-GigabitEthernet1/0/2] port hybrid vlan 200 untagged
```

Configure a one-to-two VLAN mapping on GigabitEthernet 1/0/2 to add SVLAN tag 200 to packets from VLAN 6.

```
[PE4-GigabitEthernet1/0/2] vlan mapping nest single 6 nested-vlan 200
[PE4-GigabitEthernet1/0/2] quit
```

Verifying the configuration

Verify VLAN mapping information on PE 1.

```
[PE1] display vlan mapping
Interface GigabitEthernet1/0/1:
  Outer VLAN    Inner VLAN    Translated Outer VLAN    Translated Inner VLAN
  5             N/A           100                      5
```

Verify VLAN mapping information on PE 3.

```
[PE3] display vlan mapping
Interface GigabitEthernet1/0/1:
  Outer VLAN    Inner VLAN    Translated Outer VLAN    Translated Inner VLAN
  100           5             200                      6
```

Verify VLAN mapping information on PE 4.

```
[PE4] display vlan mapping
Interface GigabitEthernet1/0/2:
  Outer VLAN    Inner VLAN    Translated Outer VLAN    Translated Inner VLAN
  6             N/A           200                      6
```

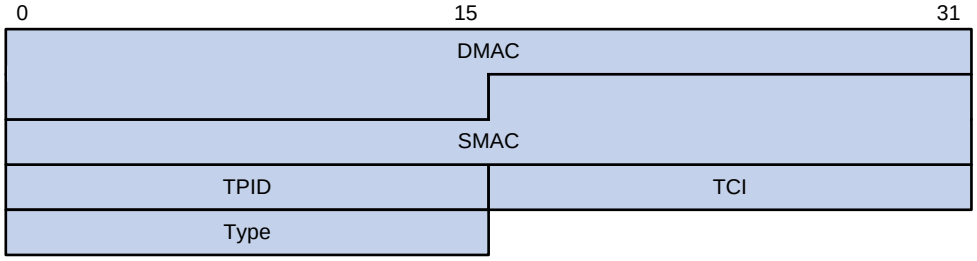
Configuring loop detection

About loop detection



The loop detection mechanism performs periodic checking for Layer 2 loops. The mechanism immediately generates a log when a loop occurs so that you are promptly notified to adjust network connections and configurations. You can configure loop detection to shut down the looped interface. Logs are maintained in the information center. For more information, see *Network Management and Monitoring Configuration Guide*.

Loop detection mechanism

The device detects loops by sending detection frames and then checking whether these frames return to any interface on the device. If they do, the device considers that the interface is on a looped link.

Loop detection usually works within a VLAN. If a detection frame is returned with a different VLAN tag than it was sent out with, an inter-VLAN loop has occurred. To remove the loop, examine the QinQ or VLAN mapping configuration for incorrect settings. For more information about QinQ and VLAN mapping, see "Configuring QinQ" and "Configuring VLAN mapping."

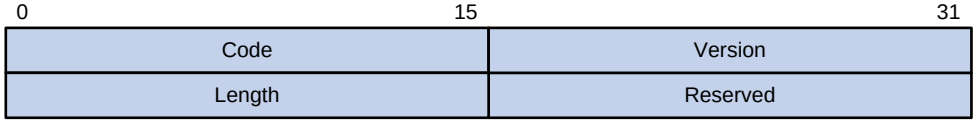


Figure 1 Ethernet frame header for loop detection

The Ethernet frame header of a loop detection packet contains the following fields:

- **DMAC**—Destination MAC address of the frame, which is the multicast MAC address 010f-e200-0007. When a loop detection-enabled device receives a frame with this destination MAC address, it performs the following operations:
  - Sends the frame to the CPU.
  - Floods the frame in the VLAN from which the frame was originally received.
- **SMAC**—Source MAC address of the frame, which is the bridge MAC address of the sending device.
- **TPID**—Type of the VLAN tag, with the value of 0x8100.
- **TCI**—Information of the VLAN tag, including the priority and VLAN ID.
- **Type**—Protocol type, with the value of 0x8918.

Figure 2 Inner frame header for loop detection

The inner frame header of a loop detection packet contains the following fields:

- **Code**—Protocol sub-type, which is 0x0001, indicating the loop detection protocol.
- **Version**—Protocol version, which is always 0x0000.
- **Length**—Length of the frame. The value includes the inner header, but excludes the Ethernet header.
- **Reserved**—This field is reserved.

Frames for loop detection are encapsulated as TLV triplets.

Table 1 TLVs supported by loop detection

TLV	Description	Remarks
End of PDU	End of a PDU.	Optional.
Device ID	Bridge MAC address of the sending device.	Required.
Port ID	ID of the PDU sending interface.	Optional.
Port Name	Name of the PDU sending interface.	Optional.
System Name	Device name.	Optional.
Chassis ID	Chassis ID of the sending interface.	Optional.
Slot ID	Slot ID of the sending interface.	Optional.
Sub Slot ID	Sub-slot ID of the sending interface.	Optional.

Loop detection interval

Loop detection is a continuous process as the network changes. Loop detection frames are sent at the loop detection interval to determine whether loops occur on interfaces and whether loops are removed.

Loop protection actions

When the device detects a loop on an interface, it generates a log but performs no action on the interface by default. You can configure the device to take one of the following actions:

- **Block**—Disables the interface from learning MAC addresses and blocks the interface.
- **No-learning**—Disables the interface from learning MAC addresses.
- **Shutdown**—Shuts down the interface to disable it from receiving and sending any frames.
- **VLAN-block**—Blocks traffic of the VLAN where the loop is detected on the interface.

  Loop detection allows you to use protected VLANs to block traffic on a per-VLAN basis. After you configure a VLAN as a protected VLAN, the device periodically sends loop detection packets in the VLAN. If the device receives a self-sent loop detection packet with the protected VLAN ID included on any interface, the device generates a log and blocks traffic of the VLAN on all interfaces configured with the VLAN-block action.

Loop protection delay

The loop protection delay enables the device to wait for a period of time before taking loop protection actions on looped interfaces. On a network protected by loop detection, the shutdown or block action taken on a looped interface of an upstream device might cause traffic interruption to its downstream devices. To minimize the impacts of loop detection on downstream traffic, set the loop protection

delay on the upstream devices. This delay allows the downstream devices to remove loops before the upstream devices take an action.

Interface status auto recovery

When the device configured with the block or no-learning loop action detects a loop on an interface, it performs the action and waits three loop detection intervals. If the device does not receive a loop detection frame within three loop detection intervals, it performs the following operations:

- Automatically sets the interface to the forwarding state.
- Notifies the user of the event.

When the device configured with the shutdown action detects a loop on an interface, the following events occur:

1. The device automatically shuts down the interface.
2. The device automatically sets the interface to the forwarding state after the detection timer set by using the **`shutdown-interval`** command expires. For more information about the **`shutdown-interval`** command, see *Fundamentals Command Reference*.
3. The device shuts down the interface again if a loop is still detected on the interface when the detection timer expires.

This process is repeated until the loop is removed.

The device performs the following operations if it has not received any loop detection packets in a blocked protected VLAN before three loop detection intervals expire:

- Enables interfaces to forward traffic from the VLAN.
- Generates a log message to report that the loop has been removed.

NOTE:

Incorrect recovery can occur when loop detection frames are discarded to reduce the load. To avoid this, use the shutdown action, or manually remove the loop.

Restriction and guidelines: Loop detection configuration

Member devices in an M-LAG system must have the same loop detection configuration. M-LAG is not supported on the S5200-EI-G switch series.

Loop detection tasks at a glance

To configure loop detection, perform the following tasks:

1. Enabling loop detection
   - Enabling loop detection globally
   - Enabling loop detection on an interface
2. Configuring protected VLANs

   To use the VLAN-block action, you must first configure protected VLANs. Do not perform this task if you use any other loop protection action.
3. (Optional) Setting the loop protection action
   - Setting the global loop protection action
   - Setting the loop protection action on an interface

4. (Optional) Setting the loop detection interval
5. (Optional) Setting the loop protection delay timer
    - Setting the global loop protection delay timer
    - Setting the loop protection delay timer on an interface

Enabling loop detection

Restrictions and guidelines for loop detection configuration

You can enable loop detection globally or on a per-interface basis. When an interface receives a detection frame in any VLAN, the loop protection action is triggered on that interface, regardless of whether loop detection is enabled on it.

Enabling loop detection globally

1. Enter system view.
   system-view
2. Globally enable loop detection.
   loopback-detection global enable vlan { *vlan-id--list* | **all** }
   By default, loop detection is globally disabled.

Enabling loop detection on an interface

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. Enable loop detection on the interface.
   loopback-detection enable vlan { *vlan-id-list* | **all** }
   By default, loop detection is disabled on interfaces.

Configuring protected VLANs

1. Enter system view.
   system-view
2. Configure protected VLANs.
   loopback-detection protected-vlan *vlan-id-list*
   By default, no protected VLANs are configured for loop detection.

Setting the loop protection action

Restrictions and guidelines for loop protection action configuration

You can set the loop protection action globally or on a per-interface basis. The global action applies to all interfaces. An interface-specific action applies to the interface on which it is configured. On an interface, the interface-specific action takes precedence over the global action.

Setting the global loop protection action

1. Enter system view.

   system-view

2. Set the global loop protection action.

   loopback-detection global action shutdown

   By default, the device generates a log but performs no action on the interface on which a loop is detected.

Setting the loop protection action on an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the loop protection action on the interface.

   loopback-detection action { **block** | **no-learning** | **shutdown** | **vlan-block** }

   By default, the device generates a log but performs no action on the interface on which a loop is detected.

   Support for the keywords of this command varies by interface type. For more information, see *Layer 2—LAN Switching Command Reference*.

Setting the loop detection interval

About this task

With loop detection enabled, the device sends loop detection frames at the loop detection interval. A shorter interval offers more sensitive detection but consumes more resources. Consider the system performance and loop detection speed when you set the loop detection interval.

Procedure

1. Enter system view.

   system-view

2. Set the loop detection interval.

   loopback-detection interval-time *interval*

   The default setting is 30 seconds.

Setting the loop protection delay timer

Restrictions and guidelines for loop protection delay timer configuration

The global delay timer applies to all interfaces enabled with loop detection. An interface-specific delay timer applies to the interface on which it is configured. On an interface, the interface-specific delay timer takes precedence over the global delay timer.

To prevent interfaces from going down or coming up concurrently, set the loop protection delay timer to different values on different devices or on different interfaces of the same device.

Setting the global loop protection delay timer

1. Enter system view.
   `system-view`
2. Set the global loop protection delay timer.
   `loopback-detection global delay-timer` *`time`*
   By default, loop protection delay is disabled globally.

Setting the loop protection delay timer on an interface

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
3. Set the loop protection delay timer on the interface.
   `loopback-detection delay-timer` *`time`*
   By default, loop protection delay is disabled on an interface.

Display and maintenance commands for loop detection

Execute **`display`** commands in any view.

Task	Command
Display the loop detection configuration and status.	**`display loopback-detection [ loop-info ]`**

Loop detection configuration examples

Example: Configuring basic loop detection functions

Network configuration

As shown in Figure 3, configure loop detection on Device A to meet the following requirements:

- Device A generates a log as a notification.
- Device A automatically shuts down the interface on which a loop is detected.

Figure 3 Network diagram

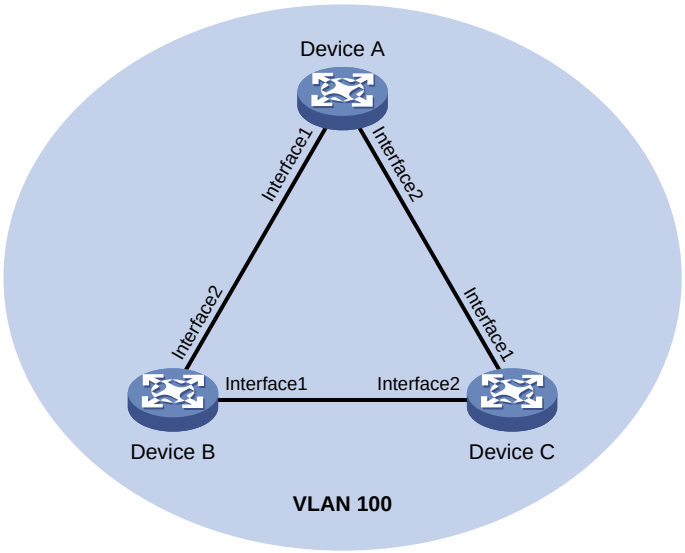

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure Device A:

   # Create VLAN 100, and globally enable loop detection for the VLAN.

   ```
   <Sysname> system-view
   [Sysname] sysname DeviceA
   [DeviceA] vlan 100
   [DeviceA-vlan100] quit
   [DeviceA] loopback-detection global enable vlan 100
   ```

   # Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 as trunk ports, and assign them to VLAN 100.

   ```
   [DeviceA] interface GigabitEthernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] port link-type trunk
   [DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 100
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 100
[DeviceA-GigabitEthernet1/0/2] quit
```

Set the global loop protection action to shutdown.

```
[DeviceA] loopback-detection global action shutdown
```

Set the loop detection interval to 35 seconds.

```
[DeviceA] loopback-detection interval-time 35
```

2. Configure Device B:

Create VLAN 100.

```
<Sysname> system-view
[Sysname] sysname DeviceB
[DeviceB] vlan 100
[DeviceB–vlan100] quit
```

Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 as trunk ports, and assign them to VLAN 100.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 100
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 100
[DeviceB-GigabitEthernet1/0/2] quit
```

3. Configure Device C:

Create VLAN 100.

```
<Sysname> system-view
[Sysname] sysname DeviceC
[DeviceC] vlan 100
[DeviceC–vlan100] quit
```

Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 as trunk ports, and assign them to VLAN 100.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 100
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 100
[DeviceC-GigabitEthernet1/0/2] quit
```

Verifying the configuration

View the system logs on devices, for example, Device A.

```
[DeviceA]
%Feb 24 15:04:29:663 2019 DeviceA LPDT/4/LPDT_LOOPED:  A loop was detected on
GigabitEthernet1/0/1.
%Feb 24 15:04:29:664 2019 DeviceA LPDT/4/LPDT_VLAN_LOOPED: A loop was detected on
GigabitEthernet1/0/1 in VLAN 100.
```

```
%Feb 24 15:04:29:667 2019 DeviceA LPDT/4/LPDT_LOOPED: A loop was detected on
GigabitEthernet1/0/2.
%Feb 24 15:04:29:668 2019 DeviceA LPDT/4/LPDT_VLAN_LOOPED: A loop was detected on
GigabitEthernet1/0/2 in VLAN 100.
%Feb 24 15:04:44:243 2019 DeviceA LPDT/5/LPDT_VLAN_RECOVERED: A loop was removed on
GigabitEthernet1/0/1 in VLAN 100.
%Feb 24 15:04:44:243 2019 DeviceA LPDT/5/LPDT_RECOVERED: All loops were removed on
GigabitEthernet1/0/1.
%Feb 24 15:04:44:248 2019 DeviceA LPDT/5/LPDT_VLAN_RECOVERED: A loop was removed on
GigabitEthernet1/0/2 in VLAN 100.
%Feb 24 15:04:44:248 2019 DeviceA LPDT/5/LPDT_RECOVERED: All loops were removed on
GigabitEthernet1/0/2.
```

The output shows the following information:

- Device A detected loops on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 within a loop detection interval.
- Loops on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 were removed.

Use the **`display loopback-detection`** command to display the loop detection configuration and status on devices, for example, Device A.

```
[DeviceA] display loopback-detection
Loop detection is enabled.
Global loop detection interval is 35 second(s).
Loop is detected on following interfaces:
  Interface                     Action mode     VLANs/VSI
  GigabitEthernet1/0/1          Shutdown        100
  GigabitEthernet1/0/2          Shutdown        100
```

The output shows that the device has removed the loops from GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 according to the shutdown action.

Display the status of GigabitEthernet 1/0/1 on devices, for example, Device A.

```
[DeviceA] display interface gigabitethernet 1/0/1
GigabitEthernet1/0/1 current state: DOWN (Loop detection down)
...
```

The output shows that GigabitEthernet 1/0/1 is already shut down by the loop detection module.

Display the status of GigabitEthernet 1/0/2 on devices, for example, Device A.

```
[DeviceA] display interface gigabitethernet 1/0/2
GigabitEthernet1/0/2 current state: DOWN (Loop detection down)
...
```

The output shows that GigabitEthernet 1/0/2 is already shut down by the loop detection module.

Configuration files

Example: Configuring loop detection for protected VLANs

Network configuration

As shown in Figure 4, configure loop detection on Device A to meet the following requirements:

- Device A generates a log as a notification.
- Device A automatically blocks a protected VLAN on an interface if a loop is detected in the VLAN on the interface.

Figure 4 Network diagram

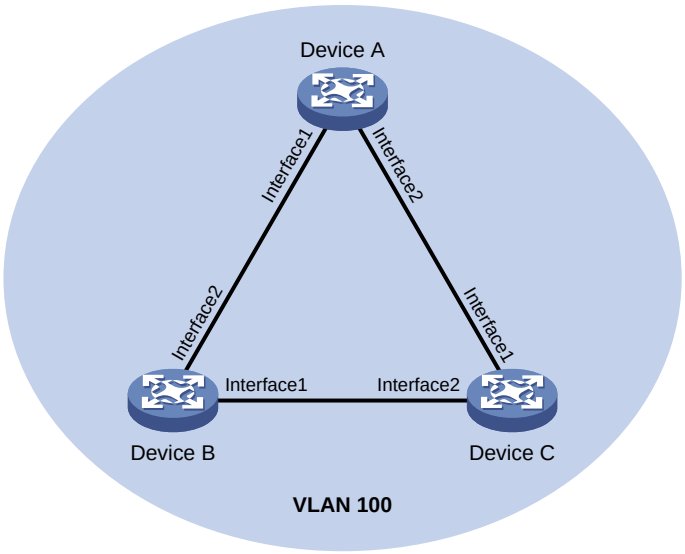

Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure Device A:

Create VLAN 100, configure it as a protected VLAN, and then globally enable loop detection for the VLAN.

```
<Sysname> system-view
[Sysname] sysname DeviceA
[DeviceA] vlan 100
[DeviceA–vlan100] quit
[DeviceA] loopback-detection protected-vlan 100
[DeviceA] loopback-detection global enable vlan 100
```

Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 as trunk ports, and assign them to VLAN 100.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 100
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 100
[DeviceA-GigabitEthernet1/0/2] quit
```

Enable VLAN-block mode on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] undo stp enable
[DeviceA-GigabitEthernet1/0/1] loopback-detection action vlan-block
```

```
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/1] undo stp enable
[DeviceA-GigabitEthernet1/0/1] loopback-detection action vlan-block
[DeviceA-GigabitEthernet1/0/1] quit
```

Set the loop detection interval to 35 seconds.

```
[DeviceA] loopback-detection interval-time 35
```

2. Configure Device B:

Create VLAN 100.

```
<Sysname> system-view
[Sysname] sysname DeviceB
[DeviceB] vlan 100
[DeviceB–vlan100] quit
```

Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 as trunk ports, and assign them to VLAN 100.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 100
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 100
[DeviceB-GigabitEthernet1/0/2] quit
```

3. Configure Device C:

Create VLAN 100.

```
<Sysname> system-view
[Sysname] sysname DeviceC
[DeviceC] vlan 100
[DeviceC–vlan100] quit
```

Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 as trunk ports, and assign them to VLAN 100.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 100
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 100
[DeviceC-GigabitEthernet1/0/2] quit
```

Verifying the configuration

View the system logs on Device A.

```
[DeviceA]
%Feb 24 15:04:29:663 2019 DeviceA LPDT/4/LPDT_LOOPED:  A loop was detected on
GigabitEthernet1/0/1.
%Feb 24 15:04:29:664 2019 DeviceA LPDT/4/LPDT_VLAN_LOOPED: A loop was detected on
GigabitEthernet1/0/1 in VLAN 100.
%Feb 24 15:04:29:667 2019 DeviceA LPDT/4/LPDT_LOOPED: A loop was detected on
GigabitEthernet1/0/2.
```

```
%Feb 24 15:04:29:668 2019 DeviceA LPDT/4/LPDT_VLAN_LOOPED: A loop was detected on
GigabitEthernet1/0/2 in VLAN 100.
```

The output shows that Device A detected loops in VLAN 100 on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 within a loop detection interval.

Use the **display loopback-detection** command to display the loop detection configuration and status on Device A.

```
[DeviceA] display loopback-detection
Loop detection is enabled.
Global loop detection interval is 35 second(s).
Loop is detected on following interfaces:
  Interface                     Action mode     VLANs/VSI
  GigabitEthernet1/0/1          VLAN-block      100
  GigabitEthernet1/0/2          VLAN-block      100
```

The output shows that the device has taken the VLAN-block action to remove the loops in VLAN 100 from GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

Configuration files

```

Example: Configuring loop detection on an M-LAG system

Network configuration

As shown in Figure 5, configure loop detection on the M-LAG system formed by Device A and Device B to meet the following requirements:

- Generates a log as a notification.
- Automatically shuts down the interface on which a loop is detected.

Figure 5 Network diagram

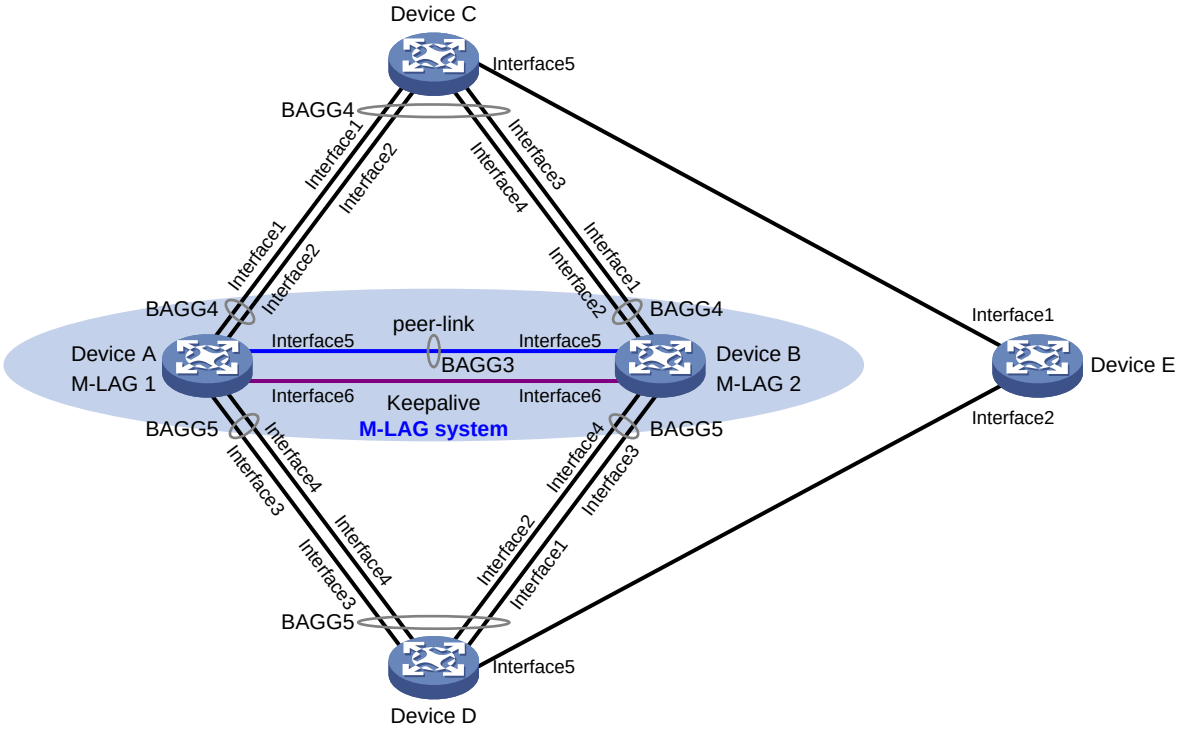

Table 4 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4
Interface5	GigabitEthernet1/0/5
Interface6	GigabitEthernet1/0/6

Hardware and feature compatibility

The S5200-EI-G switch series does not support this example.

Procedure

1. Configure Device A:

   # Create VLAN 100.

   ```
   <DeviceA> system-view
   [DeviceA] vlan 100
   [DeviceA-vlan100] quit
   ```

   # Configure M-LAG system settings.

   ```
   [DeviceA] m-lag system-mac 1-1-1
   [DeviceA] m-lag system-number 1
   [DeviceA] m-lag system-priority 123
   ```

   # Configure M-LAG keepalive packet parameters.

```
[DeviceA] m-lag keepalive ip destination 1.1.1.1 source 1.1.1.2
```

Set the link mode of GigabitEthernet 1/0/6 to Layer 3, and assign the interface an IP address. The IP address will be used as the source IP address of keepalive packets.

```
[DeviceA] interface gigabitethernet 1/0/6
[DeviceA-GigabitEthernet1/0/6] port link-mode route
[DeviceA-GigabitEthernet1/0/6] ip address 1.1.1.2 24
[DeviceA-GigabitEthernet1/0/6] quit
```

Exclude the interface used for M-LAG keepalive detection (GigabitEthernet 1/0/6) from the shutdown action by M-LAG MAD.

```
[DeviceA] drni m-lag exclude interface gigabitethernet 1/0/6
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 3, and specify it as the M-LAG peer-link interface.

```
[DeviceA] interface bridge-aggregation 3
[DeviceA-Bridge-Aggregation3] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation3] port m-lag peer-link 1
[DeviceA-Bridge-Aggregation3] quit
```

Assign GigabitEthernet 1/0/5 to aggregation group 3.

```
[DeviceA] interface gigabitethernet 1/0/5
[DeviceA-GigabitEthernet1/0/5] port link-aggregation group 3
[DeviceA-GigabitEthernet1/0/5] quit
```

Set the link type of Bridge-Aggregation 3 to trunk, and assign it to VLAN 100.

```
[DeviceA] interface bridge-aggregation 3
[DeviceA-Bridge-Aggregation3] port link-type trunk
[DeviceA-Bridge-Aggregation3] port trunk permit vlan 100
[DeviceA-Bridge-Aggregation3] quit
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 4, and assign it to M-LAG group 4.

```
[DeviceA] interface bridge-aggregation 4
[DeviceA-Bridge-Aggregation4] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation4] port m-lag group 4
[DeviceA-Bridge-Aggregation4] quit
```

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to aggregation group 4.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-aggregation group 4
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-aggregation group 4
[DeviceA-GigabitEthernet1/0/2] quit
```

Set the link type of Bridge-Aggregation 4 to trunk, and assign it to VLAN 100.

```
[DeviceA] interface bridge-aggregation 4
[DeviceA-Bridge-Aggregation4] port link-type trunk
[DeviceA-Bridge-Aggregation4] port trunk permit vlan 100
[DeviceA-Bridge-Aggregation4] quit
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 5, and assign it to M-LAG group 5.

```
[DeviceA] interface bridge-aggregation 5
[DeviceA-Bridge-Aggregation5] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation5] port m-lag group 5
```

```
[DeviceA-Bridge-Aggregation5] quit
```

Assign GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 to aggregation group 5.

```
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] port link-aggregation group 5
[DeviceA-GigabitEthernet1/0/3] quit
[DeviceA] interface gigabitethernet 1/0/4
[DeviceA-GigabitEthernet1/0/4] port link-aggregation group 5
[DeviceA-GigabitEthernet1/0/4] quit
```

Set the link type of Bridge-Aggregation 5 to trunk, and assign it to VLAN 100.

```
[DeviceA] interface bridge-aggregation 5
[DeviceA-Bridge-Aggregation5] port link-type trunk
[DeviceA-Bridge-Aggregation5] port trunk permit vlan 100
[DeviceA-Bridge-Aggregation5] quit
```

Disable the spanning tree feature.

```
[DeviceA] undo stp global enable
```

Enable loop detection for VLAN 100 globally, set the global loop protection action to shutdown, and set the loop detection interval to 35 seconds.

```
[DeviceA] loopback-detection global enable vlan 100
[DeviceA] loopback-detection global action shutdown
[DeviceA] loopback-detection interval-time 35
```

2. Configure Device B in the same way Device A is configured. Set the M-LAG system number to 2, and set the source and destination IP addresses of keepalive packets to 1.1.1.1 and 1.1.1.2, respectively. (Details not shown.)

3. Configure Device C:

Disable the spanning tree feature.

```
<DeviceC> system-view
[DeviceC] undo stp global enable
```

Create VLAN 100.

```
[DeviceC] vlan 100
[DeviceC-vlan100] quit
```

Create Layer 2 dynamic aggregate interface Bridge-Aggregation 4.

```
[DeviceC] interface bridge-aggregation 4
[DeviceC-Bridge-Aggregation4] link-aggregation mode dynamic
[DeviceC-Bridge-Aggregation4] quit
```

Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to aggregation group 4.

```
[DeviceC] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/4
[DeviceC-if-range] port link-aggregation group 4
[DeviceC-if-range] quit
```

Set the link type of Bridge-Aggregation 4 to trunk, and assign it to VLAN 100.

```
[DeviceC] interface bridge-aggregation 4
[DeviceC-Bridge-Aggregation4] port link-type trunk
[DeviceC-Bridge-Aggregation4] port trunk permit vlan 100
[DeviceC-Bridge-Aggregation4] quit
```

Set the link type of GigabitEthernet 1/0/5 to trunk, and assign it to VLAN 100.

```
[DeviceC] interface gigabitethernet 1/0/5
[DeviceC-GigabitEthernet1/0/5] port link-type trunk
[DeviceC-GigabitEthernet1/0/5] port trunk permit vlan 100
[DeviceC-GigabitEthernet1/0/5] quit
```

4. Configure Device D:

   # Disable the spanning tree feature.

```
<DeviceD> system-view
[DeviceD] undo stp global enable
```

   # Create VLAN 100.

```
[DeviceD] vlan 100
[DeviceD-vlan100] quit
```

   # Create Layer 2 dynamic aggregate interface Bridge-Aggregation 5.

```
[DeviceD] interface bridge-aggregation 5
[DeviceD-Bridge-Aggregation5] link-aggregation mode dynamic
[DeviceD-Bridge-Aggregation5] quit
```

   # Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to aggregation group 5.

```
[DeviceD] interface range gigabitethernet 1/0/1 to gigabitethernet 1/0/4
[DeviceD-if-range] port link-aggregation group 5
[DeviceD-if-range] quit
```

   # Set the link type of Bridge-Aggregation 5 to trunk, and assign it to VLAN 100.

```
[DeviceD] interface bridge-aggregation 5
[DeviceD-Bridge-Aggregation5] port link-type trunk
[DeviceD-Bridge-Aggregation5] port trunk permit vlan 100
[DeviceD-Bridge-Aggregation5] quit
```

   # Set the link type of GigabitEthernet 1/0/5 to trunk, and assign it to VLAN 100.

```
[DeviceD] interface gigabitethernet 1/0/5
[DeviceD-GigabitEthernet1/0/5] port link-type trunk
[DeviceD-GigabitEthernet1/0/5] port trunk permit vlan 100
[DeviceD-GigabitEthernet1/0/5] quit
```

5. Configure Device E:

   # Disable the spanning tree feature.

```
<DeviceE> system-view
[DeviceE] undo stp global enable
```

   # Create VLAN 100.

```
[DeviceE] vlan 100
[DeviceE-vlan100] quit
```

   # Set the link type of GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to trunk, and assign them to VLAN 100.

```
[DeviceE] interface gigabitethernet 1/0/1
[DeviceE-GigabitEthernet1/0/1] port link-type trunk
[DeviceE-GigabitEthernet1/0/1] port trunk permit vlan 100
[DeviceE-GigabitEthernet1/0/1] quit
[DeviceE] interface gigabitethernet 1/0/2
[DeviceE-GigabitEthernet1/0/2] port link-type trunk
[DeviceE-GigabitEthernet1/0/2] port trunk permit vlan 100
[DeviceE-GigabitEthernet1/0/2] quit
```

Verifying the configuration

View the system logs on Device A.

```
[DeviceA]
%Aug  1 03:28:48:110 2019 DeviceA LPDT/4/LPDT_LOOPED: A loop was detected on
 Bridge-Aggregation4.
```

```
%Aug  1 03:28:48:191 2019 DeviceA LPDT/4/LPDT_VLAN_LOOPED: A loop was detect
ed on Bridge-Aggregation4 in VLAN 100.
%Aug  1 03:28:48:194 2019 DeviceA LPDT/4/LPDT_LOOPED: A loop was detected on
 Bridge-Aggregation5.
%Aug  1 03:28:48:288 2019 DeviceA LPDT/4/LPDT_VLAN_LOOPED: A loop was detect
ed on Bridge-Aggregation5 in VLAN 100.
%Aug  1 03:28:48:290 2019 DeviceA LPDT/5/LPDT_VLAN_RECOVERED: A loop was rem
oved on Bridge-Aggregation4 in VLAN 100.
%Aug  1 03:28:48:291 2019 DeviceA LPDT/5/LPDT_RECOVERED: All loops were remo
ved on Bridge-Aggregation4.
%Aug  1 03:28:48:302 2019 DeviceA LPDT/5/LPDT_VLAN_RECOVERED: A loop was rem
oved on Bridge-Aggregation5 in VLAN 100.
%Aug  1 03:28:48:304 2019 DeviceA LPDT/5/LPDT_RECOVERED: All loops were remo
ved on Bridge-Aggregation5.
```

The output shows the following information:

- Device A detected loops on Bridge-Aggregation 4 and Bridge-Aggregation 5 within a loop detection interval.
- Loops on Bridge-Aggregation 4 and Bridge-Aggregation 5 were removed.

Use the **`display loopback-detection`** command to display the loop detection configuration and status on Device A.

```
[DeviceA] display loopback-detection
Loop detection is enabled.
Global loop detection interval is 35 second(s).
Loop is detected on following interfaces:
  Interface                     Action mode     VLANs/VSI
  Bridge-Aggregation4           Shutdown        100
  Bridge-Aggregation5           Shutdown        100
```

The output shows that the device has removed the loops from Bridge-Aggregation 4 and Bridge-Aggregation 5 according to the shutdown action.

Verify that Bridge-Aggregation 4 has been shut down by loop detection.

```
[DeviceA] display interface Bridge-Aggregation 4
Bridge-Aggregation4
The interface has assigned a M-LAG group.
Current state: DOWN (Loopback detection down)
…
```

Verify that Bridge-Aggregation 5 has been shut down by loop detection.

```
[DeviceA] display interface Bridge-Aggregation 5
Bridge-Aggregation5
The interface has assigned a M-LAG group.
Current state: DOWN (Loopback detection down)
…
```

Verify that loops have been removed on Device B. (Details not shown.)

Spanning tree protocol overview

Spanning tree protocols eliminate loops in a physical link-redundant network by selectively blocking redundant links and putting them in a standby state.

The recent versions of STP include the Rapid Spanning Tree Protocol (RSTP), the Per-VLAN Spanning Tree (PVST), and the Multiple Spanning Tree Protocol (MSTP).

About STP

STP was developed based on the 802.1d standard of IEEE to eliminate loops at the data link layer in a LAN. Networks often have redundant links as backups in case of failures, but loops are a very serious problem. Devices running STP detect loops in the network by exchanging information with one another. They eliminate loops by selectively blocking certain ports to prune the loop structure into a loop-free tree structure. This avoids proliferation and infinite cycling of packets that would occur in a loop network.

In a narrow sense, STP refers to IEEE 802.1d STP. In a broad sense, STP refers to the IEEE 802.1d STP and various enhanced spanning tree protocols derived from that protocol.

STP protocol frames

STP uses bridge protocol data units (BPDUs), also known as configuration messages, as its protocol frames. This chapter uses BPDUs to represent all types of spanning tree protocol frames.

STP-enabled devices exchange BPDUs to establish a spanning tree. BPDUs contain sufficient information for the devices to complete spanning tree calculation.

STP uses two types of BPDUs, configuration BPDUs and topology change notification (TCN) BPDUs.

Configuration BPDUs

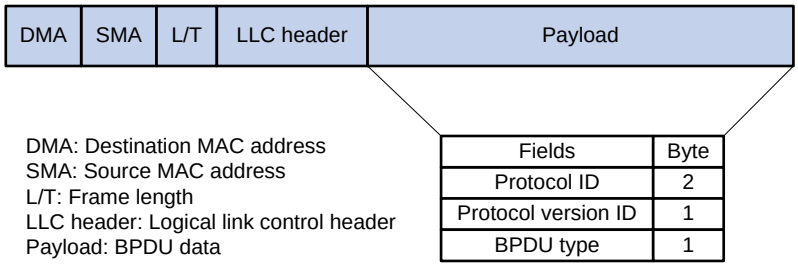
Devices exchange configuration BPDUs to elect the root bridge and determine port roles. Figure 1 shows the configuration BPDU format.

Figure 1 Configuration BPDU format

DMA: Destination MAC address
SMA: Source MAC address
L/T: Frame length
LLC header: Logical link control header
Payload: BPDU data

Fields	Byte
Protocol ID	2
Protocol version ID	1
BPDU type	1
Flags	1
Root ID	8
Root path cost	4
Bridge ID	8
Port ID	2
Message age	2
Max age	2
Hello time	2
Forward delay	2

The payload of a configuration BPDU includes the following fields:



- **Protocol ID**—Fixed at 0x0000, which represents IEEE 802.1d.
- **Protocol version ID**—Spanning tree protocol version ID. The protocol version ID for STP is 0x00.
- **BPDU type**—Type of the BPDU. The value is 0x00 for a configuration BPDU.
- **Flags**—An 8-bit field indicates the purpose of the BPDU. The lowest bit is the Topology Change (TC) flag. The highest bit is the Topology Change Acknowledge (TCA) flag. All other bits are reserved.
- **Root ID**—Root bridge ID formed by the priority and MAC address of the root bridge.
- **Root path cost**—Cost of the path to the root bridge.
- **Bridge ID**—Designated bridge ID formed by the priority and MAC address of the designated bridge.
- **Port ID**—Designated port ID formed by the priority and global port number of the designated port.
- **Message age**—Age of the configuration BPDU while it propagates in the network.
- **Max age**—Maximum age of the configuration BPDU stored on the switch.
- **Hello time**—Configuration BPDU transmission interval.
- **Forward delay**—Delay for STP bridges to transit port state.

Devices use the root bridge ID, root path cost, designated bridge ID, designated port ID, message age, max age, hello time, and forward delay for spanning tree calculation.

TCN BPDUs

Devices use TCN BPDUs to announce changes in the network topology. Figure 2 shows the TCN BPDU format.

Figure 2 TCN BPDU format

The payload of a TCN BPDU includes the following fields:

- **Protocol ID**—Fixed at 0x0000, which represents IEEE 802.1d.
- **Protocol version ID**—Spanning tree protocol version ID. The protocol version ID for STP is 0x00.
- **BPDU type**—Type of the BPDU. The value is 0x80 for a TCN BPDU.

A non-root bridge sends TCN BPDUs when one of the following events occurs on the bridge:

- A port transits to the forwarding state, and the bridge has a minimum of one designated port.
- A port transits from the forwarding or learning state to the blocking state.

The non-root bridge uses TCN BPDUs to notify the root bridge once the network topology changes. The root bridge then sets the TC flag in its configuration BPDU and propagates it to other bridges.

Basic concepts in STP

Root bridge

A tree network must have a root bridge. The entire network contains only one root bridge, and all the other bridges in the network are called leaf nodes. The root bridge is not permanent, but can change with changes of the network topology.

Upon initialization of a network, each device generates and periodically sends configuration BPDUs, with itself as the root bridge. After network convergence, only the root bridge generates and periodically sends configuration BPDUs. The other devices only forward the BPDUs.

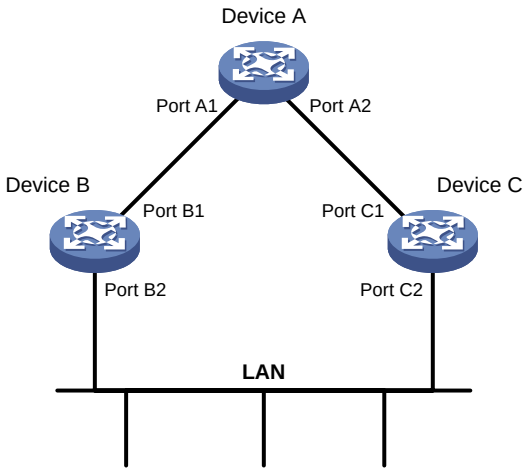
Root port

On a non-root bridge, the port nearest to the root bridge is the root port. The root port communicates with the root bridge. Each non-root bridge has only one root port. The root bridge has no root port.

Designated bridge and designated port

Classification	Designated bridge	Designated port
For a device	Device directly connected to the local device and responsible for forwarding BPDUs to the local device.	Port through which the designated bridge forwards BPDUs to this device.
For a LAN	Device responsible for forwarding BPDUs to this LAN segment.	Port through which the designated bridge forwards BPDUs to this LAN segment.

As shown in Figure 3, Device B and Device C are directly connected to a LAN.



If Device A forwards BPDUs to Device B through port A1, the designated bridge and designated port are as follows:

- The designated bridge for Device B is Device A.
- The designated port for Device B is port A1 on Device A.

If Device B forwards BPDUs to the LAN, the designated bridge and designated port are as follows:

- The designated bridge for the LAN is Device B.
- The designated port for the LAN is port B2 on Device B.

Figure 3 Designated bridges and designated ports

Port states

Table 1 lists the port states in STP.

Table 1 STP port states

State	Receives/sends BPDUs	Learns MAC addresses	Forwards user data
Disabled	No	No	No
Listening	Yes	No	No
Learning	Yes	Yes	No
Forwarding	Yes	Yes	Yes
Blocking	Receive	No	No

Path cost

Path cost is a reference value used for link selection in STP. To prune the network into a loop-free tree, STP calculates path costs to select the most robust links and block redundant links that are less robust.

Calculation process of the STP algorithm

In STP calculation, a device compares the priorities of the received configuration BPDUs from different ports, and elects the root bridge, root ports and designated ports. When the spanning tree calculation is completed, a tree-shape topology forms.

The spanning tree calculation process described in the following sections is an example of a simplified process.

Network initialization

Upon initialization of a device, each port generates a BPDU with the following contents:

- The port as the designated port.
- The device as the root bridge.
- 0 as the root path cost.
- The device ID as the designated bridge ID.

Root bridge selection

The root bridge can be selected in the following methods:

- **Automatic election**—Initially, each STP-enabled device on the network assumes itself to be the root bridge, with its own device ID as the root bridge ID. By exchanging configuration BPDUs, the devices compare their root bridge IDs to elect the device with the smallest root bridge ID as the root bridge.
- **Manual assignment**—You can configure a device as the root bridge or a secondary root bridge of a spanning tree.
  - A spanning tree can have only one root bridge. If you configure multiple devices as the root bridge for a spanning tree, the device with the lowest MAC address is selected.
  - You can configure one or multiple secondary root bridges for a spanning tree. When the root bridge fails or is shut down, a secondary root bridge can take over. If multiple secondary root bridges are configured, the one with the lowest MAC address is selected. However, if a new root bridge is configured, the secondary root bridge is not selected.

Root port and designated ports selection on the non-root bridges

Step	Description
1	A non-root-bridge device regards the port on which it received the optimum configuration BPDU as the root port. Table 2 describes how the optimum configuration BPDU is selected.

Step	Description
2	Based on the configuration BPDU and the path cost of the root port, the device calculates a designated port configuration BPDU for each of the other ports. • The root bridge ID is replaced with that of the configuration BPDU of the root port. • The root path cost is replaced with that of the configuration BPDU of the root port plus the path cost of the root port. • The designated bridge ID is replaced with the ID of this device. • The designated port ID is replaced with the ID of this port.
3	The device compares the calculated configuration BPDU with the configuration BPDU on the port whose port role will be determined. Then, the device acts depending on the result of the comparison: • If the calculated configuration BPDU is superior, the device performs the following operations: ○ Considers this port as the designated port. ○ Replaces the configuration BPDU on the port with the calculated configuration BPDU. ○ Periodically sends the calculated configuration BPDU. • If the configuration BPDU on the port is superior, the device blocks this port without updating its configuration BPDU. The blocked port can receive BPDUs, but cannot send BPDUs or forward data traffic.

When the network topology is stable, only the root port and designated ports forward user traffic. Other ports are all in the blocking state to receive BPDUs but not to forward BPDUs or user traffic.

Table 2 Selecting the optimum configuration BPDU

Step	Actions
1	Upon receiving a configuration BPDU on a port, the device compares the priority of the received configuration BPDU with that of the configuration BPDU generated by the port. • If the former priority is lower, the device discards the received configuration BPDU and keeps the configuration BPDU the port generated. • If the former priority is higher, the device replaces the content of the configuration BPDU generated by the port with the content of the received configuration BPDU.
2	The device compares the configuration BPDUs of all the ports and chooses the optimum configuration BPDU.

The following are the principles of configuration BPDU comparison:

1. The configuration BPDU with the lowest root bridge ID has the highest priority.
2. If configuration BPDUs have the same root bridge ID, their root path costs are compared. For example, the root path cost in a configuration BPDU plus the path cost of a receiving port is S. The configuration BPDU with the smallest S value has the highest priority.
3. If all configuration BPDUs have the same root bridge ID and S value, the following attributes are compared in sequence:
   a. Designated bridge IDs.
   b. Designated port IDs.
   c. IDs of the receiving ports.

   The configuration BPDU that contains a smaller designated bridge ID, designated port ID, or receiving port ID is selected.

A tree-shape topology forms when the root bridge, root ports, and designated ports are selected.

Example of STP calculation

Figure 4 provides an example showing how the STP algorithm works.

Figure 4 The STP algorithm

As shown in Figure 4, the priority values of Device A, Device B, and Device C are 0, 1, and 2, respectively. The path costs of links among the three devices are 5, 10, and 4.

Device state initialization

In Table 3, each configuration BPDU contains the following fields: root bridge ID, root path cost, designated bridge ID, and designated port ID.

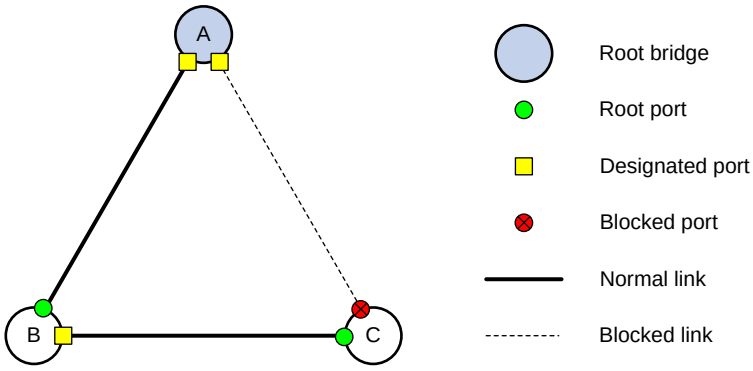
Table 3 Initial state of each device

Device	Port name	Configuration BPDU on the port
Device A	Port A1	{0, 0, 0, Port A1}
	Port A2	{0, 0, 0, Port A2}
Device B	Port B1	{1, 0, 1, Port B1}
	Port B2	{1, 0, 1, Port B2}
Device C	Port C1	{2, 0, 2, Port C1}
	Port C2	{2, 0, 2, Port C2}

Configuration BPDUs comparison on each device

In Table 4, each configuration BPDU contains the following fields: root bridge ID, root path cost, designated bridge ID, and designated port ID.

Table 4 Comparison process and result on each device



Device	Comparison process	Configuration BPDU on ports after comparison
Device A	Port A1 performs the following operations: **1.** Receives the configuration BPDU of Port B1 {1, 0, 1, Port B1}. **2.** Determines that its existing configuration BPDU {0, 0, 0, Port A1} is superior to the received configuration BPDU. **3.** Discards the received one. Port A2 performs the following operations: **4.** Receives the configuration BPDU of Port C1 {2, 0, 2, Port C1}. **5.** Determines that its existing configuration BPDU {0, 0, 0, Port A2} is superior to the received configuration BPDU. **6.** Discards the received one. Device A determines that it is both the root bridge and designated bridge in the configuration BPDUs of all its ports. It considers itself as the root bridge. It does not change the configuration BPDU of any port and starts to periodically send configuration BPDUs.	• Port A1: {0, 0, 0, Port A1} • Port A2: {0, 0, 0, Port A2}
Device B	Port B1 performs the following operations: **7.** Receives the configuration BPDU of Port A1 {0, 0, 0, Port A1}. **8.** Determines that the received configuration BPDU is superior to its existing configuration BPDU {1, 0, 1, Port B1}. **9.** Updates its configuration BPDU. Port B2 performs the following operations: **10.** Receives the configuration BPDU of Port C2 {2, 0, 2, Port C2}. **11.** Determines that its existing configuration BPDU {1, 0, 1, Port B2} is superior to the received configuration BPDU. **12.** Discards the received BPDU.	• Port B1: {0, 0, 0, Port A1} • Port B2: {1, 0, 1, Port B2}
	Device B performs the following operations: **13.** Compares the configuration BPDUs of all its ports. **14.** Decides that the configuration BPDU of Port B1 is the optimum. **15.** Selects Port B1 as the root port with the configuration BPDU unchanged. Based on the configuration BPDU and path cost of the root port, Device B calculates a designated port configuration BPDU for Port B2 {0, 5, 1, Port B2}. Device B compares it with the existing configuration BPDU of Port B2 {1, 0, 1, Port B2}. Device B determines that the calculated one is superior, and determines that Port B2 is the designated port. It replaces the configuration BPDU on Port B2 with the calculated one, and periodically sends the calculated configuration BPDU.	• Root port (Port B1): {0, 0, 0, Port A1} • Designated port (Port B2): {0, 5, 1, Port B2}
Device C	Port C1 performs the following operations: **16.** Receives the configuration BPDU of Port A2 {0, 0, 0, Port A2}. **17.** Determines that the received configuration BPDU is superior to its existing configuration BPDU {2, 0, 2,	• Port C1: {0, 0, 0, Port A2} • Port C2: {1, 0, 1, Port B2}

	Port C1}. **18.** Updates its configuration BPDU. Port C2 performs the following operations: **19.** Receives the original configuration BPDU of Port B2 {1, 0, 1, Port B2}. **20.** Determines that the received configuration BPDU is superior to the existing configuration BPDU {2, 0, 2, Port C2}. **21.** Updates its configuration BPDU.	
	Device C performs the following operations: **22.** Compares the configuration BPDUs of all its ports. **23.** Decides that the configuration BPDU of Port C1 is the optimum. **24.** Selects Port C1 as the root port with the configuration BPDU unchanged. Based on the configuration BPDU and path cost of the root port, Device C calculates the configuration BPDU of Port C2 {0, 10, 2, Port C2}. Device C compares it with the existing configuration BPDU of Port C2 {1, 0, 1, Port B2}. Device C determines that the calculated configuration BPDU is superior to the existing one, selects Port C2 as the designated port, and replaces the configuration BPDU of Port C2 with the calculated one.	• Root port (Port C1): {0, 0, 0, Port A2} • Designated port (Port C2): {0, 10, 2, Port C2}
	Port C2 performs the following operations: **25.** Receives the updated configuration BPDU of Port B2 {0, 5, 1, Port B2}. **26.** Determines that the received configuration BPDU is superior to its existing configuration BPDU {0, 10, 2, Port C2}. **27.** Updates its configuration BPDU. Port C1 performs the following operations: **28.** Receives a periodic configuration BPDU {0, 0, 0, Port A2} from Port A2. **29.** Determines that it is the same as the existing configuration BPDU. **30.** Discards the received BPDU.	• Port C1: {0, 0, 0, Port A2} • Port C2: {0, 5, 1, Port B2}
	Device C determines that the root path cost of Port C1 is larger than that of Port C2. The root path cost of Port C1 is 10, root path cost of the received configuration BPDU (0) plus path cost of Port C1 (10). The root path cost of Port C2 is 9, root path cost of the received configuration BPDU (5) plus path cost of Port C2 (4). Device C determines that the configuration BPDU of Port C2 is the optimum, and selects Port C2 as the root port with the configuration BPDU unchanged. Based on the configuration BPDU and path cost of the root port, Device C performs the following operations: **31.** Calculates a designated port configuration BPDU for Port C1 {0, 9, 2, Port C1}. **32.** Compares it with the existing configuration BPDU of Port C1 {0, 0, 0, Port A2}. **33.** Determines that the existing configuration BPDU is superior to the calculated one and blocks Port C1 with the configuration BPDU unchanged. Port C1 does not forward data until a new event triggers a spanning tree calculation process: for example, the link between Device B and Device C is down.	• Blocked port (Port C1): {0, 0, 0, Port A2} • Root port (Port C2): {0, 5, 1, Port B2}

Final calculated spanning tree

After the comparison processes described in Table 4, a spanning tree with Device A as the root bridge is established, as shown in Figure 5.

Figure 5 The final calculated spanning tree

The configuration BPDU forwarding mechanism of STP

The configuration BPDUs of STP are forwarded according to these guidelines:

- Upon network initiation, every device regards itself as the root bridge and generates configuration BPDUs with itself as the root. Then it sends the configuration BPDUs at a regular hello interval.
- If the root port receives a configuration BPDU superior to the configuration BPDU of the port, the device performs the following operations:
  - Increases the message age carried in the configuration BPDU.
  - Starts a timer to time the configuration BPDU.
  - Sends this configuration BPDU through the designated port.
- If a designated port receives a configuration BPDU with a lower priority than its configuration BPDU, the port immediately responds with its configuration BPDU.
- If a path fails, the root port on this path no longer receives new configuration BPDUs and the old configuration BPDUs will be discarded due to timeout. The device generates a configuration BPDU with itself as the root and sends the BPDUs and TCN BPDUs. This triggers a new spanning tree calculation process to establish a new path to restore the network connectivity.

However, the newly calculated configuration BPDU cannot be propagated throughout the network immediately. As a result, the old root ports and designated ports that have not detected the topology change continue forwarding data along the old path. If the new root ports and designated ports begin to forward data as soon as they are elected, a temporary loop might occur.

STP timers

The most important timing parameters in STP calculation are forward delay, hello time, and max age.

- Forward delay

  Forward delay is the delay time for port state transition. By default, the forward delay is 15 seconds.

  A path failure can cause spanning tree re-calculation to adapt the spanning tree structure to the change. However, the resulting new configuration BPDU cannot propagate throughout the network immediately. If the newly elected root ports and designated ports start to forward data immediately, a temporary loop will likely occur.

The newly elected root ports or designated ports must go through the listening and learning states before they transit to the forwarding state. This requires twice the forward delay time and allows the new configuration BPDU to propagate throughout the network.

- Hello time

  The device sends configuration BPDUs at the hello time interval to the neighboring devices to ensure that the paths are fault-free. By default, the hello time is 2 seconds. If the device does not receive configuration BPDUs within the timeout period, it recalculates the spanning tree. The formula for calculating the timeout period is timeout period = timeout factor × 3 × hello time.

- Max age

  The device uses the max age to determine whether a stored configuration BPDU has expired and discards it if the max age is exceeded. By default, the max age is 20 seconds. In the CIST of an MSTP network, the device uses the max age timer to determine whether a configuration BPDU received by a port has expired. If it is expired, a new spanning tree calculation process starts. The max age timer does not take effect on MSTIs.

If a port does not receive any configuration BPDUs within the timeout period, the port transits to the listening state. The device will recalculate the spanning tree. It takes the port 50 seconds to transit back to the forwarding state. This period includes 20 seconds for the max age, 15 seconds for the listening state, and 15 seconds for the learning state.

To ensure a fast topology convergence, make sure the timer settings meet the following formulas:

- 2 × (forward delay – 1 second) ≥ max age
- Max age ≥ 2 × (hello time + 1 second)

About RSTP

RSTP achieves rapid network convergence by allowing a newly elected root port or designated port to enter the forwarding state much faster than STP.

RSTP protocol frames

An RSTP BPDU uses the same format as an STP BPDU except that a Version1 length field is added to the payload of RSTP BPDUs. The differences between an RSTP BPDU and an STP BPDU are as follows:

- **Protocol version ID**—The value is 0x02 for RSTP.
- **BPDU type**—The value is 0x02 for RSTP BPDUs.
- **Flags**—All 8 bits are used.
- **Version1 length**—The value is 0x00, which means no version 1 protocol information is present.

RSTP does not use TCN BPDUs to advertise topology changes. RSTP floods BPDUs with the TC flag set in the network to advertise topology changes.

Basic concepts in RSTP

Port roles

In addition to root port and designated port, RSTP also uses the following port roles:

- **Alternate port**—Acts as the backup port for a root port. When the root port is blocked, the alternate port takes over.
- **Backup port**—Acts as the backup port of a designated port. When the designated port is invalid, the backup port becomes the new designated port. A loop occurs when two ports of the

same spanning tree device are connected, so the device blocks one of the ports. The blocked port is the backup port.

- **Edge port**—Directly connects to a user host rather than a network device or network segment.

Port states

RSTP uses the discarding state to replace the disabled, blocking, and listening states in STP. Table 5 shows the differences between the port states in RSTP and STP.

Table 5 Port state differences between RSTP and STP

STP port state	RSTP port state	Sends BPDU	Learns MAC addresses	Forwards user data
Disabled	Discarding	No	No	No
Blocking	Discarding	No	No	No
Listening	Discarding	Yes	No	No
Learning	Learning	Yes	Yes	No
Forwarding	Forwarding	Yes	Yes	Yes

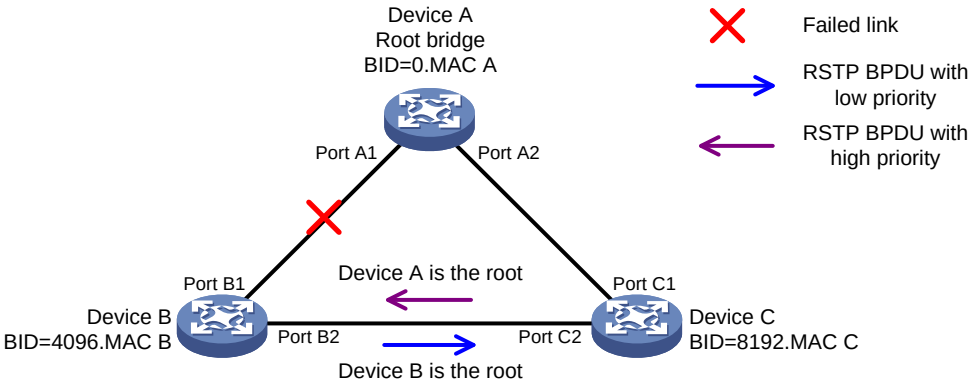
How RSTP works

During RSTP calculation, the following events occur:

- If a port in discarding state becomes an alternate port, it retains its state.
- If a port in discarding state is elected as the root port or designated port, it enters the learning state after the forward delay. The port learns MAC addresses, and enters the forwarding state after another forward delay.
  - A newly elected RSTP root port rapidly enters the forwarding state if the following requirements are met:
    - The old root port on the device has stopped forwarding data.
    - The upstream designated port has started forwarding data.
  - A newly elected RSTP designated port rapidly enters the forwarding state if one of the following requirements is met:
    - The designated port is configured as an edge port which directly connects to a user terminal.
    - The designated port connects to a point-to-point link and receives a handshake response from the directly connected device.

RSTP BPDU processing

In RSTP, a non-root bridge actively sends RSTP BPDUs at the hello time through designated ports without waiting for the root bridge to send RSTP BPDUs. This enables RSTP to quickly detect link failures. If a device fails to receive any RSTP BPDUs on a port within triple the hello time, the device considers that a link failure has occurred. After the stored configuration BPDU expires, the device floods RSTP BPDUs with the TC flag set to initiate a new RSTP calculation.



In RSTP, a port in blocking state can immediately respond to an RSTP BPDU with a lower priority than its own BPDU.

As shown in Figure 6, Device A is the root bridge. The priority of Device B is higher than the priority of Device C. Port C2 on Device C is blocked.

When the link between Device A and Device B fails, the following events occur:

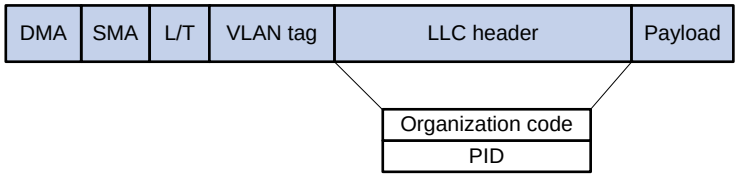
1. Device B sends an RSTP BPDU with itself as the root bridge to Device C.
2. Device C compares the RSTP BPDU with its own BPDU.
3. Because the RSTP BPDU from Device B has a lower priority, Device C sends its own BPDU to Device B.
4. Device B considers that Port B2 is the root port and stops sending RSTP BPDUs to Device C.

Figure 6 BPDU processing in RSTP

About PVST

In an STP- or RSTP-enabled LAN, all bridges share one spanning tree. Traffic from all VLANs is forwarded along the spanning tree, and ports cannot be blocked on a per-VLAN basis to prune loops.

PVST allows every VLAN to have its own spanning tree, which increases usage of links and bandwidth. Because each VLAN runs RSTP independently, a spanning tree only serves its VLAN.



A PVST-enabled H3C device can communicate with a third-party device that is running Rapid PVST or PVST. The PVST-enabled H3C device supports fast network convergence like RSTP when connected to PVST-enabled H3C devices or third-party devices enabled with Rapid PVST.

PVST protocol frames

As shown in Figure 7, a PVST BPDU uses the same format as an RSTP BPDU except the following differences:

- The destination MAC address of a PVST BPDU is 01-00-0c-cc-cc-cd, which is a private MAC address.
- Each PVST BPDU carries a VLAN tag. The VLAN tag identifies the VLAN to which the PVST BPDU belongs.
- The organization code and PID fields are added to the LLC header of the PVST BPDU.

Figure 7 PVST BPDU format

A port's link type determines the type of BPDUs the port sends.

- An access port sends RSTP BPDUs.

- A trunk or hybrid port sends RSTP BPDUs in the default VLAN and sends PVST BPDUs in other VLANs.

How PVST works

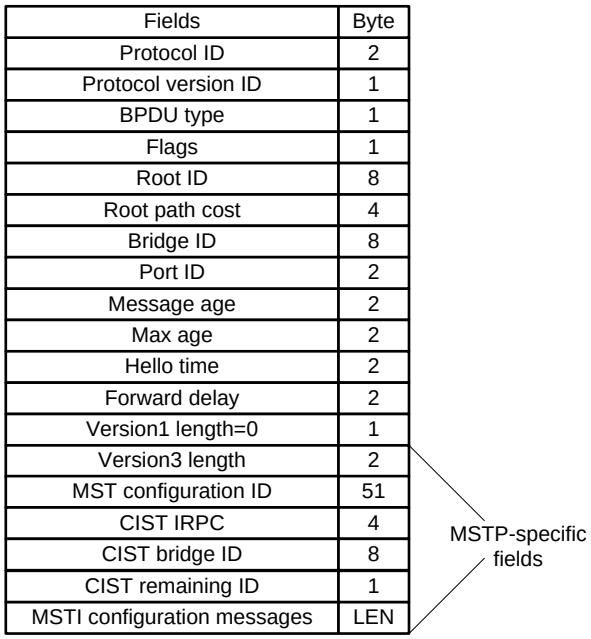
PVST implements per-VLAN spanning tree calculation by mapping each VLAN to an MSTI. In PVST, each VLAN runs RSTP independently to maintain its own spanning tree without affecting the spanning trees of other VLANs. In this way, loops in each VLAN are eliminated and traffic of different VLANs is load shared over links. PVST uses RSTP BPDUs in the default VLAN and PVST BPDUs in other VLANs for spanning tree calculation.

PVST uses the same port roles and port states as RSTP for rapid transition. For more information, see "Basic concepts in RSTP."

About MSTP

MSTP features

Developed based on IEEE 802.1s, MSTP overcomes the limitations of STP, RSTP, and PVST. In addition to supporting rapid network convergence, it allows data flows of different VLANs to be forwarded along separate paths. This provides a better load sharing mechanism for redundant links.



MSTP provides the following features:

- MSTP divides a switched network into multiple regions, each of which contains multiple spanning trees that are independent of one another.
- MSTP supports mapping VLANs to spanning tree instances by means of a VLAN-to-instance mapping table. MSTP can reduce communication overheads and resource usage by mapping multiple VLANs to one instance.
- MSTP prunes a loop network into a loop-free tree, which avoids proliferation and endless cycling of frames in a loop network. In addition, it supports load balancing of VLAN data by providing multiple redundant paths for data forwarding.
- MSTP is compatible with STP and RSTP, and partially compatible with PVST.

MSTP protocol frames

Figure 8 shows the format of an MSTP BPDU.

Figure 8 MSTP BPDU format

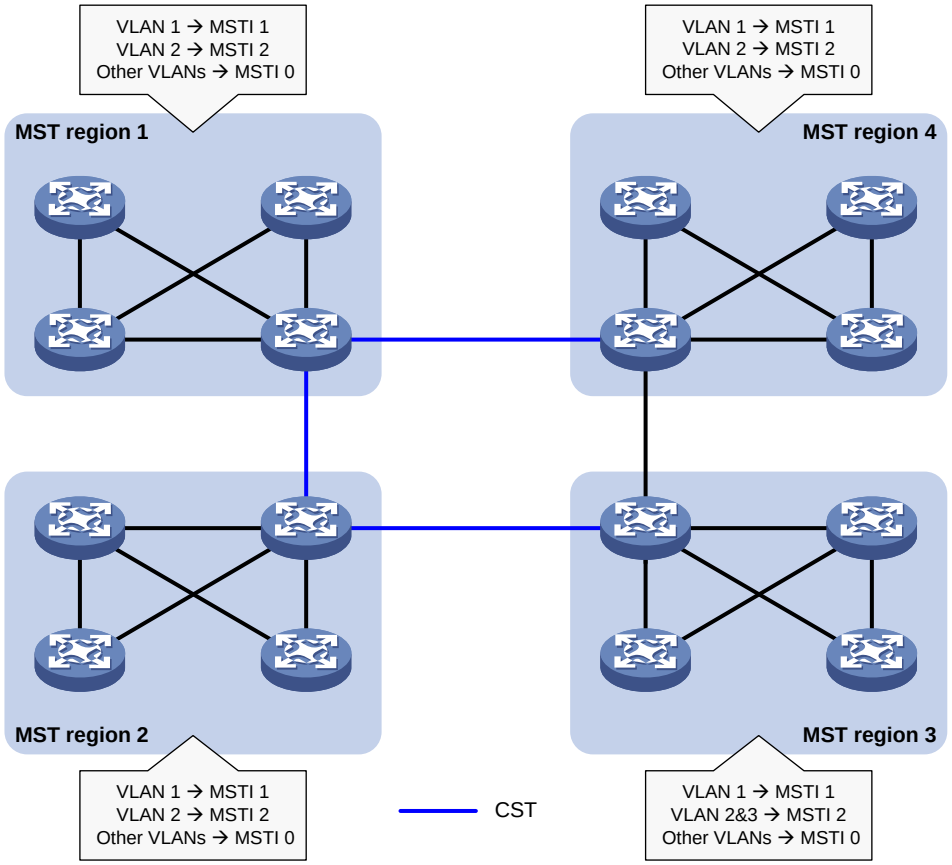
The first 13 fields of an MSTP BPDU are the same as an RSTP BPDU. The other six fields are unique to MSTP.

- **Protocol version ID**—The value is 0x03 for MSTP.
- **BPDU type**—The value is 0x02 for RSTP/MSTP BPDUs.
- **Root ID**—ID of the common root bridge.
- **Root path cost**—CIST external path cost.
- **Bridge ID**—ID of the regional root for the IST or an MSTI.
- **Port ID**—ID of the designated port in the CIST.
- **Version3 length**—Length of the MSTP-specific fields. Devices use this field for verification upon receiving an MSTP BPDU.
- **MST configuration ID**—Includes the format selector, configuration name, revision level, and configuration digest. The value for format selector is fixed at 0x00. The other parameters are used to identify the MST region for the originating bridge.
- **CIST IRPC**—Internal root path cost (IRPC) from the originating bridge to the root of the MST region.
- **CIST bridge ID**—ID of the bridge that sends the MSTP BPDU.
- **CIST remaining ID**—Remaining hop count. This field limits the scale of the MST region. The regional root sends a BPDU with the remaining hop count set to the maximum value. Each device that receives the BPDU decrements the hop count by one. When the hop count reaches zero, the BPDU is discarded. Devices beyond the maximum hops of the MST region cannot participate in spanning tree calculation. The default remaining hop count is 20.
- **MSTI configuration messages**—Contains MSTI configuration messages. Each MSTI configuration message is 16 bytes. This field can contain 0 to 64 MSTI configuration messages. The number of the MSTI configuration messages is determined by the number of MSTIs in the MST region.

Basic concepts in MSTP

Figure 9 shows a switched network that contains four MST regions, each MST region containing four MSTP devices. Figure 10 shows the networking topology of MST region 3.

Figure 9 Basic concepts in MSTP



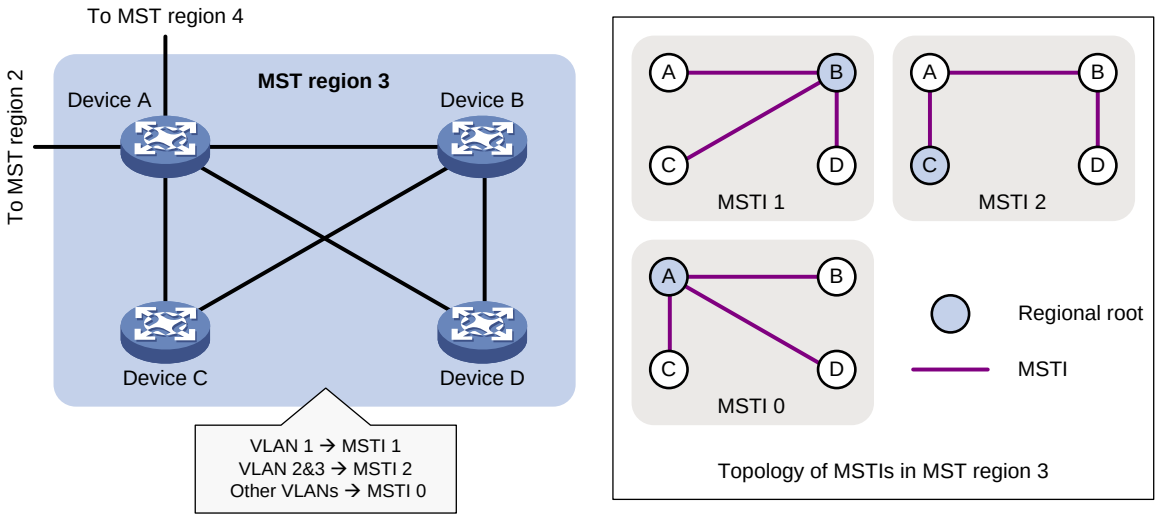


Figure 10 Network diagram and topology of MST region 3

MST region

A multiple spanning tree region (MST region) consists of multiple devices in a switched network and the network segments among them. All these devices have the following characteristics:

- A spanning tree protocol enabled
- Same region name
- Same VLAN-to-instance mapping configuration
- Same MSTP revision level
- Physically linked together

Multiple MST regions can exist in a switched network. You can assign multiple devices to the same MST region, as shown in Figure 9.

- The switched network contains four MST regions, MST region 1 through MST region 4.
- All devices in each MST region have the same MST region configuration.

MSTI

MSTP can generate multiple independent spanning trees in an MST region, and each spanning tree is mapped to the specific VLANs. Each spanning tree is referred to as a multiple spanning tree instance (MSTI).

In Figure 10, MST region 3 contains three MSTIs, MSTI 1, MSTI 2, and MSTI 0.

VLAN-to-instance mapping table

As an attribute of an MST region, the VLAN-to-instance mapping table describes the mapping relationships between VLANs and MSTIs.

In Figure 10, the VLAN-to-instance mapping table of MST region 3 is as follows:

- VLAN 1 to MSTI 1.
- VLAN 2 and VLAN 3 to MSTI 2.
- Other VLANs to MSTI 0.

MSTP achieves load balancing by means of the VLAN-to-instance mapping table.

CST

The common spanning tree (CST) is a single spanning tree that connects all MST regions in a switched network. If you regard each MST region as a device, the CST is a spanning tree calculated by these devices through STP or RSTP.

The blue lines in Figure 9 represent the CST.

IST

An internal spanning tree (IST) is a spanning tree that runs in an MST region. It is also called MSTI 0, a special MSTI to which all VLANs are mapped by default.

In Figure 9, MSTI 0 is the IST in MST region 3.

CIST

The common and internal spanning tree (CIST) is a single spanning tree that connects all devices in a switched network. It consists of the ISTs in all MST regions and the CST.

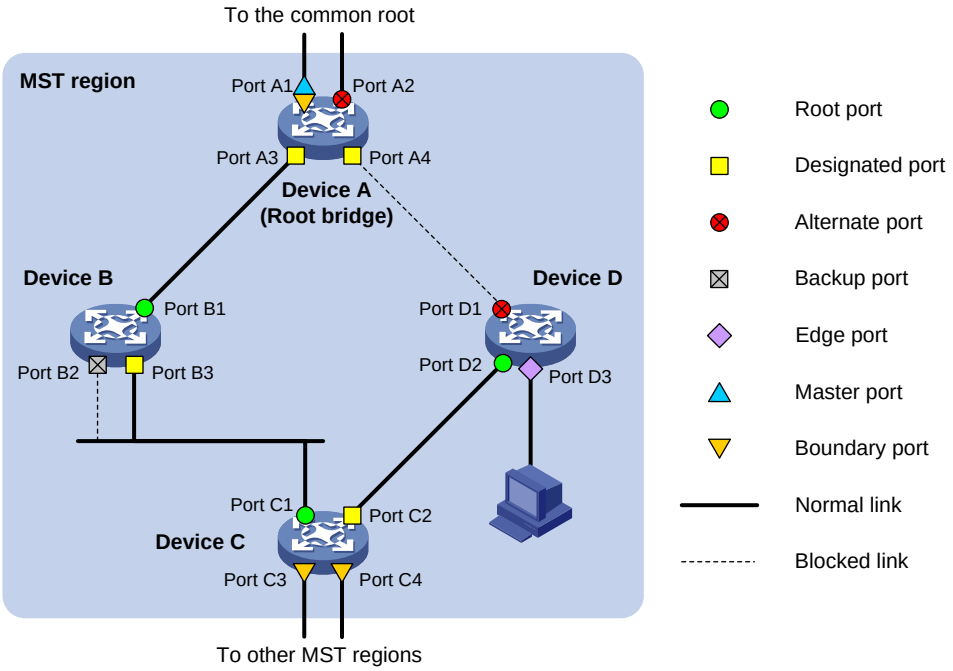
In Figure 9, the ISTs (MSTI 0) in all MST regions plus the inter-region CST constitute the CIST of the entire network.

Regional root

The root bridge of the IST or an MSTI within an MST region is the regional root of the IST or MSTI. Based on the topology, different spanning trees in an MST region might have different regional roots, as shown in MST region 3 in Figure 10.

- The regional root of MSTI 1 is Device B.
- The regional root of MSTI 2 is Device C.
- The regional root of MSTI 0 (also known as the IST) is Device A.

Common root bridge



The common root bridge is the root bridge of the CIST.

In Figure 9, the common root bridge is a device in MST region 1.

Port roles

A port can play different roles in different MSTIs. As shown in Figure 11, an MST region contains Device A, Device B, Device C, and Device D. Port A1 and port A2 of Device A connect to the common root bridge. Port B2 and Port B3 of Device B form a loop. Port C3 and Port C4 of Device C connect to other MST regions. Port D3 of Device D directly connects to a host.

Figure 11 Port roles

MSTP calculation involves the following port roles:

- **Root port**—Forwards data for a non-root bridge to the root bridge. The root bridge does not have any root port.
- **Designated port**—Forwards data to the downstream network segment or device.
- **Alternate port**—Acts as the backup port for a root port or master port. When the root port or master port is blocked, the alternate port takes over.
- **Backup port**—Acts as the backup port of a designated port. When the designated port is invalid, the backup port becomes the new designated port. A loop occurs when two ports of the same spanning tree device are connected, so the device blocks one of the ports. The blocked port acts as the backup.
- **Edge port**—Directly connects to a user host rather than a network device or network segment.
- **Master port**—Acts as a port on the shortest path from the local MST region to the common root bridge. The master port is not always located on the regional root. It is a root port on the IST or CIST and still a master port on the other MSTIs.
- **Boundary port**—Connects an MST region to another MST region or to an STP/RSTP-running device. In MSTP calculation, a boundary port's role on an MSTI is consistent with its role on the

CIST. However, that is not true with master ports. A master port on MSTIs is a root port on the CIST.

Port states

In MSTP, a port can be in one of the following states:

- **Forwarding**—The port receives and sends BPDUs, learns MAC addresses, and forwards user traffic.
- **Learning**—The port receives and sends BPDUs, learns MAC addresses, but does not forward user traffic. Learning is an intermediate port state.
- **Discarding**—The port receives and sends BPDUs, but does not learn MAC addresses or forward user traffic.

NOTE:

When in different MSTIs, a port can be in different states.

A port state is not exclusively associated with a port role. Table 6 lists the port states that each port role supports. (A check mark [√] indicates that the port supports this state, while a dash [—] indicates that the port does not support this state.)

Table 6 Port states that different port roles support

Port role (right) Port state (below)	Root port/master port	Designated port	Alternate port	Backup port
Forwarding	√	√	—	—
Learning	√	√	—	—
Discarding	√	√	√	√

How MSTP works

MSTP divides an entire Layer 2 network into multiple MST regions, which are connected by a calculated CST. Inside an MST region, multiple spanning trees, called MSTIs, are calculated. Among these MSTIs, MSTI 0 is the IST.

Like STP, MSTP uses configuration BPDUs to calculate spanning trees. An important difference is that an MSTP BPDU carries the MSTP configuration of the bridge from which the BPDU is sent.

CIST calculation

During the CIST calculation, the following process takes place:

- The device with the highest priority is elected as the root bridge of the CIST.
- MSTP generates an IST within each MST region through calculation.
- MSTP regards each MST region as a single device and generates a CST among these MST regions through calculation.

The CST and ISTs constitute the CIST of the entire network.

MSTI calculation

Within an MST region, MSTP generates different MSTIs for different VLANs based on the VLAN-to-instance mappings. For each spanning tree, MSTP performs a separate calculation process similar to spanning tree calculation in STP. For more information, see "Calculation process of the STP algorithm."

In MSTP, a VLAN frame is forwarded along the following paths:

- Within an MST region, the frame is forwarded along the corresponding MSTI.
- Between two MST regions, the frame is forwarded along the CST.

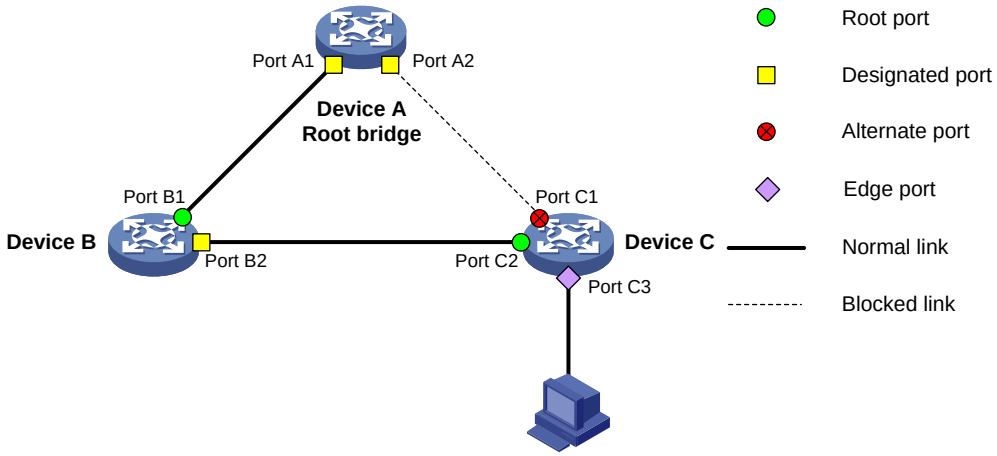
MSTP implementation on devices

MSTP is compatible with STP and RSTP. Devices that are running MSTP and that are used for spanning tree calculation can identify STP and RSTP protocol frames.

In addition to basic MSTP features, the following features are provided for ease of management:

- Root bridge hold.
- Root bridge backup.
- Root guard.
- BPDU guard.
- Loop guard.
- TC-BPDU guard.
- Port role restriction.
- TC-BPDU transmission restriction.

Rapid transition mechanism



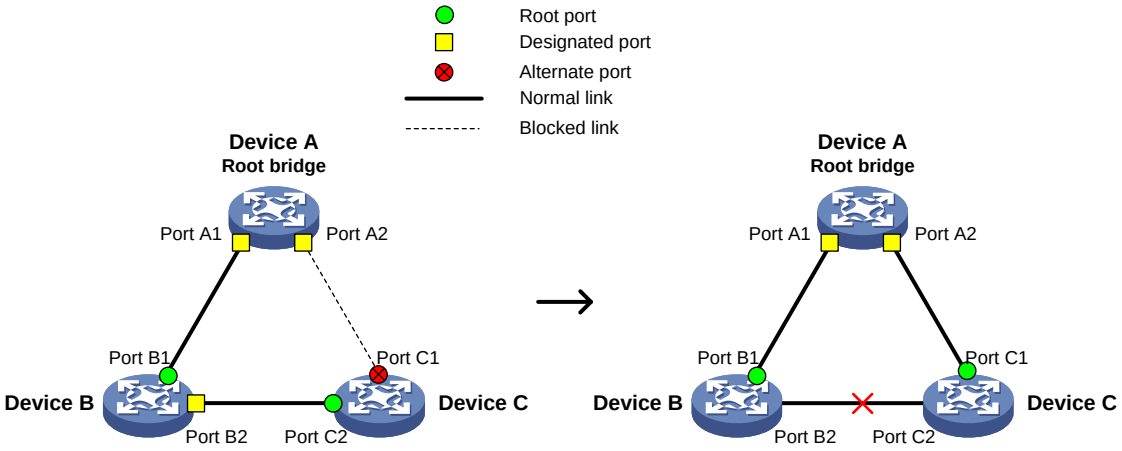
In STP, a port must wait twice the forward delay (30 seconds by default) before it transits from the blocking state to the forwarding state. The forward delay is related to the hello time and network diameter. If the forward delay is too short, loops might occur. This affects the stability of the network.

RSTP, PVST, and MSTP all use the rapid transition mechanism to speed up port state transition for edge ports, root ports, and designated ports. The rapid transition mechanism for designated ports is also known as the proposal/agreement (P/A)_transition.

Edge port rapid transition

As shown in Figure 12, Port C3 is an edge port connected to a host. When a network topology change occurs, the port can immediately transit from the blocking state to the forwarding state because no loop will be caused.

Figure 12 Edge port rapid transition



Root port rapid transition

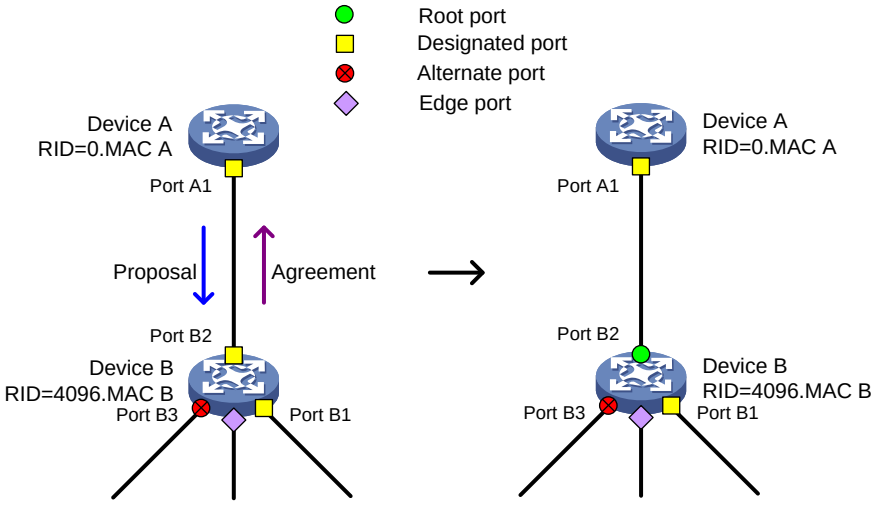
When a root port is blocked, the bridge will elect the alternate port with the highest priority as the new root port. If the new root port's peer is in the forwarding state, the new root port immediately transits to the forwarding state.

As shown in Figure 13, Port C2 on Device C is a root port and Port C1 is an alternate port. When Port C2 transits to the blocking state, Port C1 is elected as the root port and immediately transits to the forwarding state.

