If no DNS server is designated or no route is available to the designated DNS server, the DNS proxy does not forward DNS requests.

DNS spoofing

As shown in Figure 3, DNS spoofing is applied to the dial-up network.

- The device connects to a PSTN/ISDN network through a dial-up interface. The device triggers the establishment of a dial-up connection only when packets are to be forwarded through the dial-up interface.
- The device acts as a DNS proxy and is specified as a DNS server on the hosts. After the dial-up connection is established, the device dynamically obtains the DNS server address through DHCP or another autoconfiguration mechanism.

Figure 3 DNS spoofing application

The DNS proxy does not have the DNS server address or cannot reach the DNS server after startup. A host accesses the HTTP server in the following steps:

2. The host sends a DNS request to the device to resolve the domain name of the HTTP server into an IP address.
3. Upon receiving the request, the device spoofs the host by replying a configured IP address in the following conditions: no dial-up connection is established, or the device does not know the DNS server address or cannot reach any DNS server. The device must have a route to the IP address with the dial-up interface as the output interface.

   The IP address configured for DNS spoofing is not the actual IP address of the requested domain name. Therefore, the TTL field is set to 0 in the DNS reply. When the DNS client receives the reply, it creates a DNS entry and ages it out immediately.
4. Upon receiving the reply, the host sends an HTTP request to the replied IP address.
5. When forwarding the HTTP request through the dial-up interface, the device performs the following operations:
   - Establishes a dial-up connection with the network.
   - Dynamically obtains the DNS server address through DHCP or another autoconfiguration mechanism.
6. Because the DNS entry ages out immediately upon creation, the host sends another DNS request to the device to resolve the HTTP server domain name.
7. The device operates the same as a DNS proxy. For more information, see "DNS proxy."
8. After obtaining the IP address of the HTTP server, the host can access the HTTP server.

Without DNS spoofing, the device forwards the DNS requests from the host to the DNS server if it cannot find a matching local DNS entry. However, the device cannot obtain the DNS server address, because no dial-up connection is established. Therefore, the device cannot forward or answer the requests from the client. DNS resolution fails, and the client cannot access the HTTP server.

DNS tasks at a glance

To configure DNS, perform the following tasks:

1. Configuring the DNS client

   Choose the following tasks as needed:

   - Configuring static domain name resolution
   - Configuring DNS server-based domain name resolution
   - Configuring DNS server group-based domain name resolution (independent domain name rules)
   - Configuring DNS server group-based domain name resolution (domain name rules associated with domain name groups)
   - Enabling DNS server health check
2. (Optional.) Configuring DNS proxy
   - Configuring the DNS proxy
   - Configuring the DNS transparent proxy
3. (Optional.) Configuring DNS spoofing

   This feature is applied to the dial-up network.
4. (Optional.) Configuring DNS fast-reply
5. (Optional.) Specifying the source interface for DNS packets
6. (Optional.) Configuring the DNS trusted interface
7. (Optional.) Setting the DSCP value for outgoing DNS packets

Configuring the DNS client

About this task

You can create domain name-to-address mappings on the DNS client through the following methods:

- **Configure static domain name resolution**—Use this method when you use domain names to access a small number of devices or when the network does not have available DNS servers. The network administrator must configure or maintain the domain name-to-address mappings manually.
- **Configure dynamic domain name resolution**—Use this method when you use domain names to access a large number of devices and the network has an available DNS server.

A DNS client resolves a domain name in the following order:

1. Static domain name resolution.
2. Locally saved DNS mappings that have been resolved.
3. DNS server-based domain name resolution.

The resolution fails if the domain name cannot be resolved after all these methods are used.

Configuring static domain name resolution

Restrictions and guidelines

For the public network or a VPN instance, each host name maps to only one IPv4 address and one IPv6 address.

A maximum of 2048 DNS entries can be configured for the public network or each VPN instance. You can configure DNS entries for both public network and VPN instances.

Procedure

1. Enter system view.

   system-view

2. Configure a host name-to-address mapping. Choose the options to configure as needed:

   IPv4:

   ip host *host-name ip-address* [**vpn-instance** *vpn-instance-name*]

   IPv6:

   ipv6 host *host-name ipv6-address* [**vpn-instance** *vpn-instance-name*]

Configuring DNS server-based domain name resolution

Hardware and feature compatibility

The S5200-EI-G switch series does not support the **priority** keyword in the current software version.

Restrictions and guidelines

- The limit on the number of DNS servers on the device is as follows:
  - In system view, you can specify a maximum of six DNS server IPv4 addresses for the public network or each VPN instance. You can specify DNS server IPv4 addresses for both public network and VPN instances.
  - In system view, you can specify a maximum of six DNS server IPv6 addresses for the public network or each VPN instance. You can specify DNS server IPv6 addresses for both public network and VPN instances.
- A DNS server address is required so that DNS queries can be sent to a correct server for resolution. If you specify both an IPv4 address and an IPv6 address, the device performs the following operations:
  - Sends an IPv4 DNS query first to the DNS server IPv4 addresses. If the query fails, the device turns to the DNS server IPv6 addresses.
  - Sends an IPv6 DNS query first to the DNS server IPv6 addresses. If the query fails, the device turns to the DNS server IPv4 addresses.
- The DNS server address priority is as follows:
  - A DNS server address specified earlier has a higher priority.
  - A DNS server address manually specified takes priority over a DNS server address dynamically obtained, for example, through DHCP.

  The device first sends a DNS query to the DNS server address of the highest priority. If the first query fails, it sends the DNS query to the DNS server address of the second highest priority, and so on.
- You can configure a DNS suffix that the system automatically adds to the incomplete domain name that a user enters.
  - You can configure a maximum of 16 DNS suffixes for the public network or each VPN instance. You can configure DNS suffixes for both public network and VPN instances.

- A DNS suffix manually configured takes priority over a DNS suffix dynamically obtained, for example, through DHCP. A DNS suffix configured earlier has a higher priority. The device first uses the suffix that has the highest priority. If the query fails, the device uses the suffix that has the second highest priority, and so on.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Configure a DNS suffix.

   dns domain *domain-name* [**vpn-instance** *vpn-instance-name*]

   By default, no DNS suffix is configured and only the domain name that a user enters is resolved.

3. Specify a DNS server address.

   IPv4:

   dns server *ip-address* [**vpn-instance** *vpn-instance-name*] [**priority** *priority-value*]

   IPv6:

   ipv6 dns server *ipv6-address* [*interface-type interface-number*] [**vpn-instance** *vpn-instance-name*] [**priority** *priority-value*]

   By default, no DNS server address is specified.

Configuring DNS server group-based domain name resolution (independent domain name rules)

About this task

An independent domain name rule can be matched by using one of the following methods:

- **Exact match**—The match succeeds only when the domain name in the query is exactly the same as a domain name in the rule.
- **Fuzzy match**—The match succeeds if the domain name in the query contains a subdomain name.

Hardware and feature compatibility

Only the S5200-HI-G switch series supports this feature.

Restrictions and guidelines

You can add both IPv4 and IPv6 DNS server addresses to a DNS server group.

The user query can only match a domain name rule that is in the same VPN instance or on the public network as the user. The device forwards the query to DNS servers of the DNS server group bound to the matching rule as follows:

- If the DNS servers are configured with priorities, the device selects DNS servers in descending order of their priorities.
- If the DNS servers are not configured with priorities or they have the same priority, the device selects DNS servers according to the server order displayed in the **display this** command.

If the query is an IPv4 packet, the device forwards the query first to IPv4 DNS servers. If the query is an IPv6 packet, the device forwards the query first to IPv6 DNS servers.

Procedure

1. Enter system view.

   system-view

2. Create a DNS server group.

dns server-group *group-id* [**vpn-instance** *vpn-instance-name*]

By default, no DNS server groups exist.

The device supports a maximum of 16 DNS server groups. Each DNS server group can contain a maximum of 6 IPv4 DNS server addresses and a maximum of 6 IPv6 DNS server addresses.

3. Add DNS servers to the DNS server group.

   IPv4:

   dns server *ip-address* [**priority** *priority-value*]

   IPv6:

   ipv6 dns server *ipv6-address* [*interface-type interface-number*] [**priority** *priority-value*]

   By default, no DNS servers exist in the DNS server group.

4. Return to system view.

   quit

5. Configure a domain name rule.

   dns domain-rule *rule-id* { **domain-name** *domain-name* | **subdomain-name** *subdomain-name* } [**any-vpn-instance** | **vpn-instance** *vpn-instance-name*] **server-group** *group-id*

   By default, no domain name rule is configured.

Configuring DNS server group-based domain name resolution (domain name rules associated with domain name groups)

About this task

When the device uses domain name rules to match DNS queries, you can associate a domain name rule with a domain name group to simplify configuration. When multiple domain names are to be matched, you do not need to configure domain name rules multiple times.

After adding domain names or subdomain names to a domain name group, you can associate it with a domain name rule to enable the device to distribute DNS queries based on the matching results.

The relationship between a domain name rule and its associated domain name groups include the following types:

- **Include the domain name group**—The device matches the domain name in a query against the domain names in the domain name groups. The match succeeds if the domain name in the query matches any domain name in a group.

  If the domain name rule includes default domain name group **any**, any domain name can match the rule.

- **Exclude the domain name group**—The device matches the domain name in a query against the domain names in the domain name groups. The match succeeds only when the domain name in the query does not match any domain name in the domain name groups.

  If the domain name rule includes default domain name group **any**, no domain names can match the rule.

Hardware and feature compatibility

Only the S5200-HI-G switch series supports this feature.

Restrictions and guidelines

You can add both IPv4 and IPv6 DNS server addresses to a DNS server group.

The user query can only match a domain name rule that is in the same VPN instance or on the public network as the user. The device forwards the query to DNS servers of the DNS server group bound to the matching rule as follows:

- If the DNS servers are configured with priorities, the device selects DNS servers in descending order of their priorities.
- If the DNS servers are not configured with priorities or they have the same priority, the device selects DNS servers according to the server order displayed in the **display this** command.

If the query is an IPv4 packet, the device forwards the query first to IPv4 DNS servers. If the query is an IPv6 packet, the device forwards the query first to IPv6 DNS servers.

Procedure

1. Enter system view.

   system-view

2. Create a DNS server group.

   dns server-group *group-id* [**vpn-instance** *vpn-instance-name*]

   By default, no DNS server groups exist.

   The device supports a maximum of 16 DNS server groups. Each DNS server group can contain a maximum of 6 IPv4 DNS server addresses and a maximum of 6 IPv6 DNS server addresses.

3. Add DNS servers to the DNS server group.

   IPv4:

   dns server *ip-address* [**priority** *priority-value*]

   IPv6:

   ipv6 dns server *ipv6-address* [*interface-type interface-number*] [**priority** *priority-value*]

   By default, no DNS servers exist in the DNS server group.

4. Return to system view.

   quit

5. Create a domain name group and enter its view, or enter an existing domain name group view.

   dns domain-name-group *group-name*

   By default, the system has default domain name group **any**.

   The default domain name group cannot be manually created or deleted.

   You can execute this command multiple times to create multiple domain name groups. The maximum number of domain name groups that can be created varies by device.