Figure 13 Root port rapid transition

P/A transition

The P/A transition enables a designated port to rapidly transit to the forwarding state after a handshake with its peer. The P/A transition applies only to point-to-point links.



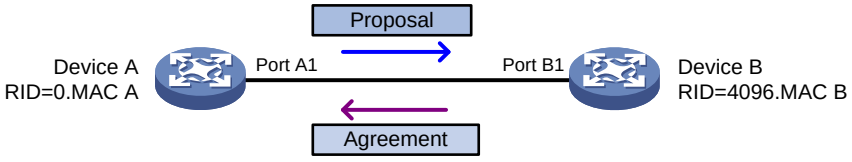
P/A transition for RSTP and PVST

In RSTP or PVST, the ports on a new link or recovered link are designated ports in blocking state. When one of the designated ports transits to the discarding or learning state, it sets the proposal flag in its BPDU. Its peer bridge receives the BPDU and determines whether the receiving port is the root port. If it is the root port, the bridge blocks the other ports except edge ports. The bridge then replies an agreement BPDU to the designated port. The designated port immediately transits to the forwarding state upon receiving the agreement BPDU. If the designated port does not receive the agreement BPDU, it waits for twice the forward delay to transit to the forwarding state.

As shown in Figure 14, the P/A transition operates as follows:

1. Device A sends a proposal BPDU to Device B through Port A1.
2. Device B receives the proposal BPDU on Port B2. Port B2 is elected as the root port.
3. Device B blocks its designated port Port B1 and alternate port Port B3 to eliminate loops.
4. The root port Port B2 transits to the forwarding state and sends an agreement BPDU to Device A.
5. The designated port Port A1 on Device A immediately transits to the forwarding state after receiving the agreement BPDU.

Figure 14 P/A transition for RSTP and PVST



P/A transition for MSTP

In MSTP, an upstream bridge sets both the proposal and agreement flags in its BPDU. If a downstream bridge receives the BPDU and its receiving port is elected as the root port, the bridge blocks all the other ports except edge ports. The downstream bridge then replies an agreement BPDU to the upstream bridge. The upstream port immediately transits to the forwarding state upon receiving the agreement BPDU. If the upstream port does not receive the agreement BPDU, it waits for twice the forward delay to transit to the forwarding state.

As shown in Figure 15, the P/A transition operates as follows:

1. Device A sets the proposal and agreement flags in its BPDU and sends it to Device B through Port A1.
2. Device B receives the BPDU. Port B1 of Device B is elected as the root port.
3. Device B then blocks all its ports except the edge ports.
4. The root port Port B1 of Device B transits to the forwarding state and sends an agreement BPDU to Device A.
5. Port A1 of Device A immediately transits to the forwarding state upon receiving the agreement BPDU.

Figure 15 P/A transition for MSTP

Protocols and standards

MSTP is documented in the following protocols and standards:

- IEEE 802.1d, *Media Access Control (MAC) Bridges*
- IEEE 802.1w, *Part 3: Media Access Control (MAC) Bridges—Amendment 2: Rapid Reconfiguration*
- IEEE 802.1s, *Virtual Bridged Local Area Networks—Amendment 3: Multiple Spanning Trees*

- IEEE 802.1Q-REV/D1.3, *Media Access Control (MAC) Bridges and Virtual Bridged Local Area Networks —Clause 13: Spanning tree Protocols*

Configuring spanning tree protocols

Restrictions and guidelines: spanning tree protocol configuration

Restrictions: Compatibility with other features

- When the spanning tree protocol is enabled for an M-LAG system, following these restrictions and guidelines:
  - Make sure the M-LAG member devices have the same spanning tree configuration, including:
    - Global spanning tree configuration.
    - Spanning tree configuration on the peer-link interface.
    - Spanning tree configuration on M-LAG interfaces.

    Violation of this rule might cause network flapping. Peer-link interfaces in the M-LAG system do not participate in spanning tree calculation.
  - If spanning tree is enabled on an M-LAG system, the M-LAG member devices still use the M-LAG system MAC address after the M-LAG system splits, which will cause spanning tree calculation issues. To avoid the issues, enable M-LAG standalone mode on the M-LAG member devices before the M-LAG system splits.

  For more information about the M-LAG system, M-LAG interfaces, peer-link interfaces, and M-LAG standalone mode, see "Configuring M-LAG."
- If both MVRP and a spanning tree protocol are enabled on a device, MVRP packets are forwarded along MSTIs. To advertise a specific VLAN within the network through MVRP, make sure this VLAN is mapped to an MSTI when you configure the VLAN-to-instance mapping table. For more information about MVRP, see "Configuring MVRP." MVRP is not supported on the S5200-EI-G switch series.
- The spanning tree configurations are mutually exclusive with any of the following features on a port: RRPP and Smart Link

Restrictions: Interface configuration

- Some spanning tree features are supported in Layer 2 Ethernet interface view and Layer 2 aggregate interface view. Unless otherwise stated, these views are collectively referred to as interface view in this document. BPDU drop can be configured only in Layer 2 Ethernet interface view.
- Configurations made in system view take effect globally. Configurations made in Layer 2 Ethernet interface view take effect only on the interface. Configurations made in Layer 2 aggregate interface view take effect only on the aggregate interface. Configurations made on an aggregation member port can take effect only after the port is removed from the aggregation group.
- After you enable a spanning tree protocol on a Layer 2 aggregate interface, the system performs spanning tree calculation on the Layer 2 aggregate interface. It does not perform spanning tree calculation on the aggregation member ports. The spanning tree protocol enable state and forwarding state of each selected member port are consistent with those of the corresponding Layer 2 aggregate interface.

- The member ports of an aggregation group do not participate in spanning tree calculation. However, the ports still reserve their spanning tree configurations for participating in spanning tree calculation after leaving the aggregation group.
- In an M-LAG system, you can use the **`display`** command to view the spanning tree information of M-LAG interfaces on both the primary M-LAG device and the member M-LAG devices.

Spanning tree protocol tasks at a glance

STP tasks at a glance

Configuring the root bridge

To configure the root bridge in STP mode, perform the following tasks:

1. Setting the spanning tree mode
2. Set the spanning tree mode to STP.
3. (Optional.) Configuring the root bridge or a secondary root bridge
4. (Optional.) Configuring the device priority
5. (Optional.) Configuring parameters that affects STP topology convergence
   - Configuring the network diameter of a switched network
   - Setting spanning tree timers
   - Setting the timeout factor
   - Configuring the BPDU transmission rate
6. (Optional.) Enabling outputting port state transition information
7. Enabling the spanning tree feature
8. (Optional.) Configuring advanced spanning tree features
   - Ignoring the specified VLANs
   - Configuring TC Snooping
   - Configuring protection features
   - Disabling the device from reactivating edge ports shut down by BPDU guard
   - Enabling BPDU transparent transmission on a port
   - Configuring TC Snooping
   - Configuring spanning tree blackhole detection
   - Enabling SNMP notifications for new-root election and topology change events

Configuring the leaf nodes

To configure the leaf nodes in STP mode, perform the following tasks:

1. Setting the spanning tree mode
2. Set the spanning tree mode to STP.
3. (Optional.) Configuring the device priority
4. (Optional.) Configuring parameters that affects STP topology convergence
   - Setting the timeout factor
   - Configuring the BPDU transmission rate
   - Configuring path costs of ports
   - Configuring the port priority
5. (Optional.) Enabling outputting port state transition information

6. Enabling the spanning tree feature
7. (Optional.) Configuring advanced spanning tree features
    - Ignoring the specified VLANs
    - Configuring TC Snooping
    - Configuring protection features
    - Disabling the device from reactivating edge ports shut down by BPDU guard
    - Enabling BPDU transparent transmission on a port
    - Configuring TC groups
    - Configuring spanning tree blackhole detection
    - Enabling SNMP notifications for new-root election and topology change events

RSTP tasks at a glance

Configuring the root bridge

To configure the root bridge in RSTP mode, perform the following tasks:

1. Setting the spanning tree mode
2. Set the spanning tree mode to RSTP.
3. (Optional.) Configuring the root bridge or a secondary root bridge
4. (Optional.) Configuring the device priority
5. (Optional.) Configuring parameters that affects RSTP topology convergence
    - Configuring the network diameter of a switched network
    - Setting spanning tree timers
    - Setting the timeout factor
    - Configuring the BPDU transmission rate
    - Configuring edge ports
    - Configuring the port link type
6. (Optional.) Enabling outputting port state transition information
7. Enabling the spanning tree feature
8. (Optional.) Configuring advanced spanning tree features
    - Performing mCheck
    - Ignoring the specified VLANs
    - Configuring TC Snooping
    - Configuring protection features
    - Disabling the device from reactivating edge ports shut down by BPDU guard
    - Enabling BPDU transparent transmission on a port
    - Configuring TC groups
    - Configuring spanning tree blackhole detection
    - Enabling SNMP notifications for new-root election and topology change events

Configuring the leaf nodes

To configure the leaf nodes in RSTP mode, perform the following tasks:

1. Setting the spanning tree mode
2. Set the spanning tree mode to RSTP.
3. (Optional.) Configuring the device priority
4. (Optional.) Configuring parameters that affects RSTP topology convergence

- Setting the timeout factor
- Configuring the BPDU transmission rate
- Configuring edge ports
- Configuring path costs of ports
- Configuring the port priority
- Configuring the port link type

5. (Optional.) Enabling outputting port state transition information
6. Enabling the spanning tree feature
7. (Optional.) Configuring advanced spanning tree features
   - Performing mCheck
   - Ignoring the specified VLANs
   - Configuring TC Snooping
   - Configuring protection features
   - Disabling the device from reactivating edge ports shut down by BPDU guard
   - Enabling BPDU transparent transmission on a port
   - Configuring TC groups
   - Configuring spanning tree blackhole detection
   - Enabling SNMP notifications for new-root election and topology change events

PVST tasks at a glance

Configuring the root bridge

To configure the root bridge in PVST mode, perform the following tasks:

1. Setting the spanning tree mode
2. Set the spanning tree mode to PVST.
3. (Optional.) Configuring the root bridge or a secondary root bridge
4. (Optional.) Configuring the device priority
5. (Optional.) Configuring parameters that affects PVST topology convergence
   - Configuring the network diameter of a switched network
   - Setting spanning tree timers
   - Setting the timeout factor
   - Configuring the BPDU transmission rate
   - Configuring edge ports
   - Configuring the port link type
6. (Optional.) Enabling outputting port state transition information
7. Enabling the spanning tree feature
8. (Optional.) Configuring advanced spanning tree features
   - Performing mCheck
   - Disabling inconsistent PVID protection
   - Ignoring the specified VLANs
   - Configuring protection features
   - Enabling the device to log events of detecting or receiving TC BPDUs
   - Disabling the device from reactivating edge ports shut down by BPDU guard
   - Enabling BPDU transparent transmission on a port

- Configuring TC groups
- Configuring spanning tree blackhole detection
- Enabling SNMP notifications for new-root election and topology change events

Configuring the leaf nodes

To configure the leaf nodes in PVST mode, perform the following tasks:

1. Setting the spanning tree mode
2. Set the spanning tree mode to PVST.
3. (Optional.) Configuring the device priority
4. (Optional.) Configuring parameters that affects PVST topology convergence
   - Setting the timeout factor
   - Configuring the BPDU transmission rate
   - Configuring edge ports
   - Configuring path costs of ports
   - Configuring the port priority
   - Configuring the port link type
5. (Optional.) Enabling outputting port state transition information
6. Enabling the spanning tree feature
7. (Optional.) Configuring advanced spanning tree features
   - Performing mCheck
   - Disabling inconsistent PVID protection
   - Ignoring the specified VLANs
   - Configuring protection features
   - Enabling the device to log events of detecting or receiving TC BPDUs
   - Disabling the device from reactivating edge ports shut down by BPDU guard
   - Enabling BPDU transparent transmission on a port
   - Configuring TC groups
   - Configuring spanning tree blackhole detection
   - Enabling SNMP notifications for new-root election and topology change events

MSTP tasks at a glance

Configuring the root bridge

To configure the root bridge in MSTP mode, perform the following tasks:

1. Setting the spanning tree mode
2. Set the spanning tree mode to MSTP.
3. Configuring an MST region
4. (Optional.) Configuring the root bridge or a secondary root bridge
5. (Optional.) Configuring the device priority
6. (Optional.) Configuring parameters that affects MSTP topology convergence
   - Configuring the maximum hops of an MST region
   - Configuring the network diameter of a switched network
   - Setting spanning tree timers
   - Setting the timeout factor
   - Configuring the BPDU transmission rate

- Configuring edge ports
- Configuring the port link type

7. (Optional.) Configuring the mode a port uses to recognize and send MSTP frames
8. (Optional.) Enabling outputting port state transition information
9. Enabling the spanning tree feature
10. (Optional.) Configuring advanced spanning tree features
    - Performing mCheck
    - Ignoring the specified VLANs
    - Configuring Digest Snooping
    - Configuring No Agreement Check
    - Configuring TC Snooping
    - Configuring protection features
    - Disabling the device from reactivating edge ports shut down by BPDU guard
    - Enabling BPDU transparent transmission on a port
    - Configuring TC groups
    - Configuring spanning tree blackhole detection
    - Enabling SNMP notifications for new-root election and topology change events

Configuring the leaf nodes

To configure the leaf nodes in MSTP mode, perform the following tasks:

1. Setting the spanning tree mode
2. Set the spanning tree mode to MSTP.
3. Configuring an MST region
4. (Optional.) Configuring the device priority
5. (Optional.) Configuring parameters that affects MSTP topology convergence
    - Setting the timeout factor
    - Configuring the BPDU transmission rate
    - Configuring edge ports
    - Configuring path costs of ports
    - Configuring the port priority
    - Configuring the port link type
6. (Optional.) Configuring the mode a port uses to recognize and send MSTP frames
7. (Optional.) Enabling outputting port state transition information
8. Enabling the spanning tree feature
9. (Optional.) Configuring advanced spanning tree features
    - Performing mCheck
    - Ignoring the specified VLANs
    - Configuring Digest Snooping
    - Configuring No Agreement Check
    - Configuring TC Snooping
    - Configuring protection features
    - Disabling the device from reactivating edge ports shut down by BPDU guard
    - Enabling BPDU transparent transmission on a port
    - Configuring TC groups
    - Configuring spanning tree blackhole detection

- Enabling SNMP notifications for new-root election and topology change events

Setting the spanning tree mode

About this task

The spanning tree modes include:

- **STP mode**—All ports of the device send STP BPDUs. Select this mode when the peer device of a port supports only STP.
- **RSTP mode**—All ports of the device send RSTP BPDUs. A port in this mode automatically transits to the STP mode when it receives STP BPDUs from the peer device. A port in this mode does not transit to the MSTP mode when it receives MSTP BPDUs from the peer device.
- **PVST mode**—All ports of the device send PVST BPDUs. Each VLAN maintains a spanning tree. In a network, the amount of spanning trees maintained by all devices equals the number of PVST-enabled VLANs multiplied by the number of PVST-enabled ports. If the amount of spanning trees exceeds the capacity of the network, device CPUs will be overloaded. Packet forwarding is interrupted, and the network becomes unstable. The device can maintain spanning trees for 128 VLANs.
- **MSTP mode**—All ports of the device send MSTP BPDUs. A port in this mode automatically transits to the STP mode when receiving STP BPDUs from the peer device. A port in this mode does not transit to the RSTP mode when receiving RSTP BPDUs from the peer device.

Restrictions and guidelines

The MSTP mode is compatible with the RSTP mode, and the RSTP mode is compatible with the STP mode.

Compatibility of the PVST mode depends on the link type of a port.

- On an access port, the PVST mode is compatible with other spanning tree modes in all VLANs.
- On a trunk port or hybrid port, the PVST mode is compatible with other spanning tree modes only in the default VLAN.

Procedure

1. Enter system view.

   `system-view`
2. Set the spanning tree mode.

   `stp mode` { **`mstp`** | **`pvst`** | **`rstp`** | **`stp`** }

   The default setting is the MSTP mode.

Configuring an MST region

About this task

Spanning tree devices belong to the same MST region if they are both connected through a physical link and configured with the following details:

- Format selector (0 by default, not configurable).
- MST region name.
- MST region revision level.
- VLAN-to-instance mapping entries in the MST region.

The configuration of MST region-related parameters (especially the VLAN-to-instance mapping table) might cause MSTP to begin a new spanning tree calculation. To reduce the possibility of topology

instability, the MST region configuration takes effect only after you activate it by doing one of the following:

- Use the **active region-configuration** command.
- Enable a spanning tree protocol by using the **stp global enable** command if the spanning tree protocol is disabled.

Restrictions and guidelines

In STP, RSTP, or PVST mode, MST region configurations do not take effect.

Procedure

1. Enter system view.
   system-view
2. Enter MST region view.
   stp region-configuration
3. Configure the MST region name.
   region-name *name*
   The default setting is the MAC address.
4. Configure the VLAN-to-instance mapping table. Choose one option as needed:
   - Map a list of VLANs to an MSTI.
   - **instance** *instance-id* **vlan** *vlan-id-list*
   - Quickly create a VLAN-to-instance mapping table.
   - **vlan-mapping modulo** *modulo*

   By default, all VLANs in an MST region are mapped to the CIST (or MSTI 0).
5. Configure the MSTP revision level of the MST region.
   revision-level *level*
   The default setting is 0.
6. (Optional.) Display the MST region configurations that are not activated yet.
   check region-configuration
7. Manually activate MST region configuration.
   active region-configuration

Configuring the root bridge or a secondary root bridge

Restrictions and guidelines

You can have the spanning tree protocol determine the root bridge of a spanning tree through calculation. You can also specify a device as the root bridge or as a secondary root bridge.

When you specify a device as the root bridge or as a secondary root bridge, follow these restrictions and guidelines:

- A device has independent roles in different spanning trees. It can act as the root bridge in one spanning tree and as a secondary root bridge in another. However, one device cannot be the root bridge and a secondary root bridge in the same spanning tree.
- If you specify the root bridge for a spanning tree, no new root bridge is elected according to the device priority settings. Once you specify a device as the root bridge or a secondary root bridge, you cannot change the priority of the device.

- You can configure a device as the root bridge by setting the device priority to 0. For the device priority configuration, see "Configuring the device priority."

Configuring the device as the root bridge of a spanning tree

1. Enter system view.
   system-view
2. Configure the device as the root bridge.
   - In STP/RSTP mode:
     stp root primary
   - In PVST mode:
     stp vlan *vlan-id-list* **root primary**
   - In MSTP mode:
     stp [**instance** *instance-list*] **root primary**

   By default, the device is not a root bridge.

Configuring the device as a secondary root bridge of a spanning tree

1. Enter system view.
   system-view
2. Configure the device as a secondary root bridge.
   - In STP/RSTP mode:
     stp root secondary
   - In PVST mode:
     stp vlan *vlan-id-list* **root secondary**
   - In MSTP mode:
     stp [**instance** *instance-list*] **root secondary**

   By default, the device is not a secondary root bridge.

Configuring the device priority

About this task

Device priority is a factor in calculating the spanning tree. The priority of a device determines whether the device can be elected as the root bridge of a spanning tree. A lower value indicates a higher priority. You can set the priority of a device to a low value to specify the device as the root bridge of the spanning tree. A spanning tree device can have different priorities in different spanning trees.

During root bridge selection, if all devices in a spanning tree have the same priority, the one with the lowest MAC address is selected. You cannot change the priority of a device after it is configured as the root bridge or as a secondary root bridge.

Procedure

1. Enter system view.
   system-view
2. Configure the priority of the device.

- In STP/RSTP mode:
  stp priority *priority*
- In PVST mode:
  stp vlan *vlan-id-list* **priority** *priority*
- In MSTP mode:
  stp [**instance** *instance-list*] **priority** *priority*

The default setting is 32768.

Configuring the maximum hops of an MST region

About this task

Restrict the region size by setting the maximum hops of an MST region. The hop limit configured on the regional root bridge is used as the hop limit for the MST region.

Configuration BPDUs sent by the regional root bridge always have a hop count set to the maximum value. When a device receives this configuration BPDU, it decrements the hop count by one, and uses the new hop count in the BPDUs that it propagates. When the hop count of a BPDU reaches zero, it is discarded by the device that received it. Devices beyond the reach of the maximum hops can no longer participate in spanning tree calculations, so the size of the MST region is limited.

Restrictions and guidelines

Make this configuration only on the root bridge. All other devices in the MST region use the maximum hop value set for the root bridge.

You can configure the maximum hops of an MST region based on the STP network size. As a best practice, set the maximum hops to a value that is greater than the maximum hops of each edge device to the root bridge.

Procedure

1. Enter system view.
   system-view
2. Configure the maximum hops of the MST region.
   stp max-hops *hops*
   The default setting is 20.

Configuring the network diameter of a switched network

About this task

Any two terminal devices in a switched network can reach each other through a specific path, and there are a series of devices on the path. The switched network diameter is the maximum number of devices on the path for an edge device to reach another one in the switched network through the root bridge. The network diameter indicates the network size. The bigger the diameter, the larger the network size.

Based on the network diameter you configured, the system automatically sets an optimal hello time, forward delay, and max age for the device.

In STP, RSTP, or MSTP mode, each MST region is considered a device. The configured network diameter takes effect only on the CIST (or the common root bridge) but not on other MSTIs.

In PVST mode, the configured network diameter takes effect only on the root bridges of the specified VLANs.

Procedure

1. Enter system view.

   system-view
2. Configure the network diameter of the switched network.
   - In STP/RSTP/MSTP mode:

     stp bridge-diameter *diameter*
   - In PVST mode:

     stp vlan *vlan-id-list* **bridge-diameter** *diameter*

   The default setting is 7.

Setting spanning tree timers

About this task

The following timers are used for spanning tree calculation:

- **Forward delay**—Delay time for port state transition. To prevent temporary loops on a network, the spanning tree feature sets an intermediate port state (the learning state) before it transits from the discarding state to the forwarding state. The feature also requires that the port transit its state after a forward delay timer. This ensures that the state transition of the local port stays synchronized with the peer.
- **Hello time**—Interval at which the device sends configuration BPDUs to detect link failures. If the device does not receive configuration BPDUs within the timeout period, it recalculates the spanning tree. The formula for calculating the timeout period is timeout period = timeout factor × 3 × hello time.
- **Max age**—In the CIST of an MSTP network, the device uses the max age timer to determine whether a configuration BPDU received by a port has expired. If it is expired, a new spanning tree calculation process starts. The max age timer does not take effect on MSTIs.

To ensure a fast topology convergence, make sure the timer settings meet the following formulas:

- 2 × (forward delay – 1 second) ≥ max age
- Max age ≥ 2 × (hello time + 1 second)

As a best practice, specify the network diameter and letting spanning tree protocols automatically calculate the timers based on the network diameter instead of manually setting the spanning tree timers. If the network diameter uses the default value, the timers also use their default values.

Set the timers only on the root bridge. The timer settings on the root bridge apply to all devices on the entire switched network.

Restrictions and guidelines

- The length of the forward delay is related to the network diameter of the switched network. The larger the network diameter is, the longer the forward delay time should be. As a best practice, use the automatically calculated value because inappropriate forward delay setting might cause temporary redundant paths or increase the network convergence time.
- An appropriate hello time setting enables the device to promptly detect link failures on the network without using excessive network resources. If the hello time is too long, the device mistakes packet loss for a link failure and triggers a new spanning tree calculation process. If the hello time is too short, the device frequently sends the same configuration BPDUs, which wastes device and network resources. As a best practice, use the automatically calculated value.

- If the max age timer is too short, the device frequently begins spanning tree calculations and might mistake network congestion as a link failure. If the max age timer is too long, the device might fail to promptly detect link failures and quickly launch spanning tree calculations, reducing the auto-sensing capability of the network. As a best practice, use the automatically calculated value.

Procedure

1. Enter system view.
   system-view
2. Set the forward delay timer.
   - In STP/RSTP/MSTP mode:
     stp timer forward-delay *time*
   - In PVST mode:
     stp vlan *vlan-id-list* **timer forward-delay** *time*

   The default setting is 15 seconds.
3. Set the hello timer.
   - In STP/RSTP/MSTP mode:
     stp timer hello *time*
   - In PVST mode:
     stp vlan *vlan-id-list* **timer hello** *time*

   The default setting is 2 seconds.
4. Set the max age timer.
   - In STP/RSTP/MSTP mode:
     stp timer max-age *time*
   - In PVST mode:
     stp vlan *vlan-id-list* **timer max-age** *time*

     The default setting is 20 seconds.

Setting the timeout factor

About this task

The timeout factor is a parameter used to decide the timeout period. The formula for calculating the timeout period is: *timeout period* = *timeout factor* × 3 × *hello time*.

In a stable network, each non-root-bridge device forwards configuration BPDUs to the downstream devices at the hello time interval to detect link failures. If a device does not receive a BPDU from the upstream device within nine times the hello time, it assumes that the upstream device has failed. Then, it starts a new spanning tree calculation process.

Restrictions and guidelines

As a best practice, set the timeout factor to 5, 6, or 7 in the following situations:

- To prevent undesired spanning tree calculations. An upstream device might be too busy to forward configuration BPDUs in time, for example, many Layer 2 interfaces are configured on the upstream device. In this case, the downstream device fails to receive a BPDU within the timeout period and then starts an undesired spanning tree calculation.
- To save network resources on a stable network.

Procedure

1. Enter system view.

system-view

2. Set the timeout factor of the device.

   stp timer-factor *factor*

   The default setting is 3.

Configuring the BPDU transmission rate

About this task

The maximum number of BPDUs a port can send within each hello time equals the BPDU transmission rate plus the hello timer value.

The higher the BPDU transmission rate, the more BPDUs are sent within each hello time, and the more system resources are used. By setting an appropriate BPDU transmission rate, you can limit the rate at which the port sends BPDUs. Setting an appropriate rate also prevents spanning tree protocols from using excessive network resources when the network topology changes.

Restrictions and guidelines

The BPDU transmission rate depends on the physical status of the port and the network structure. As a best practice, use the default setting.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the BPDU transmission rate of the ports.

   stp transmit-limit *limit*

   The default setting is 10.

Configuring edge ports

About this task

If a port directly connects to a user terminal rather than another device or a shared LAN segment, this port is regarded as an edge port. When network topology change occurs, an edge port will not cause a temporary loop. Because a device does not determine whether a port is directly connected to a terminal, you must manually configure the port as an edge port. After that, the port can rapidly transit from the blocking state to the forwarding state.

Restrictions and guidelines

- If BPDU guard is disabled on a port configured as an edge port, the port becomes a non-edge port again if it receives a BPDU from another port. To restore the edge port, re-enable it.
- If a port directly connects to a user terminal, configure it as an edge port and enable BPDU guard for it. This enables the port to quickly transit to the forwarding state when ensuring network security.
- After spanning tree is enabled on an interface, the system checks whether the interface receives BPDUs within twice the hello time plus 1 second. If no BPDUs are received, the device automatically assigns the edge port role to the interface. The edge port role assigned by using the **stp edged-port** command takes precedence over the system assigned edge port role.
- On a port, the loop guard feature and the edge port setting are mutually exclusive.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the port as an edge port.
   stp edged-port
   By default, all ports are non-edge ports.

Configuring path costs of ports

About path cost

Path cost is a parameter related to the link speed of a port. On a spanning tree device, a port can have different path costs in different MSTIs. Setting appropriate path costs allows VLAN traffic flows to be forwarded along different physical links, achieving VLAN-based load balancing.

You can have the device automatically calculate the default path cost, or you can configure the path cost for ports.

Specifying a standard for the default path cost calculation

About this task

You can specify a standard for the device to use in automatic calculation for the default path cost. The device supports the following standards:

- **dot1d-1998**—The device calculates the default path cost for ports based on IEEE 802.1d-1998.
- **dot1t**—The device calculates the default path cost for ports based on IEEE 802.1t.
- **legacy**—The device calculates the default path cost for ports based on a private standard.

Table 7 Mappings between the link speed (100M and below) and the path cost

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
0	N/A	65535	200000000	200000
10 Mbps	Single port	100	2000000	2000
	Aggregate interface containing two Selected ports		1000000	1800
	Aggregate interface containing three Selected ports		666666	1600
	Aggregate interface containing four Selected ports		500000	1400
100 Mbps	Single port	19	200000	200
	Aggregate interface containing two Selected		100000	180

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
	ports			
	Aggregate interface containing three Selected ports		66666	160
	Aggregate interface containing four Selected ports		50000	140

Table 8 Mappings between the link speed (1000M) and the path cost

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
1000 Mbps	Single port	4	20000	20
	Aggregate interface containing two Selected ports		10000	18
	Aggregate interface containing three Selected ports		6666	16
	Aggregate interface containing four Selected ports		5000	14

Table 9 Mappings between the link speed (10G) and the path cost

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
10 Gbps	Single port	2	2000	2
	Aggregate interface containing two Selected ports		1000	1
	Aggregate interface containing three Selected ports		666	1
	Aggregate interface containing four Selected ports		500	1

Table 10 Mappings between the link speed (20G) and the path cost

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
20 Gbps	Single port	1	1000	1

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
	Aggregate interface containing two Selected ports		500	1
	Aggregate interface containing three Selected ports		333	1
	Aggregate interface containing four Selected ports		250	1

Table 11 Mappings between the link speed (25G) and the path cost

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
25 Gbps	Single port	1	800	1
	Aggregate interface containing two Selected ports		400	1
	Aggregate interface containing three Selected ports		266	1
	Aggregate interface containing four Selected ports		200	1

Table 12 Mappings between the link speed (40G) and the path cost

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
40 Gbps	Single port	1	500	1
	Aggregate interface containing two Selected ports		250	1
	Aggregate interface containing three Selected ports		166	1
	Aggregate interface containing four Selected ports		125	1

Table 13 Mappings between the link speed (100G) and the path cost

Link speed	Port type	Path cost		
		IEEE 802.1d-1998	IEEE 802.1t	Private standard
100 Gbps	Single port	1	200	1
	Aggregate interface containing two Selected ports		100	1
	Aggregate interface containing three Selected ports		66	1
	Aggregate interface containing four Selected ports		50	1

Restrictions and guidelines

If you change the standard for the default path cost calculation, you restore the path costs to the default.

When the device calculates the path cost for an aggregate interface, IEEE 802.1t takes into account the number of Selected ports in its aggregation group. However, IEEE 802.1d-1998 does not take into account the number of Selected ports. The calculation formula of IEEE 802.1t is: Path cost = 200,000,000/link speed (in 100 kbps). The link speed is the sum of the link speed values of the Selected ports in the aggregation group.

IEEE 802.1d-1998 or the private standard always assigns the smallest possible value to a single port or aggregate interface with a speed exceeding 10 Gbps. The forwarding path selected based on this criterion might not be the best one. To solve this problem, perform one of the following tasks:

- Use **dot1t** as the standard for default path cost calculation.
- Manually set the path cost for the port (see "Configuring path costs of ports").

Procedure

1. Enter system view.
   system-view
2. Specify a standard for the default path costs calculation.
   stp pathcost-standard { **dot1d-1998** | **dot1t** | **legacy** }
   By default, the device uses **legacy** to calculate the default path costs of its ports.

Configuring path costs of ports

Restrictions and guidelines

When the path cost of a port changes, the system recalculates the port role and initiates a state transition.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the path cost of the ports.

- In STP/RSTP mode:
  stp cost *cost-value*
- In PVST mode:
  stp vlan *vlan-id-list* **cost** *cost-value*
- In MSTP mode:
  stp [**instance** *instance-list*] **cost** *cost-value*

By default, the system automatically calculates the path cost of each port.

Configuring the port priority

About this task

The priority of a port is a factor that determines whether the port can be elected as the root port of a device. If all other conditions are the same, the port with the highest priority is elected as the root port.

On a spanning tree device, a port can have different priorities and play different roles in different spanning trees. As a result, data of different VLANs can be propagated along different physical paths, implementing per-VLAN load balancing. You can set port priority values based on the actual networking requirements.

Restrictions and guidelines

When the priority of a port changes, the system recalculates the port role and initiates a state transition. Prepare for the network topology change before configuring the port priority.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the port priority.
   - In STP/RSTP mode:
     stp port priority *priority*
   - In PVST mode:
     stp vlan *vlan-id-list* **port priority** *priority*
   - In MSTP mode:
     stp [**instance** *instance-list*] **port priority** *priority*

   The default setting is 128 for all ports.

Configuring the port link type

About this task

A point-to-point link directly connects two devices. If two root ports or designated ports are connected over a point-to-point link, they can rapidly transit to the forwarding state after a proposal-agreement handshake process.

Restrictions and guidelines

- You can configure the link type as point-to-point for a Layer 2 aggregate interface or a port that operates in full duplex mode. As a best practice, use the default setting and let the device automatically detect the port link type.

- In PVST or MSTP mode, the **stp point-to-point force-false** or **stp point-to-point force-true** command configured on a port takes effect on all VLANs or all MSTIs.
- Before you set the link type of a port to point-to-point, make sure the port is connected to a point-to-point link. Otherwise, a temporary loop might occur.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the port link type.
   stp point-to-point { **auto** | **force-false** | **force-true** }
   By default, the link type is **auto** where the port automatically detects the link type.

Configuring the mode a port uses to recognize and send MSTP frames

About this task

A port can receive and send MSTP frames in the following formats:

- **dot1s**—802.1s-compliant standard format
- **legacy**—Compatible format

By default, the frame format recognition mode of a port is **auto**. The port automatically distinguishes the two MSTP frame formats, and determines the format of frames that it will send based on the recognized format.

You can configure the MSTP frame format on a port. Then, the port sends only MSTP frames of the configured format to communicate with devices that send frames of the same format.

By default, a port in **auto** mode sends 802.1s MSTP frames. When the port receives an MSTP frame of a legacy format, the port starts to send frames only of the legacy format. This prevents the port from frequently changing the format of sent frames. To configure the port to send 802.1s MSTP frames, shut down and then bring up the port.

Restrictions and guidelines

When the number of existing MSTIs exceeds 48, the port can send only 802.1s MSTP frames.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the mode that the port uses to recognize/send MSTP frames.
   stp compliance { **auto** | **dot1s** | **legacy** }
   The default setting is **auto**.

Enabling outputting port state transition information

About this task

In a large-scale spanning tree network, you can enable devices to output the port state transition information. Then, you can monitor the port states in real time.

Procedure

1. Enter system view.

   system-view

2. Enable outputting port state transition information.
   - In STP/RSTP mode:

     stp port-log instance 0
   - In PVST mode:

     stp port-log vlan *vlan-id-list*
   - In MSTP mode:

     stp port-log { **all** | **instance** *instance-list* }

   When the device starts up with initial settings, outputting port state transition information is disabled by default.

   When the device starts up with factory defaults, outputting port state transition information is enabled by default.

   For more information about the initial settings and factory defaults, see *Fundamentals Configuration Guide*.

Enabling the spanning tree feature

Restrictions and guidelines

You must enable the spanning tree feature for the device before any other spanning tree related configurations can take effect. In STP, RSTP, or MSTP mode, make sure the spanning tree feature is enabled globally and on the desired ports. In PVST mode, make sure the spanning tree feature is enabled globally, in the desired VLANs, and on the desired ports.

To exclude specific ports from spanning tree calculation and save CPU resources, disable the spanning tree feature for these ports with the **undo stp enable** command. Make sure no loops occur in the network after you disable the spanning tree feature on these ports.

Enabling the spanning tree feature in STP/RSTP/MSTP mode

1. Enter system view.

   system-view

2. Enable the spanning tree feature.

   stp global enable

   When the device starts up with initial settings, the spanning tree feature is globally disabled by default.

When the device starts up with factory defaults, the spanning tree feature is globally enabled by default.

For more information about the initial settings and factory defaults, see *Fundamentals Configuration Guide*.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable the spanning tree feature for the port.

   stp enable

   By default, the spanning tree feature is enabled on all ports.

Enabling the spanning tree feature in PVST mode

1. Enter system view.

   system-view

2. Enable the spanning tree feature.

   stp global enable

   When the device starts up with initial settings, the spanning tree feature is globally disabled by default.

   When the device starts up with factory defaults, the spanning tree feature is globally enabled by default.

   For more information about the initial settings and factory defaults, see *Fundamentals Configuration Guide*.

3. Enable the spanning tree feature in VLANs.

   stp vlan *vlan-id-list* **enable**

   By default, the spanning tree feature is enabled in VLANs.

4. Enter interface view.

   interface *interface-type interface-number*

5. Enable the spanning tree feature on the port.

   stp enable

   By default, the spanning tree feature is enabled on all ports.

Performing mCheck

About mCheck

The mCheck feature enables user intervention in the port state transition process.

When a port on an MSTP, RSTP, or PVST device connects to an STP device and receives STP BPDUs, the port automatically transits to the STP mode. However, the port cannot automatically transit back to the original mode when the following conditions exist:

- The peer STP device is shut down or removed.
- The port cannot detect the change.

To forcibly transit the port to operate in the original mode, you can perform an mCheck operation.

For example, Device A, Device B, and Device C are connected in sequence. Device A runs STP, Device B does not run any spanning tree protocol, and Device C runs RSTP, PVST, or MSTP. In this case, when Device C receives an STP BPDU transparently transmitted by Device B, the receiving

port transits to the STP mode. If you configure Device B to run RSTP, PVST, or MSTP with Device C, you must perform mCheck operations on the ports interconnecting Device B and Device C.

Restrictions and guidelines

The mCheck operation takes effect on devices operating in MSTP, PVST, or RSTP mode.

Performing mCheck globally

1. Enter system view.
   system-view
2. Perform mCheck.
   stp global mcheck

Performing mCheck in interface view

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Perform mCheck.
   stp mcheck

Disabling inconsistent PVID protection

About this task

In PVST, if two connected ports use different PVIDs, PVST calculation errors might occur. By default, inconsistent PVID protection is enabled to avoid PVST calculation errors. If PVID inconsistency is detected on a port, the system blocks the port.

Restrictions and guidelines

If different PVIDs are required on two connected ports, disable inconsistent PVID protection on the devices that host the ports. To avoid PVST calculation errors, make sure the following requirements are met:

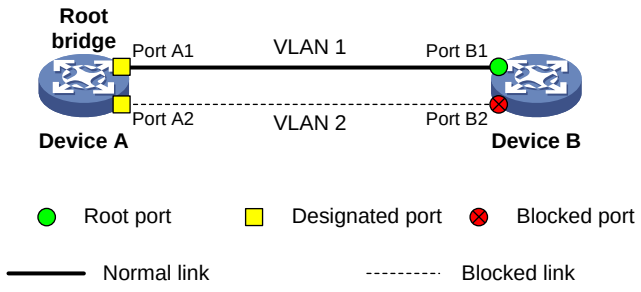
- Make sure the VLANs on one device do not use the same ID as the PVID of its peer port (except the default VLAN) on another device.
- If the local port or its peer is a hybrid port, do not configure the local and peer ports as untagged members of the same VLAN.
- Disable inconsistent PVID protection on both the local device and the peer device.

This feature takes effect only when the device is operating in PVST mode.

Procedure

1. Enter system view.
   system-view
2. Disable the inconsistent PVID protection feature.
   stp ignore-pvid-inconsistency

   By default, the inconsistent PVID protection feature is enabled.



Ignoring the specified VLANs

About this task

Traffic of a VLAN on a complex network might be blocked by the spanning tree, as shown in Figure 16.

- Port A1 on Device A allows the traffic of VLAN 1 to pass through.
- Port A2 on Device A allows the traffic of VLAN 2 to pass through.
- Port B1 on Device B allows the traffic of VLAN 1 to pass through.
- Port B2 on Device B allows the traffic of VLAN 2 to pass through.
- Device A and Device B run a spanning tree protocol. Device A is the root bridge, and Port A1 and Port A2 are designated ports. On Device B, Port B1 is the root port, and Port B2 is the blocked port. Traffic of VLAN 2 is blocked.

Figure 16 VLAN connectivity blocked by MSTP

Ignoring a VLAN can make ports of the VLAN forward frames correctly rather than comply with the spanning tree calculation result.

Procedure

1. Enter system view.

   system-view

2. Ignore the specified VLANs.

   stp ignored vlan *vlan-id-list*

   By default, no VLAN is ignored.

Configuring Digest Snooping

About this task

As defined in IEEE 802.1s, connected devices are in the same region only when they have the same MST region-related configurations, including:

- Region name.
- Revision level.
- VLAN-to-instance mappings.

A spanning tree device identifies devices in the same MST region by determining the configuration ID in BPDUs. The configuration ID includes the region name, revision level, and configuration digest. It is 16-byte long and is the result calculated through the HMAC-MD5 algorithm based on VLAN-to-instance mappings.

Because spanning tree implementations vary by vendor, the configuration digests calculated through private keys are different. The devices of different vendors in the same MST region cannot communicate with each other.

To enable communication between an H3C device and a third-party device in the same MST region, enable Digest Snooping on the H3C device port connecting them.

Restrictions and guidelines

CAUTION:

Use caution with global Digest Snooping in the following situations:

- When you modify the VLAN-to-instance mappings.
- When you restore the default MST region configuration.

If the local device has different VLAN-to-instance mappings than its neighboring devices, loops or traffic interruption will occur.

- Before you enable Digest Snooping, make sure associated devices of different vendors are connected and run spanning tree protocols.
- With Digest Snooping enabled, in-the-same-region verification does not require comparison of configuration digest. The VLAN-to-instance mappings must be the same on associated ports.
- To make Digest Snooping take effect, you must enable Digest Snooping both globally and on associated ports. As a best practice, enable Digest Snooping on all associated ports first and then enable it globally. This will make the configuration take effect on all configured ports and reduce impact on the network.
- To prevent loops, do not enable Digest Snooping on MST region edge ports.
- As a best practice, enable Digest Snooping first and then enable the spanning tree feature. To avoid traffic interruption, do not configure Digest Snooping when the network is already working well.

Prerequisites

Before configuring Digest Snooping, you need to make sure your H3C device and the third-party device both run spanning tree protocols properly.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable Digest Snooping on the interface.

   stp config-digest-snooping

   By default, Digest Snooping is disabled on ports.

4. Return to system view.

   quit

5. Enable Digest Snooping globally.

   stp global config-digest-snooping

   By default, Digest Snooping is disabled globally.

Configuring No Agreement Check

About this task

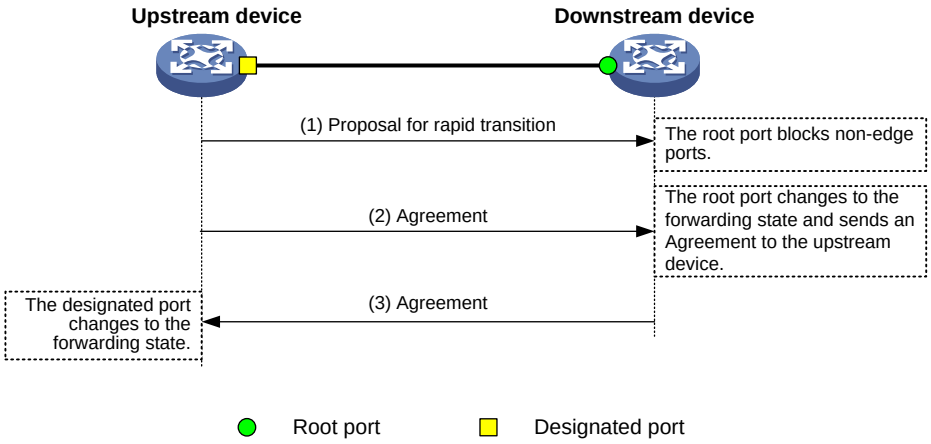
In RSTP and MSTP, the following types of messages are used for rapid state transition on designated ports:

- **Proposal**—Sent by designated ports to request rapid transition
- **Agreement**—Used to acknowledge rapid transition requests

Both RSTP and MSTP devices can perform rapid transition on a designated port only when the port receives an agreement packet from the downstream device. RSTP and MSTP devices have the following differences:

- For MSTP, the root port of the downstream device sends an agreement packet only after it receives an agreement packet from the upstream device.
- For RSTP, the downstream device sends an agreement packet whether or not an agreement packet from the upstream device is received.

Figure 17 Rapid state transition of an MSTP designated port



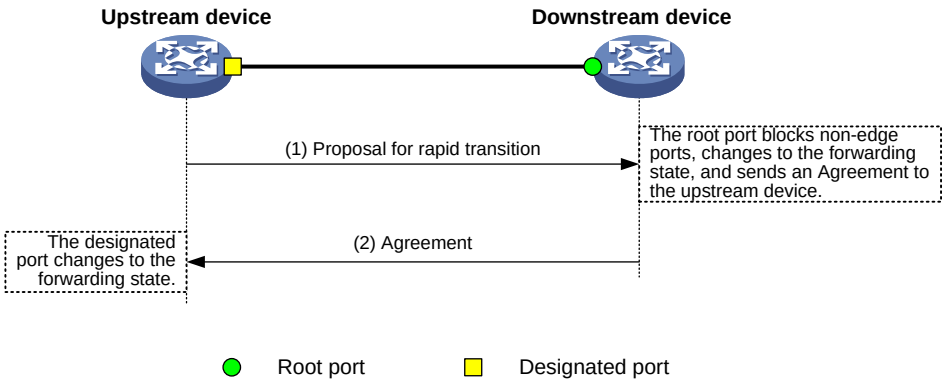


Figure 18 Rapid state transition of an RSTP designated port

If the upstream device is a third-party device, the rapid state transition implementation might be limited as follows:

- The upstream device uses a rapid transition mechanism similar to that of RSTP.
- The downstream device runs MSTP and does not operate in RSTP mode.

In this case, the following occurs:

1. The root port on the downstream device receives no agreement from the upstream device.
2. It sends no agreement to the upstream device.

As a result, the designated port of the upstream device can transit to the forwarding state only after a period twice the forward delay.

To enable the designated port of the upstream device to transit its state rapidly, enable No Agreement Check on the downstream device's port.

Restrictions and guidelines

Configure No Agreement Check on the root port of your device, because this feature takes effect only if it's configured on root ports.

Prerequisites

Before you configure the No Agreement Check feature, complete the following tasks:

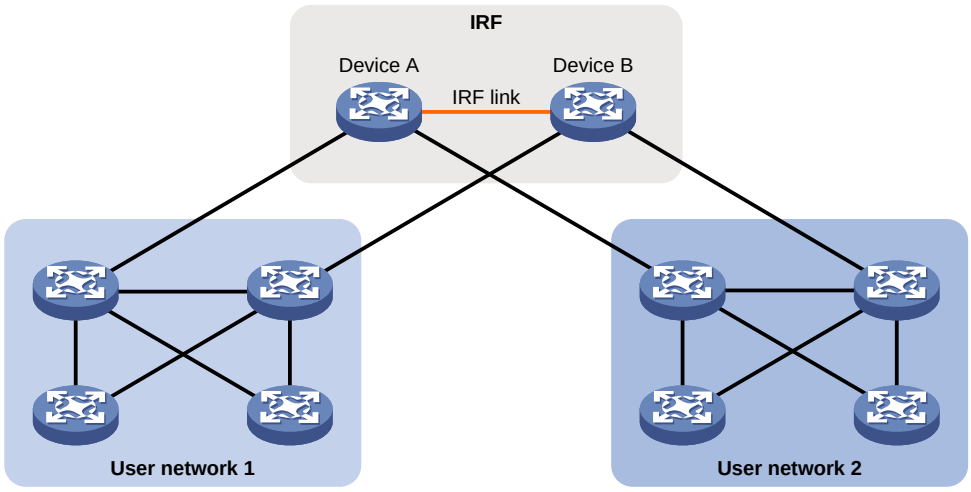
- Connect a device to a third-party upstream device that supports spanning tree protocols through a point-to-point link.
- Configure the same region name, revision level, and VLAN-to-instance mappings on the two devices.

Procedure

Enable the No Agreement Check feature on the root port.

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
3. Enable No Agreement Check.
   `stp no-agreement-check`
   By default, No Agreement Check is disabled.

Configuring TC Snooping



About this task

As shown in Figure 19, an IRF fabric connects to two user networks through double links.

- Device A and Device B form the IRF fabric.
- The spanning tree feature is disabled on Device A and Device B and enabled on all devices in user network 1 and user network 2.
- The IRF fabric transparently transmits BPDUs for both user networks and is not involved in the calculation of spanning trees.

When the network topology changes, it takes time for the IRF fabric to update its MAC address table and ARP table. During this period, traffic in the network might be interrupted.

Figure 19 TC Snooping application scenario

To avoid traffic interruption, you can enable TC Snooping on the IRF fabric. After receiving a TC-BPDU through a port, the IRF fabric updates MAC address table and ARP table entries associated with the port's VLAN. In this way, TC Snooping prevents topology change from interrupting traffic forwarding in the network. For more information about the MAC address table and the ARP table, see "Configuring the MAC address table" and *Layer 3—IP Services Configuration Guide*.

Restrictions and guidelines

- TC Snooping and the spanning tree feature are mutually exclusive. You must globally disable the spanning tree feature before enabling TC Snooping.
- TC Snooping does not support the PVST mode.

Procedure

1. Enter system view.

   `system-view`
2. Globally disable the spanning tree feature.

   `undo stp global enable`

   When the device starts up with initial settings, the spanning tree feature is globally disabled by default.

   When the device starts up with factory defaults, the spanning tree feature is globally enabled by default.

   For more information about the initial settings and factory defaults, see *Fundamentals Configuration Guide*.
3. Enable TC Snooping.

   `stp tc-snooping`

   By default, TC Snooping is disabled.

Configuring protection features

Spanning tree protection tasks at a glance

All spanning tree protection tasks are optional.

- Configuring BPDU guard

- Configuring BPDU filter
- Enabling root guard

Configuring BPDU guard

About this task

For access layer devices, the access ports can directly connect to the user terminals (such as PCs) or file servers. The access ports are configured as edge ports to allow rapid transition. When these ports receive configuration BPDUs, the system automatically sets the ports as non-edge ports and starts a new spanning tree calculation process. This causes a change of network topology. Under normal conditions, these ports should not receive configuration BPDUs. However, if someone uses configuration BPDUs maliciously to attack the devices, the network will become unstable.

The spanning tree protocol provides the BPDU guard feature to protect the system against such attacks. When ports with BPDU guard enabled receive configuration BPDUs on a device, the device performs the following operations:

- Shuts down these ports.
- Notifies the NMS that these ports have been shut down by the spanning tree protocol.

The device reactivates the ports that have been shut down when the port status detection timer expires. You can set this timer by using the **shutdown-interval** command. For more information about this command, see device management commands in *Fundamentals Command Reference*.

Restrictions and guidelines

You can configure the BPDU guard feature in system view or on a per-edge port basis. An edge port preferentially uses the port-specific BPDU guard setting. If the port-specific BPDU guard setting is not available, the edge port uses the global BPDU guard setting.

Global BPDU guard takes effect only on the edge ports configured by using the **stp edged-port** command. For the BPDU guard feature to take effect on a non-edge port, use the port-specific BPDU guard setting.

Configure BPDU guard on edge ports which directly connect to a user terminal rather than other device or shared LAN segment.

BPDU guard does not take effect on loopback-testing-enabled ports. For more information about loopback testing, see Ethernet interface configuration in *Layer 2—LAN Switching Configuration Guide*.

Enabling BPDU guard in system view

1. Enter system view.
   system-view
2. Enable BPDU guard globally.
   stp bpdu-protection
   By default, BPDU guard is globally disabled.

Configuring BPDU guard in interface view

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure BPDU guard.
   stp port bpdu-protection { **enable** | **disable** }
   By default, the enabling status of BPDU guard on an interface is the same as that of global BPDU guard. BPDU guard is not configured on non-edge ports.

Configuring BPDU filter

About this task

To prevent undesired spanning tree calculation and network flapping in the networks attached to an edge device, enable BPDU filter on the device to disable its ports from sending BPDUs.

Restrictions and guidelines

IMPORTANT:

With BPDU filter enabled, a port does not send any BPDUs and ignores all incoming BPDUs regardless of whether it is an edge port. Make sure you are fully aware of the impacts of this feature before you enable it on a port.

You can configure the BPDU filter feature globally or on a per-port basis. A port preferentially uses the port-specific BPDU filter setting. If the port-specific BPDU filter setting is not available, the port uses the global BPDU filter setting.

The global BPDU filter setting takes effect on all edge ports configured by using the **stp edged-port** command. With BPDU filter enabled globally, edge ports no longer send BPDUs, and they will become non-edge ports to participate in spanning tree calculation after receiving BPDUs.

Enabling BPDU filter globally

1. Enter system view.
   system-view
2. Enable BPDU filter globally.
   stp bpdu-filter
   By default, BPDU filter is disabled globally.

Configuring BPDU filter on a port

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure BPDU filter on the interface.
   stp port bpdu-filter { **disable** | **enable** }
   By default, the enabling status of BPDU filter on an edge port is the same as that of global BPDU filter. The BPDU filter feature is disabled on non-edge ports.

Enabling root guard

About this task

Configure root guard on a designated port.

The root bridge and secondary root bridge of a spanning tree should be located in the same MST region. Especially for the CIST, the root bridge and secondary root bridge are put in a high-bandwidth core region during network design. However, due to possible configuration errors or malicious attacks in the network, the legal root bridge might receive a configuration BPDU with a higher priority. Another device supersedes the current legal root bridge, causing an undesired change of the network topology. The traffic that should go over high-speed links is switched to low-speed links, resulting in network congestion.

To prevent this situation, MSTP provides the root guard feature. If root guard is enabled on a port of a root bridge, this port plays the role of designated port on all MSTIs. After this port receives a configuration BPDU with a higher priority from an MSTI, it performs the following operations:

- Immediately sets that port to the listening state in the MSTI.
- Does not forward the received configuration BPDU.

This is equivalent to disconnecting the link connected to this port in the MSTI. If the port receives no BPDUs with a higher priority within twice the forwarding delay, it reverts to its original state.

Restrictions and guidelines

On a port, the loop guard feature and the root guard feature are mutually exclusive.

Procedure

1. Enter system view.

   `system-view`
2. Enter interface view.

   `interface` *`interface-type interface-number`*
3. Enable the root guard feature.

   `stp root-protection`

   By default, root guard is disabled.

Enabling loop guard

About this task

Configure loop guard on the root port and alternate ports of a device.

By continuing to receive BPDUs from the upstream device, a device can maintain the state of the root port and blocked ports. However, link congestion or unidirectional link failures might cause these ports to fail to receive BPDUs from the upstream devices. In this situation, the device reselects the following port roles:

- Those ports in forwarding state that failed to receive upstream BPDUs become designated ports.
- The blocked ports transit to the forwarding state.

As a result, loops occur in the switched network. The loop guard feature can suppress the occurrence of such loops.

The initial state of a loop guard-enabled port is **discarding** in every MSTI. When the port receives BPDUs, it transits its state. Otherwise, it stays in the discarding state to prevent temporary loops.

Restrictions and guidelines

Do not enable loop guard on a port that connects user terminals. Otherwise, the port stays in the discarding state in all MSTIs because it cannot receive BPDUs.

On a port, the loop guard feature is mutually exclusive with the root guard feature or the edge port setting.

A loop guard-enabled interface can receive BPDUs and transit from the discarding state to the forwarding state after two forward delays if one of the following events occurs:

- The state of the interface changes from down to up.
- The spanning tree feature is enabled on the up interface.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable the loop guard feature.
   stp loop-protection
   By default, loop guard is disabled.

Configuring port role restriction

About this task

Make this configuration on the port that connects to the user access network.

The bridge ID change of a device in the user access network might cause a change to the spanning tree topology in the core network. To avoid this problem, you can enable port role restriction on a port. With this feature enabled, when the port receives a superior BPDU, it becomes an alternate port rather than a root port.

Restrictions and guidelines

Use this feature with caution, because enabling port role restriction on a port might affect the connectivity of the spanning tree topology.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable port role restriction.
   stp role-restriction
   By default, port role restriction is disabled.

Configuring TC-BPDU transmission restriction

About this task

Make this configuration on the port that connects to the user access network.

The topology change to the user access network might cause the forwarding address changes to the core network. When the user access network topology is unstable, the user access network might affect the core network. To avoid this problem, you can enable TC-BPDU transmission restriction on

a port. With this feature enabled, when the port receives a TC-BPDU, it does not forward the TC-BPDU to other ports.

Restrictions and guidelines

Enabling TC-BPDU transmission restriction on a port might cause the previous forwarding address table to fail to be updated when the topology changes.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable TC-BPDU transmission restriction.
   stp tc-restriction
   By default, TC-BPDU transmission restriction is disabled.

Enabling TC-BPDU guard

About this task

When a device receives topology change (TC) BPDUs (the BPDUs that notify devices of topology changes), it flushes its forwarding address entries. If someone uses TC-BPDUs to attack the device, the device will receive a large number of TC-BPDUs within a short time. Then, the device is busy with forwarding address entry flushing. This affects network stability.

TC-BPDU guard allows you to set the maximum number of immediate forwarding address entry flushes performed within 10 seconds after the device receives the first TC-BPDU. For TC-BPDUs received in excess of the limit, the device performs a forwarding address entry flush when the time period expires. This prevents frequent flushing of forwarding address entries.

Restrictions and guidelines

As a best practice, enable TC-BPDU guard.

Procedure

1. Enter system view.
   system-view
2. Enable the TC-BPDU guard feature.
   stp tc-protection
   By default, TC-BPDU guard is enabled.
3. (Optional.) Configure the maximum number of forwarding address entry flushes that the device can perform every 10 seconds.
   stp tc-protection threshold *number*
   The default setting is 6.

Enabling BPDU drop

About this task

In a spanning tree network, every BPDU arriving at the device triggers an STP calculation process and is then forwarded to other devices in the network. Malicious attackers might use the vulnerability to attack the network by forging BPDUs. By continuously sending forged BPDUs, they can make all devices in the network continue performing STP calculations. As a result, problems such as CPU overload and BPDU protocol status errors occur.

To avoid this problem, you can enable BPDU drop on ports. A BPDU drop-enabled port does not receive any BPDUs and is invulnerable to forged BPDU attacks.

Restrictions and guidelines

With this feature enabled, the packets with destination MAC addresses in the range of 0x01-80-c2-00-00-00 to 0x01-80-c2-00-00-2f will be dropped, including but not limited to packets from the following protocols: STP, RSTP, MSTP, LACP, LLDP, 802.1X, and GARP. Make sure you are fully aware of the impact of this feature when you use it on a live network.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view.
   interface *interface-type interface-number*
3. Enable BPDU drop on the interface.
   bpdu-drop any
   By default, BPDU drop is disabled.

Enabling PVST BPDU guard

About this task

This feature takes effect only when the device is operating in MSTP mode.

An MSTP-enabled device forwards PVST BPDUs as data traffic because it cannot recognize PVST BPDUs. If a PVST-enabled device in another independent network receives the PVST BPDUs, a PVST calculation error might occur. To avoid PVST calculation errors, enable PVST BPDU guard on the MSTP-enabled device. The device shuts down a port if the port receives PVST BPDUs.

Procedure

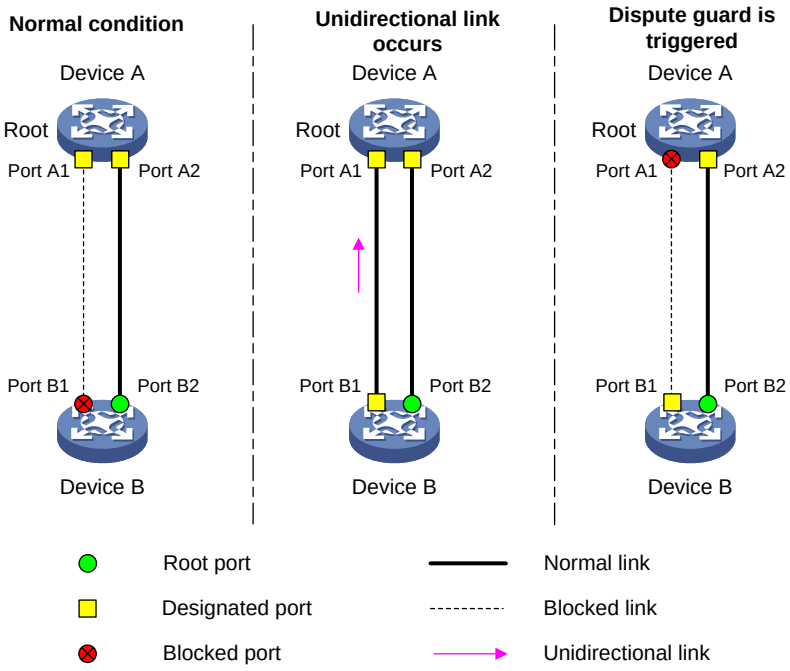
1. Enter system view.
   system-view
2. Enable PVST BPDU guard.
   stp pvst-bpdu-protection
   By default, PVST BPDU guard is disabled.

Disabling dispute guard

About this task

Dispute guard can be triggered by unidirectional link failures. If an upstream port receives inferior BPDUs from a downstream designated port in forwarding or learning state because of a unidirectional link failure, a loop appears. Dispute guard blocks the upstream designated port to prevent the loop.

As shown in Figure 20, in normal conditions, the spanning tree calculation result is as follows:



- Device A is the root bridge, and Port A1 is a designated port.
- Port B1 is blocked.

When the link between Port A1 and Port B1 fails in the direction of Port A1 to Port B1 and becomes unidirectional, the following events occur:

1. Port A1 can only receive BPDUs and cannot send BPDUs to Port B1.
2. Port B1 does not receive BPDUs from Port A1 for a certain period of time.

3. Device B determines itself as the root bridge.
4. Port B1 sends its BPDUs to Port A1.
5. Port A1 determines the received BPDUs are inferior to its own BPDUs. A dispute is detected.
6. Dispute guard is triggered and blocks Port A1 to prevent a loop.

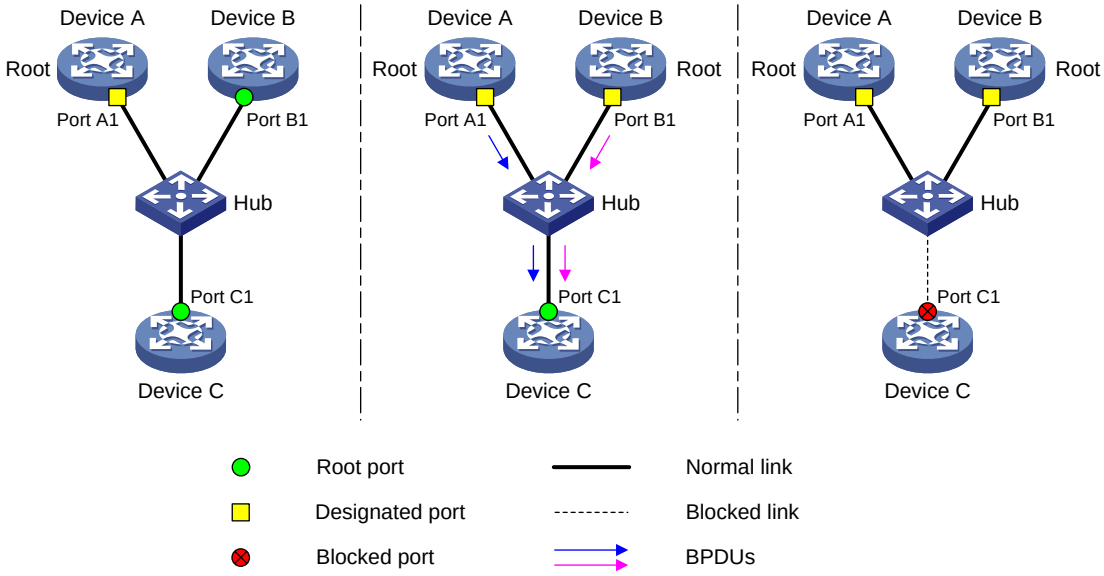


Figure 20 Dispute guard triggering scenario (on a designated port)

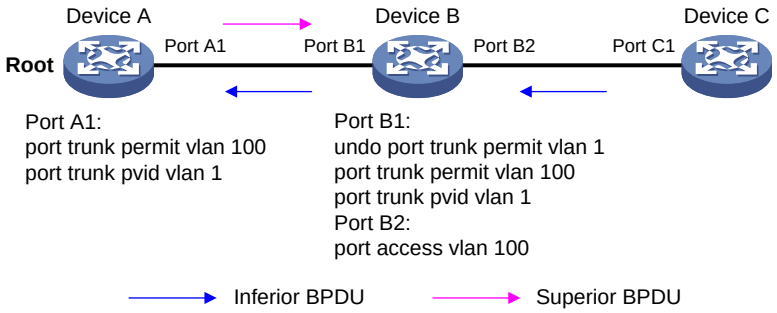
As shown in Figure 21, in normal conditions, Device A is the root bridge, and Port B1 and Port C1 are root ports. When the links between Device A and Device B become unidirectional (the links fail in the direction of Port A1 to Port B1), the following events occur:

7. Device B cannot receive BPDUs from Device A.
8. Device B determines itself as the root bridge.
9. Port B1 sends BPDUs in which the root bridge is Device B to Port C1.
10. Port C1 receives BPDUs from two root bridges, Device A and Device B. A dispute is detected.
11. Dispute guard is triggered and blocks Port C1 to avoid a loop.

Figure 21 Dispute guard triggering scenario (on a root port)



However, dispute guard might disrupt the network connectivity. You can disable dispute guard to avoid connectivity loss in VLAN networks. As shown in Figure 22, the spanning tree feature is disabled on Device B and enabled on Device A and device C. Device B transparently transmits BPDUs.

Device C cannot receive superior BPDUs of VLAN 1 from Device A because Port B1 of Device B is configured to deny packets of VLAN 1. Device C determines itself as the root bridge after a certain period of time. Then, Port C1 sends an inferior BPDU of VLAN 100 to Device A.

When Device A receives the inferior BPDU, dispute guard blocks Port A1, which causes traffic interruption. To ensure service continuity, you can disable dispute guard on Device A to prevent the link from being blocked.

Figure 22 Disabling dispute guard application scenario

Restrictions and guidelines

You can disable dispute guard if the network does not have unidirectional link failures.

Procedure

1. Enter system view.
   - **`system-view`**
2. Disable dispute guard.
   - **`undo stp dispute-protection`**
   - By default, dispute guard is enabled.

Disabling loopback guard

About this task

By default, loopback guard is enabled on interfaces. The device blocks a loopback guard-enabled interface to remove loops when the interface receives a BPDU sent by itself. In some scenarios, an interface can receive the BPDUs sent by itself when no loop exists. For example, a fiber-to-copper converter might reflect back BPDUs. To prevent the device from blocking loopless interfaces in those scenarios and ensure a stable network topology, you can disable loopback guard.

Restrictions and guidelines

Disabling loopback guard might cause loops. Disable this feature unless necessary. Make sure you are fully aware of the impact when you disable loopback guard on a live network.

In Layer 2 Ethernet interface view, loopback guard configuration takes effect only on that interface.

In Layer 2 aggregate interface view, loopback guard configuration takes effect only on the aggregate interface.

On a member port in an aggregation group, loopback guard configuration takes effect only after the port leaves the aggregation group.

Procedure

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
3. Enable loopback guard.
   `undo stp loopback-protection`
   - By default, loopback guard is enabled on interfaces.

Enabling the device to log events of detecting or receiving TC BPDUs

About this task

This feature allows the device to generate logs when it detects or receives TC BPDUs. This feature applies only to PVST mode.

Procedure

1. Enter system view.
   `system-view`
2. Enable the device to log events of receiving or detecting TC BPDUs.
   `stp log enable tc`

   By default, the device does not generate logs when it detects or receives TC BPDUs.

Disabling the device from reactivating edge ports shut down by BPDU guard

About this task

BPDU guard shuts down edge ports that have received configuration BPDUs and notifies the NMS of the shutdown event.

The device reactivates the ports that have been shut down when the port status detection timer expires. You can set this timer by using the **shutdown-interval** command. For more information about this command, see device management commands in *Fundamentals Command Reference*.

Restrictions and guidelines

This feature prevents the device from reactivating edge ports shut down by BPDU guard after this feature is configured. The device does not bring up the shutdown ports if you execute the **undo stp port shutdown permanent** command. To bring up these ports, use the **undo shutdown** command.

Procedure

1. Enter system view.

   system-view

2. Disable the device from reactivating edge ports shut down by BPDU guard.

   stp port shutdown permanent

   By default, the device reactivates an edge port shut down by BPDU guard after the port status detection timer expires.

Enabling BPDU transparent transmission on a port

Restrictions and guidelines

Perform this task to enable a port to transmit BPDUs transparently. Whether the spanning tree protocols are enabled on a port does not affect the BPDU transparent transmission feature.

If this feature and the spanning tree protocol are enabled on a port which is inferior to its downstream port, the downstream port can receive BPDUs from that port. To prevent network flapping caused by this problem, disable the spanning tree protocol before you enable BPDU transparent transmission on the port.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

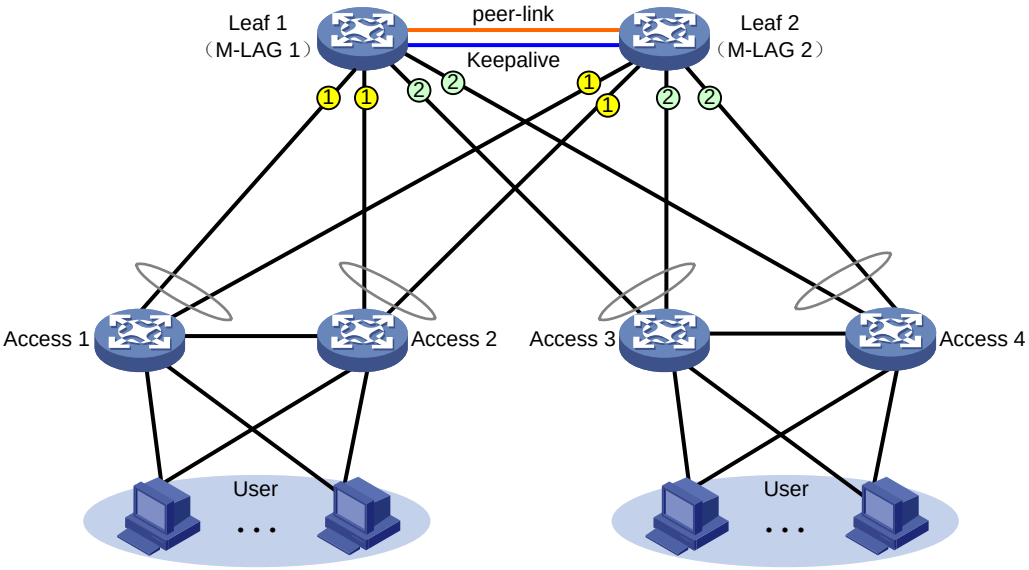
3. Enable BPDU transparent transmission.

   stp transparent enable

   By default, the BPDU transparent transmission feature is disabled on a port.

Configuring TC groups

About this task



As shown in Figure 23, two devices at the leaf tier form an M-LAG system. The M-LAG system is connected to two loops (Access 1 — Access 2 — M-LAG and Access 3 — Access 4 — M-LAG), and STP runs on all devices. By default, any topology change by a device causes TC-BPDUs to be sent to both loops and create excessive TC-BPDUs in the network, which impacts system stability. If the topology changes, the interfaces for the user onboarding service on the leaf devices might change. In this case, users must be re-authenticated on other interfaces of the leaf devices to come online. During the re-authentication process, service traffic might be lost.

Figure 23 Network diagram

To address this issue, you can configure topology change (TC) groups. A TC group is a logical combination of multiple interfaces on a device, and supports a maximum of two interfaces. As shown in Figure 24, the two M-LAG interfaces connecting to Access 1 and Access 2 are added to TC group 1, and the two M-LAG interfaces connecting to Access 3 and Access 4 are added to TC group 2 on the leaf devices.

Figure 24 Network diagram

After TC groups are configured, the network can achieve the following functions:

- When an M-LAG interface in a TC group receives a TC-BPDU, it forwards it only to the other M-LAG interface in the same TC group. This mechanism reduces the number of TC-BPDUs in the entire network, isolating the TC-BPDUs of the Access 1—Access 2—M-LAG loop and those of the Access 3—Access 4—M-LAG loop. When leaf devices are connected to many loops, this mechanism reduces the impact of exchanging TC-BPDU packets among loops.
- When the network topology changes, static users, MAC authentication users, and 802.1X users in the same TC group can migrate between the two M-LAG interfaces in the TC group without authentication, enabling users to quickly come online again. For more information about the configuration procedures, migration conditions, and migration rules for authentication-free migration, see port security configuration in *Security Configuration Guide*.

Restrictions and guidelines

You can add interfaces to a TC group in either of the following methods:

- Execute the **port stp tc-group** command in interface view.
- Execute the **port** command in TC group view.

Both methods have the same effect, but their configurations cannot conflict with each other. Once an interface is added to a TC group in one method, it can be removed from the TC group in the other method. However, you cannot directly modify the TC group to which the interface belongs in the other method.

Procedure

1. Enter system view.

   system-view
2. Create a TC group and enter its view.

   stp tc-group *group-id*
3. Add interfaces to the TC group in one of the following methods:
   - Add interfaces to the TC group in TC group view.

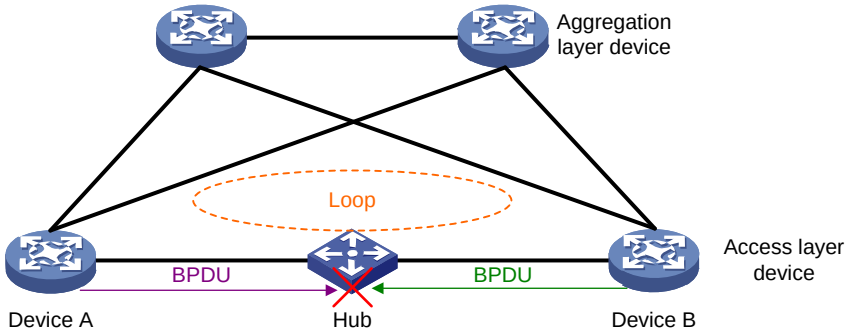
     port *interface-type interface-number*
   - Execute the following commands in sequence to add interfaces to the TC group in Layer 2 aggregate interface view.

     quit

interface *interface-type interface-number*

port stp tc-group *group-id*

By default, an interface is not added to any TC group.



A maximum of two interfaces can be added to a TC group.

Configuring spanning tree blackhole detection

About this task

As shown in Figure 25, Device A and Device B are connected via a HUB, which creates a loop in the network. Since BPDUs are point-to-point frames, once they are transmitted from a device and received by the next node, their transmission is terminated. The HUB acts as a blackhole for BPDUs. BPDUs cannot be transmitted between Device A and Device B through the HUB, and Device A and Device B cannot eliminate the loop through correct spanning tree topology calculation. Therefore, a method to detect BPDU blackholes is crucial for devices to block links to blackholes when detecting them, effectively eliminating potential loop risks.

Figure 25 Network diagram

Spanning tree blackhole detection feature can detect the presence of BPDU blackholes in the port links. Its working mechanism is as follows.

1. Blackhole verification phase.

   A port enabled with spanning tree blackhole detection will start the BPDU reception timer of the blackhole detection feature. If the port receives a BPDU before the BPDU reception timer expires, the port resets the BPDU reception timer. If the BPDU reception timer expires, BPDU blackholes might exist on the network. As a result, the device fails to receive BPDUs for a long time, and the port starts to send spanning tree blackhole detection packets continuously.

   Spanning tree blackhole detection packet is a type of Layer 2 packets defined by H3C. Different from the BPDU, the spanning tree blackhole detection packet can be transparently transmitted by the HUB, and will be sent continuously at a fixed time interval after being triggered to send.

   Use the **stp global blackhole-detection rx-bpdu timeout** command to set the BPDU reception timer. Use the **stp timer blackhole-detection-interval** or **stp global timer blackhole-detection-interval** command to set the interval for sending spanning tree blackhole detection packets.

2. Blackhole confirmation phase.

   If the port is triggered to send spanning tree blackhole detection packets and receives a BPDU, it proves that no BPDU blackhole exist between the devices. The port stops transmitting the spanning tree blackhole detection packets and resets the BPDU reception timer.

   If a port with the spanning tree blackhole detection feature enabled receives a blackhole detection frame while its BPDU reception timer is in a timeout state, it indicates that the link between the local and remote devices is connected. Both devices are capable of sending BPDUs, but neither device receives BPDUs. The local device determines that a BPDU blackhole exists between the two ends of the link.

3. Blackhole handling phase.

   After the device discovers a BPDU blackhole, it blocks the port that receives the spanning tree blackhole detection packet. Loops in the network are eliminated by preventing ports from sending and receiving any user data packets. You can use the **stp timer rx-blackhole-timeout** or **stp global timer rx-blackhole-timeout** command to specify the timeout period of the blocked port for spanning tree blackhole detection. If the port does not receive the spanning tree blackhole detection packet again within the timeout period, it means that the BPDU blackhole is eliminated, and the port returns to the normal forwarding state. Otherwise, the port continues to retain the blocking state.

The **stp timer blackhole-detection-interval** and **stp global timer blackhole-detection-interval** commands affect the frequency at which the specified port sends spanning tree blackhole detection packets. Set an appropriate packet sending interval as needed.

- When the sending interval is short, the port sends spanning tree blackhole packets more frequently. The advantage is that the network is more sensitive in detection and response to BPDU blackholes. The disadvantage is that it takes up more device CPU resources. Set a short sending interval in scenarios with strong device performance or a strong need to prevent loops.
- When the sending interval is long, the port sends spanning tree blackhole packets slowly. The advantage is that it occupies less CPU resources of the device. The disadvantage is that the network detects and responds more slowly to BPDU blackholes. Set a long sending interval in the scenario where the device performance is weak or tolerant of loops.

Restrictions and guidelines

The spanning tree blackhole detection feature takes effect when the following conditions are met:

- On the devices at both ends of a link, the spanning tree blackhole detection is enabled both globally and on ports.
- The link status of the port on which the spanning tree blackhole detection is enabled is up, and the spanning tree feature is enabled.

If the spanning tree blackhole detection is disabled on the port, or the BPDU reception timer on the port has not expired, the port does not perform any processing after receiving the spanning tree blackhole detection packet.

On a device with a long interval for sending BPDUs, set a longer value for the BPDU reception timer to prevent the device port from being blocked when no BPDU blackhole exists on the network. On the device with a short interval for sending BPDUs, set a shorter value for the BPDU reception timer to improve the network's detection speed of BPDU blackholes.

You can use the **stp timer blackhole-detection-interval** and **stp global timer blackhole-detection-interval** commands to modify the interval for sending spanning tree blackhole detection packets on a port. When both commands are configured at the same time, the configuration of the **stp timer blackhole-detection-interval** command takes effect. If no command is configured on the port, the port inherits the configuration of the **stp global timer blackhole-detection-interval** command.

You can use the **stp timer rx-blackhole-timeout** and **stp global timer rx-blackhole-timeout** commands to modify the timeout timer for receiving spanning tree blackhole detection packets on a port. When both commands are configured at the same time, the configuration of the **stp timer rx-blackhole-timeout** command takes effect. If no command is configured on the port, the port inherits the configuration of the **stp global timer rx-blackhole-timeout** command.

Procedure

1. Enter system view.

   system-view

2. Enable spanning tree blackhole detection globally.

stp global blackhole-detection enable

By default, spanning tree blackhole detection is disabled globally.

3. (Optional.) Set the BPDU reception timer for the blackhole detection feature.

   stp global blackhole-detection rx-bpdu timeout *timeout*

   By default, the BPDU reception timer of the blackhole detection feature is 18 seconds.

4. (Optional.) Set the interval for sending spanning tree blackhole detection packets globally.

   stp global timer blackhole-detection-interval *interval*

   By default, the interval for sending spanning tree blackhole detection packets is 2 seconds.

5. (Optional.) Set the detection packet reception timer for spanning tree blackhole detection globally.

   stp global timer rx-blackhole-timeout *timeout*

   By default, the formula for calculating the timeout period (seconds) for receiving spanning tree blackhole packets is: Multiply the sending interval of spanning tree blackhole detection packets on a port by 3 and add 10.

6. Enter Layer 2 Ethernet interface view.

   interface *interface-type interface-number*

7. (Optional.) Enable spanning tree blackhole detection on the port.

   stp blackhole-detection enable

   By default, spanning tree blackhole detection on the port is enabled.

8. (Optional.) Set the interval for sending spanning tree blackhole detection packets on the port.

   stp timer blackhole-detection-interval *interval*

   By default, the interval for sending spanning tree blackhole detection packets is 2 seconds.

9. (Optional.) Set the detection packet reception timer for spanning tree blackhole detection on the port.

   stp timer rx-blackhole-timeout *timeout*

   By default, the formula for calculating the timeout period (seconds) for receiving spanning tree blackhole packets on the port is: Multiply the sending interval of spanning tree blackhole detection packets on a port by 3 and add 10.

Enabling SNMP notifications for new-root election and topology change events

About this task

This task enables the device to generate logs and report new-root election events or spanning tree topology changes to SNMP. For the event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

When you use the **snmp-agent trap enable stp** [**new-root** | **tc**] command, follow these guidelines:

- The **new-root** keyword applies only to STP, MSTP, and RSTP modes.
- The **tc** keyword applies only to PVST mode.
- In STP, MSTP, or RSTP mode, the **snmp-agent trap enable stp** command enables SNMP notifications for new-root election events.
- In PVST mode, the **snmp-agent trap enable stp** command enables SNMP notifications for spanning tree topology changes.

Procedure

1. Enter system view.
   system-view
2. Enable SNMP notifications for new-root election and topology change events.
   snmp-agent trap enable stp [**new-root** | **tc**]
   The default settings are as follows:
   - SNMP notifications are disabled for new-root election events.
   - In MSTP mode, SNMP notifications are enabled in MSTI 0 and disabled in other MSTIs for spanning tree topology changes.
   - In PVST mode, SNMP notifications are disabled for spanning tree topology changes in all VLANs.

Display and maintenance commands for the spanning tree protocols

Execute **display** commands in any view and **reset** command in user view.

Task	Command
Display the spanning tree status and statistics.	**display stp** [**instance** *instance-list* | **vlan** *vlan-id-list*] [**interface** *interface-list* | **slot** *slot-number*] [**brief**]
Display the port role calculation history for the specified MSTI or all MSTIs.	**display stp** [**instance** *instance-list* | **vlan** *vlan-id-list*] **history** [**slot** *slot-number*]
Display the incoming and outgoing TC/TCN BPDU statistics by all ports in the specified MSTI or all MSTIs.	**display stp** [**instance** *instance-list* | **vlan** *vlan-id-list*] **tc** [**slot** *slot-number*]
Display history about ports blocked by spanning tree protection features.	**display stp abnormal-port**
Display BPDU statistics on ports.	**display stp bpdu-statistics** [**interface** *interface-type interface-number* [**instance** *instance-list*]]
Display information about ports shut down by spanning tree protection features.	**display stp down-port**
Display the ignored VLANs.	**display stp ignored-vlan**
Display the MST region configuration information that has taken effect.	**display stp region-configuration**
Display the root bridge information of all MSTIs.	**display stp root**
Display information about TC groups.	**display stp tc-group** [*group-id*]
Display information about ports blocked by the spanning tree	**display stp blackhole-detection blocked-port**

Task	Command

Spanning tree configuration examples

Example: Configuring MSTP

Network configuration

As shown in Figure 26, all devices on the network are in the same MST region. Device A and Device B work at the distribution layer. Device C and Device D work at the access layer.

Configure MSTP so that frames of different VLANs are forwarded along different spanning trees.

- VLAN 10 frames are forwarded along MSTI 1.
- VLAN 30 frames are forwarded along MSTI 3.
- VLAN 40 frames are forwarded along MSTI 4.
- VLAN 20 frames are forwarded along MSTI 0.

VLAN 10 and VLAN 30 are terminated on the distribution layer devices, and VLAN 40 is terminated on the access layer devices. The root bridges of MSTI 1 and MSTI 3 are Device A and Device B, respectively, and the root bridge of MSTI 4 is Device C.