6. Add a domain name to the domain name group.

   domain-name *domain-name*

   By default, a domain name group does not have domain names.

7. Add a subdomain name to a domain name group.

   subdomain-name *subdomain-name*

   By default, a domain name group does not have subdomain names.

8. Return to system view.

   quit

9. Configure a domain name rule.

   - Associate the domain name group with a domain name rule and configure the domain name rule to match a DNS query when the domain name in the query is in the domain name group.

dns domain-rule *rule-id* **domain-name-group** *group-name* [**any-vpn-instance** | **vpn-instance** *vpn-instance-name*] **server-group** *group-id*

- Associate the domain name group with a domain name rule and configure the domain name rule to match a DNS query when the domain name in the query is not in the domain name group.

  dns domain-rule *rule-id* **exclude domain-name-group** *group-name* [**any-vpn-instance** | **vpn-instance** *vpn-instance-name*] **server-group** *group-id*

By default, no domain name rule is configured.

Enabling DNS server health check

About this task

This feature enables the device to detect the availability of DNS servers in a DNS server group, which prevents the device from forwarding packets to unavailable DNS servers.

When the device receives a DNS request that matches a domain name rule, the device forwards the request to a DNS server. The DNS server is selected as follows:

- If the DNS servers are configured with priorities, the device selects DNS servers in descending order of their priorities.
- If the DNS servers are not configured with priorities or they have the same priority, the device selects DNS servers according to the server order displayed in the **display this** command.

After the device forwards the request to a DNS server, if it does not receive a DNS reply from the DNS server within two seconds, it reselects a DNS server. To prevent the device from selecting an unavailable DNS server, execute the **health-check enable** command to detect the availability of DNS servers. After you execute the command on the device, it works as follows:

1. The device periodically sends a DNS request to each DNS server in the DNS server group.
2. If the device receives a DNS reply from a DNS server, it regards the DNS server available.
3. If the device does not receive any DNS reply from a DNS server after it sends a DNS request to the DNS server for three consecutive times, it regards the DNS server unavailable.

After obtaining the availability of each DNS server in the DNS server group, the device automatically ignores the unavailable DNS servers and selects an available DNS server for packet forwarding according to the above selection mechanism.

Hardware and feature compatibility

Only the S5200-HI-G switch series supports this feature.

Procedure

1. Enter system view.

   system-view

2. Create a DNS server group and enter its view.

   dns server-group *group-id* [**vpn-instance** *vpn-instance-name*]

3. Enable DNS server health check.

   health-check enable

   By default, DNS server health check is disabled.

Configuring the DNS proxy

Enabling DNS proxy

1. Enter system view.
   system-view
2. Enable DNS proxy.
   dns proxy enable
   By default, DNS proxy is disabled.

Specifying DNS server addresses

Hardware and feature compatibility

The S5200-EI-G switch series does not support the **priority** keyword in the current software version.

Restrictions and guidelines

You can specify multiple DNS servers. The DNS proxy forwards a request to the DNS server that has the highest priority. If having not received a reply, it forwards the request to a DNS server that has the second highest priority, and so on.

You can specify both an IPv4 address and an IPv6 address.

- A DNS proxy forwards an IPv4 name query first to IPv4 DNS servers. If no reply is received, it forwards the request to IPv6 DNS servers.
- A DNS proxy forwards an IPv6 name query first to IPv6 DNS servers. If no reply is received, it forwards the request to IPv4 DNS servers.

Procedure

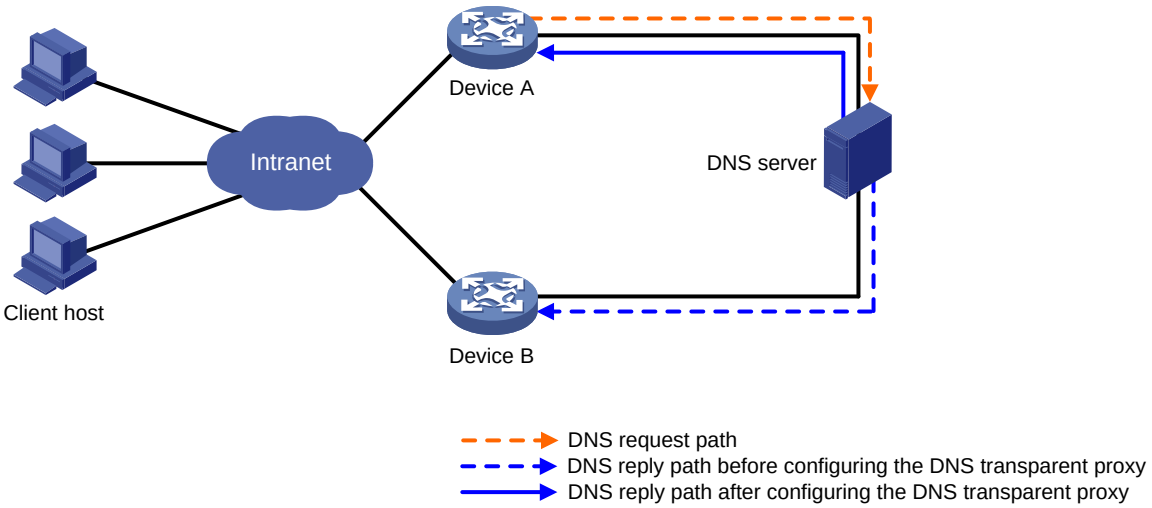
1. Enter system view.
   system-view
2. Specify a DNS server address.
   IPv4:
   dns server *ip-address* [**vpn-instance** *vpn-instance-name*] [**priority** *priority-value*]
   IPv6:
   ipv6 dns server *ipv6-address* [*interface-type interface-number*] [**vpn-instance** *vpn-instance-name*] [**priority** *priority-value*]
   By default, no DNS server address is specified.

Configuring a DNS server group

For more information, see "Configuring DNS server group-based domain name resolution (independent domain name rules)" and "Configuring DNS server group-based domain name resolution (domain name rules associated with domain name groups)."

Configuring the DNS transparent proxy

About this task



DNS transparent proxy modifies the source address in DNS requests so that the DNS client seems to receive a DNS reply directly from the DNS server. This feature is applicable to domain name-based policies, such as security policies and bandwidth policies.

The DNS client does not configure the DNS server address as the DNS transparent proxy address, which simplifies the DNS client configuration. As a best practice, enable DNS transparent proxy in some load balancing scenarios.

The device enabled with DNS transparent proxy monitors received DNS requests and replies and records DNS mappings as follows:

1. The device monitors all received DNS packets. Upon receiving a DNS request, the device specifies a local IP address that can reach the DNS server as the source IP address for the request.
2. Upon receiving the DNS reply, the device records the DNS mapping and forwards the reply to the DNS client.
3. The device searches the local entries after receiving another request. If a match is found, the device returns a DNS reply to the client. If no match is found, the device forwards the query to the DNS server for domain name resolution.

Figure 4 Network diagram

As shown in Figure 4, a DNS transparent proxy operates as follows:

4. Device A is enabled with DNS transparent proxy. Upon receiving a DNS request, Device A changes the source address in the request to its own address and forwards the query to the DNS server.
5. Upon receiving the DNS reply, Device A records the domain name-to-IP address mapping and forwards the reply to the DNS client.

Hardware and feature compatibility

Only the S5200-HI-G switch series supports this feature.

Restrictions and guidelines

Do not configure both the DNS transparent proxy and DNS fast-reply features on the device.

The DNS transparent proxy feature cannot be used across VPNs. Make sure the input and output interfaces of DNS packets on the device belong to the same VPN.

Procedure

1. Enter system view.
   system-view
2. Enable DNS transparent proxy.
   dns transparent-proxy enable [**authorizing**]
   By default, DNS transparent proxy is disabled.

Configuring DNS spoofing

Restrictions and guidelines

You can configure only one replied IPv4 address and one replied IPv6 address for the public network or a VPN instance. If you execute the command multiple times, the most recent configuration takes effect.

You can configure DNS spoofing for both public network and VPN instances.

After DNS spoofing takes effect, the device spoofs a DNS request even though a matching static DNS entry exists.

Prerequisites

The DNS proxy is enabled on the device.

No DNS server or route to any DNS server is specified on the device.

Procedure

1. Enter system view.
   system-view
2. Enable DNS proxy.
   dns proxy enable
   By default, DNS proxy is disabled.
3. Enable DNS spoofing and specify the IP address used to spoof DNS requests. Choose one option as needed:
   IPv4:
   dns spoofing *ip-address* [**vpn-instance** *vpn-instance-name*]
   IPv6:
   ipv6 dns spoofing *ipv6-address* [**vpn-instance** *vpn-instance-name*]
   By default, DNS spoofing is disabled.

Configuring DNS fast-reply

About this task

With this feature enabled, the device monitors the received DNS requests (only UDP packets are supported in the current software version). Then, it resolves the domain names in the requests, and searches for a match in the local static domain name resolution table.

- If a match is found, the device sends a DNS reply to the DNS client.
- If no match is found, the device forwards the query to the DNS server.

As DNS fast-reply can process a large number of DNS requests per second, use this feature in scenarios that require high DNS packet processing performance.

Hardware and feature compatibility

Only the S5200-HI-G switch series supports this feature.

Restrictions and guidelines

This command does not take effect on labeled DNS packets.

Procedure

1. Enter system view.
   system-view
2. Enable DNS fast-reply.
   dns fast-reply enable
   By default, DNS fast-reply is disabled.

Specifying the source interface for DNS packets

About this task

This task enables the device to always use the primary IP address of the specified source interface as the source IP address of outgoing DNS packets. This feature applies to scenarios in which the DNS server responds only to DNS requests sourced from a specific IP address. If no IP address is configured on the source interface, no DNS packets can be sent out.

Restrictions and guidelines

When sending an IPv6 DNS request, the device follows the method defined in RFC 3484 to select an IPv6 address of the source interface.

You can configure only one source interface on the public network or a VPN instance. You can configure source interfaces for both public network and VPN instances.

Make sure the source interface belongs to the specified VPN instance if you specify the **vpn-instance** *vpn-instance-name* option.

Procedure

1. Enter system view.
   system-view
2. Specify the source interface for DNS packets.
   dns source-interface *interface-type interface-number* [**vpn-instance** *vpn-instance-name*]
   By default, no source interface for DNS packets is specified.

Configuring the DNS trusted interface

About this task

This task enables the device to use only the DNS suffix and domain name server information obtained through the trusted interface. The device can then obtain the correct resolved IP address. This feature protects the device against attackers that act as the DHCP server to assign incorrect DNS suffix and domain name server address.

Restrictions and guidelines

You can configure a maximum of 128 DNS trusted interfaces.

Procedure

1. Enter system view.

system-view

2. Specify the DNS trusted interface.

   dns trust-interface *interface-type interface-number*

   By default, no DNS trusted interface is specified.

Setting the DSCP value for outgoing DNS packets

About this task

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet. A bigger DSCP value represents a higher priority.

Procedure

1. Enter system view.

   system-view

2. Set the DSCP value for DNS packets sent by a DNS client or a DNS proxy.

   IPv4:

   dns dscp *dscp-value*

   By default, the DSCP value is 0 in IPv4 DNS packets sent by a DNS client or a DNS proxy.

   IPv6:

   ipv6 dns dscp *dscp-value*

   By default, the DSCP value is 0 in IPv6 DNS packets sent by a DNS client or a DNS proxy.

Display and maintenance commands for DNS

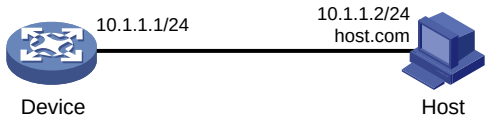
Execute **display** commands in any view and **reset** commands in user view.

NOTE:

The S5200-EI-G switch series does not support the **display dns server health status** or **display dns transparent host** command in the current software version.

Task	Command
Display DNS suffixes.	**display dns domain** [**dynamic**] [**vpn-instance** *vpn-instance-name*]
Display the domain name resolution table.	**display dns host** [**ip** | **ipv6**] [**vpn-instance** *vpn-instance-name*]
Display IPv4 DNS server information.	**display dns server** [**dynamic**] [**vpn-instance** *vpn-instance-name*]
Display health status of DNS servers.	**display dns server health status**
Display dynamic entries for domain name-to-IP address mappings recorded by DNS transparent proxy.	**display dns transparent host** [**ip** | **ipv6**] [**vpn-instance** *vpn-instance-name*]
Display IPv6 DNS server information.	**display ipv6 dns server** [**dynamic**] [**vpn-instance** *vpn-instance-name*]
Clear dynamic DNS entries.	**reset dns host** [**ip** | **ipv6**] [**vpn-instance**

Task	Command
	vpn-instance-name]



IPv4 DNS configuration examples

Example: Configuring static domain name resolution

Network configuration

As shown in Figure 5, the host at 10.1.1.2 is named **host.com**. Configure static IPv4 DNS on the device so that the device can use the easy-to-remember domain name rather than the IP address to access the host.

Figure 5 Network diagram

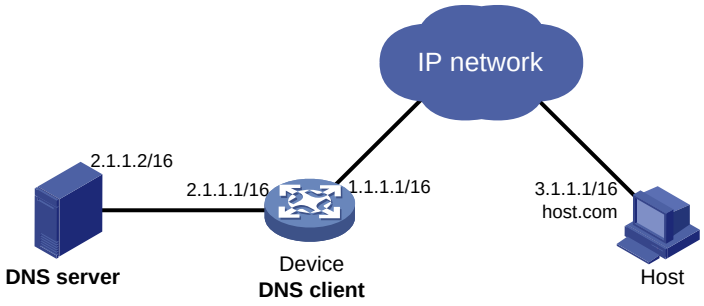
Procedure

Configure a mapping between host name **host.com** and IP address 10.1.1.2.

```
<Sysname> system-view
[Sysname] ip host host.com 10.1.1.2
```

Verify that the device can use static domain name resolution to resolve domain name **host.com** into IP address 10.1.1.2.

```
[Sysname] ping host.com
Ping host.com (10.1.1.2): 56 data bytes, press CTRL+C to break
56 bytes from 10.1.1.2: icmp_seq=0 ttl=255 time=1.000 ms
56 bytes from 10.1.1.2: icmp_seq=1 ttl=255 time=1.000 ms
56 bytes from 10.1.1.2: icmp_seq=2 ttl=255 time=1.000 ms
56 bytes from 10.1.1.2: icmp_seq=3 ttl=255 time=1.000 ms
56 bytes from 10.1.1.2: icmp_seq=4 ttl=255 time=2.000 ms



--- Ping statistics for host.com ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 1.000/1.200/2.000/0.400 ms
```

Example: Configuring dynamic domain name resolution

Network configuration

As shown in Figure 6, configure the DNS server to store the mapping between the host's domain name **host** and IPv4 address 3.1.1.1/16 in the **com** domain. Configure dynamic IPv4 DNS and DNS suffix **com** on the device so that the device can use domain name **host** to access the host.

Figure 6 Network diagram

Prerequisites

Before performing the following configuration, make sure that:

- The device and the host can reach each other.
- The IP addresses of the interfaces are configured as shown in Figure 6.

Procedure

1. Configure the DNS server:

   The configuration might vary by DNS server. The following configuration is performed on a PC running Windows Server 2008 R2.

   a. Select **Start** > **Programs** > **Administrative Tools** > **DNS**.

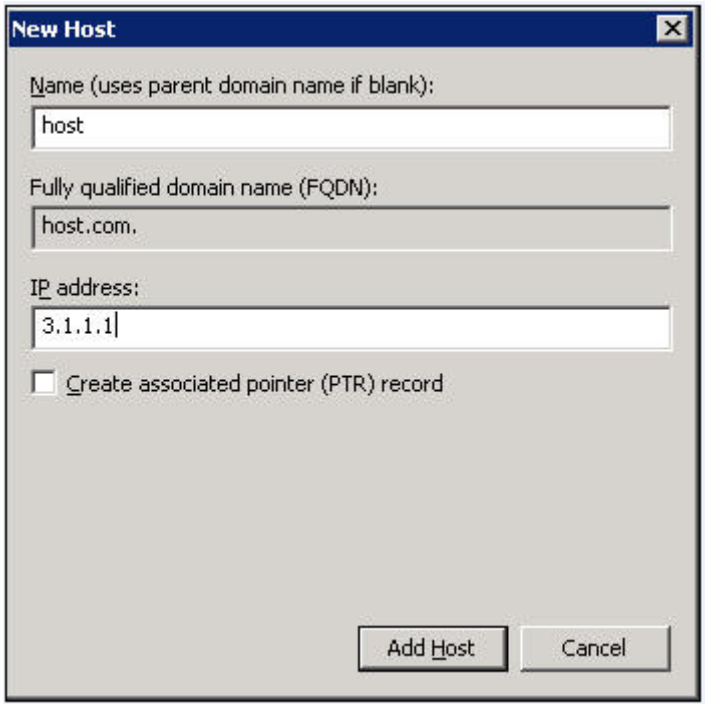
      The DNS server configuration page appears, as shown in Figure 7.

   b. Right-click **Forward Lookup Zones**, select **New Zone**, and then follow the wizard to create a new zone named **com**.

      Figure 7 Creating a zone

   c. On the DNS server configuration page, right-click zone **com** and select **New Host**.

Figure 8 Adding a host



d. On the page that appears, enter host name **host** and IP address **3.1.1.1**.

e. Click **Add Host**.

The mapping between the IP address and host name is created.

Figure 9 Adding a mapping between domain name and IP address

2. Configure the DNS client:

Specify the DNS server 2.1.1.2.

```
<Sysname> system-view
[Sysname] dns server 2.1.1.2
```

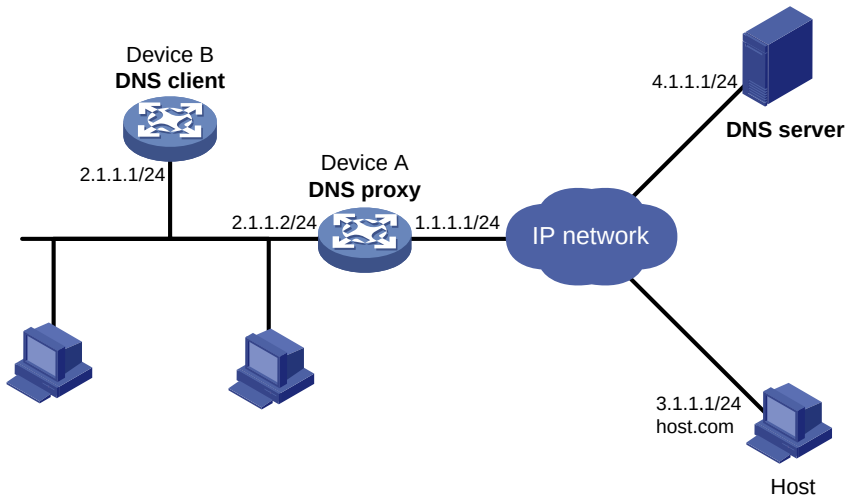
Specify **com** as the name suffix.

```
[Sysname] dns domain com
```

Verifying the configuration

Verify that the device can use the dynamic domain name resolution to resolve domain name **host.com** into IP address 3.1.1.1.

```
[Sysname] ping host
Ping host.com (3.1.1.1): 56 data bytes, press CTRL+C to break
56 bytes from 3.1.1.1: icmp_seq=0 ttl=255 time=1.000 ms
56 bytes from 3.1.1.1: icmp_seq=1 ttl=255 time=1.000 ms
56 bytes from 3.1.1.1: icmp_seq=2 ttl=255 time=1.000 ms
56 bytes from 3.1.1.1: icmp_seq=3 ttl=255 time=1.000 ms
56 bytes from 3.1.1.1: icmp_seq=4 ttl=255 time=2.000 ms



--- Ping statistics for host ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 1.000/1.200/2.000/0.400 ms
```

Example: Configuring DNS proxy

Network configuration

As shown in Figure 10, configure Device A as the DNS proxy to forward DNS packets between the DNS client (Device B) and the DNS server at 4.1.1.1.

Figure 10 Network diagram

Prerequisites

Before performing the following configuration, make sure that:

- Device A, the DNS server, and the host can reach each other.
- The IP addresses of the interfaces are configured as shown in Figure 10.

Procedure

1. Configure the DNS server:

The configuration might vary by DNS server. When a PC running Windows Server 2008 R2 acts as the DNS server, see "Example: Configuring dynamic domain name resolution" for configuration information.

2. Configure the DNS proxy:

   # Specify the DNS server 4.1.1.1.

   ```
   <DeviceA> system-view
   [DeviceA] dns server 4.1.1.1
   ```

   # Enable DNS proxy.

   ```
   [DeviceA] dns proxy enable
   ```

3. Configure the DNS client:

   ```
   <DeviceB> system-view
   ```

   # Specify the DNS server 2.1.1.2.

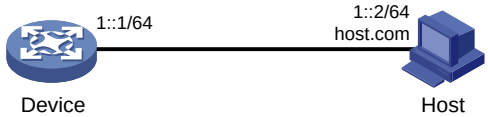
   ```
   [DeviceB] dns server 2.1.1.2
   ```

Verifying the configuration

Verify that DNS proxy on Device A functions.

```
[DeviceB] ping host.com
Ping host.com (3.1.1.1): 56 data bytes, press CTRL+C to break
56 bytes from 3.1.1.1: icmp_seq=0 ttl=255 time=1.000 ms
56 bytes from 3.1.1.1: icmp_seq=1 ttl=255 time=1.000 ms
56 bytes from 3.1.1.1: icmp_seq=2 ttl=255 time=1.000 ms
56 bytes from 3.1.1.1: icmp_seq=3 ttl=255 time=1.000 ms
56 bytes from 3.1.1.1: icmp_seq=4 ttl=255 time=2.000 ms

--- Ping statistics for host.com ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 1.000/1.200/2.000/0.400 ms
```



IPv6 DNS configuration examples

Example: Configuring static domain name resolution

Network configuration

As shown in Figure 11, the host at 1::2 is named **host.com**. Configure static IPv6 DNS on the device so that the device can use the easy-to-remember domain name rather than the IPv6 address to access the host.