Figure 26 Network diagram

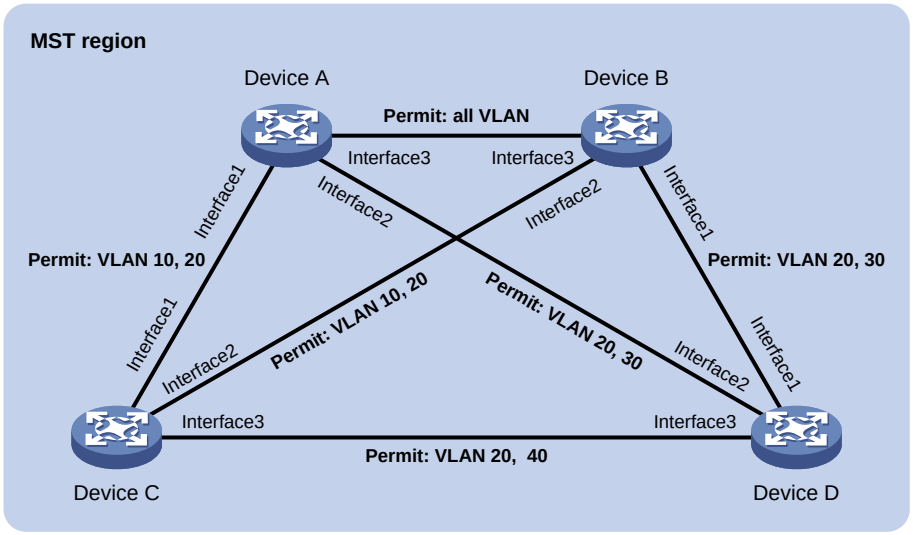

Table 14 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure VLANs and VLAN member ports. (Details not shown.)

- Create VLAN 10, VLAN 20, and VLAN 30 on both Device A and Device B.
- Create VLAN 10, VLAN 20, and VLAN 40 on Device C.
- Create VLAN 20, VLAN 30, and VLAN 40 on Device D.
- Configure the ports on these devices as trunk ports and assign them to related VLANs.

2. Configure Device A:

Enter MST region view, and configure the MST region name as **example**.

```
<DeviceA> system-view
[DeviceA] stp region-configuration
[DeviceA-mst-region] region-name example
```

Map VLAN 10, VLAN 30, and VLAN 40 to MSTI 1, MSTI 3, and MSTI 4, respectively.

```
[DeviceA-mst-region] instance 1 vlan 10
[DeviceA-mst-region] instance 3 vlan 30
[DeviceA-mst-region] instance 4 vlan 40
```

Configure the revision level of the MST region as 0.

```
[DeviceA-mst-region] revision-level 0
```

Activate MST region configuration.

```
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit
```

Configure the Device A as the root bridge of MSTI 1.

```
[DeviceA] stp instance 1 root primary
```

Enable the spanning tree feature globally.

```
[DeviceA] stp global enable
```

3. Configure Device B:

Enter MST region view, and configure the MST region name as **example**.

```
<DeviceB> system-view
[DeviceB] stp region-configuration
[DeviceB-mst-region] region-name example
```

Map VLAN 10, VLAN 30, and VLAN 40 to MSTI 1, MSTI 3, and MSTI 4, respectively.

```
[DeviceB-mst-region] instance 1 vlan 10
[DeviceB-mst-region] instance 3 vlan 30
[DeviceB-mst-region] instance 4 vlan 40
```

Configure the revision level of the MST region as 0.

```
[DeviceB-mst-region] revision-level 0
```

Activate MST region configuration.

```
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

Configure Device B as the root bridge of MSTI 3.

```
[DeviceB] stp instance 3 root primary
```

Enable the spanning tree feature globally.

```
[DeviceB] stp global enable
```

4. Configure Device C:

Enter MST region view, and configure the MST region name as **example**.

```
<DeviceC> system-view
[DeviceC] stp region-configuration
[DeviceC-mst-region] region-name example
```

Map VLAN 10, VLAN 30, and VLAN 40 to MSTI 1, MSTI 3, and MSTI 4, respectively.

```
[DeviceC-mst-region] instance 1 vlan 10
[DeviceC-mst-region] instance 3 vlan 30
[DeviceC-mst-region] instance 4 vlan 40
```

Configure the revision level of the MST region as 0.

```
[DeviceC-mst-region] revision-level 0
```

Activate MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Configure the Device C as the root bridge of MSTI 4.

```
[DeviceC] stp instance 4 root primary
```

Enable the spanning tree feature globally.

```
[DeviceC] stp global enable
```

5. Configure Device D:

Enter MST region view, and configure the MST region name as **example**.

```
<DeviceD> system-view
[DeviceD] stp region-configuration
[DeviceD-mst-region] region-name example
```

Map VLAN 10, VLAN 30, and VLAN 40 to MSTI 1, MSTI 3, and MSTI 4, respectively.

```
[DeviceD-mst-region] instance 1 vlan 10
[DeviceD-mst-region] instance 3 vlan 30
[DeviceD-mst-region] instance 4 vlan 40
```

Configure the revision level of the MST region as 0.

```
[DeviceD-mst-region] revision-level 0
```

Activate MST region configuration.

```
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

Enable the spanning tree feature globally.

```
[DeviceD] stp global enable
```

Verifying the configuration

In this example, Device B has the lowest root bridge ID. As a result, Device B is elected as the root bridge in MSTI 0.

When the network is stable, you can use the **`display stp brief`** command to display brief spanning tree information on each device.

Display brief spanning tree information on Device A.

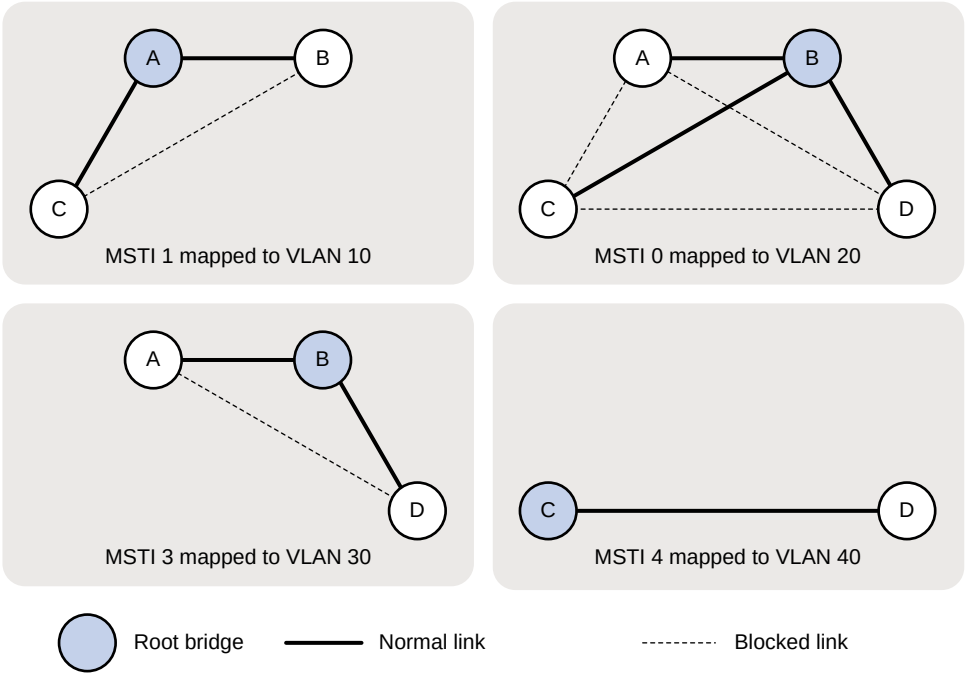
```
[DeviceA] display stp brief
 MST ID      Port                        Role  STP State     Protection
 0           GigabitEthernet1/0/1        ALTE  DISCARDING    NONE
 0           GigabitEthernet1/0/2        DESI  FORWARDING    NONE
 0           GigabitEthernet1/0/3        ROOT  FORWARDING    NONE
 1           GigabitEthernet1/0/1        DESI  FORWARDING    NONE
 1           GigabitEthernet1/0/3        DESI  FORWARDING    NONE
 3           GigabitEthernet1/0/2        DESI  FORWARDING    NONE
 3           GigabitEthernet1/0/3        ROOT  FORWARDING    NONE
```

Display brief spanning tree information on Device B.

```
[DeviceB] display stp brief
 MST ID      Port                        Role  STP State     Protection
```

```
 0           GigabitEthernet1/0/1          DESI  FORWARDING    NONE
 0           GigabitEthernet1/0/2          DESI  FORWARDING    NONE
 0           GigabitEthernet1/0/3          DESI  FORWARDING    NONE
 1           GigabitEthernet1/0/2          DESI  FORWARDING    NONE
 1           GigabitEthernet1/0/3          ROOT  FORWARDING    NONE
 3           GigabitEthernet1/0/1          DESI  FORWARDING    NONE
 3           GigabitEthernet1/0/3          DESI  FORWARDING    NONE
```

Display brief spanning tree information on Device C.



```
[DeviceC] display stp brief
 MST ID      Port                          Role  STP State     Protection
 0           GigabitEthernet1/0/1          DESI  FORWARDING    NONE
 0           GigabitEthernet1/0/2          ROOT  FORWARDING    NONE
 0           GigabitEthernet1/0/3          DESI  FORWARDING    NONE
 1           GigabitEthernet1/0/1          ROOT  FORWARDING    NONE
 1           GigabitEthernet1/0/2          ALTE  DISCARDING    NONE
 4           GigabitEthernet1/0/3          DESI  FORWARDING    NONE
```

Display brief spanning tree information on Device D.

```
[DeviceD] display stp brief
 MST ID      Port                          Role  STP State     Protection
 0           GigabitEthernet1/0/1          ROOT  FORWARDING    NONE
 0           GigabitEthernet1/0/2          ALTE  DISCARDING    NONE
 0           GigabitEthernet1/0/3          ALTE  DISCARDING    NONE
 3           GigabitEthernet1/0/1          ROOT  FORWARDING    NONE
 3           GigabitEthernet1/0/2          ALTE  DISCARDING    NONE
 4           GigabitEthernet1/0/3          ROOT  FORWARDING    NONE
```

Based on the output, you can draw each MSTI mapped to each VLAN, as shown in Figure 27.

Figure 27 MSTIs mapped to different VLANs

Example: Configuring PVST

Network configuration

As shown in Figure 28, Device A and Device B work at the distribution layer, and Device C and Device D work at the access layer.

Configure PVST to meet the following requirements:

- Frames of a VLAN are forwarded along the spanning trees of the VLAN.
- VLAN 10, VLAN 20, and VLAN 30 are terminated on the distribution layer devices, and VLAN 40 is terminated on the access layer devices.
- The root bridge of VLAN 10 and VLAN 20 is Device A.
- The root bridge of VLAN 30 is Device B.
- The root bridge of VLAN 40 is Device C.

Figure 28 Network diagram

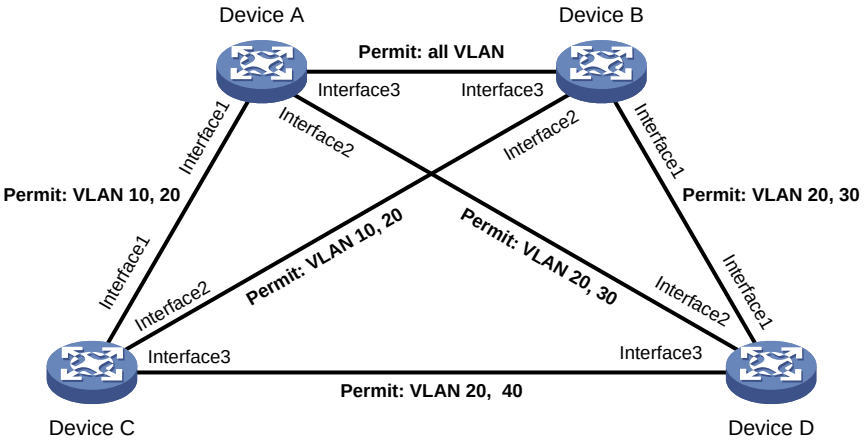


Table 15 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure VLANs and VLAN member ports. (Details not shown.)
   - Create VLAN 10, VLAN 20, and VLAN 30 on both Device A and Device B.
   - Create VLAN 10, VLAN 20, and VLAN 40 on Device C.
   - Create VLAN 20, VLAN 30, and VLAN 40 on Device D.
   - Configure the ports on these devices as trunk ports and assign them to related VLANs.
2. Configure Device A:

   # Set the spanning tree mode to PVST.

   ```
   <DeviceA> system-view
   [DeviceA] stp mode pvst
   ```

   # Configure the device as the root bridge of VLAN 10 and VLAN 20.

   ```
   [DeviceA] stp vlan 10 20 root primary
   ```

Enable the spanning tree feature globally and in VLAN 10, VLAN 20, and VLAN 30.

```
[DeviceA] stp global enable
[DeviceA] stp vlan 10 20 30 enable
```

3. Configure Device B:

Set the spanning tree mode to PVST.

```
<DeviceB> system-view
[DeviceB] stp mode pvst
```

Configure the device as the root bridge of VLAN 30.

```
[DeviceB] stp vlan 30 root primary
```

Enable the spanning tree feature globally and in VLAN 10, VLAN 20, and VLAN 30.

```
[DeviceB] stp global enable
[DeviceB] stp vlan 10 20 30 enable
```

4. Configure Device C:

Set the spanning tree mode to PVST.

```
<DeviceC> system-view
[DeviceC] stp mode pvst
```

Configure the device as the root bridge of VLAN 40.

```
[DeviceC] stp vlan 40 root primary
```

Enable the spanning tree feature globally and in VLAN 10, VLAN 20, and VLAN 40.

```
[DeviceC] stp global enable
[DeviceC] stp vlan 10 20 40 enable
```

5. Configure Device D:

Set the spanning tree mode to PVST.

```
<DeviceD> system-view
[DeviceD] stp mode pvst
```

Enable the spanning tree feature globally and in VLAN 20, VLAN 30, and VLAN 40.

```
[DeviceD] stp global enable
[DeviceD] stp vlan 20 30 40 enable
```

Verifying the configuration

When the network is stable, you can use the **`display stp brief`** command to display brief spanning tree information on each device.

Display brief spanning tree information on Device A.

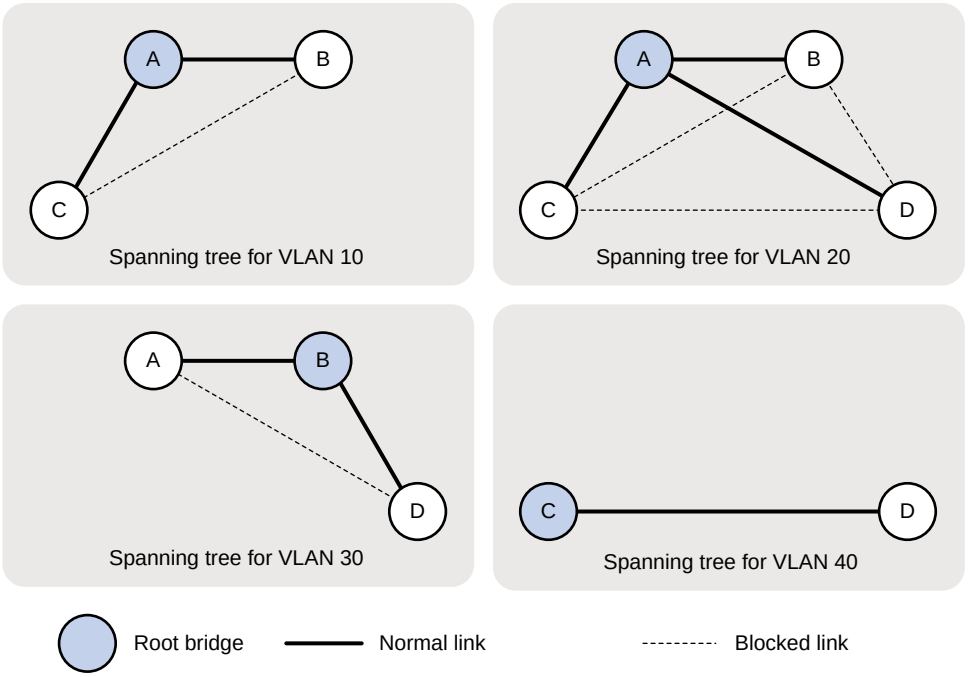
```
[DeviceA] display stp brief
 VLAN ID     Port                        Role  STP State     Protection
 10          GigabitEthernet1/0/1        DESI  FORWARDING    NONE
 10          GigabitEthernet1/0/3        DESI  FORWARDING    NONE
 20          GigabitEthernet1/0/1        DESI  FORWARDING    NONE
 20          GigabitEthernet1/0/2        DESI  FORWARDING    NONE
 20          GigabitEthernet1/0/3        DESI  FORWARDING    NONE
 30          GigabitEthernet1/0/2        DESI  FORWARDING    NONE
 30          GigabitEthernet1/0/3        ROOT  FORWARDING    NONE
```

Display brief spanning tree information on Device B.

```
[DeviceB] display stp brief
 VLAN ID     Port                        Role  STP State     Protection
 10          GigabitEthernet1/0/2        DESI  FORWARDING    NONE
 10          GigabitEthernet1/0/3        ROOT  FORWARDING    NONE
```

```
 20          GigabitEthernet1/0/1          DESI  FORWARDING    NONE
 20          GigabitEthernet1/0/2          DESI  FORWARDING    NONE
 20          GigabitEthernet1/0/3          ROOT  FORWARDING    NONE
 30          GigabitEthernet1/0/1          DESI  FORWARDING    NONE
 30          GigabitEthernet1/0/3          DESI  FORWARDING    NONE
```

Display brief spanning tree information on Device C.



```
[DeviceC] display stp brief
 VLAN ID     Port                          Role  STP State     Protection
 10          GigabitEthernet1/0/1          ROOT  FORWARDING    NONE
 10          GigabitEthernet1/0/2          ALTE  DISCARDING    NONE
 20          GigabitEthernet1/0/1          ROOT  FORWARDING    NONE
 20          GigabitEthernet1/0/2          ALTE  DISCARDING    NONE
 20          GigabitEthernet1/0/3          DESI  FORWARDING    NONE
 40          GigabitEthernet1/0/3          DESI  FORWARDING    NONE
```

Display brief spanning tree information on Device D.

```
[DeviceD] display stp brief
 VLAN ID     Port                          Role  STP State     Protection
 20          GigabitEthernet1/0/1          ALTE  DISCARDING    NONE
 20          GigabitEthernet1/0/2          ROOT  FORWARDING    NONE
 20          GigabitEthernet1/0/3          ALTE  DISCARDING    NONE
 30          GigabitEthernet1/0/1          ROOT  FORWARDING    NONE
 30          GigabitEthernet1/0/2          ALTE  DISCARDING    NONE
 40          GigabitEthernet1/0/3          ROOT  FORWARDING    NONE
```

Based on the output, you can draw a topology for each VLAN spanning tree, as shown in Figure 29.

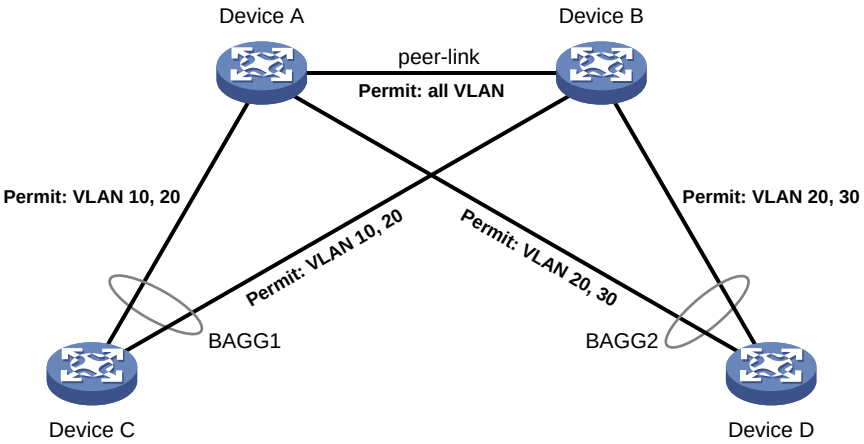
Figure 29 VLAN spanning tree topologies

Example: Configuring M-LAG with PVST

Network configuration

As shown in Figure 30, Device A and Device B work at the distribution layer, and Device C and Device D work at the access layer.

Configure M-LAG on Device A and Device B. In the M-LAG system, Device A is the primary M-LAG device, and Device B is the secondary M-LAG device.



Configure PVST on the devices to meet the following requirements:

- Frames of a VLAN are forwarded along the spanning trees of the VLAN.
- VLAN 10, VLAN 20, and VLAN 30 are terminated on the distribution layer devices.
- The root bridge of VLAN 10, VLAN 20, and VLAN 30 is the M-LAG system formed by Device A and Device B.

NOTE:

- As a best practice, do not connect ports on Device A and Device B that have the same port ID with each other, for example Layer 2 aggregate ports. Otherwise, when Device A and Device B communicate through the link, the spanning tree protocol determines that the device receives its own BPDUs. Loop guard will block the link, though spanning tree features are not affected.
- You can view port IDs of interfaces on the device by using the **`display stp interface`** command.
- The preceding restrictions do not apply to peer-link interfaces and their member ports.

Figure 30 Network diagram

Hardware and feature compatibility

The S5200-EI-G switch series does not support this example.

Procedure

1. Configure VLANs and VLAN member ports. (Details not shown.)
   - Create VLAN 10, VLAN 20, and VLAN 30 on both Device A and Device B.
   - Create VLAN 10, and VLAN 20 on Device C.
   - Create VLAN 20, and VLAN 30 on Device D.
   - Configure the ports on these devices as trunk ports and assign them to related VLANs.
2. Configure M-LAG on Device A and Device B. (Details not shown.)

   For more information about M-LAG, see "Configuring M-LAG."
3. Configure Device A:

Set the spanning tree mode to PVST.

```
<DeviceA> system-view
[DeviceA] stp mode pvst
```

Configure the device as the root bridge of VLAN 10 and VLAN 20.

```
[DeviceA] stp vlan 10 20 root primary
```

Enable the spanning tree feature globally and in VLAN 10, VLAN 20, and VLAN 30.

```
[DeviceA] stp global enable
[DeviceA] stp vlan 10 20 30 enable
```

4. Configure Device B in the same way Device A is configured. (Details not shown.)
5. Configure Device C:

Set the spanning tree mode to PVST.

```
<DeviceC> system-view
[DeviceC] stp mode pvst
```

Enable the spanning tree feature globally and in VLAN 10, and VLAN 20.

```
[DeviceC] stp global enable
[DeviceC] stp vlan 10 20 enable
```

6. Configure Device D:

Set the spanning tree mode to PVST.

```
<DeviceD> system-view
[DeviceD] stp mode pvst
```

Enable the spanning tree feature globally and in VLAN 20, and VLAN 30.

```
[DeviceD] stp global enable
[DeviceD] stp vlan 20 30 enable
```

Verifying the configuration

When the network is stable, you can use the **display stp brief** command to display brief spanning tree information on each device.

Display brief spanning tree information of the M-LAG system on the primary M-LAG device, Device A.

```
[DeviceA] display stp brief
VLAN ID     Port                           Role  STP State     Protection
 10         Bridge-Aggregation1 (M-LAG)    DESI  FORWARDING    NONE
 20         Bridge-Aggregation1 (M-LAG)    DESI  FORWARDING    NONE
 20         Bridge-Aggregation2 (M-LAG)    DESI  FORWARDING    NONE
 30         Bridge-Aggregation2 (M-LAG)    DESI  FORWARDING    NONE
```

Display brief spanning tree information on Device C.

```
[DeviceC] display stp brief
VLAN ID     Port                           Role  STP State     Protection
 10         Bridge-Aggregation1            ROOT  FORWARDING    NONE
 20         Bridge-Aggregation1            ROOT  FORWARDING    NONE
```

Display brief spanning tree information on Device D.

```
[DeviceD] display stp brief
VLAN ID     Port                           Role  STP State     Protection
 20         Bridge-Aggregation2            ROOT  FORWARDING    NONE
 30         Bridge-Aggregation2            ROOT  FORWARDING    NONE
```

Configuring LLDP

About LLDP

The Link Layer Discovery Protocol (LLDP) is a standard link layer protocol that allows network devices from different vendors to discover neighbors and exchange system and configuration information.

In an LLDP-enabled network, a device advertises local device information in LLDP Data Units (LLDPDUs) to the directly connected devices. The information distributed through LLDP is stored by its recipients in standard MIBs, making it possible for the information to be accessed by a Network Management System (NMS) through SNMP.

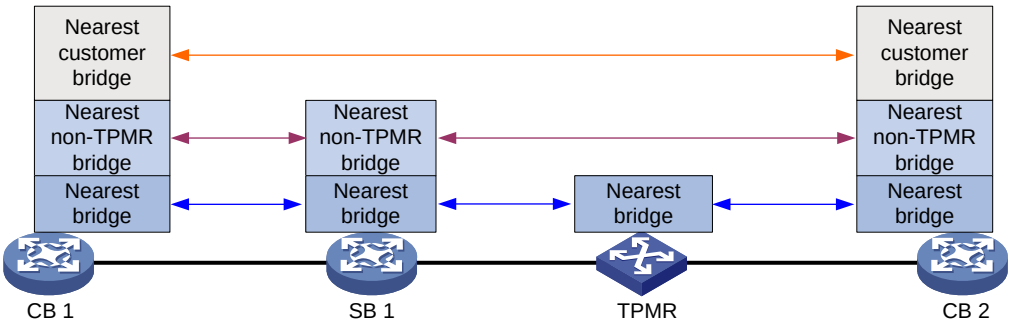
Information that can be distributed through LLDP includes (but is not limited to):

- Major capabilities of the system.
- Management IP address of the system.
- Device ID.
- Port ID.

LLDP agents and bridge modes

An LLDP agent is a mapping of a protocol entity that implements LLDP. Multiple LLDP agents can run on the same interface.

LLDP agents are classified into the following types:



- Nearest bridge agent.
- Nearest customer bridge agent.
- Nearest non-TPMR bridge agent.

  A Two-port MAC Relay (TPMR) is a type of bridge that has only two externally-accessible bridge ports. It supports a subset of the features of a MAC bridge. A TPMR is transparent to all frame-based media-independent protocols except for the following protocols:

  - Protocols destined for the TPMR.
  - Protocols destined for reserved MAC addresses that the relay feature of the TPMR is configured not to forward.

LLDP exchanges packets between neighbor agents and creates and maintains neighbor information for them. Figure 1 shows the neighbor relationships for these LLDP agents.

Figure 1 LLDP neighbor relationships

The types of supported LLDP agents vary with the bridge mode in which LLDP operates. LLDP supports the following bridge modes: customer bridge (CB) and service bridge (SB).

- **Customer bridge mode**—LLDP supports nearest bridge agent, nearest non-TPMR bridge agent, and nearest customer bridge agent. LLDP processes the LLDP frames with destination MAC addresses for these agents and transparently transmits the LLDP frames with other destination MAC addresses in VLANs.
- **Service bridge mode**—LLDP supports nearest bridge agent and nearest non-TPMR bridge agent. LLDP processes the LLDP frames with destination MAC addresses for these agents and transparently transmits the LLDP frames with other destination MAC addresses in VLANs.

LLDP frame formats

LLDP sends device information in LLDP frames. LLDP frames are encapsulated in Ethernet II or Subnetwork Access Protocol (SNAP) format.

LLDP frame encapsulated in Ethernet II

Figure 2 Ethernet II-encapsulated LLDP frame

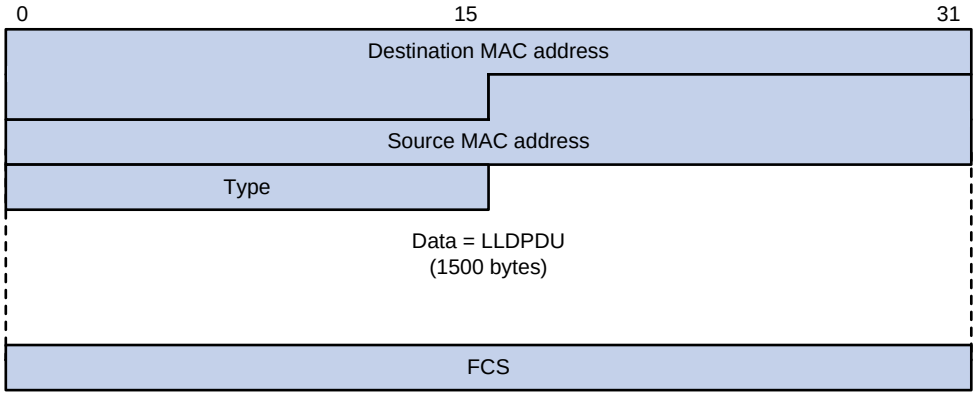


Table 1 Fields in an Ethernet II-encapsulated LLDP frame

Field	Description
Destination MAC address	MAC address to which the LLDP frame is advertised. LLDP specifies different multicast MAC addresses as destination MAC addresses for LLDP frames destined for agents of different types. This helps distinguish between LLDP frames sent and received by different agent types on the same interface. The destination MAC address is fixed to one of the following multicast MAC addresses: • 0x0180-c200-000E for LLDP frames destined for nearest bridge agents. • 0x0180-c200-0000 for LLDP frames destined for nearest customer bridge agents. • 0x0180-c200-0003 for LLDP frames destined for nearest non-TPMR bridge agents.
Source MAC address	MAC address of the sending port.
Type	Ethernet type for the upper-layer protocol. This field is 0x88CC for LLDP.
Data	LLDPDU.
FCS	Frame check sequence, a 32-bit CRC value used to determine the validity of the received Ethernet frame.

LLDP frame encapsulated in SNAP

Figure 3 SNAP-encapsulated LLDP frame

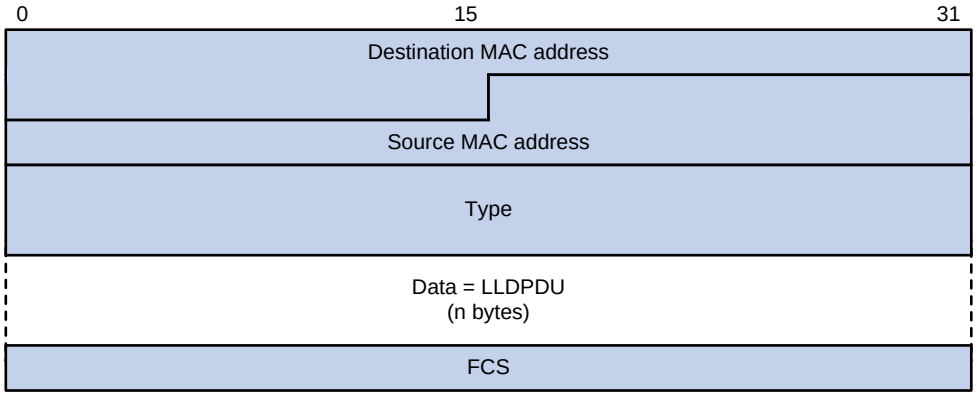

Table 2 Fields in a SNAP-encapsulated LLDP frame

Field	Description
Destination MAC address	MAC address to which the LLDP frame is advertised. It is the same as that for Ethernet II-encapsulated LLDP frames.
Source MAC address	MAC address of the sending port.
Type	SNAP type for the upper-layer protocol. This field is 0xAAAA-0300-0000-88CC for LLDP.
Data	LLDPDU.
FCS	Frame check sequence, a 32-bit CRC value used to determine the validity of the received Ethernet frame.

LLDPDUs

Each LLDP frame contains one LLDPDU. Each LLDPDU is a sequence of type-length-value (TLV) structures.

Figure 4 LLDPDU encapsulation format

As shown in Figure 4, each LLDPDU starts with the following mandatory TLVs: Chassis ID TLV, Port ID TLV, and Time to Live TLV. The mandatory TLVs are followed by a maximum of 29 optional TLVs.

TLVs

A TLV is an information element that contains the type, length, and value fields.

LLDPDU TLVs include the following categories:

- Basic management TLVs.
- Organizationally (IEEE 802.1 and IEEE 802.3) specific TLVs.
- LLDP-MED (media endpoint discovery) TLVs.

Basic management TLVs are essential to device management.

Organizationally specific TLVs and LLDP-MED TLVs are used for enhanced device management. They are defined by standardization or other organizations and are optional for LLDPDUs.

Basic management TLVs

Table 3 lists the basic management TLV types. Some of them are mandatory for LLDPDUs.

Table 3 Basic management TLVs

Type	Description	Remarks
Chassis ID	Specifies the bridge MAC address of the sending device.	Mandatory.
Port ID	Specifies the ID of the sending port: • If the LLDPDU carries LLDP-MED TLVs, the port ID TLV carries the MAC address of the sending port. • Otherwise, the port ID TLV carries the port name.	
Time to Live	Specifies the life of the transmitted information on the receiving device.	
End of LLDPDU	Marks the end of the TLV sequence in the LLDPDU.	
Port Description	Specifies the description for the sending port.	Optional.
System Name	Specifies the assigned name of the sending device.	
System Description	Specifies the description for the sending device.	
System Capabilities	Identifies the primary features of the sending device and the enabled primary features.	
Management Address	Specifies the following elements: • The management address of the local device. • The interface number and object identifier (OID) associated with the address.	

IEEE 802.1 organizationally specific TLVs

Table 4 lists the IEEE 802.1 organizationally specific TLVs.

The device can receive protocol identity TLVs and VID usage digest TLVs, but it cannot send these TLVs.

Layer 3 Ethernet ports support only link aggregation TLVs.

Table 4 IEEE 802.1 organizationally specific TLVs

Type	Description
Port VLAN ID (PVID)	Specifies the port PVID.
Port And Protocol VLAN ID (PPVID)	Indicates whether the device supports protocol VLANs and, if so, what VLAN IDs these protocols will be associated with.
VLAN Name	Specifies the textual name of any VLAN to which the port belongs.
Protocol Identity	Indicates protocols supported on the port.
DCBX	Data center bridging exchange protocol. DCBX TLVs are not supported in the current software version.
EVB module	Edge Virtual Bridging module, including EVB TLV and CDCP TLV. EVB module TLVs are not supported in the current software version.
Link Aggregation	Indicates whether the port supports link aggregation, and if yes, whether link

Type	Description
	aggregation is enabled.
Management VID	Management VLAN ID.
VID Usage Digest	VLAN ID usage digest.
ETS Configuration	Enhanced Transmission Selection configuration. ETS configuration TLVs are not supported in the current software version.
ETS Recommendation	ETS recommendation. ETS recommendation TLVs are not supported in the current software version.
PFC	Priority-based Flow Control. PFC TLVs are not supported in the current software version.
APP	Application protocol. APP TLVs are not supported in the current software version.
QCN	Quantized Congestion Notification. QCN TLVs are not supported in the current software version.

IEEE 802.3 organizationally specific TLVs

Table 5 shows the IEEE 802.3 organizationally specific TLVs.

The Power Stateful Control TLV is defined in IEEE P802.3at D1.0 and is not supported in later versions. The device sends this type of TLVs only after receiving them.

Table 5 IEEE 802.3 organizationally specific TLVs

Type	Description
MAC/PHY Configuration/Status	Contains the bit-rate and duplex capabilities of the port, support for autonegotiation, enabling status of autonegotiation, and the current rate and duplex mode.
Link Aggregation	Indicates whether the port supports link aggregation, and if yes, whether link aggregation is enabled.
Power Via MDI	Contains the power supply capabilities of the port: Power Via MDI TLVs are not supported in the current software version.
Maximum Frame Size	Indicates the supported maximum frame size.
Power Stateful Control	Indicates the power state control configured on the sending port, including the following: • Power supply mode of the PSE/PD. • PSE/PD priority. • PSE/PD power. Power Stateful Control TLVs are not supported in the current software version.
Energy-Efficient Ethernet	Indicates Energy Efficient Ethernet (EEE). Energy-Efficient Ethernet TLVs are not supported in the current software version.

LLDP-MED TLVs

LLDP-MED TLVs provide multiple advanced applications for voice over IP (VoIP), such as basic configuration, network policy configuration, and address and directory management. LLDP-MED

TLVs provide a cost-effective and easy-to-use solution for deploying voice devices in Ethernet. LLDP-MED TLVs are shown in Table 6.

If the MAC/PHY configuration/status TLV is not advertisable, none of the LLDP-MED TLVs will be advertised even if they are advertisable.

If the LLDP-MED capabilities TLV is not advertisable, the other LLDP-MED TLVs will not be advertised even if they are advertisable.

Table 6 LLDP-MED TLVs

Type	Description
LLDP-MED Capabilities	Allows a network device to advertise the LLDP-MED TLVs that it supports.
Network Policy	Allows a network device or terminal device to advertise the VLAN ID of a port, the VLAN type, and the Layer 2 and Layer 3 priorities for specific applications.
Extended Power-via-MDI	Allows a network device or terminal device to advertise power supply capability. This TLV is an extension of the Power Via MDI TLV.
Hardware Revision	Allows a terminal device to advertise its hardware version.
Firmware Revision	Allows a terminal device to advertise its firmware version.
Software Revision	Allows a terminal device to advertise its software version.
Serial Number	Allows a terminal device to advertise its serial number.
Manufacturer Name	Allows a terminal device to advertise its vendor name.
Model Name	Allows a terminal device to advertise its model name.
Asset ID	Allows a terminal device to advertise its asset ID. The typical case is that the user specifies the asset ID for the endpoint to facilitate directory management and asset tracking.
Location Identification	Allows a network device to advertise the appropriate location identifier information for a terminal device to use in the context of location-based applications.

Management address

The network management system uses the management address of a device to identify and manage the device for topology maintenance and network management. The management address is encapsulated in the management address TLV.

LLDP operating modes

An LLDP agent can operate in one of the following modes:

- **TxRx mode**—An LLDP agent in this mode can send and receive LLDP frames.
- **Tx mode**—An LLDP agent in this mode can only send LLDP frames.
- **Rx mode**—An LLDP agent in this mode can only receive LLDP frames.
- **Disable mode**—An LLDP agent in this mode cannot send or receive LLDP frames.

Each time the operating mode of an LLDP agent changes, its LLDP protocol state machine reinitializes. A configurable reinitialization delay prevents frequent initializations caused by frequent

changes to the operating mode. If you configure the reinitialization delay, an LLDP agent must wait the specified amount of time to initialize LLDP after the LLDP operating mode changes.

Transmitting and receiving LLDP frames

Transmitting LLDP frames

An LLDP agent operating in TxRx mode or Tx mode sends LLDP frames to its directly connected devices both periodically and when the local configuration changes. To prevent LLDP frames from overwhelming the network during times of frequent changes to local device information, LLDP uses the token bucket mechanism to rate limit LLDP frames. For more information about the token bucket mechanism, see *ACL and QoS Configuration Guide*.

LLDP automatically enables the fast LLDP frame transmission mechanism in either of the following cases:

- A new LLDP frame is received and carries device information new to the local device.
- The LLDP operating mode of the LLDP agent changes from Disable or Rx to TxRx or Tx.

The fast LLDP frame transmission mechanism successively sends the specified number of LLDP frames at a configurable fast LLDP frame transmission interval. The mechanism helps LLDP neighbors discover the local device as soon as possible. Then, the normal LLDP frame transmission interval resumes.

Receiving LLDP frames

An LLDP agent operating in TxRx mode or Rx mode confirms the validity of TLVs carried in every received LLDP frame. If the TLVs are valid, the LLDP agent saves the information and starts an aging timer. The initial value of the aging timer is equal to the TTL value in the Time To Live TLV carried in the LLDP frame. When the LLDP agent receives a new LLDP frame, the aging timer restarts. When the aging timer decreases to zero, all saved information ages out.

Collaboration with Track

You can configure a track entry and associate it with an LLDP interface. The LLDP module checks the neighbor availability of the LLDP interface and reports the check result to the Track module. The Track module changes the track entry status accordingly so the associated application module can take correct actions.

The Track module changes the track entry status based on the neighbor availability of a monitored LLDP interface as follows:

- If the neighbor of the LLDP interface is available, the Track module sets the track entry to Positive state.
- If the neighbor of the LLDP interface is unavailable, the Track module sets the track entry to Negative state.

For more information about collaboration between Track and LLDP, see the track configuration in *High Availability Configuration Guide.*

Protocols and standards

- IEEE 802.1AB-2005, *Station and Media Access Control Connectivity Discovery*
- IEEE 802.1AB-2009, *Station and Media Access Control Connectivity Discovery*
- ANSI/TIA-1057, *Link Layer Discovery Protocol for Media Endpoint Devices*
- IEEE Std 802.1Qaz-2011, *Media Access Control (MAC) Bridges and Virtual Bridged Local Area Networks-Amendment 18: Enhanced Transmission Selection for Bandwidth Sharing Between Traffic Classes*

Restrictions and guidelines: LLDP configuration

When you configure LLDP, follow these restrictions and guidelines:

- Some of the LLDP configuration tasks are available in different interface views (see Table 7).

  Table 7 Support of LLDP configuration tasks in different views

Tasks	Supported views
Enabling LLDP	Layer 2 Ethernet interface view Layer 3 Ethernet interface view Management Ethernet interface view Layer 2 aggregate interface view Layer 3 aggregate interface view IRF physical interface view
Setting the LLDP operating mode	
Configuring the advertisable TLVs	
Configuring advertisement of the management address TLV	
Setting the encapsulation format for LLDP frames	
Enabling LLDP polling	
Configuring LLDP trapping	
Configuring port ID subtype of port ID TLVs advertised by LLDP (not supported in Layer 2 aggregate interface view and Layer 3 aggregate interface view)	

- You can configure LLDP on an IRF physical interface to monitor the connection and link status of the IRF physical link. An LLDP-enabled IRF physical interface supports only the nearest bridge agent.

LLDP tasks at a glance

To configure LLDP, perform the following tasks:

1. Enabling LLDP
2. Setting the LLDP bridge mode
3. Setting the LLDP operating mode
4. (Optional.) Setting the LLDP reinitialization delay
5. (Optional.) Configuring LLDP packet-related settings
   - Configuring the advertisable TLVs
   - Configuring advertisement of the management address TLV
   - Setting the encapsulation format for LLDP frames
   - Setting LLDP frame transmission parameters
   - Setting the timeout for receiving LLDP frames
   - Configuring port ID subtype of port ID TLVs advertised by LLDP
6. (Optional.) Configuring LLDP extended features
   - Enabling LLDP polling
   - Disabling LLDP PVID inconsistency check
   - Configuring CDP compatibility
   - Configuring LLDP trapping and LLDP-MED trapping
   - Configuring MAC address learning for DCN
   - Enabling transparent transmission of LLDP frames

- Configuring LLDP black hole detection
- Configuring LLDP cross-domain detection
- Disabling AP restart through LLDP
- Disabling LLDP control over PoE

Enabling LLDP

Restrictions and guidelines

For LLDP to take effect on a port, you must enable LLDP both globally and on the port.

The enabling status of LLDP on an aggregate interface will not be synchronized to its member ports.

Procedure

7. Enter system view.
   `system-view`
8. Enable LLDP globally.
   `lldp global enable`
   By default:
   - If the device starts up with the initial configuration, LLDP is disabled globally.
   - If the device starts up with the factory defaults, LLDP is enabled globally.

   For more information about device startup with the initial configuration or factory defaults, see configuration file management in *Fundamentals Configuration Guide*.
9. Enter interface view.
   `interface` *`interface-type interface-number`*
10. Enable LLDP.
    `lldp enable`
    By default, LLDP is disabled on ONU subinterfaces and is enabled on the other interfaces.

Setting the LLDP bridge mode

11. Enter system view.
    `system-view`
12. Set the LLDP bridge mode.
    - Set the LLDP bridge mode to service bridge.
      `lldp mode service-bridge`
      By default, LLDP operates in customer bridge mode.
    - Set the LLDP bridge mode to customer bridge.
      `undo lldp mode`

    By default, LLDP operates in customer bridge mode.

Setting the LLDP operating mode

13. Enter system view.
    `system-view`
14. Enter interface view.

interface *interface-type interface-number*

15. Set the LLDP operating mode.
    - In Layer 2/Layer 3 Ethernet interface view or management Ethernet interface view:

      lldp [**agent** { **nearest-customer** | **nearest-nontpmr** }] **admin-status** { **disable** | **rx** | **tx** | **txrx** }

      In Ethernet interface view, if you do not specify an agent type, the command sets the operating mode for the nearest bridge agent.
    - In Layer 2/Layer 3 aggregate interface view:

      lldp agent { **nearest-customer** | **nearest-nontpmr** } **admin-status** { **disable** | **rx** | **tx** | **txrx** }

      In aggregate interface view, you can set the operating mode only for the nearest customer bridge agent and nearest non-TPMR bridge agent.
    - In IRF physical interface view:

      lldp admin-status { **disable** | **rx** | **tx** | **txrx** }

      In IRF physical interface view, you can set the operating mode only for the nearest bridge agent.

    By default, the nearest bridge agent operates in **TxRx** mode, and the other agents operate in **Disable** mode.

Setting the LLDP reinitialization delay

About this task

When the LLDP operating mode changes on a port, the port initializes the protocol state machines after an LLDP reinitialization delay. By adjusting the delay, you can avoid frequent initializations caused by frequent changes to the LLDP operating mode on a port.

Procedure

16. Enter system view.

    system-view

17. Set the LLDP reinitialization delay.

    lldp timer reinit-delay *delay*

    The default LLDP reinitialization delay is 2 seconds.

Configuring the advertisable TLVs

18. Enter system view.

    system-view

19. Enter interface view.

    interface *interface-type interface-number*

20. Configure the advertisable TLVs.
    - In Layer 2 Ethernet interface view:

      lldp tlv-enable { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address* | **interface loopback** *interface-number*] } | **dot1-tlv** { **all** | **port-vlan-id** | **link-aggregation** | **protocol-vlan-id** [*vlan-id*] | **vlan-name** [*vlan-id-list*] | **management-vid** [*mvlan-id*] } | **dot3-tlv** { **all** | **link-aggregation** | **mac-physic** | **max-frame-size** | **power** } | **med-tlv**

{ **all** | **capability** | **inventory** | **network-policy** [*vlan-id*] | **power-over-ethernet** | **location-id** { **civic-address** *device-type country-code* { *ca-type ca-value* }&<1-10> | **elin-address** *tel-number* } } }

By default, the nearest bridge agent advertises all supported TLVs except the following TLVs:

- Location identification TLVs.
- Port and protocol VLAN ID TLVs.
- VLAN name TLVs.
- Management VLAN ID TLVs.
- Link aggregation TLVs.

lldp agent nearest-nontpmr tlv-enable { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address*] } | **dot1-tlv** { **all** | **port-vlan-id** | **link-aggregation** } | **dot3-tlv** { **all** | **link-aggregation** } }

lldp tlv-enable dot1-tlv { **protocol-vlan-id** [*vlan-id*] | **vlan-name** [*vlan-id-list*] | **management-vid** [*mvlan-id*] }

By default, the nearest non-TPMR bridge agent does not advertise any TLVs.

lldp agent nearest-customer tlv-enable { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address*] } | **dot1-tlv** { **all** | **port-vlan-id** | **link-aggregation** } | **dot3-tlv** { **all** | **link-aggregation** } }

lldp tlv-enable dot1-tlv { **protocol-vlan-id** [*vlan-id*] | **vlan-name** [*vlan-id-list*] | **management-vid** [*mvlan-id*] }

By default, the nearest customer bridge agent advertises all the supported basic management TLVs and port VLAN ID TLVs and link aggregation TLVs in the IEEE 802.1 organizationally specific TLV set.

- In Layer 3 Ethernet interface view:

lldp tlv-enable { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address* | **interface loopback** *interface-number*] } | **dot1-tlv** { **all** | **link-aggregation** } | **dot3-tlv** { **all** | **link-aggregation** | **mac-physic** | **max-frame-size** | **power** } | **med-tlv** { **all** | **capability** | **inventory** | **power-over-ethernet** | **location-id** { **civic-address** *device-type country-code* { *ca-type ca-value* }&<1-10> | **elin-address** *tel-number* } } }

By default, the nearest bridge agent advertises the following TLVs:

- Link aggregation TLVs in the 802.1 organizationally specific TLV set.
- All supported 802.3 organizationally specific TLVs except the Energy-Efficient Ethernet TLVs.
- All supported LLDP-MED TLVs except the network policy TLVs.

lldp agent { **nearest-nontpmr** | **nearest-customer** } **tlv-enable** { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address*] } | **dot1-tlv** { **all** | **link-aggregation** } | **dot3-tlv** { **all** | **link-aggregation** } }

By default:

- The nearest non-TPMR bridge agent does not advertise any TLVs.

- The nearest customer bridge agent advertises all supported basic management TLVs and link aggregation TLVs in the IEEE 802.1 organizationally specific TLV set.

- In management Ethernet interface view:

  lldp tlv-enable { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address*] } | **dot1-tlv** { **all** | **link-aggregation** } | **dot3-tlv** { **all** | **link-aggregation** | **mac-physic** | **max-frame-size** | **power** } | **med-tlv** { **all** | **capability** | **inventory** | **power-over-ethernet** | **location-id** { **civic-address** *device-type country-code* { *ca-type ca-value* }&<1-10> | **elin-address** *tel-number* } } }

  By default, the nearest bridge agent advertises the following TLVs:

  - All supported basic management TLVs.
  - Link aggregation TLVs in the 802.1 organizationally specific TLV set.
  - All supported 802.3 organizationally specific TLVs except the link aggregation TLVs.
  - All supported LLDP-MED TLVs except the network policy TLVs and location Identification TLVs.

  lldp agent { **nearest-nontpmr** | **nearest-customer** } **tlv-enable** { **basic-tlv** { **all** | **port-description** | **system-capability** | **system-description** | **system-name** | **management-address-tlv** [**ipv6**] [*ip-address*] } | **dot1-tlv** { **all** | **link-aggregation** } | **dot3-tlv** { **all** | **link-aggregation** } }

  By default:

  - The nearest non-TPMR bridge agent does not advertise any TLVs.
  - The nearest customer bridge agent advertises all supported basic management TLVs and link aggregation TLVs in the IEEE 802.1 organizationally specific TLV set.

- In Layer 2 aggregate interface view:

  lldp tlv-enable dot1-tlv { **protocol-vlan-id** [*vlan-id*] | **vlan-name** [*vlan-id-list*] | **management-vid** [*mvlan-id*]

  lldp agent nearest-nontpmr tlv-enable { **basic-tlv** { **all** | **management-address-tlv** [**ipv6**] [*ip-address* | **interface loopback** *interface-number*] | **port-description** | **system-capability** | **system-description** | **system-name** } | **dot1-tlv** { **all** | **port-vlan-id** } }

  By default, the nearest non-TPMR bridge agent does not advertise any TLVs.

  lldp agent nearest-customer tlv-enable { **basic-tlv** { **all** | **management-address-tlv** [**ipv6**] [*ip-address*] | **port-description** | **system-capability** | **system-description** | **system-name** } | **dot1-tlv** { **all** | **port-vlan-id** } }

  By default, the nearest customer bridge agent advertises all supported basic management TLVs and port VLAN ID TLVs in the IEEE 802.1 organizationally specific TLV set.

  The nearest bridge agent is not supported.

- In Layer 3 aggregate interface view:

  lldp agent { **nearest-customer** | **nearest-nontpmr** } **tlv-enable basic-tlv** { **all** | **management-address-tlv** [**ipv6**] [*ip-address*] | **port-description** | **system-capability** | **system-description** | **system-name** }

  By default:

  - The nearest non-TPMR bridge agent does not advertise any TLVs.
  - The nearest customer bridge agent advertises all supported basic management TLVs.

The nearest bridge agent is not supported.

- In IRF physical interface view:

  lldp tlv-enable basic-tlv { **port-description** | **system-capability** | **system-description** | **system-name** }

  By default, the nearest bridge agent advertises all supported basic management TLVs.

  Only the nearest bridge agent is supported.

Configuring advertisement of the management address TLV

About this task

LLDP encodes management addresses in numeric or string format in management address TLVs.

If a neighbor encodes its management address in string format, set the encoding format of the management address to **string** on the connecting port. This guarantees normal communication with the neighbor.

You can configure advertisement of the management address TLV globally or on a per-interface basis. The device selects the management address TLV advertisement setting for an interface in the following order:

21. Interface-based setting, configured by using the **lldp tlv-enable** command with the **management-address-tlv** keyword.
22. Global setting, configured by using the **lldp global tlv-enable basic-tlv management-address-tlv** command.
23. Default setting for the interface.

    By default:

    - The nearest bridge agent and nearest customer bridge agent advertise the management address TLV.
    - The nearest non-TPMR bridge agent does not advertise the management address TLV.

Procedure

24. Enter system view.

    system-view

25. Enable advertisement of the management address TLV globally and set the management address to be advertised.

    lldp [**agent** { **nearest-customer** | **nearest-nontpmr** }] **global tlv-enable basic-tlv management-address-tlv** [**ipv6**] { *ip-address* | **interface loopback** *interface-number* | **interface m-gigabitethernet** *interface-number* | **interface vlan-interface** *interface-number* }

    By default, advertisement of the management address TLV is disabled globally.

26. Enter interface view.

    interface *interface-type interface-number*

27. Enable advertisement of the management address TLV on the interface and set the management address to be advertised.

    - In Layer 2 Ethernet interface view:

      lldp tlv-enable basic-tlv management-address-tlv [**ipv6**] [*ip-address* | **interface loopback** *interface-number*]

      lldp agent { **nearest-customer** | **nearest-nontpmr** } **tlv-enable basic-tlv management-address-tlv** [**ipv6**] [*ip-address*]

- In management interface view:

  lldp [**agent** { **nearest-customer** | **nearest-nontpmr** }] **tlv-enable basic-tlv management-address-tlv** [**ipv6**] [*ip-address*]

- In Layer 3 Ethernet interface view:

  lldp tlv-enable basic-tlv management-address-tlv [**ipv6**] [*ip-address* | **interface loopback** *interface-number*]

  lldp agent { **nearest-customer** | **nearest-nontpmr** } **tlv-enable basic-tlv management-address-tlv** [**ipv6**] [*ip-address*]

- In Layer 2/Layer 3 aggregate interface view:

  lldp agent { **nearest-customer** | **nearest-nontpmr** } **tlv-enable basic-tlv management-address-tlv** [**ipv6**] [*ip-address*]

By default:

- The nearest bridge agent and nearest customer bridge agent advertise the management address TLVs.
- The nearest non-TPMR bridge agent does not advertise the management address TLV.

28. Set the encoding format of the management address to string.

- In Layer 2/Layer 3 Ethernet interface view or management Ethernet interface view:

  lldp [**agent** { **nearest-customer** | **nearest-nontpmr** }] **management-address-format string**

- In Layer 2/Layer 3 aggregate interface view:

  lldp agent { **nearest-customer** | **nearest-nontpmr** } **management-address-format string**

The default management address encoding format is numeric.

The device supports only the numeric encoding format for IPv6 management addresses.

Setting the encapsulation format for LLDP frames

About this task

Earlier versions of LLDP require the same encapsulation format on both ends to process LLDP frames. To successfully communicate with a neighboring device running an earlier version of LLDP, the local device must be set with the same encapsulation format.

Procedure

29. Enter system view.

system-view

30. Enter interface view.

interface *interface-type interface-number*

31. Set the encapsulation format for LLDP frames to SNAP.

- In Layer 2/Layer 3 Ethernet interface view or management Ethernet interface view:

  lldp [**agent** { **nearest-customer** | **nearest-nontpmr** }] **encapsulation snap**

- In Layer 2/Layer 3 aggregate interface view:

  lldp agent { **nearest-customer** | **nearest-nontpmr** } **encapsulation snap**

- In IRF physical interface view:

  lldp encapsulation snap

By default, the Ethernet II encapsulation format is used.

Setting LLDP frame transmission parameters

About this task

The Time to Live TLV carried in an LLDPDU determines how long the device information carried in the LLDPDU can be saved on a recipient device.

By setting the TTL multiplier, you can configure the TTL of locally sent LLDPDUs. The TTL is expressed by using the following formula:

TTL = Min (65535, (TTL multiplier × LLDP frame transmission interval + 1))

As the expression shows, the TTL can be up to 65535 seconds. TTLs greater than 65535 will be rounded down to 65535 seconds.

Procedure

32. Enter system view.

system-view

33. Set the TTL multiplier.

lldp hold-multiplier *value*

The default setting is 4.

34. Set the LLDP frame transmission interval.

lldp timer tx-interval *interval*

The default setting is 30 seconds.

35. Set the token bucket size for sending LLDP frames.

lldp max-credit *credit-value*

The default setting is 5.

36. Set the number of LLDP frames sent each time fast LLDP frame transmission is triggered.

lldp fast-count *count*

The default setting is 4.

37. Set the fast LLDP frame transmission interval.

lldp timer fast-interval *interval*

The default setting is 1 second.

Setting the timeout for receiving LLDP frames

About this task

This feature allows the device to detect the presence of directly connected neighbors by setting the timeout timer for receiving LLDP frames. If an interface has not received any frames when the timeout timer expires, the device reports a no LLDP neighbor event to the NETCONF module.

Restrictions and guidelines

To avoid misdetection, make sure the timeout for receiving LLDP frames is greater than the LLDP frame transmission interval.

Procedure

38. Enter system view.

system-view

39. Set the timeout for receiving LLDP frames.

lldp timer rx-timeout *timeout*

By default, no timeout is set for receiving LLDP frames, and the device does not report no LLDP neighbor events.

Configuring port ID subtype of port ID TLVs advertised by LLDP

About this task

This task enables an H3C device to advertise only port ID TLVs that contain interface names. By default, an H3C device advertises port ID TLVs that contain interface MAC addresses or interface names. The media devices from some vendors can obtain interface information from H3C devices only through LLDP. For the media devices to obtain interface names, you must configure H3C devices to generate port ID TLVs that use interface names as the port ID subtype.

Restrictions and guidelines

Perform this task only when LLDP neighbors must obtain interface names from LLDPDUs. Do not perform this task in any other scenarios.

Procedure

40. Enter system view.

system-view

41. Enter Layer 2 Ethernet interface view/Layer 3 Ethernet interface view/management Ethernet interface view/IRF physical interface view.

interface *interface-type interface-number*

42. Configure the port ID subtype of port ID TLVs advertised by LLDP.

lldp tlv-config basic-tlv port-id *type-id*

By default, an interface advertises port ID TLVs that contain interface MAC addresses if it receives LLDP-MED TLVs, and advertises port ID TLVs that contain interface names if no LLDP-MED TLVs are received.

Enabling LLDP polling

About this task

With LLDP polling enabled, a device periodically searches for local configuration changes. When the device detects a configuration change, it sends LLDP frames to inform neighboring devices of the change.

Procedure

43. Enter system view.

system-view

44. Enter interface view.

interface *interface-type interface-number*

45. Enable LLDP polling and set the polling interval.

- In Layer 2/Layer 3 Ethernet interface view or management Ethernet interface view:

  lldp [**agent** { **nearest-customer** | **nearest-nontpmr** }] **check-change-interval** *interval*

- In Layer 2/Layer 3 aggregate interface view:

  lldp agent { **nearest-customer** | **nearest-nontpmr** } **check-change-interval** *interval*

- In IRF physical interface view:
  lldp check-change-interval *interval*

By default, LLDP polling is disabled.

Disabling LLDP PVID inconsistency check

About this task

By default, when the system receives an LLDP packet, it compares the PVID value contained in the packet with the PVID configured on the receiving interface. If the two PVIDs do not match, a log message will be printed to notify the user.

You can disable PVID inconsistency check if different PVIDs are required on a link.

Procedure

46. Enter system view.
system-view

47. Disable LLDP PVID inconsistency check.
lldp ignore-pvid-inconsistency

By default, LLDP PVID inconsistency check is enabled.

Configuring CDP compatibility

About this task

To enable your device to exchange information with a directly connected Cisco device that supports only CDP, you must enable CDP compatibility.

CDP compatibility enables your device to receive and recognize CDP packets from the neighboring CDP device and send CDP packets to the neighboring device. The CDP packets sent to the neighboring CDP device carry the following information:

- Device ID.
- ID of the port connecting to the neighboring device.
- Port IP address.
- TTL.

The port IP address is the primary IP address of a VLAN interface in up state. The VLAN ID of the VLAN interface must be the lowest among the VLANs permitted on the port. If no VLAN interfaces of the permitted VLANs are assigned an IP address or all VLAN interfaces are down, no port IP address will be advertised.

You can view the neighboring CDP device information that can be recognized by the device in the output of the **display lldp neighbor-information** command. For more information about the **display lldp neighbor-information** command, see LLDP commands in *Layer 2—LAN Switching Command Reference*.

To make your device work with Cisco IP phones, you must enable CDP compatibility.

If your LLDP-enabled device cannot recognize CDP packets, it does not respond to the requests of Cisco IP phones for the voice VLAN ID configured on the device. As a result, a requesting Cisco IP phone sends voice traffic without any tag to your device. Your device cannot differentiate the voice traffic from other types of traffic.

CDP compatibility enables your device to receive and recognize CDP packets from a Cisco IP phone and respond with CDP packets carrying TLVs with the configured voice VLAN. If no voice VLAN is configured for CDP packets, CDP packets carry the voice VLAN of the port or the voice VLAN

assigned by the RADIUS server. The assigned voice VLAN has a higher priority. According to TLVs with the voice VLAN configuration, the IP phone automatically configures the voice VLAN. As a result, the voice traffic is confined in the configured voice VLAN and is differentiated from other types of traffic.

For more information about voice VLANs, see "Configuring voice VLANs."

When the device is connected to a Cisco IP phone that has a host attached to its data port, the host must access the network through the Cisco IP phone. If the data port goes down, the IP phone will send a CDP packet to the device so the device can log out the user.

CDP-compatible LLDP operates in one of the following modes:

- **TxRx**—CDP packets can be transmitted and received.
- **Rx**—CDP packets can be received but cannot be transmitted.
- **Disable**—CDP packets cannot be transmitted or received.

Restrictions and guidelines

When you configure CDP compatibility for LLDP, follow these restrictions and guidelines:

- To make CDP-compatible LLDP take effect on a port, follow these steps:
  a. Enable CDP-compatible LLDP globally.
  b. Configure CDP-compatible LLDP to operate in TxRx mode on the port.
- The maximum TTL value that CDP allows is 255 seconds. To make CDP-compatible LLDP work correctly with Cisco IP phones, configure the LLDP frame transmission interval to be no more than 1/3 of the TTL value.

Prerequisites

Before you configure CDP compatibility, complete the following tasks:

- Globally enable LLDP.
- Enable LLDP on the port connecting to a CDP device.
- Configure LLDP to operate in TxRx mode on the port.

Procedure

48. Enter system view.
system-view

49. Enable CDP compatibility globally.
lldp compliance cdp
By default, CDP compatibility is disabled globally.

50. Enter Layer 2/Layer 3 Ethernet interface view or management Ethernet interface view.
interface *interface-type interface-number*

51. Configure CDP-compatible LLDP to operate in TxRx mode.
lldp compliance admin-status cdp txrx
By default, CDP-compatible LLDP operates in **disable** mode.

52. Set the voice VLAN ID carried in CDP packets.
cdp voice-vlan *vlan-id*
By default, no voice VLAN ID is configured to be carried in CDP packets.

Configuring LLDP trapping and LLDP-MED trapping

About this task

LLDP trapping or LLDP-MED trapping notifies the network management system of events such as newly detected neighboring devices and link failures.

Before you set a trap transmission interval for LLDP, make sure you understand the following influences of the LLDP trap and LLDP-MED trap transmission interval:

- If the interval value is large, the trap sending frequency is low, which occupies fewer system resources. This is suitable for scenarios where the network topology on the device changes frequently. However, do not set the interval to a too large value. If the interval value is too large, the network management system cannot identify neighbor changes in time, which will cause the network topology on the device not to update in time.
- If the interval value is small, the trap sending frequency is high. This is suitable for topology-sensitive scenarios. However, do not set the interval to a too small value. If the interval value is too small, the network management system will frequently refresh the neighbor status information. This will not only occupies too many system resources but also cause network topology vibration on the device.

Restrictions and guidelines

In the early stage of networking, the network topology changes frequently. If LLDP trapping or LLDP-MED trapping is enabled, the device will frequently send trap information to the network management system, which increases the system burden and wastes resources. As a best practice, do not enable LLDP trapping or LLDP-MED trapping in the early stage of networking.

Procedure

53. Enter system view.

system-view

54. Enter interface view.

interface *interface-type interface-number*

55. Enable LLDP trapping.

- In Layer 2/Layer 3 Ethernet interface view or management Ethernet interface view:

  lldp [**agent** { **nearest-customer** | **nearest-nontpmr** }] **notification remote-change enable**

- In Layer 2/Layer 3 aggregate interface view:

  lldp agent { **nearest-customer** | **nearest-nontpmr** } **notification remote-change enable**

- In IRF physical interface view:

  lldp notification remote-change enable

By default, LLDP trapping is disabled.

56. (In Layer 2/Layer 3 Ethernet interface view or management Ethernet interface view.) Enable LLDP-MED trapping.

lldp notification med-topology-change enable

By default, LLDP-MED trapping is disabled.

57. Return to system view.

quit

58. (Optional.) Set the LLDP trap transmission interval.

lldp timer notification-interval *interval*

The default setting is 30 seconds.

Configuring MAC address learning for DCN

About MAC address learning for DCN

For the data communication network (DCN) to implement operation, administration, and maintenance on network elements (NEs), you must configure the NEs to learn their neighbors' MAC addresses through LLDP.

An NE learns the MAC address of its neighbor through the ARP or ND entry generated based on the management address TLV in LLDP frames received from the neighbor. For more information about DCN, see *Layer 3—IP Routing Configuration Guide*.

Setting the source MAC address of LLDP frames

About this task

This feature must be configured with generation of ARP or ND entries for received management address TLVs to meet the following requirements:

- The source MAC address of outgoing LLDP frames is the MAC address of a VLAN interface instead of the MAC address of the egress interface.
- The neighbor device can generate correct ARP or ND entries for the local device.

In Layer 2 Ethernet interface view or Layer 2 aggregate interface view, this feature sets the source MAC address of outgoing LLDP frames to the MAC address of a VLAN interface to which the specified VLAN ID belongs. The source MAC address of outgoing LLDP frames is the MAC address of the Layer 2 interface in the following situations:

- The specified VLAN or the corresponding VLAN interface does not exist.
- The VLAN interface to which the VLAN ID belongs is physically down.

In Layer 3 Ethernet interface view, the MAC address of the Layer 3 Ethernet interface is always used as the source MAC address of outgoing LLDP frames.

Procedure

59. Enter system view.

```
system-view
```

60. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or Layer 3 Ethernet interface view.

```
interface interface-type interface-number
```

61. Set the source MAC address of LLDP frames to the MAC address of a VLAN interface or the Layer 3 Ethernet interface.

```
lldp source-mac vlan vlan-id
```

By default, the source MAC address of LLDP frames is the MAC address of the egress interface.

Enabling generation of ARP or ND entries for received management address TLVs

About this task

This feature enables the device to generate an ARP or ND entry after receiving an LLDP frame containing a management address TLV on an interface. The ARP or ND entry maps the advertised management address to the source MAC address of the frame.

You can enable generation of both ARP and ND entries on an interface. If the management address TLV contains an IPv4 address, the device generates an ARP entry. If the management address TLV contains an IPv6 address, the device generates an ND entry.

In Layer 2 Ethernet interface view or Layer 2 aggregate interface view, this feature sets the Layer 2 interface to the output interface in the generated entries. The VLAN to which the entries belong is the VLAN specified by this feature. The device cannot generate ARP or ND entries in one of the following situations:

- The specified VLAN or the corresponding VLAN interface does not exist.
- The VLAN interface to which the VLAN ID belongs is physically down.

In Layer 3 Ethernet interface view, the Layer 3 Ethernet interface is always recorded as the output interface, no matter whether you specify a VLAN ID.

Restrictions and guidelines

This feature must be configured with the feature of setting the source MAC address of LLDP frames to meet the following requirements:

- The device uses the MAC address of a VLAN interface instead of the egress interface's MAC address as the source MAC address of LLDP frames.
- The neighbor device can generate correct ARP or ND entries.

Procedure

62. Enter system view.

system-view

63. Enter Layer 2 Ethernet interface view, Layer 2 aggregate interface view, or Layer 3 Ethernet interface view.

interface *interface-type interface-number*

64. Enable generation of ARP or ND entries for management address TLVs received on the interface.

- In Layer 2 Ethernet interface view or Layer 2 aggregate interface view:

  lldp management-address { **arp-learning** | **nd-learning** } **vlan** *vlan-id*

- In Layer 3 Ethernet interface view:

  lldp management-address { **arp-learning** | **nd-learning** } [**vlan** *vlan-id*]

By default, generation of ARP or ND entries for received management address TLVs is disabled on an interface.

In Layer 2 Ethernet interface view, the **vlan** *vlan-id* option specifies the ID of the VLAN to which the generated ARP or ND entry belongs. To prevent the ARP or ND entries from overwriting each other, do not specify the same VLAN ID for different Layer 2 Ethernet interfaces.

You can enable generation of both ARP and ND entries on an interface.

Enabling transparent transmission of LLDP frames

About this task

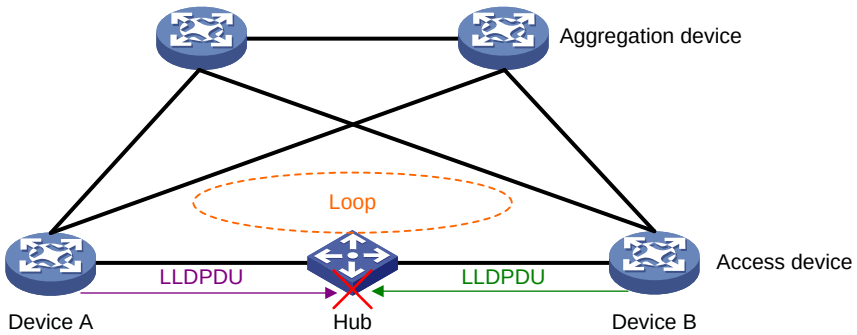
On an MPLS L2VPN network, you can enable transparent LLDP frame transmission on the PE interfaces connected to CEs so the CEs can establish neighbor relationships across the PEs.

An interface configured with this feature can transmit LLDP frames transparently, no matter whether or not LLDP is enabled on it.

Restrictions and guidelines

Before you enable transparent LLDP frame transmission on a PE interface connected to a CE, disable LLDP on the interface to prevent the CE from establishing neighbor relationships with the PE and the resulting topology errors.

Procedure



65. Enter system view.
    `system-view`
66. Enter interface view.
    `interface` *`interface-type interface-number`*
67. Enable transparent LLDP frame transmission on the interface.
    `lldp transparent enable`
    By default, transparent LLDP frame transmission is disabled on an interface.

Configuring LLDP black hole detection

About this task

As shown in Figure 5, Device A and Device B are connected through a hub, causing a loop in the network. However, since LLDP packets are point-to-point packets, they are terminated at the next node after being sent from the device. Therefore, the hub acts as a black hole for LLDP packets and LLDP packets cannot be transmitted between Device A and Device B through the HUB. As a result, Device A and Device B cannot use LLDP to learn about the physical link between them and the formed loop, and therefore the loop cannot be eliminated in time. In order to eliminate potential loop risks, it required to detect LLDP packet black holes and block the links leading to the black holes.

Figure 5 LLDP black hole detection application scenario

The LLDP black hole detection feature can detect the presence of LLDP black holes in links on ports. The operating mechanism is as follows:

68. Triggering the sending of black hole detection packets

The ports enabled with LLDP black hole detection will carry black hole detection TLVs in the transmitted LLDP packets. The black hole detection TLV is a type of TLV defined by H3C. If an LLDP packet carrying the black hole detection TLV is received, it indicates that there is no LLDP black hole between the device and its neighbor, and LLDP packets can be sent and received successfully. Only H3C devices can send and recognize the black hole detection TLV carried in LLDP packets.

After LLDP black hole detection is enabled on a port, the port will activate the LLDP packet receiving timer for black hole detection. If no LLDP packets are received on the port until the timer expires, it indicates a potential LLDP packet black hole in the network, causing the device to not receive LLDP packets. The port then starts sending LLDP black hole detection packets continuously. If the port receives an LLDP packet carrying the black hole detection TLV before the timer expires, the port terminates the timer and takes no further action.

After LLDP black hole detection is enabled, if a port receives an LLDP packet without the black hole detection TLV, the port will start sending LLDP black hole detection packets continuously.

LLDP black hole detection packet is an H3C proprietary Layer 2 packet type. Unlike LLDP packets, LLDP black hole detection packets can be transparently transmitted by a hub and are continuously sent at fixed intervals after being triggered.

The timeout for receiving LLDP packets is configured through the **lldp global blackhole-detection rx-lldpdu timeout** command. The interval for sending LLDP black hole detection packets is configured through the **lldp timer blackhole-detection-interval** command or the **lldp global timer blackhole-detection-interval** command.

69. Black hole confirmation

After a port starts to send LLDP black hole detection packets, if it receives an LLDP packet carrying the black hole detection TLV, it determines that no LLDP black hole exists between the port and its neighbor, stops sending LLDP black hole detection packets, and resets the LLDP packet receiving timer.

If a port enabled with LLDP black hole detection receives an LLDP black hole detection packet and the LLDP packet receiving timer on this port has timed out, it indicates that the local device and the peer device are connected with a link and both devices have the ability to send LLDP packets. However, neither of the devices has received LLDP packets, and therefore the local device concludes that there is an LLDP black hole between the two ends of the link.

70. Black hole processing

After detecting an LLDP black hole, the device blocks the port receiving LLDP black hole detection packets to eliminate network loops and prevent the transmission of user data packets. If the blocked port receives no LLDP black hole detection packets within the timeout period specified by the **lldp timer rx-blackhole-timeout** or **lldp global timer rx-blackhole-timeout** command, it means that the LLDP black hole is eliminated and the port resumes normal forwarding. Otherwise, it remains blocked.

The **lldp timer blackhole-detection-interval** and **lldp global timer blackhole-detection-interval** commands affect the interval at which the specified ports send LLDP black hole detection packets. Set a suitable packet sending interval based on actual requirements.

- When the sending interval is short, the port sends LLDP black hole detection packets frequently. The advantage is that the network detects and responds to LLDP black holes more sensitively. The disadvantage is that it occupies more device CPU resources. Configure a short sending interval in scenarios where the device performance is high or there is a strong demand for loop prevention.
- When the sending interval is long, the port sends LLDP black hole detection packets slowly. The advantage is that it occupies less CPU resources of the device; while the disadvantage is that the device cannot detect and respond to LLDP black holes quickly. Configure longer sending intervals in scenarios where device performance is weaker or loop tolerance is higher.

Restrictions and guidelines

The LLDP black hole detection feature takes effect only if the following conditions are met:

- On both ends of the LLDP connection, both global and port-level LLDP black hole detection functions are enabled.
- On the ports with LLDP black hole detection enabled, the link status is UP, LLDP is enabled, and the operating mode is TxRx.

If LLDP black hole detection is not enabled on a port or the LLDP packet receiving timer of the port has not timed out, the port will not process any LLDP black hole detection packets received.

On devices with a long LLDP packet sending interval, configure a longer LLDP packet receiving timeout. Otherwise, it might result in device ports being blocked even if no LLDP black hole exists in the network. Configure a shorter LLDP receiving timeout on devices with a shorter LLDP packet sending interval for more efficient LLDP black hole detection.

The **lldp timer blackhole-detection-interval** and **lldp global timer blackhole-detection-interval** commands can both set the interval at which ports send LLDP black hole detection packets. When both commands are configured, the **lldp timer blackhole-detection-interval** command takes precedence. If the interval is not set on a port, the port uses the global interval set by the **lldp global timer blackhole-detection-interval** command.

The timeout for receiving LLDP black hole detection packets on a port can be configured by using the **lldp timer rx-blackhole-timeout** and **lldp global timer rx-blackhole-timeout** commands. When both commands are used, the **lldp timer rx-blackhole-timeout** command takes precedence. If a port is not configured with a timeout, it uses the global timeout set by the **lldp global timer rx-blackhole-timeout** command.

The timeout for receiving LLDP black hole detection packets on the local device should not be less than the interval for sending LLDP black hole detection packets on the peer device. Otherwise, LLDP black hole detection will not take effect.

As a best practice, do not enable LLDP black hole detection on a member port of an aggregate interface. If you fail to do so, LLDP black hole detection might fail to take effect.

Procedure

71. Enter system view.

system-view

72. Enable global LLDP black hole detection.

lldp global blackhole-detection enable

By default, global LLDP black hole detection is disabled.

73. (Optional.) Configure the LLDP packet receiving timeout for black hole detection.

lldp global blackhole-detection rx-lldpdu timeout *timeout*

By default, the LLDP packet receiving timeout for black hole detection is 120 seconds.

74. (Optional.) Set the global interval for sending LLDP black hole detection packets.

lldp global timer blackhole-detection-interval *interval*

By default, the interval for sending LLDP black hole detection packets is 2 seconds.

75. (Optional.) Set the global timeout for receiving LLDP black hole detection packets.

lldp global timer rx-blackhole-timeout *timeout*

By default, the timeout for receiving LLDP black hole detection packets is (the global interval for sending LLDP black hole detection packets × 3 + 10) seconds.

76. (Optional.) Enter Layer 2 Ethernet interface view.

interface *interface-type interface-number*

77. (Optional.) Enable LLDP black hole detection for a port.

lldp blackhole-detection enable

By default, LLDP black hole detection is enabled for a port.

78. (Optional.) Set the interval at which the port sends LLDP black hole detection packets.

    lldp timer blackhole-detection-interval *interval*

    By default, the interval for sending LLDP black hole detection packets is 2 seconds.

79. (Optional.) Set the timeout for receiving LLDP black hole detection packets on the port.

    lldp timer rx-blackhole-timeout *timeout*

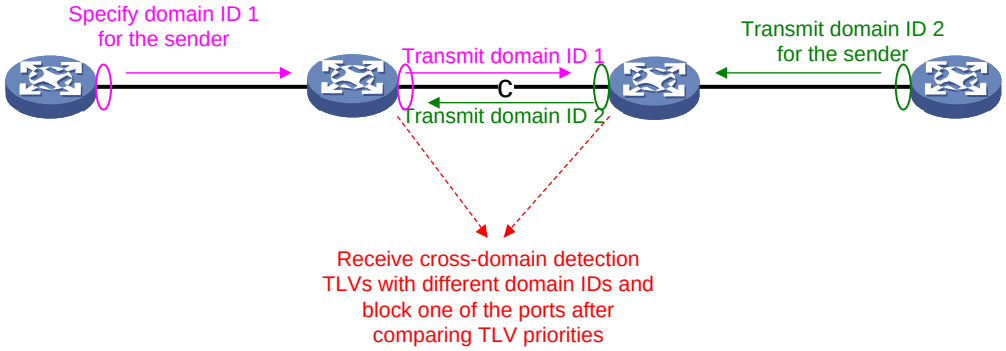
    By default, the timeout for receiving LLDP black hole detection packets on a port is (the port's sending interval for LLDP black hole detection packets × 3 + 10) seconds.

Configuring LLDP cross-domain detection

About this task

As shown in Figure 6, Device A and Device B belongs to different branch networks. If a link exists between Device A and Device B, a loop might occur in the network. After configuring LLDP cross-domain detection, you can manually assign the devices to different domains, and use LLDP to detect whether the specified LLDP neighbor is in the local domain. In addition, you can block the link to neighbors in other domains to eliminate the potential loop risk.

Figure 6 LLDP cross-domain detection application scenario



The LLDP cross-domain detection feature defines a private type of TLV for LLDP, that is, the cross-domain detection TLV. This TLV is used to advertise the local domain to the LLDP neighbor at the peer end. The LLDP cross-domain detection feature takes effect on a port only after you execute the **lldp global cross-domain-detection enable** or **lldp cross-domain-detection** command to enable LLDP cross-domain detection. Then, LLDP packets sent by the device will carry cross-domain detection TLVs.

The domain ID in a cross-domain detection TLV is key information, because it indicates the domain to which the port that sends the cross-domain detection TLV belongs. If you execute the **lldp cross-domain-detection domain-id** command to specify a domain ID for a port, the cross-domain detection TLVs sent by this port must carry the specified domain ID. If you do not specify a domain ID for a port, the cross-domain detection TLVs sent by this port carry a domain ID in the cross-domain detection TLVs received by the device. If the device has received multiple cross-domain detection TLVs with different domain IDs, it will compare the priorities of these TLVs. When sending a cross-domain detection TLV, the device will carry only the domain ID of the optimal TLV it received, and block ports that receive non-optimal TLVs with different domain IDs. This will help eliminating potential loops in the network, as shown in Figure 7. A blocked port can restore

normal forwarding status when LLDP cross-domain detection is disabled or it does not receive any cross-domain detection TLV that carries a different domain ID.

Figure 7 Domain ID transmission

Restrictions and guidelines

As a best practice, enable LLDP cross-domain detection only on a port of the start device of a domain ID (typically the spine device in a spine-leaf architecture), and do not enable LLDP cross-domain detection globally. If you fail to do so, LLDP cross-domain detection might fail to take effect.

If the domain ID is not configured for LLDP cross-domain detection, or the port is not enabled with the cross-domain detection TLV advertisement capability, the cross-domain detection feature cannot take effect on the port. In this case, the device cannot identify cross-domain detection TLVs carried in LLDP packets or add cross-domain detection TLVs to LLDP packets.

You can use the **lldp global cross-domain-detection enable** or **lldp cross-domain-detection** command to enable LLDP cross-domain detection for a port. If the **lldp cross-domain-detection** command is not used for the port, the global setting (configured with the **lldp global cross-domain-detection enable** command) applies. If both commands are configured for the port, the port-specific setting (configured with the **lldp cross-domain-detection** command) applies.

Procedure

80. Enter system view.

system-view

81. Enable LLDP cross-domain detection globally.

lldp global cross-domain-detection enable

By default, LLDP cross-domain detection is disabled globally.

82. Enter Layer 2 Ethernet interface view.

interface *interface-type interface-number*

83. Configure the domain ID for LLDP cross-domain detection.

lldp cross-domain-detection domain-id *domain-id*

By default, the domain ID is not configured for LLDP cross-domain detection.

84. Enable or disable LLDP cross-domain detection for the port.

lldp cross-domain-detection { **enable** | **disable** }

By default, the global setting (configured with the **lldp global cross-domain-detection enable** command) applies.

Disabling AP restart through LLDP

About this task

When the device acts as Power Sourcing Equipment (PSE), it can use the LLDP aging mechanism to determine the status of the directly connected AP it powers. If the AP fails and cannot send LLDP packets, the device calls the PoE module to restart the interface, thus achieving the function of rebooting the connected AP. This function is known as AP restart through LLDP.

AP restart through LLDP identifies abnormal APs as follows:

- When the device receives an LLDP packet from a neighbor, if the System Capabilities TLV contains the WlanAccessPoint field, the neighbor is considered to be an AP neighbor.
- The device determines if the directly connected AP neighbor is abnormal by aging out the LLDP neighbor. The device considers the AP neighbor as abnormal only when the LLDP packet reception times out and the physical status of the interface directly connected to the AP neighbor is UP. If the neighbor ages out and the physical status of the interface directly connected to the AP neighbor is DOWN, the device will not trigger the restart mechanism but will directly delete the LLDP neighbor.
- The AP restart through LLDP mechanism can only be triggered when only one AP neighbor is connected to the interface.

After confirming that the AP is abnormal, the device invokes the PoE module to restart the interface, causing the AP connected to that interface to be rebooted through power-off and re-powering.

By default, the AP restart through LLDP feature is enabled. To avoid accidental restarts of the AP, you can disable this feature.

Restrictions and guidelines

The device configured with this feature must be a PSE that supports PoE, and the AP neighbor that needs to be restarted must be a Powered Device (PD). The interface that is directly connected to the AP neighbor must be a PoE interface with the PoE feature enabled. For more information about PSE, PD, and PoE interfaces, see *Network Management and Monitoring Configuration Guide*.

Procedure

85. Enter system view.

```
system-view
```

86. Disable AP restart through LLDP.

```
undo lldp ap-timeout-reset enable
```

By default, the AP restart through LLDP feature is enabled.

Disabling LLDP control over PoE

About this task

In scenarios where a switch is connected to a large number of APs and provides PoE power to these APs, LLDP neighbors must be disconnected during batch maintenance of APs. At such times, if LLDP still maintains control over PoE, this might cause power disruption or reboot of APs, resulting in maintenance failure. In this scenario, it is necessary for LLDP not to control the switch's PoE power supply to ensure the smooth maintenance of AP devices.

After you disable LLDP control over PoE, LLDP no longer participates in the PoE power provisioning process and does not handle the Power Via MDI TLV defined by IEEE 802.3. This achieves the decoupling of LLDP functionality and PoE capability.

Procedure

87. Enter system view.

system-view

88. Disabling LLDP control over PoE.

    undo lldp process-poe enable

    By default, LLDP control over PoE is enabled.

Display and maintenance commands for LLDP

Execute **display** commands in any view.