Figure 11 Network diagram

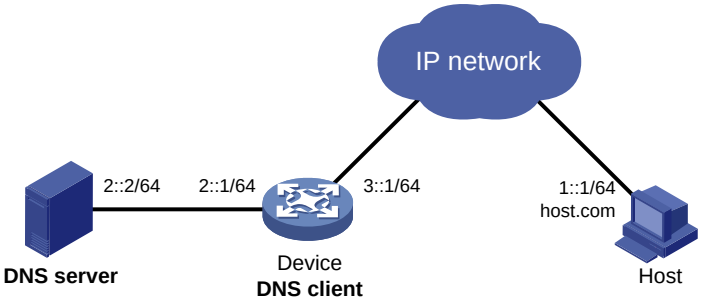
Procedure

Configure a mapping between host name **host.com** and IPv6 address 1::2.

```
<Device> system-view
[Device] ipv6 host host.com 1::2
```

Verify that the device can use static domain name resolution to resolve domain name **host.com** into IPv6 address 1::2.

```
[Sysname] ping ipv6 host.com
Ping6(56 data bytes) 1::1 --> 1::2, press CTRL+C to break
56 bytes from 1::2, icmp_seq=0 hlim=128 time=1.000 ms
56 bytes from 1::2, icmp_seq=1 hlim=128 time=0.000 ms
56 bytes from 1::2, icmp_seq=2 hlim=128 time=1.000 ms
56 bytes from 1::2, icmp_seq=3 hlim=128 time=1.000 ms
56 bytes from 1::2, icmp_seq=4 hlim=128 time=0.000 ms



--- Ping6 statistics for host.com ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 0.000/0.600/1.000/0.490 ms
```

Example: Configuring dynamic domain name resolution

Network configuration

As shown in Figure 12, configure the DNS server to store the mapping between the host's domain name **host** and IPv6 address 1::1/64 in the **com** domain. Configure dynamic IPv6 DNS and DNS suffix **com** on the device so that the device can use domain name **host** to access the host.

Figure 12 Network diagram

Prerequisites

Before performing the following configuration, make sure that:

- The device and the host can reach each other.
- The IPv6 addresses of the interfaces are configured as shown in Figure 12.

Procedure

1. Configure the DNS server:

   The configuration might vary by DNS server. The following configuration is performed on a PC running Windows Server 2008 R2. Make sure that the DNS server supports IPv6 DNS so that the server can process IPv6 DNS packets and its interfaces can forward IPv6 packets.

   a. Select **Start** > **Programs** > **Administrative Tools** > **DNS**.

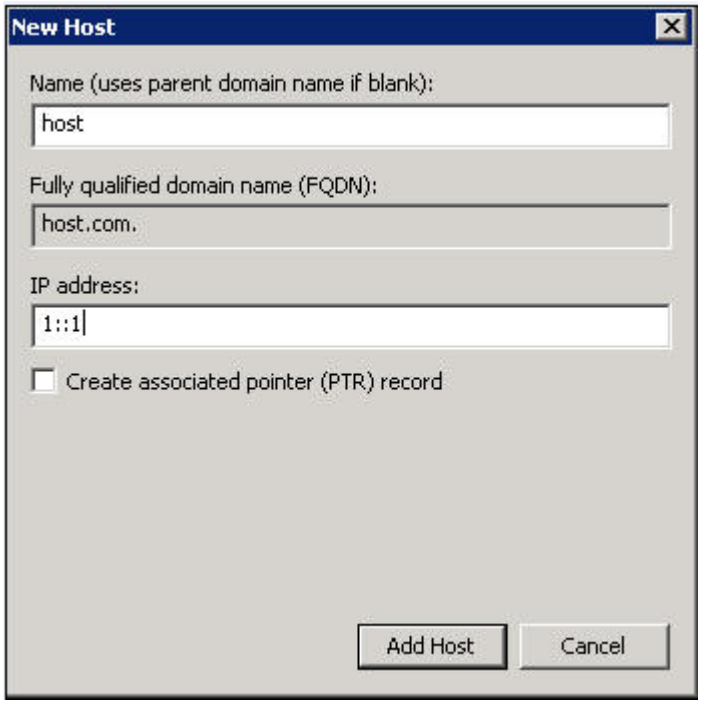
      The DNS server configuration page appears, as shown in Figure 13.

   b. Right-click **Forward Lookup Zones**, select **New Zone**, and then follow the wizard to create a new zone named **com**.

Figure 13 Creating a zone

c. On the DNS server configuration page, right-click zone **com** and select **New Host**.

Figure 14 Adding a host



d. On the page that appears, enter host name **host** and IPv6 address **1::1**.

e. Click **Add Host**.

The mapping between the IPv6 address and host name is created.

Figure 15 Adding a mapping between domain name and IPv6 address

2. Configure the DNS client:

   # Specify the DNS server 2::2.

   ```
   <Device> system-view
   [Device] ipv6 dns server 2::2
   ```

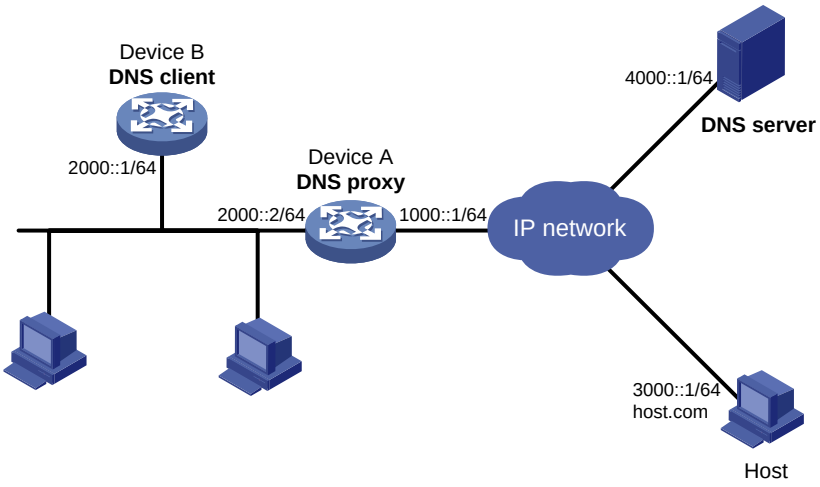
   # Configure **com** as the DNS suffix.

   ```
   [Device] dns domain com
   ```

Verifying the configuration

Verify that the device can use the dynamic domain name resolution to resolve the domain name **host.com** into the IP address 1::1.

```
[Device] ping ipv6 host
Ping6(56 data bytes) 3::1 --> 1::1, press CTRL+C to break
56 bytes from 1::1, icmp_seq=0 hlim=128 time=1.000 ms
56 bytes from 1::1, icmp_seq=1 hlim=128 time=0.000 ms
56 bytes from 1::1, icmp_seq=2 hlim=128 time=1.000 ms
56 bytes from 1::1, icmp_seq=3 hlim=128 time=1.000 ms
56 bytes from 1::1, icmp_seq=4 hlim=128 time=0.000 ms



--- Ping6 statistics for host ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 0.000/0.600/1.000/0.490 ms
```

Example: Configuring DNS proxy

Network configuration

As shown in Figure 16, configure Device A as the DNS proxy to forward DNS packets between the DNS client (Device B) and the DNS server at 4000::1.

Figure 16 Network diagram

Prerequisites

Before performing the following configuration, make sure that:

- Device A, the DNS server, and the host are reachable to each other.
- The IPv6 addresses of the interfaces are configured as shown in Figure 16.

Procedure

1. Configure the DNS server:

   This configuration might vary by DNS server. When a PC running Windows Server 2008 R2 acts as the DNS server, see "Example: Configuring dynamic domain name resolution" for configuration information.

2. Configure the DNS proxy:

   # Specify the DNS server 4000::1.

   ```
   <DeviceA> system-view
   [DeviceA] ipv6 dns server 4000::1
   ```

   # Enable DNS proxy.

   ```
   [DeviceA] dns proxy enable
   ```

3. Configure the DNS client:

   # Specify the DNS server 2000::2.

   ```
   <DeviceB> system-view
   [DeviceB] ipv6 dns server 2000::2
   ```

Verifying the configuration

Verify that DNS proxy on Device A functions.

```
[DeviceB] ping host.com
Ping6(56 data bytes) 2000::1 --> 3000::1, press CTRL+C to break
56 bytes from 3000::1, icmp_seq=0 hlim=128 time=1.000 ms
56 bytes from 3000::1, icmp_seq=1 hlim=128 time=0.000 ms
56 bytes from 3000::1, icmp_seq=2 hlim=128 time=1.000 ms
56 bytes from 3000::1, icmp_seq=3 hlim=128 time=1.000 ms
56 bytes from 3000::1, icmp_seq=4 hlim=128 time=0.000 ms

--- Ping6 statistics for host.com ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
```

```
round-trip min/avg/max/std-dev = 0.000/0.600/1.000/0.490 ms
```

Troubleshooting DNS configuration

Failure to resolve IPv4 addresses

Symptom

After enabling dynamic domain name resolution, the user cannot get the correct IP address.

Solution

To resolve the problem:

1. Use the **`display dns host ip`** command to verify that the specified domain name is in the cache.
2. If the specified domain name does not exist, check that the DNS client can communicate with the DNS server.
3. If the specified domain name is in the cache, but the IP address is incorrect, check that the DNS client has the correct IP address of the DNS server.
4. Verify that the mapping between the domain name and IP address is correct on the DNS server.

Failure to resolve IPv6 addresses

Symptom

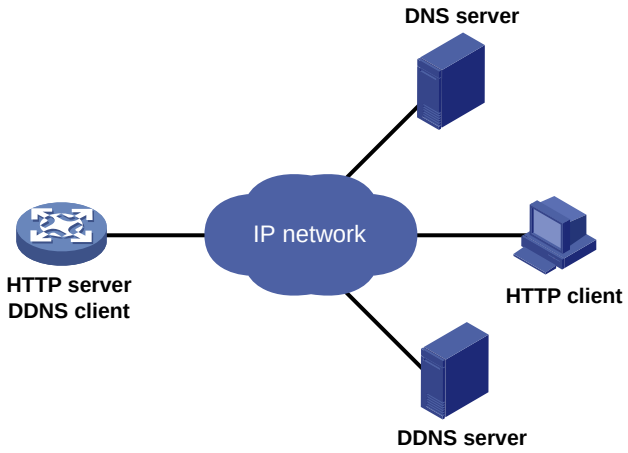
After enabling dynamic domain name resolution, the user cannot get the correct IPv6 address.

Solution

To resolve the problem:

1. Use the **`display dns host ipv6`** command to verify that the specified domain name is in the cache.
2. If the specified domain name does not exist, check that dynamic domain name resolution is enabled, and that the DNS client can communicate with the DNS server.
3. If the specified domain name is in the cache, but the IPv6 address is incorrect, check that the DNS client has the correct IPv6 address of the DNS server.
4. Verify that the mapping between the domain name and IPv6 address is correct on the DNS server.

Configuring DDNS



About DDNS

DNS provides only the static mappings between domain names and IP addresses. When the IP address of a node changes, your access to the node fails.