Task	Command
Display local LLDP information.	**display lldp local-information** [**global** | **interface** *interface-type interface-number*]
Display the information contained in the LLDP TLVs sent from neighboring devices.	**display lldp neighbor-information** [[[**interface** *interface-type interface-number*] [**agent** { **nearest-bridge** | **nearest-customer** | **nearest-nontpmr** }] [**verbose**]] | **list** [**system-name** *system-name*]]
Display LLDP statistics.	**display lldp statistics** [**global** | [**interface** *interface-type interface-number*] [**agent** { **nearest-bridge** | **nearest-customer** | **nearest-nontpmr** }]]
Display LLDP status of a port.	**display lldp status** [**interface** *interface-type interface-number*] [**agent** { **nearest-bridge** | **nearest-customer** | **nearest-nontpmr** }]
Display types of advertisable optional LLDP TLVs.	**display lldp tlv-config** [**interface** *interface-type interface-number*] [**agent** { **nearest-bridge** | **nearest-customer** | **nearest-nontpmr** }]
Clear LLDP statistics on ports.	**reset lldp statistics** [**interface** *interface-type interface number*] [**agent** { **nearest-bridge** | **nearest-customer** | **nearest-nontpmr** }]

LLDP configuration examples

Example: Configuring basic LLDP functions

Network configuration

As shown in Figure 8, enable LLDP globally on Switch A and Switch B to perform the following tasks:

- Monitor the link between Switch A and Switch B on the NMS.
- Monitor the link between Switch A and the MED device on the NMS.

Figure 8 Network diagram

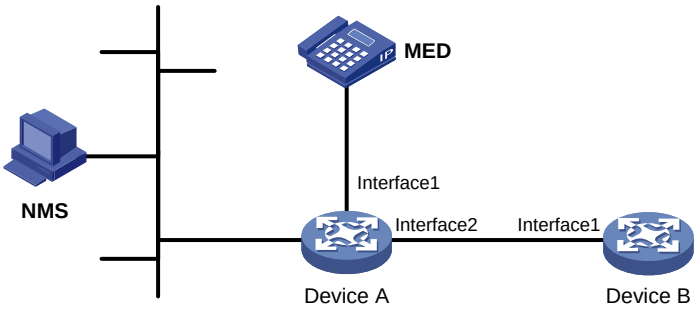


Table 8 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

89. Configure Switch A:

Enable LLDP globally.

```
<SwitchA> system-view
[SwitchA] lldp global enable
```

Enable LLDP on GigabitEthernet 1/0/1. By default, LLDP is enabled on ports.

```
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] lldp enable
```

Set the LLDP operating mode to Rx on GigabitEthernet 1/0/1.

```
[SwitchA-GigabitEthernet1/0/1] lldp admin-status rx
[SwitchA-GigabitEthernet1/0/1] quit
```

Enable LLDP on GigabitEthernet 1/0/2. By default, LLDP is enabled on ports.

```
[SwitchA] interface gigabitethernet 1/0/2
[SwitchA-GigabitEthernet1/0/2] lldp enable
```

Set the LLDP operating mode to Rx on GigabitEthernet 1/0/2.

```
[SwitchA-GigabitEthernet1/0/2] lldp admin-status rx
[SwitchA-GigabitEthernet1/0/2] quit
```

90. Configure Switch B:

Enable LLDP globally.

```
<SwitchB> system-view
[SwitchB] lldp global enable
```

Enable LLDP on GigabitEthernet 1/0/1. By default, LLDP is enabled on ports.

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] lldp enable
```

Set the LLDP operating mode to Tx on GigabitEthernet 1/0/1.

```
[SwitchB-GigabitEthernet1/0/1] lldp admin-status tx
[SwitchB-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Verify the following items:

- GigabitEthernet 1/0/1 of Switch A connects to a MED device.
- GigabitEthernet 1/0/2 of Switch A connects to a non-MED device.
- Both ports operate in Rx mode, and they can receive LLDP frames but cannot send LLDP frames.

```
[SwitchA] display lldp status
Global status of LLDP: Enable
Bridge mode of LLDP: customer-bridge

Example: Configuring LLDP cross-domain detection

Network configuration

As shown in Figure 9, in a spine-leaf architecture, Device A, Device C, Device D, and Device G belong to the same branch, and Device B, Device E, Device F, and Device H belong to the other. To prevent loops caused by incorrect wiring between devices, make sure only the devices within the same branch can exchange data. To meet these requirements, configure LLDP cross-domain detection. Assign Device A and its downstream devices to one domain and Device B and its downstream devices to another. Then, the ports that connect different domains will be blocked to prevent data traffic between different branches.

Figure 9 Network diagram

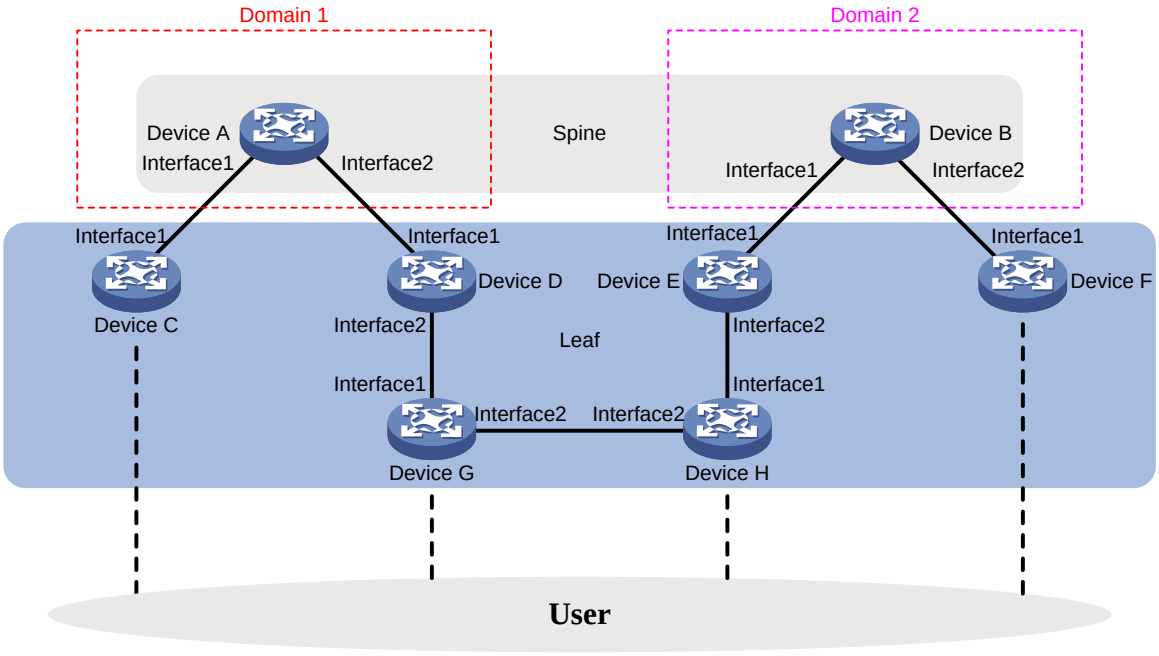

Table 9 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

91. Configure Device A:

Enable LLDP globally.

```
<DeviceA> system-view
[DeviceA] lldp global enable
```

Enable LLDP on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 separately. By default, LLDP is enabled on ports.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] lldp enable
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] lldp enable
[DeviceA-GigabitEthernet1/0/2] quit
```

Specify domain ID 1 for GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 and enable LLDP cross-domain detection.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] lldp cross-domain-detection domain-id 1
[DeviceA-GigabitEthernet1/0/1] lldp cross-domain-detection enable
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] lldp cross-domain-detection domain-id 1
[DeviceA-GigabitEthernet1/0/2] lldp cross-domain-detection enable
[DeviceA-GigabitEthernet1/0/2] quit
```

92. Configure Device B:

Enable LLDP globally.

```
<DeviceB> system-view
[DeviceB] lldp global enable
```

Enable LLDP on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 separately. By default, LLDP is enabled on ports.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] lldp enable
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] lldp enable
[DeviceB-GigabitEthernet1/0/2] quit
```

Specify domain ID 2 for GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 and enable LLDP cross-domain detection.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] lldp cross-domain-detection domain-id 2
[DeviceB-GigabitEthernet1/0/1] lldp cross-domain-detection enable
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] lldp cross-domain-detection domain-id 2
[DeviceB-GigabitEthernet1/0/2] lldp cross-domain-detection enable
[DeviceB-GigabitEthernet1/0/2] quit
```

93. Configure Device C:

Enable LLDP globally.

```
<DeviceC> system-view
```

```
[DeviceC] lldp global enable
```

Enable LLDP cross-domain detection globally.

```
[DeviceC] lldp global cross-domain-detection enable
```

Enable LLDP on GigabitEthernet 1/0/1. By default, LLDP is enabled on ports.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] lldp enable
[DeviceC-GigabitEthernet1/0/1] quit
```

94. Configure Device D

Enable LLDP globally.

```
<DeviceD> system-view
[DeviceD] lldp global enable
```

Enable LLDP cross-domain detection globally.

```
[DeviceD] lldp global cross-domain-detection enable
```

Enable LLDP on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2. By default, LLDP is enabled on ports.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] lldp enable
[DeviceD-GigabitEthernet1/0/1] quit
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] lldp enable
[DeviceD-GigabitEthernet1/0/2] quit
```

95. Configure Device G in the same steps as Device D.

96. Configure Device E:

Enable LLDP globally.

```
<DeviceE> system-view
[DeviceE] lldp global enable
```

Enable LLDP cross-domain detection globally.

```
[DeviceE] lldp global cross-domain-detection enable
```

Enable LLDP on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2. By default, LLDP is enabled on ports.

```
[DeviceE] interface gigabitethernet 1/0/1
[DeviceE-GigabitEthernet1/0/1] lldp enable
[DeviceE-GigabitEthernet1/0/1] quit
[DeviceE] interface gigabitethernet 1/0/2
[DeviceE-GigabitEthernet1/0/2] lldp enable
[DeviceE-GigabitEthernet1/0/2] quit
```

97. Configure Device H in the same steps as Device E.

98. Configure F:

Enable LLDP globally.

```
<DeviceF> system-view
[DeviceF] lldp global enable
```

Enable LLDP cross-domain detection globally.

```
[DeviceF] lldp global cross-domain-detection enable
```

Enable LLDP on GigabitEthernet 1/0/1. By default, LLDP is enabled on ports.

```
[DeviceF] interface gigabitethernet 1/0/1
[DeviceF-GigabitEthernet1/0/1] lldp enable
[DeviceF-GigabitEthernet1/0/1] quit
```

Verifying the configuration

On Device H, obtain the global LLDP status and LLDP status on all ports.

```
[DeviceG] display lldp status
Global status of LLDP: Enable
Bridge mode of LLDP: customer-bridge
The current number of LLDP neighbors: 2

Configuring Ethernet interfaces

About Ethernet interface

The Switch Series supports Ethernet interfaces, management Ethernet interfaces, Console interfaces, and USB interfaces. For the interface types and the number of interfaces supported by a switch model, see the installation guide and hardware manuals.

This chapter describes how to configure management Ethernet interfaces and Ethernet interfaces.

Configuring a management Ethernet interface

About this task

You can connect a management Ethernet interface to a PC for software loading and system debugging, or connect it to a remote NMS for remote system management.

Procedure

1. Enter system view.
   system-view
2. Enter management Ethernet interface view.
   interface M-GigabitEthernet *interface-number*
3. (Optional.) Set the interface description.
   description *text*
   The default setting is **M-GigabitEthernet0/0/0 Interface**.
4. (Optional.) Set the duplex mode for the management Ethernet interface.
   duplex { **auto** | **full** | **half** }
   By default, the duplex mode is **auto** for a management Ethernet interface.
5. (Optional.)_Set the speed for the management Ethernet interface.
   speed { **10** | **100** | **1000** | **auto** }
   By default, the speed is **auto** for a management Ethernet interface.
6. (Optional.) Shut down the interface.
   shutdown
   By default, the management Ethernet interface is up.

△ **CAUTION:**
Executing the **shutdown** command on an interface will disconnect the link of the interface and interrupt communication. Use this command with caution.

Ethernet interface naming conventions

The Ethernet interfaces are named in the format of **interface type A/B/C**. The letters that follow the interface type represent the following elements:

- **A**—IRF member ID. If the switch is not in an IRF fabric, A is 1 by default.

- **B**—Card slot number. **0** indicates the interface is a fixed interface of the switch. **1** indicates the interface is on expansion interface card 1. **2** indicates the interface is on expansion interface card 2.
- **C**—Port index.

Configuring common Ethernet interface settings

This section describes the settings common to Layer 2 Ethernet interfaces, Layer 3 Ethernet interfaces, and Layer 3 Ethernet subinterfaces. For more information about the settings specific to Layer 2 Ethernet interfaces, see "Configuring a Layer 2 Ethernet interface." For more information about the settings specific to Layer 3 Ethernet interfaces or subinterfaces, see "Configuring a Layer 3 Ethernet interface or subinterface."

Configuring the physical type for a combo interface (single combo interface)

About this task

A combo interface is a logical interface that physically comprises one fiber combo port and one copper combo port. The two ports share one forwarding channel and one interface view. As a result, they cannot work simultaneously. When you activate one port, the other port is automatically disabled. If you execute the **combo enable auto** command on a combo interface, the interface automatically identifies the media inserted and activates the corresponding combo port. In the interface view, you can activate the fiber or copper combo port, and configure other port attributes such as the interface rate and duplex mode.

Prerequisites

Before you configure combo interfaces, complete the following tasks:

- Determine the combo interfaces on your device. Identify the two physical interfaces that belong to each combo interface according to the marks on the device panel.
- Use the **display interface** command to determine which port (fiber or copper) of each combo interface is active:
  - If the copper port is active, the output includes "Media type is twisted pair."
  - If the fiber port is active, the output does not include this information.

Procedure

1. Enter system view.

   system-view
2. Enter Ethernet interface view.

   interface *interface-type interface-number*
3. Activate the copper combo port or fiber combo port.

   combo enable { **auto** | **copper** | **fiber** }

   By default, an interface automatically identifies the media inserted and activates the corresponding combo port.

Configuring basic settings of an Ethernet interface

About this task

You can configure an Ethernet interface to operate in one of the following duplex modes:

- **Full-duplex mode**—The interface can send and receive packets simultaneously.
- **Half-duplex mode**—The interface can only send or receive packets at a given time.
- **Autonegotiation mode**—The interface negotiates a duplex mode with its peer.

You can set the speed of an Ethernet interface or enable it to automatically negotiate a speed with its peer. For a 100-Mbps or 1000-Mbps Layer 2 Ethernet interface, you can also set speed options for autonegotiation. The two ends can select a speed only from the available options. For more information, see "Setting speed options for autonegotiation on an Ethernet interface."

Restrictions and guidelines

The **shutdown**, **port up-mode**, and **loopback** commands are mutually exclusive.

Procedure

1. Enter system view.
   system-view
2. Configure the device to display the default description for interfaces when it displays the interface information.
   interface default-description output
3. Enter Ethernet interface view.
   interface *interface-type interface-number*
4. Set the description for the Ethernet interface.
   description *text*
   The default setting is *interface-name* **Interface**. For example, **GigabitEthernet1/0/1 Interface**.
5. Set the duplex mode for the Ethernet interface.
   duplex { **auto** | **full** | **half** }
   By default, the duplex mode is **auto** for Ethernet interfaces.
   Ethernet copper ports that operate in 1000 Mbps or 10000 Mbps and fiber ports do not support the **half** keyword.
6. Set the speed for the Ethernet interface.
   speed { **10** | **100** | **1000** | **10000** | **25000** | **40000** | **100000** | **auto** }
   By default, an Ethernet interface negotiates a speed with its peer.
7. Set the expected bandwidth for the Ethernet interface.
   bandwidth *bandwidth-value*
   By default, the expected bandwidth (in kbps) is the interface baud rate divided by 1000.
8. Bring up the Ethernet interface.
   undo shutdown
   By default, Ethernet interfaces are in up state.

Configuring basic settings of an Ethernet subinterface

About this task

By default, a Layer 3 Ethernet subinterface processes packets for only the VLAN whose ID is the same as the subinterface number.

Restrictions and guidelines for Ethernet subinterface basic settings

- The **shutdown**, **port up-mode**, and **loopback** commands are mutually exclusive.
- The **shutdown** command cannot be executed on an Ethernet interface in a loopback test.

- When an Ethernet subinterface is used as the egres interface of the public network, it cannot forward traffic of the public network.

Procedure

1. Enter system view.

   system-view
2. Configure the device to display the default description for interfaces when it displays the interface information.

   interface default-description output
3. Create an Ethernet subinterface.

   interface *interface-type interface-number.subnumber*
4. Set the description for the Ethernet subinterface.

   description *text*

   The default setting is *interface-name* **Interface**. For example, **GigabitEthernet1/0/1.1 Interface**.
5. Set the expected bandwidth for the Ethernet subinterface.

   bandwidth *bandwidth-value*

   By default, the expected bandwidth (in kbps) is the interface baud rate divided by 1000.
6. Bring up the Ethernet subinterface.

   undo shutdown

   By default, Ethernet subinterfaces are in up state.

Enabling automatic negotiation for speed downgrading

About this task

Perform this task to enable GE10-GE interfaces at two ends of a link to automatically negotiate about downgrading their speed when the following conditions exist:

- The interfaces automatically negotiate a speed of 1000 Mbps or 10000 Mbps.
- The interfaces cannot operate at 1000 Mbps or 10000 Mbps because of link restrictions.

Take a GE Ethernet interface as an example. When a GE interface can only operate at 100 Mbps because of the aging of the network cable, packet loss occurs. You can enable automatic negotiation for speed downgrading for the interface to automatically negotiate a speed of 100 Mbps to ensure normal operation of the interface.

Restrictions and guidelines

This feature is available only on GE 10GE interfaces.

Procedure

1. Enter system view.

   system-view
2. Enter Ethernet interface view.

   interface *interface-type interface-number*
3. Enable automatic negotiation for speed downgrading.

   speed auto downgrade

   The default settings vary by device model.

Configuring the link mode of an Ethernet interface

About this task

Interfaces on the device can operate either as Layer 2 or Layer 3 Ethernet interfaces. You can use commands to set the link mode to bridge or route.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Configure the link mode of the Ethernet interface.
   port link-mode { **bridge** | **route** }
   By default, all Ethernet interfaces on the device operate in bridge mode.

CAUTION:

After you change the link mode of an Ethernet interface, all commands (except the **description**, **duplex**, **jumboframe enable**, **speed**, **shutdown**, **port fec mode** , and **combo enable** commands) on the Ethernet interface are restored to their defaults in the new link mode.

Configuring jumbo frame support

About this task

Jumbo frames are frames larger than 1536 bytes and are typically received by an Ethernet interface during high-throughput data exchanges, such as file transfers.

The Ethernet interface processes jumbo frames in the following ways:

- When the Ethernet interface is configured to deny jumbo frames (by using the **undo jumboframe enable** command), the Ethernet interface discards jumbo frames.
- When the Ethernet interface is configured with jumbo frame support, the Ethernet interface performs the following operations:
  - Processes jumbo frames within the specified length.
  - Discards jumbo frames that exceed the specified length.

Restrictions and guidelines

If you execute this command multiple times on the same interface, the most recent configuration takes effect.

If you execute this command on multiple interfaces in the same slot, the most recent configuration takes effect on all interfaces of the slot.

To assign a physical interface to an aggregate interface, make sure the physical interface is configured with the same maximum jumbo frame size (13312) as the aggregate interface. After assigning a physical interface to an aggregate interface, you cannot modify the maximum jumbo frame size of the physical interface.

If a physical interface in a slot is configured as an IRF physical interface, the maximum jumbo frame size is restored to the default for all physical interfaces in the slot and cannot be modified.

You cannot modify the maximum jumbo frame size of an aggregate interface.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Configure jumbo frame support.
   jumboframe enable [*size*]
   By default, the device allows jumbo frames within 13312 bytes to pass through.

Configuring physical state change suppression on an Ethernet interface

About this task

The physical link state of an Ethernet interface is either up or down. Each time the physical link of an interface comes up or goes down, the interface immediately reports the change to the CPU. The CPU then performs the following operations:

- Notifies the upper-layer protocol modules (such as routing and forwarding modules) of the change for guiding packet forwarding.
- Automatically generates traps and logs to inform users to take the correct actions.

To prevent frequent physical link flapping from affecting system performance, configure physical state change suppression. You can configure this feature to suppress only link-down events, only link-up events, or both. If an event of the specified type still exists when the suppression interval expires, the system reports the event to the CPU.

Restrictions and guidelines

Do not enable this feature on an interface that has RRPP, spanning tree protocols, or Smart Link enabled.

You can configure different suppression intervals for link-up and link-down events.

If you execute the **link-delay** command multiple times on an interface, the following rules apply:

- You can configure the suppression intervals for link-up and link-down events separately.
- If you configure the suppression interval multiple times for link-up or link-down events, the most recent configuration takes effect.

The **link-delay**, **dampening**, and **port link-flap protect enable** commands are mutually exclusive on an Ethernet interface.

Procedure

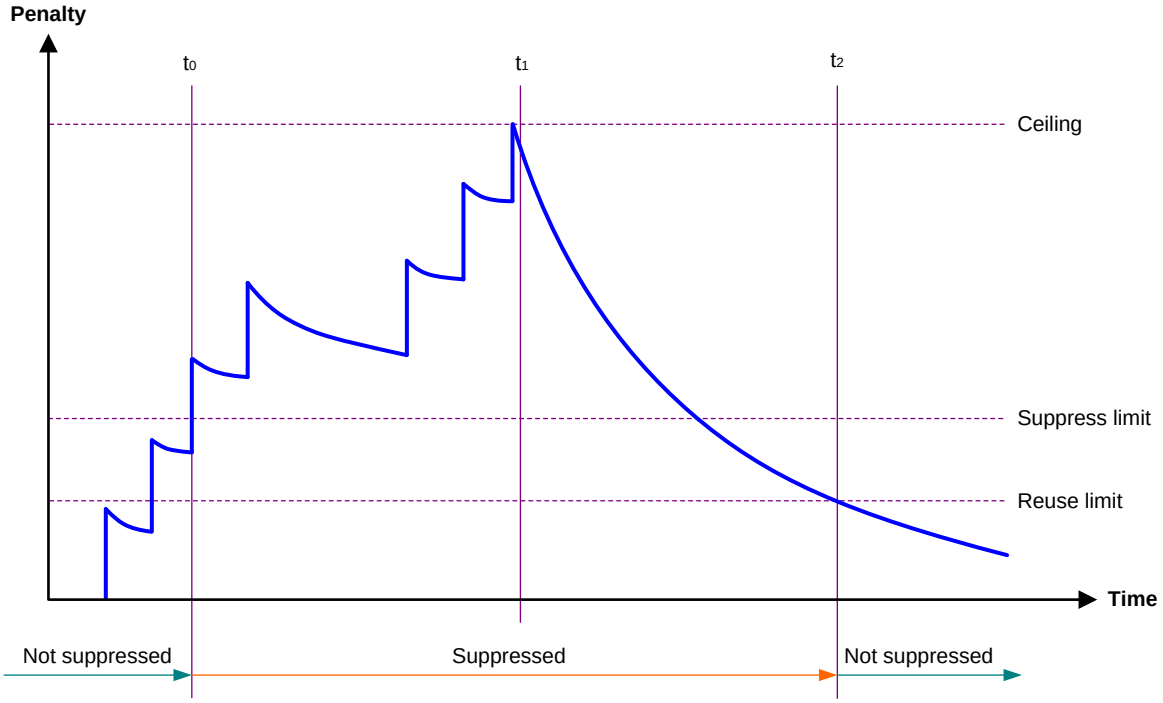
1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Configure physical state change suppression.
   link-delay { **down** | **up** } [**msec**] *delay-time*
   By default, each time the physical link of an interface goes up or comes down, the interface immediately reports the change to the CPU.

Configuring dampening on an Ethernet interface

About this task

The interface dampening feature uses an exponential decay mechanism to prevent excessive interface flapping events from adversely affecting routing protocols and routing tables in the network. Suppressing interface state change events protects the system resources.

If an interface is not dampened, its state changes are reported. For each state change, the system also generates an SNMP trap and log message.



After a flapping interface is dampened, it does not report its state changes to the CPU. For state change events, the interface only generates SNMP trap and log messages.

Parameters

- **Penalty**—The interface has an initial penalty of 0. When the interface flaps, the penalty increases by 1000 for each down event until the ceiling is reached. It does not increase for up events. When the interface stops flapping, the penalty decreases by half each time the half-life timer expires until the penalty drops to the reuse threshold.
- **Ceiling**—The penalty stops increasing when it reaches the ceiling.
- **Suppress-limit**—The accumulated penalty that triggers the device to dampen the interface. In dampened state, the interface does not report its state changes to the CPU. For state change events, the interface only generates SNMP traps and log messages.
- **Reuse-limit**—When the accumulated penalty decreases to this reuse threshold, the interface is not dampened. Interface state changes are reported to the upper layers. For each state change, the system also generates an SNMP trap and log message.
- **Decay**—The amount of time (in seconds) after which a penalty is decreased.
- **Max-suppress-time**—The maximum amount of time the interface can be dampened. If the penalty is still higher than the reuse threshold when this timer expires, the penalty stops increasing for down events. The penalty starts to decrease until it drops below the reuse threshold.
- When configuring the **`dampening`** command, follow these rules to set the values mentioned above:
- The ceiling is equal to $2^{(\text{Max-suppress-time/Decay})}$ × reuse-limit. It is not user configurable.
- The configured suppress limit is lower than or equal to the ceiling.
- The ceiling is lower than or equal to the maximum suppress limit supported.

Figure 1 shows the change rule of the penalty value. The lines t_0 and t_2 indicate the start time and end time of the suppression, respectively. The period from t_0 to t_2 indicates the suppression period, t_0 to t_1 indicates the max-suppress-time, and t_1 to t_2 indicates the complete decay period.

Figure 1 Change rule of the penalty value

Restrictions and guidelines

- The **dampening**, **link-delay**, and **port link-flap protect enable** commands are mutually exclusive on an interface.
- The **dampening** command does not take effect on the administratively down events. When you execute the **shutdown** command, the penalty restores to 0, and the interface reports the down event to the upper-layer protocols.
- Do not enable the dampening feature on an interface with RRPP, MSTP, or Smart Link enabled.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Enable dampening on the interface.
   dampening [*half-life reuse suppress max-suppress-time*]
   By default, interface dampening is disabled on Ethernet interfaces.

Enabling link flapping protection on an interface

About this task

Link flapping on an interface changes network topology and increases the system overhead. For example, in an active/standby link scenario, when interface status on the active link changes between **UP** and **DOWN**, traffic switches between active and standby links. To solve this problem, configure this feature on the interface.

With this feature enabled on an interface, when the interface goes down, the system enables link flapping detection. During the link flapping detection interval, if the number of detected flaps reaches or exceeds the link flapping detection threshold, the system shuts down the interface.

When a port is shut down automatically by a feature, the device starts a port status detection timer. When the timer expires, the device restores the port status to its actual physical status automatically.

Restrictions and guidelines

This feature takes effect only if it is configured in both the system view and interface view.

If you specify the **down-auto-recovery** keyword in both system view and interface view, an interface comes up automatically when the port status detection timer for the ports that are shut down by the link flapping protection feature expires.

When you configure this feature on an interface, how link flapping protection is triggered depends on the parameters specified:

- If you specify level-1 link flapping protection parameters but do not specify level-2 parameters, link flapping protection will be triggered and the interface will be shut down when the level-1 link flapping protection conditions are met.
- If you specify both level-1 and level-2 link flapping protection parameters, link flapping protection will be triggered and the interface will be shut down when either of level-1 and level-2 link flapping protection conditions are met.

IRF system stability might be affected by IRF physical link flapping. For IRF system stability, this feature is enabled by default on IRF physical interfaces and the enabling status of this feature is not affected by the status of global link flapping protection. When the number of flaps detected on an IRF physical interface exceeds the threshold within the detection interval, the device outputs a log rather than shuts down the IRF physical interface.

The **dampening**, **link-delay**, and **port link-flap protect enable** commands are mutually exclusive on an Ethernet interface.

To bring up an interface that has been shut down by link flapping protection, execute the **undo shutdown** command.

In the **display interface** command output, the **Link-Flap DOWN** value of the **Current state** field indicates that the interface has been shut down by link flapping protection.

If you change the timer setting during port detection, the device compares the new setting (T1) with the time that elapsed since the port was shut down (T).

- If T < T1, the port will be brought up after T1 – T seconds.
- If T ≥ T1, the port is brought up immediately.

For example, the timer setting is 30 seconds. If you change it to 10 seconds 2 seconds after the port is shut down, the port will come up 8 seconds later. If you change the timer setting to 2 seconds 10 seconds after the port is shut down, the port comes up immediately.

Procedure

1. Enter system view.

   system-view

2. Enable link flapping protection globally.

   link-flap protect enable [**down-auto-recovery**]

   By default, link flapping protection is disabled globally.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Enable link flapping protection on the Ethernet interface.

   port link-flap protect enable [**down-auto-recovery**] [**interval** *interval* | **threshold** *threshold*] * [**second-interval** *second-interval* **second-threshold** *second-threshold*]

   By default, link flapping protection is disabled on an Ethernet interface.

5. Return to system view.

quit

6. Set the port status detection timer for the ports that are shut down by the link flapping protection feature.

   shutdown-interval [**link-flap**] *interval*

   By default, the timer is 30 seconds.

Configuring broadcast/multicast/unknown unicast storm suppression

About this task

The storm suppression feature ensures that the size of a particular type of traffic (broadcast, multicast, or unknown unicast traffic) does not exceed the threshold on an interface. When the broadcast, multicast, or unknown unicast traffic on the interface exceeds this threshold, the system discards packets until the broadcast, multicast, or unknown unicast traffic drops below this threshold.

Both storm suppression and storm control can suppress storms on an interface. Storm suppression uses the chip to suppress traffic. Storm suppression has less impact on the device performance than storm control, which uses software to suppress traffic.

Restrictions and guidelines

- For the traffic suppression result to be determined, do not configure storm control together with storm suppression for the same type of traffic (broadcast/multicast/unknown unicast traffic). For more information about storm control, see "Configuring storm control on an Ethernet interface."
- The configured suppression threshold value in pps or kbps will be converted into a multiple of the step value supported by the chip. As a result, the effective suppression threshold might be different from the configured one. For information about the suppression threshold that takes effect, see the prompt on the device.

Procedure

1. Enter system view.

   system-view

2. Enter Ethernet interface view.

   interface *interface-type interface-number*

3. Enable broadcast suppression and set the broadcast suppression threshold.

   broadcast-suppression { *ratio* | **pps** *max-pps* | **kbps** *max-kbps* }

   By default, broadcast suppression is disabled.

4. Enable multicast suppression and set the multicast suppression threshold.

   multicast-suppression { *ratio* | **pps** *max-pps* | **kbps** *max-kbps* }

   By default, multicast suppression is disabled.

5. Enable unknown unicast suppression and set the unknown unicast suppression threshold.

   unicast-suppression { *ratio* | **pps** *max-pps* | **kbps** *max-kbps* }

   By default, unknown unicast suppression is disabled.

Configuring generic flow control on an Ethernet interface

About this task

To avoid dropping packets on a link, you can enable generic flow control at both ends of the link. When traffic congestion occurs at the receiving end, the receiving end sends a flow control (Pause)

frame to ask the sending end to suspend sending packets. Generic flow control includes the following types:

- **TxRx-mode generic flow control**—Enabled by using the **flow-control** command. With TxRx-mode generic flow control enabled, an interface can both send and receive flow control frames:
  - When congestion occurs, the interface sends a flow control frame to its peer.
  - When the interface receives a flow control frame from its peer, it suspends sending packets to its peer.
- **Rx-mode generic flow control**—Enabled by using the **flow-control receive enable** command. With Rx-mode generic flow control enabled, an interface can receive flow control frames, but it cannot send flow control frames:
  - When congestion occurs, the interface cannot send flow control frames to its peer.
  - When the interface receives a flow control frame from its peer, it suspends sending packets to its peer.

To handle unidirectional traffic congestion on a link, configure the **flow-control receive enable** command at one end and the **flow-control** command at the other end. To enable both ends of a link to handle traffic congestion, configure the **flow-control** command at both ends.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Enable generic flow control.
   - Enable TxRx-mode generic flow control.
     flow-control
   - Enable Rx-mode generic flow control.
     flow-control receive enable

   By default, generic flow control is disabled on an Ethernet interface.

Enabling energy saving features on an Ethernet interface

About this task

With Energy Efficient Ethernet (EEE) enabled, a link-up interface enters low power state if it has not received any packet for a period of time. The time period depends on the chip specifications and is not configurable. When a packet arrives later, the device automatically restores power supply to the interface and the interface restores to the normal state.

Restrictions and guidelines

Fiber ports do not support this feature.

Configuring EEE on an Ethernet interface

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Enable EEE on the Ethernet interface.
   eee enable

By default, EEE is disabled on an Ethernet interface.

Setting the statistics polling interval

About this task

By setting the statistics polling interval, you can collect statistics of packets and analyze packets at the specified interval. Based on the interface traffic statistics, you can take traffic control measures promptly to avoid network congestion and service interruption.

- When network congestion is detected, you can set the statistics polling interval to be smaller than 300 seconds (30 seconds when congestion deteriorates). Then, check traffic distribution on interfaces within a short period of time. For data packets that cause congestion, take traffic control measures.
- When the network bandwidth is sufficient and services are operating normally, you can set the statistics polling interval to be greater than 300 seconds. Once traffic parameter anomalies occur, modify the statistics polling interval promptly so that you can observe the traffic parameter trend in real time.

To display the interface statistics collected in the last statistics polling interval, use the **display interface** command. To clear the interface statistics, use the **reset counters interface** command.

Setting the statistics polling interval in Ethernet interface view

1. Enter system view.

   system-view
2. Enter Ethernet interface view.

   interface *interface-type interface-number*
3. Set the statistics polling interval for the Ethernet interface.

   flow-interval *interval*

   By default, the statistics polling interval is 300 seconds.

Enabling interframe gap and preamble statistics in the traffic statistics

About this task

With the **display interface** command executed, the **Last 300 seconds input rate** or **Last 300 seconds output rate** field in the command output displays the average outbound or inbound traffic rate in the last 300 seconds.

By default, traffic rate = native frame length × packet count per second. Execute the **traffic-statistic include-interframe** command if you need the total traffic statistics, including the native frame length, interframe gap length and preamble length, for a specific time period. With this command executed, traffic rate = (native frame length + interframe gap length + preamble length) × packet count per second.

By default, the interframe gap length and preamble length are fixed. However, you can execute the **itf number** command to adjust the interframe gap length. Adjusting the interframe gap length causes inaccuracy in only the traffic statistics being collected.

Procedure

1. Enter system view.

   system-view
2. Enter Ethernet interface view.

interface *interface-type interface-number*

3. Enable interframe gap and preamble statistics in the traffic statistics.

   traffic-statistic include-interframe

   By default, interframe gap and preamble statistics in the traffic statistics are disabled.

Enabling loopback testing on an Ethernet interface

About this task

Perform this task to determine whether an Ethernet link works correctly.

Internal loopback testing tests the device where the Ethernet interface resides. The Ethernet interface sends outgoing packets back to the local device. If the device fails to receive the packets, the device fails.

Restrictions and guidelines

- After you enable this feature on an Ethernet interface, the interface does not forward data traffic.

The **shutdown**, **port up-mode**, and **loopback** commands are mutually exclusive.

- After you enable this feature on an Ethernet interface, the Ethernet interface switches to full duplex mode. After you disable this feature, the Ethernet interface restores to its duplex setting.

Procedure

1. Enter system view.

   system-view

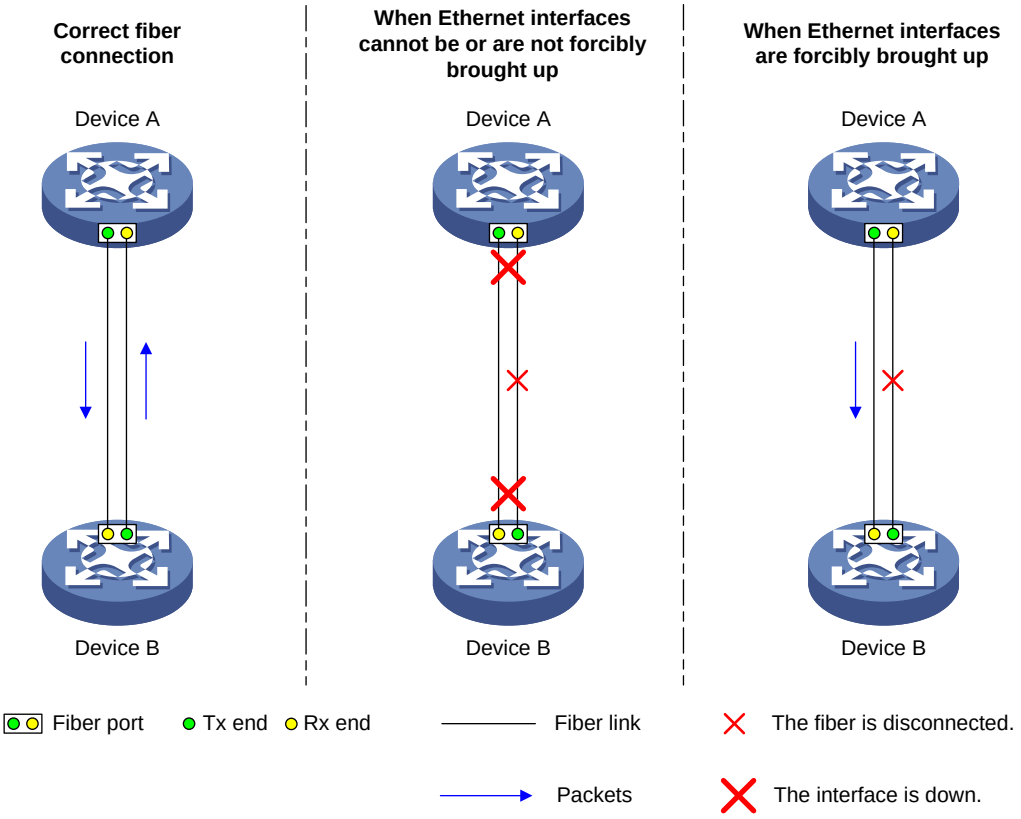
2. Enter Ethernet interface view.

   interface *interface-type interface-number*

3. Configure loopback testing on the Ethernet interface.
   - Enable loopback testing on the Ethernet interface.

     loopbackinternal

     By default, loopback testing is disabled on an Ethernet interface.



Forcibly bringing up a fiber port

About this task

As shown in Figure 2, a fiber port uses separate fibers for transmitting and receiving packets. The physical state of the fiber port is up only when both transmit and receive fibers are physically connected. If one of the fibers is disconnected, the fiber port does not work.

To enable a fiber port to forward traffic over a single link, you can use the **port up-mode** command. This command forcibly brings up a fiber port, even when no fiber links or transceiver modules are present for the fiber port. When one fiber link is present and up, the fiber port can forward packets over the link unidirectionally.

Figure 2 Forcibly bring up a fiber port

Restrictions and guidelines

- Copper ports do not support this feature.
- The **port up-mode**, **shutdown**, and **loopback** commands are mutually exclusive.
- A fiber port does not support this feature if the port is shut down by a protocol or by using the **shutdown** command.
- A fiber port forcibly brought up stays physically up whether or not a transceiver module or a fiber link is present for the port.
- A GE fiber port forcibly brought up cannot correctly forward traffic if it is installed with a fiber-to-copper converter, 100/1000-Mbps transceiver module, or 100-Mbps transceiver module. To solve the problem, use the **undo port up-mode** command on the fiber port.

Procedure

1. Enter system view.

   system-view
2. Enter Ethernet interface view.

   interface *interface-type interface-number*
3. Forcibly bring up the fiber port.

   port up-mode

   By default, a fiber port is not forcibly brought up, and the physical state of a fiber port depends on the physical state of the fibers.

Configuring interface alarm functions

About this task

With the interface alarm functions enabled, when the number of error packets on an interface in normal state within the specified interval exceeds the upper threshold, the interface generates an upper threshold exceeding alarm and enters the alarm state. When the number of error packets on an interface in the alarm state within the specified interval drops below the lower threshold, the interface generates a recovery alarm and restores to the normal state.

When a port is shut down automatically by a feature, the device starts a port status detection timer. When the timer expires, the device restores the port status to its actual physical status automatically.

Restrictions and guidelines

You can configure the interface alarm parameters in system view and interface view.

- The configuration in system view takes effect on all interfaces of the specified slot. The configuration in interface view takes effect only on the current interface.
- For an interface, the configuration in interface view takes priority, and the configuration in system view is used only when no configuration is made in interface view.

An interface that is shut down because of error packet alarms cannot automatically recover. To bring up the interface, execute the **undo shutdown** command on the interface.

If you change the timer setting during port detection, the device compares the new setting (T1) with the time that elapsed since the port was shut down (T).

- If T < T1, the port will be brought up after T1 – T seconds.
- If T ≥ T1, the port is brought up immediately.

For example, the timer setting is 30 seconds. If you change it to 10 seconds 2 seconds after the port is shut down, the port will come up 8 seconds later. If you change the timer setting to 2 seconds 10 seconds after the port is shut down, the port comes up immediately.

Configuring CRC error packet parameters

1. Enter system view.

   system-view

2. Configure global CRC error packet alarm parameters.

   ifmonitor crc-error slot *slot-number* **high-threshold** *high-value* **low-threshold** *low-value* **interval** *interval* [**down-auto-recovery** | **shutdown**]

   By default, the upper threshold is 1000, the lower threshold is 100, and the statistics collection and comparison interval is 10 seconds for CRC error packets.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Configure CRC error packet alarm parameters for the interface.

   port ifmonitor crc-error [**ratio**] **high-threshold** *high-value* **low-threshold** *low-value* **interval** *interval* [**down-auto-recovery** | **shutdown**]

   By default, an interface uses the global CRC error packet alarm parameters.

5. Return to system view.

   quit

6. Set the port status detection timer for the ports that are shut down by the CRC error packet alarm feature.

   shutdown-interval [**crc-error**] *interval*

By default, the timer is 30 secondsthe timer is 0 seconds.

Configuring input error packet alarm parameters

1. Enter system view.

   system-view

2. Configure global input error packet alarm parameters.

   ifmonitor input-error slot *slot-number* **high-threshold** *high-value* **low-threshold** *low-value* **interval** *interval* [**shutdown**]

   By default, the upper threshold is 1000, the lower threshold is 100, and the statistics collection and comparison interval is 10 seconds for input error packets.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Configure input error packet alarm parameters for the interface.

   port ifmonitor input-error high-threshold *high-value* **low-threshold** *low-value* **interval** *interval* [**shutdown**]

   By default, an interface uses the global input error packet alarm parameters.

Configuring output error packet alarm parameters

1. Enter system view.

   system-view

2. Configure global output error packet alarm parameters.

   ifmonitor output-error slot *slot-number* **high-threshold** *high-value* **low-threshold** *low-value* **interval** *interval* [**shutdown**]

   By default, the upper threshold is 1000, the lower threshold is 100, and the statistics collection and comparison interval is 10 seconds for output error packets.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Configure output error packet alarm parameters.

   port ifmonitor output-error high-threshold *high-value* **low-threshold** *low-value* **interval** *interval* [**shutdown**]

   By default, an interface uses the global output error packet alarm parameters.

Configuring input bandwidth usage alarm parameters

1. Enter system view.

   system-view

2. Configure global input bandwidth usage alarm parameters.

   ifmonitor input-usage slot *slot-number* **high-threshold** *high-value* **low-threshold** *low-value*

   By default, the upper threshold is 90 and the lower threshold is 80 for input bandwidth usage alarms.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Configure input bandwidth usage alarm parameters.

   port ifmonitor input-usage high-threshold *high-value* **low-threshold** *low-value*

   By default, an interface uses the global input bandwidth usage alarm parameters.

Configuring output bandwidth usage alarm parameters

1. Enter system view.

   system-view

2. Configure global output bandwidth usage alarm parameters.

   ifmonitor output-usage slot *slot-number* **high-threshold** *high-value* **low-threshold** *low-value*

   By default, the upper threshold is 90 and the lower threshold is 80 for output bandwidth usage alarms.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Configure output bandwidth usage alarm parameters.

   port ifmonitor output-usage high-threshold *high-value* **low-threshold** *low-value*

   By default, an interface uses the global output bandwidth usage alarm parameters.

Configuring received pause frame alarm parameters

1. Enter system view.

   system-view

2. Configure global received pause frame alarm parameters.

   ifmonitor rx-pause slot *slot-number* **high-threshold** *high-value* **low-threshold** *low-value* **interval** *interval*

   By default, the upper threshold is 500, the lower threshold is 100, and the statistics collection and comparison interval is 10 seconds for received pause frames.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Configure received pause frame alarm parameters.

   port ifmonitor rx-pause high-threshold *high-value* **low-threshold** *low-value* **interval** *interval*

   By default, an interface uses the global received pause frame alarm parameters.

Configuring sent pause frame alarm parameters

1. Enter system view.

   system-view

2. Configure global sent pause frame alarm parameters.

   ifmonitor tx-pause slot *slot-number* **high-threshold** *high-value* **low-threshold** *low-value* **interval** *interval* [**shutdown**]

   By default, the upper threshold is 500, the lower threshold is 100, and the statistics collection and comparison interval is 10 seconds for sent pause frames.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Configure sent pause frame alarm parameters.

   port ifmonitor tx-pause high-threshold *high-value* **low-threshold** *low-value* **interval** *interval* [**shutdown**]

   By default, an interface uses the global sent pause frame alarm parameters.

Configuring SDH error packet alarm parameters

1. Enter system view.

system-view

2. Configure global SDH error packet alarm parameters.

   ifmonitor sdh-error slot *slot-number* **high-threshold** *high-value* **low-threshold** *low-value* **interval** *interval* [**shutdown**]

   By default, the upper threshold is 1000, the lower threshold is 100, and the statistics collection and comparison interval is 10 seconds for SDH error packets.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Configure SDH error packet alarm parameters for the interface.

   port ifmonitor sdh-error high-threshold *high-value* **low-threshold** *low-value* **interval** *interval* [**shutdown**]

   By default, an interface uses the global SDH error packet alarm parameters.

Configuring SDH-B1 error packet alarm parameters

1. Enter system view.

   system-view

2. Configure global SDH-B1 error packet alarm parameters.

   ifmonitor sdh-b1-error slot *slot-number* **high-threshold** *high-value* **low-threshold** *low-value* **interval** *interval* [**shutdown**]

   By default, the upper threshold is 1000, the lower threshold is 100, and the statistics collection and comparison interval is 10 seconds for SDH-B1 error packets.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Configure SDH-B1 error packet alarm parameters for the interface.

   port ifmonitor sdh-b1-error high-threshold *high-value* **low-threshold** *low-value* **interval** *interval* [**shutdown**]

   By default, an interface uses the global SDH-B1 error packet alarm parameters.

Configuring SDH-B2 error packet alarm parameters

1. Enter system view.

   system-view

2. Configure global SDH-B2 error packet alarm parameters.

   ifmonitor sdh-b2-error slot *slot-number* **high-threshold** *high-value* **low-threshold** *low-value* **interval** *interval* [**shutdown**]

   By default, the upper threshold is 1000, the lower threshold is 100, and the statistics collection and comparison interval is 10 seconds for SDH-B2 error packets.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Configure SDH-B2 error packet alarm parameters for the interface.

   port ifmonitor sdh-b2-error high-threshold *high-value* **low-threshold** *low-value* **interval** *interval* [**shutdown**]

   By default, an interface uses the global SDH-B2 error packet alarm parameters.

Configuring packet-drop alarm parameters for the ingress buffer

1. Enter system view.

   system-view

2. Configure packet-drop alarm parameters for the ingress buffer globally.

ifmonitor input-buffer-drop slot *slot-number* **high-threshold** *high-value* **low-threshold** *low-value* **interval** *interval* [**shutdown**]

By default, the upper threshold is 1000, the lower threshold is 100, and the statistics collection and comparison interval is 10 seconds.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Configure packet-drop alarm parameters for the ingress buffer.

   port ifmonitor input-buffer-drop high-threshold *high-value* **low-threshold** *low-value* **interval** *interval* [**shutdown**]

   By default, an interface uses the packet-drop alarm parameters globally configured for the ingress buffer.

Configuring packet-drop alarm parameters for the egress buffer

1. Enter system view.

   system-view

2. Configure packet-drop alarm parameters for the egress buffer globally.

   ifmonitor output-buffer-drop slot *slot-number* **high-threshold** *high-value* **low-threshold** *low-value* **interval** *interval* [**shutdown**]

   By default, the upper threshold is 1000, the lower threshold is 100, and the statistics collection and comparison interval is 10 seconds.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Configure packet-drop alarm parameters for the egress buffer.

   port ifmonitor output-buffer-drop high-threshold *high-value* **low-threshold** *low-value* **interval** *interval* [**shutdown**]

   By default, an interface uses the packet-drop alarm parameters globally configured for the egress buffer.

Enabling SNMP notifications for the ETH module

About this task

To report critical ETH events to an SNMP NMS, enable SNMP notifications for the ETH module. For ETH SNMP notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see SNMP configuration in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for the ETH module.

   snmp-agent trap enable eth

   By default, SNMP notifications are disabled for the ETH module.

Shutting down all physical interfaces

About this task

This feature shuts down all physical interfaces except the management Ethernet interfaces on the device. Physical interfaces shut down by using this command are in ADM state.

Restrictions and guidelines

To shut down all physical interfaces or the specified interface, execute the **shutdown all-physical-interfaces** command in system view or execute the **shutdown** command in interface view.

To bring up interfaces shut down by using the **shutdown all-physical-interfaces** command, execute its **undo** form in system view. To bring up an interface shut down by using the **shutdown** command, execute its **undo** form in interface view.

If you execute the **shutdown all-physical-interfaces** command with the **include irf-physical-interface** keyword multiple times, this command shuts down all physical interfaces except the management Ethernet interfaces on the device.

Procedure

1. Enter system view.
   system-view
2. Shut down all physical interfaces except management Ethernet interfaces.
   shutdown all-physical-interfaces [**include irf-physical-interface**]
   By default, physical interfaces are up.

Restoring the default settings for an interface

Restrictions and guidelines

CAUTION:
This feature might interrupt ongoing network services. Make sure you are fully aware of the impacts of this feature when you use it in a live network.

This feature might fail to restore the default settings for some commands because of command dependencies or system restrictions. You can use the **display this** command in interface view to check for these commands and perform their **undo** forms or follow the command reference to restore their default settings. If your restoration attempt still fails, follow the error message to resolve the problem.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view or Ethernet subinterface view.
   interface *interface-type* { *interface-number* | *interface-number.subnumber* }
3. Restore the default settings for the interface.
   default

Enabling flow statistics collection for the buffer on an interface

About this task

With this feature enabled, the device starts collecting flow statistics (5-tuple information) in the buffer of an interface when the buffer usage exceeds the upper threshold for the first time. It stops collecting statistics when the buffer usage falls below the lower threshold for the first time. Then, it reports the flow statistics collected during this period to the gRPC or NETCONF module.

Restrictions and guidelines

To enable flow statistics collection for the buffer on multiple interfaces, repeat the **port ifmonitor buffer flow-information enable** command.

The maximum number of interfaces on which the device or card can collect flow statistics for the buffer simultaneously depends on the device model.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Enable flow statistics collection for the buffer on the interface.
   port ifmonitor buffer flow-information enable
   By default, flow statistics collection is disabled for the buffer on an interface.
4. (Optional.) Set the upper and lower buffer usage thresholds on the interface.
   port ifmonitor buffer usage threshold high *high-percent* **low** *low-percent*
   The default for this command depends on the device model.

Enabling packet latency detection

About this task

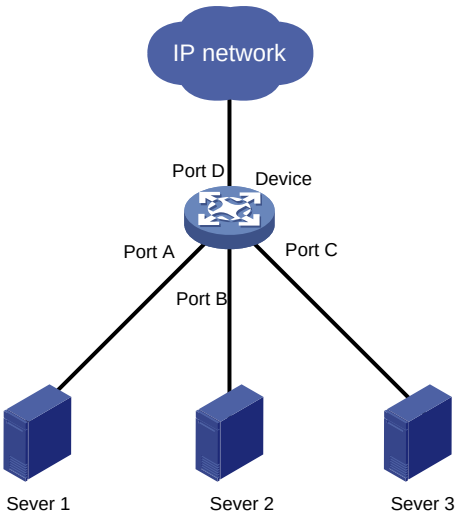
With this feature enabled on an interface, the device continuously monitors forwarding latency of packets transmitted through the interface within the device and assigns latency levels to the packets. You can determine the quality of packet forwarding accordingly.

Restrictions and guidelines

A higher level threshold cannot be lower than a lower level threshold.

Procedure

1. Enter system view.
   system-view
2. (Optional.) Configure the packet latency level threshold.
   ifmonitor latency { **level0** *level0-value* | **level1** *level1-value* | **level2** *level2-number* | **level3** *level3-number* | **level4** *level4-number* | **level5** *level5-number* | **level6** *level6-number* | **level7** *level7-number* }*
   The default for this command depends on the device model.
3. Enter Ethernet interface view.
   interface *interface-type interface-number*
4. Enable packet latency detection.
   port ifmonitor buffer flow-information enable
   By default, packet latency detection is not enabled.



Configuring a Layer 2 Ethernet interface

Setting speed options for autonegotiation on an Ethernet interface

About this task

By default, speed autonegotiation enables an Ethernet interface to negotiate with its peer for the highest speed that both ends support. You can narrow down the speed option list for negotiation.

Figure 3 Speed autonegotiation application scenario

As shown in Figure 3:

- All interfaces on the device are operating in speed autonegotiation mode, with the highest speed of 1000 Mbps.
- Port D provides access to the Internet for the servers.

If the transmission rate of each server in the server cluster is 1000 Mbps, their total transmission rate exceeds the capability of Port D.

To avoid congestion on Port D, configure 100 Mbps as the only option available for speed negotiation on interfaces Port A, Port B, and Port C. As a result, the transmission rate on each interface connected to a server is limited to 100 Mbps.

Restrictions and guidelines

The **speed** and **speed auto** commands supersede each other, and whichever is configured last takes effect.

Procedure

1. Enter system view.
   system-view
2. Enter 100-Mbps or 1000-Mbps Layer 2 Ethernet interface view.
   interface *interface-type interface-number*
3. Set speed options for autonegotiation.
   speed auto { **10** | **100** | **1000** } *
   By default, no speed options are set for autonegotiation.

Setting the MDIX mode of an Ethernet interface

IMPORTANT:

Fiber ports do not support the MDIX mode setting.

About this task

A physical Ethernet interface has eight pins, each of which plays a dedicated role. For example, pins 1 and 2 transmit signals, and pins 3 and 6 receive signals. You can use both crossover and straight-through Ethernet cables to connect copper Ethernet interfaces. To accommodate these types of cables, a copper Ethernet interface can operate in one of the following Medium Dependent Interface-Crossover (MDIX) modes:

- **MDIX mode**—Pins 1 and 2 are receive pins and pins 3 and 6 are transmit pins.
- **MDI mode**—Pins 1 and 2 are transmit pins and pins 3 and 6 are receive pins.
- **AutoMDIX mode**—The interface negotiates pin roles with its peer.

NOTE:

This feature does not take effect on pins 4, 5, 7, and 8 of physical Ethernet interfaces.

- Pins 4, 5, 7, and 8 of interfaces operating at 10 Mbps or 100 Mbps do not receive or transmit signals.
- Pins 4, 5, 7, and 8 of interfaces operating at 1000 Mbps or higher rates receive and transmit signals.

Restrictions and guidelines

To enable a copper Ethernet interface to communicate with its peer, set the MDIX mode of the interface by following these guidelines:

- Typically, set the MDIX mode of the interface to AutoMDIX. Set the MDIX mode of the interface to MDI or MDIX only when the device cannot determine the cable type.
- When a straight-through cable is used, configure the interface to operate in an MDIX mode different than its peer.
- When a crossover cable is used, perform one of the following tasks:
  - Configure the interface to operate in the same MDIX mode as its peer.
  - Configure either end to operate in AutoMDIX mode.

Procedure

1. Enter system view.

   system-view
2. Enter Ethernet interface view.

   interface *interface-type interface-number*
3. Set the MDIX mode of the Ethernet interface.

   mdix-mode { **automdix** | **mdi** | **mdix** }

   By default, a copper Ethernet interface operates in auto mode to negotiate pin roles with its peer.

Configuring storm control on an Ethernet interface

About this task

Storm control compares broadcast, multicast traffic regularly with their respective traffic thresholds on an Ethernet interface. For each type of traffic, storm control provides a lower threshold and an upper threshold.

Depending on your configuration, when a particular type of traffic exceeds its upper threshold, the interface performs either of the following operations:

- **Blocks this type of traffic and forwards other types of traffic**—Even though the interface does not forward the blocked traffic, it still counts the traffic. When the blocked traffic drops below the lower threshold, the interface begins to forward the traffic.
- **Goes down automatically**—The interface goes down automatically and stops forwarding any traffic. When the blocked traffic drops below the lower threshold, the interface does not automatically come up. To bring up the interface, use the **undo shutdown** command or disable the storm control feature.

You can configure an Ethernet interface to output threshold event traps and log messages when monitored traffic meets one of the following conditions:

- Exceeds the upper threshold.
- Drops below the lower threshold.

Both storm suppression and storm control can suppress storms on an interface. Storm suppression uses the chip to suppress traffic. Storm suppression has less impact on the device performance than storm control, which uses software to suppress traffic. For more information about storm suppression, see "Configuring broadcast/multicast/unknown unicast storm suppression."

Storm control uses a complete polling cycle to collect traffic data, and analyzes the data in the next cycle. An interface takes one to two polling intervals to take a storm control action.

Restrictions and guidelines

For the traffic suppression result to be determined, do not configure storm control together with storm suppression for the same type of traffic.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Set the statistics polling interval of the storm control module.

   storm-constrain interval *interval*

   The default setting is 10 seconds.

   For network stability, use the default or set a longer statistics polling interval.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Enable storm control, and set the lower and upper thresholds for broadcast, multicast, or unknown unicast traffic.

   storm-constrain { **broadcast** | **multicast** } { **pps** | **kbps** | **ratio** } *upperlimit lowerlimit*

   By default, storm control is disabled.

5. Set the control action to take when monitored traffic exceeds the upper threshold.

   storm-constrain control { **block** | **shutdown** }

   By default, storm control is disabled.

6. Enable the Ethernet interface to output log messages when it detects storm control threshold events.

   storm-constrain enable log

   By default, the Ethernet interface outputs log messages when monitored traffic exceeds the upper threshold or drops below the lower threshold from a value above the upper threshold.

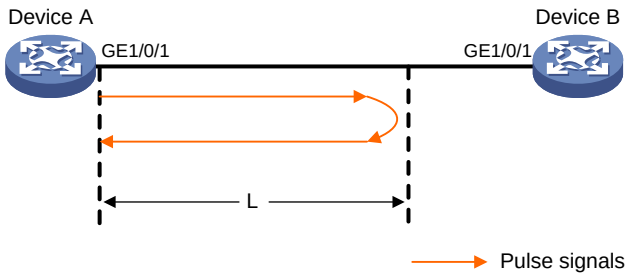
7. Enable the Ethernet interface to send storm control threshold event traps.

   storm-constrain enable trap

   By default, the Ethernet interface sends traps when monitored traffic exceeds the upper threshold or drops below the lower threshold from the upper threshold from a value above the upper threshold.

Testing the cable connection of an Ethernet interface

IMPORTANT:



If the link of an Ethernet interface is up, testing its cable connection will cause the link to go down and then come up.

About this task

The virtual cable test (VCT) technology uses time domain reflectometry (TDR) to detect the cable status. When pulse signals are transmitted in a cable, some energy of the signals is reflected at the end or a failure point on the cable. This phenomenon is called TDR. The VCT algorithm measures the time spent in transmitting pulse signals over a cable, reaching the failure point, and returning the pulse signals. The measured time is converted into the distance.

As shown in Figure 4, GE 1/0/1 on Device A is connected to GE 1/0/1 on Device B through a cable. A failure point exists on the cable. After VCT is configured on GE 1/0/1 on Device A, the system will generate pulse signals. Some energy of the signals is reflected at the failure point on the cable. Suppose the distance from Device A to the failure point is L, the interval between sending signals and receiving reflected signals is T, and the signal transmission speed on the cable is V. Then, the distance between GE 1/0/1 on Device A and the failure point can be calculated as follows: L=(V×T)/2.

Figure 4 Schematic diagram for VCT

VCT detects the network cable failure type and identifies the failure point, facilitating failure location on network cables.

Restrictions and guidelines

Fiber ports do not support this feature.

Procedure

1. Enter system view.

   system-view

2. Enter Ethernet interface view.

interface *interface-type interface-number*

3. Perform a test for the cable connected to the Ethernet interface.
   - **virtual-cable-test**

Enabling bridging on an Ethernet interface

About this task

By default, the device drops packets whose outgoing interface and incoming interface are the same.

To enable the device to forward such packets rather than drop them, enable the bridging feature in Ethernet interface view.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Enable bridging on the Ethernet interface.
   port bridge enable
   By default, bridging is disabled on an Ethernet interface.

Configuring a Layer 3 Ethernet interface or subinterface

Setting the MTU for an Ethernet interface or subinterface

About this task

The maximum transmission unit (MTU) determines the maximum number of bytes in a single IP packet that can be sent. The length of an IP packet refers to the number of bytes starting from the IP header to the payload.

When the IP layer receives an IP data packet to be sent, the IP layer determines the local destination interface of the packet and obtains the MTU of the interface. The IP layer compares the MTU with the length of the data packet to be sent. If the length is greater than the MTU, the IP layer fragments the packet. The length of a fragment can be smaller than or equal to the MTU to ensure that big packets are not lost on the network.

As a best practice, use the default MTU. When the packet length or the packet receiver changes, you can adjust the MTU as needed. When configuring the MTU, follow these restrictions and guidelines:

- If the configured MTU is small but the packet length is large, the following events might occur:
  - Packets will be dropped when they are forwarded by hardware.
  - Packets will be fragmented into too many fragments when packets are forwarded through the CPUs, which affects normal data transmission.
- If the configured MTU is too large, the MTU will exceed the receiving capabilities of the receiver or a device along the transmission path. As a result, packets will be fragmented or even dropped, which increases the network transmission load and affects data transmission.

Restrictions and guidelines

The MTU of an Ethernet interface or subinterface affects the fragmentation and reassembly of IP packets on the interface. Typically, you do not need to modify the MTU of an interface.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type* { *interface-number* | *interface-number.subnumber* }
3. Set the MTU for the interface.
   mtu *size*
   The default setting is 1500 bytes.

Setting the MAC address of an Ethernet interface or subinterface

About this task

In a network, when the Layer 3 Ethernet interfaces or subinterfaces of different devices have the same MAC address, the devices might fail to communicate correctly. To eliminate the MAC address conflicts, use the **mac-address** command to modify the MAC addresses of Layer 3 Ethernet interfaces or subinterfaces.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type* { *interface-number* | *interface-number.subnumber* }
3. Set the interface MAC address.
   mac-address *mac-address*
   By default, no MAC address is set for an Ethernet interface.
   As a best practice, do not set a MAC address in the VRRP-reserved MAC address range for a Layer 3 Ethernet subinterface.

Display and maintenance commands for Ethernet interfaces

For more information about the **display diagnostic-information** command, see device management in *Fundamentals Command Reference*.

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display interface traffic statistics.	**display counters** { **inbound** | **outbound** } **interface** [*interface-type* [*interface-number*]]

Task	Command
Display traffic rate statistics of interfaces in up state over the last statistics polling interval.	**display counters rate** { **inbound** | **outbound** } **interface** [*interface-type* [*interface-number*]]

About cut-through Layer 2 forwarding 1
Restrictions and guidelines for cut-through Layer 2 forwarding configuration 1
Procedure 1

Configuring cut-through Layer 2 forwarding

About cut-through Layer 2 forwarding

A cut-through forwarding-enabled device forwards a frame after it receives the first 64 bytes of the frame. This feature reduces the transmission time of a frame and enhances forwarding performance.

Restrictions and guidelines for cut-through Layer 2 forwarding configuration

With cut-through forwarding, the device forwards CRC-error frames because it starts forwarding frames before their CRC field is received.

In an IRF fabric, cut-through Layer 2 forwarding does not take effect for traffic where the ingress and egress interfaces are not on the same member device.

Cut-through Layer 2 forwarding takes effect only on multicast packets.

Procedure

1. Enter system view.
   `system-view`
2. Enable cut-through forwarding.
   `cut-through enable`
   By default, cut-through forwarding is disabled.

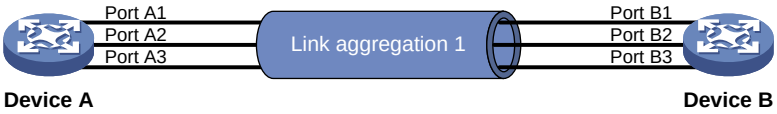
Configuring Ethernet link aggregation

About Ethernet link aggregation



Ethernet link aggregation bundles multiple physical Ethernet links into one logical link (called an aggregate link). Link aggregation provides the following benefits:

- Increased bandwidth beyond the limits of a single individual link. In an aggregate link, traffic is distributed across the member ports.
- Improved link reliability. The member ports dynamically back up one another. When a member port fails, its traffic is automatically switched to other member ports.

Ethernet link aggregation application scenario

As shown in Figure 1, Device A and Device B are connected by three physical Ethernet links. These physical Ethernet links are combined into an aggregate link called link aggregation 1. The bandwidth of this aggregate link can reach up to the total bandwidth of the three physical Ethernet links. At the same time, the three Ethernet links back up one another. When a physical Ethernet link fails, the traffic transmitted on the failed link is switched to the other two links.

Figure 1 Ethernet link aggregation diagram

Aggregate interface, aggregation group, and member port

Each link aggregation is represented by a logical aggregate interface. Each aggregate interface has an automatically created aggregation group, which contains member ports to be used for aggregation. The type and number of an aggregation group are the same as its aggregate interface.

Supported aggregate interface types

An aggregate interface can be one of the following types:

- **Layer 2**—A Layer 2 aggregate interface is created manually. The member ports in a Layer 2 aggregation group can only be Layer 2 Ethernet interfaces.
- **Layer 3**—A Layer 3 aggregate interface is created manually. The member ports in its Layer 3 aggregation group can only be Layer 3 Ethernet interfaces.

  On a Layer 3 aggregate interface, you can create subinterfaces. A Layer 3 aggregate subinterface processes traffic only for the VLAN numbered with the same ID as the subinterface number.

The port rate of an aggregate interface equals the total rate of its Selected member ports. Its duplex mode is the same as that of the Selected member ports. For more information about Selected member ports, see "Aggregation states of member ports in an aggregation group."

Aggregation states of member ports in an aggregation group

A member port in an aggregation group can be in any of the following aggregation states:

- **Selected**—A Selected port can forward traffic.
- **Unselected**—An Unselected port cannot forward traffic.

- **Individual**—An Individual port can forward traffic as a normal physical port. This state is peculiar to the member ports of edge aggregate interfaces. A Selected or Unselected member port of an edge aggregate interface is placed in Individual state if the LACP timeout timer expires because it has not received LACPDUs.

  For more information about edge aggregate interfaces, see "Edge aggregate interface."

Operational key

When aggregating ports, the system automatically assigns each port an operational key based on port information, such as port rate and duplex mode. Any change to this information triggers a recalculation of the operational key.

In an aggregation group, all Selected ports have the same operational key.

Configuration types

Port configuration includes the attribute configuration and protocol configuration. Attribute configuration affects the aggregation state of the port but the protocol configuration does not.

Attribute configuration

To become a Selected port, a member port must have the same attribute configuration as the aggregate interface. Table 1 describes the attribute configuration.

Table 1 Attribute configuration

Feature	Attribute configuration
Port isolation	Membership of the port in an isolation group. Isolation group number.
QinQ	QinQ status (enabled/disabled)and TPID for VLAN tags. For information about QinQ, see "Configuring QinQ."
VLAN mapping	VLAN mapping configured on the port. For more information about VLAN mapping, see "Configuring VLAN mapping."
VLAN	VLAN attribute settings: • Permitted VLAN IDs. • PVID. • Link type (trunk, hybrid, or access). • VLAN tagging mode. For information about VLANs, see "Configuring VLANs."

Protocol configuration

Protocol configuration of a member port does not affect the aggregation state of the member port. MAC address learning and spanning tree settings are examples of the protocol configuration.

Link aggregation modes

An aggregation group operates in one of the following modes:

- **Static**—Static aggregation is stable. An aggregation group in static mode is called a static aggregation group. The aggregation states of the member ports in a static aggregation group are not affected by the peer ports.
- **Dynamic**—An aggregation group in dynamic mode is called a dynamic aggregation group. Dynamic aggregation is implemented through IEEE 802.3ad Link Aggregation Control Protocol

(LACP). The local system and the peer system automatically maintain the aggregation states of the member ports. Dynamic link aggregation reduces the administrators' workload.

How static link aggregation works

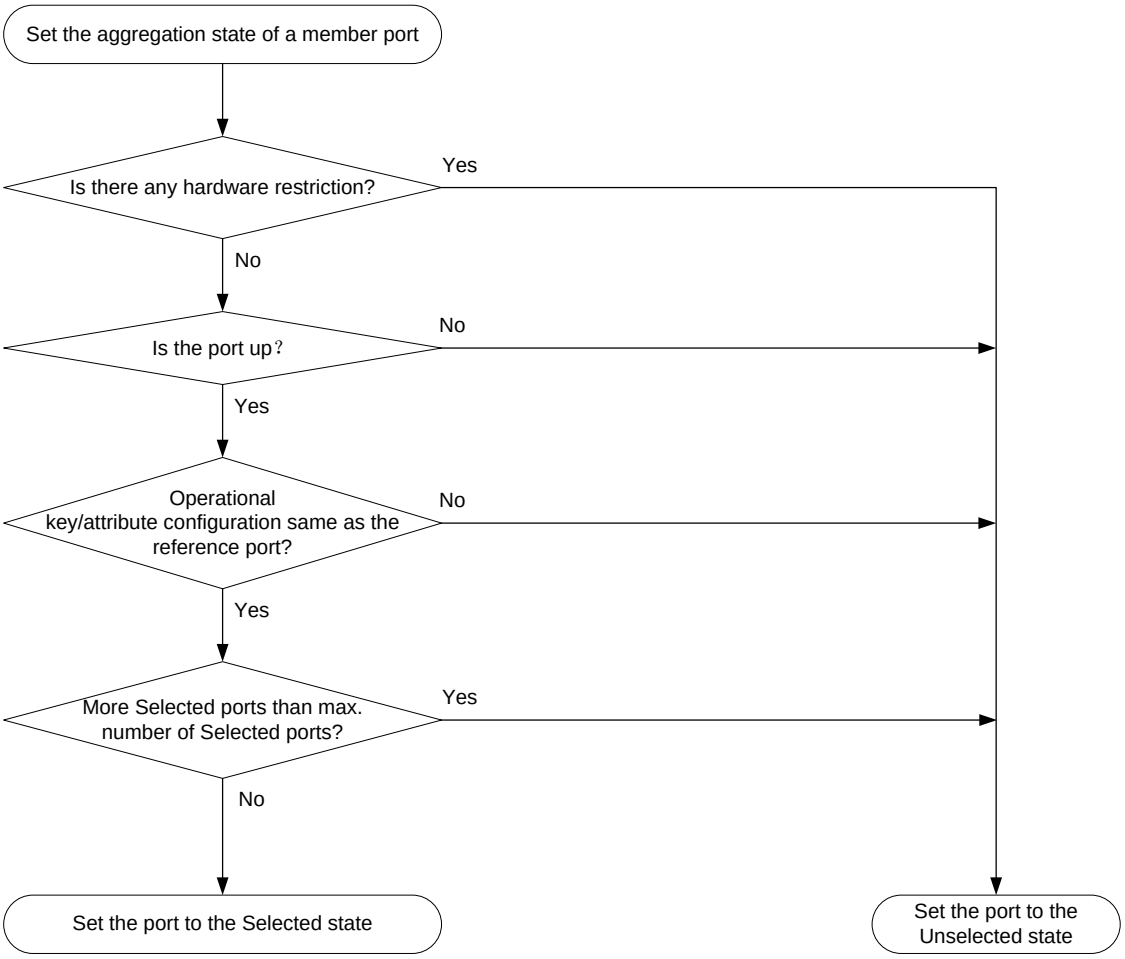
Reference port selection process

When setting the aggregation states of the ports in an aggregation group, the system automatically chooses a member port as the reference port. A Selected port must have the same operational key and attribute configurations as the reference port.

The system chooses a reference port from the member ports in up state.

The candidate reference ports are organized into different priority levels following these rules:

1. In descending order of port priority.
2. Full duplex.
3. In descending order of speed.
4. Half duplex.
5. In descending order of speed.



From the candidate ports with the same attribute configurations as the aggregate interface, the one with the highest priority level is chosen as the reference port.

- If multiple ports have the same priority level, the port that has been Selected (if any) is chosen. If multiple ports with the same priority level have been Selected, the one with the smallest port number is chosen.
- If multiple ports have the same priority level and none of them has been Selected, the port with the smallest port number is chosen.

Setting the aggregation state of each member port

After the reference port is chosen, the system sets the aggregation state of each member port in the static aggregation group.

Figure 2 Setting the aggregation state of a member port in a static aggregation group

After the limit on Selected ports is reached, the aggregation state of a new member port varies by following conditions:

- The port is placed in Unselected state if the port and the Selected ports have the same port priority. This mechanism prevents traffic interruption on the existing Selected ports. A device reboot can cause the device to recalculate the aggregation states of member ports.
- The port is placed in Selected state when the following conditions are met:
  - The port and the Selected ports have different port priorities, and the port has a higher port priority than a minimum of one Selected port.
  - The port has the same attribute configurations as the aggregate interface.

Any operational key or attribute configuration change might affect the aggregation states of link aggregation member ports.

Dynamic link aggregation

About LACP

Dynamic aggregation is implemented through IEEE 802.3ad Link Aggregation Control Protocol (LACP).

LACP uses LACPDUs to exchange aggregation information between LACP-enabled devices. Each member port in a dynamic aggregation group can exchange information with its peer. When a member port receives an LACPDU, it compares the received information with information received

on the other member ports. In this way, the two systems reach an agreement on which ports are placed in Selected state.

LACP functions

LACP offers basic LACP functions and extended LACP functions, as described in Table 2.

Table 2 Basic and extended LACP functions

Category	Description
Basic LACP functions	Implemented through the basic LACPDU fields, including the LACP system priority, system MAC address, port priority, port number, and operational key.
Extended LACP functions	Implemented by extending the LACPDU with new TLV fields. Extended LACP can implement LACP MAD for the IRF feature. For more information about IRF and the LACP MAD mechanism, see *Virtual Technologies Configuration Guide*. The device can participate in LACP MAD as either an IRF member device or an intermediate device.

LACP operating modes

LACP can operate in active or passive mode.

When LACP is operating in passive mode on a local member port and its peer port, both ports cannot send LACPDUs. When LACP is operating in active mode on either end of a link, both ports can send LACPDUs.

LACP priorities

LACP priorities include LACP system priority and port priority, as described in Table 3. The smaller the priority value, the higher the priority.

Table 3 LACP priorities

Type	Description
LACP system priority	Used by two peer devices (or systems) to determine which one is superior in link aggregation. In dynamic link aggregation, the system that has higher LACP system priority sets the Selected state of member ports on its side. The system that has lower priority sets the aggregation state of local member ports the same as their respective peer ports.
Port priority	Determines the likelihood of a member port to be a Selected port on a system. A port with a higher port priority is more likely to become Selected.

LACP timeout interval

The LACP timeout interval specifies how long a member port waits to receive LACPDUs from the peer port, and it can be either short or long.

- **Long timeout interval**—By default, the LACP timeout interval for a port is long (90 seconds). If a local member port does not receive an LACPDU from the peer within the LACP timeout interval plus 3 seconds (93 seconds), the system considers the peer member port down.
- **Short timeout interval**—Use the **`lacp period short`** command to set the LACP timeout interval to short for a port.
  - **Do not specify the timeout parameter**—In this method, the short timeout interval is set to a fixed value of 3 seconds. In this case, if a local member port does not receive LACPDUs from its peer member port within 6 seconds (3 seconds of LACP timeout interval + 3 seconds), the peer member port is considered to have failed.
  - **Specify the timeout parameter**—In this method, you can configure a short timeout interval in the range of 3 to 90 seconds. If a local member port does not receive LACPDUs from its

peer member port within the configured LACP short timeout interval, the peer member port is considered to have failed.

The LACP timeout interval also determines the LACPDU sending rate of the peer. LACP timeout intervals include the following types:

- **Short timeout interval**—The peer sends one LACPDU per second.
- **Long timeout interval**—The peer sends one LACPDU every 30 seconds.

Methods to assign interfaces to a dynamic link aggregation group

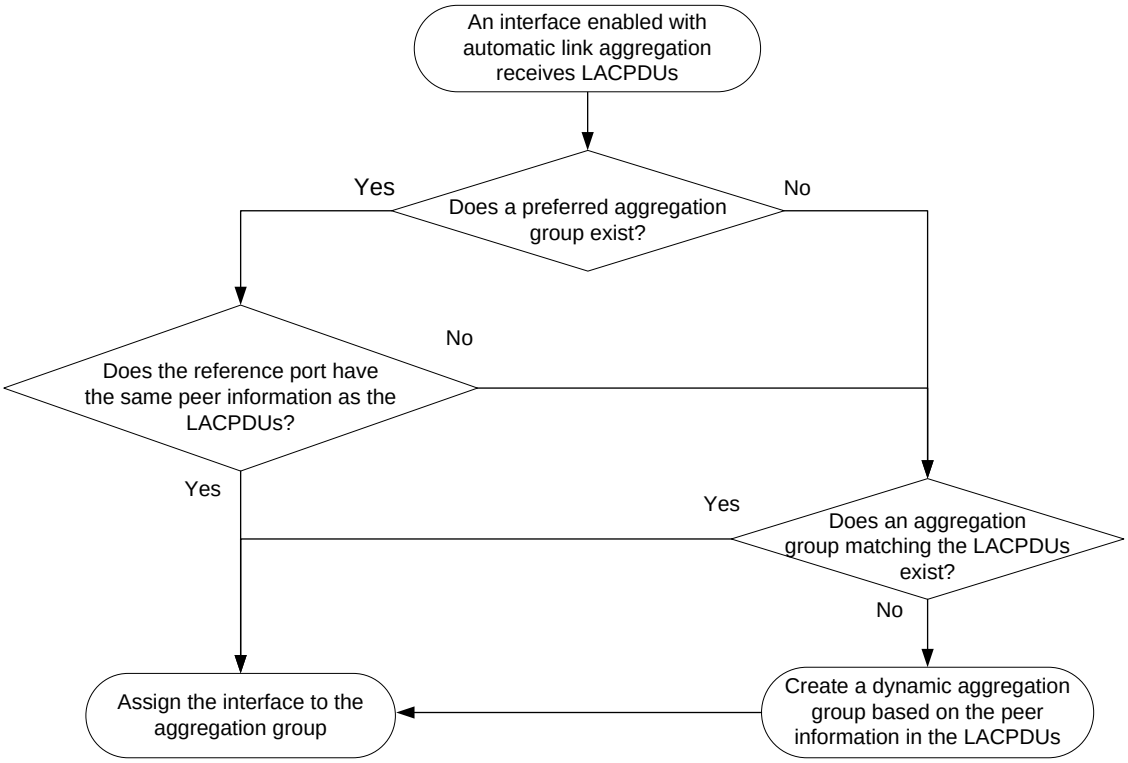
You can use one of the following methods to assign interfaces to a dynamic link aggregation group:

- **Manual assignment**—Manually assign interfaces to the dynamic link aggregation group.
- **Automatic assignment**—Enable automatic assignment on interfaces to have them automatically join a dynamic link aggregation group depending on the peer information in the received LACPDUs.

NOTE:

When you use automatic assignment on one end, you must use manual assignment on the other end.

Alternatively, you can use automatic link aggregation for two devices to automatically create a dynamic link aggregation between them by using LLDP.



Automatic member port assignment

This feature automates the assignment of aggregation member ports to an aggregation group. You can use this feature when setting up an aggregate link to a server.

As shown in Figure 3, an interface enabled with automatic assignment joins a dynamic aggregation group based on the peer information in the LACPDUs received from the aggregation peer. If none of the existing dynamic aggregation groups is qualified, the device automatically creates a new dynamic aggregation group, Then, the device assigns the interface to that group and synchronizes the interface's attribute configurations to the aggregate interface.

A dynamic aggregation group that contains automatically assigned member ports selects a reference port and Selected ports as described in "How dynamic link aggregation works." The assignment methods of member ports do not change the processes of reference port selection and Selected port selection.

Figure 3 Automatic member port assignment process

Automatic link aggregation

Automatic link aggregation enables two devices to automatically create a dynamic link aggregation between them by using LLDP.

After you enable automatic link aggregation and LLDP on two connected devices, they automatically establish a dynamic link aggregation based on the information in incoming LLDP frames. The devices each automatically create a dynamic aggregate interface and assign the redundant ports connected to the peer to the aggregation group of that interface. When assigning the first member port to the aggregate group, the device synchronizes the member port's attribute configuration to the aggregate interface.

An automatically created dynamic aggregation group selects a reference port and Selected ports as described in "How dynamic link aggregation works." The aggregation group creation methods do not change the processes of reference port selection and Selected port selection.

IMPORTANT:

As a best practice to ensure correct operation of dynamic aggregation groups, do not use automatic link aggregation and automatic member port assignment together.

How dynamic link aggregation works

Choosing a reference port

The system chooses a reference port from the member ports in up state. A Selected port must have the same operational key and attribute configurations as the reference port.

The local system (the actor) and the peer system (the partner) negotiate a reference port by using the following workflow:

1. The two systems determine the system with the smaller system ID.

A system ID contains the LACP system priority and the system MAC address.

a. The two systems compare their LACP priority values.

The lower the LACP priority, the smaller the system ID. If the LACP priority values are the same, the two systems proceed to step b.

b. The two systems compare their MAC addresses.

The lower the MAC address, the smaller the system ID.

2. The system with the smaller system ID chooses the port with the smallest port ID as the reference port.

A port ID contains a port priority and a port number. The lower the port priority, the smaller the port ID.

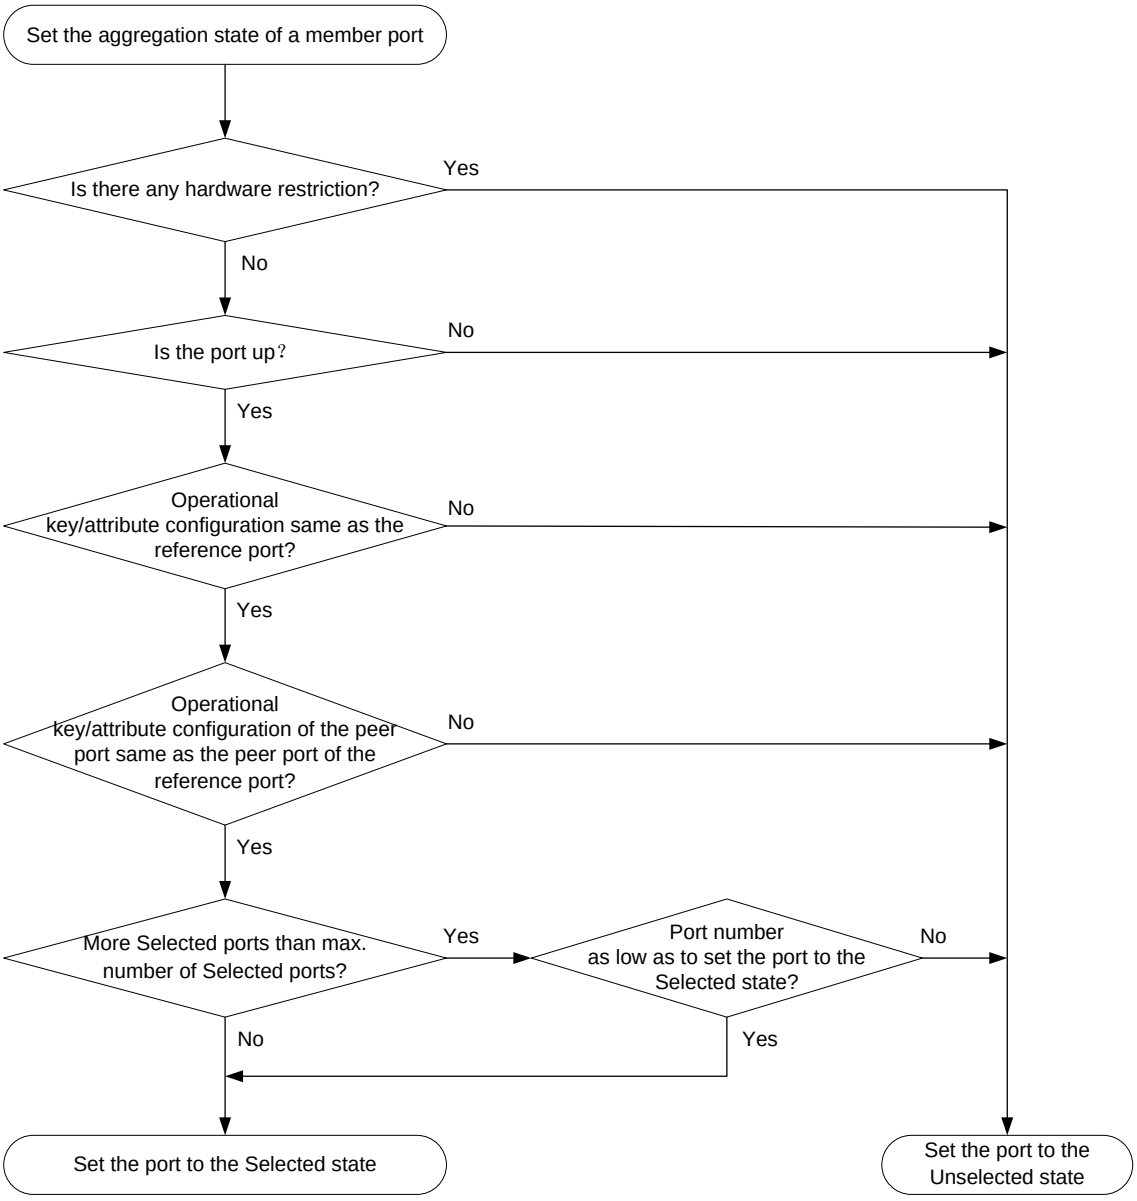
a. The system chooses the port with the lowest priority value as the reference port.

If the ports have the same priority, the system proceeds to step b.

b. The system compares their port numbers.

The smaller the port number, the smaller the port ID.

The port with the smallest port number and the same attribute configurations as the aggregate interface is chosen as the reference port.



NOTE:

To identify the port numbers of aggregation member ports, execute the **`display link-aggregation verbose`** command and examine the **`Index`** field in the command output.

Setting the aggregation state of each member port

After the reference port is chosen, the system with the smaller system ID sets the state of each member port on its side.

Figure 4 Setting the state of a member port in a dynamic aggregation group

The system with the greater system ID can detect the aggregation state changes on the peer system. The system with the greater system ID sets the aggregation state of local member ports the same as their peer ports.

When you aggregate interfaces in dynamic mode, follow these guidelines:

- A dynamic link aggregation group chooses only full-duplex ports as the Selected ports.
- For stable aggregation and service continuity, do not change the operational key or attribute configurations on any member port.
- When a member port changes to the Selected or Unselected state, its peer port changes to the same aggregation state.
- After the Selected port limit is reached, a newly joining port becomes a Selected port if it is more eligible than a current Selected port.

Edge aggregate interface

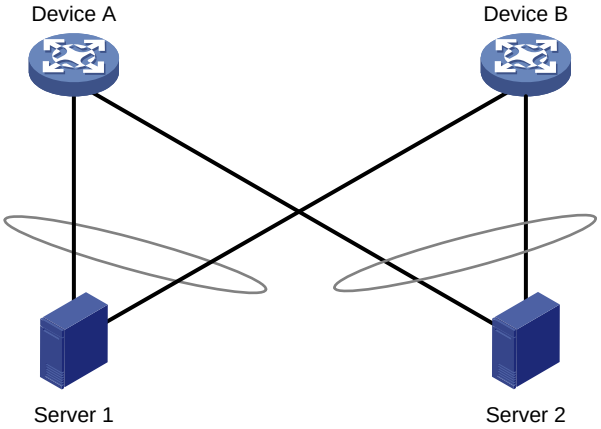
Dynamic link aggregation fails on a server-facing aggregate interface if dynamic link aggregation is configured only on the device. The device forwards traffic by using only one of the physical ports that are connected to the server.

To improve link reliability, configure the aggregate interface as an edge aggregate interface. This feature enables all member ports of the aggregation group to forward traffic. When a member port fails, its traffic is automatically switched to other member ports.

After dynamic link aggregation is configured on the server, the device can receive LACPDUs from the server. Then, link aggregation between the device and the server operates correctly.

An edge aggregate interface takes effect only when it is configured on an aggregate interface corresponding to a dynamic aggregation group.

Load sharing modes for link aggregation groups



In a link aggregation group, traffic can be load shared across the Selected ports based on any of the following modes:

- **Per-flow load sharing**—Distributes traffic on a per-flow basis. The load sharing mode classifies packets into flows and forwards packets of the same flow on the same link. This mode can be one of or a combination of the following traffic classification criteria:
  - Ingress port.
  - Source or destination IP.
  - Source or destination MAC.
  - Source or destination port number.
- **Intelligent load sharing**—Distributes traffic based on the bandwidth usage of Selected member ports. In this mode, the device periodically samples the bandwidth usage of Selected member ports and adjusts traffic distribution if the bandwidth usage of a Selected member port exceeds a threshold. The threshold varies by device model. After you set the intelligent load sharing mode, the device distributes traffic based on the default load sharing mode and then optimizes traffic distribution based on the bandwidth usage.

S-MLAG

As shown in Figure 5, simple multichassis link aggregation (S-MLAG) aggregates multiple physical devices on the aggregation layer into one device to implement simple cross-device link aggregation and provide device-level redundancy protection and load sharing in server interconnect scenarios.

Figure 5 S-MLAG application scenario

Restrictions and guidelines: Mixed use of manual and automatic link aggregation configuration

To avoid unexpected aggregation issues, do not use manual assignment, automatic assignment, and automatic link aggregation in any combination. If you use any two of these features in combination, an automatically assigned member port might move between aggregation groups or undesirably change from Selected to Unselected in some situations.

To avoid unexpected aggregation issues, do not use the manual aggregation and semi-automatic in the same aggregation group.

For a mirroring group, do not assign the source port to an aggregation group other than the one that accommodates the destination port, egress port, or reflector port. If the source port is in a different aggregation group than the other ports, mirrored LACPDUs will be transmitted between the aggregation groups and cause aggregate interface flapping.

Ethernet link aggregation tasks at a glance

To configure Ethernet link aggregation, perform the following tasks:

1. Configuring the system ID
2. Configuring link aggregation modes
   - Configuring a manual link aggregation
   - Configuring automatic link aggregation
   - Configuring S-MLAG
3. (Optional.) Configuring an aggregate interface
   - Configuring the description of an aggregate interface
   - Setting the MAC address for an aggregate interface
   - Setting the MTU for a Layer 3 aggregate interface
   - Setting the expected bandwidth for an aggregate interface
   - Configuring an edge aggregate interface

     An edge aggregate interface uses all member ports to forward traffic when the aggregation peer is not enabled with dynamic link aggregation.
   - Configuring physical state change suppression on an aggregate interface

- Shutting down an aggregate interface
- Enabling interframe gap and preamble statistics in the traffic statistics
- Restoring the default settings for an aggregate interface

4. (Optional.) Adjusting aggregation states of link aggregation member ports
   - Setting the minimum and maximum numbers of Selected ports for an aggregation group
   - Disabling the default action of selecting a Selected port for dynamic aggregation groups that have not received LACPDUs
   - Configuring a dynamic aggregation group to use port speed as the prioritized criterion for reference port selection
   - Ignoring port speed in setting the aggregation states of member ports
   - Enabling port selection preemption on an aggregate interface
5. (Optional.) Configuring load sharing for link aggregation groups
   - Setting static load sharing modes for link aggregation groups
   - Enabling local-first load sharing for link aggregation
   - Configuring link aggregation load sharing algorithm settings
6. (Optional.) Optimizing traffic forwarding
   - Specifying link aggregation management VLANs and link aggregation management port

     Perform this task to enable an aggregation group to forward Layer 3 data traffic of some VLANs through a specific member port.
   - Enabling link-aggregation traffic redirection

     This feature redirects traffic on an unavailable Selected port to the remaining available Selected ports of an aggregation group to avoid traffic interruption.
   - Isolating aggregate interfaces on the device
7. (Optional.) Enabling BFD for an aggregation group

Configuring the system ID

About this task

The two ends of a dynamic aggregate link choose a reference port from the end with a smaller system ID.

The system ID contains the LACP system priority and LACP system MAC address. Two devices use the following rules to compare their system IDs:

- If their system IDs contain different LACP system priorities, the system ID with a smaller LACP system priority value is smaller.
- If their system IDs contain the same LACP system priority, the system ID with a lower LACP system MAC address is smaller.

To view the LACP system MAC address and LACP system priority, execute the **`display link-aggregation verbose`** command.

You can configure the system ID globally and in aggregate interface view. The global system ID takes effect on all aggregation groups, and an aggregate-interface-specific system ID takes precedence over the global system ID.

Restrictions and guidelines

Member devices in an S-MLAG system must use the same LACP system priority and LACP system MAC address.

On an M-LAG system, M-LAG interfaces in the same M-LAG group must use the same LACP system MAC address.

For member ports to be selected correctly, do not modify the LACP system priority and LACP system MAC address after a dynamic link aggregation is established.

Procedure

1. Enter system view.
   system-view
2. Set the LACP system MAC address globally.
   lacp system-mac *mac-address*
   By default, the LACP system MAC address is the bridge MAC address of the device.
3. Set the LACP system priority globally.
   lacp system-priority *priority*
   By default, the LACP system priority is 32768.
4. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.
     interface route-aggregation *interface-number*
5. Set the LACP system MAC address on the aggregate interface.
   port lacp system-mac *mac-address*
   By default, the LACP system MAC address is the bridge MAC address of the device.
6. Set the LACP system priority on the aggregate interface.
   port lacp system-priority *priority*
   By default, the LACP system priority is 32768.

Configuring a manual link aggregation

Restrictions and guidelines for aggregation group configuration

Layer 2 aggregation group restrictions

You cannot assign an interface to a Layer 2 aggregation group if any features in Table 4 are configured on that interface.

Table 4 Features incompatible with Layer 2 aggregation member ports

Feature on the interface	Reference
MAC authentication	MAC authentication in *Security Configuration Guide*
Port security	Port security in *Security Configuration Guide*
802.1X	802.1X in *Security Configuration Guide*

Aggregation member port restrictions

Deleting an aggregate interface also deletes its aggregation group and causes all member ports to leave the aggregation group.

If an interface has different attribute configurations from the aggregate interface, the interface cannot join the aggregation group.

After joining an aggregation group, an interface inherits the attribute configurations on the aggregate interface. You can modify the attribute configurations only on the aggregate interface.

After an interface leaves an aggregation group, VLAN settings on the interface will not be restored to the default.

To avoid a loop, shut down an interface before removing the interface from an aggregation group.

Do not assign a reflector port for port mirroring to an aggregation group. For more information about reflector ports, see *Network Management and Monitoring Configuration Guide*.

You cannot assign monitor ports for port mirroring to an aggregation group.

Attribute and protocol configuration restrictions

For a link aggregation, attribute configurations are configurable only on the aggregate interface and are automatically synchronized to all member ports. You cannot configure attribute configurations on a member port until it is removed from the link aggregation group. After the aggregate interface is deleted, the configurations that have been synchronized from the aggregate interface are retained on the member ports.

If an attribute setting on the aggregate interface fails to be synchronized to a Selected member port, the port might change to the Unselected state.

The protocol configurations for an aggregate interface take effect only on the current aggregate interface. The protocol configurations for a member port take effect only when the port leaves its aggregation group.

Configuration consistency requirements

You must configure the same aggregation mode at the two ends of an aggregate link.

- For a successful static aggregation, make sure the ports at both ends of each link are in the same aggregation state.
- For a successful dynamic aggregation:
  - Make sure the ports at both ends of a link are assigned to the correct aggregation group. The two ends can automatically negotiate the aggregation state of each member port.
  - If you use automatic interface assignment on one end, you must use manual assignment on the other end.

Configuring a Layer 2 aggregation group

Configuring a Layer 2 dynamic aggregation group

1. Enter system view.

   system-view

2. Create a Layer 2 aggregate interface and enter Layer 2 aggregate interface view.

   interface bridge-aggregation *interface-number*

   When you create a Layer 2 aggregate interface, the system automatically creates a Layer 2 static aggregation group numbered the same as that interface.

3. Configure the aggregation group to operate in dynamic mode.

   link-aggregation mode dynamic

   By default, an aggregation group operates in static mode.

4. Return to system view.

   quit

5. (Optional.) Allow only interfaces with the default VLAN configuration to join aggregation groups and restore the default VLAN configuration when they leave aggregation groups.

   link-aggregation bind-mode bagg-vlan-default

By default, the feature that allows only interfaces with the default VLAN configuration to join aggregation groups and restores the default VLAN configuration when they leave aggregation groups is not configured.

6. Assign an interface to the Layer 2 aggregation group:
   a. Enter Layer 2 Ethernet interface view.
      interface *interface-type interface-number*
   b. Assign the interface to the Layer 2 aggregation group or enable automatic assignment on that interface.
      port link-aggregation group { *group-id* [**force**] | **auto** [*group-id*] }

   Repeat these two substeps to assign more Layer 2 Ethernet interfaces to the aggregation group.

   To synchronize the attribute configurations from the aggregate interface when the current interface joins the aggregation group, specify the **force** keyword.

   To enable automatic assignment, specify the **auto** keyword. As a best practice, do not modify the configuration on an automatically created aggregate interface or its member ports.
7. Set the LACP operating mode for the interface.
   - Set the LACP operating mode to passive.
     lacp mode passive
   - Set the LACP operating mode to active.
     undo lacp mode

   By default, LACP is operating in active mode.
8. (Optional.) Set the port priority for the interface.
   link-aggregation port-priority *priority*

   The default setting is 32768.
9. (Optional.) Set the short LACP timeout interval for the interface.
   lacp period short [**timeout** *timeout*]

   By default, the long LACP timeout interval (90 seconds) is used by the interface.

   To avoid traffic interruption during an ISSU, do not set the short LACP timeout interval before performing the ISSU. For more information about ISSU, see *Fundamentals Configuration Guide*.

Configuring a Layer 3 aggregation group

Configuring a Layer 3 dynamic aggregation group

1. Enter system view.
   system-view
2. Create a Layer 3 aggregate interface and enter Layer 3 aggregate interface view.
   interface route-aggregation *interface-number*

   When you create a Layer 3 aggregate interface, the system automatically creates a Layer 3 static aggregation group numbered the same as that interface.
3. Configure the aggregation group to operate in dynamic mode.
   link-aggregation mode dynamic

   By default, an aggregation group operates in static mode.
4. Return to system view.
   quit
5. Assign an interface to the Layer 3 aggregation group:

a. Enter Layer 3 Ethernet interface view.

   interface *interface-type interface-number*

b. Assign the interface to the Layer 3 aggregation group or enable automatic assignment on that interface.

   port link-aggregation group { *group-id* | **auto** [*group-id*] }

Repeat these two substeps to assign more Layer 3 Ethernet interfaces to the aggregation group.

To enable automatic assignment, specify the **auto** keyword. As a best practice, do not modify the configuration on an automatically created aggregate interface or its member ports.

6. Set the LACP operating mode for the interface.
   - Set the LACP operating mode to passive.

     lacp mode passive
   - Set the LACP operating mode to active.

     undo lacp mode

   By default, LACP is operating in active mode.
7. (Optional.) Set the port priority of the interface.

   link-aggregation port-priority *priority*

   The default setting is 32768.
8. (Optional.) Set the short LACP timeout interval for the interface.

   lacp period short [**timeout** *timeout*]

   By default, the long LACP timeout interval (90 seconds) is used by the interface.

   To avoid traffic interruption during an ISSU, do not set the short LACP timeout interval before performing the ISSU. For more information about ISSU, see *Fundamentals Configuration Guide*.

Configuring a Layer 3 aggregate subinterface

1. Enter system view.

   system-view
2. Create a Layer 3 aggregate subinterface, and enter Layer 3 aggregate subinterface view.

   interface route-aggregation *interface-number.subnumber*

Configuring automatic link aggregation

About this task

You can use automatic link aggregation to aggregate the redundant physical links between devices to ease management and increase bandwidth and availability.

Restrictions and guidelines

On an interface, the **port link-aggregation group** setting takes precedence over automatic link aggregation. The interface will not be added to the aggregation group of an automatically created aggregate interface if it has been the member port of a manually created aggregate interface.

If automatic link aggregation is enabled, subinterface creation might fail on LLDP-enabled Layer 3 Ethernet interfaces. As a best practice, do not create subinterfaces on LLDP-enabled Layer 3 Ethernet interfaces.

To ensure correct operation of an automatically created aggregate interface ,do not modify the configuration on the member ports of its aggregation group. Doing so might cause the member ports to be removed from the aggregation group.

For M-LAG to operate correctly, do not configure automatic link aggregation on an M-LAG system.

As a best practice to ensure correct operation of dynamic aggregation groups, do not use automatic link aggregation and automatic member port assignment together.

Prerequisites

Before you configure automatic link aggregation, enable LLDP on the peer devices.

Procedure

1. Enter system view.
   system-view
2. Enable automatic link aggregation.
   link-aggregation auto-aggregation enable
   By default, automatic link aggregation is disabled.

Configuring S-MLAG

Restrictions and guidelines

Use S-MLAG only to establish aggregate links with servers.

S-MLAG is intended for a non-IRF environment. Do not configure it on an IRF fabric. For more formation about IRF, see *Virtual Technologies Configuration Guide*.

Each S-MLAG group can contain only one aggregate interface on each device.

The aggregate interfaces in an S-MLAG group cannot be used as M-LAG interfaces or M-LAG peer-link interfaces. For more information about M-LAG interfaces and peer-link interfaces, see M-LAG configuration in *Layer 2—LAN Switching Configuration Guide*.

On S-MLAG devices, make sure the member ports in an aggregation group have the same speed and duplex mode. Inconsistency in these settings might cause reference port reselection and interrupt traffic forwarding when new member ports join the aggregation group.

Do not configure the following settings on S-MLAG devices:

- LACP MAD.
- Link-aggregation traffic redirection.
- Maximum or minimum number of Selected ports.
- Automatic member port assignment.
- Ignoring port speed in setting the aggregation states of member ports.
- Spanning tree. For more information, see "Configuring spanning tree protocols."

As a best practice, maintain consistency across S-MLAG devices in service feature configuration.

Prerequisites

Configure the link aggregation settings other than S-MLAG settings on each S-MLAG device. Make sure the settings are consistent across the S-MLAG devices.

Procedure

1. Enter system view.
   system-view
2. Set the LACP system MAC address.
   lacp system-mac *mac-address*
   By default, the LACP system MAC address is the bridge MAC address of the device.
   All S-MLAG devices must use the same LACP system MAC address.

3. Set the LACP system priority.
   lacp system-priority *priority*
   By default, the LACP system priority is 32768.
   All S-MLAG devices must use the same LACP system priority.
4. Set the LACP system number.
   lacp system-number *number*
   By default, the LACP system number is not set.
   You must assign a unique LACP system number to each S-MLAG device.
5. Enter Layer 2 aggregate interface view.
   interface bridge-aggregation *interface-number*
6. Set the link aggregation mode to dynamic.
   link-aggregation mode dynamic
   By default, an aggregation group operates in static mode.
7. Assign the aggregate interface to an S-MLAG group.
   port s-mlag group *group-id*
   By default, an aggregate interface is not assigned to any S-MLAG group.

Configuring an aggregate interface

Most settings that can be made on Layer 2 or Layer 3 Ethernet interfaces can also be made on Layer 2 or Layer 3 aggregate interfaces.

Configuring the description of an aggregate interface

About this task

You can configure the description of an aggregate interface for administration purposes, for example, describing the purpose of the interface.

Procedure

1. Enter system view.
   system-view
2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.
     interface route-aggregation *interface-number*
   - Enter Layer 3 aggregate subinterface view.
     interface route-aggregation *interface-number.subnumber* }
3. Configure the interface description.
   description *text*
   By default, the description of an interface is *interface-name* **Interface**.

Setting the MAC address for an aggregate interface

About this task

Typically, all aggregate interfaces on a device use the same MAC address, and aggregate interfaces on different devices use different MAC addresses. However, you must set different MAC addresses for aggregate interfaces on a device in some situations.

Procedure

1. Enter system view.
   system-view
   - Enter Layer 3 aggregate interface view.
     interface route-aggregation *interface-number*
   - Enter Layer 3 aggregate subinterface view.
     interface route-aggregation *interface-number.subnumber*
2. Set the MAC address for the aggregate interface.
   mac-address *mac-address*
   By default, MAC addresses are not configured for aggregate interfaces on the device.

Setting the MTU for a Layer 3 aggregate interface

About this task

The MTU of an interface affects IP packets fragmentation and reassembly on the interface.

Restrictions and guidelines

The **mtu** command applies only to protocol packets and does not affect forwarded data packets.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 3 aggregate interface or subinterface view.
   interface route-aggregation { *interface-number* | *interface-number.subnumber* }
3. Set the MTU.
   mtu *size*
   The default setting is 1500 bytes.

Setting the expected bandwidth for an aggregate interface

About this task

Expected bandwidth is an informational parameter used only by higher-layer protocols for calculation. You cannot adjust the actual bandwidth of an interface by performing this task.

Procedure

1. Enter system view.
   system-view
2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.

interface bridge-aggregation *interface-number*

- Enter Layer 3 aggregate interface view.
  interface route-aggregation *interface-number*
- Enter Layer 3 aggregate subinterface view.
  interface route-aggregation *interface-number.subnumber* }

3. Set the expected bandwidth for the interface.
   bandwidth *bandwidth-value*
   By default, the expected bandwidth (in kbps) is the interface baud rate divided by 1000.

Configuring an edge aggregate interface

Restrictions and guidelines

This configuration takes effect only on aggregate interfaces in dynamic mode.

Link-aggregation traffic redirection cannot operate correctly on an edge aggregate interface. For more information about link-aggregation traffic redirection, see "Enabling link-aggregation traffic redirection."

Procedure

1. Enter system view.
   system-view
2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.
     interface route-aggregation *interface-number*
3. Configure the aggregate interface as an edge aggregate interface.
   lacp edge-port
   By default, an aggregate interface does not operate as an edge aggregate interface.

Configuring physical state change suppression on an aggregate interface

About this task

The physical link state of an aggregate interface is either up or down. Each time the physical link of an interface comes up or goes down, the system immediately reports the change to the CPU. The CPU then notifies the upper-layer protocol modules (such as routing and forwarding modules) of the change, and the device automatically generates traps and log messages and sends them to the SNMP and information center modules. You can configure SNMP and information center to output these messages.

To prevent frequent physical link flapping from affecting system performance, configure physical state change suppression. You can configure this feature to suppress link-down events, link-up events, or both. If an event of the specified type still exists when the suppression interval expires, the system reports the event to the CPU.

Restrictions and guidelines

When you configure suppression interval settings on an aggregate interface, make sure its peer interface is also an aggregate interface in the same aggregation mode. In addition, the suppression interval settings must be the same between the peer aggregate interfaces.

As a best practice, use the default setting in an S-MLAG environment.

On an interface, you can configure different suppression intervals for link-up and link-down events. If you execute the **link-delay** command multiple times for an event type, the most recent configuration takes effect on that event type.

Use this feature on an aggregate interface to reduce the impact of interface flapping on upper-layer services, for example, on an M-LAG peer-link interface. For more information about peer-link interfaces, see "Configuring M-LAG."

Procedure

1. Enter system view.
   system-view
2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.
     interface route-aggregation *interface-number*
3. Configure physical state change suppression.
   link-delay { **down** | **up** } [**msec**] *delay-time*

   By default, each time the physical link of an aggregate interface goes up or comes down, the system immediately reports the change to the CPU.

Shutting down an aggregate interface

Restrictions and guidelines

Shutting down or bringing up an aggregate interface affects the aggregation states and link states of member ports in the corresponding aggregation group as follows:

- When an aggregate interface is shut down, all its Selected ports become Unselected and all member ports go down.
- When an aggregate interface is brought up, the aggregation states of all its member ports are recalculated.

When you shut down or bring up a Layer 3 aggregate interface, all its aggregate subinterfaces are also shut down or brought up. Shutting down or bringing up a Layer 3 aggregate subinterface does not affect the state of the main aggregate interface.

Procedure

1. Enter system view.
   system-view
2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.
     interface route-aggregation *interface-number*
   - Enter Layer 3 aggregate subinterface view.
     interface route-aggregation *interface-number.subnumber* }
3. Shut down the interface.
   shutdown

CAUTION:

The **shutdown** command will disconnect all links established on an interface. Make sure you are fully aware of the impacts of this command when you use it on a live network.

Enabling interframe gap and preamble statistics in the traffic statistics

About this task

If you execute the **display interface** command, the Last 300 seconds input rate or Last 300 seconds output rate field in the command output displays the average outbound or inbound traffic rate in the last 300 seconds.

By default, traffic rate = native frame length × packet throughput per second. Execute the **traffic-statistic include-interframe** command if you need the total traffic statistics, including the native frame length, interframe gap length and preamble length, for a specific time period. If you execute this command, traffic rate = (native frame length + interframe gap length + preamble length) × packet throughput per second.

Restrictions and guidelines

If you perform this task on an aggregate interface, the configuration takes effect on all Ethernet interfaces in the aggregation group of the aggregate interface. The interframe gap and preamble statistics setting configured in Ethernet interface view do not take effect. If an Ethernet interface is removed from the aggregation group, the interframe gap and preamble statistics setting configured in Ethernet interface view takes effect.

Procedure

1. Enter system view.

   system-view
2. Enter Ethernet interface view.
   - Enter Layer 2 Ethernet interface view.

     interface bridge-aggregation *interface-number*
   - Enter Layer 3 Ethernet interface view.

     interface route-aggregation *interface-number*
3. Enable interframe gap and preamble statistics in the traffic statistics.

   traffic-statistic include-interframe

   The default for this command varies by device model.

Restoring the default settings for an aggregate interface

Restrictions and guidelines

CAUTION:

The **default** command might interrupt ongoing network services. Make sure you are fully aware of the impacts of this command when you execute it on a live network.

The **default** command might fail to restore the default settings for some commands for reasons such as command dependencies and system restrictions.

To resolve this issue:

1. Use the **display this** command in interface view to identify these commands.

2. Use their **undo** forms or follow the command reference to restore their default settings.
3. If the restoration attempt still fails, follow the error message instructions to resolve the issue.

Procedure

1. Enter system view.
   system-view
2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.
     interface route-aggregation *interface-number*
   - Enter Layer 3 aggregate subinterface view.
     interface route-aggregation *interface-number.subnumber* }
3. Restore the default settings for the aggregate interface.
   Default

Setting the minimum and maximum numbers of Selected ports for an aggregation group

About this task

The bandwidth of an aggregate link increases as the number of Selected member ports increases. To avoid congestion, you can set the minimum number of Selected ports required for bringing up an aggregate interface.

This minimum threshold setting affects the aggregation states of aggregation member ports and the state of the aggregate interface.

- When the number of member ports eligible to be Selected ports is smaller than the minimum threshold, the following events occur:
  - The eligible member ports are placed in Unselected state.
  - The link layer state of the aggregate interface becomes down.
- When the number of member ports eligible to be Selected ports reaches or exceeds the minimum threshold, the following events occur:
  - The eligible member ports are placed in Selected state.
  - The link layer state of the aggregate interface becomes up.

The maximum number of Selected ports allowed in an aggregation group is limited by either manual configuration or hardware limitation, whichever value is smaller.

You can implement backup between two ports by performing the following tasks:

- Assigning two ports to an aggregation group.
- Setting the maximum number of Selected ports to 1 for the aggregation group.

Then, only one Selected port is allowed in the aggregation group, and the Unselected port acts as a backup port.

Restrictions and guidelines

IMPORTANT:

After you set the minimum percentage of Selected ports for an aggregation group, aggregate interface flapping might occur when ports join or leave an aggregation group. Make sure you are fully aware of the impacts of this setting when you configure it on a live network.

You can set either the minimum number or the minimum percentage of Selected ports for an aggregation group. If you configure both settings on an aggregate interface, the higher Selected port number limit takes effect.

The minimum and maximum numbers of Selected ports must be the same between the two ends of an aggregate link.

The minimum percentage of Selected ports must be the same between the two ends of an aggregate link.

For an aggregation group, the maximum number of Selected ports must be equal to or higher than the minimum number of Selected ports. If you set the minimum percentage of Selected ports for the aggregation group, do not set the maximum number of Selected ports. If you set the maximum number of Selected ports, the calculated minimum number of Selected ports might be larger than the maximum number of Selected ports.

Procedure

1. Enter system view.

   system-view

2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.

     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.

     interface route-aggregation *interface-number*

3. Set the minimum number of Selected ports for the aggregation group. Choose one of the following methods:
   - Set the minimum number of Selected ports.

     link-aggregation selected-port minimum *min-number*
   - Set the minimum percentage of Selected ports.

     link-aggregation selected-port minimum percentage *number*

   By default, the minimum number of Selected ports is not specified for an aggregation group.

4. Set the maximum number of Selected ports for the aggregation group.

   link-aggregation selected-port maximum *max-number* [**lacp-sync**]

   By default, the maximum number of Selected ports for an aggregation group is 64.

   For a static aggregate link, you must set the maximum number of Selected ports to the same value at its two ends.

   For a dynamic aggregate link, you must set the maximum number of Selected ports to the same value at its two ends if you do not specify the **lacp-sync** keyword. If you specify this keyword, the two ends of the aggregate link compare their maximum Selected port number settings and use the smaller value.

Disabling the default action of selecting a Selected port for dynamic aggregation groups that have not received LACPDUs

About this task

The default port selection action applies to dynamic aggregation groups.

This action automatically chooses the port with the lowest ID from among all up member ports as a Selected port if none of them has received LACPDUs before the LACP timeout interval expires.

After this action is disabled, a dynamic aggregation group will not have any Selected ports to forward traffic if it has not received LACPDUs before the LACP timeout interval expires.

Procedure

1. Enter system view.
   `system-view`
2. Disable the default port selection action.
   `lacp default-selected-port disable`
   By default, the default port selection action is enabled for dynamic aggregation groups.

Configuring a dynamic aggregation group to use port speed as the prioritized criterion for reference port selection

About this task

Perform this task to ensure that a dynamic aggregation group selects a high-speed member port as the reference port. After you perform this task, the reference port will be selected based on the criteria in order of device ID, port speed, and port ID.

Restrictions and guidelines

Changing reference port selection criteria might cause transient traffic interruption. Make sure you understand the impact of this task on your network.

As a best practice, shut down the peer aggregate interfaces before you execute this command and bring up the interfaces after this command is executed on both of them.

Procedure

1. Enter system view.
   `system-view`
2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.
     `interface bridge-aggregation` *`interface-number`*
   - Enter Layer 3 aggregate interface view.
     `interface route-aggregation` *`interface-number`*
3. Specify port speed as the prioritized criterion for reference port selection.
   `lacp select speed`

By default, port ID is the prioritized criterion for reference port selection of a dynamic aggregation group.

Ignoring port speed in setting the aggregation states of member ports

About this task

This feature allows ports at a different speed than the reference port to become Selected by ignoring the port speed during operational key calculation.

You must configure the same port speed ignoring setting at the two ends of a static configuration to ensure that the peer ports are placed in the same aggregation state. This requirement does not apply to a dynamic aggregation, on which the two ends negotiate the aggregation state of the peer ports automatically.

Restriction and guidelines

Make sure you are fully aware of the impacts of this feature when you use it on a live network.

- When you execute the **`link-aggregation ignore speed`** command or its **`undo`** form, the operational key changes and the aggregate interface flaps temporarily.
- The **`link-aggregation ignore speed`** command might cause traffic loss on Selected ports operating at a speed lower than the other Selected ports in the aggregation group when traffic is distributed among the ports.

Procedure

1. Enter system view.

   `system-view`
2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.

     `interface bridge-aggregation` *`interface-number`*
   - Enter Layer 3 aggregate interface view.

     `interface route-aggregation` *`interface-number`*
3. Configure the aggregation group to ignore port speed in setting the aggregation states of member ports.

   `link-aggregation ignore speed`

   By default, an aggregation group does not ignore port speed in setting the aggregation states of member ports.

Enabling port selection preemption on an aggregate interface

About this task

When port A fails in a dynamic aggregation group, the device selects the highest priority member port, port B for example, as the new selected port. If port selection preemption is enabled and port A recovers from failure, it replaces port B. If port selection preemption is disabled, port B is still selected even though port A has higher priority, and traffic loss caused by selected port preemption is reduced.

If port selection preemption is enabled and port A recovers from failure, it immediately replaces port B. This might cause packet loss if port A's link status is unstable. To avoid this issue, configure a port selection preemption delay.

Procedure

1. Enter system view.
   system-view
2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.
     interface route-aggregation *interface-number*
3. Enable port selection preemption on an aggregate interface.
   lacp preempt enable

   By default, port selection preemption is enabled on an aggregate interface.
4. Set the port selection preemption delay.
   lacp preempt delay *delay-time*

   By default, the port selection preemption delay is 0 seconds on an aggregate interface, which means port selection preemption is performed without delay.

Configuring load sharing for link aggregation groups

Setting static load sharing modes for link aggregation groups

About this task

You can set the static global or group-specific load sharing mode. A link aggregation group preferentially uses the group-specific load sharing mode. If the group-specific load sharing mode is not available, the group uses the global load sharing mode.

Restrictions and guidelines

After you enable symmetric load sharing, link-aggregation load sharing also uses the symmetric load sharing mode. For more information about symmetric load sharing, see IP forwarding basics configuration in *Layer 3—IP Services Configuration Guide*.

The following are global load sharing modes supported on the device:

- Any combination of destination IP address, destination MAC address, destination port, source IP address, source MAC address, source port, GRE key, and VXLAN ID.
- Any combination of ingress port, source MAC address, and destination MAC address.

The device does not support load sharing IPv6 packets with extension headers based on the service port numbers.

As a best practice, configure GRE key, destination port, and source port simultaneously because they use the same hashing field.

Setting the global link-aggregation load sharing mode

1. Enter system view.
   system-view
2. Set the global link-aggregation load sharing mode.

link-aggregation global load-sharing mode { **destination-ip** | **destination-mac** | **destination-port** | **gre-key** | **ingress-port** | **ip-protocol** | **source-ip** | **source-mac** | **source-port** | **vxlan-id** } *

By default, packets are load shared depending on their packet type, as follows:

- Layer 2 frames are load shared based on the source and destination MAC addresses.
- Layer 3 packets are load shared based on the source and destination IP addresses.
- Layer 4 packets are load shared based on the source and destination IP addresses, and source and destination port numbers.

The S5200-EI-G switch does not support the **gre-key**, **ip-protocol**, or **vxlan-id** keyword.

Setting the group-specific load sharing mode

1. Enter system view.

   system-view

2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.

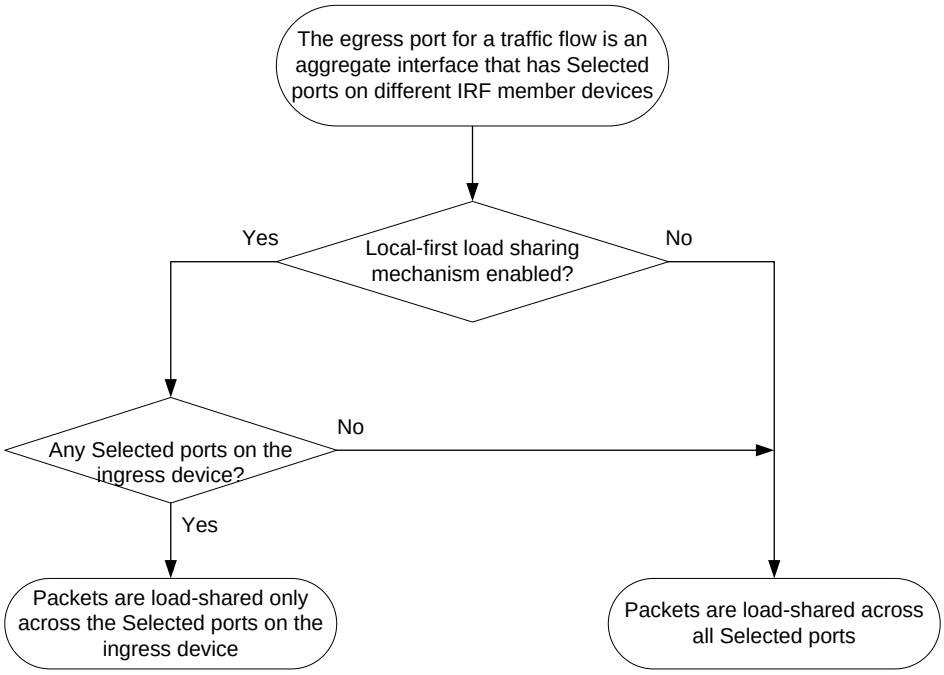
     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.

     interface route-aggregation *interface-number*
3. Set the load sharing mode for the aggregation group.

   link-aggregation load-sharing mode { { **destination-ip** | **destination-mac** | **source-ip** | **source-mac** } * | **per-packet** }

   By default, group-specific load sharing mode is the same as the global load sharing mode.

   The device supports per-packet load sharing only for the known unicast traffic forwarded by an aggregate interface.



Enabling local-first load sharing for link aggregation

About this task

Use local-first load sharing in a multidevice link aggregation scenario to distribute traffic preferentially across member ports on the ingress slot.

When you aggregate ports on different member devices in an IRF fabric, you can use local-first load sharing to reduce traffic on IRF links, as shown in Figure 6. For more information about IRF, see *Virtual Technologies Configuration Guide*.

Figure 6 Load sharing for multidevice link aggregation in an IRF fabric

Restrictions and guidelines for local-first load sharing

This feature is available only in IRF mode.

You can use this feature only after physical interfaces are bound to an IRF port.

After you execute the **ip forward-broadcast** command, disable local-first load sharing on a Layer 2 aggregate interface if it is a traffic outgoing interface for directed broadcasts destined for the directly connected network. For more information about this command, see IP performance optimization in *Layer 3—IP Services Configuration Guide*.

If you enable local-first load sharing on the device, an OpenFlow controller cannot create group entries on the device. For more information about OpenFlow, see *OpenFlow Configuration Guide*.

Enabling local-first load sharing for link aggregation globally

1. Enter system view.
   system-view
2. Enable local-first load sharing for link aggregation globally.
   link-aggregation load-sharing mode local-first
   By default, local-first load sharing is enabled globally.

Enabling local-first load sharing for an aggregate interface

1. Enter system view.
   system-view
2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.
     interface route-aggregation *interface-number*
3. Enable local-first load sharing on the aggregate interface.
   link-aggregation group load-sharing mode local-first

By default, local-first load sharing is not configured on aggregate interfaces. An aggregate interface uses the global local-first load-sharing setting.

Configuring link aggregation load sharing algorithm settings

About this task

Use the link aggregation load sharing algorithm to optimize traffic distribution on aggregate links when the default load sharing mode is used. Each algorithm represents a CRC calculation method.

Restrictions and guidelines

Change the link aggregation load sharing algorithm if different flows are not distributed to all member links of an aggregate link.

Procedure

1. Enter system view.
   system-view
2. Configure a link aggregation load sharing algorithm.
   link-aggregation global load-sharing algorithm *algorithm-number*
   By default, algorithm CRC is used.

Specifying link aggregation management VLANs and link aggregation management port

About this task

For an aggregation group to forward Layer 3 data traffic of some VLANs through a specific port, specify the VLANs as management VLANs and the port as a management port.

Procedure

1. Enter system view.
   system-view
2. Specify link aggregation management VLANs.
   link-aggregation management-vlan *vlan-id-list*
   By default, no link aggregation management VLANs are specified.
3. Enter Layer 2 Ethernet interface view.
   interface *interface-type interface-number*
4. Configure the port as a management port for its aggregation group.
   link-aggregation management-port
   By default, a port does not act as a management port in its aggregation group.

Enabling link-aggregation traffic redirection

About link-aggregation traffic redirection

This feature operates on dynamic link aggregation groups. It redirects traffic on a Selected port to the remaining available Selected ports of an aggregation group if one of the following events occurs:

- The port is shut down by using the **shutdown** command.

- The slot that hosts the port reboots, and the aggregation group spans multiple slots.

NOTE:

The device does not redirect traffic to member ports that become Selected during the traffic redirection process.

This feature ensures zero packet loss for known unicast traffic, but does not protect unknown unicast traffic.

You can enable link-aggregation traffic redirection globally or for an aggregation group. Global link-aggregation traffic redirection settings take effect on all aggregation groups. A link aggregation group preferentially uses the group-specific link-aggregation traffic redirection settings. If group-specific link-aggregation traffic redirection is not configured, the group uses the global link-aggregation traffic redirection settings.

Restrictions and guidelines for link-aggregation traffic redirection

Link-aggregation traffic redirection applies only to dynamic link aggregation groups.

As a best practice, enable link-aggregation traffic redirection on a per-interface basis. If you enable this feature globally, communication with a third-party peer device might be affected if the peer is not compatible with this feature.

To prevent traffic interruption, enable link-aggregation traffic redirection at both ends of the aggregate link.

To prevent packet loss that might occur at a reboot, do not enable the spanning tree feature together with link-aggregation traffic redirection.

Link-aggregation traffic redirection does not operate correctly on an edge aggregate interface.

After the **`link-aggregation lacp traffic-redirect-notification enable`** command is executed, the device will add a proprietary field to the end of the LACP packets. Because the peer device cannot verify this proprietary field, LACP packets might fail to be verified and exchanged. As a result, the aggregation member ports cannot become Selected. To prevent this issue, you must disable link-aggregation traffic redirection on the H3C device when the H3C device connects to a third-party device.

Enabling link-aggregation traffic redirection globally

1. Enter system view.
   `system-view`
2. Enable link-aggregation traffic redirection globally.
   `link-aggregation lacp traffic-redirect-notification enable`
   By default, link-aggregation traffic redirection is disabled globally.

Enabling link-aggregation traffic redirection for an aggregation group

1. Enter system view.
   `system-view`
2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.

interface bridge-aggregation *interface-number*

- Enter Layer 3 aggregate interface view.

  interface route-aggregation *interface-number*

3. Enable link-aggregation traffic redirection for the aggregation group.

   link-aggregation lacp traffic-redirect-notification enable

By default, link-aggregation traffic redirection is disabled for an aggregation group.

Isolating aggregate interfaces on the device

About this task

Aggregate interface isolation is applicable to dynamic aggregate interfaces when the device acts a M-LAG member device in an M-LAG system. It gracefully changes all dynamic aggregate interfaces on the device to the Unselected state and switch traffic over to their counterpart M-LAG interfaces on the other M-LAG member device.

Restrictions and guidelines

This feature takes effect only on dynamic aggregate interfaces. It cannot isolate static aggregate interfaces or M-LAG peer-link interfaces.

As a best practice, make sure no M-LAG interfaces are in M-LAG MAD DOWN state before you isolate them. If one of the M-LAG interfaces is in M-LAG MAD DOWN state when you isolate them, M-LAG interface will persist in that state and cannot forward traffic after the isolation is removed.

Procedure

1. Enter system view.

   system-view

2. Isolate aggregate interfaces.

   link-aggregation lacp isolate [**bagg** | **ragg**]

   By default, aggregate interfaces are not isolated.

   To remove DR interface isolation, execute the **undo** form of this command.

Enabling BFD for an aggregation group

About this task

You can use BFD to monitor member link status in an aggregation group. After you enable BFD on an aggregate interface, each Selected port in the aggregation group establishes a BFD session with its peer port. BFD operates differently depending on the aggregation mode.

- **BFD on a static aggregation**—When BFD detects a link failure, BFD notifies the Ethernet link aggregation module that the peer port is unreachable. The local port is then placed in Unselected state. However, the BFD session between the local and peer ports remains, and the local port keeps sending BFD packets. When BFD on the local port receives packets from the peer port upon link recovery, BFD notifies the Ethernet link aggregation module that the peer port is reachable. Then, the local port is placed in Selected state again. This mechanism ensures that the local and peer ports of a static aggregate link have the same aggregation state.
- **BFD on a dynamic aggregation**—When BFD detects a link failure, BFD notifies the Ethernet link aggregation module that the peer port is unreachable. At the same time, BFD clears the session and stops sending BFD packets. When the local port is placed in Selected state again upon link recovery, the local port establishes a new session with the peer port and BFD notifies the Ethernet link aggregation module that the peer port is reachable. Because BFD provides fast failure detection, the local and peer systems of a dynamic aggregate link can negotiate the aggregation state of their member ports faster.

For more information about BFD, see *High Availability Configuration Guide*.

Restrictions and guidelines

When you enable BFD for an aggregation group, follow these restrictions and guidelines:

- Make sure the source and destination IP addresses are reversed between the two ends of an aggregate link. For example, if you execute **link-aggregation bfd ipv4 source 1.1.1.1 destination 2.2.2.2** at the local end, execute **link-aggregation bfd ipv4 source 2.2.2.2 destination 1.1.1.1** at the peer end. The source and destination IP addresses cannot be the same.
- The BFD parameters configured on an aggregate interface take effect on all BFD sessions established by the member ports in its aggregation group. BFD on a link aggregation supports only control packet mode for session establishment and maintenance. The two ends of an established BFD session can only operate in **Asynchronous** mode.
- As a best practice, do not configure BFD for any protocols on a BFD-enabled aggregate interface.
- Make sure the number of member ports in a BFD-enabled aggregation group is less than or identical to the number of BFD sessions supported by the device. If the aggregation group contains more member ports than the supported sessions, some Selected ports might change to the Unselected state.
- If the number of BFD sessions differs between the two ends of an aggregate link, check their settings for inconsistency in the maximum number of Selected ports. You must make sure the two ends have the same setting for the maximum number of Selected ports.
- If both IPv4 and IPv6 BFD sessions exist on an aggregate interface, the device places the aggregation member ports in Unselected state when either IPv4 or IPv6 BFD detects a link failure.
- In the current software version, you cannot enable BFD for link aggregation on a Layer 2 aggregate interface.

Procedure

1. Enter system view.

   system-view
2. Enter aggregate interface view.
   - Enter Layer 2 aggregate interface view.

     interface bridge-aggregation *interface-number*
   - Enter Layer 3 aggregate interface view.

     interface route-aggregation *interface-number*
3. (Optional.) Enable BFD compatible mode for link aggregation.

   link-aggregation bfd-compatible enable

   By default, BFD compatible mode for link aggregation is disabled.
4. Enable BFD for the aggregation group.

   link-aggregation bfd ipv4 source *ipv4-address* **destination** *ipv4-address*

   link-aggregation bfd ipv6 source *ipv6-address* **destination** *ipv6-address*

   By default, BFD is disabled for an aggregation group.

Display and maintenance commands for Ethernet link aggregation

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display information about aggregate interfaces.	**display interface** [{ **bridge-aggregation** | **route-aggregation** } [*interface-number*]] [**brief** [**description** | **down**]]
Display the local system ID.	**display lacp system-id**
Display the global or group-specific link-aggregation load sharing modes.	**display link-aggregation load-sharing mode** [**interface** [{ **bridge-aggregation** | **route-aggregation** } *interface-number*]]
Display detailed link aggregation information about link aggregation member ports.	**display link-aggregation member-port** [*interface-list* | **auto**]
Display summary information about all aggregation groups.	**display link-aggregation summary**
Display the aggregation states of aggregation member ports and the reason why a port was placed in Unselected state.	**display link-aggregation troubleshooting** [{ **bridge-aggregation** | **route-aggregation** } [*interface-number*]]
Display detailed information about the specified aggregation groups.	**display link-aggregation verbose** [{ **bridge-aggregation** | **route-aggregation** } [*interface-number*]] [**all-configuration**]
Clear statistics for the specified aggregate interfaces.	**reset counters interface** [{ **bridge-aggregation** | **route-aggregation** } [*interface-number*]]
Clear LACP statistics for the specified link aggregation member ports.	**reset lacp statistics** [**interface** *interface-list*]

Ethernet link aggregation configuration examples

Example: Configuring a Layer 2 static aggregation group

Network configuration

On the network shown in Figure 7, perform the following tasks:

- Configure a Layer 2 static aggregation group on both Device A and Device B.
- Enable VLAN 10 at one end of the aggregate link to communicate with VLAN 10 at the other end.

- Enable VLAN 20 at one end of the aggregate link to communicate with VLAN 20 at the other end.

Figure 7 Network diagram

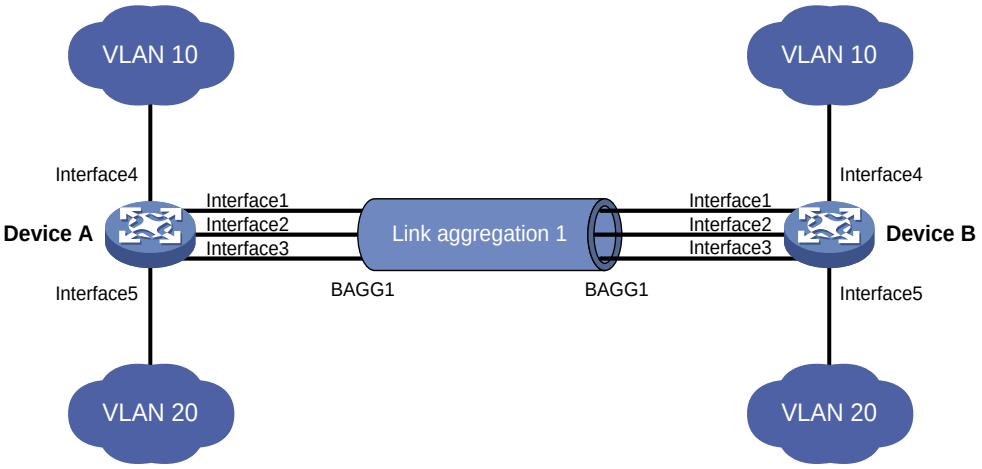


Table 5 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4
Interface5	GigabitEthernet1/0/5

Procedure

1. Configure Device A:

Create VLAN 10, and assign port GigabitEthernet 1/0/4 to VLAN 10.

```
<DeviceA> system-view
[DeviceA] vlan 10
[DeviceA-vlan10] port gigabitethernet 1/0/4
[DeviceA-vlan10] quit
```

Create VLAN 20, and assign port GigabitEthernet 1/0/5 to VLAN 20.

```
[DeviceA] vlan 20
[DeviceA-vlan20] port gigabitethernet 1/0/5
[DeviceA-vlan20] quit
```

Create Layer 2 aggregate interface Bridge-Aggregation 1.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] quit
```

Assign ports GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to link aggregation group 1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/2] quit
[DeviceA] interface gigabitethernet 1/0/3
```

```
[DeviceA-GigabitEthernet1/0/3] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/3] quit
```

Configure Layer 2 aggregate interface Bridge-Aggregation 1 as a trunk port and assign it to VLANs 10 and 20.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] port link-type trunk
[DeviceA-Bridge-Aggregation1] port trunk permit vlan 10 20
[DeviceA-Bridge-Aggregation1] quit
```

2. Configure Device B in the same way Device A is configured. (Details not shown.)

Verifying the configuration

Display detailed information about all aggregation groups on Device A.

```
[DeviceA] display link-aggregation verbose
Loadsharing Type: Shar -- Loadsharing, NonS -- Non-Loadsharing
Port Status: S -- Selected, U -- Unselected, I -- Individual
Port: A -- Auto port, M -- Management port, R -- Reference port
Flags:  A -- LACP_Activity, B -- LACP_Timeout, C -- Aggregation,
        D -- Synchronization, E -- Collecting, F -- Distributing,
        G -- Defaulted, H -- Expired

Aggregate Interface: Bridge-Aggregation1
Aggregation Mode: Static
Loadsharing Type: Shar
Management VLANs: None
  Port             Status  Priority Oper-Key
  GE1/0/1(R)       S       32768    1
  GE1/0/2          S       32768    1
  GE1/0/3          S       32768    1
```

The output shows that link aggregation group 1 is a Layer 2 static aggregation group that contains three Selected ports.

Example: Configuring a Layer 2 dynamic aggregation group

Network configuration

On the network shown in Figure 8, perform the following tasks:

- Configure a Layer 2 dynamic aggregation group on both Device A and Device B.
- Enable VLAN 10 at one end of the aggregate link to communicate with VLAN 10 at the other end.
- Enable VLAN 20 at one end of the aggregate link to communicate with VLAN 20 at the other end.

Figure 8 Network diagram

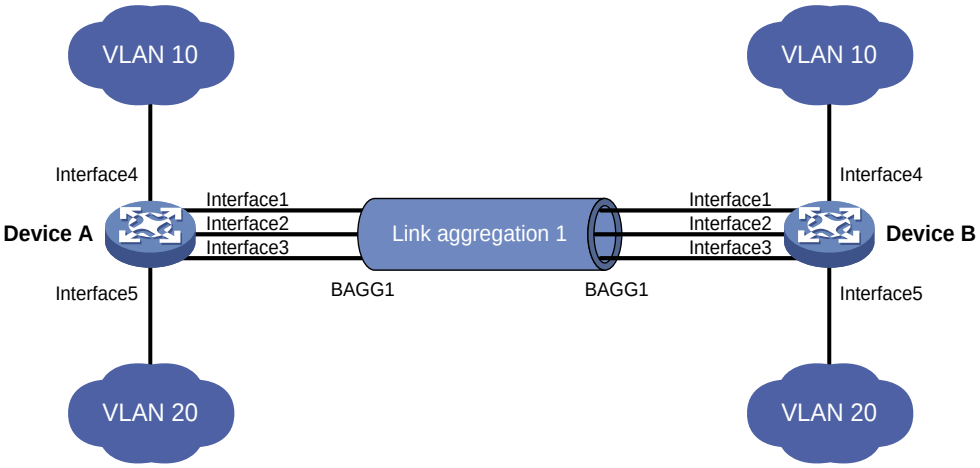

Table 6 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3
Interface4	GigabitEthernet1/0/4
Interface5	GigabitEthernet1/0/5

Procedure

1. Configure Device A:

Create VLAN 10, and assign the port GigabitEthernet 1/0/4 to VLAN 10.

```
<DeviceA> system-view
[DeviceA] vlan 10
[DeviceA-vlan10] port gigabitethernet 1/0/4
[DeviceA-vlan10] quit
```

Create VLAN 20, and assign the port GigabitEthernet 1/0/5 to VLAN 20.

```
[DeviceA] vlan 20
[DeviceA-vlan20] port gigabitethernet 1/0/5
[DeviceA-vlan20] quit
```

Create Layer 2 aggregate interface Bridge-Aggregation 1, and set the link aggregation mode to dynamic.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] link-aggregation mode dynamic
[DeviceA-Bridge-Aggregation1] quit
```

Assign ports GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to link aggregation group 1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/2] quit
[DeviceA] interface gigabitethernet 1/0/3
```

```
[DeviceA-GigabitEthernet1/0/3] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/3] quit
```

Configure Layer 2 aggregate interface Bridge-Aggregation 1 as a trunk port and assign it to VLANs 10 and 20.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] port link-type trunk
[DeviceA-Bridge-Aggregation1] port trunk permit vlan 10 20
[DeviceA-Bridge-Aggregation1] quit
```

2. Configure Device B in the same way Device A is configured. (Details not shown.)

Verifying the configuration

Display detailed information about all aggregation groups on Device A.

```
[DeviceA] display link-aggregation verbose
Loadsharing Type: Shar -- Loadsharing, NonS -- Non-Loadsharing
Port Status: S -- Selected, U -- Unselected, I -- Individual
Port: A -- Auto port, M -- Management port, R -- Reference port
Flags:  A -- LACP_Activity, B -- LACP_Timeout, C -- Aggregation,

        G -- Defaulted, H -- Expired

Aggregate Interface: Bridge-Aggregation1
Creation Mode: Manual
Aggregation Mode: Dynamic
Loadsharing Type: Shar
Management VLANs: None
System ID: 0x8000, 000f-e267-6c6a
Local:
  Port                Status   Priority Index    Oper-Key               Flag
  GE1/0/1(R)          S        32768    11       1                      {ACDEF}
  GE1/0/2             S        32768    12       1                      {ACDEF}
  GE1/0/3             S        32768    13       1                      {ACDEF}
Remote:
  Actor               Priority Index    Oper-Key SystemID               Flag
  GE1/0/1             32768    81       1        0x8000, 000f-e267-57ad {ACDEF}
  GE1/0/2             32768    82       1        0x8000, 000f-e267-57ad {ACDEF}
  GE1/0/3             32768    83       1        0x8000, 000f-e267-57ad {ACDEF}
```

The output shows that link aggregation group 1 is a Layer 2 dynamic aggregation group that contains three Selected ports.

Example: Configuring a Layer 2 edge aggregate interface

Network configuration

As shown in Figure 9, a Layer 2 dynamic aggregation group is configured on the device. The server is not configured with dynamic link aggregation.

Configure an edge aggregate interface so that both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 can forward traffic to improve link reliability.

Figure 9 Network diagram

Table 7 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

Create Layer 2 aggregate interface Bridge-Aggregation 1, and set the link aggregation mode to dynamic.

```
<Device> system-view
[Device] interface bridge-aggregation 1
[Device-Bridge-Aggregation1] link-aggregation mode dynamic
```

Configure Layer 2 aggregate interface Bridge-Aggregation 1 as an edge aggregate interface.

```
[Device-Bridge-Aggregation1] lacp edge-port
[Device-Bridge-Aggregation1] quit
```

Assign ports GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to link aggregation group 1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] port link-aggregation group 1
[Device-GigabitEthernet1/0/1] quit
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] port link-aggregation group 1
[Device-GigabitEthernet1/0/2] quit
```

Verifying the configuration

Display detailed information about all aggregation groups on the device when the server is not configured with dynamic link aggregation.

```
[Device] display link-aggregation verbose
Loadsharing Type: Shar -- Loadsharing, NonS -- Non-Loadsharing
Port Status: S -- Selected, U -- Unselected, I -- Individual
Port: A -- Auto port, M -- Management port, R -- Reference port
Flags:  A -- LACP_Activity, B -- LACP_Timeout, C -- Aggregation,
        D -- Synchronization, E -- Collecting, F -- Distributing,
        G -- Defaulted, H -- Expired

Aggregate Interface: Bridge-Aggregation1
Creation Mode: Manual
Aggregation Mode: Dynamic
Loadsharing Type: Shar
Management VLANs: None
System ID: 0x8000, 000f-e267-6c6a
Local:
  Port               Status   Priority Index    Oper-Key               Flag
```

```
  GE1/0/1             I        32768    11       1                    {AG}
  GE1/0/2             I        32768    12       1                    {AG}

Remote:
  Actor               Priority Index    Oper-Key SystemID             Flag
  GE1/0/1             32768    81       0        0x8000, 0000-0000-0000 {DEF}
  GE1/0/2             32768    82       0        0x8000, 0000-0000-0000 {DEF}
```

The output shows that GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are in Individual state when they do not receive LACPDUs from the server. Both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 can forward traffic. When one port fails, its traffic is automatically switched to the other port.

Example: Configuring a Layer 3 static aggregation group

Network configuration

On the network shown in Figure 10, perform the following tasks:

- Configure a Layer 3 static aggregation group on both Device A and Device B.
- Configure IP addresses and subnet masks for the corresponding Layer 3 aggregate interfaces.

Figure 10 Network diagram

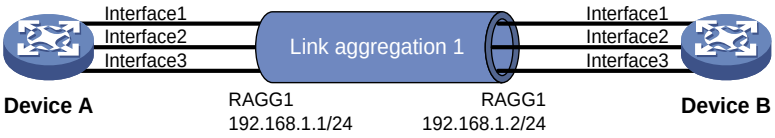

Table 8 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure Device A:

   # Create Layer 3 aggregate interface Route-Aggregation 1, and configure an IP address and subnet mask for the aggregate interface.

   ```
   <DeviceA> system-view
   [DeviceA] interface route-aggregation 1
   [DeviceA-Route-Aggregation1] ip address 192.168.1.1 24
   [DeviceA-Route-Aggregation1] quit
   ```

   # Assign Layer 3 Ethernet interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to aggregation group 1.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] port link-aggregation group 1
   [DeviceA-GigabitEthernet1/0/1] quit
   [DeviceA] interface gigabitethernet 1/0/2
   [DeviceA-GigabitEthernet1/0/2] port link-aggregation group 1
   [DeviceA-GigabitEthernet1/0/2] quit
   [DeviceA] interface gigabitethernet 1/0/3
   ```

```
[DeviceA-GigabitEthernet1/0/3] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/3] quit
```

2. Configure Device B in the same way Device A is configured. (Details not shown.)

Verifying the configuration

Display detailed information about all aggregation groups on Device A.

```
[DeviceA] display link-aggregation verbose
Loadsharing Type: Shar -- Loadsharing, NonS -- Non-Loadsharing
Port Status: S -- Selected, U -- Unselected, I -- Individual
Port: A -- Auto port, M -- Management port, R -- Reference port
Flags:  A -- LACP_Activity, B -- LACP_Timeout, C -- Aggregation,
        D -- Synchronization, E -- Collecting, F -- Distributing,
        G -- Defaulted, H -- Expired

Aggregate Interface: Route-Aggregation1
Aggregation Mode: Static
Loadsharing Type: Shar
Management VLANs: None
  Port             Status  Priority Oper-Key
  GE1/0/1(R)       S       32768    1

  GE1/0/3          S       32768    1
```

The output shows that link aggregation group 1 is a Layer 3 static aggregation group that contains three Selected ports.

Example: Configuring a Layer 3 dynamic aggregation group

Network configuration

On the network shown in Figure 11, perform the following tasks:

- Configure a Layer 3 dynamic aggregation group on both Device A and Device B.
- Configure IP addresses and subnet masks for the corresponding Layer 3 aggregate interfaces.

Figure 11 Network diagram

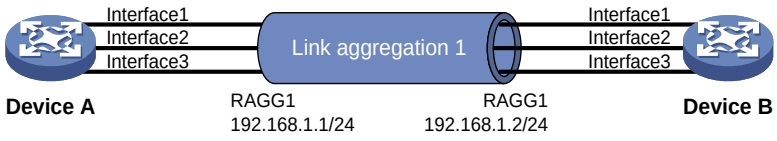

Table 9 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure Device A:

   # Create Layer 3 aggregate interface Route-Aggregation 1.

```
<DeviceA> system-view
[DeviceA] interface route-aggregation 1
```

Set the link aggregation mode to dynamic.

```
[DeviceA-Route-Aggregation1] link-aggregation mode dynamic
```

Configure an IP address and subnet mask for Route-Aggregation 1.

```
[DeviceA-Route-Aggregation1] ip address 192.168.1.1 24
[DeviceA-Route-Aggregation1] quit
```

Assign Layer 3 Ethernet interfaces GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to aggregation group 1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/1] quit
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/2] quit
[DeviceA] interface gigabitethernet 1/0/3
[DeviceA-GigabitEthernet1/0/3] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/3] quit
```

2. Configure Device B in the same way Device A is configured. (Details not shown.)

Verifying the configuration

Display detailed information about all aggregation groups on Device A.

```
[DeviceA] display link-aggregation verbose
Loadsharing Type: Shar -- Loadsharing, NonS -- Non-Loadsharing
Port Status: S -- Selected, U -- Unselected, I -- Individual
Port: A -- Auto port, M -- Management port, R -- Reference port
Flags:  A -- LACP_Activity, B -- LACP_Timeout, C -- Aggregation,

  GE1/0/1(R)          S        32768    11       1                      {ACDEF}
  GE1/0/2             S        32768    12       1                      {ACDEF}
  GE1/0/3             S        32768    13       1                      {ACDEF}
Remote:
  Actor               Priority Index    Oper-Key SystemID               Flag
  GE1/0/1             32768    81       1        0x8000, 000f-e267-57ad {ACDEF}
  GE1/0/2             32768    82       1        0x8000, 000f-e267-57ad {ACDEF}
  GE1/0/3             32768    83       1        0x8000, 000f-e267-57ad {ACDEF}
```

The output shows that link aggregation group 1 is a Layer 3 dynamic aggregation group that contains three Selected ports.

Example: Configuring S-MLAG

Network configuration

To meet service high availability requirements, configure link aggregation between Device A/Device B and Server 1/Server 2. This provides device-level redundancy for the servers and implements traffic load sharing.

- Device A and Device B connect to Server 1 and Server 2 through Layer 2 Ethernet interfaces GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2, respectively.
- Configure S-MLAG on Device A and Device B. When both Device A and Device B run correctly, they forward traffic simultaneously. When one device fails, the other device takes over all service traffic.
- Server 1 and Server 2 can communicate at Layer 2.

Figure 12 Network diagram

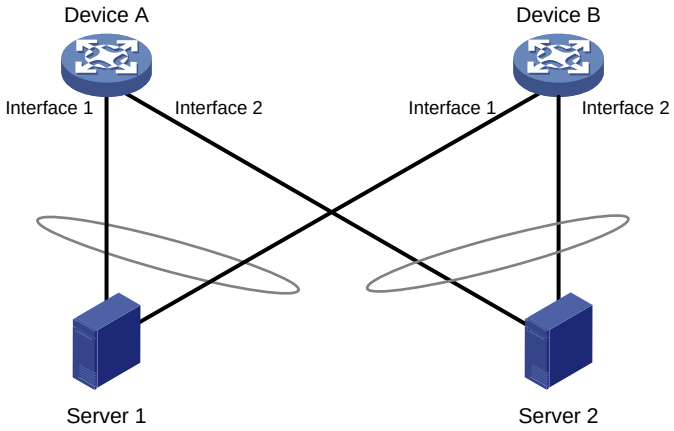

Table 10 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure Device A:

Set the LACP system MAC address to 0000-5e00-0101.

```
<DeviceA> system-view
[DeviceA] lacp system-mac 0000-5e00-0101
```

Set the LACP system priority to 200.

```
[DeviceA] lacp system-priority 200
```

Set the LACP system number to 1.

```
[DeviceA] lacp system-number 1
```

Create Layer 2 aggregate interface Bridge-Aggregation 1, and set the link aggregation mode to dynamic.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] link-aggregation mode dynamic
```

Assign Bridge-Aggregation 1 to S-MLAG group 100.

```
[DeviceA-Bridge-Aggregation1] port s-mlag group 100
```

Assign GigabitEthernet 1/0/1 to aggregation group 1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-aggregation group 1
[DeviceA-GigabitEthernet1/0/1] quit
```

Create Layer 2 aggregate interface Bridge-Aggregation 2, and set the link aggregation mode to dynamic.

```
[DeviceA] interface bridge-aggregation 2
[DeviceA-Bridge-Aggregation2] link-aggregation mode dynamic
```

Assign Bridge-Aggregation 2 to S-MLAG group 200.

```
[DeviceA-Bridge-Aggregation2] port s-mlag group 200
```

Assign GigabitEthernet 1/0/2 to aggregation group 2.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-aggregation group 2
[DeviceA-GigabitEthernet1/0/2] quit
```

Create VLAN 100.

```
[DeviceA] vlan 100
[DeviceA-vlan100] quit
```

Configure Layer 2 aggregate interface Bridge-Aggregation 1 as a trunk port, assign the trunk port to VLAN 100, and set the PVID to 100.

```
[DeviceA] interface bridge-aggregation 1
[DeviceA-Bridge-Aggregation1] port link-type trunk
[DeviceA-Bridge-Aggregation1] port trunk permit vlan 100
[DeviceA-Bridge-Aggregation1] port trunk pvid vlan 100
```

Remove the trunk port from VLAN 1.

```
[DeviceA-Bridge-Aggregation1] undo port trunk permit vlan 1
[DeviceA-Bridge-Aggregation1] quit
```

Configure Layer 2 aggregate interface Bridge-Aggregation 2 as a trunk port, assign the trunk port to VLAN 100, and set the PVID to 100.

```
[DeviceA] interface bridge-aggregation 2
[DeviceA-Bridge-Aggregation2] port link-type trunk
[DeviceA-Bridge-Aggregation2] port trunk permit vlan 100
[DeviceA-Bridge-Aggregation2] port trunk pvid vlan 100
```

Remove the trunk port from VLAN 1.

```
[DeviceA-Bridge-Aggregation2] undo port trunk permit vlan 1
[DeviceA-Bridge-Aggregation2] quit
```

2. Configure Device B:

Set the LACP system MAC address to 0000-5e00-0101.

```
<DeviceB> system-view
[DeviceB] lacp system-mac 0000-5e00-0101
```

Set the LACP system priority to 200.

```
[DeviceB] lacp system-priority 200
```

Set the LACP system number to 2.

```
[DeviceB] lacp system-number 2
```

Create Layer 2 aggregate interface Bridge-Aggregation 1, and set the link aggregation mode to dynamic.

```
[DeviceB] interface bridge-aggregation 1
[DeviceB-Bridge-Aggregation1] link-aggregation mode dynamic
```

Assign Bridge-Aggregation 1 to S-MLAG group 100.

```
[DeviceB-Bridge-Aggregation1] port s-mlag group 100
```

Assign GigabitEthernet 1/0/1 to aggregation group 1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-aggregation group 1
[DeviceB-GigabitEthernet1/0/1] quit
```

Create Layer 2 aggregate interface Bridge-Aggregation 2, and set the link aggregation mode to dynamic.

```
[DeviceB] interface bridge-aggregation 2
[DeviceB-Bridge-Aggregation2] link-aggregation mode dynamic
```

Assign Bridge-Aggregation 2 to S-MLAG group 200.

```
[DeviceB-Bridge-Aggregation2] port s-mlag group 200
```

Assign GigabitEthernet 1/0/2 to aggregation group 2.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-aggregation group 2
[DeviceB-GigabitEthernet1/0/2] quit
```

Create VLAN 100.

```
[DeviceB] vlan 100
[DeviceB-vlan100] quit
```

Configure Layer 2 aggregate interface Bridge-Aggregation 1 as a trunk port, assign the trunk port to VLAN 100, and set the PVID to 100.

```
[DeviceB] interface bridge-aggregation 1
[DeviceB-Bridge-Aggregation1] port link-type trunk
[DeviceB-Bridge-Aggregation1] port trunk permit vlan 100
[DeviceB-Bridge-Aggregation1] port trunk pvid vlan 100
```

Remove the trunk port from VLAN 1.

```
[DeviceB-Bridge-Aggregation1] undo port trunk permit vlan 1
[DeviceB-Bridge-Aggregation1] quit
```

Configure Layer 2 aggregate interface Bridge-Aggregation 2 as a trunk port, assign the trunk port to VLAN 100, and set the PVID to 100.

```
[DeviceB] interface bridge-aggregation 2
[DeviceB-Bridge-Aggregation2] port link-type trunk
[DeviceB-Bridge-Aggregation2] port trunk permit vlan 100
[DeviceB-Bridge-Aggregation2] port trunk pvid vlan 100
```

Remove the trunk port from VLAN 1.

```
[DeviceB-Bridge-Aggregation2] undo port trunk permit vlan 1
[DeviceB-Bridge-Aggregation2] quit
```

Verifying the configuration

View detailed information about all aggregation groups on Device A to verify that the S-MLAG aggregation group members are in **Selected** state.

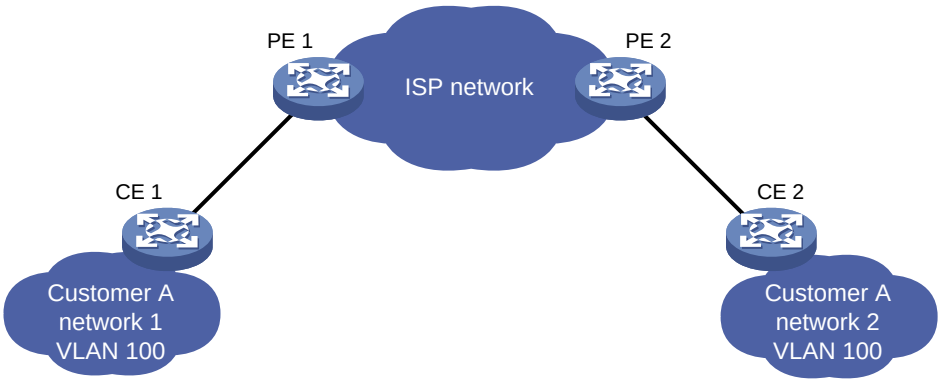
Configuring L2PT

About L2PT

Layer 2 Protocol Tunneling (L2PT) can transparently send Layer 2 protocol packets from geographically dispersed customer networks across a service provider network or drop them.



L2PT application scenario

Dedicated lines are used in a service provider network to build user-specific Layer 2 networks. As a result, a customer network contains sites located at different sides of the service provider network.

As shown in Figure 1, Customer A's network is divided into network 1 and network 2, which are connected by the service provider network. For Customer A's network to implement Layer 2 protocol calculations, the Layer 2 protocol packets must be transmitted across the service provider network.

Upon receiving a Layer 2 protocol packet, the PEs cannot determine whether the packet is from the customer network or the service provider network. They must deliver the packet to the CPU for processing. In this case, the Layer 2 protocol calculation in Customer A's network is mixed with the Layer 2 protocol calculation in the service provider network. Neither the customer network nor the service provider network can implement independent Layer 2 protocol calculations.

Figure 1 L2PT application scenario

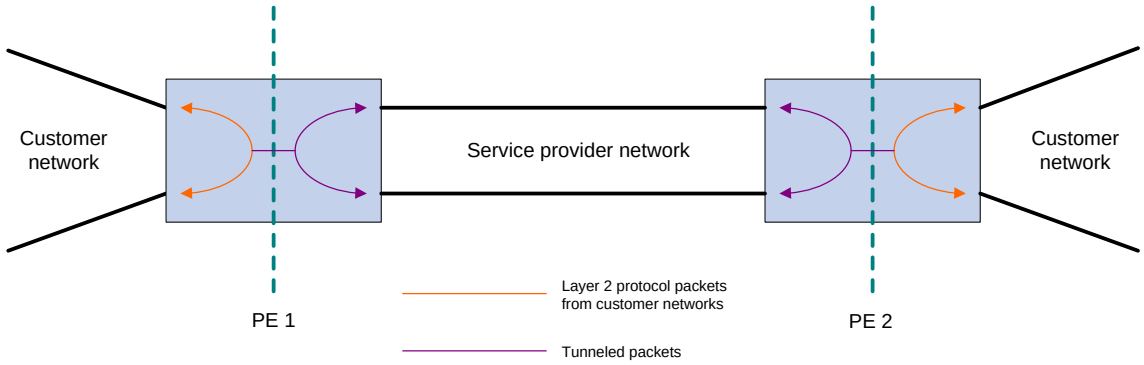
L2PT is introduced to resolve the problem. L2PT provides the following functions:

- Multicasts Layer 2 protocol packets from a customer network in a VLAN. Dispersed customer networks can complete an independent Layer 2 protocol calculation, which is transparent to the service provider network.
- Isolates Layer 2 protocol packets from different customer networks through different VLANs.

Supported protocols

H3C devices support L2PT for the following protocols:

- CDP.
- DLDP.
- EOAM.
- GVRP.
- LACP.



- LLDP.
- MVRP.
- PVST.
- STP (including STP, RSTP, and MSTP).

L2PT operating mechanism

As shown in Figure 2, L2PT operates as follows:

- When a port of PE 1 receives a Layer 2 protocol packet from the customer network in a VLAN, it performs the following operations:
  - Multicasts the packet out of all customer-facing ports in the VLAN except the receiving port.
  - Encapsulates the packet with a specified destination multicast address, and multicasts it out of all ISP-facing ports in the VLAN. The encapsulated packet is called the BPDU tunneled packet.
- When a port of PE 2 in the VLAN receives the tunneled packet from the service provider network, it performs the following operations:
  - Multicasts the packet out of all ISP-facing ports in the VLAN except the receiving port.
  - Decapsulates the packet and multicasts the decapsulated packet out of all customer-facing ports in the VLAN.

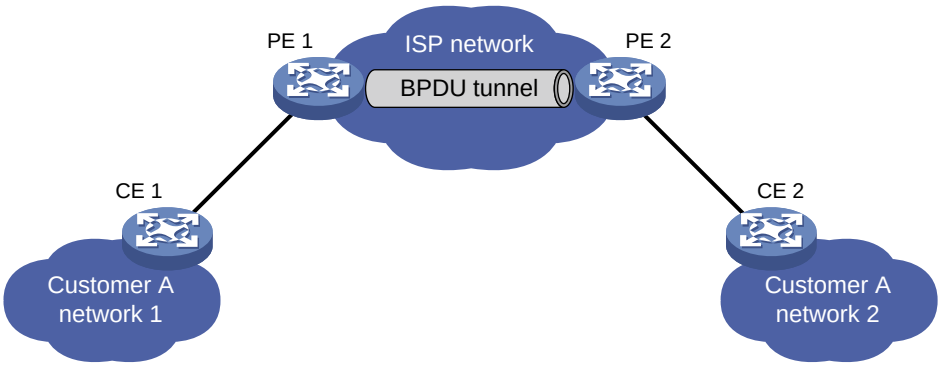
Figure 2 L2PT operating mechanism

For example, as shown in Figure 3, PE 1 receives an STP packet (BPDU) from network 1 to network 2. CEs are the edge devices on the customer network, and PEs are the edge devices on the service provider network. L2PT processes the packet as follows:

1. At the ingress of the ISP network, when an interface of PE 1 receives a BPDU from CE 1, the system matches the protocol packet based on locally configured L2PT protocol entries in a specific order. If a match is found, PE 1 replaces the destination MAC address of the original Layer 2 protocol packet with a fixed multicast MAC address (010f-e200-0003 by default) and forwards the protocol packet in the same broadcast domain.
2. At the egress of the ISP network, after PE 2 receives the packet with destination MAC address 010f-e200-0003, the system matches the packet based on locally configured L2PT protocol entries in a specific order. When a match is found, PE 2 restores the destination MAC address of the original packet according to the matching protocol and forwards the BPDU to CE 2.

Through L2PT, both the ISP network and Customer A's network can perform independent spanning tree calculations.

The L2PT protocol entries follow this matching order:



3. First, the system preferentially matches the L2PT protocols specified on an interface.

4. If no match is found, the system then matches the user-defined Layer 2 protocols. If an L2PT protocol on the interface is matched, the system does not continue to match the user-defined Layer 2 protocols.

NOTE:

When the ingress matches a packet with user-defined Layer 2 protocols for L2TP, the system compares the protocol type, encapsulation type, and destination MAC address. A match succeeds only if all three values are the same as those of a user-defined Layer 2 protocol. However, the protocol packet received at the egress has its destination MAC address replaced with a unified one. In this case, the egress cannot match the destination MAC address information. A match succeeds as long as the received packet matches the protocol type and encapsulation type of a user-defined Layer 2 protocol.

Figure 3 L2PT network diagram

L2PT tasks at a glance

To configure L2PT, perform the following tasks:

1. Enabling L2PT

   This feature is applicable only to customer-facing ports.
2. (Optional.) Setting the destination multicast MAC address for tunneled packets
3. (Optional.) Configuring the maximum rate of transparently transmitting packets of the specified protocol on an L2TP-enabled interface

Enabling L2PT

Restrictions and guidelines for L2PT

- To enable L2PT for a Layer 2 protocol on a port, perform the following tasks:
  - Enable the protocol on the connected CE, and disable the protocol on the port.
  - When a PE establishes a connection to a network device within the service provider network through CDP, you must enable CDP compatibility for LLDP on the PE. CDP compatibility for LLDP can be enabled only globally, and cannot be disabled separately on customer-facing interfaces. As a result, the CDP packets from the CE cannot be transparently transmitted within the service provider network. In this case, as a best practice, do not enable L2PT for CDP on the PE. For L2PT to take effect on CDP on the PE, you must disable CDP compatibility for LLDP globally on the PE, which will cause the PE to fail to communicate with the network devices within the service provider network through CDP. Before you disable CDP compatibility for LLDP on the PE, make sure you know its

influence on the network. For more information about CDP compatibility of LLDP, see "Configuring LLDP."

- Disable the protocol (for example, STP) on the PE ports connecting to an aggregate interface on a CE when the following conditions exist:
  - The protocol is running on the aggregate interface on the CE.
  - The aggregate interface on the CE connects to an L2PT-enabled port on the PE.
- Enable L2PT on PE ports connected to a customer network. If you enable L2PT on ports connected to the service provider network, L2PT determines that the ports are connected to a customer network.
- Make sure the VLAN tags of Layer 2 protocol packets are not changed or deleted for the tunneled packets to be transmitted correctly across the service provider network.

- L2PT for LLDP supports LLDP packets from only nearest bridge agents.
- You can enable L2PT on a member port of a Layer 2 aggregation group, but the configuration does not take effect.

Enabling L2PT for a protocol in Layer 2 Ethernet interface view

Restrictions and guidelines

LACP and EOAM require point-to-point transmission. If you enable L2PT on a Layer 2 Ethernet interface for LACP or EOAM, L2PT multicasts LACP or EOAM packets out of customer-facing ports. As a result, the transmission between two CEs is not point-to-point. To ensure point-to-point transmission for the LACP or EOAM packets, you must configure other features (for example, VLAN).

Procedure

1. Enter system view.

   system-view
2. Enter Layer 2 Ethernet interface view.

   interface *interface-type interface-number*
3. Enable L2PT for a protocol.

   l2protocol { **cdp** | **dldp** | **eoam** | **gvrp** | **lacp** | **lldp** | **mvrp** | **pvst** | **stp** } **tunnel dot1q**

   By default, L2PT is disabled for all protocols.

Enabling L2PT for a protocol in Layer 2 aggregate interface view

1. Enter system view.

   system-view
2. Enter Layer 2 aggregate interface view.

   interface bridge-aggregation *interface-type interface-number*
3. Enable L2PT for a protocol.

   l2protocol { **cdp** | **gvrp** | **lacp** | **lldp** | **mvrp** | **pvst** | **stp** } **tunnel dot1q**

   l2protocol { **all** | **cdp** | **gvrp** | **lacp** | **lldp** | **mvrp** | **pagp** | **pvst** | **stp** | **udld** | **vtp** } **tunnel dot1q** [**vlan**]

   By default, L2PT is disabled for all protocols.

Setting the destination multicast MAC address for tunneled packets

About this task

The default destination multicast MAC address for tunneled packets is 010f-e200-0003. You can modify the destination multicast MAC address for tunneled packets of the specific protocol or all protocols.

Restrictions and guidelines

The **l2protocol tunnel-dmac** command sets the destination multicast MAC address for tunneled packets of all protocols. The **l2protocol type tunnel-dmac** command sets the destination multicast MAC address for tunneled packets of the specified protocol. If both commands are executed, the **l2protocol type tunnel-dmac** command takes priority.

For tunneled packets to be recognized, set the same destination multicast MAC addresses for packets of the same protocol on PEs that are connected to the same customer network.

As a best practice, set different destination multicast MAC addresses on PEs connected to different customer networks. It prevents L2PT from sending packets of a customer network to another customer network.

Procedure

1. Enter system view.
   system-view
2. Set the destination multicast MAC address for tunneled packets of all protocols.
   l2protocol tunnel-dmac *mac-address*
   By default, 010f-e200-0003 is used for tunneled packets.

Configuring the maximum rate of transparently transmitting packets of the specified protocol on an L2TP-enabled interface

About this task

When there are a large number of protocol packets on the user side, the bandwidth resources of an L2TP-enabled interface might be all occupied by few protocols. As a result, packets of the other protocols will be congested and cannot be transparently transmitted. By configuring the maximum rate of transparently transmitting packets of each protocol on an interface, you can easily plan the bandwidth ratio for each protocol and fully utilize the interface bandwidth resources.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter Layer 2 aggregate interface view.
     interface bridge-aggregation *interface-number*

3. Configure the maximum rate of transparently transmitting packets of the specified protocol on the L2TP-enabled interface.
   - In Layer 2 Ethernet interface view:

     l2protocol rate-limit *rate* [**cdp** | **dldp** | **eoam** | **gvrp** | **lacp** | **lldp** | **mvrp** | **pvst** | **stp**]
   - In Layer 2 aggregate interface view:

     l2protocol rate-limit *rate* [**cdp** | **gvrp** | **lacp** | **lldp** | **mvrp** | **pvst** | **stp**]

   By default, the device does not limit the rate of transparently transmitting packets of a protocol on an L2TP-enabled interface.

   If you do not specify any protocol, this command configures the maximum rate of transparently transmitting packets of each protocol.

Display and maintenance commands for L2PT

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display L2PT statistics.	**display l2protocol statistics** [**interface** *interface-type interface-number*]
Clear L2PT statistics.	**reset l2protocol statistics** [**interface** *interface-type interface-number*]

L2PT configuration examples

Example: Configuring L2PT for STP

Network configuration

As shown in Figure 4, the MAC addresses of CE 1 and CE 2 are 00e0-fc02-5800 and 00e0-fc02-5802, respectively. MSTP is enabled in Customer A's network, and default MSTP settings are used.