Dynamic Domain Name System (DDNS) can dynamically update the mappings between domain names and IP addresses for DNS servers.

Figure 17 shows the typical DDNS application.

Figure 17 DDNS application

DDNS works on the client-server model.

- **DDNS client**—A device that needs to update the mapping between its domain name and IP address dynamically on the DNS server when its IP address changes. An Internet user typically accesses an application layer server such as an HTTP server or an FTP server by using the server's domain name. When its IP address changes, the application layer server runs as a DDNS client. It sends a request to the DDNS server for updating the mapping between its domain name and its IP address.
- **DDNS server**—Informs the DNS server of latest mappings. When receiving the mapping update request from a DDNS client, the DDNS server tells the DNS server to re-map the domain name and the IP address of the DDNS client. Therefore, the Internet users can use the same domain name to access the DDNS client even if the IP address of the DDNS client has changed.

The device can function as a DDNS client to update the domain name-IP address mappings on the DNS servers through DDNS servers such as www.3322.org and PeanutHull.

NOTE:

The DDNS update process does not have a unified standard but varies by DDNS server that the DDNS client contacts.

Restrictions and guidelines: DDNS configuration

DDNS is supported by only IPv4 DNS and not supported by IPv6 DNS. It is used to update the mappings between domain names and IPv4 addresses.

DDNS client tasks at a glance

To configure a DDNS client, perform the following tasks:

1. Configuring a DDNS policy
2. Applying the DDNS policy to an interface
3. (Optional.) Setting the DSCP value for outgoing DDNS packets

Configuring a DDNS policy

About this task

A DDNS policy contains the DDNS server address, port number, login ID, password, time interval, associated SSL client policy, and update time interval. After creating a DDNS policy, you can apply it to multiple interfaces to simplify DDNS configuration.

Restrictions and guidelines

The URL address for update requests varies by DDNS server.

Table 1 Common URL addresses

DDNS server	URL address for DDNS update requests
www.3322.org	http://members.3322.org/dyndns/update?system=dyndns&hostname=<h>&myip=<a>
DYNDNS	http://members.dyndns.org/nic/update?system=dyndns&hostname=<h>&myip=<a>
DYNS	http://www.dyns.cx/postscript.php?host=<h>&ip=<a>
ZONEEDIT	http://dynamic.zoneedit.com/auth/dynamic.html?host=<h>&dnsto=<a>
TZO	http://cgi.tzo.com/webclient/signedon.html?TZOName=<h>IPAddress=<a>
EASYDNS	http://members.easydns.com/dyn/ez-ipupdate.php?action=edit&myip=<a>&host_id=<h>
HEIPV6TB	http://dyn.dns.he.net/nic/update?hostname=<h>&myip=<a>
CHANGE-IP	http://nic.changeip.com/nic/update?hostname=<h>&offline=1
NO-IP	http://dynupdate.no-ip.com/nic/update?hostname=<h>&myip=<a>
DHS	http://members.dhs.org/nic/hosts?domain=dyn.dhs.org&hostname=<h>&hostscmd=edit&hostscmdstage=2&type=1&ip=<a>
HP	https://server-name/nic/update?group=group-name&myip=<a>
ODS	ods://update.ods.org
GNUDIP	gnudip://*server-name*
PeanutHull	Select the URL according to your network situation: • oray://phddns60.oray.net • oray://phservice2.oray.net

Identify the DDNS server type in your network and follow the following restrictions and guidelines to set an appropriate URL address:

- The URL address for an update request can start with:
  - **http://**—The HTTP-based DDNS server.
  - **https://**—The HTTPS-based DDNS server.

    - **ods://**—The TCP-based ODS server.
    - **gnudip://**—The TCP-based GNUDIP server.
    - **oray://**—The TCP-based PeanutHull DDNS server.
- HP and GNUDIP are common DDNS update protocols. The *server-name* argument is the domain name or IP address of the service provider's server using one of the update protocols.
- The port number in the URL address is optional. If no port is specified, the system uses the default port numbers: port 80 for HTTP, port 443 for HTTPS, and port 6060 for PeanutHull DDNS server.
- The <h> value can be automatically filled with an FQDN if it is specified in the command for applying a DDNS policy to an interface. The <a> value is automatically filled with the primary IP address of the interface to which the DDNS policy is applied. For more information about applying DDNS policies, see "Applying the DDNS policy to an interface."
- You can also manually specify an FQDN and an IP address for the <h> and <a> fields. In this case, the FQDN specified at the CLI does not take effect. As a best practice, do not manually change the <h> and <a> because your configuration might be incorrect.
- No FQDN or IP address can be specified in the URL address for update requests sent to the PeanutHull DDNS server. You can specify the FQDN when applying the DDNS policy to an interface. The IP address is the primary IP address of the interface to which the DDNS policy is applied.

Prerequisites

Visit the website of a DDNS service provider, register an account, and apply for a domain name for the DDNS client. When the DDNS client updates the mapping between the domain name and the IP address through the DDNS server, the DDNS server checks the following:

- Whether the account information is correct.
- Whether the domain name to be updated belongs to the account.

Procedure

1. Enter system view.

   system-view
2. Create a DDNS policy and enter its view.

   ddns policy *policy-name*
3. Specify a URL address for DDNS update requests.

   url *request-url*

   By default, no URL address is specified for DDNS update requests.

   The URL address cannot contain a username or password. To configure them, use the **username** command and the **password** command.
4. Specify the username for logging in to the DDNS server.

   username *username*

   By default, no username is specified.
5. Specify the password for logging in to the DDNS server.

   password { **cipher** | **simple** } *string*

   By default, no password is specified.
6. (Optional.) Specify the parameter transmission method for sending DDNS update requests to HTTP/HTTPS-based DDNS servers.

   method { **http-get** | **http-post** }

   By default, the **http-get** method is used.

   This step is effective for communicating with HTTP/HTTPS-based DDNS servers.

Specify the **http-post** keyword for DDNS update with a DHS server.

7. (Optional.) Associate an SSL client policy with the DDNS policy.

   ssl-client-policy *policy-name*

   By default, no SSL client policy is associated with the DDNS policy.

   This step is only effective and a must for HTTP-based DDNS update requests. For SSL client policy configuration, see *Security Configuration Guide*.

8. (Optional.) Specify the interval for sending update requests.

   interval *days* [*hours* [*minutes*]]

   By default, the time interval is one hour.

Applying the DDNS policy to an interface

About this task

After you apply the DDNS policy to an interface and specify the FQDN for update, the DDNS client can send requests to the DDNS server. The requests are to update the mapping between the domain name and the primary IP address of the interface.

Restrictions and guidelines

- The **fqdn** *domain-name* option is a must for all DDNS servers except the PeanutHull DDNS server.
- The **fqdn** *domain-name* option is optional for PeanutHull DDNS server. If no FQDN is specified, the DDNS server updates all domain names for the DDNS client account. If an FQDN is specified, the DDNS server updates only the mapping between the specified FQDN and the primary IP address.

Prerequisites

Before you apply a DDNS policy to an interface, complete the following tasks:

- Specify the primary IP address of the interface and make sure the DDNS server and the interface can reach each other.
- Configure static or dynamic domain name resolution to translate the domain name of the DDNS server into the IPv4 address. For more information, see "Configuring the DNS client."

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Apply the DDNS policy to the interface to update the mapping between the specified FQDN and the primary IP address of the interface, and enable DDNS update.

   ddns apply policy *policy-name* [**fqdn** *domain-name*]

   By default, no DDNS policy is applied to the interface, no FQDN is specified for update, and DDNS update is disabled.

   An FQDN, including a host name and a domain name, is the only identifier for a network node and can be resolved as an IP address.

Setting the DSCP value for outgoing DDNS packets

About this task

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet. A bigger DSCP value represents a higher priority.

Procedure

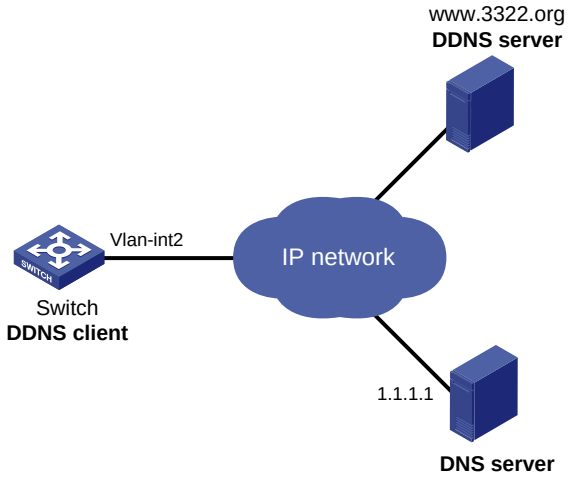
1. Enter system view.
   system-view
2. Set the DSCP value for outgoing DDNS packets.
   ddns dscp *dscp-value*
   By default, the DSCP value for outgoing DDNS packets is 0.

Display and maintenance commands for DDNS

Execute **display** commands in any view.

Task	Command
Display DDNS policy information.	**display ddns policy** [*policy-name*]

DDNS configuration examples



Example: Configuring DDNS with www.3322.org

Network configuration

As shown in Figure 18, the switch is a Web server with domain name **example.3322.org** and uses an IP address dynamically obtained through DHCP. To make sure the switch can always provide Web services at **example.3322.org** when its IP address changes, perform the following tasks on the switch:

- Configure a DDNS policy to update the switch's domain name-to-IP address mapping on the DDNS server. The DDNS server then updates the mapping on the DNS server.
- Specify the IP address of the DNS server so that the switch can access the DDNS server through domain name.

Figure 18 Network diagram

Procedure

Before configuring DDNS on the switch, perform the following tasks:

- Register with username **steven** and password **nevets** at http://www.3322.org/.
- Configure a DDNS policy to update the mapping between the switch's FQDN and IP address.
- Make sure the devices can reach each other.

Create a DDNS policy named **3322.org**, and enter its view.

```
<Switch> system-view
[Switch] ddns policy 3322.org
```

Specify the URL address, username, and password for DDNS update requests.

```
[Switch-ddns-policy-3322.org] url
http://members.3322.org/dyndns/update?system=dyndns&hostname=<h>&myip=<a>
[Switch-ddns-policy-3322.org] username steven
[Switch-ddns-policy-3322.org] password simple nevets
```

Set the interval to 15 minutes for sending DDNS update requests.

```
[Switch-ddns-policy-3322.org] interval 0 0 15
[Switch-ddns-policy-3322.org] quit
```

Specify the IP address of the DNS server as 1.1.1.1.