Perform the following tasks on the PEs:

- Configure the ports that connect to CEs as access ports, and configure the ports in the service provider network as trunk ports. Configure ports in the service provider network to allow packets from any VLAN to pass.
- Enable L2PT for STP to enable Customer A's network to implement independent spanning tree calculation across the service provider network.
- Set the destination multicast MAC address to 0100-0ccd-cdd0 for tunneled packets.

Figure 4 Network diagram

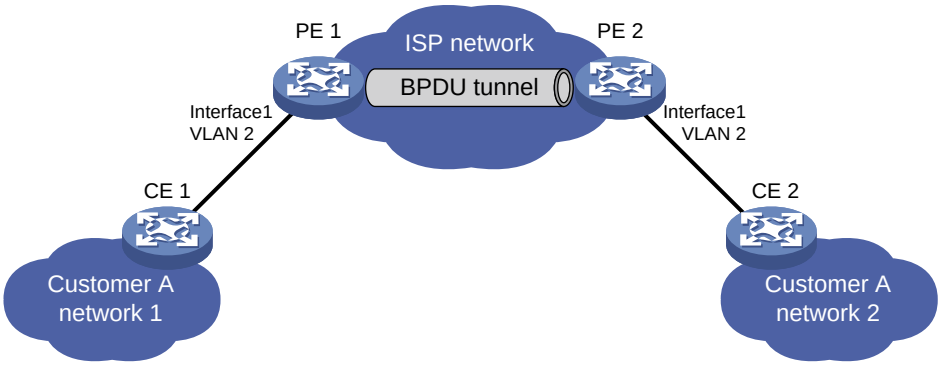


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

1. Configure PE 1:

   # Set the destination multicast address to 0100-0ccd-cdd0 for tunneled packets.

   ```
   <PE1> system-view
   [PE1] l2protocol tunnel-dmac 0100-0ccd-cdd0
   ```

   # Create VLAN 2.

   ```
   [PE1] vlan 2
   [PE1-vlan2] quit
   ```

   # Configure GigabitEthernet 1/0/1 as an access port and assign the port to VLAN 2.

   ```
   [PE1] interface gigabitethernet 1/0/1
   [PE1-GigabitEthernet1/0/1] port access vlan 2
   ```

   # Disable STP and enable L2PT for STP on GigabitEthernet 1/0/1.

   ```
   [PE1-GigabitEthernet1/0/1] undo stp enable
   [PE1-GigabitEthernet1/0/1] l2protocol stp tunnel dot1q
   [PE1-GigabitEthernet1/0/1] quit
   ```

   # Configure GigabitEthernet 1/0/2 connected to the service provider network as a trunk port, and assign the port to all VLANs.

   ```
   [PE1] interface gigabitethernet 1/0/2
   [PE1-GigabitEthernet1/0/2] port link-type trunk
   [PE1-GigabitEthernet1/0/2] port trunk permit vlan all
   [PE1-GigabitEthernet1/0/2] quit
   ```

2. Configure PE 2 in the same way PE 1 is configured. (Details not shown.)

Verifying the configuration

Verify that the root bridge of Customer A's network is CE 1.

```
<CE2> display stp root
 MST ID   Root Bridge ID       ExtPathCost IntPathCost Root Port
 0        32768.00e0-fc02-5800 0           0
```

Verify that the root bridge of the service provider network is not CE 1.

```
[PE1] display stp root
 MST ID   Root Bridge ID       ExtPathCost IntPathCost Root Port
 0        32768.0cda-41c5-ba50 0           0
```

Example: Configuring L2PT for LACP

Network configuration

As shown in Figure 5, the MAC addresses of CE 1 and CE 2 are 0001-0000-0000 and 0004-0000-0000, respectively.

Perform the following tasks:

- Configure Ethernet link aggregation on CE 1 and CE 2.
- Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 on CE 1 to form aggregate links with GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 on CE 2, respectively.
- Enable L2PT for LACP to enable CE 1 and CE 2 to implement Ethernet link aggregation across the service provider network.

Figure 5 Network diagram

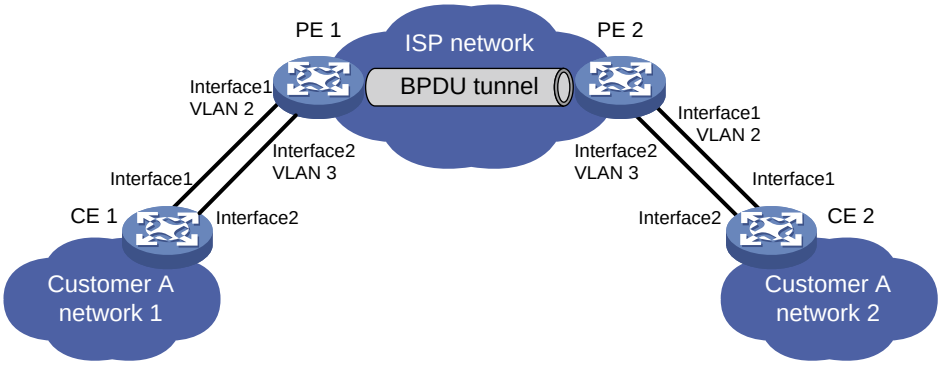

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Requirements analysis

To meet the network requirements, perform the following tasks:

- For Ethernet link aggregation to operate correctly, configure VLANs on the PEs to ensure point-to-point transmission between CE 1 and CE 2 in an aggregation group.
  - Set the PVIDs to VLAN 2 and VLAN 3 for GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 on PE 1, respectively.
  - Configure PE 2 in the same way PE 1 is configured.
  - Configure ports that connect to the CEs as trunk ports.
- To retain the VLAN tag of the customer network, enable QinQ on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 on both PE 1 and PE 2.
- For packets from any VLAN to be transmitted, configure all ports in the service provider network as trunk ports.

Procedure

1. Configure CE 1:

   # Configure Layer 2 aggregation group Bridge-Aggregation 1 to operate in dynamic aggregation mode.

```
<CE1> system-view
[CE1] interface bridge-aggregation 1
[CE1-Bridge-Aggregation1] port link-type access
[CE1-Bridge-Aggregation1] link-aggregation mode dynamic
[CE1-Bridge-Aggregation1] quit
```

   # Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to Bridge-Aggregation 1.

```
[CE1] interface gigabitethernet 1/0/1
[CE1-GigabitEthernet1/0/1] port link-aggregation group 1
[CE1-GigabitEthernet1/0/1] quit
[CE1] interface gigabitethernet 1/0/2
[CE1-GigabitEthernet1/0/2] port link-aggregation group 1
[CE1-GigabitEthernet1/0/2] quit
```

2. Configure CE 2 in the same way CE 1 is configured. (Details not shown.)
3. Configure PE 1:

   # Create VLANs 2 and 3.

```
<PE1> system-view
[PE1] vlan 2
[PE1-vlan2] quit
[PE1] vlan 3
[PE1-vlan3] quit
```

   # Configure GigabitEthernet 1/0/1 as a trunk port, assign the port to VLAN 2, and set the PVID to VLAN 2.

```
[PE1] interface gigabitethernet 1/0/1
[PE1-GigabitEthernet1/0/1] port link-mode bridge
[PE1-GigabitEthernet1/0/1] port link-type trunk
[PE1-GigabitEthernet1/0/1] port trunk permit vlan 2
[PE1-GigabitEthernet1/0/1] port trunk pvid vlan 2
```

   # Enable QinQ on GigabitEthernet 1/0/1.

```
[PE1-GigabitEthernet1/0/1] qinq enable
```

   # Enable L2PT for LACP on GigabitEthernet 1/0/1.

```
[PE1-GigabitEthernet1/0/1] l2protocol lacp tunnel dot1q
[PE1-GigabitEthernet1/0/1] quit
```

   # Configure GigabitEthernet 1/0/2 as a trunk port, assign the port to VLAN 3, and set the PVID to VLAN 3.

```
[PE1] interface gigabitethernet 1/0/2
[PE1-GigabitEthernet1/0/2] port link-mode bridge
[PE1-GigabitEthernet1/0/2] port link-type trunk
[PE1-GigabitEthernet1/0/2] port trunk permit vlan 3
[PE1-GigabitEthernet1/0/2] port trunk pvid vlan 3
```

   # Enable QinQ on GigabitEthernet 1/0/2.

```
[PE1-GigabitEthernet1/0/2] qinq enable
```

   # Enable L2PT for LACP on GigabitEthernet 1/0/2.

```
[PE1-GigabitEthernet1/0/2] l2protocol lacp tunnel dot1q
[PE1-GigabitEthernet1/0/2] quit
```

4. Configure PE 2 in the same way PE 1 is configured. (Details not shown.)

Verifying the configuration

Verify that CE 1 and CE 2 have completed Ethernet link aggregation successfully.

```
[CE1] display link-aggregation member-port

Preface

This configuration guide describes the IP services fundamentals and configuration procedures.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

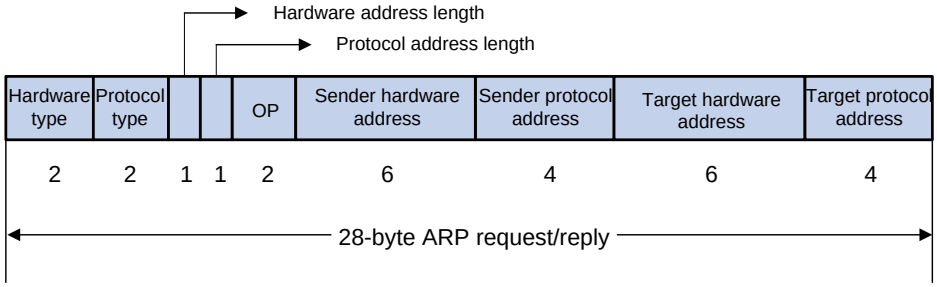
Configuring ARP



About ARP

ARP resolves IP addresses into MAC addresses on Ethernet networks.

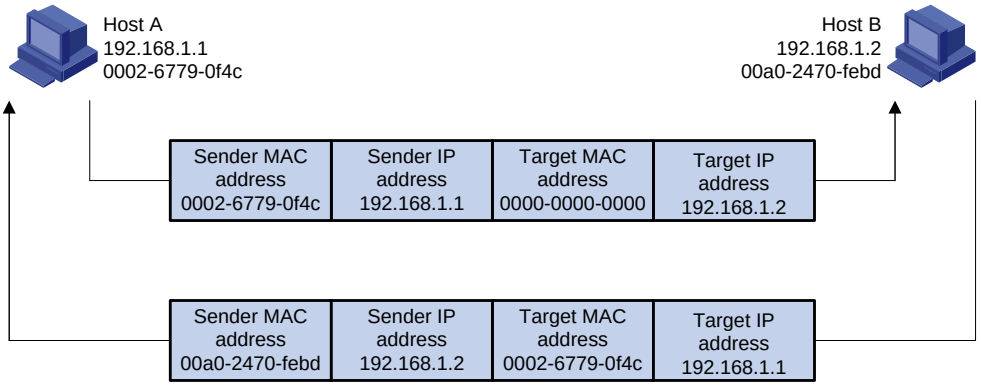
ARP message format

ARP uses two types of messages: ARP request and ARP reply. Figure 1 shows the format of ARP request/reply messages. Numbers in the figure refer to field lengths.

Figure 1 ARP message format

- **Hardware type**—Hardware address type. The value 1 represents Ethernet.
- **Protocol type**—Type of the protocol address to be mapped. The hexadecimal value 0x0800 represents IP.
- **Hardware address length and protocol address length**—Length, in bytes, of a hardware address and a protocol address. For an Ethernet address, the value of the hardware address length field is 6. For an IPv4 address, the value of the protocol address length field is 4.
- **OP**—Operation code, which describes the type of ARP message. The value 1 represents an ARP request, and the value 2 represents an ARP reply.
- **Sender hardware address**—Hardware address of the device sending the message.
- **Sender protocol address**—Protocol address of the device sending the message.
- **Target hardware address**—Hardware address of the device to which the message is being sent.
- **Target protocol address**—Protocol address of the device to which the message is being sent.

ARP operating mechanism



As shown in Figure 2, Host A and Host B are on the same subnet. Host A sends a packet to Host B as follows:

1. Host A looks through the ARP table for an ARP entry for Host B. If one entry is found, Host A uses the MAC address in the entry to encapsulate the IP packet into a data link layer frame. Then Host A sends the frame to Host B.
2. If Host A finds no entry for Host B, Host A buffers the packet and broadcasts an ARP request. The payload of the ARP request contains the following information:
   - **Sender IP address and sender MAC address**—Host A's IP address and MAC address.
   - **Target IP address**—Host B's IP address.
   - **Target MAC address**—An all-zero MAC address.

All hosts on this subnet can receive the broadcast request, but only the requested host (Host B) processes the request.

3. Host B compares its own IP address with the target IP address in the ARP request. If they are the same, Host B operates as follows:
   a. Adds the sender IP address and sender MAC address into its ARP table.
   b. Encapsulates its MAC address into an ARP reply.
   c. Unicasts the ARP reply to Host A.
4. After receiving the ARP reply, Host A operates as follows:
   a. Adds the MAC address of Host B into its ARP table.
   b. Encapsulates the MAC address into the packet and sends the packet to Host B.

Figure 2 ARP address resolution process

If Host A and Host B are on different subnets, Host A sends a packet to Host B as follows:

5. Host A broadcasts an ARP request where the target IP address is the IP address of the gateway.
6. The gateway responds with its MAC address in an ARP reply to Host A.
7. Host A uses the gateway's MAC address to encapsulate the packet, and then sends the packet to the gateway.
8. If the gateway has an ARP entry for Host B, it forwards the packet to Host B directly. If not, the gateway broadcasts an ARP request, in which the target IP address is the IP address of Host B.
9. After the gateway gets the MAC address of Host B, it sends the packet to Host B.

ARP entry types

An ARP table stores dynamic ARP entries, OpenFlow ARP entries, Rule ARP entries, and static ARP entries.

Dynamic ARP entry

ARP automatically creates and updates dynamic entries. A dynamic ARP entry is removed when its aging timer expires or the output interface goes down. In addition, a dynamic ARP entry can be overwritten by a static ARP entry.

Static ARP entry

A static ARP entry is manually configured and maintained. It does not age out and cannot be overwritten by any dynamic ARP entry.

Static ARP entries protect communication between devices because attack packets cannot modify the IP-to-MAC mapping in a static ARP entry.

The device supports the following types of static ARP entries:

- **Long static ARP entry**—It is directly used for forwarding packets. A long static ARP entry contains the IP address, MAC address, VLAN, and output interface.
- **Short static ARP entry**—It contains only the IP address and MAC address.

  If the output interface is a Layer 3 Ethernet interface, the short ARP entry can be directly used to forward packets.

  If the output interface is a VLAN interface, the device sends an ARP request whose target IP address is the IP address in the short entry. If the sender IP and MAC addresses in the received ARP reply match the short static ARP entry, the device performs the following operations:
  - Adds the interface that received the ARP reply to the short static ARP entry.
  - Uses the resolved short static ARP entry to forward IP packets.
- **Multiport ARP entry**—It contains the IP address, MAC address, and VLAN information.

  The device can use a multiport ARP entry that has the same MAC address and VLAN as a multicast or multiport unicast MAC address entry for packet forwarding. A multiport ARP entry is manually configured. It does not age out and cannot be overwritten by any dynamic ARP entry.

To communicate with a host by using a fixed IP-to-MAC mapping, configure a short static ARP entry on the device. To communicate with a host by using a fixed IP-to-MAC mapping through an interface in a VLAN, configure a long static ARP entry on the device.

OpenFlow ARP entry

ARP creates OpenFlow ARP entries by learning from the OpenFlow module. An OpenFlow ARP entry does not age out, and it cannot be updated. An OpenFlow ARP entry can be used directly to forward packets. For more information about OpenFlow, see *OpenFlow Configuration Guide*.

Rule ARP entry

Rule ARP entries can be directly used for packet forwarding. A Rule ARP entry does not age out, and it cannot be updated. It can be overwritten by a static ARP entry.

ARP creates Rule ARP entries by learning from the following modules:

- Portal. For more information about portal, see *Security Configuration Guide*.

ARP tasks at a glance

All ARP tasks are optional.

- Configuring a static ARP entry
  - Configuring a short static ARP entry
  - Configuring a long static ARP entry
  - Configuring a multiport ARP entry
- Configuring features for dynamic ARP entries
  - Setting the dynamic ARP learning limit for a device
  - Setting the dynamic ARP learning limit for an interface
  - Setting the aging timer for dynamic ARP entries
  - Setting the maximum number of probes for dynamic ARP entries
  - Setting the interval for probing dynamic ARP entries
  - Enabling dynamic ARP entry check
- Synchronizing ARP entries across all member devices
- Enabling user information checking for ARP entries
  - Enabling recording user IP address conflicts
  - Enabling interface consistency check between ARP and MAC address entries

    - Enabling recording user port migrations
    - Enabling ARP entry consistency check
- Enabling unknown source MAC-triggered ARP probing
- Enabling ARP logging
- Enabling error logging for ARP entry deployment to hardware
- Enabling the device to send only ARP broadcast requests destined for a VLAN interface on it to the CPU
- (Optional.) Disabling the device from aging or deleting ARP entries in response to network topology changes
- (Optional.) Disabling sending ARP requests when data packets trigger ARP resolution

Configuring a static ARP entry

Static ARP entries are effective when the device functions correctly.

Configuring a short static ARP entry

Restrictions and guidelines

A resolved short static ARP entry becomes unresolved upon certain events, for example, when the resolved output interface goes down, or the corresponding VLAN or VLAN interface is deleted.

Procedure

1. Enter system view.

   system-view
2. Configure a short static ARP entry.

   arp static *ip-address mac-address* [**vpn-instance** *vpn-instance-name*] [**description** *text*]

Configuring a long static ARP entry

About this task

Long static ARP entries can be effective or ineffective. Ineffective long static ARP entries cannot be used for packet forwarding. A long static ARP entry is ineffective when any of the following conditions exists:

- The IP address in the entry conflicts with a local IP address.
- No local interface has an IP address in the same subnet as the IP address in the ARP entry.

A long static ARP entry for a VLAN is deleted if the VLAN or VLAN interface is deleted.

Procedure

1. Enter system view.

   system-view
2. Configure a long static ARP entry.

   arp static *ip-address mac-address* [*vlan-id interface-type interface-number* | *interface-type interface-number interface-type interface-number*] [**vpn-instance** *vpn-instance-name*] [**description** *text*]

Configuring a multiport ARP entry

About this task

A multiport ARP entry contains an IP address, MAC address, output interface, and VLAN ID information. The VLAN and output interfaces are specified by a multiport unicast MAC address entry or a multicast MAC address entry. For more information about multiport unicast MAC address entries, see *Layer 2—LAN Switching Configuration Guide*. For more information about multicast MAC address entries, see IGMP snooping configuration in *IP Multicast Configuration Guide*.

A multiport ARP entry can overwrite a dynamic, short static or long static ARP entry. Conversely, a short static or long static ARP entry can overwrite a multiport ARP entry.

Restrictions and guidelines

For a multiport ARP entry to be effective for packet forwarding, make sure the following conditions are met:

- A multiport unicast MAC address entry or a multicast MAC address entry exists.
- The multiport ARP entry must have the same MAC address and VLAN ID as the multiport unicast MAC address entry or the multicast MAC address entry.
- The IP address in the multiport ARP entry must reside on the same subnet as the VLAN interface of the specified VLAN.

Procedure

1. Enter system view.

   system-view
2. Configure a multiport unicast MAC address entry or a multicast MAC address entry.
   - Configure a multiport unicast MAC address entry.

     mac-address multiport *mac-address* **interface** *interface-list* **vlan** *vlan-id*
   - Configure a multicast MAC address entry.

     mac-address multicast *mac-address* **interface** *interface-list* **vlan** *vlan-id*
3. Configure a multiport ARP entry.

   arp multiport *ip-address mac-address vlan-id* [**vpn-instance** *vpn-instance-name*] [**description** *text*]

Configuring features for dynamic ARP entries

Setting the dynamic ARP learning limit for a device

About this task

A device can dynamically learn ARP entries. To prevent a device from holding too many ARP entries, you can set the maximum number of dynamic ARP entries that the device can learn. When the limit is reached, the device stops ARP learning.

If you set a value lower than the number of existing dynamic ARP entries, the device does not delete the existing entries unless they age out. You can use the **reset arp dynamic** command to clear dynamic ARP entries.

Procedure

1. Enter system view.

   system-view

2. Set the dynamic ARP learning limit for the device.

   arp max-learning-number *max-number* **slot** *slot-number*

   For the S5200-HI-G switch series, a device can learn a maximum of 32768 dynamic ARP entries. For the S5200-EI-G switch series, a device can learn a maximum of 12288 dynamic ARP entries.

   To disable the device from dynamic ARP learning, set the value to 0.

Setting the dynamic ARP learning limit for an interface

About this task

An interface can dynamically learn ARP entries. To prevent an interface from holding too many ARP entries, you can set the maximum number of dynamic ARP entries that the interface can learn. When the limit is reached, the interface stops ARP learning.

You can set limits for both a Layer 2 interface and the VLAN interface for a permitted VLAN on the Layer 2 interface. The Layer 2 interface learns an ARP entry only when neither limit is reached.

The total dynamic ARP learning limit for all interfaces will not be higher than the dynamic ARP learning limit for the device.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the dynamic ARP learning limit for the interface.

   arp max-learning-num *max-number* [**alarm** *alarm-threshold*]

   For the S5200-HI-G switch series, an interface can learn a maximum of 32768 dynamic ARP entries. For the S5200-EI-G switch series, an interface can learn a maximum of 12288 dynamic ARP entries.

   To disable the interface from dynamic ARP learning, set the value to 0.

Setting the aging timer for dynamic ARP entries

About this task

Each dynamic ARP entry in the ARP table has a limited lifetime, called an aging timer. The aging timer of a dynamic ARP entry is reset each time the dynamic ARP entry is updated. A dynamic ARP entry that is not updated before its aging timer expires is deleted from the ARP table.

You can set the aging timer for dynamic ARP entries in system view or in interface view. The aging timer set in interface view takes precedence over the aging timer set in system view.

Procedure

1. Enter system view.

   system-view

2. Set the aging timer for dynamic ARP entries.
   - Set the aging timer for dynamic ARP entries in system view.

     arp timer aging { *aging-minutes* | **second** *aging-seconds* }

     By default, the aging timer for dynamic ARP entries in system view is 20 minutes.
   - Execute the following commands in sequence to set the aging timer for dynamic ARP entries in interface view:

interface *interface-type interface-number*

arp timer aging { *aging-minutes* | **second** *aging-seconds* }

By default, the aging timer for dynamic ARP entries in interface view is the aging timer set in system view.

Setting the maximum number of probes for dynamic ARP entries

About this task

This probe mechanism keeps legal dynamic ARP entries valid and avoids unnecessary ARP resolution during later traffic forwarding. It sends ARP requests for the IP address in a dynamic ARP entry.

- If the device receives an ARP reply before the entry aging timer expires, the device resets the aging timer.
- If the device does not receive any ARP reply after the maximum number of probes is made, the device deletes the entry when the entry aging timer expires.

You can set the maximum number of probes in system view or in interface view. The setting in interface view takes precedence over that in system view.

Procedure

1. Enter system view.

   system-view

2. Set the maximum number of probes for dynamic ARP entries.
   - Set the maximum number of probes for dynamic ARP entries in system view.

     arp timer aging probe-count *count*

     By default, the maximum number of probes for dynamic ARP entries is 3 in system view.
   - Execute the following commands in sequence to set the maximum number of probes for dynamic ARP entries on an interface:

     interface *interface-type interface-number*

     arp timer aging probe-count *count*

     By default, the maximum number of probes for dynamic ARP entries set on an interface is that set in system view.

Setting the interval for probing dynamic ARP entries

About this task

The probing feature keeps legal dynamic ARP entries valid and avoids unnecessary ARP resolution during later traffic forwarding.

Before a dynamic ARP entry is aged out, the device sends ARP requests for the IP address in the ARP entry.

- If the device receives an ARP reply during the probe interval, the device resets the aging timer.
- If the device does not receive any ARP reply during the probe interval, the device starts a new probe.
- If the maximum number probes are made, and still no ARP reply is received, the device deletes the entry.

You can set the probe interval in system view and in interface view. The probe interval in interface view takes precedence over the probe interval in system view.

Restrictions and guidelines

- If massive traffic exists in the network, set a long interval.
- During the dynamic ARP entry probing process, a dynamic ARP entry will not be deleted when its aging time expires. If a reply is received during the probe, the aging timer of the ARP entry is reset.
- To allow the device to perform the specified number of probes, make sure the following requirement is met:

  Aging time of the dynamic ARP entries > the maximum number of probes × probe interval

Procedure

1. Enter system view.

   system-view
2. Set the interval for probing dynamic ARP entries.
   - Set the interval for probing dynamic ARP entries in system view.

     arp timer aging probe-interval *interval*

     By default, the probe interval is 5 seconds.
   - Execute the following commands in sequence to set the interval for probing dynamic ARP entries on an interface:

     interface *interface-type interface-number*

     arp timer aging probe-interval *interval*

     By default, the probe interval equals the setting in system view.

Enabling dynamic ARP entry check

About this task

The dynamic ARP entry check feature disables the device from supporting dynamic ARP entries that contain multicast MAC addresses. The device cannot learn dynamic ARP entries containing multicast MAC addresses. You cannot manually add static ARP entries containing multicast MAC addresses.

When dynamic ARP entry check is disabled, ARP entries containing multicast MAC addresses are supported. The device can learn dynamic ARP entries containing multicast MAC addresses obtained from the ARP packets sourced from a unicast MAC address. You can also manually add static ARP entries containing multicast MAC addresses.

Procedure

1. Enter system view.

   system-view
2. Enable dynamic ARP entry check.

   arp check enable

   By default, dynamic ARP entry check is enabled.

Synchronizing ARP entries across all member devices

About this task

This task ensures that all IRF member devices in an IRF fabric have the same ARP entries.

Restrictions and guidelines

To synchronize ARP entries across all member devices in a timely manner, you can schedule the device to automatically execute the **arp smooth** command. For information about scheduling a task, see the device management configuration in *Fundamentals Configuration Guide*.

Procedure

To synchronize ARP entries from the master device to all subordinate devices, execute the following command in user view:

arp smooth

Enabling recording user IP address conflicts

About this task

This feature enables the device to detect and record user IP address conflicts. The device determines that a conflict occurs if an incoming ARP packet has the same sender IP address as an existing ARP entry but a different sender MAC address. The device generates a user IP address conflict record, logs the conflict, and sends the log to the information center. For information about the log destination and output rule configuration in the information center, see the information center in *Network Management and Monitoring Configuration Guide*.

After you enable SNMP notifications for user IP address conflict events, the device sends a notification to the SNMP module when a user IP address conflict occurs. The notification includes the sender IP and MAC addresses in the conflicting ARP packet, and MAC address in the corresponding local ARP entry. For ARP event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*. For more information about SNMP notifications for ARP, see ARP attack protection configuration in *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable recording user IP address conflicts.

   arp user-ip-conflict record enable

   By default, recording user IP address conflicts is disabled.

3. (Optional.) Enable SNMP notifications for ARP.

   snmp-agent trap enable arp [**user-ip-conflict**]

   By default, SNMP notifications for ARP are disabled.

   If you do not specify the **user-ip-conflict** keyword, this command enables all types of SNMP notifications for ARP. If you specify the **user-ip-conflict** keyword, this command enables SNMP notifications for user IP address conflict events.

Enabling interface consistency check between ARP and MAC address entries

About this task

In an unstable network, the receiving interface for packets from a user might change. The interface in the MAC address entry can be updated immediately while the interface in the ARP entry cannot. In this case, the packets matching the ARP entry will be sent out of an incorrect interface. To solve this problem, you can use this feature to periodically check the interface consistency between the ARP

and MAC address entry for a user. If the interfaces are not the same, ARP sends ARP requests in the VLAN of the ARP entry and updates the entry with the ARP reply receiving interface.

Use **display mac-address** to display MAC address entries. For more information about this command, see MAC address table in *Layer 2—LAN Switching Command Reference.*

Procedure

1. Enter system view.

   system-view
2. Enable interface consistency check between ARP and MAC address entries.

   arp mac-interface-consistency check enable

   By default, interface consistency check between ARP and MAC address entries is disabled.

Enabling recording user port migrations

About this task

This feature enables the device to detect and record user port migration events. A user port migrates if an incoming ARP packet has the same sender IP address and sender MAC address as an existing ARP entry but a different ingress port. The device generates a user port migration record, logs the migration event, sends the log to the information center, and updates the interface for the ARP entry. For information about the log destination and output rule configuration in the information center, see the information center in *Network Management and Monitoring Configuration Guide*.

After you enable SNMP notifications for user port migration events, the device sends a notification to the SNMP module when a user port migration occurs. The notification includes the IP and MAC addresses of the user who has a different ingress port, original port name, and new port name. For ARP event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*. For more information about SNMP notifications for ARP, see ARP attack protection configuration in *Security Configuration Guide*.

Restrictions and guidelines

To avoid device performance degradation, disable recording user port migrations if too many user port migration logs are generated.

Procedure

1. Enter system view.

   system-view
2. Enable recording user port migrations.

   arp user-move record enable

   By default, recording user port migrations is disabled.
3. (Optional.) Enable SNMP notifications for ARP.

   snmp-agent trap enable arp [**user-move**]

   By default, SNMP notifications for ARP are disabled.

   If you do not specify the **user-move** keyword, this command enables all types of SNMP notifications for ARP. If you specify the **user-move** keyword, this command enables SNMP notifications for user port migration events.

Enabling ARP entry consistency check

About this task

This feature enables the device to periodically deploy all ARP software entries to the driver for ARP software and hardware entry consistency check. If an inconsistency is identified, the device generates a log, and refreshes the hardware entry based on the software entry.

Procedure

1. Enter system view.
   system-view
2. Enable ARP entry consistency check between software and hardware entries.
   arp consistency-check enable
   By default, ARP entry consistency check between software and hardware entries is disabled.

Enabling unknown source MAC-triggered ARP probing

About this task

By default, upon receiving a data packet with an unknown source MAC address from a user, the device learns a MAC address entry. It does not learn an ARP entry so the device cannot send packets destined for the user. To resolve this issue, you can enable unknown source MAC-triggered ARP probing.

This feature enables the device to perform ARP probing upon receiving a data packet with an unknown source MAC address. During ARP probing, the device sends an ARP request out of the receiving interface with the source IP address of the data packet as the target MAC address. If the device receives an ARP reply, the device creates an ARP entry.

In inter-AC roaming, a client roams among APs that are managed by different ACs with its IP address unchanged. For the client to receive packets after it roams to a new AC, enable this feature on the ACs.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable unknown source MAC-triggered ARP probing.
   arp unknown-source-mac-probing enable
   By default, unknown source MAC-triggered ARP probing is disabled.

Enabling ARP logging

About this task

This feature enables a device to log ARP events when ARP cannot resolve IP addresses correctly. The log information helps administrators locate and solve problems. The device can log the following ARP events:

- On a proxy ARP-disabled interface, the target IP address in a received ARP packet is not one of the following IP addresses:

    - The IP address of the receiving interface.
    - The virtual IP address of the VRRP group.
- The sender IP address in a received ARP reply conflicts with one of the following IP addresses:
    - The IP address of the receiving interface.
    - The virtual IP address of the VRRP group.

The device sends ARP log messages to the information center. You can use the **info-center source** command to specify the log output rules for the information center. For more information about information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enable ARP logging.
   arp check log enable
   By default, ARP logging is disabled.

Enabling error logging for ARP entry deployment to hardware

About this task

After the device learns ARP entries, it deploys the ARP entries to hardware for packet forwarding. After you enable this feature, the device logs the errors that occur during the deployment. The logs are sent to the information center of the device. For the logs to be output correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

Log generation occupies memory. As a best practice, enable this feature only when traffic forwarding is abnormal for troubleshooting.

If the maximum number of logs that can be output per second is reached, no new error logs will be output.

Procedure

1. Enter system view.
   system-view
2. Enable error logging for ARP entry deployment to hardware.
   arp hardware log enable [**count-limit** *count-limit-value*]
   By default, error logging for ARP entry deployment to hardware is disabled.

Enabling the device to send only ARP broadcast requests destined for a VLAN interface on it to the CPU

About this task

By default, the device sends all received ARP broadcast requests to the CPU, which consumes a lot of CPU resources. To resolve the issue, use this command to enable the device to send only ARP broadcast requests that have the same IP address as that of a VLAN interface on the device to the CPU.

Restrictions and guidelines

This feature is mutually exclusive with the proxy ARP and local proxy ARP features.

Procedure

1. Enter system view.

   system-view

2. Enter VLAN interface view.

   interface vlan-interface *interface-number*

3. Enable the device to send only ARP broadcast requests destined for a VLAN interface on it to the CPU.

   arp broadcast pass-through enable

   By default, the device sends all received ARP broadcast requests to the CPU.

Disabling the device from aging or deleting ARP entries in response to network topology changes

About this task

After you configure STP for the device in a tree-shaped network topology, the system notifies the ARP module to age or delete the learned ARP entries when the loop protocol detects a network topology change. Then, the device must learn ARP entries again to obtain the latest ARP entry information. If the network topology changes frequently, a large number of ARP packets might occur when the device relearns ARP entries, which occupies too many system resources and affects the normal operation of other services. To avoid such an issue, you can execute the **undo arp topology-change enable** command. Even if the network topology changes, the device does not age or delete ARP entries.

Restrictions and guidelines

After you disable the device from aging or deleting ARP entries in response to network topology changes, the ARP entries saved by the device might not be the latest ones, which causes user traffic interruption. As a best practice, use this command only when necessary.

Procedure

1. Enter system view.

   system-view

2. Disable the device from aging or deleting ARP entries in response to network topology changes.

   undo arp topology-change enable

By default, the device ages or deletes ARP entries in response to network topology changes.

Disabling sending ARP requests when data packets trigger ARP resolution

About this task

By default, when the device receives a data packet not destined for it and cannot find a match for the next hop in the ARP table, it performs the following tasks:

1. Sends an ARP request to obtain the MAC address of the next hop.
2. Generates an ARP entry based on the obtained MAC address.

A large number of ARP requests consume too many network resources, affecting normal service operation. To resolve the issue, use this feature to disable the device from sending ARP requests for ARP learning when data packets trigger ARP resolution. This suppresses ARP flooding by reducing ARP packets on the network.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Disable the device from sending ARP requests for ARP learning when data packets trigger ARP resolution.

   arp fib-miss drop

   By default, the device sends ARP requests for ARP learning when data packets trigger ARP resolution.

Display and maintenance commands for ARP

CAUTION:

Clearing ARP entries from the ARP table might cause communication failures. Make sure the entries to be cleared do not affect current communications.

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display ARP entries.	**display arp** [[**all** | **dynamic** | **static**] [**slot** *slot-number*] | **vlan** *vlan-id* | **interface** *interface-type interface-number*] [**count** | **verbose**]
Display the maximum number of ARP entries that a device supports.	**display arp entry-limit**
Display the ARP entry for an IP address.	**display arp** *ip-address* [**slot** *slot-number*] [**verbose**]
Display the number of OpenFlow ARP entries.	**display arp openflow count** [**slot** *slot-number*]
Display the aging timer of dynamic ARP	**display arp timer aging**

Task	Command
entries.	
Display the ARP table usage.	**display arp usage**
Display user IP address conflicts.	**display arp user-ip-conflict record** [**slot** *slot-number*]
Display user port migrations.	**display arp user-move record** [**slot** *slot-number*]

ARP configuration examples

Example: Configuring a long static ARP entry

Network configuration

As shown in Figure 3, hosts are connected to Device B. Device B is connected to Device A through interface GigabitEthernet 1/0/1 in VLAN 10.

To ensure secure communications between Device A and Device B, configure a long static ARP entry for Device A on Device B.

Figure 3 Network diagram

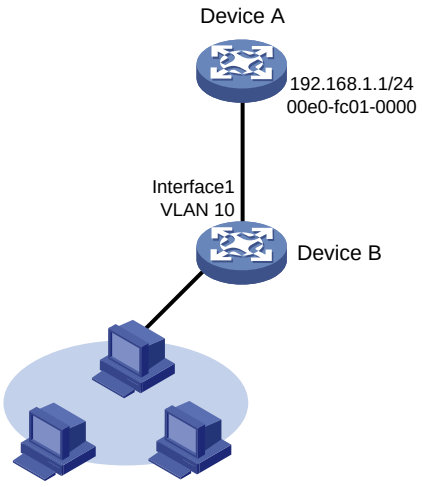

Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1

Procedure

Create VLAN 10.

```
<DeviceB> system-view
[DeviceB] vlan 10
[DeviceB-vlan10] quit
```

Add interface GigabitEthernet 1/0/1 to VLAN 10.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port access vlan 10
[DeviceB-GigabitEthernet1/0/1] quit
```

Create VLAN-interface 10 and configure its IP address.

```
[DeviceB] interface vlan-interface 10
[DeviceB-vlan-interface10] ip address 192.168.1.2 8
[DeviceB-vlan-interface10] quit
```

Configure a long static ARP entry that has IP address 192.168.1.1, MAC address 00e0-fc01-0000, and output interface GigabitEthernet 1/0/1 in VLAN 10.

```
[DeviceB] arp static 192.168.1.1 00e0-fc01-0000 10 gigabitethernet 1/0/1
```

Verifying the configuration

Verify that Device B has a long static ARP entry for Device A.

```
[DeviceB] display arp static
  Type: S-Static   D-Dynamic   O-Openflow   R-Rule   I-Invalid
IP address      MAC address    VLAN/VSI name Interface               Aging Type
192.168.1.1     00e0-fc01-0000 10            GE1/0/1                 --    S
```

Example: Configuring a short static ARP entry

Network configuration

As shown in Figure 4, hosts are connected to Device B. Device B is connected to Device A through interface GigabitEthernet 1/0/2.

To ensure secure communications between Device A and Device B, configure a short static ARP entry for Device A on Device B.

Figure 4 Network diagram

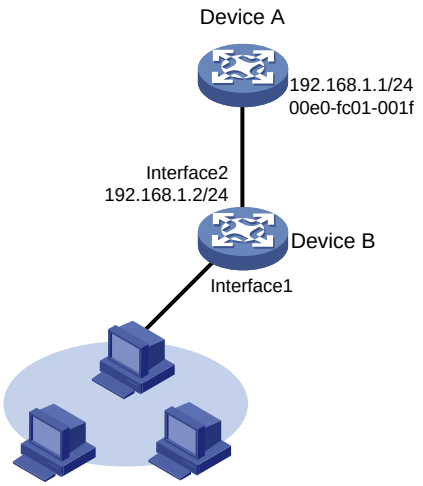

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

Configure an IP address for GigabitEthernet 1/0/2.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] ip address 192.168.1.2 24
[DeviceB-GigabitEthernet1/0/2] quit
```

Configure a short static ARP entry that has IP address 192.168.1.1 and MAC address 00e0-fc01-001f.

```
[DeviceB] arp static 192.168.1.1 00e0-fc01-001f
```

Verifying the configuration

Verify that Device B has a short static ARP entry for Device A

```
[DeviceB] display arp static
  Type: S-Static   D-Dynamic   O-Openflow   R-Rule   I-Invalid
IP address      MAC address    VLAN/VSI name Interface               Aging Type
192.168.1.1     00e0-fc01-001f --            --                      --    S
```

Configuring gratuitous ARP

About gratuitous ARP

In a gratuitous ARP packet, the sender IP address and the target IP address are the IP address of the sending device.

A device sends a gratuitous ARP packet for either of the following purposes:

- Determine whether its IP address is already used by another device. If the IP address is already used, the device is informed of the conflict by an ARP reply.
- Inform other devices of a MAC address change.

IP conflict detection

When an interface obtains an IP address, the device broadcasts gratuitous ARP packets in the LAN where the interface resides. If the device receives an ARP reply, its IP address conflicts with the IP address of another device in the LAN. The device displays a log message about the conflict and informs the administrator to change the IP address. The device will not use the conflicting IP address. If no ARP reply is received, the device uses the IP address.

Gratuitous ARP packet learning

This feature enables a device to create or update ARP entries by using the sender IP and MAC addresses in received gratuitous ARP packets.

When this feature is disabled, the device uses received gratuitous ARP packets to update existing ARP entries only. ARP entries are not created based on the received gratuitous ARP packets, which saves ARP table space.

Periodic sending of gratuitous ARP packets

Periodic sending of gratuitous ARP packets helps downstream devices update ARP entries or MAC entries in a timely manner.

This feature can implement the following functions:

- Prevent gateway spoofing.

  Gateway spoofing occurs when an attacker uses the gateway address to send gratuitous ARP packets to the hosts on a network. The traffic destined for the gateway from the hosts is sent to the attacker instead. As a result, the hosts cannot access the external network.

  To prevent such gateway spoofing attacks, you can enable the gateway to send gratuitous ARP packets at intervals. Gratuitous ARP packets contain the primary IP address and manually configured secondary IP addresses of the gateway, so hosts can learn correct gateway information.
- Prevent ARP entries from aging out.

  If network traffic is heavy or if the host CPU usage is high, received ARP packets can be discarded or are not promptly processed. Eventually, the dynamic ARP entries on the receiving host age out. The traffic between the host and the corresponding devices is interrupted until the host re-creates the ARP entries.

  To prevent this problem, you can enable the gateway to send gratuitous ARP packets periodically. Gratuitous ARP packets contain the primary IP address and manually configured secondary IP addresses of the gateway, so the receiving hosts can update ARP entries in a timely manner.
- Prevent the virtual IP address of a VRRP group from being used by a host.

  The master router of a VRRP group can periodically send gratuitous ARP packets to the hosts on the local network. The hosts can then update local ARP entries and avoid using the virtual IP address of the VRRP group. The sender MAC address in the gratuitous ARP packet is the virtual MAC address of the virtual router. For more information about VRRP, see *High Availability Configuration Guide*.

Gratuitous ARP tasks at a glance

All gratuitous ARP tasks are optional. If all of the following features are disabled, gratuitous ARP still provides the IP conflict detection function.

- Enabling notification for passive IP conflict detection
- Enabling gratuitous ARP packet learning
- Enabling periodic sending of gratuitous ARP packets
- Enabling sending gratuitous ARP packets for ARP requests with sender IP address on a different subnet
- Configuring gratuitous ARP packet retransmission for the device MAC address change

Enabling notification for passive IP conflict detection

About this task

With this feature disabled, the device does not immediately generate an IP conflict notification if it receives an ARP request with the same sender IP address as its interface IP address, or an ARP request with sender IP address 0.0.0.0 and the same target IP address as its interface IP address. Instead, it actively sends a gratuitous ARP packet for confirmation and generates an IP conflict notification only after it receives an ARP reply from the peer.

With this feature enabled, the device immediately generates an IP conflict notification if it receives an ARP request with the same sender IP address as its interface IP address, or an ARP request with sender IP address 0.0.0.0 and the same target IP address as its interface IP address. This helps identify IP conflicts earlier and improves operations efficiency.

Procedure

1. Enter system view.
   `system-view`
2. Enable notification for passive IP conflict detection.
   `arp ip-conflict log prompt`
   By default, notification for passive IP conflict detection is disabled.

Enabling gratuitous ARP packet learning

1. Enter system view.
   `system-view`
2. Enable gratuitous ARP packet learning.
   `gratuitous-arp-learning enable`
   By default, gratuitous ARP packet learning is enabled.

Enabling periodic sending of gratuitous ARP packets

Restrictions and guidelines

- You can enable periodic sending of gratuitous ARP packets on a maximum of 1024 interfaces.
- Periodic sending of gratuitous ARP packets takes effect on an interface only when the following conditions are met:
  - The data link layer state of the interface is up.
  - The interface has an IP address.
- If you change the sending interval for gratuitous ARP packets, the configuration takes effect at the next sending interval.
- The sending interval for gratuitous ARP packets might be much longer than the specified sending interval in any of the following circumstances:
  - This feature is enabled on multiple interfaces.
  - Each interface is configured with multiple secondary IP addresses.
  - A small sending interval is configured when the previous two conditions exist.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable periodic sending of gratuitous ARP packets.
   arp send-gratuitous-arp [**interval** *interval*]
   By default, periodic sending of gratuitous ARP packets is disabled.

Enabling sending gratuitous ARP packets for ARP requests with sender IP address on a different subnet

1. Enter system view.
   system-view
2. Enable the device to send gratuitous ARP packets upon receiving ARP requests whose sender IP address belongs to a different subnet.
   gratuitous-arp-sending enable
   By default, a device does not send gratuitous ARP packets upon receiving ARP requests whose sender IP address belongs to a different subnet.

Configuring gratuitous ARP packet retransmission for the device MAC address change

About this task

The device sends a gratuitous ARP packet to inform other devices of its MAC address change. However, the other devices might fail to receive the packet because the device sends the gratuitous ARP packet once only by default. Configure the gratuitous ARP packet retransmission feature to ensure that the other devices can receive the packet.

Procedure

1. Enter system view.
   system-view
2. Set the times and the interval for retransmitting a gratuitous ARP packet for the device MAC address change.
   gratuitous-arp mac-change retransmit *times* **interval** *seconds*
   By default, the device sends a gratuitous packet to inform its MAC address change once only.

Configuring proxy ARP

About proxy ARP

Proxy ARP enables a device on one network to answer ARP requests for an IP address on another network. With proxy ARP, hosts on different broadcast domains can communicate with each other as they would on the same broadcast domain.

Proxy ARP includes common proxy ARP and local proxy ARP.

- **Common proxy ARP**—Allows communication between hosts that connect to different Layer 3 interfaces and reside in different broadcast domains.
- **Local proxy ARP**—Allows communication between hosts that connect to the same Layer 3 interface and reside in different broadcast domains.

Enabling common proxy ARP

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
   The following interface types are supported:
   - VLAN interface.
   - Layer 3 Ethernet interface.
   - Layer 3 Ethernet subinterface.
   - Layer 3 aggregate interface.
   - Layer 3 aggregate subinterface.
3. Enable common proxy ARP.
   proxy-arp enable
   By default, common proxy ARP is disabled.

Enabling local proxy ARP

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
   The following interface types are supported:
   - VLAN interface.
   - Layer 3 Ethernet interface.
   - Layer 3 Ethernet subinterface.
   - Layer 3 aggregate interface.
   - Layer 3 aggregate subinterface.
3. Enable local proxy ARP.
   local-proxy-arp enable [**ip-range** *start-ip-address* **to** *end-ip-address*]

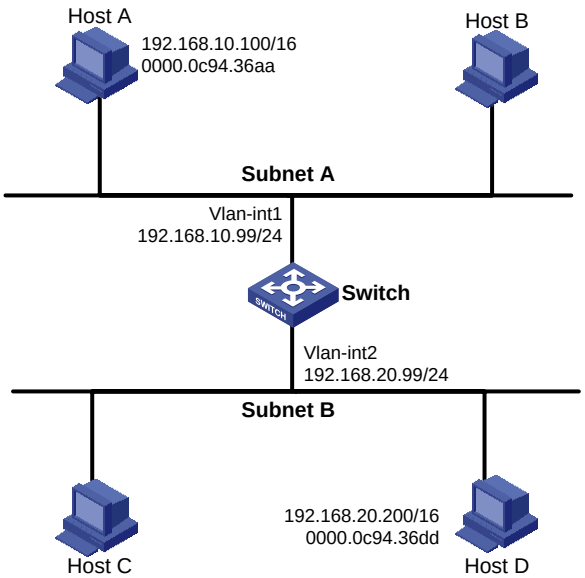
By default, local proxy ARP is disabled.

Display and maintenance commands for proxy ARP

Execute **display** commands in any view.

Task	Command
Display common proxy ARP status.	**display proxy-arp** [**interface** *interface-type interface-number*]
Display local proxy ARP status.	**display local-proxy-arp** [**interface** *interface-type interface-number*]
Display statistics about proxy ARP reply packets.	**display proxy-arp statistics**

Common proxy ARP configuration example



Example: Configuring common proxy ARP

Network configuration

As shown in Figure 5, Host A and Host D have the same IP prefix and mask, but they are located on different subnets separated by the switch. Host A belongs to VLAN 1, and Host D belongs to VLAN 2. No default gateway is configured on Host A and Host D.

Configure common proxy ARP on the switch to enable communication between the two hosts.

Figure 5 Network diagram

Procedure

Create VLAN 2.

```
<Switch> system-view
[Switch] vlan 2
[Switch-vlan2] quit
```

Configure the IP address of VLAN-interface 1.

```
[Switch] interface vlan-interface 1
[Switch-Vlan-interface1] ip address 192.168.10.99 255.255.255.0
```

Enable common proxy ARP on VLAN-interface 1.

```
[Switch-Vlan-interface1] proxy-arp enable
[Switch-Vlan-interface1] quit
```

Configure the IP address of VLAN-interface 2.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.20.99 255.255.255.0
```

Enable common proxy ARP on VLAN-interface 2.

```
[Switch-Vlan-interface2] proxy-arp enable.
```

Verifying the configuration

Verify that Host A and Host D can ping each other.

Configuring ARP snooping

About ARP snooping

ARP snooping is used in Layer 2 switching networks. It creates ARP snooping entries by using information in ARP packets. ARP fast-reply and MFF can use the ARP snooping entries. For more information about MFF, see *Security Configuration Guide*.

Creation of ARP snooping entries

If you enable ARP snooping for a VLAN, ARP packets received in the VLAN are redirected to the CPU. For the VLAN, the CPU uses the sender IP and MAC addresses, VLAN, and input interface of the ARP packets to create ARP snooping entries.

If you enable ARP snooping on an interface, ARP packets received by the interface are redirected to the CPU. The CPU uses the sender IP and MAC addresses, VLAN, and input interface of the ARP packets to create ARP snooping entries.

Aging of ARP snooping entries

The aging timer and valid period of an ARP snooping entry are 25 minutes and 15 minutes. If an ARP snooping entry is not updated in 12 minutes, the device sends an ARP request. The ARP request uses the IP address of the entry as the target IP address. If an ARP snooping entry is not updated in 15 minutes, it becomes invalid and cannot be used. After that, if an ARP packet matching the entry is received, the entry becomes valid, and its aging timer restarts.

If the aging timer of an ARP snooping entry expires, the entry is removed.

Protection for ARP snooping

An attack occurs if an ARP packet has the same sender IP address as a valid ARP snooping entry but a different sender MAC address. The ARP snooping entry becomes invalid, and it is removed in 1 minute.

Restrictions and guidelines: ARP snooping configuration

A Layer 2 Ethernet interface is enabled with ARP snooping after you enable ARP snooping on the interface or in the VLAN to which the interface belongs.

A Layer 2 Ethernet interface is disabled with ARP snooping only after you disable ARP snooping both on the interface and in the VLAN to which the interface belongs.

Enabling ARP snooping for a VLAN

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*

3. Enable ARP snooping for the VLAN.

   arp snooping enable

   By default, ARP snooping is disabled for a VLAN.

Enabling ARP snooping for an Layer 2 interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

   Only Layer 2 Ethernet interfaces and Layer 2 aggregate interfaces are supported.

3. Enable ARP snooping for the interface.

   arp snooping enable

   By default, ARP snooping is disabled for an interface.

Configuring an interface as an uplink interface to disable it from learning ARP snooping entries

About this task

After you enable ARP snooping on an access device by using the **arp snooping enable** command, the access device will generate ARP snooping entries by listening to ARP packets. On a network where the aggregate device acts as the gateway, if you enable local proxy ARP on the gateway by using the **local-proxy-arp enable** command, the uplink interface of the access device will also learn ARP snooping entries. As a result, the input interface of an ARP snooping entry flaps between the uplink and downlink interfaces. To avoid such an issue, you can configure this feature on the access device.

After you configure this feature on an access device enabled with ARP snooping, the uplink interface no longer learns ARP snooping entries from incoming ARP packets.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

   Supported interface types include Layer 2 Ethernet interface and Layer 2 aggregate interface.

3. Configure the interface as an uplink interface to disable it from learning ARP snooping entries.

   arp snooping uplink

   By default, an interface is not an uplink interface for ARP snooping. After you enable ARP snooping, the interface learns ARP snooping entries.

Display and maintenance commands for ARP snooping

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display ARP snooping entries.	**display arp snooping vlan** [*vlan-id*] [**slot** *slot-number*] [**count**] **display arp snooping** { **interface** | **vlan** } **ip** *ip-address* [**slot** *slot-number*]
Delete ARP snooping entries.	**reset arp snooping vlan** [*vlan-id*] **reset arp snooping** { **interface** | **vlan** } **ip** *ip-address*

Configuring ARP fast-reply

About ARP fast-reply

ARP fast-reply enables a device to directly answer ARP requests according to IP source guard entries or ARP snooping entries. ARP fast-reply functions in a VLAN. For information about IP source guard, see IP source guard configuration in *Security Configuration Guide*.

If the target IP address of a received ARP request is the IP address of the VLAN interface, the device delivers the request to the ARP module. If not, the device takes the following steps to process the packet:

1. Search the IP source guard binding table for a match by using the target IP address.
2. If a match is found, whether the device returns a reply depends on the type of interface in the matching entry.
   - If the interface is the Ethernet interface that received the ARP request, the device does not return any reply.
   - If the interface is an Ethernet interface other than the receiving interface, the device returns a reply according to the matching entry.
3. If no matching IP source guard entry is found and ARP snooping is enabled, the device searches the ARP snooping table.
   - If the interface in the matching entry is the Ethernet interface that received the ARP request, the device does not return any reply.
   - If the interface is an Ethernet interface other than the receiving interface, the device returns a reply according to the ARP snooping entry.
4. If no match is found in both tables, the ARP request is forwarded to other interfaces except the receiving interface in the VLAN, or delivered to other modules.

Enabling ARP fast-reply

Restrictions and guidelines

To improve the availability of ARP fast-reply, enable ARP snooping at the same time.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable ARP fast-reply.
   arp fast-reply enable
   By default, ARP fast-reply is disabled.

Enabling ARP gateway proxy

About this task

To connect hosts that require intercommunication to the same Layer 3 interface on a gateway and make them belong to different broadcast domains, you can enable local proxy ARP on the gateway.

This allows the gateway to respond to ARP requests and achieves Layer 2 isolation and Layer 3 communication.

However, in a large campus or enterprise network, a large number of endpoints connected to the access layer might generate substantial ARP requests per second. The gateway in the core layer might not efficiently process the requests. To resolve such an issue, you can enable ARP gateway proxy on a device in the access or distribution layer. Then, the device responds to the ARP requests, which alleviates the pressure on the gateway.

Enabled with ARP gateway proxy, the device actively records the gateway MAC address when it receives an ARP packet sourced from the gateway IP address. After the device receives an ARP request from an endpoint, it replies with the gateway MAC address. If the device does not learn the gateway MAC address, it does not respond to the ARP request.

Restrictions and guidelines

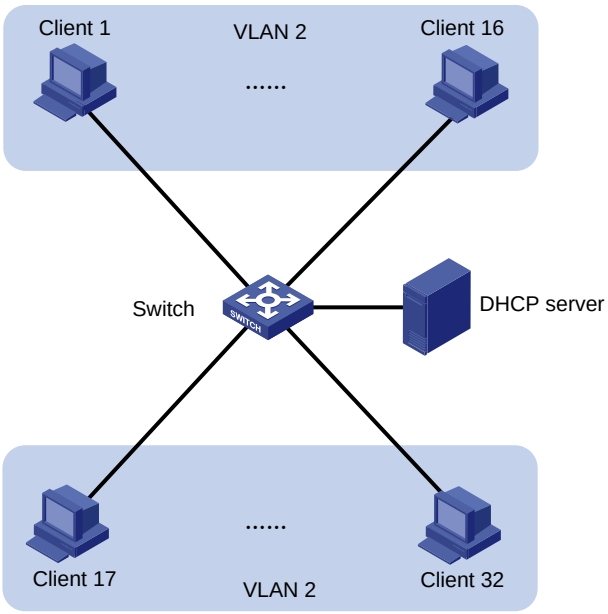
You must specify the gateway IP address when you configure ARP gateway proxy.

To avoid replied MAC address confusion, do not configure this feature and ARP fast-reply simultaneously on the device.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable ARP gateway proxy.
   arp fast-reply l2-proxy gateway *ip-address*
   By default, ARP gateway proxy is disabled.

ARP fast-reply configuration example



Example: Configuring ARP fast-reply

Network configuration

As shown in Figure 6, all clients are in VLAN 2, and access the network through the switch. They have obtained IP addresses through DHCP.

Enable ARP snooping and ARP fast-reply for VLAN 2. The switch directly returns an ARP reply without broadcasting received ARP requests in the VLAN.

Figure 6 Network diagram

Procedure

Enable ARP snooping for VLAN 2 on the switch.

```
<Switch> system-view
[Switch] vlan 2
[Switch-vlan2] arp snooping enable
```

Enable ARP fast-reply for VLAN 2 on the switch.

```
[Switch-vlan2] arp fast-reply enable
[Switch-vlan2] quit
```

Configuring ARP direct route advertisement

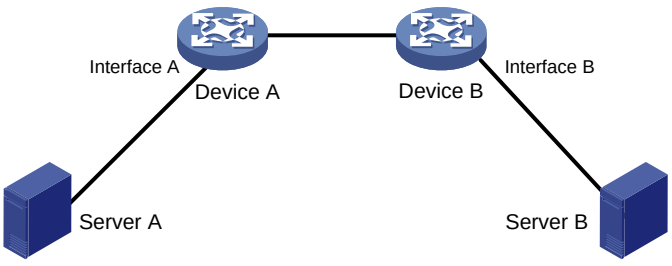
Configuring ARP direct route advertisement

About ARP direct route advertisement

This feature generates direct routes based on ARP entries for packet forwarding and route advertisement. The route preference value determines the match order of a route. Dynamic routing protocols use the tag value as the route identifier when redistributing the route.

After you enable ARP direct route advertisement, the device generates direct routes and adjacency entries based on ARP entries. If the direct routes are generated earlier than the adjacency entries, packet loss will occur due to lack of Layer 2 information during packet encapsulation. To avoid such an issue, you can set the delay time for ARP direct route generation.

After you enable ARP direct route advertisement and set a delay time for ARP direct route generation, the device starts a timer after it has learned an ARP entry. Then, it generates an ARP direct route when the timer value reaches the delay time. If you edit the direct route advertisement configuration within the delay time, the device advertises the direct route based on the new configuration immediately.



Restrictions and guidelines

The **`arp route-direct advertise`** command is mutually exclusive with the **`arp route-direct advertise mad-down-single-homed`** command. If you execute both of them, the most recent command takes effect.

Application in Layer 3 access networks

As shown in Figure 7, ARP direct route advertisement is enabled on Interface A and Interface B. This feature generates a direct route to Server A and a direct route to Server B for the routing protocols to advertise. So each device forwards only the traffic destined to the server within the network, which saves bandwidth.

Figure 7 Application in a Layer 3 access network

Procedure

1. Enter system view.
   `system-view`

2. Enter interface view.
   interface *interface-type interface-number*
3. (Optional.) Set the delay time for ARP direct route generation.
   arp route-direct advertise delay *delay-time*
   By default, ARP direct route generation is not delayed.
4. Enable the ARP direct route advertisement feature.
   arp route-direct advertise [**preference** *preference-value* | **tag** *tag-value*] *
   By default, the ARP direct route advertisement feature is disabled.

Enabling ARP direct route advertisement for single-homing interfaces in M-LAG MAD DOWN state

About this task

If the peer link of an M-LAG system fails, M-LAG Multi-Active Detection (MAD) will shut down all interfaces on the secondary member device upon M-LAG system split, except for the interfaces excluded from the shutdown action by IRF MAD or M-LAG MAD. An interface in M-LAG MAD DOWN state cannot forward traffic. As a result, traffic cannot be forwarded for the devices single-homed to the secondary member device.

To ensure traffic forwarding for single-homed devices, enable ARP direct route advertisement for single-homing interfaces in M-LAG MAD DOWN state. When the peer link fails, the ARP module on the secondary member device will send ARP entries to the routing management module, and the routing management module will generate direct routes based on the ARP entries. The direct routes are used to direct traffic forwarding or are advertised by routing protocols to the single-homed devices.

Restrictions and guidelines

The **arp route-direct advertise mad-down-single-homed** and **arp route-direct advertise** commands are mutually exclusive. If you execute both of them, the most recent command takes effect.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN interface view.
   interface vlan-interface *interface-number*
3. Enable ARP direct route advertisement for single-homing interfaces in M-LAG MAD DOWN state.
   arp route-direct advertise mad-down-single-homed
   By default, ARP direct route advertisement is disabled for single-homing interfaces in M-LAG MAD DOWN state.

Display and maintenance commands for ARP direct route advertisement

Execute **display** commands in any view.

Task	Command
Display information about ARP direct route advertisement.	**display arp route-direct advertise interface** *interface-type interface-number*

Configuring ARP ping

Configuring ARP ping for IPv4 addresses

About this task

This feature enables you to test whether an IPv4 address in a LAN is being used by sending ARP requests.

After the device sends an ARP request to an IPv4 address, if it receives an ARP reply within the wait time, it determines that the IP address is being used. If an ARP reply is not received within the wait time, the device sends another ARP request. After the device sends the maximum number of ARP requests but no ARP reply is received, the device stops sending ARP requests and regards the IPv4 address as an unused address.

Compared with the **ping** command, the **ping arp ip** command avoids a wrong result when the destination host is enabled with a firewall that blocks ICMP packets. In addition, it consumes fewer network resources because an ARP request is shorter than an ICMP packet.

Restrictions and guidelines

If multiple devices exist on the LAN, executing the **ping arp ip** command will take some time. To stop an ongoing test, press **Ctrl** + **C**.

Prerequisites

To execute the **ping arp ip** command by specifying the destination host name, configure the DNS feature first. For more information about DNS, see "Configuring DNS."

Procedure

Execute the following command in any view:

ping arp ip *host* [**interface** *interface-type interface-number* [**vlan** *vlan-id*]] [**timeout** *timeout*] [**count** *count*]

Configuring ARP ping for MAC addresses

About this task

To obtain the corresponding IPv4 address of a MAC address, use the **ping arp mac** command to broadcast Layer 3 ICMP packets.

After the device sends an ICMP echo request, if an ICMP echo reply is not received within the wait time, the device sends another ICMP echo request. After the device sends the maximum number of ICMP echo requests but no ICMP echo reply is received, the device stops sending ICMP echo requests and regards the MAC address as a nonexistent address.

Restrictions and guidelines

If multiple devices exist in the network, executing the **ping arp mac** command will take some time. To stop an ongoing test, press **Ctrl** + **C**.

Procedure

Execute the following command in any view:

ping arp mac *mac-address* { **interface** *interface-type interface-number* |**ip** *ipv4-address* [**vpn-instance** *vpn-instance-name*] } [**timeout** *timeout*] [**count** *count*]

Configuring IP addressing

About IP addressing

The IP addresses in this chapter refer to IPv4 addresses unless otherwise specified.

IP address representation and classes

IP addressing uses a 32-bit address to identify each host on an IPv4 network. To make addresses easier to read, they are written in dotted decimal notation, each address being four octets in length. For example, address 00001010000000010000000100000001 in binary is written as 10.1.1.1.

Each IP address breaks down into the following sections:

- **Net ID**—Identifies a network. The first several bits of a net ID, known as the class field or class bits, identify the class of the IP address.
- **Host ID**—Identifies a host on a network.

IP addresses are divided into five classes, as shown in Figure 1. The shaded areas represent the address class. The first three classes are most commonly used.

Figure 1 IP address classes

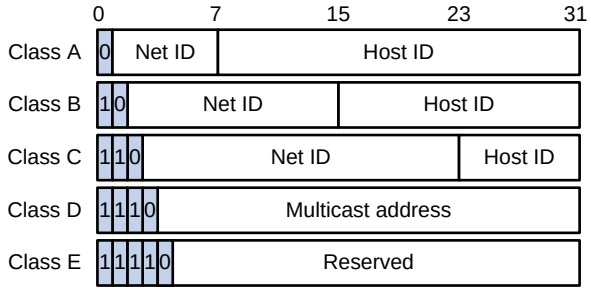

Table 1 IP address classes and ranges

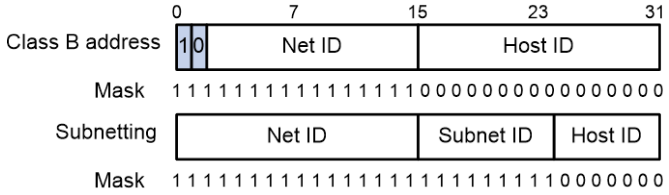
Class	Address range	Remarks
A	0.0.0.0 to 127.255.255.255	The IP address 0.0.0.0 is used by a host at startup for temporary communication. This address is never a valid destination address. Addresses starting with 127 are reserved for loopback test. Packets destined to these addresses are processed locally as input packets rather than sent to the link.
B	128.0.0.0 to 191.255.255.255	N/A
C	192.0.0.0 to 223.255.255.255	N/A
D	224.0.0.0 to 239.255.255.255	Multicast addresses.
E	240.0.0.0 to 255.255.255.255	Reserved for future use, except for the broadcast address 255.255.255.255.

Special IP addresses

The following IP addresses are for special use and cannot be used as host IP addresses:

- **IP address with an all-zero net ID**—Identifies a host on the local network. For example, IP address 0.0.0.16 indicates the host with a host ID of 16 on the local network.
- **IP address with an all-zero host ID**—Identifies a network.
- **IP address with an all-one host ID**—Identifies a directed broadcast address. For example, a packet with the destination address of 192.168.1.255 will be broadcast to all the hosts on the network 192.168.1.0.

Subnetting and masking



Subnetting divides a network into smaller networks called subnets by using some bits of the host ID to create a subnet ID.

Masking identifies the boundary between the host ID and the combination of net ID and subnet ID.

Each subnet mask comprises 32 bits that correspond to the bits in an IP address. In a subnet mask, consecutive ones represent the net ID and subnet ID, and consecutive zeros represent the host ID.

Before being subnetted, Class A, B, and C networks use these default masks (also called natural masks): 255.0.0.0, 255.255.0.0, and 255.255.255.0, respectively.

Figure 2 Subnetting a Class B network

Subnetting increases the number of addresses that cannot be assigned to hosts. Therefore, using subnets means accommodating fewer hosts.

For example, a Class B network without subnetting can accommodate 1022 more hosts than the same network subnetted into 512 subnets.

- **Without subnetting**—65534 (2^{16} – 2) hosts. (The two deducted addresses are the broadcast address, which has an all-one host ID, and the network address, which has an all-zero host ID.)
- **With subnetting**—Using the first nine bits of the host-id for subnetting provides 512 (2^9) subnets. However, only seven bits remain available for the host ID. This allows 126 (2^7 – 2) hosts in each subnet, a total of 64512 (512 × 126) hosts.

IP address assignment

The following are methods available for assigning an IP address to an interface:

- Manual assignment. This chapter describes only manual IP address assignment for interfaces.
- BOOTP. For information about BOOTP, see "Configuring the BOOTP client."
- DHCP. For information about DHCP, see "Configuring the DHCP client."

These methods are mutually exclusive. If you change the IP address assignment method, the new IP address will overwrite the previous address.

Assigning an IP address to an interface

About this task

An interface can have one primary address and multiple secondary addresses.

Typically, you need to configure a primary IP address for an interface. If the interface connects to multiple subnets, configure primary and secondary IP addresses on the interface so the subnets can communicate with each other through the interface.

In an IRF fabric, you can assign an IP address to the management Ethernet port of each member in the management Ethernet port view of the master. Only the IP address assigned to the management Ethernet port of the master takes effect. After an IRF fabric split, the IP addresses assigned to the management Ethernet ports of the new masters (original subordinates) take effect. Then you can use these IP addresses to log in to the new masters for troubleshooting.

Restrictions and guidelines

- An interface can have only one primary IP address. If you execute this command multiple times to specify different primary IP addresses on an interface, the most recent configuration takes effect.
- You cannot assign secondary IP addresses to an interface that obtains an IP address through IP unnumbered, BOOTP, or DHCP.
- The primary and secondary IP addresses assigned to the interface can be located on the same network segment. Different interfaces on your device must reside on different network segments.
- After an IRF split, the routing information on the original master might not be updated immediately. As a result, the management Ethernet port of the original master cannot be pinged from the master (original subordinate) in another IRF fabric. To resolve the problem, wait until route synchronization between the devices is completed or enable NSR for the routing protocol. For information about NSR, see *Layer 3—IP Routing Configuration Guide*.
- The following commands are mutually exclusive. You can configure only one of these commands to assign an IP address to the management Ethernet port of the IRF master.
  - The **ip address** command with the **irf-member** *member-id* option that specifies the master.
  - The **ip address** command that does not contain the **irf-member** *member-id* option.
  - The **mad ip address** command.
  - The **ip address dhcp-alloc** command.
- Exclude the management Ethernet port of the master from being shut down if MAD is enabled in the IRF fabric. The port can be kept in up state when the MAD status transits to Recovery.
- You can assign interfaces IP addresses that have different masks but the same network address if ANDed with the shortest mask. For example, 1.1.1.1/16 and 1.1.2.1/24 have the same network address 1.1.0.0 if ANDed with 255.255.0.0. You can assign the IP addresses to two interfaces on the device. By default, users connected to the two interfaces cannot communicate with each other. For the users to communicate, you must configure common proxy ARP on the device. For more information, see "Configuring proxy ARP."

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Assign an IP address to the interface.

ip address *ip-address* { *mask-length* | *mask* } [**irf-member** *member-id* | **sub**]

By default, no IP address is assigned to the interface.

To assign an IP address to the management Ethernet port of an IRF member device, enter the master's management Ethernet port view and specify the **irf-member** *member-id* option.

Configuring IP unnumbered

About this task

You can configure an interface to borrow an IP address from other interfaces. This is called IP unnumbered, and the interface borrowing the IP address is called IP unnumbered interface.

You can use IP unnumbered to save IP addresses when available IP addresses are inadequate or when an interface is used only occasionally.

Restrictions and guidelines

- Loopback interfaces cannot borrow IP addresses of other interfaces, but other interfaces can borrow IP addresses of loopback interfaces.
- An interface cannot borrow an IP address from an unnumbered interface.
- Multiple interfaces can use the same unnumbered IP address.
- If an interface has multiple manually configured IP addresses, only the manually configured primary IP address can be borrowed.
- A Layer 3 Ethernet subinterface or Layer 3 aggregate subinterface cannot learn the ARP entry for the IP address it borrows. As a best practice, do not configure IP unnumbered on Layer 3 Ethernet subinterfaces or Layer 3 aggregate subinterfaces.

Prerequisites

Configure an IP address for the interface from which you want to borrow the IP address. You can manually assign an IP address to the interface or configure the interface to obtain one through BOOTP or DHCP.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify the interface to borrow the IP address of the specified interface.
   ip address unnumbered interface *interface-type interface-number*
   By default, the interface does not borrow IP addresses from other interfaces.

Display and maintenance commands for IP addressing

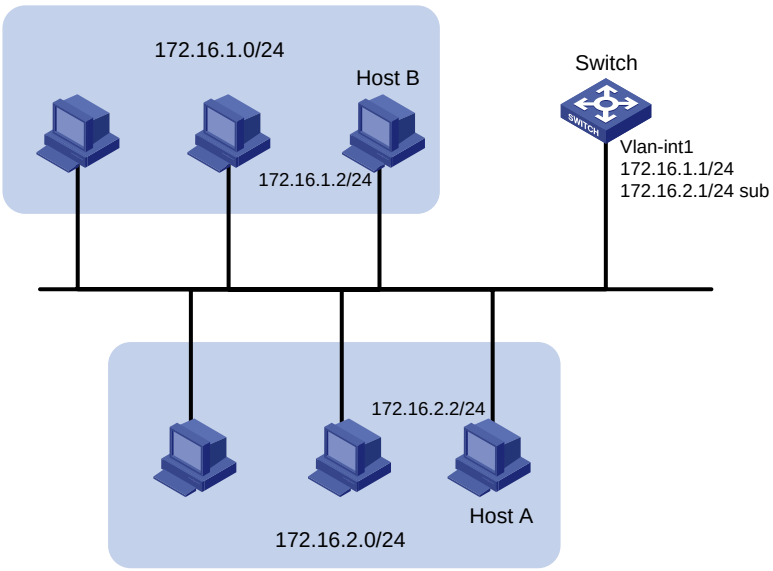
Execute **display** commands in any view.

Task	Command
Display IP configuration and statistics for the specified or all Layer 3 interfaces.	**display ip interface** [*interface-type* [*interface-number*]]

Task	Command
Display brief IP configuration for Layer 3 interfaces.	**display ip interface** [*interface-type* [*interface-number*]] **brief** [**description**]

IP addressing configuration examples

Example: Manually specifying an IP address



Network configuration

As shown in Figure 3, a port in VLAN 1 on a switch is connected to a LAN comprising two segments: 172.16.1.0/24 and 172.16.2.0/24.

To enable the hosts on the two network segments to communicate with the external network through the switch, and to enable the hosts on the LAN to communicate with each other:

- Assign a primary IP address and a secondary IP address to VLAN-interface 1 on the switch.
- Set the primary IP address of the switch as the gateway address of the PCs on subnet 172.16.1.0/24, and set the secondary IP address of the switch as the gateway address of the PCs on subnet 172.16.2.0/24.

Figure 3 Network diagram

Procedure

Assign a primary IP address and a secondary IP address to VLAN-interface 1.

```
<Sysname> system-view
[Sysname] sysname Switch
[Switch] interface vlan-interface 1
[Switch-Vlan-interface1] ip address 172.16.1.1 255.255.255.0
[Switch-Vlan-interface1] ip address 172.16.2.1 255.255.255.0 sub
[Switch-Vlan-interface1] quit
```

Set the gateway address to 172.16.1.1 on the PCs attached to subnet 172.16.1.0/24, and to 172.16.2.1 on the PCs attached to subnet 172.16.2.0/24.

Verifying the configuration

Verify the connectivity between a host on subnet 172.16.1.0/24 and the switch.

```
[Switch] ping 172.16.1.2
Ping 172.16.1.2 (172.16.1.2): 56 data bytes, press CTRL_C to break
56 bytes from 172.16.1.2: icmp_seq=0 ttl=128 time=7.000 ms
56 bytes from 172.16.1.2: icmp_seq=1 ttl=128 time=2.000 ms
56 bytes from 172.16.1.2: icmp_seq=2 ttl=128 time=1.000 ms
56 bytes from 172.16.1.2: icmp_seq=3 ttl=128 time=1.000 ms
56 bytes from 172.16.1.2: icmp_seq=4 ttl=128 time=2.000 ms
--- Ping statistics for 172.16.1.2 ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 1.000/2.600/7.000/2.245 ms
```

Verify the connectivity between a host on subnet 172.16.2.0/24 and the switch.

```
[Switch] ping 172.16.2.2
Ping 172.16.2.2 (172.16.2.2): 56 data bytes, press CTRL_C to break
56 bytes from 172.16.2.2: icmp_seq=0 ttl=128 time=2.000 ms
56 bytes from 172.16.2.2: icmp_seq=1 ttl=128 time=7.000 ms
56 bytes from 172.16.2.2: icmp_seq=2 ttl=128 time=1.000 ms
56 bytes from 172.16.2.2: icmp_seq=3 ttl=128 time=2.000 ms
56 bytes from 172.16.2.2: icmp_seq=4 ttl=128 time=1.000 ms
--- Ping statistics for 172.16.2.2 ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 1.000/2.600/7.000/2.245 ms
```

Verify the connectivity between a host on subnet 172.16.1.0/24 and a host on subnet 172.16.2.0/24. The ping operation succeeds.

Configuration files

```
#
 sysname Switch
#
interface Vlan-interface1
 port link-mode route
 ip address 172.16.1.1 255.255.255.0
 ip address 172.16.2.1 255.255.255.0 sub
#
```

DHCP overview

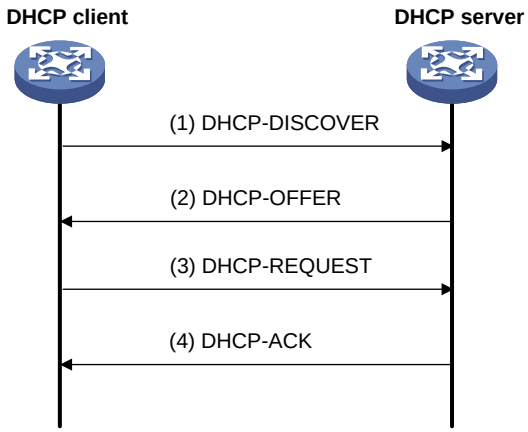
DHCP network model

The Dynamic Host Configuration Protocol (DHCP) provides a framework to assign configuration information to network devices.

Figure 1 shows a typical DHCP application scenario where the DHCP clients and the DHCP server reside on the same subnet. The DHCP clients can also obtain configuration parameters from a DHCP server on another subnet through a DHCP relay agent. For more information about the DHCP relay agent, see "Configuring the DHCP relay agent."

Figure 1 A typical DHCP application

DHCP address allocation



Allocation mechanisms

DHCP supports the following allocation mechanisms:

- **Static allocation**—The network administrator assigns an IP address to a client, such as a WWW server, and DHCP conveys the assigned address to the client.
- **Automatic allocation**—DHCP assigns a permanent IP address to a client.
- **Dynamic allocation**—DHCP assigns an IP address to a client for a limited period of time, which is called a lease. Most DHCP clients obtain their addresses in this way.

IP address allocation process

Figure 2 IP address allocation process

As shown in Figure 2, a DHCP server assigns an IP address to a DHCP client in the following process:

1. The client broadcasts a DHCP-DISCOVER message to locate a DHCP server.
2. Each DHCP server offers configuration parameters such as an IP address to the client in a DHCP-OFFER message. The sending mode of the DHCP-OFFER is determined by the flag field in the DHCP-DISCOVER message. For more information, see "DHCP message format."
3. If the client receives multiple offers, it accepts the first received offer, and broadcasts it in a DHCP-REQUEST message to formally request the IP address. (IP addresses offered by other DHCP servers can be assigned to other clients.)
4. All DHCP servers receive the DHCP-REQUEST message. However, only the server selected by the client does one of the following operations:
   - Returns a DHCP-ACK message to confirm that the IP address has been allocated to the client.
   - Returns a DHCP-NAK message to deny the IP address allocation.

After receiving the DHCP-ACK message, the client verifies the following details before using the assigned IP address:

- The assigned IP address is not in use. To verify this, the client broadcasts a gratuitous ARP packet. The assigned IP address is not in use if no response is received within the specified time.
- The assigned IP address is not on the same subnet as any IP address in use on the client.

Otherwise, the client sends a DHCP-DECLINE message to the server to request an IP address again.

IP address lease extension

A dynamically assigned IP address has a lease. When the lease expires, the IP address is reclaimed by the DHCP server. To continue using the IP address, the client must extend the lease duration.

When about half of the lease duration elapses, the DHCP client unicasts a DHCP-REQUEST to the DHCP server to extend the lease. Depending on the availability of the IP address, the DHCP server returns one of the following messages:

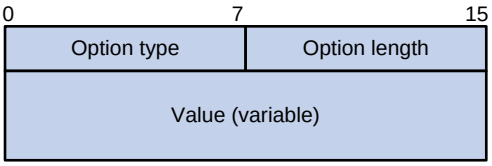
- A DHCP-ACK unicast confirming that the client's lease duration has been extended.
- A DHCP-NAK unicast denying the request.

If the client receives no reply, it broadcasts another DHCP-REQUEST message for lease extension when about seven-eighths of the lease duration elapses. Again, depending on the availability of the IP address, the DHCP server returns either a DHCP-ACK unicast or a DHCP-NAK unicast.

DHCP message format

Figure 3 shows the DHCP message format. DHCP uses some of the fields in significantly different ways. The numbers in parentheses indicate the size of each field in bytes.

Figure 3 DHCP message format



- **op**—Message type defined in options field. 1 = REQUEST, 2 = REPLY
- **htype**, **hlen**—Hardware address type and length of the DHCP client.
- **hops**—Number of relay agents a request message traveled.
- **xid**—Transaction ID, a random number chosen by the client to identify an IP address allocation.
- **secs**—Filled in by the client, the number of seconds elapsed since the client began address acquisition or renewal process. This field is reserved and set to 0.
- **flags**—The leftmost bit is defined as the BROADCAST (B) flag. If this flag is set to 0, the DHCP server sent a reply back by unicast. If this flag is set to 1, the DHCP server sent a reply back by broadcast. The remaining bits of the flags field are reserved for future use.
- **ciaddr**—Client IP address if the client has an IP address that is valid and usable. Otherwise, set to zero. (The client does not use this field to request an IP address to lease.)
- **yiaddr**—Your IP address. It is an IP address assigned by the DHCP server to the DHCP client.
- **siaddr**—Server IP address, from which the client obtained configuration parameters.
- **giaddr**—Gateway IP address. It is the IP address of the first relay agent to which a request message travels.
- **chaddr**—Client hardware address.
- **sname**—Server host name, from which the client obtained configuration parameters.
- **file**—Boot file (also called system software image) name and path information, defined by the server to the client.
- **options**—Optional parameters field that is variable in length. Optional parameters include the message type, lease duration, subnet mask, domain name server IP address, and WINS IP address.

DHCP options

DHCP extends the message format as an extension to BOOTP for compatibility. DHCP uses the options field to carry information for dynamic address allocation and provide additional configuration information for clients.

Figure 4 DHCP option format

Common DHCP options

The following are common DHCP options:

- **Option 3**—Router option. It specifies the gateway address to be assigned to the clients. If both Option 3 and Option 121 exist, Option 3 is ignored.
- **Option 6**—DNS server option. It specifies the DNS server IP address to be assigned to the clients.
- **Option 33**—Static route option. It specifies a list of classful static routes (the destination addresses in these static routes are classful) that a client should add into its routing table. If both Option 33 and Option 121 exist, Option 33 is ignored.
- **Option 51**—IP address lease option.
- **Option 53**—DHCP message type option. It identifies the type of the DHCP message.
- **Option 55**—Parameter request list option. It is used by a DHCP client to request specified configuration parameters. The option includes values that correspond to the parameters requested by the client.
- **Option 60**—Vendor class identifier option. A DHCP client uses this option to identify its vendor. A DHCP server uses this option to distinguish DHCP clients, and assigns IP addresses to them.
- **Option 66**—TFTP server name option. It specifies the TFTP server domain name to be assigned to the clients.
- **Option 67**—Boot file name option. It specifies the boot file name to be assigned to the client.
- **Option 121**—Classless route option. It specifies a list of classless static routes (the destination addresses in these static routes are classless) that a client should add into its routing table. If Option 3, Option 33, and Option 121 all exist, Option 3 and Option 33 are ignored.
- **Option 150**—TFTP server IP address option. It specifies the TFTP server IP address to be assigned to the clients.

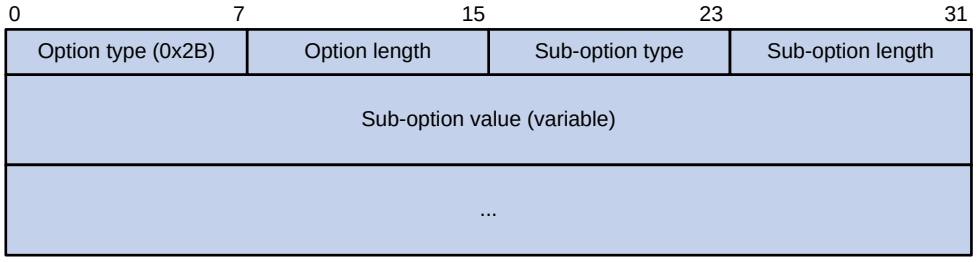
For more information about DHCP options, see RFC 2132 and RFC 3442.

Custom DHCP options

Some options, such as Option 43, Option 82, and Option 184, have no standard definitions in RFC 2132.

Vendor-specific option (Option 43)

Option 43 function



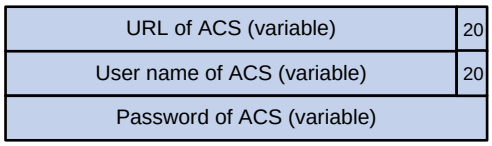
DHCP servers and clients use Option 43 to exchange vendor-specific configuration information.

The DHCP client can obtain the following information through Option 43:

- ACS parameters, including the ACS URL, username, and password.
- Service provider identifier, which is acquired by the CPE from the DHCP server and sent to the ACS for selecting vender-specific configurations and parameters. For more information about CPE and ACS, see *Network Management and Monitoring Configuration Guide*.
- PXE server address, which is used to obtain the boot file or other control information from the PXE server.

Option 43 format

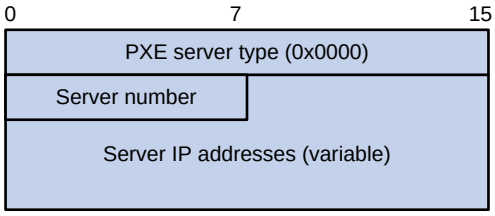
Figure 5 Option 43 format



Network configuration parameters are carried in different sub-options of Option 43 as shown in Figure 5.

- **Sub-option type**—The field value can be 0x01 (ACS parameter sub-option), 0x02 (service provider identifier sub-option), or 0x80 (PXE server address sub-option).
- **Sub-option length**—Excludes the sub-option type and sub-option length fields.
- **Sub-option value**—The value format varies by sub-option.

Sub-option value field format



- **ACS parameter sub-option value field**—Includes the ACS URL, username, and password separated by spaces (hexadecimal number 20) as shown in Figure 6.

  Figure 6 ACS parameter sub-option value field

- **Service provider identifier sub-option value field**—Includes the service provider identifier.
- **PXE server address sub-option value field**—Includes the PXE server type that can only be 0, the server number that indicates the number of PXE servers contained in the sub-option, and server IP addresses, as shown in Figure 7.

Figure 7 PXE server address sub-option value field

Relay agent option (Option 82)

Option 82 is the relay agent option. It records the location information about the DHCP client. When a DHCP relay agent or DHCP snooping device receives a client's request, it adds Option 82 to the request and sends it to the server.

The administrator can use Option 82 to locate the DHCP client and further implement security control and accounting. The DHCP server can use Option 82 to provide individual configuration policies for the clients.

Option 82 can contain a maximum of 255 sub-options and must contain a minimum of one sub-option.

The device supports the following sub-options:

- Sub-option 1 (Circuit ID).
- Sub-option 2 (Remote ID).
- Sub-option 5 (Link Selection).
- Sub-option 9 (Vendor-Specific).

Option 82 does not have standard definitions. Its padding formats vary by vendor.

- Circuit ID has the following padding modes:
  - **String padding mode**—Includes a character string specified by the user.
  - **Normal padding mode**—Includes the VLAN ID and interface number of the interface that receives the client's request.
  - **Verbose padding mode**—Includes the access node identifier specified by the user, and the VLAN ID, interface number and interface type of the interface that receives the client's request.
- Remote ID has the following padding modes:
  - **String padding mode**—Includes a character string specified by the user.
  - **Normal padding mode**—Includes the MAC address of the DHCP relay agent interface or the MAC address of the DHCP snooping device that receives the client's request.
  - **Sysname padding mode**—Includes the name of the device. To set the device name, use the **sysname** command in system view.
- The Link Selection sub-option carries one of the following IP addresses:
  - Gateway address in the AAA-authorized address pool or the address pool bound to the relay interface.
  - IP address of the relay interface.

  To have the DHCP relay agent forward requests with Option 82 and sub-option 5, perform the following tasks first:
  - Enable the DHCP relay agent to support Option 82 by using the **dhcp relay information enable** command.

    - Specify a source IP address for relayed DHCP requests by using the **dhcp relay source-address** command.
- The Vendor-Specific sub-option supports only the bas padding mode. The padding content includes the user-configured access node identifier and the VLAN ID, interface number, and interface type of the interface that receives the client's request. This sub-option is supported only on DHCP snooping devices.

Option 184

Option 184 is a reserved option. You can define the parameters in the option as needed. The device supports Option 184 carrying voice related parameters, so a DHCP client with voice functions can get voice parameters from the DHCP server.

Option 184 has the following sub-options:

- **Sub-option 1**—Specifies the IP address of the primary network calling processor. The primary processor acts as the network calling control source and provides program download services. For Option 184, you must define sub-option 1 to make other sub-options take effect.
- **Sub-option 2**—Specifies the IP address of the backup network calling processor. DHCP clients contact the backup processor when the primary one is unreachable.
- **Sub-option 3**—Specifies the voice VLAN ID and the result whether the DHCP client takes this VLAN as the voice VLAN.
- **Sub-option 4**—Specifies the failover route that includes the IP address and the number of the target user. A SIP VoIP user uses this IP address and number to directly establish a connection to the target SIP user when both the primary and backup calling processors are unreachable.

Option 252

Option 252 is a vendor-specific DHCP option that records the verification password from the cloud platform server. On receipt of a reply from the DHCP server, a DHCP client automatically obtains the verification password by parsing Option 252. Then, the client can authenticate to the cloud platform server by using this password. For more information about cloud servers, see cloud connection configuration in *Network Management and Monitoring Configuration Guide*.

Option 253

Option 253 is a vendor-specific DHCP option that records the domain name of a cloud server. On receipt of a reply from the DHCP server, a DHCP client obtains the domain name of the cloud server by parsing Option 253. With the obtained domain name, the DHCP client can then remotely logs in to the cloud server for management purposes. For more information about cloud servers, see cloud connection configuration in *Network Management and Monitoring Configuration Guide*.

To have the device correctly obtain the IPv4 domain name in Option 253, make sure the value in Option 253 use one of the following formats:

- Domain name with a port number specified:
    - **Domain name format**—*domain name:port number*, for example, example.com:17443.
    - **IPv4 address format**—*X.X.X.X:port number*, for example, 192.168.1.1:17443.
    - **IPv6 address format**—*[X:X::X:X]:port number*, for example, [1::1]:64.
- Domain name without a port number specified (the default port number is used):
    - **Domain name format**—*domain name*, for example, example.com.
    - **IPv4 address format**—*X.X.X.X*, for example, 192.168.1.1.
    - **IPv6 address format**—*X:X::X:X* or *[X:X::X:X]*, for example, 1::1 or [1::1].

Configuring the DHCP server

About DHCP server

A DHCP server manages a pool of IP addresses and client configuration parameters. It selects an IP address and configuration parameters from the address pool and allocates them to a requesting DHCP client.

DHCP address assignment mechanisms

Configure the following address assignment mechanisms as needed:

- **Static address allocation**—Manually bind the MAC address or ID of a client to an IP address in a DHCP address pool. When the client requests an IP address, the DHCP server assigns the IP address in the static binding to the client.
- **Dynamic address allocation**—Specify IP address ranges in a DHCP address pool. Upon receiving a DHCP request, the DHCP server dynamically selects an IP address from the matching IP address range in the address pool.

You can specify IP address ranges in an address pool by using either of the following methods:

- **Method 1**—A primary subnet being divided into multiple address ranges in an address pool
- **Method 2**—A primary subnet and multiple secondary subnets in an address pool

A primary subnet being divided into multiple address ranges in an address pool

An address range includes a common IP address range and IP address ranges for DHCP user classes.

Upon receiving a DHCP request, the DHCP server finds a user class matching the client and selects an IP address in the address range of the user class for the client. A user class can include multiple matching rules, and a client matches the user class as long as it matches any of the rules. In address pool view, you can specify different address ranges for different user classes.

The DHCP server selects an IP address for a client by performing the following steps:

1. DHCP server compares the client against DHCP user classes in the order they are configured.
2. If the client matches a user class, the DHCP server selects an IP address from the address range of the user class.
3. If the matching user class has no assignable addresses, the DHCP server compares the client against the next user class. If all the matching user classes have no assignable addresses, the DHCP server selects an IP address from the common address range.
4. If the DHCP client does not match any DHCP user class, the DHCP server selects an address in the IP address range specified by the **`address range`** command. If the address range has no assignable IP addresses or it is not configured, the address allocation fails.

NOTE:

All address ranges must belong to the primary subnet. If an address range does not reside on the primary subnet, DHCP cannot assign the addresses in the address range.

A primary subnet and multiple secondary subnets in an address pool

The DHCP server selects an IP address from the primary subnet first. If there is no assignable IP address on the primary subnet, the DHCP server selects an IP address from secondary subnets in the order they are configured.

Principles for selecting an address pool

The DHCP server observes the following principles to select an address pool for a client:

1. If the receiving interface has a DHCP policy and the DHCP client matches a user class, the DHCP server selects the address pool that is bound to the matching user class. If no matching user class is found, the server assigns an IP address and other parameters from the default DHCP address pool. If no default address pool is specified or the default address pool does not have assignable IP addresses, the address assignment fails.
2. If there is an address pool where an IP address is statically bound to the MAC address or ID of the client, the DHCP server selects this address pool and assigns the statically bound IP address and other configuration parameters to the client.
3. If the receiving interface has an address pool applied, the DHCP server selects an IP address and other configuration parameters from this address pool.
4. If the above conditions are not met, the DHCP server selects an address pool depending on the client location.
    - **Client on the same subnet as the server**—The DHCP server compares the IP address of the receiving interface with the primary subnets of all address pools.
        - If a match is found, the server selects the address pool with the longest-matching primary subnet.
        - If no match is found, the DHCP server compares the IP address with the secondary subnets of all address pools. The server selects the address pool with the longest-matching secondary subnet.
    - **Client on a different subnet than the server**—The DHCP server compares the IP address in the **giaddr** field of the DHCP request with the primary subnets of all address pools.
        - If a match is found, the server selects the address pool with the longest-matching primary subnet.
        - If no match is found, the DHCP server compares the IP address with the secondary subnets of all address pools. The server selects the address pool with the longest-matching secondary subnet.

For example, two address pools 1.1.1.0/24 and 1.1.1.0/25 are configured but not applied to any DHCP server's interfaces.

- If the IP address of the receiving interface is 1.1.1.1/25, the DHCP server selects the address pool 1.1.1.0/25. If the address pool has no available IP addresses, the DHCP server will not select the other pool and the address allocation will fail.
- If the IP address of the receiving interface is 1.1.1.130/25, the DHCP server selects the address pool 1.1.1.0/24.

To ensure correct address allocation, keep the IP addresses used for dynamic allocation on one of the subnets:

- **Clients on the same subnet as the server**—Subnet where the DHCP server receiving interface resides.
- **Clients on a different subnet than the server**—Subnet where the first DHCP relay interface that faces the clients resides.

NOTE:

As a best practice, configure a minimum of one matching primary subnet in your network. Otherwise, the DHCP server selects only the first matching secondary subnet for address allocation. If the network has more DHCP clients than the assignable IP addresses in the secondary subnet, not all DHCP clients can obtain IP addresses.

IP address allocation sequence

The DHCP server selects an IP address for a client in the following sequence:

1. IP address statically bound to the client's MAC address or ID.
2. IP address that was ever assigned to the client.
3. IP address designated by the Option 50 field in the DHCP-DISCOVER message sent by the client.

   Option 50 is the Requested IP Address option. The client uses this option to specify the wanted IP address in a DHCP-DISCOVER message. The content of Option 50 is user defined.
4. First assignable IP address found in the way discussed in "DHCP address assignment mechanisms" and "Principles for selecting an address pool."
5. IP address that was a conflict or passed its lease duration. If no IP address is assignable, the server does not respond.

NOTE:

- If a client moves to another subnet, the DHCP server selects an IP address in the address pool matching the new subnet. It does not assign the IP address that was once assigned to the client.
- Conflicted IP addresses can be assigned to other DHCP clients only after the addresses are in conflict for an hour.

DHCP server tasks at a glance

To configure the DHCP server, perform the following tasks:

1. (Optional.) Creating a DHCP user class
2. Configuring an address pool on the DHCP server
3. (Optional.) Modifying the address pool selection method on the DHCP server
   - Applying an address pool to an interface
   - Configuring a DHCP policy for dynamic assignment
4. Enabling DHCP
5. Enabling the DHCP server on an interface
6. (Optional.) Configuring advanced DHCP features
   - Configuring IP address conflict detection
   - Enabling handling of Option 82
   - Configuring the DHCP server security features
   - Configuring DHCP server compatibility
   - Setting the DSCP value for DHCP packets sent by the DHCP server
   - Configuring DHCP binding auto backup
   - Enabling client offline detection on the DHCP server
7. (Optional.) Configuring SNMP notification and logging
   - Configuring SNMP notifications for the DHCP server
   - Enabling DHCP logging on the DHCP server
   - Enabling IP exhaustion event logging

Creating a DHCP user class

About this task

The DHCP server classifies DHCP users into different user classes according to the hardware address, option information, or the **giaddr** field in the received DHCP requests. The server allocates IP addresses and configuration parameters to DHCP clients in different user classes.

Procedure

1. Enter system view.

   system-view
2. Create a DHCP user class and enter DHCP user class view.

   dhcp class *class-name*
3. Configure a match rule for the DHCP user class.

   if-match rule *rule-number* { **hardware-address** *hardware-address* **mask** *hardware-address-mask* | **option** *option-code* [**ascii** *ascii-string* [**offset** *offset* | **partial**] | **hex** *hex-string* [**mask** *mask* | **offset** *offset* **length** *length* | **partial**]] | **relay-agent** *gateway-address* }

   By default, no match rule is configured for a DHCP user class.

Configuring an address pool on the DHCP server

DHCP address pool tasks at a glance

To configure a DHCP address pool, perform the following tasks:

1. Creating a DHCP address pool
2. Specifying IP address ranges in a DHCP address pool

   In one DHCP address pool, the two dynamic allocation methods cannot be both configured, but static and dynamic address allocations can be both implemented.
   - Specifying a primary subnet and multiple address ranges in a DHCP address pool
   - Specifying a primary subnet and multiple secondary subnets in a DHCP address pool
   - Configuring a static binding in a DHCP address pool
3. Specifying other configuration parameters to be assigned to DHCP clients
   - Specifying gateways for DHCP clients
   - Specifying a domain name suffix for DHCP clients
   - Specifying DNS servers for DHCP clients
   - Specifying WINS servers and NetBIOS node type for DHCP clients
   - Specifying BIMS server for DHCP clients
   - Specifying the configuration file for DHCP client automatic configuration
   - Specifying a server for DHCP clients
   - Configuring Option 184 parameters for DHCP clients
   - Customizing DHCP options
4. (Optional.) Applying a DHCP address pool to a VPN instance
5. (Optional.) Configuring the DHCP user class whitelist
6. (Optional.) Binding gateways to DHCP server's MAC address
7. (Optional.) Advertising subnets that are assigned to clients

Creating a DHCP address pool

1. Enter system view.
   system-view
2. Create a DHCP address pool and enter its view.
   dhcp server ip-pool *pool-name*

Specifying a primary subnet and multiple address ranges in a DHCP address pool

About this task

Some scenarios need to classify DHCP clients on the same subnet into different address groups. To meet this need, you can configure DHCP user classes and specify different address ranges for the classes. The clients matching a user class can then get the IP addresses of an address range. In addition, you can specify a common address range for the clients that do not match any user class. If no common address range is specified, such clients fail to obtain IP addresses.

If there is no need to classify clients, you do not need to configure DHCP user classes or their address ranges.

Restrictions and guidelines

- If you execute the **network** or **address range** command multiple times for the same address pool, the most recent configuration takes effect.
- If you execute the **forbidden-ip** command multiple times, you exclude multiple address ranges from dynamic allocation.
- IP addresses specified by the **forbidden-ip** command are not assignable in the current address pool, but are assignable in other address pools. IP addresses specified by the **dhcp server forbidden-ip** command are not assignable in any address pool.
- You can use **class range** to modify an existing address range, and the new address range can include IP addresses that are being used by clients. Upon receiving a lease extension request for such an IP address, the DHCP server allocates a new IP address to the requesting client. But the original lease continues aging in the address pool, and will be released when the lease duration is reached. To release such lease without waiting for its timeout, execute the **reset dhcp server ip-in-use** command.
- The **address range** command is mutually exclusive with the **network secondary** command. You cannot use them together in the same address pool.
- The **class range** command is mutually exclusive with the **network secondary** command. You cannot use them together in the same address pool.

Procedure

1. Enter system view.
   system-view
2. Enter DHCP address pool view.
   dhcp server ip-pool *pool-name*
3. Specify the primary subnet in the address pool.
   network *network-address* [*mask-length* | **mask** *mask*]
   By default, no primary subnet is specified.
4. (Optional.) Specify the common address range.
   address range *start-ip-address end-ip-address*

By default, no IP address range is specified.

5. (Optional.) Specify an IP address range for a DHCP user class.

   class *class-name* **range** *start-ip-address end-ip-address*

   By default, no IP address range is specified for a user class.

   The DHCP user class must already be created by using the **dhcp class** command.

6. (Optional.) Set the address lease duration.

   expired { **day** *day* [**hour** *hour* [**minute** *minute* [**second** *second*]]] | **unlimited** }

   The default setting is 1 day.

7. (Optional.) Exclude the specified IP addresses in the address pool from dynamic allocation.

   forbidden-ip *ip-address*&<1-8>

   By default, all IP addresses in the DHCP address pool are assignable.

8. (Optional.) Exclude the specified IP addresses from automatic allocation in system view.

   a. Return to system view.

      quit

   b. Exclude the specified IP addresses from automatic allocation globally.

      dhcp server forbidden-ip *start-ip-address* [*end-ip-address*] [**vpn-instance** *vpn-instance-name*]

      By default, except for the IP address of the DHCP server interface, IP addresses in all address pools are assignable.

Specifying a primary subnet and multiple secondary subnets in a DHCP address pool

About this task

If an address pool has a primary subnet and multiple secondary subnets, the server assigns IP addresses on a secondary subnet when the primary subnet has no assignable IP addresses.

Restrictions and guidelines

IP addresses specified by the **forbidden-ip** command are not assignable in the current address pool, but are assignable in other address pools. IP addresses specified by the **dhcp server forbidden-ip** command are not assignable in any address pool.

The **network secondary** command is mutually exclusive with the **address range** command or the **class range** command. You cannot use them together in the same address pool.

Specifying a primary subnet and multiple secondary subnets

1. Enter system view.

   system-view

2. Enter DHCP address pool view.

   dhcp server ip-pool *pool-name*

3. Specify the primary subnet.

   network *network-address* [*mask-length* | **mask** *mask*]

   By default, no primary subnet is specified.

   You can specify only one primary subnet in each address pool. If you execute the **network** command multiple times, the most recent configuration takes effect.

4. (Optional.) Specify a secondary subnet.

network *network-address* [*mask-length* | **mask** *mask*] **secondary**

By default, no secondary subnet is specified.

You can specify a maximum of 32 secondary subnets in one address pool.

5. (Optional.) Return to address pool view.

quit

Setting the lease duration for dynamically allocation IP addresses

1. Enter system view.

system-view

2. Enter DHCP address pool view.

dhcp server ip-pool *pool-name*

3. Set the address lease duration.

expired { **day** *day* [**hour** *hour* [**minute** *minute* [**second** *second*]]] | **unlimited** }

The default setting is 1 day.

Excluding IP addresses from dynamic allocation

1. Enter system view.

system-view

2. Enter DHCP address pool view.

dhcp server ip-pool *pool-name*

3. Exclude the specified IP addresses from dynamic allocation.

forbidden-ip *ip-address*&<1-8>

By default, all IP addresses in the DHCP address pool are assignable.

To exclude multiple address ranges from the address pool, repeat this step.

4. (Optional.) Exclude the specified IP addresses from dynamic allocation in system view.

   a. Return to system view.

   quit

   b. Exclude the specified IP addresses from dynamic allocation globally.

   dhcp server forbidden-ip *start-ip-address* [*end-ip-address*] [**vpn-instance** *vpn-instance-name*]

   By default, except for the IP address of the DHCP server interface, IP addresses in all address pools are assignable.

   To exclude multiple address ranges globally, repeat this step.

Configuring a static binding in a DHCP address pool

About this task

Some DHCP clients, such as a WWW server, need fixed IP addresses. To provide a fixed IP address for a client, you can statically bind the MAC address or ID of the client to an IP address in a DHCP address pool. When the client requests an IP address, the DHCP server assigns the IP address in the static binding to the client.

Restrictions and guidelines

- The IP address of a static binding cannot be the address of the DHCP server interface. Otherwise, an IP address conflict occurs and the bound client cannot obtain an IP address correctly.

- Multiple interfaces on the same device might all use DHCP to request a static IP address. In this case, use client IDs rather than the device's MAC address to identify the interfaces. Otherwise, IP address allocation will fail.

Procedure

1. Enter system view.

   system-view

2. Enter DHCP address pool view.

   dhcp server ip-pool *pool-name*

3. Configure a static binding.

   static-bind ip-address *ip-address* [*mask-length* | **mask** *mask*] { **client-identifier** *client-identifier* | **hardware-address** *hardware-address* [**ethernet** | **token-ring**] }

   By default, no static binding is configured.

   One IP address can be bound to only one client MAC or client ID. You cannot modify bindings that have been created. To change the binding for a DHCP client, you must delete the existing binding first.

4. (Optional.) Set the lease duration for the IP address.

   expired { **day** *day* [**hour** *hour* [**minute** *minute* [**second** *second*]]] | **unlimited** }

   By default, the lease duration is 1 day.

Specifying gateways for DHCP clients

About this task

DHCP clients send packets destined for other networks to a gateway. The DHCP server can assign the gateway address to the DHCP clients.

Restrictions and guidelines

You can specify gateway addresses in each address pool on the DHCP server. A maximum of 64 gateways can be specified in DHCP address pool view or secondary subnet view.

The DHCP server assigns gateway addresses to clients on a secondary subnet in the following ways:

- If gateways are specified in both address pool view and secondary subnet view, DHCP assigns those specified in the secondary subnet view.
- If gateways are specified in address pool view but not in secondary subnet view, DHCP assigns those specified in address pool view.

Procedure

1. Enter system view.

   system-view

2. Enter DHCP address pool view.

   dhcp server ip-pool *pool-name*

3. Specify gateways.

   gateway-list *ip-address*&<1-64>

   By default, no gateway is specified.

4. (Optional.) Specify gateways in secondary subnet view.

   a. Enter secondary subnet view.

      network *network-address* [*mask-length* | **mask** *mask*] **secondary**

b. Specify gateways.

gateway-list *ip-address*&<1-64>

By default, no gateway is specified.

Specifying a domain name suffix for DHCP clients

About this task

You can specify a domain name suffix in a DHCP address pool on the DHCP server. With this suffix assigned, the client only needs to input part of a domain name, and the system adds the domain name suffix for name resolution. For more information about DNS, see "Configuring DNS."

Procedure

1. Enter system view.

   system-view
2. Enter DHCP address pool view.

   dhcp server ip-pool *pool-name*
3. Specify a domain name suffix.

   domain-name *domain-name*

   By default, no domain name is specified.

Specifying DNS servers for DHCP clients

About this task

To access hosts on the Internet through domain names, a DHCP client must contact a DNS server to resolve names. You can specify up to eight DNS servers in a DHCP address pool.

Procedure

1. Enter system view.

   system-view
2. Enter DHCP address pool view.

   dhcp server ip-pool *pool-name*
3. Specify DNS servers.

   dns-list *ip-address*&<1-8>

   By default, no DNS server is specified.

Specifying WINS servers and NetBIOS node type for DHCP clients

About this task

A Microsoft DHCP client using NetBIOS protocol must contact a WINS server for name resolution.

In addition, you must specify one of the following NetBIOS node types to approach name resolution:

- **b (broadcast)-node**—A b-node client sends the destination name in a broadcast message. The destination returns its IP address to the client after receiving the message.
- **p (peer-to-peer)-node**—A p-node client sends the destination name in a unicast message to the WINS server. The WINS server returns the destination IP address.

- **m (mixed)-node**—An m-node client broadcasts the destination name. If it receives no response, it unicasts the destination name to the WINS server to get the destination IP address.
- **h (hybrid)-node**—An h-node client unicasts the destination name to the WINS server. If it receives no response, it broadcasts the destination name to get the destination IP address.

Procedure

1. Enter system view.
   system-view
2. Enter DHCP address pool view.
   dhcp server ip-pool *pool-name*
   By default, no DHCP address pool exists.
3. Specify WINS servers.
   nbns-list *ip-address*&<1-8>
   By default, no WINS server is specified.
   This step is optional for b-node. You can specify a maximum of eight WINS servers for such clients in one DHCP address pool.
4. Specify the NetBIOS node type.
   netbios-type { **b-node** | **h-node** | **m-node** | **p-node** }
   By default, no NetBIOS node type is specified.

Specifying BIMS server for DHCP clients

About this task

Perform this task to provide the BIMS server IP address, port number, and shared key for the clients. The DHCP clients contact the BIMS server to get configuration files and perform software upgrade and backup.

Procedure

1. Enter system view.
   system-view
2. Enter DHCP address pool view.
   dhcp server ip-pool *pool-name*
3. Specify the BIMS server IP address, port number, and shared key.
   bims-server ip *ip-address* [**port** *port-number*] **sharekey** { **cipher** | **simple** } *string*
   By default, no BIMS server information is specified.

Specifying the configuration file for DHCP client automatic configuration

About this task

Automatic configuration enables a device to automatically obtain a set of configuration settings at startup. The server-based automatic configuration requires the cooperation of the DHCP server and file server (TFTP or HTTP server). The device uses the obtained parameters to contact the file server to get the configuration file. For more information about automatic configuration, see *Fundamentals Configuration Guide*.

Specifying the configuration file on a TFTP file server

1. Enter system view.
   system-view
2. Enter DHCP address pool view.
   dhcp server ip-pool *pool-name*
   By default, no DHCP address pool exists.
3. Specify the IP address or the name of a TFTP server.
   - Specify the IP address of the TFTP server.
     tftp-server ip-address *ip-address*
     By default, no TFTP server IP address is specified.
   - Specify the name of the TFTP server.
     tftp-server domain-name *domain-name*
     By default, no TFTP server name is specified.
4. Specify the configuration file name.
   bootfile-name *bootfile-name*
   By default, no configuration file name is specified.

Specifying the URL of the configuration file on an HTTP file server

1. Enter system view.
   system-view
2. Enter DHCP address pool view.
   dhcp server ip-pool *pool-name*
3. Specify the URL of the configuration file.
   bootfile-name *url*
   By default, no configuration file URL is specified.

Specifying a server for DHCP clients

About this task

Some DHCP clients need to obtain configuration information from a server, such as a TFTP server. You can specify the IP address of that server. The DHCP server sends the server's IP address to DHCP clients along with other configuration information.

Procedure

1. Enter system view.
   system-view
2. Enter DHCP address pool view.
   dhcp server ip-pool *pool-name*
3. Specify the IP address of a server.
   next-server *ip-address*
   By default, no server is specified.

Configuring Option 184 parameters for DHCP clients

About this task

To assign calling parameters to DHCP clients with voice service, you must configure Option 184 on the DHCP server. For more information about Option 184, see "Option 184."

Procedure

1. Enter system view.
   system-view
2. Enter DHCP address pool view.
   dhcp server ip-pool *pool-name*
3. Specify the IP address of the primary network calling processor.
   voice-config ncp-ip *ip-address*
   By default, no primary network calling processor is specified.
   After you configure this command, the other Option 184 parameters take effect.
4. (Optional.) Specify the IP address of the backup server.
   voice-config as-ip *ip-address*
   By default, no backup network calling processor is specified.
5. (Optional.) Configure the voice VLAN.
   voice-config voice-vlan *vlan-id* { **disable** | **enable** }
   By default, no voice VLAN is configured.
6. (Optional.) Specify the failover IP address and dialer string.
   voice-config fail-over *ip-address dialer-string*
   By default, no failover IP address or dialer string is specified.

Customizing DHCP options

DHCP option customization applications

You can customize DHCP options for the following purposes:

- Add newly released options.
- Add options for which the vendor defines the contents, for example, Option 43.
- Add options for which the CLI does not provide a dedicated configuration command. For example, you can use the **option 4 ip-address 1.1.1.1** command to define the time server address 1.1.1.1 for DHCP clients.
- Add all option values if the actual requirement exceeds the limit for a dedicated option configuration command. For example, the **dns-list** command can specify up to eight DNS servers. To specify more than eight DNS servers, you must use the **option 6** command to define all DNS servers.

Common DHCP options

Table 1 lists common DHCP options and their parameters.

Table 1 Common DHCP options

Option	Option name	Corresponding command	Recommended parameter in the `option` command
3	Router Option	**gateway-list**	**ip-address**

Option	Option name	Corresponding command	Recommended parameter in the `option` command
6	Domain Name Server Option	**dns-list**	**ip-address**
15	Domain Name	**domain-name**	**ascii**
44	NetBIOS over TCP/IP Name Server Option	**nbns-list**	**ip-address**
46	NetBIOS over TCP/IP Node Type Option	**netbios-type**	**hex**
66	TFTP server name	**tftp-server**	**ascii**
67	Boot file name	**bootfile-name**	**ascii**
43	Vendor Specific Information	N/A	**hex**
252	Opt252 Password	N/A	**ascii**
253	Cloud Domain Name	N/A	**ascii**

Restrictions and guidelines

Use caution when customizing DHCP options because the configuration might affect DHCP operation.

You can customize a DHCP option in a DHCP address pool

You can customize a DHCP option in a DHCP option group, and specify the option group for a user class in an address pool. A DHCP client in the user class will obtain the option configuration.

Customizing a DHCP option in a DHCP address pool

1. Enter system view.

   system-view
2. Enter DHCP address pool view.

   dhcp server ip-pool *pool-name*
3. Customize a DHCP option.

   option *code* { **ascii** *ascii-string* | **hex** *hex-string* | **ip-address** *ip-address*&<1-8> }

   By default, no DHCP option is customized in a DHCP address pool.

   DHCP options specified in DHCP option groups take precedence over those specified in DHCP address pools.

Customizing a DHCP option in a DHCP option group

1. Enter system view.

   system-view
2. Create a DHCP option group and enter DHCP option group view.

   dhcp option-group *option-group-number*
3. Customize a DHCP option.

   option *code* { **ascii** *ascii-string* | **hex** *hex-string* | **ip-address** *ip-address*&<1-8> }

   By default, no DHCP option is customized in a DHCP option group.

   If multiple DHCP option groups have the same option, the server selects the option in the DHCP option group first matching the user class.

4. Return to system view.
   quit
5. Enter DHCP address pool view.
   dhcp server ip-pool *pool-name*
6. Specify the DHCP option group for the DHCP user class.
   class *class-name* **option-group** *option-group-number*
   By default, no DHCP option group is specified for a DHCP user class.

Applying a DHCP address pool to a VPN instance

About this task

If a DHCP address pool is applied to a VPN instance, the DHCP server assigns IP addresses in this address pool to clients in the VPN instance. Addresses in this address pool will not be assigned to clients on the public network.

The DHCP server can obtain the VPN instance to which a DHCP client belongs from the following information:

- The client's VPN information stored in authentication modules, such as IPoE.
- The VPN information of the DHCP server's interface that receives DHCP packets from the client.

If both VPN instances can be obtained, the VPN information from authentication modules takes priority over the VPN information of the receiving interface.

An MCE acting as the DHCP server can assign IP addresses not only to clients on public networks, but also to clients on private networks. The IP address ranges of public and private networks or those of private networks on the DHCP server cannot overlap. For more information about MCE, see *MCE Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter DHCP address pool view.
   dhcp server ip-pool *pool-name*
3. Apply the address pool to a VPN instance.
   vpn-instance *vpn-instance-name*
   By default, the address pool is not applied to any VPN instance.

Configuring the DHCP user class whitelist

About this task

The DHCP user class whitelist functions as follows:

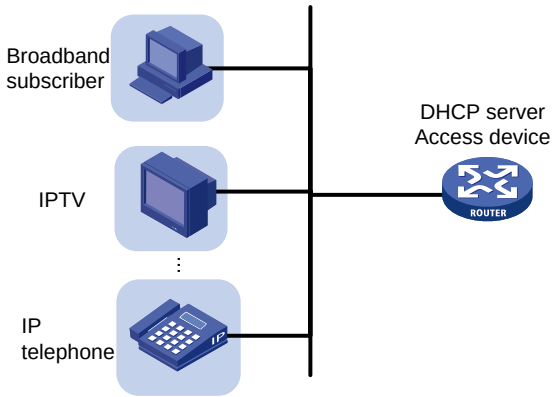
- When no online DHCP users exist, the DHCP server only processes the following requests:
  - Requests from users in the DHCP user class whitelist.
  - Lease renewal requests from users that are not in the DHCP user class whitelist. The DHCP server will reply DHCP-NAK messages to those requests.
- When online DHCP users exist, the DHCP server processes requests only from users in the DHCP user class whitelist.

Restrictions and guidelines

The whitelist does not take effect on clients who request static IP addresses, and the server always processes their requests.

Procedure

1. Enter system view.
   system-view
2. Enter DHCP address pool view.
   dhcp server ip-pool *pool-name*
3. Enable the DHCP user class whitelist.
   verify class
   By default, the DHCP user class whitelist is disabled.
4. Add DHCP user classes to the DHCP user class whitelist.
   valid class *class-name*&<1-8>
   By default, no DHCP user class is on the DHCP user class whitelist.



Binding gateways to DHCP server's MAC address

About this task

This feature enables the DHCP server to assign different gateway IP addresses to DHCP clients. In addition, the DHCP server uses the gateway IP addresses and the server's MAC address to reply to ARP requests from the clients.

As shown in Figure 8, the DHCP server is configured on the access device that provides access for clients of different service types, such as broadband, IPTV, and IP telephone. The clients of different types obtain IP addresses on different subnets. For the clients to access the network, the access interface typically has no IP address configured. You must bind the gateways to the DHCP server's MAC address when specifying gateways for the DHCP clients.

Figure 8 Network diagram

Restrictions and guidelines

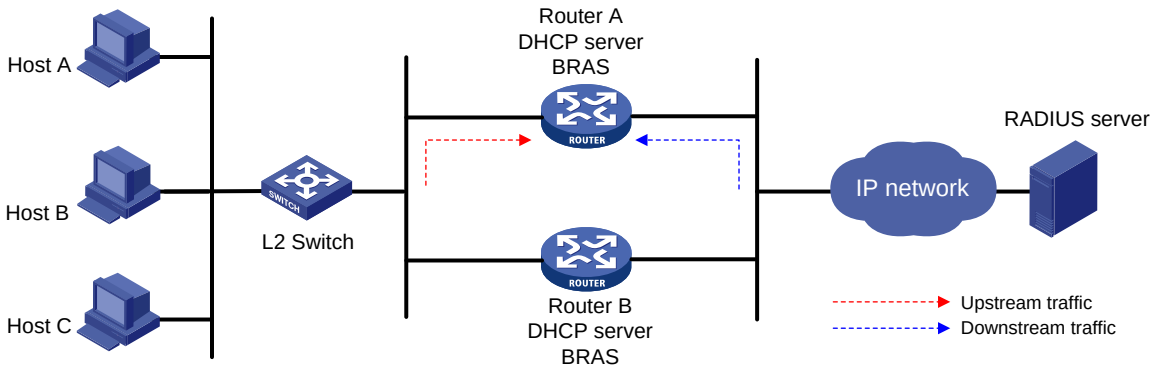
The gateway binding feature on the master device takes effect if the DHCP address pool is bound to a VSRP instance.

If the address pool is applied to a VPN instance, make sure the VPN instance already exists.

Procedure

1. Enter system view.
   system-view

2. Enter DHCP address pool view.
   dhcp server ip-pool *pool-name*
3. Bind the gateways to the device's MAC address.
   gateway-list *ip-address*&<1-64> **export-route**
   By default, gateways are not bound to any MAC address.



Advertising subnets that are assigned to clients

About this task

This feature enables the route management module to advertise subnets assigned to DHCP clients. This feature achieves symmetric routing for traffic of the same host.

As shown in Figure 9, Router A and Router B act as both the DHCP server and the BRAS device. The BRAS devices send accounting packets to the RADIUS server. To enable the BRAS devices to collect correct accounting information for each RADIUS user, configure the DHCP server to advertise subnets assigned to clients. The upstream and downstream traffic of a RADIUS user will pass through the same BRAS device.

Figure 9 Network diagram

Restrictions and guidelines

The subnet advertising on the master device takes effect if the DHCP address pool is bound to a VSRP instance. If the address pool is applied to a VPN instance, make sure the VPN instance already exists.

Procedure

1. Enter system view.
   system-view
2. Create a DHCP address pool and enter its view.
   dhcp server ip-pool *pool-name*
3. Advertise subnets assigned to DHCP clients.
   network *network-address* [*mask-length* | **mask** *mask*] [**secondary**] **export-route**
   By default, the subnets assigned to DHCP clients are not advertised.

Applying an address pool to an interface

About this task

Perform this task to apply a DHCP address pool to an interface.

Upon receiving a DHCP request from the interface, the DHCP server performs address allocation in the following ways:

- If a static binding is found for the client, the server assigns the static IP address and configuration parameters from the address pool that contains the static binding.
- If no static binding is found for the client, the server uses the address pool applied to the interface for address and configuration parameter allocation.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Apply an address pool to the interface.

   dhcp server apply ip-pool *pool-name*

   By default, no address pool is applied to an interface.

   If the applied address pool does not exist, the DHCP server fails to perform dynamic address allocation.

Configuring a DHCP policy for dynamic assignment

About this task

In a DHCP policy, each DHCP user class has a bound DHCP address pool. Clients matching different user classes obtain IP addresses and other parameters from different address pools. The DHCP policy must be applied to the interface that acts as the DHCP server. When receiving a DHCP request, the DHCP server compares the packet against the user classes in the order that they are configured.

- If a matching user class is found and the bound address pool has assignable IP addresses, the server assigns an IP address and other parameters from the address pool. If the address pool does not have assignable IP addresses, the address assignment fails.
- If no match is found, the server assigns an IP address and other parameters from the default DHCP address pool. If no default address pool is specified or the default address pool does not have assignable IP addresses, the address assignment fails.

For successful address assignment, make sure the applied DHCP policy and the bound address pools exist.

Restrictions and guidelines

A DHCP policy take effect only after it is applied to an interface.

Procedure

1. Enter system view.

   system-view
2. Create a DHCP policy and enter DHCP policy view.

   dhcp policy *policy-name*
3. Specify a DHCP address pool for a DHCP user class.

   class *class-name* **ip-pool** *pool-name*

   By default, no address pool is specified for a user class.
4. Specify the default DHCP address pool.

default ip-pool *pool-name*

By default, no default address pool is specified.

5. Return to system view.

   quit

6. Enter interface view.

   interface *interface-type interface-number*

7. Apply the DHCP policy to the interface.

   dhcp apply-policy *policy-name*

   By default, no DHCP policy is applied to an interface.

Enabling DHCP

Restrictions and guideline

You must enable DHCP to make other DHCP configurations take effect.

Procedure

1. Enter system view.

   system-view

2. Enable DHCP.

   dhcp enable

   By default, DHCP is disabled.

Enabling the DHCP server on an interface

About this task

Perform this task to enable the DHCP server on an interface. Upon receiving a DHCP request on the interface, the DHCP server assigns the client an IP address and other configuration parameters from a DHCP address pool.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the DHCP server on the interface.

   dhcp select server

   By default, the DHCP server is enabled on the interface.

Configuring IP address conflict detection

About this task

Before assigning an IP address, the DHCP server pings that IP address.

- If the server receives a response within the specified period, it selects and pings another IP address.
- If it receives no response, the server continues to ping the IP address until the maximum number of ping packets are sent. If still no response is received, the server assigns the IP

address to the requesting client. The DHCP client uses gratuitous ARP to perform IP address conflict detection.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. (Optional.) Set the maximum number of ping packets to be sent for conflict detection.
   ```
   dhcp server ping packets number
   ```
   The default setting is one.
   To disable IP address conflict detection, set the value to **0**.
3. (Optional.) Set the ping timeout time.
   ```
   dhcp server ping timeout milliseconds
   ```
   The default setting is 500 ms.
   To disable IP address conflict detection, set the value to **0**.

Enabling handling of Option 82

About this task

Perform this task to enable the DHCP server to handle Option 82. Upon receiving a DHCP request that contains Option 82, the DHCP server adds Option 82 into the DHCP response.

If you disable the DHCP to handle Option 82, it does not add Option 82 into the response message.

You must enable handling of Option 82 on both the DHCP server and the DHCP relay agent to ensure correct processing for Option 82. For information about enabling handling of Option 82 on the DHCP relay agent, see "Configuring DHCP relay agent support for Option 82."

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable the server to handle Option 82.
   ```
   dhcp server relay information enable
   ```
   By default, handling of Option 82 is enabled.

Configuring the DHCP server security features

Restrictions and guidelines

The DHCP server security features are not applicable if a DHCP relay agent exists in the network. This is because the MAC address of the DHCP relay agent is encapsulated as the source MAC address in the DHCP request received by the DHCP server. In this case, you must configure the DHCP relay agent security features. For more information, see "Configuring the DHCP relay agent security features."

Configuring DHCP starvation attack protection

About this task

A DHCP starvation attack occurs when an attacker constantly sends forged DHCP requests using different MAC addresses in the **chaddr** field to a DHCP server. This exhausts the IP address

resources of the DHCP server so legitimate DHCP clients cannot obtain IP addresses. The DHCP server might also fail to work because of exhaustion of system resources. For information about the fields in the DHCP messages, see "DHCP message format."

The following methods are available to relieve or prevent such attacks.

- To relieve a DHCP starvation attack that uses DHCP packets encapsulated with different source MAC addresses, perform the following configuration on an interface:
  - Execute the **mac-address max-mac-count** command to set the MAC learning limit. For more information about this command, see *Layer 2—LAN Switching Command Reference*.
  - Disable unknown frame forwarding when the MAC learning limit is reached.
- To prevent a DHCP starvation attack that uses DHCP requests encapsulated with the same source MAC address, you can enable MAC address check on the DHCP server. The DHCP server compares the **chaddr** field of a received DHCP request with the source MAC address in the frame header. If they are the same, the DHCP server verifies this request as legal and processes it. If they are not the same, the server discards the DHCP request.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable MAC address check.

   dhcp server check mac-address

   By default, MAC address check is disabled.

Configuring DHCP server compatibility

Perform this task to enable the DHCP server to support DHCP clients that are incompliant with RFC.

Configuring the DHCP server to always broadcast responses

About this task

By default, the DHCP server broadcasts a response only when the broadcast flag in the DHCP request is set to 1. You can configure the DHCP server to ignore the broadcast flag and always broadcast a response. This feature is useful when some clients set the broadcast flag to 0 but do not accept unicast responses.

The DHCP server always unicasts a response in the following situations, regardless of whether this feature is configured or not:

- The DHCP request is from a DHCP client that has an IP address (the **ciaddr** field is not 0).
- The DHCP request is forwarded by a DHCP relay agent from a DHCP client (the **giaddr** field is not 0).

Procedure

1. Enter system view.

   system-view
2. Enable the DHCP server to always broadcast all responses.

   dhcp server always-broadcast

   By default, the DHCP server reads the broadcast flag to decide whether to broadcast or unicast a response.

Enabling the DHCP server to return a DHCP-NAK message upon client notions of incorrect IP addresses

About this task

A DHCP client can send a DHCP-REQUEST message directly or upon receiving a DHCP-OFFER message. Upon receiving the request, the DHCP server will check if the client notion of its IP address is correct. If the requested IP address is different from the allocated one or has no matching lease record, the DHCP server remains silent by default. After the allocated IP address lease for the client expires, the DHCP server will make response to request from the client.

This feature enables the DHCP server to return DHCP-NAK messages if the client notions of their IP addresses are incorrect. After receiving the DHCP-NAK message, the DHCP client will request an IP address again.

Procedure

1. Enter system view.

   `system-view`

2. Enable the DHCP server to return a DHCP-NAK message if the client notions of their IP addresses are incorrect.

   `dhcp server request-ip-address check`

   The DHCP server does not return a DHCP-NAK message if the client notions of their IP addresses are incorrect.

Configuring the DHCP server to ignore BOOTP requests

About this task

The lease duration of the IP addresses obtained by the BOOTP clients is unlimited. For some scenarios that do not allow unlimited leases, you can configure the DHCP server to ignore BOOTP requests.

Procedure

1. Enter system view.

   `system-view`

2. Configure the DHCP server to ignore BOOTP requests.

   `dhcp server bootp ignore`

   By default, the DHCP server processes BOOTP requests.

Configuring the DHCP server to send BOOTP responses in RFC 1048 format

About this task

Not all BOOTP clients can send requests that are compatible with RFC 1048. By default, the DHCP server does not process the Vend field of RFC 1048-incompliant requests but copies the Vend field into responses.

This feature enables the DHCP server to fill the Vend field in RFC 1048-compliant format in DHCP responses to RFC 1048-incompliant requests sent by BOOTP clients.

Procedure

1. Enter system view.

system-view

2. Enable the DHCP server to send BOOTP responses in RFC 1048 format to the RFC 1048-incompliant BOOTP requests.

   dhcp server bootp reply-rfc-1048

   By default, the DHCP server directly copies the Vend field of such requests into the responses.

Setting the DSCP value for DHCP packets sent by the DHCP server

About this task

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet.

Procedure

1. Enter system view.

   system-view

2. Set the DSCP value for DHCP packets sent by the DHCP server.

   dhcp dscp *dscp-value*

   By default, the DSCP value in DHCP packets sent by the DHCP server is 56.

Configuring DHCP binding auto backup

About this task

The auto backup feature saves bindings to a backup file and allows the DHCP server to download the bindings from the backup file at the server reboot. The bindings include the lease bindings and conflicted IP addresses. They cannot survive a reboot on the DHCP server.

The DHCP server does not provide services during the download process. If a connection error occurs during the process and cannot be repaired in a short amount of time, you can terminate the download operation. Manual interruption allows the DHCP server to provide services without waiting for the connection to be repaired.

Procedure

1. Enter system view.

   system-view

2. Configure the DHCP server to back up the bindings to a file.

   dhcp server database filename { *filename* | **url** *url* [**username** *username* [**password** { **cipher** | **simple** } *string*]] }

   By default, the DHCP server does not back up the DHCP bindings.

   With this command executed, the DHCP server backs up its bindings immediately and runs auto backup.

3. (Optional.) Manually save the DHCP bindings to the backup file.

   dhcp server database update now

4. (Optional.) Set the waiting time after a DHCP binding change for the DHCP server to update the backup file.

   dhcp server database update interval *interval*

   By default, the DHCP server waits 300 seconds to update the backup file after a DHCP binding change. If no DHCP binding changes, the backup file is not updated.

5. (Optional.) Terminate the download of DHCP bindings from the backup file.
   dhcp server database update stop
   This command only triggers one termination.

Enabling client offline detection on the DHCP server

About this task

The client offline detection feature reclaims an assigned IP address and deletes the binding entry when the ARP entry for the IP address ages out.

Restrictions and guidelines

The feature does not function if an ARP entry is manually deleted.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable client offline detection.
   dhcp client-detect
   By default, client offline detection is disabled on the DHCP server.

Configuring SNMP notifications for the DHCP server

About SNMP DHCP server notifications

Perform this task to configure the device to send SNMP notifications of DHCP server alarms. The following are available DHCP server alarm notifications:

- **IP exhaustion notifications**—All assignable IP addresses in an IP pool are used up or an IP pool has recovered from the IP exhaustion condition.
- **IP usage alarm notifications**—The IP address usage of an IP pool has reached or exceeded the specified threshold, or an IP pool has recovered from an IP usage alarm condition.

The SNMP notifications are sent to the SNMP module. For the SNMP notifications to be sent correctly, you must also configure SNMP. For more information about SNMP configuration, see SNMP configuration in *Network Management and Monitoring Configuration Guide*.

When the IP pool usage is not lower than the threshold or drops below 90% of the threshold, the DHCP module also sends a log message to the information center. For log messages to be sent correctly, configure the information center to set log message filtering and output rules, including output destinations. For information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Enabling IP exhaustion notifications

1. Enter system view.

system-view

2. Enable IP exhaustion notifications.
   snmp-agent trap enable dhcp server address-exhaust
   By default, IP exhaustion notifications are enabled.
3. Enter IP address pool view.
   dhcp server ip-pool *pool-name*
4. (Optional.) Enable IP exhaustion notifications for an IP pool.
   exhaustion trap enable
   By default, IP exhaustion notifications are enabled for an IP pool.

Enabling IP usage alarm notifications

1. Enter system view.
   system-view
2. Enable IP usage alarm notifications.
   snmp-agent trap enable dhcp server ip-in-use
   By default, IP usage alarm notifications are enabled.
3. Enter IP pool view.
   dhcp server ip-pool *pool-name*
4. (Optional.) Set the IP address usage threshold for the IP pool.
   ip-in-use threshold *threshold-value*
   The default threshold is 100%.

Enabling DHCP logging on the DHCP server

About this task

The DHCP logging feature enables the DHCP server to generate DHCP logs and send them to the information center. The information helps administrators locate and solve problems. For information about the log destination and output rule configuration in the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

As a best practice, disable this feature if the log generation affects the device performance or reduces the address allocation efficiency. For example, this situation might occur when a large number of clients frequently come online or go offline.

Procedure

1. Enter system view.
   system-view
2. Enable DHCP logging.
   dhcp log enable
   By default, DHCP logging is disabled.

Enabling IP exhaustion event logging

About this task

This feature enables the DHCP module to send IP exhaustion logs to the information center. IP exhaustion events include IP exhaustion alarms and recoveries from IP exhaustion alarm conditions.

An IP exhaustion log message is generated for an IP pool when one of the following events occurs:

NOTE:

If the IP address usage threshold for the IP pool is 100%, the DHCP module generates an alarm message instead of a log message for one of the following events. To set the IP address usage threshold for an IP pool, use the **ip-in-use threshold** command.

- The IP pool does not have assignable IP addresses.
- The IP address usage of the IP pool drops below 90% after IP address exhaustion. The IP address usage is calculated by using the following formula:

  (Total number of IP addresses – number of assignable IP addresses)/total number of IP addresses

For log messages to be sent correctly, configure the information center to set log message filtering and output rules, including output destinations. For more information about configuring the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

This feature is not affected if DHCP logging is disabled on the DHCP server.

Procedure

1. Enter system view.

   system-view
2. Enter IP pool view.

   dhcp server ip-pool *pool-name*
3. Enable IP exhaustion event logging.

   exhaustion log enable

   By default, IP exhaustion event logging is disabled.

Display and maintenance commands for DHCP server

IMPORTANT:

A restart of the DHCP server or execution of the **reset dhcp server ip-in-use** command deletes all lease information. The DHCP server denies any DHCP request for lease extension, and the client must request an IP address again.

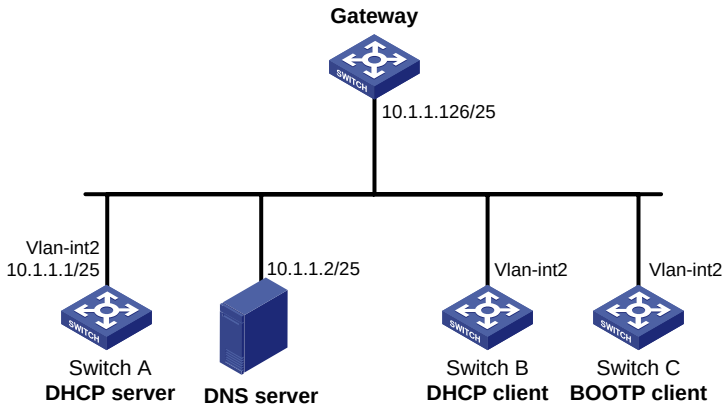
Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display information about IP address conflicts.	**display dhcp server conflict** [**ip** *ip-address*] [**vpn-instance** *vpn-instance-name*]

Task	Command
Display information about DHCP binding auto backup.	**display dhcp server database**
Display information about lease-expired IP addresses.	**display dhcp server expired** [[**ip** *ip-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]
Display information about assignable IP addresses.	**display dhcp server free-ip** [**pool** *pool-name* | **vpn-instance** *vpn-instance-name*]
Display information about assigned IP addresses.	**display dhcp server ip-in-use** [[**ip** *ip-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]
Display information about DHCP address pools.	**display dhcp server pool** [*pool-name* | **vpn-instance** *vpn-instance-name*]
Display DHCP server statistics.	**display dhcp server statistics** [**pool** *pool-name* | **vpn-instance** *vpn-instance-name*]
Clear information about IP address conflicts.	**reset dhcp server conflict** [**ip** *ip-address*] [**vpn-instance** *vpn-instance-name*]
Clear information about lease-expired IP addresses.	**reset dhcp server expired** [[**ip** *ip-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]
Clear information about assigned IP addresses.	**reset dhcp server ip-in-use** [[**ip** *ip-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]
Clear DHCP server statistics.	**reset dhcp server statistics** [**vpn-instance** *vpn-instance-name*]

DHCP server configuration examples

Example: Configuring static IP address assignment



Network configuration

As shown in Figure 10, Switch B (DHCP client) and Switch C (BOOTP client) obtain the IP address, DNS server address, and gateway address from Switch A (DHCP server).

The client ID of VLAN-interface 2 on Switch B is 0030-3030-662e-6532-3030-2e30-3030-322d-4574-6865-726e-6574.

The MAC address of VLAN-interface 2 on Switch C is 000f-e200-01c0.

Figure 10 Network diagram

Procedure

1. Specify an IP address for VLAN-interface 2 on Switch A.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 10.1.1.1 25
[SwitchA-Vlan-interface2] quit
```

2. Configure the DHCP server:

Create DHCP address pool 0.

```
[SwitchA] dhcp server ip-pool 0
```

Configure a static binding for Switch B.

```
[SwitchA-dhcp-pool-0] static-bind ip-address 10.1.1.5 25 client-identifier
0030-3030-662e-6532-3030-2e30-3030-322d-4574-6865-726e-6574
```

Configure a static binding for Switch C.

```
[SwitchA-dhcp-pool-0] static-bind ip-address 10.1.1.6 25 hardware-address
000f-e200-01c0
```

Specify the DNS server address and the gateway address.

```
[SwitchA-dhcp-pool-0] dns-list 10.1.1.2
[SwitchA-dhcp-pool-0] gateway-list 10.1.1.126
[SwitchA-dhcp-pool-0] quit
```

Enable DHCP.

```
[SwitchA] dhcp enable
```

Enable the DHCP server on VLAN-interface 2.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] dhcp select server
[SwitchA-Vlan-interface2] quit
```

Verifying the configuration

Verify that Switch B can obtain IP address 10.1.1.5 and all other network parameters from Switch A. (Details not shown.)

Verify that Switch C can obtain IP address 10.1.1.6 and all other network parameters from Switch A. (Details not shown.)

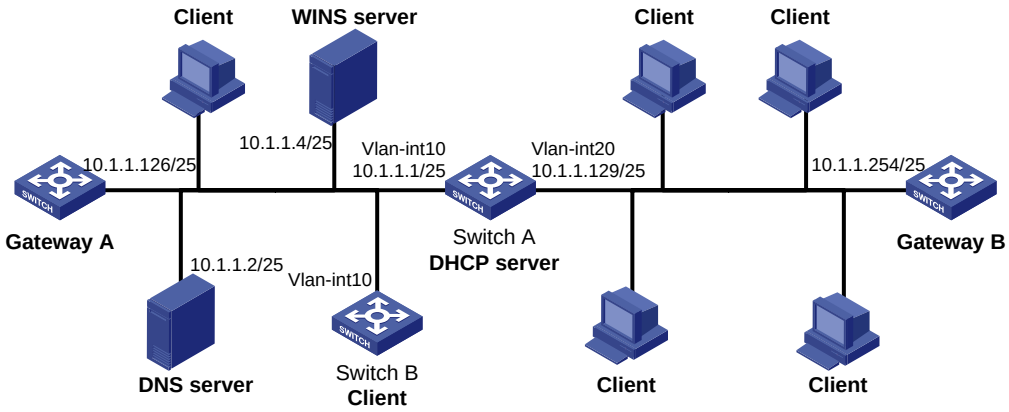
On the DHCP server, display the IP addresses assigned to the clients.

```
[SwitchA] display dhcp server ip-in-use
IP address       Client-identifier/    Lease expiration      Type
```

```
                Hardware address
10.1.1.5        0030-3030-662e-6532-  Jan 21 14:27:27 2014  Static(C)
                3030-2e30-3030-322d-
                4574-6865-726e-6574
10.1.1.6        000f-e200-01c0        Unlimited             Static(C)
```

Example: Configuring dynamic IP address assignment

Network configuration



As shown in Figure 11, the DHCP server (Switch A) assigns IP addresses to clients on subnet 10.1.1.0/24, which is subnetted into 10.1.1.0/25 and 10.1.1.128/25.

Configure DHCP server on Switch A to implement the following assignment scheme.

Table 2 Assignment scheme

DHCP clients	IP address	Lease	Other configuration parameters
Clients connected to VLAN-interface 10	IP addresses on subnet 10.1.1.0/25	10 days and 12 hours	• Gateway: 10.1.1.126/25 • DNS server: 10.1.1.2/25 • Domain name: aabbcc.com • WINS server: 10.1.1.4/25
Clients connected to VLAN-interface 20	IP addresses on subnet 10.1.1.128/25	Five days	• Gateway: 10.1.1.254/25 • DNS server: 10.1.1.2/25 • Domain name: aabbcc.com

Figure 11 Network diagram

Procedure

1. Specify IP addresses for the VLAN interfaces. (Details not shown.)
2. Configure the DHCP server:

   # Exclude the DNS server address, WINS server address, and gateway addresses from dynamic allocation.

```
<SwitchA> system-view
[SwitchA] dhcp server forbidden-ip 10.1.1.2
[SwitchA] dhcp server forbidden-ip 10.1.1.4
[SwitchA] dhcp server forbidden-ip 10.1.1.126
[SwitchA] dhcp server forbidden-ip 10.1.1.254
```

Configure DHCP address pool 1 to assign IP addresses and other configuration parameters to clients on subnet 10.1.1.0/25.

```
[SwitchA] dhcp server ip-pool 1
[SwitchA-dhcp-pool-1] network 10.1.1.0 mask 255.255.255.128
[SwitchA-dhcp-pool-1] expired day 10 hour 12
[SwitchA-dhcp-pool-1] domain-name aabbcc.com
[SwitchA-dhcp-pool-1] dns-list 10.1.1.2
[SwitchA-dhcp-pool-1] gateway-list 10.1.1.126
[SwitchA-dhcp-pool-1] nbns-list 10.1.1.4
[SwitchA-dhcp-pool-1] quit
```

Configure DHCP address pool 2 to assign IP addresses and other configuration parameters to clients on subnet 10.1.1.128/25.

```
[SwitchA] dhcp server ip-pool 2

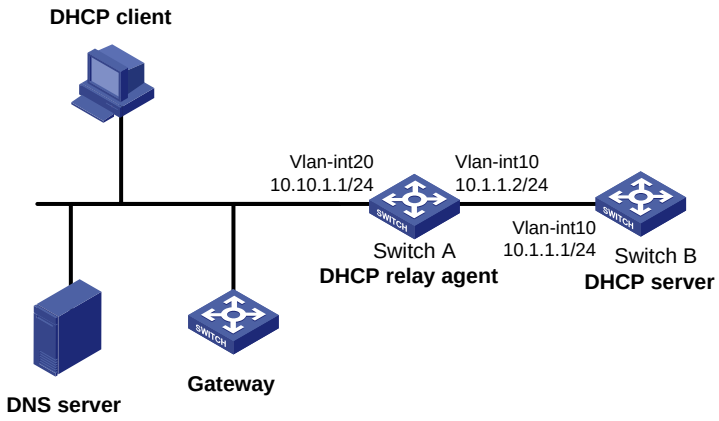
Example: Configuring DHCP user class

Network requirement



As shown in Figure 12, the DHCP relay agent (Switch A) forwards DHCP packets between DHCP clients and the DHCP server (Switch B). Enable switch A to support Option 82 so that switch A can add Option 82 in the DHCP requests sent by the DHCP clients.

Configure the address allocation scheme as follows:

Assign IP addresses	To clients
10.10.1.2 to 10.10.1.10	The DHCP request contains Option 82.
10.10.1.11 to 10.10.1.26	The hardware address in the request is six bytes long and begins with **aabb-aabb-aab**.

For clients on subnet 10.10.1.0/24, the DNS server address is 10.10.1.20/24 and the gateway address is 10.10.1.254/24.

Figure 12 Network diagram

Procedure

1. Specify IP addresses for interfaces on the DHCP server and the DHCP relay agent. (Details not shown.)
2. Configure DHCP services:

   # Create DHCP user class **tt** and configure a match rule to match client requests with Option 82.

   ```
   <SwitchB> system-view
   [SwitchB] dhcp class tt
   [SwitchB-dhcp-class-tt] if-match rule 1 option 82
   [SwitchB-dhcp-class-tt] quit
   ```

   # Create DHCP user class **ss** and configure a match rule to match DHCP requests in which the hardware address is six bytes long and begins with **aabb-aabb-aab**.

   ```
   [SwitchB] dhcp class ss
   ```

```
[SwitchB-dhcp-class-ss] if-match rule 1 hardware-address aabb-aabb-aab0 mask
ffff-ffff-fff0
[SwitchB-dhcp-class-ss] quit
```

Create DHCP address pool **aa**.

```
[SwitchB] dhcp server ip-pool aa
```

Specify the subnet for dynamic allocation.

```
[SwitchB-dhcp-pool-aa] network 10.10.1.0 mask 255.255.255.0
```

Specify the address range for dynamic allocation.

```
[SwitchB-dhcp-pool-aa] address range 10.10.1.2 10.10.1.100
```

Specify the address range for user class **tt**.

```
[SwitchB-dhcp-pool-aa] class tt range 10.10.1.2 10.10.1.10
```

Specify the address range for user class **ss**.

```
[SwitchB-dhcp-pool-aa] class ss range 10.10.1.11 10.10.1.26
```

Specify the gateway address and the DNS server address.

```
[SwitchB-dhcp-pool-aa] gateway-list 10.10.1.254
[SwitchB-dhcp-pool-aa] dns-list 10.10.1.20
[SwitchB-dhcp-pool-aa] quit
```

Enable DHCP and configure the DHCP server to handle Option 82.

```
[SwitchB] dhcp enable
[SwitchB] dhcp server relay information enable
```

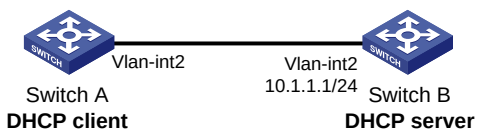
Enable DHCP server on VLAN-interface 10.

```
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] dhcp select server
[SwitchB-Vlan-interface10] quit
```

Verifying the configuration

Verify that clients matching the user classes can obtain IP addresses in the specified ranges and all other configuration parameters from the DHCP server. (Details not shown.)

Display the IP address assigned by the DHCP server.



```
[SwitchB] display dhcp server ip-in-use
IP address       Client-identifier/    Lease expiration      Type
                 Hardware address
10.10.1.2        0031-3865-392e-6262-  Jan 14 22:25:03 2015  Auto(C)
                 3363-2e30-3230-352d-
                 4745-302f-30
10.10.1.11       aabb-aabb-aab1        Jan 14 22:25:03 2015  Auto(C)
```

Example: Configuring DHCP user class whitelist

Network configuration

As shown in Figure 13, configure the DHCP user class whitelist to allow the DHCP server to assign IP addresses to clients whose hardware addresses are six bytes long and begin with **aabb-aabb**.

Figure 13 Network diagram

Procedure

1. Specify IP addresses for the interfaces on the DHCP server. (Details not shown.)
2. Configure DHCP:

   # Create DHCP user class **ss** and configure a match rule to match DHCP requests in which the hardware address is six bytes long and begins with **aabb-aabb**.

   ```
   <SwitchB> system-view
   [SwitchB] dhcp class ss
   [SwitchB-dhcp-class-ss] if-match rule 1 hardware-address aabb-aabb-0000 mask ffff-ffff-0000
   [SwitchB-dhcp-class-ss] quit
   ```

   # Create DHCP address pool **aa**.

   ```
   [SwitchB] dhcp server ip-pool aa
   ```

   # Specify the subnet for dynamic allocation.

   ```
   [SwitchB-dhcp-pool-aa] network 10.1.1.0 mask 255.255.255.0
   ```

   # Enable the DHCP user class whitelist.

   ```
   [SwitchB-dhcp-pool-aa] verify class
   ```

   # Add DHCP user class **ss** to the DHCP user class whitelist.

   ```
   [SwitchB-dhcp-pool-aa] valid class ss
   [SwitchB-dhcp-pool-aa] quit
   ```

   # Enable DHCP.

   ```
   [SwitchB] dhcp enable
   ```

   # Enable DHCP server on VLAN-interface 2.

   ```
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] dhcp select server
   [SwitchB-Vlan-interface2] quit
   ```

Verifying the configuration

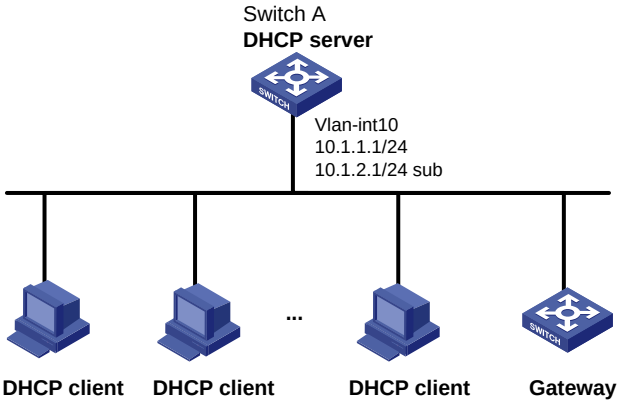
Verify that clients matching the DHCP user class can obtain IP addresses on subnet 10.1.1.0/24 from the DHCP server. (Details not shown.)

On the DHCP server, display the IP addresses assigned to the clients.

```
[SwitchB] display dhcp server ip-in-use
IP address       Client-identifier/    Lease expiration      Type
                 Hardware address
10.1.1.2         aabb-aabb-ab01        Jan 14 22:25:03 2015  Auto(C)
```

Example: Configuring primary and secondary subnets

Network configuration



As shown in Figure 14, the DHCP server (Switch A) dynamically assigns IP addresses to clients in the LAN.

Configure two subnets in the address pool on the DHCP server: 10.1.1.0/24 as the primary subnet and 10.1.2.0/24 as the secondary subnet. The DHCP server selects IP addresses from the secondary subnet when the primary subnet has no assignable addresses.

Switch A assigns the following parameters:

- The default gateway 10.1.1.254/24 to clients on subnet 10.1.1.0/24.
- The default gateway 10.1.2.254/24 to clients on subnet 10.1.2.0/24.

Figure 14 Network diagram

Procedure

Create DHCP address pool **aa**.

```
<SwitchA> system-view
[SwitchA] dhcp server ip-pool aa
```

Specify the primary subnet and the gateway address for dynamic allocation.

```
[SwitchA-dhcp-pool-aa] network 10.1.1.0 mask 255.255.255.0
[SwitchA-dhcp-pool-aa] gateway-list 10.1.1.254
```

Specify the secondary subnet and the gateway address for dynamic allocation.

```
[SwitchA-dhcp-pool-aa] network 10.1.2.0 mask 255.255.255.0 secondary
[SwitchA-dhcp-pool-aa-secondary] gateway-list 10.1.2.254
[SwitchA-dhcp-pool-aa-secondary] quit
[SwitchA-dhcp-pool-aa] quit
```

Enable DHCP.

```
[SwitchA] dhcp enable
```

Configure the primary and secondary IP addresses of VLAN-interface 10.

```
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] ip address 10.1.1.1 24
[SwitchA-Vlan-interface10] ip address 10.1.2.1 24 sub
```

Enable the DHCP server on VLAN-interface 10.

```
[SwitchA-Vlan-interface10] dhcp select server
[SwitchA-Vlan-interface10] quit
```

Verifying the configuration

Verify that the DHCP server assigns clients IP addresses and gateway address from the secondary subnet when no address is available from the primary subnet. (Details not shown.)

Display the primary and secondary subnet IP addresses the DHCP server has assigned. The following is part of the command output.

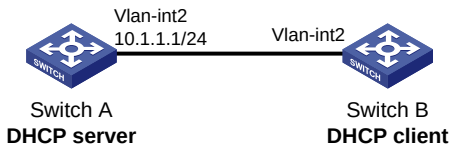
```
[SwitchA] display dhcp server ip-in-use
IP address       Client-identifier/    Lease expiration      Type
                 Hardware address
10.1.1.2         0031-3865-392e-6262-  Jan 14 22:25:03 2015  Auto(C)
                 3363-2e30-3230-352d-
                 4745-302f-30
10.1.2.2         3030-3030-2e30-3030-  Jan 14 22:25:03 2015  Auto(C)
```

```
662e-3030-3033-2d45-
7568-6572-1e
```

Example: Customizing DHCP option

Network configuration

As shown in Figure 15, DHCP clients obtain IP addresses and PXE server addresses from the DHCP server (Switch A). The subnet for address allocation is 10.1.1.0/24.



Configure the address allocation scheme as follows:

Assign PXE addresses	To clients
2.3.4.5 and 3.3.3.3	The hardware address in the request is six bytes long and begins with **aabb-aabb**.
1.2.3.4 and 2.2.2.2.	Other clients.

The DHCP server assigns PXE server addresses to DHCP clients through Option 43, a customized option. The format of Option 43 and that of the PXE server address sub-option are shown in Figure 5 and Figure 7. For example, the value of Option 43 configured in the DHCP address pool is 80 0B 00 00 02 01 02 03 04 02 02 02 02.

- The number 80 is the value of the sub-option type.
- The number 0B is the value of the sub-option length.
- The numbers 00 00 are the value of the PXE server type.
- The number 02 indicates the number of servers.
- The numbers 01 02 03 04 02 02 02 02 indicate that the PXE server addresses are 1.2.3.4 and 2.2.2.2.

Figure 15 Network diagram

Procedure

1. Specify IP addresses for the interfaces. (Details not shown.)
2. Configure the DHCP server:

   # Create DHCP user class **ss** and configure a match rule to match DHCP requests in which the hardware address is six bytes long and begins with **aabb-aabb**.

   ```
   <SwitchA> system-view
   [SwitchA] dhcp class ss
   [SwitchA-dhcp-class-ss] if-match rule 1 hardware-address aabb-aabb-0000 mask
   ffff-ffff-0000
   [SwitchA-dhcp-class-ss] quit
   ```

   # Create DHCP option group 1 and customize Option 43.

   ```
   [SwitchA] dhcp option-group 1
   [SwitchA-dhcp-option-group-1] option 43 hex 800B000002020304050303030303
   ```

   # Enable the DHCP server on VLAN-interface 2.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] dhcp select server
   ```

```
[SwitchA-Vlan-interface2] quit
```

Create DHCP address pool 0.

```
[SwitchA] dhcp server ip-pool 0
```

Specify the subnet for dynamic address allocation.

```
[SwitchA-dhcp-pool-0] network 10.1.1.0 mask 255.255.255.0
```

Customize Option 43.

```
[SwitchA-dhcp-pool-0] option 43 hex 800B000002010203040202020 2
```

Associate DHCP user class **ss** with option group 1.

```
[SwitchA-dhcp-pool-0] class ss option-group 1
[SwitchA-dhcp-pool-0] quit
```

Enable DHCP.

```
[SwitchA] dhcp enable
```

Verifying the configuration

Verify that Switch B can obtain an IP address on subnet 10.1.1.0/24 and the corresponding PXE server addresses from Switch A. (Details not shown.)

On the DHCP server, display the IP addresses assigned to the clients.

```
[SwitchA] display dhcp server ip-in-use
IP address       Client-identifier/    Lease expiration      Type
                 Hardware address
10.1.1.2         aabb-aabb-ab01        Jan 14 22:25:03 2015  Auto(C)
```

Troubleshooting DHCP server configuration

Failure to obtain a non-conflicting IP address

Symptom

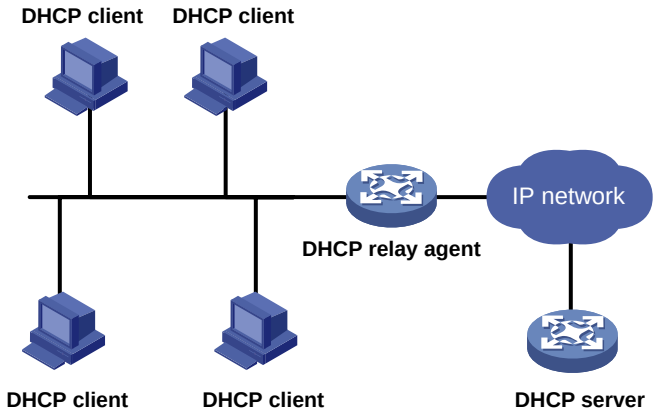
A client's IP address obtained from the DHCP server conflicts with an IP address of another host.

Solution

Another host on the subnet might have the same IP address.

To resolve the problem:

1. Disable the client's network adapter or disconnect the client's network cable. Ping the IP address of the client from another host to check whether there is a host using the same IP address.
2. If a ping response is received, the IP address has been manually configured on a host. Execute the **dhcp server forbidden-ip** command on the DHCP server to exclude the IP address from dynamic allocation.
3. Enable the network adapter or connect the network cable, release the IP address, and obtain another one on the client. For example, to release the IP address and obtain another one on a Windows XP DHCP client:
   a. In Windows environment, execute the **cmd** command to enter the DOS environment.
   b. Enter **ipconfig /release** to relinquish the IP address.
   c. Enter **ipconfig /renew** to obtain another IP address.



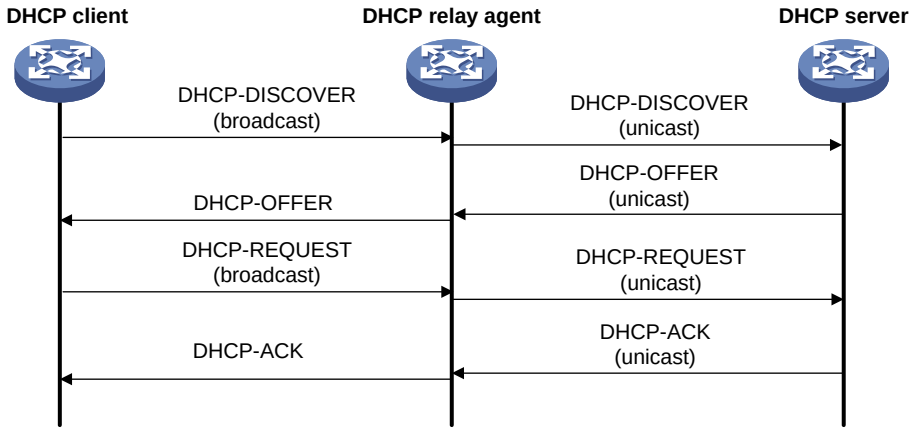
Configuring the DHCP relay agent

About DHCP relay agent

The DHCP relay agent enables clients to get IP addresses and configuration parameters from a DHCP server on another subnet.

Figure 16 shows a typical application of the DHCP relay agent.

Figure 16 DHCP relay agent application



DHCP relay agent operation

The DHCP server and client interact with each other in the same way regardless of whether the relay agent exists. For the interaction details, see "IP address allocation process." The following only describes steps related to the DHCP relay agent:

1. After receiving a DHCP-DISCOVER or DHCP-REQUEST broadcast message from a DHCP client, the DHCP relay agent processes the message as follows:
   a. Fills the **giaddr** field of the message with its IP address.
   b. Unicasts the message to the designated DHCP server.
2. Based on the **giaddr** field, the DHCP server returns an IP address and other configuration parameters in a response.
3. The relay agent conveys the response to the client.

Figure 17 DHCP relay agent operation

DHCP relay agent support for Option 82

Option 82 records the location information about the DHCP client. It enables the administrator to perform the following tasks:

- Locate the DHCP client for security and accounting purposes.
- Assign IP addresses in a specific range to clients.

For more information about Option 82, see "Relay agent option (Option 82)."

If the DHCP relay agent supports Option 82, it handles DHCP requests by following the strategies described in Table 3.

If a response returned by the DHCP server contains Option 82, the DHCP relay agent removes the Option 82 before forwarding the response to the client.

Table 3 Handling strategies of the DHCP relay agent

If a DHCP request has…	Handling strategy	The DHCP relay agent…
Option 82	Drop	Drops the message.
	Keep	Forwards the message without changing Option 82.
	Replace	Forwards the message after replacing the original Option 82 with the Option 82 padded according to the configured padding format, padding content, and code type.
No Option 82	N/A	Forwards the message after adding Option 82 padded according to the configured padding format, padding content, and code type.

DHCP relay agent support for MCE

An MCE device acting as the DHCP relay agent can forward DHCP packets between a DHCP server and clients on either a public network or a private network. For more information about MCE, see *MCE Configuration Guide*.

DHCP relay agent tasks at a glance

To configure a DHCP relay agent, perform the following tasks:

1. Enabling DHCP
2. Enabling the DHCP relay agent on an interface
3. Specifying DHCP servers
4. (Optional.) Configuring advanced features:
   - Specifying a DHCP relay address pool for DHCP clients
   - Configuring the DHCP relay agent security features
   - Configuring the DHCP relay agent to release an IP address
   - Disabling release notification
   - Configuring DHCP relay agent support for Option 82
   - Enabling Option 60 insertion into DHCP requests
   - Setting the DSCP value for DHCP packets sent by the DHCP relay agent
   - Specifying the DHCP relay agent address for the giaddr field
   - Specifying the source IP address for relayed DHCP requests
   - Configuring support for forwarding DHCP replies based on MAC address table

Enabling DHCP

Restrictions and guidelines

You must enable DHCP to make other DHCP relay agent settings take effect.

Procedure

1. Enter system view.
   `system-view`
2. Enable DHCP.
   `dhcp enable`
   By default, DHCP is disabled.

Enabling the DHCP relay agent on an interface

About this task

With the DHCP relay agent enabled, an interface forwards incoming DHCP requests to a DHCP server.

An IP address pool that contains the IP address of the DHCP relay interface must be configured on the DHCP server. Otherwise, the DHCP clients connected to the relay agent cannot obtain correct IP addresses.

Procedure

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
3. Enable the DHCP relay agent.
   `dhcp select relay`
   By default, when DHCP is enabled, an interface operates in the DHCP server mode.

Specifying DHCP servers

Specifying DHCP servers on a relay agent

About this task

To improve availability, you can specify several DHCP servers on the DHCP relay agent. When the interface receives request messages from clients, the relay agent forwards them to all DHCP servers.

Restrictions and guidelines

The IP address of any specified DHCP server must not reside on the same subnet as the IP address of the relay interface. Otherwise, the clients might fail to obtain IP addresses.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify a DHCP server address on the relay agent.

   dhcp relay server-address *ip-address* [**class** *class-name*] [**public** | **vpn-instance** *vpn-instance-name*]

   By default, no DHCP server address is specified on the relay agent.

   To specify multiple DHCP server addresses, repeat this step. You can specify a maximum of eight DHCP servers.

Specifying DHCP servers in a DHCP relay address pool

About this task

DHCP address pools created on a DHCP relay agent are called DHCP relay address pools. You can create a relay address pool and specify DHCP servers in this address pool. This feature allows DHCP clients of the same type to obtain IP addresses and other configuration parameters from the DHCP servers specified in the matching DHCP relay address pool.

It applies to scenarios where the DHCP relay agent connects to clients of the same access type but classified into different types by their locations. In this case, the relay interface typically has no IP address configured. You can use the **gateway-list** command to specify gateway addresses for clients matching the same DHCP relay address pool and bind the gateway addresses to the device's MAC address.

Upon receiving a DHCP DISCOVER or REQUEST from a client that matches a DHCP relay address pool, the relay agent processes the packet as follows:

- Fills the **giaddr** field of the packet with a specified gateway address.
- Forwards the packet to all DHCP servers in the matching DHCP relay address pool.

The DHCP servers select a DHCP relay address pool according to the gateway address.

Restrictions and guidelines

If PPPoE users are in the network, follow these restrictions and guidelines when you configure the DHCP relay address pool:

- Enable the DHCP relay agent to record DHCP relay entries by using the **dhcp relay client-information record** command. When a PPPoE user goes offline, the DHCP relay agent can find a matching relay entry and send a DHCP-RELEASE message to the DHCP

server. This mechanism ensures the DHCP server is aware of the releasing of the IP address in a timely manner.

- The **remote-server** command also configures the device as a DHCP relay agent. You do not need to enable the DHCP relay agent by using the **dhcp select relay** command.

Procedure

1. Enter system view.
   system-view
2. Create a DHCP relay address pool and enter its view.
   dhcp server ip-pool *pool-name*
3. Specify gateways in the DHCP relay address pool.
   gateway-list *ip-address*&<1-64> **export-route**
   By default, no gateway address is specified.
4. Specify DHCP servers in the DHCP relay address pool.
   remote-server *ip-address*&<1-8> [**public** | **vpn-instance** *vpn-instance-name*]
   By default, no DHCP server is specified in the DHCP relay address pool.
   You can specify a maximum of eight DHCP servers in one DHCP relay address pool for high availability.

Specifying the DHCP server selecting algorithm

About this task

The DHCP relay agent supports the **polling** and **master-backup** DHCP server selecting algorithms.

By default, the DHCP relay agent uses the **polling** algorithm. It forwards DHCP requests to all DHCP servers. The DHCP clients select the DHCP server from which the first received DHCP reply comes.

If the DHCP relay agent uses the **master-backup** algorithm, it forwards DHCP requests to the master DHCP server first. If the master DHCP server is not available, the relay agent forwards the subsequent DHCP requests to a backup DHCP server. If the backup DHCP server is not available, the relay agent selects the next backup DHCP server, and so on. If no backup DHCP server is available, it repeats the process starting from the master DHCP server.

The master DHCP server is determined in one of the following ways:

- In a common network where multiple DHCP server addresses are specified on the DHCP relay interface, the first specified DHCP server is the master. The other DHCP servers are backup.
- In a network where DHCP relay address pools are configured on the DHCP relay agent, the first specified DHCP server in a DHCP relay address pool is the master. The other DHCP servers in the DHCP relay address pool are backup.

DHCP server selection supports the following functions:

- **DHCP server response timeout time**—The DHCP relay agent determines that a DHCP server is not available if it does not receive any response from the server within the DHCP server response timeout time. The DHCP server response timeout time is configurable and the default is 30 seconds.
- **DHCP server switchback**—If the DHCP relay agent selects a backup DHCP server, it does not switch back to the master DHCP server by default. You can configure the DHCP relay agent to switch back to the master DHCP server after a delay. If the master DHCP server is available, the DHCP relay agent forwards DHCP requests to the master DHCP server. If the master DHCP server is not available, the DHCP relay agent still uses the backup DHCP server.

Specifying the DHCP server selecting algorithm in interface view

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify the DHCP server selecting algorithm.
   dhcp relay server-address algorithm { **master-backup** | **polling** }
   By default, the **polling** algorithm is used. The DHCP relay agent forwards DHCP requests to all DHCP servers.
4. (Optional.) Set the DHCP server response timeout time for DHCP server switchover.
   dhcp relay dhcp-server timeout *time*
   By default, the DHCP server response timeout time is 30 seconds.
5. (Optional.) Enable the switchback to the master DHCP server and set the delay time.
   dhcp relay master-server switch-delay *delay-time*
   By default, the DHCP relay agent does not switch back to the master DHCP server.

Specifying the DHCP server selecting algorithm in DHCP relay address pool view

1. Enter system view.
   system-view
2. Enter DHCP relay address pool view.
   dhcp server ip-pool *pool-name*
3. Specify the DHCP server selecting algorithm.
   dhcp relay server-address algorithm { **master-backup** | **polling** }
   By default, the **polling** algorithm is used. The DHCP relay agent forwards DHCP requests to all DHCP servers.
4. (Optional.) Set the DHCP server response timeout time for DHCP server switchover.
   dhcp-server timeout *time*
   By default, the DHCP server response timeout time is 30 seconds.
5. (Optional.) Enable the switchback to the master DHCP server and set the delay time.
   master-server switch-delay *delay-time*
   By default, the DHCP relay agent does not switch back to the master DHCP server.

Specifying a DHCP relay address pool for DHCP clients

About this task

After you configure multiple DHCP relay address pools on a DHCP relay agent, you can specify these pools on an interface. To match DHCP clients based on options, you can define option settings when you specify the relay address pools.

If you specify multiple DHCP relay address pools on an interface, the relay agent selects a DHCP relay address pool for a DHCP client as follows:

1. Compares option values in the DHCP request in descending order against option values in DHCP relay address pools.
   - If a match (other than 60) is found, the matching process stops and the relay agent selects that matching relay address pool.

- If an Option 60 match is found, the relay agent continues to compare the Option 60 content in the request and the Option 60 strings in the relay address pools configured with the *option-text* argument:
  - If the Option 60 content matches the Option 60 string in a relay address pool, the relay address pool is selected.
  - If the Option 60 content does not match the Option 60 string in any relay address pool, the relay agent selects the relay address pool that is not configured with the *option-text* argument.

2. If still no DHCP relay address pool is matched, the relay agent selects the DHCP relay address pool with no options specified.

Restrictions and guidelines

If you specify DHCP servers by configuring both of the following methods on an interface, the DHCP relay address pool setting takes effect.

- Specify DHCP relay address pools by using the **dhcp relay pool** command.
- Specify DHCP servers directly on an interface by using the **dhcp relay server-address** command.

When you specify a DHCP relay address pool on an interface to define the DHCP servers, make sure the **remote-server** command is configured in the DHCP relay address pool. Otherwise, the relay agent drops DHCP requests. The DHCP requests are not forwarded to any DHCP server even if the **dhcp relay server-address** command is configured.