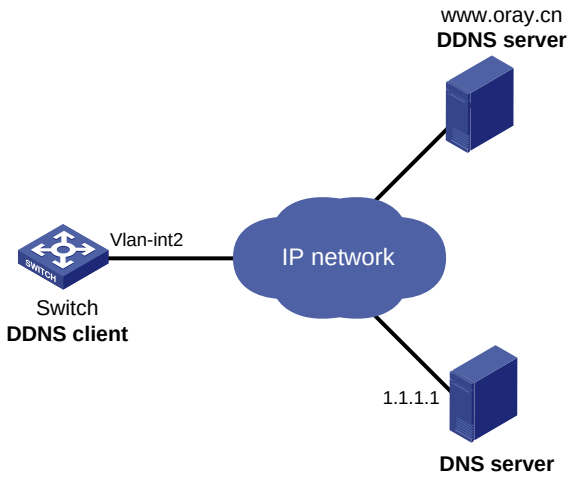
```
[Switch] dns server 1.1.1.1
```

Apply DDNS policy **3322.org** to VLAN-interface 2 to enable DDNS update. The mapping between domain name **example.3322.org** and the primary IP address of VLAN-interface 2 will be dynamically updated.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ddns apply policy 3322.org fqdn example.3322.org
[Switch-Vlan-interface2] quit
```

Verifying the configuration

Verify that the switch can update its domain name-IP mapping through the DDNS provider **www.3322.org** when its IP address changes. The Internet users can resolve the correct IP address through the domain name **example.3322.org** to access the Web service.



Example: Configuring DDNS with PeanutHull server

Network configuration

As shown in Figure 19, the switch is a Web server with domain name **example.gicp.cn** and uses an IP address dynamically obtained through DHCP. To make sure the switch can always provide Web services at **example.gicp.cn** when its IP address changes, perform the following tasks on the switch:

- Configure a DDNS policy to update the switch's domain name-to-IP address mapping on the DDNS server. The DDNS server then updates the mapping on the DNS server.
- Specify the IP address of the DNS server so that the switch can access the DDNS server through domain name.

Figure 19 Network diagram

Procedure

Before configuring DDNS on the switch, perform the following tasks:

- Register with username **steven** and password **nevets** at http://www.oray.cn/.
- Configure a DDNS policy to update the mapping between the switch's FQDN and IP address.
- Make sure the devices can reach each other.

Create a DDNS policy named **oray.cn** and enter its view.

```
<Switch> system-view
[Switch] ddns policy oray.cn
```

Specify the URL address, username, and password for DDNS update requests.

```
[Switch-ddns-policy-oray.cn] url oray://phddns60.oray.net
[Switch-ddns-policy-oray.cn] username steven
[Switch-ddns-policy-oray.cn] password simple nevets
```

Set the DDNS update request interval to 12 minutes.

```
[Switch-ddns-policy-oray.cn] interval 0 0 12
[Switch-ddns-policy-oray.cn] quit
```

Specify the IP address of the DNS server as 1.1.1.1.

```
[Switch] dns server 1.1.1.1
```

Apply DDNS policy **oray.cn** to VLAN-interface 2 to enable DDNS update. The mapping between domain name **example.gicp.cn** and the primary IP address of VLAN-interface 2 will be dynamically updated.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ddns apply policy oray.cn fqdn example.gicp.cn
[Switch-Vlan-interface2] quit
```

Verifying the configuration

Verify that the switch can update its domain name-IP mapping through the Peanuthull DDNS provider when its IP address changes. The Internet users can resolve the correct IP address through the domain name **example.gicp.cn** to access the Web service.

Configuring IP forwarding basic settings

About FIB table

A device uses the FIB table to make packet forwarding decisions.

A device selects optimal routes from the routing table, and puts them into the FIB table. Each FIB entry specifies the next hop IP address and output interface for packets destined for a specific subnet or host.

For more information about the routing table, see *Layer 3—IP Routing Configuration Guide*.

Use the **display fib** command to display the FIB table. The following example displays the entire FIB table.

```
<Sysname> display fib

Destination count: 8 FIB entry count: 8

Flag:
  U:Usable   G:Gateway   H:Host   B:Blackhole   D:Dynamic   S:Static
  R:Relay     F:FRR

Destination/Mask   Nexthop         Flag     OutInterface/Token       Label
0.0.0.0/32         127.0.0.1       UH       InLoop0                  Null
127.0.0.0/8        127.0.0.1       U        InLoop0                  Null
127.0.0.0/32       127.0.0.1       UH       InLoop0                  Null
127.0.0.1/32       127.0.0.1       UH       InLoop0                  Null
127.255.255.255/32 127.0.0.1       UH       InLoop0                  Null
224.0.0.0/4        0.0.0.0         UB       NULL0                    Null
224.0.0.0/24       0.0.0.0         UB       NULL0                    Null
255.255.255.255/32 127.0.0.1       UH       InLoop0                  Null
```

A FIB entry includes the following items:

- **Destination**—Destination IP address.
- **Mask**—Network mask. The mask and the destination address identify the destination network. A logical AND operation between the destination address and the network mask yields the address of the destination network. For example, if the destination address is 192.168.1.40 and the mask 255.255.255.0, the address of the destination network is 192.168.1.0. A network mask includes a certain number of consecutive 1s. It can be expressed in dotted decimal format or by the number of the 1s.
- **Nexthop**—IP address of the next hop.
- **Flag**—Route flag.
- **OutInterface**—Output interface.
- **Token**—MPLS Label Switched Path index number.
- **Label**—Inner label.

Saving the IP forwarding entries to a file

Restrictions and guidelines

The feature automatically creates the file if you specify a nonexistent file. If the file already exists, this feature overwrites the file content.

This feature triggers one-time saving of the IP forwarding entries.

To automatically save the IP forwarding entries periodically, configure a schedule for the device to automatically run the **ip forwarding-table save** command. For information about scheduling a task, see *Fundamentals Configuration Guide*.

Procedure

To save the IP forwarding entries to a file, execute the following command in any view:

ip forwarding-table save filename *filename*

Enabling split horizon forwarding

About this task

This feature prevents IPv4, IPv6, and MPLS packets from being forwarded out of the physical interface on which they were received, avoiding network loops.

Procedure (System view)

1. Enter system view.

   system-view
2. Enable split horizon forwarding.

   forwarding split-horizon

   By default, split horizon forwarding is disabled.

Enabling IPv4 fast traffic migration

About this task

After IPv4 fast traffic migration is enabled on a VLAN interface, the device immediately steers IPv4 traffic forwarded through the VLAN interface to other forwarding paths upon network topology changes or user port migrations. This reduces traffic disruption time to improve overall network response speed and user experience.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable IPv4 fast traffic migration.

   ip forwarding fast-move

   By default, IPv4 fast traffic migration is disabled.

Enabling IPv4 FIB entry consistency check

About this task

Packet drops or incorrect forwarding might occur when the IPv4 FIB entries in hardware are inconsistent with FIB entries configured in software. To prevent these issues, enable IPv4 FIB entry consistency check.

This feature compares all IPv4 FIB entries in software with the IPv4 FIB entries in hardware regularly. If the device detects an inconsistency, the device performs the following tasks:

- Generates a log.
- Updates the IPv4 FIB entry in hardware with the IPv4 FIB entry in software.

Procedure

1. Enter system view.

   system-view
2. Enable IPv4 FIB entry consistency check.

   fib consistency-check enable

   By default, IPv4 FIB entry consistency check is disabled.

Enabling SNMP notifications for FIB events

About this task

This feature enables the FIB module to generate SNMP notifications for critical FIB events, such as the exceeding of the message queue length threshold. The SNMP notifications are sent to the SNMP module.

For the SNMP notifications to be sent correctly, you must also configure SNMP. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Enable SNMP notifications for FIB events.

   snmp-agent trap enable fib [**deliver-failed** | **ecmp-limit** | **entry-consistency** | **entry-limit**] *

   By default, SNMP notifications for FIB events are enabled.

Enabling SNMP notifications for IP forwarding events

About this task

This feature enables the IP forwarding module to generate SNMP notifications for critical IP forwarding events. The SNMP notifications are sent to the SNMP module. For the SNMP notifications to be sent correctly, you must also configure SNMP. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*.

You can enable SNMP notifications for the following IP forwarding events as needed:

- After you enable SNMP notifications about TTL timeout, the device checks the number of dropped packets at the specified time interval. An SNMP notification is generated and sent to

the SNMP module when the number of dropped packets reaches or exceeds the specified threshold.

- After you enable SNMP notifications about MBUF allocation failures, an SNMP notification is generated and sent to the SNMP module when MBUF allocation fails.

If you do not specify any parameters, the command enables all types of SNMP notifications for IP forwarding events.

After you disable the SNMP notifications for IP forwarding events, the device sends only logs to the device's information center module. In this case, you can configure the log output destinations and output rules to view the log information of the basic IPv6 modules. For more information about configuring the information center, see information center configuration in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   `system-view`
2. Enable SNMP notifications for IP forwarding events.
   `snmp-agent trap enable ip-forwarding` [**`ttl-expired`** | **`mbuf-alloc`**]
   By default, SNMP notifications for IP forwarding events are enabled.

Enabling FIB logging

About this task

The logs are sent to the information center of the device. For the logs to be output correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

To avoid memory consumption caused by log recording, you can use the **`undo fib log enable`** command to disable FIB logging.

Procedure

1. Enter system view.
   `system-view`
2. Enable FIB logging.
   `fib log enable`
   By default, FIB logging is disabled.

Display and maintenance commands for FIB table

Execute **`display`** commands in any view.

Task	Command
Display FIB entries.	**`display fib`** [*`ip-address`* [*`mask`* | *`mask-length`*]]
Display FIB table usage information.	**`display fib usage`**

Configuring load sharing

About load sharing

If a routing protocol finds multiple equal-cost best routes to the same destination, the device forwards packets over the equal-cost routes to implement load sharing.

Configuring load sharing mode

About this task

Restrictions and guidelines

- When the traffic is not shared equally, you can use the **seed** and **shift** keywords to improve load sharing.
- The load sharing hash seed feature does not take effect on unknown unicast packets.
- The load sharing feature for IP Tunnel packets does not take effect on unknown unicast packets.

Procedure

1. Enter system view.

   system-view

2. Configure load sharing.

   ip load-sharing mode { **per-flow** [**algorithm** *algorithm-number* [**seed** *seed-number*] [**shift** *shift-number*] | [**dest-ip** | **dest-port** | **ingress-port** | **ip-pro** | **src-ip** | **src-port**] * | **tunnel** { **inner** | **outer** }] | **per-packet** } { **global** | **slot** *slot-number* }

   By default, the device performs per-flow load sharing based on the following criteria: source IP address, destination IP address, source port number, destination port number, IP protocol number, and ingress port.

3. Display the load sharing path selected for a flow.

   display ip load-sharing path ingress-port *interface-type interface-number* **packet-format** { **ipv4oe dest-ip** *ip-address* [**src-ip** *ip-address*] | **ipv6oe dest-ipv6** *ipv6-address* [**src-ipv6** *ipv6-address*] } [**dest-port** *port-id* | **ip-pro** *protocol-id* | **src-port** *port-id* | **vpn-instance** *vpn-instance-name*] *

   The option settings in this command must match both the options displayed in the **display ip load-sharing mode** command and the field values in load shared packets. If the option settings do not meet the requirement, the path displayed by this command might be different from the real path for load sharing.

Enabling local-first load sharing

About this task

Local-first load sharing distributes traffic preferentially across the output interfaces on the receiving IRF member device if output interfaces for multiple equal-cost routes are on different members. This feature enhances packets forwarding efficiency.

Procedure

1. Enter system view.
   system-view
2. Enable local-first load sharing.
   ip load-sharing local-first enable
   By default, local-first load sharing is enabled.

Enabling symmetric load sharing

About this task

Symmetric load sharing ensures that bidirectional traffic specific to a source and destination address pair flow along the same path.

Restrictions and guidelines

Symmetric load sharing takes effect only on known unicast packets.

Procedure

1. Enter system view.
   system-view
2. Enable symmetric load sharing.
   ip load-sharing symmetric enable
   By default, symmetric load sharing is disabled.

Display and maintenance commands for load sharing

Execute **display** commands in any view.

Task	Command
Display the load sharing mode in use.	**display ip load-sharing mode slot** *slot-number*
Display the load sharing path selected for a flow.	**display ip load-sharing path ingress-port** *interface-type interface-number* **packet-format** { **ipv4oe dest-ip** *ip-address* [**src-ip** *ip-address*] | **ipv6oe dest-ipv6** *ipv6-address* [**src-ipv6** *ipv6-address*] } [**dest-port** *port-id* | **ip-pro** *protocol-id* | **src-port** *port-id* | **vpn-instance** *vpn-instance-name*] *

Loading sharing configuration examples

Example: Configuring load sharing based on source and destination addresses

Network configuration

As shown in Figure 1, Switch A has two equal-cost routes to Switch B. Configure load sharing on Switch A to forward packets through Switch B to the destination IP address 1.2.3.4/24.

Figure 1 Network diagram

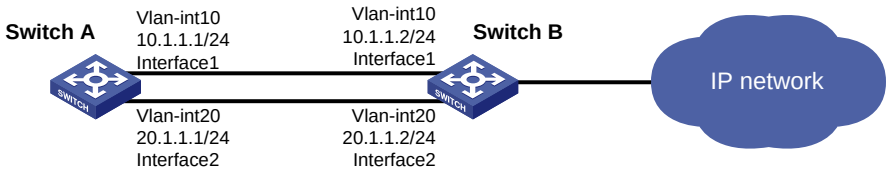

Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2

Procedure

On Switch A, assign GigabitEthernet 1/0/1 to VLAN 10, and GigabitEthernet 1/0/2 to VLAN 20.

```
<SwitchA> system-view
[SwitchA] vlan 10
[SwitchA-vlan10] port gigabitethernet 1/0/1
[SwitchA-vlan10] quit
[SwitchA] vlan 20
[SwitchA-vlan20] port gigabitethernet 1/0/2
[SwitchA-vlan20] quit
```

On Switch A, configure IP addresses for VLAN-interface 10 and VLAN-interface 20.

```
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] ip address 10.1.1.1 24
[SwitchA-Vlan-interface10] quit
[SwitchA] interface vlan-interface 20
[SwitchA-Vlan-interface20] ip address 20.1.1.1 24
[SwitchA-Vlan-interface20] quit
```

On Switch B, assign GigabitEthernet 1/0/1 to VLAN 10, and GigabitEthernet 1/0/2 to VLAN 20.

```
<SwitchB> system-view
[SwitchB] vlan 10
[SwitchB-vlan10] port gigabitethernet 1/0/1
[SwitchB-vlan10] quit
[SwitchB] vlan 20
[SwitchB-vlan20] port gigabitethernet 1/0/2
[SwitchB-vlan20] quit
```

On Switch B, configure IP addresses for VLAN-interface 10 and VLAN-interface 20.

```
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] ip address 10.1.1.2 24
[SwitchB-Vlan-interface10] quit
[SwitchB] interface vlan-interface 20
[SwitchB-Vlan-interface20] ip address 20.1.1.2 24
[SwitchB-Vlan-interface20] quit
```

On Switch A, configure two static routes to the destination IP address.

```
<SwitchA> system-view
[SwitchA] ip route-static 1.2.3.4 24 10.1.1.2
[SwitchA] ip route-static 1.2.3.4 24 20.1.1.2
[SwitchA] quit
```

On Switch A, display FIB entries matching the destination IP address 1.2.3.4.

```
<SwitchA> display fib 1.2.3.4
Destination count: 1 FIB entry count: 2
Flag:
  U:Usable   G:Gateway   H:Host   B:Blackhole   D:Dynamic   S:Static
  R:Relay     F:FRR
Destination/Mask   Nexthop         Flag     OutInterface/Token       Label
1.2.3.0/24         10.1.1.2        USGR     Vlan10                   Null
1.2.3.0/24         20.1.1.2        USGR     Vlan20                   Null
```

On Switch A, configure per-flow load sharing based on the source IP address and destination IP address.

```
<SwitchA> system-view
[SwitchA] ip load-sharing mode per-flow dest-ip src-ip global
```

Verifying the configuration

Verify that Switch A implements load sharing.

```
<SwitchA> display counters outbound interface GigabitEthernet
Interface         Total (pkts)   Broadcast (pkts)   Multicast (pkts)  Err (pkts)
GE1/0/1                 1045                  0                  0           0
GE1/0/2                 1044                  0                  0           0
```

Configuring fast forwarding 1
About fast forwarding 1
Restrictions and guidelines: Fast forwarding configuration 1
Configuring the aging time for software fast forwarding entries 1
Configuring fast forwarding load sharing for software 1
Display and maintenance commands for fast forwarding 2

Configuring fast forwarding

About fast forwarding

Fast forwarding reduces route lookup time and improves packet forwarding efficiency by using a high-speed cache and data-flow-based technology. It identifies a data flow by using the following fields: source IP address, source port number, destination IP address, destination port number, and protocol number. After a flow's first packet is forwarded through the routing table, fast forwarding creates an entry and uses the entry to forward subsequent packets of the flow.

Restrictions and guidelines: Fast forwarding configuration

Fast forwarding can process fragmented IP packets, but it does not fragment IP packets.

Configuring the aging time for software fast forwarding entries

About this task

The fast forwarding table uses an aging timer for each forwarding entry. If an entry is not updated before the timer expires, the device deletes the entry. If an entry has a hit within the aging time, the aging timer restarts.

Procedure

1. Enter system view.

   system-view
2. Configure the aging time for fast forwarding entries on the software side.

   ip fast-forwarding aging-time *aging-time*

   By default, the aging time is 30 seconds for fast forwarding entries on the software side.

Configuring fast forwarding load sharing for software

About this task

Software fast forwarding load sharing enables the device to identify a data flow by using the packet information.

If fast forwarding load sharing is disabled on the software side, the device identifies a data flow by the packet information and the input interface.

Procedure

1. Enter system view.

   system-view
2. Configure fast forwarding load sharing on the software side. Choose one option as needed:

- Enable fast forwarding load sharing on the software side.
  ip fast-forwarding load-sharing
- Disable fast forwarding load sharing on the software side.
  undo ip fast-forwarding load-sharing

By default, fast forwarding load sharing is enabled on the software side.

Display and maintenance commands for fast forwarding

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the aging time of fast forwarding entries.	**display ip fast-forwarding aging-time**
Display fast forwarding entries.	**display ip fast-forwarding cache** [*ip-address*] [**slot** *slot-number*]
Display fast forwarding entries about fragmented packets.	**display ip fast-forwarding fragcache** [*ip-address*] [**slot** *slot-number*]
Clear the fast forwarding table.	**reset ip fast-forwarding cache** [**slot** *slot-number*]

Displaying the adjacency table 1
About the adjacency table 1
Display and maintenance commands for adjacency table 1

Displaying the adjacency table

About the adjacency table

The adjacency table stores information about directly connected neighbors for IP forwarding. The neighbor information in this chapter refers to non-Ethernet neighbor information.

This table is not user configurable. The neighbor information is generated, updated, and deleted by link layer protocols through negotiation or through manual configuration. An adjacency entry includes the following information:

- Neighbor network layer address (next hop).
- Output interface.
- Link layer protocol type.
- Link layer address.

When forwarding an IP packet, the device performs the following tasks:

- Searches the FIB to find the output interface and next hop.
- Uses the output interface and next hop address to search the adjacency table for link layer forwarding information.

NOTE:

Ethernet and non-Ethernet neighbor information is stored and managed together.

Display and maintenance commands for adjacency table

NOTE:

The device only supports displaying adjacency entries about tunnel interfaces whose link layer protocol is P2P.

Execute **display** commands in any view.

Task	Command
Display IPv4 adjacency table information.	**display adjacent-table** { **all** | **physical-interface** *interface-type interface-number* | **routing-interface** *interface-type interface-number* | **slot** *slot-number* } [**count** | **verbose**]
Display IPv6 adjacency table information.	**display ipv6 adjacent-table** { **all** | **physical-interface** *interface-type interface-number* | **routing-interface** *interface-type interface-number* | **slot** *slot-number* } [**count** | **verbose**]

IRDP configuration examples 4
Example: Configuring IRDP 4

Configuring IRDP

About IRDP

ICMP Router Discovery Protocol (IRDP), an extension of the ICMP, is independent of any routing protocol. It allows hosts to discover the IP addresses of neighboring routers that can act as default gateways to reach devices on other IP networks.

IRDP enables hosts to track dynamic changes in router availability. It does not require you to configure the default gateways on hosts or configure hosts to listen to routing protocols to obtain IP addresses of routers.

IRDP operation

IRDP uses the following types of ICMP messages:

- **Router advertisement (RA)**—Sent by a router to advertise IP addresses (including the primary and secondary IP addresses) and preference.
- **Router solicitation (RS)**—Sent by a host to request the IP addresses of routers on the subnet.

An interface with IRDP enabled periodically broadcasts or multicasts an RA message to advertise its IP addresses and their preferences. A receiving host adds the IP addresses to its routing table, and selects the IP address with the highest preference as the default gateway.

When a host attached to the subnet starts up, the host multicasts an RS message to request immediate advertisements. If the host does not receive any advertisements, it retransmits the RS several times. If the host does not discover the IP addresses of neighboring routers because of network problems, the host can still discover them from periodic RAs.

IRDP allows hosts to discover neighboring routers, but it does not suggest the best route to a destination. If a host sends a packet to a router that is not the best next hop, the host will receive an ICMP redirect message from the router.

Protocols and standards

RFC 1256: *ICMP Router Discovery Messages*

IRDP tasks at a glance

To configure IRDP, perform the following tasks:

1. Enabling IRDP
2. (Optional.) Specifying the preference of advertised IP addresses
3. (Optional.) Setting the lifetime of advertised IP addresses
4. (Optional.) Setting the advertising intervals
5. (Optional.) Specifying the multicast address as the destination address for RAs
6. (Optional.) Specifying a proxy-advertised IP address

Restrictions and guidelines: IRDP configuration

- IRDP takes effect on any Layer 3 interface (except the loopback interface) if the interface has an IP address.
- After IRDP is enabled on an interface, the IRDP configurations take effect, and the device sends RA messages out of the interface.

Enabling IRDP

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable IRDP on the interface.
   ip irdp
   By default, IRDP is disabled on an interface.

Specifying the preference of advertised IP addresses

About this task

Every IP address advertised in RAs has a preference value. A larger preference value represents a higher preference. The IP address with the highest preference is selected as the default gateway address.

You can specify the preference for IP addresses to be advertised on a router interface.