Procedure

1. Enter system view.

   system-view

2. Create a DHCP relay address pool and enter its view.

   dhcp server ip-pool *pool-name*

   By default, no DHCP relay address pools exist.

3. Specify DHCP servers in the DHCP relay address pool.

   remote-server *ip-address*&<1-8> [**public** | **vpn-instance** *vpn-instance-name*]

   By default, no DHCP server is specified in the DHCP relay address pool.

4. Specify gateway addresses for the clients matching the DHCP relay address pool.

   gateway-list *ip-address*&<1-64> **export-route**

   By default, no gateway address is specified.

5. Specify the DHCP server selecting algorithm.

   remote-server algorithm { **master-backup** | **polling** }

   By default, the **polling** algorithm is used. The DHCP relay agent forwards DHCP requests to all DHCP servers at the same time.

6. Return to system view.

   quit

7. Enter interface view.

   interface *interface-type interface-number*

8. Specify a DHCP relay address pool for DHCP clients.

   dhcp relay pool *pool-name* [**option** *code* [*option-text*]]

   By default, no DHCP relay address pool is specified for DHCP clients.

Configuring the DHCP relay agent security features

Restrictions and guidelines for DHCP relay agent security feature configuration

If the relay agent must record and refresh relay entries, enable the DHCP server proxy on the relay agent. When DHCP requests pass through the DHCP server proxy, it records or refreshes the client's IP-to-MAC bindings.

Enabling the DHCP relay agent to record relay entries

About this task

Perform this task to enable the DHCP relay agent to automatically record clients' IP-to-MAC bindings (relay entries) after they obtain IP addresses through DHCP.

Some security features use the relay entries to check incoming packets and block packets that do not match any entry. In this way, illegal hosts are not able to access external networks through the relay agent. Examples of the security features are ARP address check, authorized ARP, and IP source guard.

Restrictions and guidelines

The DHCP relay agent does not record IP-to-MAC bindings for DHCP clients running on synchronous/asynchronous serial interfaces.

Procedure

1. Enter system view.

   `system-view`

2. Enable the relay agent to record relay entries.

   `dhcp relay client-information record`

   By default, the relay agent does not record relay entries.

Enabling periodic refresh of dynamic relay entries

About this task

A DHCP client unicasts a DHCP-RELEASE message to the DHCP server to release its IP address. The DHCP relay agent conveys the message to the DHCP server and does not remove the IP-to-MAC entry of the client.

With this feature, the DHCP relay agent uses the IP address of a relay entry to periodically send a DHCP-REQUEST message to the DHCP server.

The relay agent maintains the relay entries depending on what it receives from the DHCP server:

- If the server returns a DHCP-ACK message or does not return any message within an interval, the DHCP relay agent removes the relay entry. In addition, upon receiving the DHCP-ACK message, the relay agent sends a DHCP-RELEASE message to release the IP address.
- If the server returns a DHCP-NAK message, the relay agent keeps the relay entry.

With this mechanism, the DHCP relay agent might mistakenly remove the relay entry for an online DHCP client when the DHCP server restarts. To resolve this issue, use the **`record-keep-time`** *`time`* option in the **`dhcp relay client-information refresh`** command to prolong the

keep time for DHCP relay entries. When the DHCP server does not reply to a DHCP-REQUEST message three times in a row, the DHCP relay agent does not remove the corresponding relay entry. Instead, it starts the keep time counter and keeps sending the DHCP-REQUEST message to the DHCP server at refresh intervals.

- If the DHCP server returns a DHCP-ACK message or does not return any message before the keep time elapses, the DHCP relay agent removes the relay entry.
- If the DHCP server returns a DHCP-NAK message before the keep time elapses, the DHCP relay agent keeps the relay entry and resets the keep time counter.

  The DHCP relay agent will start the keep time counter again if the DHCP server does not reply to another DHCP-REQUEST message three times in a row.

Procedure

1. Enter system view.

   system-view
2. Enable periodic refresh of dynamic relay entries.

   dhcp relay client-information refresh enable

   By default, periodic refresh of dynamic relay entries is enabled.
3. (Optional.) Set the refresh interval.

   dhcp relay client-information refresh { **auto** | **interval** *interval* } [**record-keep-time** *time*]

   By default, the refresh interval is **auto**, which is calculated based on the number of total relay entries. The keep time for DHCP relay entries is 0 minutes.

Enabling DHCP starvation attack protection

About this task

A DHCP starvation attack occurs when an attacker constantly sends forged DHCP requests using different MAC addresses in the **chaddr** field to a DHCP server. This exhausts the IP address resources of the DHCP server so legitimate DHCP clients cannot obtain IP addresses. The DHCP server might also fail to work because of exhaustion of system resources. The following methods are available to relieve or prevent such attacks.

- To relieve a DHCP starvation attack that uses DHCP packets encapsulated with different source MAC addresses, you can use one of the following methods:
  - Limit the number of ARP entries that a Layer 3 interface can learn.
  - Set the MAC learning limit for a Layer 2 port, and disable unknown frame forwarding when the MAC learning limit is reached.
- To prevent a DHCP starvation attack that uses DHCP requests encapsulated with the same source MAC address, you can enable MAC address check on the DHCP relay agent. The DHCP relay agent compares the **chaddr** field of a received DHCP request with the source MAC address in the frame header. If they are the same, the DHCP relay agent forwards the request to the DHCP server. If not, the relay agent discards the request.

Enable MAC address check only on the DHCP relay agent directly connected to the DHCP clients. A DHCP relay agent changes the source MAC address of DHCP packets before sending them.

A MAC address check entry has an aging time. When the aging time expires, both of the following occur:

- The entry ages out.
- The DHCP relay agent rechecks the validity of DHCP requests sent from the MAC address in the entry.

Procedure

1. Enter system view.
   system-view
2. Set the aging time for MAC address check entries.
   dhcp relay check mac-address aging-time *time*
   The default aging time is 30 seconds.
   This command takes effect only after you execute the **dhcp relay check mac-address** command.
3. Enter the interface view.
   interface *interface-type interface-number*
4. Enable MAC address check.
   dhcp relay check mac-address
   By default, MAC address check is disabled.

Enabling DHCP server proxy on the DHCP relay agent

About this task

The DHCP server proxy feature isolates DHCP servers from DHCP clients and protects DHCP servers against attacks.

Upon receiving a response from the server, the DHCP server proxy modifies the server's IP address as the relay interface's IP address before sending out the response. The DHCP client takes the DHCP relay agent as the DHCP server.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable DHCP relay agent and DHCP server proxy on the interface.
   dhcp select relay proxy
   By default, the interface operates in DHCP server mode after DHCP is enabled.

Enabling client offline detection on the DHCP relay agent

About this task

The client offline detection on the DHCP relay agent detects the user online status based on the ARP entry aging. When an ARP entry ages out, the DHCP client offline detection feature deletes the relay entry for the IP address and sends a RELEASE message to the DHCP server.

If DHCP relay agent and DHCP snooping are configured on the same device, the DHCP snooping module deletes its DHCP snooping entries after it obtains the RELEASE messages from the relay agent module.

Restrictions and guidelines

The feature does not function if an ARP entry is manually deleted.

Procedure

1. Enter system view.
   system-view

2. Enable the relay agent to record relay entries.
   dhcp relay client-information record
   By default, the relay agent does not record relay entries.
   Without relay entries, client offline detection cannot function correctly.
3. Enter interface view.
   interface *interface-type interface-number*
4. Enable the DHCP relay agent.
   dhcp select relay
   By default, when DHCP is enabled, an interface operates in the DHCP server mode.
5. Enable client offline detection.
   dhcp client-detect
   By default, client offline detection is disabled on the DHCP relay agent.

Configuring the DHCP relay agent to release an IP address

About this task

Configure the relay agent to release the IP address for a relay entry. The relay agent sends a DHCP-RELEASE message to the server and meanwhile deletes the relay entry. Upon receiving the DHCP-RELEASE message, the DHCP server releases the IP address.

This command can release only the IP addresses in the recorded relay entries.

Procedure

1. Enter system view.
   system-view
2. Configure the DHCP relay agent to release an IP address.
   dhcp relay release ip *ip-address* [**vpn-instance** *vpn-instance-name*]

Disabling release notification

About this task

Users might roam among different gateways on a wireless network. When a user roams to a new gateway, the ARP entry of the user on the old gateway will age out. With DHCP client offline detection enabled, the DHCP relay agent deletes the relay entry of the user after the user's ARP entry expires. It also sends a DHCP-RELEASE message to the server to release the user address. When the DHCP server assigns that address to another user, an address conflict occurs. To avoid this situation, execute the **undo dhcp relay release-agent** command to disable the relay agent from sending release messages to the DHCP server when it deletes relay entries. This feature also applies when the DHCP relay entries are manually deleted by using the **reset** command.

Restrictions and guidelines

Disabling release notification does not affect relaying DHCP-RELEASE messages that are sent from DHCP clients. The DHCP relay agent forwards these messages to the DHCP server after receiving them from DHCP clients.

Procedure

1. Enter system view.

system-view

2. Disable release notification.

   undo dhcp relay release-agent

   By default, release notification is enabled.

Configuring DHCP relay agent support for Option 82

For Option 82 to function correctly, you must configure both the DHCP server and relay agent. For server-side Option 82 configuration, see "Enabling handling of Option 82."

When you use the **dhcp relay information link-selection** command, follow these guidelines:

- For this command to take effect, perform the following tasks first:
  - Enable the DHCP relay agent to support Option 82 by using the **dhcp relay information enable** command.
  - Specify a source IP address for relayed DHCP requests by using the **dhcp relay source-address** command.
- To ensure successful IP address allocation, the IP address specified in sub-option 5 must belong to the same network segment as one of the following:
  - Gateway address in the AAA-authorized address pool or the address pool bound to the relay interface.
  - IP address of the DHCP relay interface.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the relay agent to handle Option 82.

   dhcp relay information enable

   By default, handling of Option 82 is disabled.

4. (Optional.) Configure the strategy for handling DHCP requests that contain Option 82.

   dhcp relay information strategy { **drop** | **keep** | **replace** }

   By default, the handling strategy is **replace**.

   If the handling strategy is **replace**, configure a padding mode and a padding format for Option 82. If the handling strategy is **keep** or **drop**, you do not need to configure a padding mode or padding format for Option 82.

5. (Optional.) Configure the padding mode and padding format for the Circuit ID sub-option.

   dhcp relay information circuit-id { **bas** | **string** *circuit-id* | { **normal** | **verbose** [**node-identifier** { **mac** | **sysname** | **user-defined** *node-identifier* }] [**interface**] } [**format** { **ascii** | **hex** }] }

   By default, the padding mode for Circuit ID sub-option is **normal**, and the padding format is **hex**.

   The device name (**sysname**) must not include spaces if it is configured as the padding content for sub-option 1. Otherwise, the DHCP relay agent will fail to add or replace Option 82.

6. (Optional.) Configure the padding mode and padding format for the Remote ID sub-option.

dhcp relay information remote-id { **normal** [**format** { **ascii** | **hex** }] | **string** *remote-id* | **sysname** }

By default, the padding mode for the Remote ID sub-option is **normal**, and the padding format is **hex**.

7. (Optional.) Configure the IP address to be inserted in sub-option 5 of Option 82.

   dhcp relay information link-selection *link-selection-address*

   By default, the relay agent inserts either of the following addresses in sub-option 5 of Option 82:

   - Gateway address in the AAA-authorized address pool or the address pool bound to the relay interface.
   - IP address of the relay interface.

Enabling Option 60 insertion into DHCP requests

About this task

Option 60 records vendor class identifier information of DHCP clients. It allows the clients to obtain IP addresses from different address ranges. After receiving a DHCP request with Option 60 encapsulated, the DHCP server follows the procedure to assign an IP address:

1. Uses Option 60 to determine a user class for the client.
2. Selects an IP address from the address range that matches the user class and assigns the address to the client.

After you enable Option 60 insertion on the DHCP relay agent, the relay agent first examines whether the received DHCP request contains Option 60.

- If the request does not contain Option 60, the relay agent inserts the option string into the request before forwarding the request to the DHCP server.
- If the request contains Option 60, the relay agent forwards the request to the DHCP server without processing this option.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable Option 60 insertion into DHCP requests on the DHCP relay agent.

   dhcp relay insert option60 *option-text*

   By default, the DHCP relay agent does not insert Option 60 into DHCP requests.

Setting the DSCP value for DHCP packets sent by the DHCP relay agent

About this task

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet.

Procedure

1. Enter system view.

   system-view

2. Set the DSCP value for DHCP packets sent by the DHCP relay agent.

   dhcp dscp *dscp-value*

   By default, the DSCP value in DHCP packets sent by the DHCP relay agent is 56.

Specifying the DHCP relay agent address for the **giaddr** field

Manually specifying the DHCP relay agent address for the **giaddr** field

About this task

This task allows you to specify the IP addresses to be encapsulated to the **giaddr** field of the DHCP requests. If you do not specify any DHCP relay agent address, the primary IP address of the DHCP relay interface is encapsulated to the **giaddr** field of DHCP requests.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify the DHCP relay agent address to be encapsulated in relayed DHCP requests.

   dhcp relay gateway *ip-address*

   By default, the primary IP address of the DHCP relay interface is encapsulated in the relayed DHCP requests.

Configuring smart relay to specify the DHCP relay agent address for the **giaddr** field

About this task

By default, the relay agent only encapsulates the primary IP address to the **giaddr** field of all requests before relaying them to the DHCP server. The DHCP server then selects an IP address on the same subnet as the address in the **giaddr** filed. If no assignable addresses on the subnet are available, the DHCP server does not assign any IP address. The DHCP smart relay feature is introduced to allow the DHCP relay agent to encapsulate secondary IP addresses when the DHCP server does not send back a DHCP-OFFER message.

The relay agent initially encapsulates its primary IP address to the **giaddr** field before forwarding a request to the DHCP server. If no DHCP-OFFER is received, the relay agent allows the client to send a maximum of two requests to the DHCP server by using the primary IP address. If no DHCP-OFFER is returned after two retries, the relay agent switches to a secondary IP address. If the DHCP server still does not respond, the next secondary IP address is used. After the secondary IP addresses are all tried and the DHCP server does not respond, the relay agent repeats the process by starting from the primary IP address.

Procedure

1. Enter system view.

   system-view

2. Enable the DHCP smart relay feature.

dhcp smart-relay enable

By default, the DHCP smart relay feature is disabled.

Specifying the source IP address for relayed DHCP requests

About this task

This task is required if multiple relay interfaces share the same IP address or if a relay interface does not have routes to DHCP servers. You can specify an IP address or the IP address of another interface, typically the loopback interface, on the DHCP relay agent as the source IP address for DHCP requests. The relay interface inserts the source IP address in the source IP address field as well as the **giaddr** field in DHCP requests.

If multiple relay interfaces share the same IP address, you must also configure the relay interface to support Option 82. Upon receiving a DHCP request, the relay interface inserts the subnet information in sub-option 5 in Option 82. The DHCP server assigns an IP address according to sub-option 5. The DHCP relay agent looks up the output interface in the MAC address table to forward the DHCP reply.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify the source IP address for DHCP requests.

   dhcp relay source-address { *ip-address* | **interface** *interface-type interface-number* } [**default-giaddr**]

   By default, the relay agent chooses the default source IP address for relayed requests depending on whether its server-side interface and the DHCP server belong to the same VPN instance:

   - If they belong to the same VPN instance, the relay agent uses the IP address of the output interface for relayed requests as the default source IP address.
   - If they belong to different VPN instances, the relay agent uses the lowest IP address that is in the same VPN instance as the DHCP server as the default source address.

Configuring support for forwarding DHCP replies based on MAC address table

About this task

When a DHCP client sends a request to its connected EVPN gateway, the gateway records the request forwarding information for the client before relaying the request to the DHCP server. The request forwarding information contains the MAC address of the DHCP client and output interface of the request packet. If the reply for this request is received by another EVPN gateway, the reply is discarded by default because it does not have the matching request forwarding information on the gateway. As a result, the client cannot obtain the IP address.

This feature allows the relay agent to look up the MAC address table for the output interface for the replies that do not have the request forwarding information. This feature ensures that DHCP clients receive DHCP reply packets.

If the **broadcast** keyword is specified, the DHCP relay agent broadcasts the DHCP reply out of the interface in the matching MAC address entry. When the DHCP relay agent connecting to the requesting DHCP client receives the reply, it sends the reply to its CPU before broadcasting the reply. If recording relay entries is enabled on this relay agent, a relay entry is generated for the DHCP client.

If the **broadcast** keyword is not specified, the DHCP relay agent connecting to the requesting client will directly forward the reply based on the MAC address instead of delivering it up to the CPU. In this case, the DHCP relay agent cannot be aware that the packet is a DHCP reply, thus no relay entry is generated for the client even if the recording of relay entries is enabled.

Procedure

1. Enter system view.

   system-view

2. Enable MAC address table lookup for DHCP replies that do not have request forwarding information.

   dhcp relay mac-forward enable [**broadcast**]

   By default, the DHCP relay agent discards a DHCP reply if the relay agent does not have the request forwarding information for the reply.

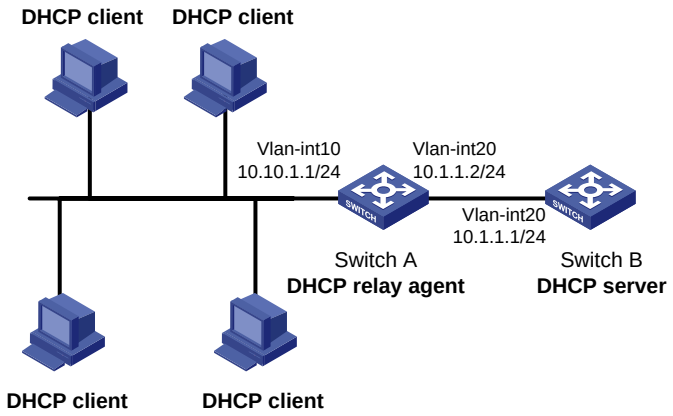
Display and maintenance commands for DHCP relay agent

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display MAC address check entries on the DHCP relay agent.	**display dhcp relay check mac-address**
Display relay entries on the DHCP relay agent.	**display dhcp relay client-information** [**interface** *interface-type interface-number* | **ip** *ip-address* [**vpn-instance** *vpn-instance-name*]]
Display Option 82 configuration information on the DHCP relay agent.	**display dhcp relay information** [**interface** *interface-type interface-number*]
Display M-LAG status information recorded on the DHCP relay agent.	**display dhcp relay m-lag-status**
Display information about DHCP servers on an interface.	**display dhcp relay server-address** [**interface** *interface-type interface-number*]
Display packet statistics on the DHCP relay agent.	**display dhcp relay statistics** [**interface** *interface-type interface-number*]
Clear relay entries on the DHCP relay agent.	**reset dhcp relay client-information** [**interface** *interface-type interface-number* | **ip** *ip-address* [**vpn-instance** *vpn-instance-name*]]
Clear packet statistics on the DHCP relay agent.	**reset dhcp relay statistics** [**interface** *interface-type interface-number*]

DHCP relay agent configuration examples

Example: Configuring basic DHCP relay agent



Network configuration

As shown in Figure 18, configure the DHCP relay agent on Switch A. The DHCP relay agent enables DHCP clients to obtain IP addresses and other configuration parameters from the DHCP server on another subnet.

The DHCP relay agent and server are on different subnets. Configure static or dynamic routing to make them reachable to each other.

Perform the configuration on the DHCP server to guarantee the client-server communication. For DHCP server configuration information, see "DHCP server configuration examples."

Figure 18 Network diagram

Procedure

Specify IP addresses for the interfaces. (Details not shown.)

Enable DHCP.

```
<SwitchA> system-view
[SwitchA] dhcp enable
```

Enable the DHCP relay agent on VLAN-interface 10.

```
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] dhcp select relay
```

Specify the IP address of the DHCP server on the relay agent.

```
[SwitchA-Vlan-interface10] dhcp relay server-address 10.1.1.1
```

Verifying the configuration

Verify that DHCP clients can obtain IP addresses and all other network parameters from the DHCP server through the DHCP relay agent. (Details not shown.)

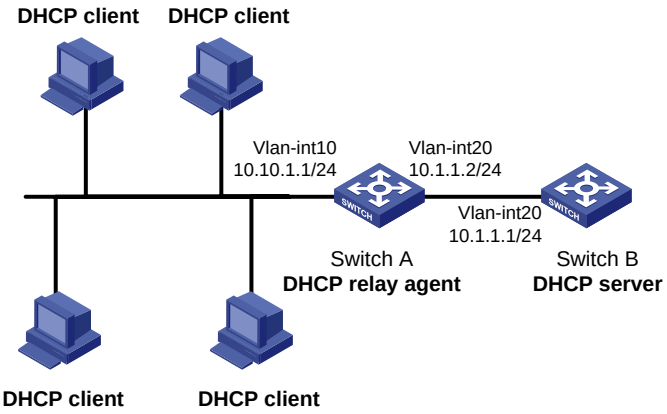
Display the statistics of DHCP packets forwarded by the DHCP relay agent.

```
[SwitchA] display dhcp relay statistics
```

Display relay entries if you have enabled relay entry recording on the DHCP relay agent.

```
[SwitchA] display dhcp relay client-information
```

Example: Configuring Option 82



Network configuration

As shown by the network diagram in "Example: Configuring basic DHCP relay agent," the DHCP relay agent (Switch A) replaces Option 82 in DHCP requests before forwarding them to the DHCP server (Switch B).

- The Circuit ID sub-option is **company001.**
- The Remote ID sub-option is **device001**.

To use Option 82, you must also enable the DHCP server to handle Option 82.

Figure 19 Network diagram

Procedure

Specify IP addresses for the interfaces. (Details not shown.)

Enable DHCP.

```
<SwitchA> system-view
[SwitchA] dhcp enable
```

Enable the DHCP relay agent on VLAN-interface 10.

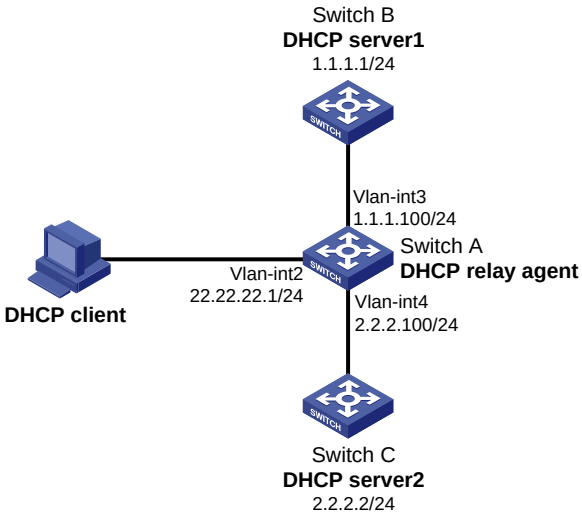
```
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] dhcp select relay
```

Specify the IP address of the DHCP server.

```
[SwitchA-Vlan-interface10] dhcp relay server-address 10.1.1.1
```

Configure the handling strategies and padding content of Option 82.

```
[SwitchA-Vlan-interface10] dhcp relay information enable
[SwitchA-Vlan-interface10] dhcp relay information strategy replace
[SwitchA-Vlan-interface10] dhcp relay information circuit-id string company001
[SwitchA-Vlan-interface10] dhcp relay information remote-id string device001
```



Example: Configuring DHCP server selection

Network configuration

As shown in Figure 20, the DHCP client and the DHCP servers are in different subnets. DHCP server 1 and DHCP server 2 both have a DHCP address pool that contains IP addresses in subnet 22.22.22.0/24, but neither has DHCP enabled.

Configure the DHCP relay agent for the DHCP client to obtain an IP address in subnet 22.22.22.0/24 and other configuration parameters from a DHCP server. The DHCP relay agent is connected to the DHCP client through VLAN-interface 2, to DHCP server 1 through VLAN-interface 3, and to DHCP server 2 through VLAN-interface 4.

Figure 20 Network diagram

Procedure

1. Assign IP addresses to interfaces on the switches. (Details not shown.)
2. Configure Switch B and Switch C as DHCP servers. (Details not shown.)
3. Configure the DHCP relay agent on Switch A:

   # Enable DHCP.

   ```
   <SwitchA> system-view
   [SwitchA] dhcp enable
   ```

   # Enable the DHCP relay agent on VLAN-interface 2.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] dhcp select relay
   ```

   # Specify the IP addresses of the DHCP servers.

   ```
   [SwitchA-Vlan-interface2] dhcp relay server-address 1.1.1.1
   [SwitchA-Vlan-interface2] dhcp relay server-address 2.2.2.2
   ```

   # Specify the DHCP server selecting algorithm as **master-backup**.

   ```
   [SwitchA-Vlan-interface2] dhcp relay server-address algorithm master-backup
   ```

   # Configure the DHCP relay agent to switch back to the master DHCP server 3 minutes after it switches to the backup DHCP server.

   ```
   [SwitchA-Vlan-interface2] dhcp relay master-server switch-delay 3
   ```

Verifying the configuration

Verify that the DHCP client cannot obtain an IP address and that the following log is output in about 30 seconds.

```
DHCPR/3/DHCPR_SERVERCHANGE:
 Switched to the server at 2.2.2.2 because the current server did not respond.
```

Enable DHCP on the DHCP server at 1.1.1.1. (Details not shown.)

Verify that the DHCP client cannot obtain an IP address and that the following log is output in about 3 minutes.

```
DHCPR/3/DHCPR_SWITCHMASTER:
 Switched to the master DHCP server at 1.1.1.1.
```

Verify that the DHCP client obtains an IP address. (Details not shown.)

Troubleshooting DHCP relay agent configuration

Failure of DHCP clients to obtain configuration parameters through the DHCP relay agent

Symptom

DHCP clients cannot obtain configuration parameters through the DHCP relay agent.

Solution

Some problems might occur with the DHCP relay agent or server configuration.

To locate the problem, enable debugging and execute the **display** command on the DHCP relay agent to view the debugging information and interface state information.

Check that:

- DHCP is enabled on the DHCP server and relay agent.
- The DHCP server has an address pool on the same subnet as the DHCP clients.
- The DHCP server and DHCP relay agent can reach each other.
- The DHCP server address specified on the DHCP relay interface connected to the DHCP clients is correct.

Configuring the DHCP client

About DHCP client

You can configure an interface to act as a DHCP client to obtain configuration parameters such as an IP address from the DHCP server.

Support of DHCP Client for gateway availability detection

The DHCP client performs gateway availability detection after obtaining an IP address, ensuring that it can correctly obtain usable gateway information and access to external networks

The gateway availability detection feature is implemented through a ping operation. The DHCP client sends an ICMP echo request to the gateway address carried in the received DHCP reply, and then waits for an ICMP echo reply from the gateway:

- If the client receives an ICMP echo reply from the gateway within one minute, the gateway is determined reachable. The client can use the obtained IP address to access external networks.
- If the client does not receive an ICMP echo reply from the gateway within one minute, the detection attempt fails and the client pings the gateway again. When the number of consecutive failed detection attempts reaches the upper limit, the gateway availability detection fails and the gateway is determined unreachable. The client will then release the obtained IP address and request a new IP address.

In the current software version, only VLAN-interface 1 supports the gateway availability detection feature.

Restrictions and guidelines: DHCP client configuration

The DHCP client configuration is supported only on Layer 3 Ethernet interfaces (or subinterfaces), VLAN interfaces, and Layer 3 aggregate interfaces.

DHCP client tasks at a glance

To configure a DHCP client, perform the following tasks:

1. Enabling the DHCP client on an interface
2. Configuring a DHCP client ID for an interface

   Perform this task if the DHCP client uses the client ID to obtain IP addresses.
3. (Optional.) Enabling duplicated address detection
4. (Optional.) Setting the DSCP value for DHCP packets sent by the DHCP client
5. (Optional.) Configuring SNMP notifications for the DHCP client

Enabling the DHCP client on an interface

Restrictions and guidelines

- If the number of IP address request failures reaches the system-defined amount, the DHCP client-enabled interface uses a default IP address.

- An interface can be configured to acquire an IP address in multiple ways. The new configuration overwrites the old.
- Secondary IP addresses cannot be configured on an interface that is enabled with the DHCP client.
- If the interface obtains an IP address on the same segment as another interface on the device, the interface does not use the assigned address. Instead, it requests a new IP address from the DHCP server.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure an interface to use DHCP for IP address acquisition.
   ip address dhcp-alloc
   By default, an interface does not use DHCP for IP address acquisition.

Configuring a DHCP client ID for an interface

About this task

A DHCP client ID is added to the DHCP option 61 to uniquely identify a DHCP client. A DHCP server can assign IP addresses to clients based on their DHCP client IDs.

DHCP client ID includes an ID type and a type value. Each ID type has a fixed type value. You can specify a DHCP client ID by using one of the following methods:

- Use an ASCII string as the client ID. If an ASCII string is used, the type value is 00.
- Use a hexadecimal number as the client ID. If a hexadecimal number is used, the type value is the first two characters in the number.
- Use the MAC address of an interface to generate a client ID. If this method is used, the type value is 01.

To identify the type value of a DHCP client ID, execute the **display dhcp server ip-in-use** or **display dhcp client** command.

Restrictions and guidelines

Make sure the ID for each DHCP client is unique.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure a DHCP client ID for the interface.
   dhcp client identifier { **ascii** *ascii-string* | **hex** *hex-string* | **mac** *interface-type interface-number* }
   By default, an interface generates the DHCP client ID based on its MAC address. If the interface does not have a MAC address, it uses the MAC address of the first Ethernet interface to generate its client ID.

Enabling duplicated address detection

About this task

DHCP client detects IP address conflict through ARP packets. An attacker can act as the IP address owner to send an ARP reply. The spoofing attack makes the client unable to use the IP address assigned by the server. As a best practice, disable duplicate address detection when ARP attacks exist on the network.

Procedure

1. Enter system view.
   system-view
2. Enable duplicate address detection.
   dhcp client dad enable
   By default, the duplicate address detection feature is enabled on an interface.

Setting the DSCP value for DHCP packets sent by the DHCP client

About this task

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet.

Procedure

1. Enter system view.
   system-view
2. Set the DSCP value for DHCP packets sent by the DHCP client.
   dhcp client dscp *dscp-value*
   By default, the DSCP value in DHCP packets sent by the DHCP client is 56.

Configuring SNMP notifications for the DHCP client

About this task

This task enables the DHCP client module to report critical events in SNMP notifications to network administrators.

- **IP application failure notifications**—An IP application failure notification is generated when the DHCP client module fails to apply for an IP address.
- **Local address conflict notifications**—A local address conflict notification is generated when the DHCP client module obtains an IP address that is in the same subnet as one of the local interface addresses.

The SNMP notifications are sent to the SNMP module. For the SNMP notifications to be sent correctly, you must also configure SNMP. For more information about SNMP configuration, see SNMP configuration in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

system-view

2. Enable SNMP notifications for the DHCP client module.

   snmp-agent trap enable dhcp-client [**ip-apply-failed** | **local-conflict**]*

   By default, all SNMP notifications are enabled for the DHCP client module.

Display and maintenance commands for DHCP client

Execute **display** command in any view.

Task	Command
Display DHCP client information.	**display dhcp client** [**verbose**] [**interface** *interface-type interface-number*]

DHCP client configuration examples

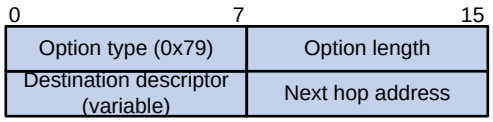
Example: Configuring DHCP client

Network configuration

As shown in Figure 22, on a LAN, Switch B contacts the DHCP server through VLAN-interface 2 to obtain an IP address, a DNS server address, and static route information. The DHCP client's IP address resides on subnet 10.1.1.0/24. The DNS server address is 20.1.1.1. The next hop of the static route to subnet 20.1.1.0/24 is 10.1.1.2.

The DHCP server uses Option 121 to assign static route information to DHCP clients. Figure 21 shows the Option 121 format. The destination descriptor field contains the following parts: subnet mask length and destination network address, both in hexadecimal notation. In this example, the destination descriptor is 18 14 01 01 (the subnet mask length is 24 and the network address is 20.1.1.0 in dotted decimal notation). The next hop address is 0A 01 01 02 (10.1.1.2 in dotted decimal notation).

Figure 21 Option 121 format



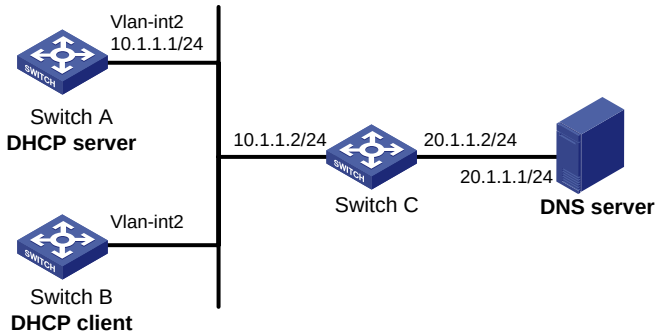


Figure 22 Network diagram

Procedure

1. Configure Switch A:

   # Specify an IP address for VLAN-interface 2.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ip address 10.1.1.1 24
   [SwitchA-Vlan-interface2] quit
   ```

   # Exclude an IP address from dynamic allocation.

   ```
   [SwitchA] dhcp server forbidden-ip 10.1.1.2
   ```

   # Configure DHCP address pool 0. Specify the subnet, lease duration, DNS server address, and a static route to subnet 20.1.1.0/24.

   ```
   [SwitchA] dhcp server ip-pool 0
   [SwitchA-dhcp-pool-0] network 10.1.1.0 mask 255.255.255.0
   [SwitchA-dhcp-pool-0] expired day 10
   [SwitchA-dhcp-pool-0] dns-list 20.1.1.1
   [SwitchA-dhcp-pool-0] option 121 hex 18 14 01 01 0A 01 01 02
   [SwitchA-dhcp-pool-0] quit
   ```

   # Enable DHCP.

   ```
   [SwitchA] dhcp enable
   ```

2. Configure Switch B:

   # Configure VLAN-interface 2 to use DHCP for IP address acquisition.

   ```
   <SwitchB> system-view
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] ip address dhcp-alloc
   [SwitchB-Vlan-interface2] quit
   ```

Verifying the configuration

Display the IP address and other network parameters assigned to Switch B.

```
[SwitchB-Vlan-interface2] display dhcp client verbose
Vlan-interface2 DHCP client information:
 Current state: BOUND
 Allocated IP: 10.1.1.3 255.255.255.0
 Allocated lease: 864000 seconds, T1: 331858 seconds, T2: 756000 seconds
 Lease from May 21 19:00:29 2012   to   May 31 19:00:29 2012
 DHCP server: 10.1.1.1
 Transaction ID: 0xcde72232
```

```
 Classless static routes:
   Destination: 20.1.1.0, Mask: 255.255.255.0, NextHop: 10.1.1.2
 DNS servers: 20.1.1.1
 Client ID type: acsii(type value=00)
 Client ID value: 000c.29d3.8659-Vlan2
 Client ID (with type) hex: 0030-3030-632e-3239-
                            6433-2e38-3635-392d-
                            4574-6830-2f30-2f32
 T1 will timeout in 3 days 19 hours 48 minutes 43 seconds
```

Display the route information on Switch B. The output shows that a static route to subnet 20.1.1.0/24 is added to the routing table.

```
[SwitchB] display ip routing-table
Destinations : 11        Routes : 11
Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.1.1.0/24         Direct 0    0            10.1.1.3        Vlan2
10.1.1.3/32         Direct 0    0            127.0.0.1       InLoop0

```

Configuring DHCP snooping

About DHCP snooping

DHCP snooping is a security feature for DHCP.

DHCP snooping works between the DHCP client and server, or between the DHCP client and DHCP relay agent. It guarantees that DHCP clients obtain IP addresses from authorized DHCP servers. Also, it records IP-to-MAC bindings of DHCP clients (called DHCP snooping entries) for security purposes.

DHCP snooping defines trusted and untrusted ports to make sure clients obtain IP addresses only from authorized DHCP servers.

- **Trusted**—A trusted port can forward DHCP messages correctly to make sure the clients get IP addresses from authorized DHCP servers.
- **Untrusted**—An untrusted port discards received DHCP-ACK and DHCP-OFFER messages to prevent unauthorized servers from assigning IP addresses.

DHCP snooping reads DHCP-ACK messages received from trusted ports and DHCP-REQUEST messages to create DHCP snooping entries. A DHCP snooping entry includes the MAC and IP addresses of a client, the port that connects to the DHCP client, and the VLAN.

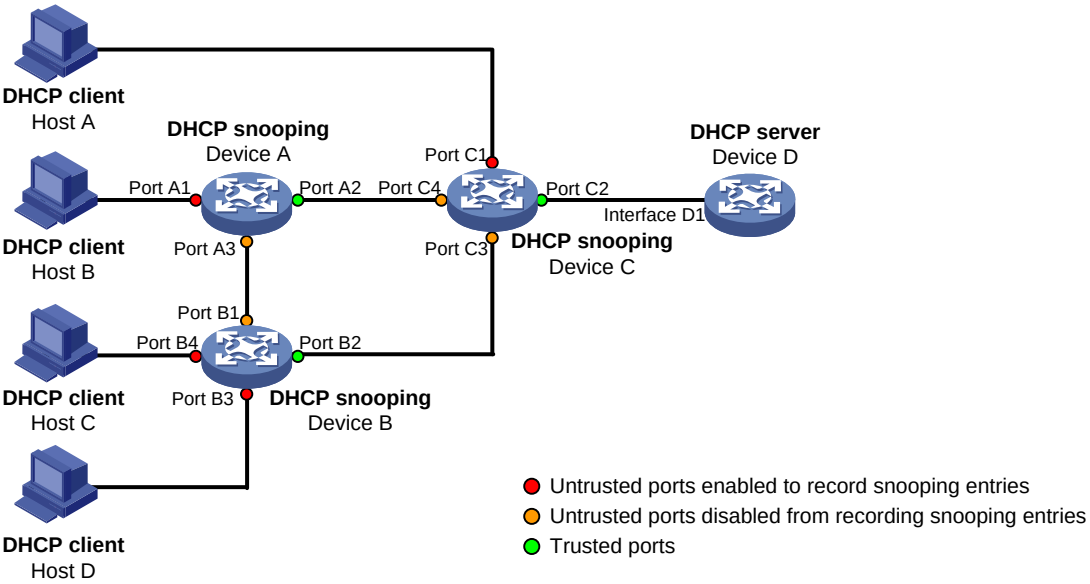
The following features need to use DHCP snooping entries:

- **ARP fast-reply**—Uses DHCP snooping entries to reduce ARP broadcast traffic. For more information, see "Configuring ARP fast-reply."
- **ARP attack detection**—Uses DHCP snooping entries to filter ARP packets from unauthorized clients. For more information, see *Security Configuration Guide*.
- **MAC-forced forwarding (MFF)**—Auto-mode MFF performs the following tasks:
  - Intercepts ARP requests from clients.
  - Uses DHCP snooping entries to find the gateway address.
  - Returns the gateway MAC address to the clients.

  This feature forces the client to send all traffic to the gateway so that the gateway can monitor client traffic to prevent malicious attacks among clients. For more information, see *Security Configuration Guide*.
- **IP source guard**—Uses DHCP snooping entries to filter illegal packets on a per-port basis. For more information, see *Security Configuration Guide*.
- **VLAN mapping**—Uses DHCP snooping entries to replace service provider VLAN in packets with customer VLAN before sending the packets to clients. For more information, see *Layer 2—LAN Switching Configuration Guide*.

Application of trusted and untrusted ports

Configure ports facing the DHCP server as trusted ports, and configure other ports as untrusted ports.



As shown in Figure 23, configure the DHCP snooping device's port that is connected to the DHCP server as a trusted port. The trusted port forwards response messages from the DHCP server to the client. The untrusted port connected to the unauthorized DHCP server discards incoming DHCP response messages.

Figure 23 Trusted and untrusted ports

In a cascaded network as shown in Figure 24, configure the DHCP snooping devices' ports facing the DHCP server as trusted ports. To save system resources, you can enable only the untrusted ports directly connected to the DHCP clients to record DHCP snooping entries.

Figure 24 Trusted and untrusted ports in a cascaded network

DHCP snooping support for Option 82

Option 82 records the location information about the DHCP client so the administrator can locate the DHCP client for security and accounting purposes. For more information about Option 82, see "Relay agent option (Option 82)."

Sub-option 9 (Vendor-Specific) in Option 82 is supported only on DHCP snooping devices. Each DHCP snooping device with the **append** Option 82 handling strategy adds the following information to the sub-option in the received DHCP request:

- Node identifier of the current DHCP snooping device.
- Information about the client-side interface.

- VLAN of the DHCP client.

After the management device receives the DHCP request, it can determine the network topology that the request has travelled and locate the DHCP client.

DHCP snooping uses the same strategies as the DHCP relay agent to handle Option 82 for DHCP request messages, as shown in Table 4. If a response returned by the DHCP server contains Option 82, DHCP snooping removes Option 82 before forwarding the response to the client. If the response contains no Option 82, DHCP snooping forwards it directly.

Table 4 Handling strategies

If a DHCP request has…	Handling strategy	DHCP snooping…
Option 82	Append	• Forwards the message after padding the Vendor-Specific sub-option with the content specified in the **dhcp snooping information vendor-specific** command. • Forwards the message without changing Option 82 if the **dhcp snooping information vendor-specific** command is not configured.
	Drop	Drops the message.
	Keep	Forwards the message without changing Option 82.
	Replace	Forwards the message after replacing the original Option 82 with the Option 82 padded according to the configured padding format, padding content, and code type.
No Option 82	N/A	Forwards the message after adding the Option 82 padded according to the configured padding format, padding content, and code type.

Restrictions and guidelines: DHCP snooping configuration

- The DHCP snooping configuration does not take effect on a Layer 2 Ethernet interface that is an aggregation member port. The configuration takes effect when the interface leaves the aggregation group.
- Specify the ports connected to authorized DHCP servers as trusted ports to make sure that DHCP clients can obtain valid IP addresses. The trusted ports and the ports connected to DHCP clients must be in the same VLAN.
- You can specify the following interfaces as trusted ports: Layer 2 Ethernet interfaces, Layer 2 aggregate interfaces, Layer 3 Ethernet interfaces, and Layer 3 aggregate interfaces. For more information about aggregate interfaces, see Ethernet link aggregation in *Layer 2—LAN Switching Configuration Guide*.

DHCP snooping tasks at a glance

To configure DHCP snooping, perform the following tasks:

1. Configuring basic DHCP snooping features
2. (Optional.) Configuring DHCP snooping support for Option 82
3. (Optional.) Configuring DHCP snooping entry auto backup
4. (Optional.) Setting the maximum number of DHCP snooping entries

5. (Optional.) Configuring DHCP snooping security features
6. (Optional.) Enabling recording untrusted DHCP servers
7. (Optional.) Enabling the giaddr field check in DHCP requests
8. (Optional.) Enabling client offline detection on the DHCP snooping device
9. (Optional.) Enabling DHCP snooping logging
10. (Optional.) Enabling DHCP snooping alarm notifications
11. (Optional.) Enabling alarm log generation for packet drop events
12. (Optional.) Disabling DHCP snooping on an interface

Configuring basic DHCP snooping features

Configuring basic DHCP snooping features in a common network

About this task

Basic DHCP snooping features refer to the following:

- Enabling DHCP snooping.
- Configuring DHCP snooping trusted ports.
- Enabling recording client information in DHCP snooping entries.

If you enable DHCP snooping globally, DHCP snooping is enabled on all interfaces on the device.

You can also enable DHCP snooping for specific VLANs. After enabling DHCP snooping for a VLAN, you can configure the other basic DHCP snooping features in the VLAN.

Restrictions and guidelines

If the basic DHCP snooping features are configured globally, you can only use the undo form of the global configuration commands to disable the settings globally. The VLAN-specific configuration commands cannot disable the settings.

If the basic DHCP snooping features are configured in a VLAN, you can only use the undo form of the VLAN-specific configuration commands to disable the settings in the VLAN. The global configuration command cannot disable the settings.

Configuring basic DHCP snooping features globally

1. Enter system view.
   `system-view`
2. Enable DHCP snooping globally.
   `dhcp snooping enable`
   By default, DHCP snooping is disabled globally.
3. Enter interface view.
   `interface` *`interface-type interface-number`*
   This interface must connect to the DHCP server.
4. Specify the port as a trusted port.
   `dhcp snooping trust`
   By default, all ports are untrusted ports after DHCP snooping is enabled.
5. (Optional.) Enable the recording of DHCP snooping entries.
   a. Return to system view.

quit

b. Enter interface view.

interface *interface-type interface-number*

This interface must connect to the DHCP client.

c. Enable the recording of DHCP snooping entries.

dhcp snooping binding record

By default, the recording of DHCP snooping entries is disabled.

Configuring basic DHCP snooping features for VLANs

1. Enter system view.

   system-view

2. Enable DHCP snooping for VLANs.

   dhcp snooping enable vlan *vlan-id-list*

   By default, DHCP snooping is disabled for all VLANs.

3. Enter VLAN view

   vlan *vlan-id*

   Make sure DHCP snooping is enabled for the VLAN.

4. Configure an interface in the VLAN as a trusted port.

   dhcp snooping trust interface *interface-type interface-number*

   By default, all interfaces in the VLAN are untrusted ports.

5. (Optional.) Enable recording of client information in DHCP snooping entries.

   dhcp snooping binding record

   By default, recording of client information in DHCP snooping entries is disabled.

Configuring DHCP snooping support for Option 82

Restrictions and guidelines

- The Option 82 configuration on a Layer 2 Ethernet interface that has been added to an aggregation group does not take effect unless the interface leaves the aggregation group.
- To support Option 82, you must configure Option 82 on both the DHCP server and the DHCP snooping device. For information about configuring Option 82 on the DHCP server, see "Enabling handling of Option 82."
- If Option 82 contains the device name, the device name must contain no spaces. Otherwise, DHCP snooping drops the message. You can use the **sysname** command to specify the device name. For more information about this command, see *Fundamentals Command Reference*.
- DHCP snooping uses "outer VLAN tag.inner VLAN tag" to fill the VLAN ID field of sub-option 1 in verbose padding format if either of the following conditions exists:
  - DHCP snooping and QinQ work together.
  - DHCP snooping receives a DHCP packet with two VLAN tags.

  For example, if the outer VLAN tag is 10 and the inner VLAN tag is 20, the VLAN ID field is 000a.0014. The hexadecimal digit **a** represents the outer VLAN tag 10, and the hexadecimal digit **14** represents the inner VLAN tag 20.

Configuring DHCP snooping support for Option 82 in interface view

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable DHCP snooping to support Option 82.

   dhcp snooping information enable

   By default, DHCP snooping does not support Option 82.

4. (Optional.) Configure a handling strategy for DHCP requests that contain Option 82.

   dhcp snooping information strategy { **append** | **drop** | **keep** | **replace** }

   By default, the handling strategy is **replace**.

   If the handling strategy is **append** or **replace**, configure a padding mode and padding format for Option 82. If the handling strategy is **keep** or **drop**, you do not need to configure any padding mode or padding format for Option 82.

5. (Optional.) Configure the padding mode and padding format for the Circuit ID sub-option.

   dhcp snooping information circuit-id { **normal-extended** | [**vlan** *vlan-id*] **string** *circuit-id* | { **normal** | **verbose** [**node-identifier** { **mac** | **sysname** | **user-defined** *node-identifier* }] } [**format** { **ascii** | **hex** }] }

   By default, the padding mode is **normal** and the padding format is **hex** for the Circuit ID sub-option.

   If the device name (**sysname**) is configured as the padding content for sub-option 1, make sure the device name does not include spaces. Otherwise, the DHCP snooping device will fail to add or replace Option 82.

6. (Optional.) Configure the padding mode and padding format for the Remote ID sub-option.

   dhcp snooping information remote-id { **normal** [**format** { **ascii** | **hex** }] | [**vlan** *vlan-id*] { **hex** *remote-id* | **string** *remote-id* | **sysname** } }

   By default, the padding mode is **normal** and the padding format is **hex** for the Remote ID sub-option.

7. (Optional.) Configure the padding mode for the Vendor-Specific sub-option.

   dhcp snooping information vendor-specific [**vlan** *vlan-id*] **bas** [**node-identifier** { **mac** | **sysname** | **user-defined** *string* }]

   By default, the device does not insert any content into the Vendor-Specific sub-option.

Configuring DHCP snooping support for Option 82 in VLAN view

1. Enter system view.

   system-view

2. Enter VLAN view.

   vlan *vlan-id*

3. Enable DHCP snooping to support Option 82.

   dhcp snooping information enable

   By default, DHCP snooping does not support Option 82.

4. (Optional.) Configure a handling strategy for DHCP requests that contain Option 82.

   dhcp snooping information strategy { **append** | **drop** | **keep** | **replace** }

   By default, the handling strategy is **replace**.

   If the handling strategy is **append** or **replace**, configure a padding mode and padding format for Option 82. If the handling strategy is **keep** or **drop**, you do not need to configure any padding mode or padding format for Option 82.

5. (Optional.) Configure the padding mode and padding format for the Circuit ID sub-option.

dhcp snooping information circuit-id { **normal-extended** | **string** *circuit-id* | { **normal** | **verbose** [**node-identifier** { **mac** | **sysname** | **user-defined** *node-identifier* }] } [**format** { **ascii** | **hex** }] }

By default, the padding mode is **normal** and the padding format is **hex** for the Circuit ID sub-option.

If the device name (**sysname**) is configured as the padding content for the Circuit ID sub-option, make sure the device name does not include spaces. Otherwise, the DHCP snooping device will fail to add or replace Option 82.

6. (Optional.) Configure the padding mode and padding format for the Remote ID sub-option.

   dhcp snooping information remote-id { **normal** [**format** { **ascii** | **hex** }] | **hex** *remote-id* | **string** *remote-id* | **sysname** }

   By default, the padding mode is **normal** and the padding format is **hex** for the Remote ID sub-option.

7. (Optional.) Configure the padding mode for the Vendor-Specific sub-option.

   dhcp snooping information vendor-specific bas [**node-identifier** { **mac** | **sysname** | **user-defined** *string* }]

   By default, the device does not insert any content into the Vendor-Specific sub-option.

Configuring DHCP snooping entry auto backup

About this task

The auto backup feature saves DHCP snooping entries to a backup file, and allows the DHCP snooping device to download the entries from the backup file at device reboot. The entries on the DHCP snooping device cannot survive a reboot. The auto backup helps the security features provide services if these features (such as IP source guard) must use DHCP snooping entries for user authentication.

Restrictions and guidelines

If you disable DHCP snooping with the **undo dhcp snooping enable** command, the device deletes all DHCP snooping entries, but entries stored in the backup file still exist. They are deleted next time the device updates the backup file.

Procedure

1. Enter system view.

   system-view

2. Configure the DHCP snooping device to back up DHCP snooping entries to a file.

   dhcp snooping binding database filename { *filename* | **url** *url* [**username** *username* [**password** { **cipher** | **simple** } *string*]] }

   By default, the DHCP snooping device does not back up DHCP snooping entries.

   With this command executed, the DHCP snooping device backs up DHCP snooping entries immediately and runs auto backup.

   This command automatically creates the file if you specify a non-existent file.

3. (Optional.) Manually save DHCP snooping entries to the backup file.

   dhcp snooping binding database update now

4. (Optional.) Set the waiting time after a DHCP snooping entry change for the DHCP snooping device to update the backup file.

   dhcp snooping binding database update interval *interval*

By default, the DHCP snooping device waits 300 seconds to update the backup file after a DHCP snooping entry change. If no DHCP snooping entry changes, the backup file is not updated.

Setting the maximum number of DHCP snooping entries

About this task

Perform this task to prevent the system resources from being overused.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the maximum number of DHCP snooping entries for the interface to learn.
   dhcp snooping max-learning-num *max-number*
   By default, the number of DHCP snooping entries for an interface to learn is unlimited.

Configuring DHCP snooping security features

Enabling DHCP starvation attack protection

About this task

A DHCP starvation attack occurs when an attacker constantly sends forged DHCP requests that contain identical or different sender MAC addresses in the **chaddr** field to a DHCP server. This attack exhausts the IP address resources of the DHCP server so legitimate DHCP clients cannot obtain IP addresses. The DHCP server might also fail to work because of exhaustion of system resources. For information about the fields of DHCP packet, see "DHCP message format."

You can prevent DHCP starvation attacks in the following ways:

- If the forged DHCP requests contain different sender MAC addresses, use the **mac-address max-mac-count** command to set the MAC learning limit on a Layer 2 port. For more information about the command, see *Layer 2—LAN Switching Command Reference*.
- If the forged DHCP requests contain the same sender MAC address, perform this task to enable MAC address check for DHCP snooping. This feature compares the **chaddr** field of a received DHCP request with the source MAC address field in the frame header. If they are the same, the request is considered valid and forwarded to the DHCP server. If not, the request is discarded.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable MAC address check.
   dhcp snooping check mac-address
   By default, MAC address check is disabled.

Enabling DHCP-REQUEST attack protection

About this task

DHCP-REQUEST messages include DHCP lease renewal packets, DHCP-DECLINE packets, and DHCP-RELEASE packets. This feature prevents the unauthorized clients that forge the DHCP-REQUEST messages from attacking the DHCP server.

Attackers can forge DHCP lease renewal packets to renew leases for legitimate DHCP clients that no longer need the IP addresses. These forged messages disable the victim DHCP server from releasing the IP addresses.

Attackers can also forge DHCP-DECLINE or DHCP-RELEASE packets to terminate leases for legitimate DHCP clients that still need the IP addresses.

To prevent such attacks, you can enable DHCP-REQUEST check. This feature uses DHCP snooping entries to check incoming DHCP-REQUEST messages.

- If a matching entry is found for a message, this feature compares the entry with the message information.
  - If they are consistent, the message is considered as valid and forwarded to the DHCP server.
  - If they are different, the message is considered as a forged message and is discarded.
- If no matching entry is found, the message is considered valid and forwarded to the DHCP server.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable DHCP-REQUEST check.

   dhcp snooping check request-message

   By default, DHCP-REQUEST check is disabled.

Configuring a DHCP packet blocking port

About this task

Perform this task to configure a port as a DHCP packet blocking port. This blocking port drops all incoming DHCP requests.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Configure the port to block DHCP requests.

   dhcp snooping deny

   By default, the port does not block DHCP requests.

CAUTION:

To avoid IP address acquisition failure, configure a port to block DHCP packets only if no DHCP

clients are attached to it.

Enabling recording untrusted DHCP servers

About this task

Typically, a DHCP snooping device identifies the DHCP servers that are connected to the untrusted ports as untrusted. The snooping device drops incoming DHCP replies through these ports. With feature enabled, the snooping device will record the DHCP servers for dropped DHCP replies, and generate and send log messages to the information center. With the information center, you can set log message filtering and output rules, including output destinations.

Procedure

1. Enter system view.

   `system-view`
2. Enable recording untrusted DHCP servers.

   `dhcp snooping untrusted-server-record enable`

   By default, the device does not record untrusted DHCP servers.

Enabling the giaddr field check in DHCP requests

About this task

A DHCP snooping device functions between DHCP clients and a DHCP server, or between DHCP clients and a DHCP relay agent. The **giaddr** field in a DHCP request records the address information of the first relay agent that the request passes by. If the DHCP snooping devices receives a DHCP request where the **giaddr** field value is not 0, it indicates that the DHCP snooping device location is not correct. In this case, the DHCP snooping device cannot work correctly.

This feature enables the DHCP snooping device to examine the **giaddr** field value in received DHCP packets and drop them if the **giaddr** field is not 0. When the number of dropped DHCP requests reaches or exceeds the threshold, the device generates a log for administrators to adjust locations of the DHCP devices.

Procedure

1. Enter system view.

   `system-view`
2. Enter interface view.

   `interface` *`interface-type interface-number`*
3. Enable the **giaddr** field check in DHCP requests.

   `dhcp snooping check giaddr`

   By default, the device does not check the **giaddr** field in DHCP requests.

Enabling client offline detection on the DHCP snooping device

About this task

When a DHCP client goes offline abnormally, it does not send a message to the DHCP server to release the IP address. As a result, the DHCP server is not aware of the offline event and cannot release the client lease in a timely manner.

With this feature enabled, the DHCP snooping device performs the following operations when the ARP entry of a client ages out:

1. Deletes the DHCP snooping entry for the client.
2. Sends a DHCP-RELEASE message to the DHCP server to inform the server to release the address lease of the client.

Procedure

1. Enter system view.

   `system-view`
2. Enable client offline detection.

   `dhcp snooping client-detect`

   By default, client offline detection is disabled.

Enabling DHCP snooping logging

About this task

The DHCP snooping logging feature enables the DHCP snooping device to generate DHCP snooping logs and send them to the information center. The information helps administrators locate and solve problems. For information about the log destination and output rule configuration in the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

As a best practice, disable this feature if the log generation affects the device performance.

Procedure

1. Enter system view.

   `system-view`
2. Enable DHCP snooping logging.

   `dhcp snooping log enable`

   By default, DHCP snooping logging is disabled.

Enabling DHCP snooping alarm notifications

About DHCP snooping alarm notifications

The DHCP snooping device can report critical DHCP snooping events to network administrators in the following alarm notifications:

- **Binding-exhaust** alarm notifications: The DHCP snooping device generates this type of alarm notifications when the DHCP snooping entry resource is exhausted or recovers from the exhaustion condition.

- **Binding-mismatch** alarm notifications: The DHCP snooping device generates this type of alarm notifications when the number of DHCP requests dropped due to DHCP snooping entry mismatch has reached the alarm threshold.
- **Binding-threshold** alarm notifications: The DHCP snooping device generates this type of alarm notifications when the usage of DHCP snooping entry resources has reached or dropped below the alarm threshold.
- **Chaddr-mismatch** alarm notifications: The DHCP snooping device generates this type of alarm notifications when the number of DHCP requests dropped due to MAC address mismatch has reached the alarm threshold.
- **Rate-limit** alarm notifications: The DHCP snooping device generates this type of alarm notifications when the number of DHCP requests dropped due to reception rate limit exceeding has reached the alarm threshold.
- **Untrust-reply** alarm notifications: The DHCP snooping device generates this type of alarm notifications when the number of DHCP server replies dropped on untrusted interfaces has reached the alarm threshold.

After you enable DHCP snooping alarm notifications, the DHCP snooping module reports critical DHCP snooping events in alarm notifications to the SNMP module. For DHCP snooping event notifications to be sent correctly, you must configure SNMP on the device. For more information about SNMP configuration, see SNMP configuration in *Network Management and Monitoring Configuration Guide*.

Enabling the binding-exhaust alarm

1. Enter system view.
   system-view
2. Enable the binding-exhaust alarm.
   snmp-agent trap enable dhcp snooping binding-exhaust
   By default, the binding-exhaust alarm is disabled for DHCP snooping.
3. Enter interface view.
   interface *interface-type interface-number*
4. (Optional.) Enable the binding-exhaust alarm on the interface.
   dhcp snooping exhaustion trap enable
   By default, the binding-exhaust alarm is disabled on the interface.

Enabling the binding-threshold alarm

1. Enter system view.
   system-view
2. Enable the binding-threshold alarm.
   snmp-agent trap enable dhcp snooping binding-threshold
   By default, the binding-threshold alarm is disabled for DHCP snooping.
3. Enter interface view.
   interface *interface-type interface-number*
4. (Optional.) Set the alarm threshold on the usage of DHCP snooping entry resources.
   dhcp snooping learning-num-threshold *threshold-value*
   By default, the alarm threshold on the usage of DHCP snooping entry resources is 100%.

Enabling the binding-mismatch or chaddr-mismatch packet drop alarm

About this task

This chapter introduces how to enable the **binding-mismatch** or **chaddr-mismatch** packet drop alarm.

Procedure

1. Enter system view.

   system-view

2. Enable the **binding-mismatch** or **chaddr-mismatch** alarm for the SNMP module.

   snmp-agent trap enable dhcp snooping [**binding-mismatch** | **chaddr-mismatch**] *

   By default, both the **binding-mismatch** and **chaddr-mismatch** alarms are disabled for the SNMP module.

3. Set the global alarm threshold that triggers packet drop alarm generation.

   dhcp snooping alarm { **mac-address** | **request-message** } **threshold** *threshold*

   By default, the global alarm threshold that triggers packet drop alarm generation is 100.

   For an interface, the **mac-address** keyword has the same effect as the **chaddr-mismatch** keyword in the **dhcp snooping alarm** { **binding-mismatch** | **chaddr-mismatch** } **threshold** command.

   For an interface, the **request-message** keyword has the same effect as the **binding-mismatch** keyword in the **dhcp snooping alarm** { **binding-mismatch** | **chaddr-mismatch** } **threshold** command.

4. Enter interface view.

   interface *interface-type interface-number*

5. (Optional.) Disable alarm log generation for packet drop events on the interface.

   undo dhcp snooping trap { **binding-mismatch** | **chaddr-mismatch** } **enable**

   By default, the packet drop alarm is disabled on the interface.

6. (Optional.) Set the global threshold that triggers alarm log generation for packet drop events on the interface.

   dhcp snooping trap { **binding-mismatch** | **chaddr-mismatch** } **threshold** *threshold*

   By default, the global threshold configured in system view takes effect on the interface.

Enabling the rate-limit or untrust-reply packet drop alarm

About this task

This chapter introduces how to enable the **rate-limit** or **untrust-reply** packet drop alarm.

After you enable the **rate-limit** or **untrust-reply** packet drop alarm for the SNMP module and the DHCP module, both modules generate alarm notifications when the alarm threshold is reached.

Restrictions and guidelines

- After you enable the **rate-limit** packet drop alarm for the SNMP or DHCP module, the module generates an alarm notification when the alarm threshold is reached. To set the alarm threshold

that triggers the **rate-limit** packet drop alarm, use the **dhcp snooping trap threshold rate-limit** command.

- After you enable the **untrust-reply** packet drop alarm for the DHCP module, this feature functions as follows:
  - If you specify the **software** keyword, the software side collects statistics about the DHCP server replies dropped on each interface. When the number of DHCP server replies dropped on an interface reaches the alarm threshold, the DHCP module generates an alarm notification.
  - If you specify the **hardware** keyword, the hardware side collects statistics about the DHCP server replies dropped on untrusted interfaces of the device. When the total number of dropped DHCP server replies reaches the alarm threshold, the DHCP module generates an alarm notification.

Procedure

1. Enter system view.
   system-view
2. Enable the **rate-limit** or **untrust-reply** alarm for the SNMP module.
   snmp-agent trap enable dhcp snooping [**rate-limit** | **untrust-reply**] *
   By default, both the **rate-limit** and **untrust-reply** alarms are disabled for the SNMP module.
3. Enable the **rate-limit** or **untrust-reply** alarm for the DHCP module.
   dhcp snooping trap { **rate-limit** | **untrust-reply** { **software** | **hardware** } } **enable**
   By default, all types of packet drop alarms are disabled.
4. Set the global threshold that triggers packet drop alarm generation.
   dhcp snooping trap { **rate-limit** | **untrust-reply** { **software** | **hardware** } } **threshold** *threshold*
   By default, the global threshold is 100 for all packet drop types.
5. Enter interface view.
   interface *interface-type interface-number*
6. (Optional.) Disable the packet drop alarm on the interface.
   undo dhcp snooping trap { **rate-limit** | **untrust-reply software** } **enable**
   By default, all types of packet drop alarms are disabled on the interface.
7. (Optional.) Set the packet drop alarm threshold on the interface.
   dhcp snooping trap { **rate-limit** | **untrust-reply software** } **threshold** *threshold*
   By default, the global threshold configured in system view takes effect on the interface.

Enabling alarm log generation for packet drop events

About this task

After you enable alarm log generation for a packet drop type, the device generates an alarm log when the number of packets dropped reaches the alarm threshold. Then, the device clears the current packet drop statistics and counts packet drops again.

The alarm log is sent to the information center. For information about the log destination and output rule configuration in the information center, see *Network Management and Monitoring Configuration Guide*.

To set the alarm threshold, use the **dhcp snooping alarm threshold** command.

Restrictions and guidelines

For this feature to take effect, you must first execute the **dhcp snooping log enable** command to enable DHCP snooping logging.

Procedure

1. Enter system view.
   system-view
2. Enable alarm log generation for packet drop events.
   dhcp snooping alarm { **giaddr** | **mac-address** | **request-message** } **enable**
   By default, alarm log generation is disabled for packet drop events.
3. Set the global threshold that triggers packet drop alarm log generation.
   dhcp snooping alarm { **giaddr** | **mac-address** | **request-message** } **threshold** *threshold*
   By default, the global threshold is 100.

Disabling DHCP snooping on an interface

About this task

This feature allows you to narrow down the interface range where DHCP snooping takes effect. For example, to enable DHCP snooping globally except for a specific interface, you can enable DHCP snooping globally and disable DHCP snooping on the target interface.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Disable DHCP snooping on the interface.
   dhcp snooping disable
   By default:
   - If you enable DHCP snooping globally or for a VLAN, DHCP snooping is enabled on all interfaces on the device or on all interfaces in the VLAN.
   - If you do not enable DHCP snooping globally or for a VLAN, DHCP snooping is disabled on all interfaces on the device or on all interfaces in the VLAN.

Display and maintenance commands for DHCP snooping

Execute **display** commands in any view, and **reset** commands in user view.

Task	Command
Display the packet drop statistics on	**display dhcp snooping alarm packet statistics**

Task	Command
an interface enabled with the packet drop alarm.	**interface** *interface-type interface-number*
Display DHCP snooping entries.	**display dhcp snooping binding** [**ip** *ip-address* [**vlan** *vlan-id*] | **interface** *interface-type interface-number*] [**verbose**]
Display information about the file that stores DHCP snooping entries.	**display dhcp snooping binding database**
Display statistics about the packets exchanged between M-LAG member devices for DHCP snooping entry synchronization.	**display dhcp snooping m-lag-statistics**
Display M-LAG status information.	**display dhcp snooping m-lag-status**
Display Option 82 configuration information on the DHCP snooping device.	**display dhcp snooping information** { **all** | **interface** *interface-type interface-number* }
Display DHCP packet statistics on the DHCP snooping device.	**display dhcp snooping packet statistics** [**slot** *slot-number*]
Display information about trusted ports.	**display dhcp snooping trust**
Clear the packet drop statistics on an interface.	**reset dhcp snooping alarm packet statistics interface** *interface-type interface-number*
Clear DHCP snooping entries.	**reset dhcp snooping binding** { **all** | **ip** *ip-address* [**vlan** *vlan-id*] }
Clear statistics about the packets exchanged between M-LAG member devices for DHCP snooping entry synchronization.	**reset dhcp snooping m-lag-statistics**
Clear DHCP packet statistics on the DHCP snooping device.	**reset dhcp snooping packet statistics** [**slot** *slot-number*]

DHCP snooping configuration examples

Example: Configuring basic DHCP snooping features globally

Network configuration

As shown in Figure 25, Switch B is connected to the authorized DHCP server through GigabitEthernet 1/0/1, to the unauthorized DHCP server through GigabitEthernet 1/0/3, and to the DHCP client through GigabitEthernet 1/0/2.

Configure only the port connected to the authorized DHCP server to forward the responses from the DHCP server. Enable the DHCP snooping device to record clients' IP-to-MAC bindings by reading DHCP-ACK messages received from the trusted port and the DHCP-REQUEST messages.

Figure 25 Network diagram

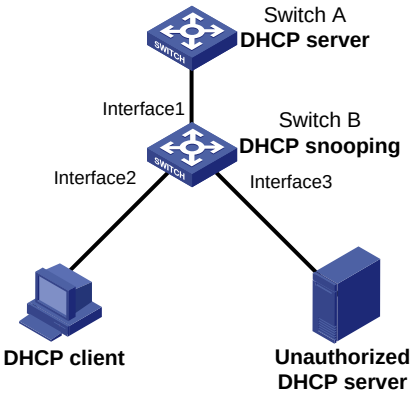


Table 5 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

Enable DHCP snooping globally.

```
<SwitchB> system-view
[SwitchB] dhcp snooping enable
```

Configure GigabitEthernet 1/0/1 as a trusted port.

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] dhcp snooping trust
[SwitchB-GigabitEthernet1/0/1] quit
```

Enable recording clients' IP-to-MAC bindings on GigabitEthernet 1/0/2.

```
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] dhcp snooping binding record
[SwitchB-GigabitEthernet1/0/2] quit
```

Verifying the configuration

Verify that the DHCP client can obtain an IP address and other configuration parameters only from the authorized DHCP server. (Details not shown.)

Display the DHCP snooping entry recorded for the client.

```
[SwitchB] display dhcp snooping binding
```

Example: Configuring basic DHCP snooping features for a VLAN

Network configuration

As shown in Figure 26, Switch B is connected to the authorized DHCP server through GigabitEthernet 1/0/1, to the unauthorized DHCP server through GigabitEthernet 1/0/3, and to the DHCP client through GigabitEthernet 1/0/2.

Configure only the port in VLAN 100 connected to the authorized DHCP server to forward the responses from the DHCP server. Enable the port in VLAN 100 to record clients' IP-to-MAC bindings by reading DHCP-ACK messages received from the trusted port and the DHCP-REQUEST messages.

Figure 26 Network diagram

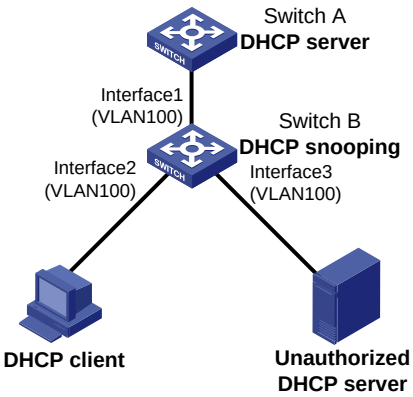

Table 6 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

Assign GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 to VLAN 100.

```
<SwitchB> system-view
[SwitchB] vlan 100
[SwitchB-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/3
[SwitchB-vlan100] quit
```

Enable DHCP snooping for VLAN 100.

```
[SwitchB] dhcp snooping enable vlan 100
```

Configure GigabitEthernet 1/0/1 as DHCP snooping trusted port.

```
[SwitchB] vlan 100
[SwitchB-vlan100] dhcp snooping trust interface gigabitethernet 1/0/1
```

Enable recording clients' IP-to-MAC bindings in VLAN 100.

```
[SwitchB-vlan100] dhcp snooping binding record
[SwitchB-vlan100] quit
```

Verifying the configuration

Verify that the DHCP client can obtain an IP address and other configuration parameters only from the authorized DHCP server. (Details not shown.)

Display the DHCP snooping entry recorded for the client.

```
[SwitchB] display dhcp snooping binding
```

Example: Configuring DHCP snooping support for Option 82

Network configuration

As shown in Figure 27, enable DHCP snooping and configure Option 82 on Switch B as follows:

- Configure the handling strategy for DHCP requests that contain Option 82 as **`replace`**.
- On GigabitEthernet 1/0/2, configure the padding content for the Circuit ID sub-option as **`company001`** and for the Remote ID sub-option as **`device001`**.
- On GigabitEthernet 1/0/3, configure the padding mode for the Circuit ID sub-option as **`verbose`**, access node identifier as **`sysname`**, and padding format as **`ascii`**. Configure the padding content for the Remote ID sub-option as **`device001`**.

Figure 27 Network diagram

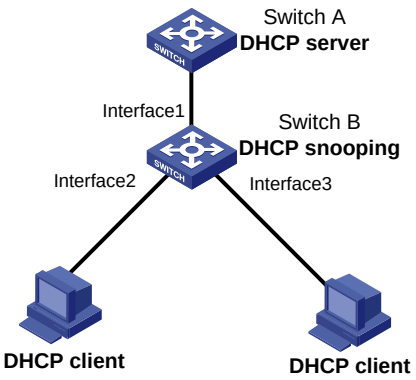

Table 7 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

Enable DHCP snooping.

```
<SwitchB> system-view
[SwitchB] dhcp snooping enable
```

Configure GigabitEthernet 1/0/1 as a trusted port.

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] dhcp snooping trust
[SwitchB-GigabitEthernet1/0/1] quit
```

Configure Option 82 on GigabitEthernet 1/0/2.

```
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] dhcp snooping information enable
[SwitchB-GigabitEthernet1/0/2] dhcp snooping information strategy replace
[SwitchB-GigabitEthernet1/0/2] dhcp snooping information circuit-id string company001
[SwitchB-GigabitEthernet1/0/2] dhcp snooping information remote-id string device001
[SwitchB-GigabitEthernet1/0/2] quit
```

Configure Option 82 on GigabitEthernet 1/0/3.

```
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] dhcp snooping information enable
[SwitchB-GigabitEthernet1/0/3] dhcp snooping information strategy replace
[SwitchB-GigabitEthernet1/0/3] dhcp snooping information circuit-id verbose
node-identifier sysname format ascii
[SwitchB-GigabitEthernet1/0/3] dhcp snooping information remote-id string device001
```

Verifying the configuration

Display Option 82 configuration information on GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3 on the DHCP snooping device.

```
[SwitchB] display dhcp snooping information
```

Configuring the BOOTP client

About BOOTP client

BOOTP client application

An interface that acts as a BOOTP client can use BOOTP to obtain information (such as IP address) from the BOOTP server.

To use BOOTP, an administrator must configure a BOOTP parameter file for each BOOTP client on the BOOTP server. The parameter file contains information such as MAC address and IP address of a BOOTP client. When a BOOTP client sends a request to the BOOTP server, the BOOTP server searches for the BOOTP parameter file and returns the corresponding configuration information.

BOOTP is usually used in relatively stable environments. In network environments that change frequently, DHCP is more suitable.

Because a DHCP server can interact with a BOOTP client, you can use the DHCP server to assign an IP address to the BOOTP client instead of using a BOOTP server. The DHCP server will assign an IP address to the BOOTP client based on the IP address allocation sequence.

Obtaining an IP address dynamically

A BOOTP client dynamically obtains an IP address from a BOOTP server as follows:

1. The BOOTP client broadcasts a BOOTP request, which contains its own MAC address.
2. Upon receiving the request, the BOOTP server searches the configuration file for the IP address and other information according to the BOOTP client's MAC address.
3. The BOOTP server returns a BOOTP response to the BOOTP client.
4. The BOOTP client obtains the IP address from the received response.

A DHCP server can take the place of the BOOTP server in the following dynamic IP address acquisition.

Protocols and standards

- RFC 951, *Bootstrap Protocol (BOOTP)*
- RFC 2132, *DHCP Options and BOOTP Vendor Extensions*
- RFC 1542, *Clarifications and Extensions for the Bootstrap Protocol*

Configuring an interface to use BOOTP for IP address acquisition

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*

   BOOTP client configuration applies only to Layer 3 Ethernet interfaces (including subinterfaces), Layer 3 aggregate interfaces, and VLAN interfaces.

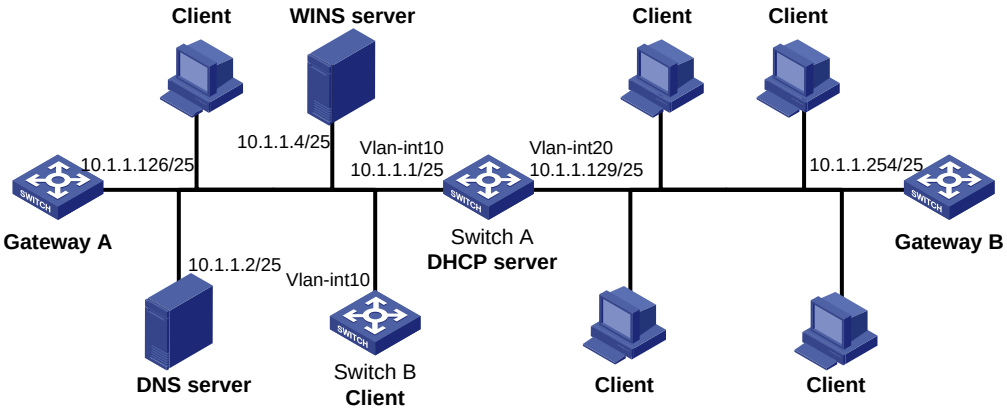
3. Configure an interface to use BOOTP for IP address acquisition.
   ip address bootp-alloc
   By default, an interface does not use BOOTP for IP address acquisition.

Display and maintenance commands for BOOTP client

Execute **display** command in any view.

Task	Command
Display BOOTP client information.	**display bootp client** [**interface** *interface-type interface-number*]

BOOTP client configuration examples



Example: Configuring BOOTP client

Network configuration

As shown in Figure 28, Switch B's port belonging to VLAN 10 is connected to the LAN. VLAN-interface 10 obtains an IP address from the DHCP server by using BOOTP.

To make the BOOTP client obtain an IP address from the DHCP server, you must perform configuration on the DHCP server. For more information, see "DHCP server configuration examples."

Figure 28 Network diagram

Procedure

The following describes the configuration on Switch B, which acts as a client.

Configure VLAN-interface 10 to dynamically obtain an IP address from the DHCP server.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] ip address bootp-alloc
```

Verifying the configuration

Display the IP address assigned to the BOOTP client.

```
[SwitchB] display bootp client
```

Configuring DNS

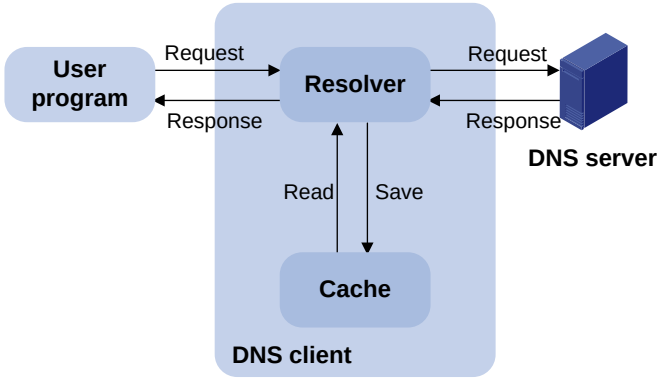
About DNS

Domain Name System (DNS) is a distributed database used by TCP/IP applications to translate domain names into IP addresses. The domain name-to-IP address mapping is called a DNS entry.

Types of DNS services

DNS services can be static or dynamic. After a user specifies a name, the device checks the static name resolution table for an IP address. If no IP address is available, it contacts the DNS server for dynamic name resolution, which takes more time than static name resolution. To improve efficiency, you can put frequently queried name-to-IP address mappings in the local static name resolution table.

Static domain name resolution



Static domain name resolution means manually creating mappings between domain names and IP addresses. For example, you can create a static DNS mapping for a device so that you can Telnet to the device by using the domain name.

DNS server-based domain name resolution

Architecture

Figure 1 shows the relationship between the user program, DNS client, and DNS server. The DNS client includes the resolver and cache. The user program and DNS client can run on the same device or different devices. The DNS server and the DNS client usually run on different devices.

Figure 1 DNS server-based domain name resolution

The device can function as a DNS client, but not a DNS server.

If an alias is configured for a domain name on the DNS server, the device can resolve the alias into the IP address of the host.

Resolution process

The DNS server-based domain name resolution process is as follows:

1. A user program sends a name query to the resolver of the DNS client.

2. The DNS resolver looks up the local domain name cache for a match. If the resolver finds a match, it sends the corresponding IP address back. If not, it sends a query to the DNS server.
3. The DNS server looks up the corresponding IP address of the domain name in its DNS database. If no match is found, the server sends a query to other DNS servers. This process continues until a result, whether successful or not, is returned.
4. After receiving a response from the DNS server, the DNS client returns the resolution result to the user program.

Caching

DNS server-based domain name resolution allows the DNS client to store latest DNS entries in the DNS cache. The DNS client does not need to send a request to the DNS server for a repeated query within the aging time. To make sure the entries from the DNS server are up to date, a DNS entry is removed when its aging timer expires. The DNS server determines how long a mapping is valid, and the DNS client obtains the aging information from DNS responses.

DNS suffixes

You can configure a domain name suffix list so that the resolver can use the list to supply the missing part of an incomplete name.

For example, you can configure **com** as the suffix for example.com. The user only needs to enter **example** to obtain the IP address of example.com. The resolver adds the suffix and delimiter before passing the name to the DNS server.

The name resolver handles the queries based on the domain names that the user enters:

- If the user enters a domain name without a dot (.) (for example, example), the resolver considers the domain name to be a host name. It adds a DNS suffix to the host name before performing the query operation. If no match is found for any host name and suffix combination, the resolver uses the user-entered domain name (for example, example) for the IP address query.
- If the user enters a domain name with a dot (.) among the letters (for example, www.example), the resolver directly uses this domain name for the query operation. If the query fails, the resolver adds a DNS suffix for another query operation.
- If the user enters a domain name with a dot (.) at the end (for example, example.com.), the resolver considers the domain name an FQDN and returns the successful or failed query result. The dot at the end of the domain name is considered a terminating symbol.

DNS server group-based domain name resolution

This feature allows the device (DNS client or proxy) to search for a matching domain name rule and send queries to servers in the DNS server group bound to the rule.

When the device receives a user query and fails to find a local matching DNS entry, the device determines whether a matching domain name rule exists in the same VPN instance or on the public network as the user. If a matching rule exists, the device forwards the query to DNS servers in the DNS server group bound to the rule. If no matching rule exists, the device does not forward the query to DNS servers in DNS server groups.

A domain name rule can be matched by using one of the following methods:

- **Exact match**—The match succeeds only when the domain name in the query is exactly the same as a domain name in the rule.
- **Fuzzy match**—The match succeeds if the domain name in the query contains a subdomain name.
- **Include the domain name group**—The device matches the domain name in a query against the domain names in the domain name groups. The match succeeds if the domain name in the query matches any domain name in a group.

If the domain name rule includes default domain name group **any**, any domain name can match the rule.

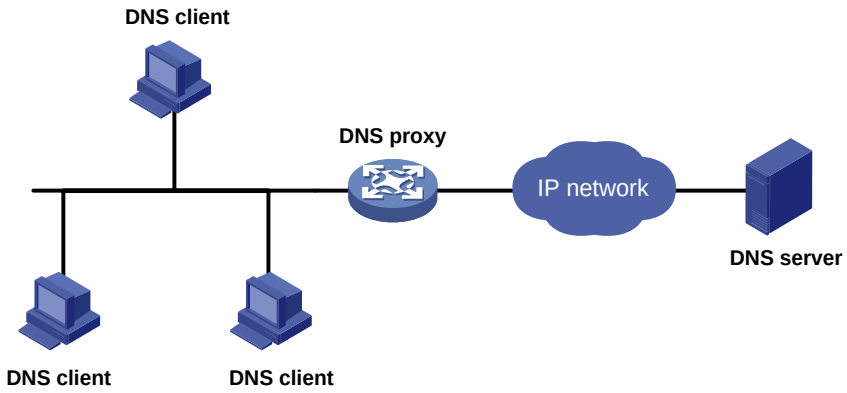
- **Exclude the domain name group**—The device matches the domain name in a query against the domain names in the domain name groups. The match succeeds only when the domain name in the query does not match any domain name in the domain name groups.

  If the domain name rule includes default domain name group **any**, no domain names can match the rule.

The device looks for a matching domain name rule in ascending order of rule IDs and compares the domain name in the query with domain names and subdomain names one by one. The domain name match order is the same as the order displayed in the **`display this`** command for the rule.

- If the domain name in the query matches a domain name or subdomain name in a rule, the device sends the query to DNS servers in the DNS server group bound to the rule.
  - After receiving the reply, the device sends the reply to the user and stores the DNS mapping in its local DNS cache.
  - If no reply is received, the device turns to the next domain name rule.
- If the domain name in the query does not match any domain names or subdomain names in all rules, the domain name resolution fails.

DNS proxy



The DNS proxy performs the following functions:

- Forwards the request from the DNS client to the designated DNS server.
- Conveys the reply from the DNS server to the client.

The DNS proxy simplifies network management. When the DNS server address is changed, you can change the configuration only on the DNS proxy instead of on each DNS client.

Figure 2 shows the typical DNS proxy application.

Figure 2 DNS proxy application

A DNS proxy operates as follows:

2. A DNS client considers the DNS proxy as the DNS server, and sends a DNS request to the DNS proxy. The destination address of the request is the IP address of the DNS proxy.
3. The DNS proxy searches the local static domain name resolution table and dynamic domain name resolution cache after receiving the request. If the requested information is found, the DNS proxy returns a DNS reply to the client.
4. If the requested information is not found, the DNS proxy forwards the request as follows:
   a. If a matching DNS server group exists, the proxy forwards the request to DNS servers in the DNS server group bound to the rule.

b. If no matching DNS server group exists but a DNS server is specified, the DNS proxy sends the request to the DNS server for domain name resolution.

5. After receiving a reply from the DNS server, the DNS proxy records the IP address-to-domain name mapping and forwards the reply to the DNS client.