An address with the minimum preference value (-2147483648) will not be used as a default gateway address.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify the preference of advertised primary and secondary IP addresses on the interface.
   ip irdp preference *preference-value*
   The default preference is 0.
   The preference applies to all advertised primary and secondary IP addresses on the interface.

Setting the lifetime of advertised IP addresses

About this task

An RA contains a lifetime field that specifies the lifetime of advertised IP addresses. If the host does not receive a new RA for an IP address within the address lifetime, the host removes the route entry.

All the IP addresses advertised by an interface, including proxy-advertised IP addresses and the interface IP address, have the same lifetime.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the lifetime of advertised IP addresses.
   ip irdp lifetime *lifetime-value*
   The default lifetime is 1800 seconds.
   The lifetime cannot be shorter than the maximum advertising interval.

Setting the advertising intervals

About this task

A router interface with IRDP enabled sends out RAs randomly between the minimum and maximum advertising intervals. This mechanism prevents the local link from being overloaded by a large number of RAs sent simultaneously from routers.

As a best practice, shorten the advertising interval on a link that suffers high packet loss rates.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the maximum and minimum advertising intervals.
   ip irdp interval *max-interval* [*min-interval*]
   By default, the maximum interval is 600 seconds, and the minimum interval is 3/4 of the maximum interval.

Specifying the multicast address as the destination address for RAs

About this task

An RA uses either of the following destination IP addresses:

- Broadcast address 255.255.255.255.
- Multicast address 224.0.0.1, which identifies all hosts on the local link.

By default, the destination IP address of an RA is the broadcast address. If all listening hosts in a local area network support IP multicast, specify 224.0.0.1 as the destination IP address.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*

3. Specify the multicast address 224.0.0.1 as the destination IP address of RAs.

   ip irdp multicast

   By default, RAs use the broadcast address 255.255.255.255 as the destination IP address.

Specifying a proxy-advertised IP address

About this task

By default, an interface advertises its primary and secondary IP addresses. You can specify IP addresses of other gateways for an interface to proxy-advertise.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

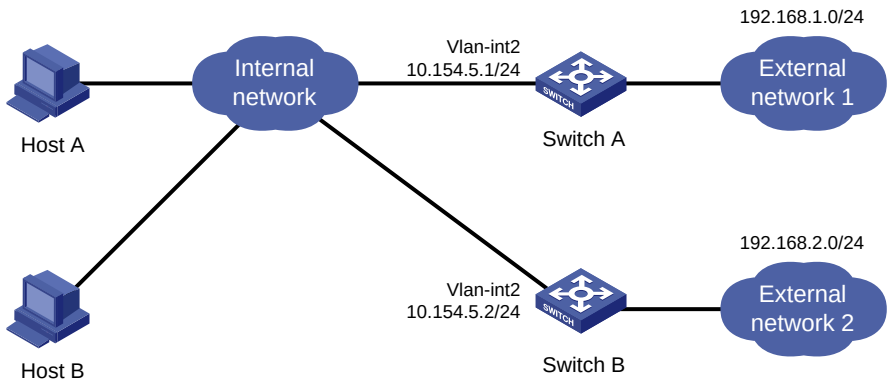
3. Specify a proxy-advertised IP address and its preference.

   ip irdp address *ip-address preference-value*

   By default, no proxy-advertised IP address is specified.

   You can repeat this command to specify a maximum of four proxy-advertised IP addresses on an interface.

IRDP configuration examples



Example: Configuring IRDP

Network configuration

As shown in Figure 1, Host A and Host B that run Linux support IRDP, and they are in the internal network. Switch A and Switch B act as the egress routers and connect to external networks 192.168.1.0/24 and 192.168.2.0/24, respectively.

Configure Switch A as the default gateway for the hosts. Make sure Switch A has routes to reach both External network 1 and External network 2, so that packets to these external networks can be correctly routed.

Figure 1 Network diagram

Procedure

1. Configure Switch A:

Configure a route for Switch A to reach External network 2. (Details not shown.)

Specify an IP address for VLAN-interface 2.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 10.154.5.1 24
```

Enable IRDP on VLAN-interface 2.

```
[SwitchA-Vlan-interface2] ip irdp
```

Specify preference 1000 for advertised IP addresses on VLAN-interface 2.

```
[SwitchA-Vlan-interface2] ip irdp preference 1000
```

Specify the multicast address 224.0.0.1 as the destination IP address for RAs sent by VLAN-interface 2.

```
[SwitchA-Vlan-interface2] ip irdp multicast
```

Specify the IP address 192.168.1.0 and preference 400 for VLAN-interface 2 to proxy-advertise.

```
[SwitchA-Vlan-interface2] ip irdp address 192.168.1.0 400
```

2. Configure Switch B:

Specify an IP address for VLAN-interface 2.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 10.154.5.2 24
```

Enable IRDP on VLAN-interface 2.

```
[SwitchB-Vlan-interface2] ip irdp
```

Specify preference 500 for advertised IP addresses on VLAN-interface 2.

```
[SwitchB-Vlan-interface2] ip irdp preference 500
```

Specify the multicast address 224.0.0.1 as the destination IP address for RAs sent by VLAN-interface 2.

```
[SwitchB-Vlan-interface2] ip irdp multicast
```

Specify the IP address 192.168.2.0 and preference 400 for VLAN-interface 2 to proxy-advertise.

```
[SwitchB-Vlan-interface2] ip irdp address 192.168.2.0 400
```

Verifying the configuration

Display the routing table for Host A.

```
[HostA@localhost ~]$ netstat -rne
Kernel IP routing table
Destination     Gateway         Genmask         Flags Metric Ref    Use Iface
10.154.5.0      0.0.0.0         255.255.255.0   U     0      0        0 eth1
192.168.1.0     0.0.0.0         255.255.255.0   U     0      0        0 eth1
192.168.2.0     0.0.0.0         255.255.255.0   U     0      0        0 eth1
0.0.0.0         10.154.5.1      0.0.0.0         UG    0      0        0 eth1
```

The output shows that the default route on Host A points to IP address 10.154.5.1, and Host A has routes to 192.168.1.0/24 and 192.168.2.0/24.

Display the routing table for Host B.

```
[HostB@localhost ~]$ netstat -rne
Kernel IP routing table
Destination     Gateway         Genmask         Flags Metric Ref    Use Iface
```

```
10.154.5.0      0.0.0.0         255.255.255.0   U     0      0        0 eth1
192.168.1.0     0.0.0.0         255.255.255.0   U     0      0        0 eth1
192.168.2.0     0.0.0.0         255.255.255.0   U     0      0        0 eth1
0.0.0.0         10.154.5.1      0.0.0.0         UG    0      0        0 eth1
```

The output shows that the default route on Host B points to IP address 10.154.5.1, and Host B has routes to 192.168.1.0/24 and 192.168.2.0/24.

Optimizing IP performance

IP performance optimization tasks at a glance

All IP performance optimization tasks are optional.

1. Configuring features for IP packets
   - Enabling an interface to forward directed broadcasts destined for the directly connected network
   - Setting the interface MTU for IPv4 packets
   - Enabling Layer 3 packet statistics collection
   - Enabling IPv4 local fragment reassembly
   - This feature is applicable in IRF networks.
   - Enabling processing IP options in IP packets
   - Enabling IP packet isolation between management port and service port
   - Enabling TTL expiry alarm generation
2. Configuring features for ICMP messages
   - Enabling sending ICMP error messages
   - Configuring rate limit for ICMP error messages
   - Disabling forwarding ICMP fragments
   - Specifying the source address for ICMP packets
   - Disabling response to broadcast echo requests
   - Disabling sending a specific type of ICMP messages
   - Disabling receiving a specific type of ICMP messages
   - Enable SNMP notifications for attack events on ports
3. Configuring features for TCP packets
   - Setting TCP MSS for an interface
   - Configuring TCP path MTU discovery
   - Enabling SYN Cookie
   - Setting the TCP buffer size
   - Setting TCP timers
   - Enabling the Timestamps option encapsulation in outgoing TCP packets
   - Enabling SNMP notifications for TCP events

Enabling an interface to forward directed broadcasts destined for the directly connected network

About forwarding broadcasts destined for the directly connected network

A directed broadcast packet is destined for all hosts on a specific network. In the destination IP address of the directed broadcast, the network ID identifies the target network, and the host ID is made up of all ones.

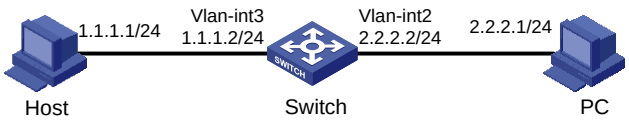
If an interface is allowed to forward directed broadcasts destined for the directly connected network, hackers can exploit this vulnerability to attack the target network. In some scenarios, however, an interface must send such directed broadcast packets to support the following features:

- **UDP helper**—Converts the directed broadcasts to unicasts and forwards them to a specific server.
- **Wake on LAN**—Sends the directed broadcasts to wake up the hosts on the target network.

You can configure this function to enable the interface to forward directed broadcast packets that are destined for directly connected network.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable the interface to forward directed broadcasts destined for the directly connected network.
   ip forward-broadcast [**acl** *acl-number*]
   By default, an interface cannot forward directed broadcasts destined for the directly connected network.



Example: Enabling an interface to forward directed broadcasts destined for the directly connected network

Network configuration

As shown in Figure 1, the default gateway of the host is 1.1.1.2/24, the IP address of VLAN-interface 3 of the switch.

The PC can receive directed broadcasts from the host to IP address 2.2.2.255.

Figure 1 Network diagram

Procedure

1. Specify IP addresses for VLAN-interface 3 and VLAN-interface 2.

```
<Switch> system-view
[Switch] interface vlan-interface 3
[Switch-Vlan-interface3] ip address 1.1.1.2 24
[Switch-Vlan-interface3] quit
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 2.2.2.2 24
```

2. Enable VLAN-interface 2 to forward broadcasts directed for the directly connected network.

```
[Switch-Vlan-interface2] ip forward-broadcast
```

Verifying the configuration

After the configurations are completed, if you ping the subnet-directed broadcast address 2.2.2.255 on the host, the PC can receive the ping packets. If you remove the **ip forward-broadcast** configuration on the switch, the PC cannot receive the ping packets.

Setting the interface MTU for IPv4 packets

About this task

The interface MTU for IPv4 packets defines the largest size of an IPv4 packet that an interface can transmit without fragmentation. When a packet exceeds the MTU of the sending interface, the device processes the packet in one of the following ways:

- If the packet disallows fragmentation, the device discards it.
- If the packet allows fragmentation, the device fragments it and forwards the fragments.

Fragmentation and reassembling consume system resources, so set the MTU based on the network environment to avoid fragmentation.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the interface MTU for IPv4 packets.

   ip mtu *mtu-size*

   By default, the interface MTU is not set.

Enabling Layer 3 packet statistics collection

About this task

With this feature enabled on an interface, the device counts incoming and outgoing IP packets on the interface. To display the collected statistics, execute the **display interface** command.

Restrictions and guidelines

When the interface is processing a large number of packets, Layer 3 packet statistics collection will cause high CPU usage and degrade forwarding performance. If the statistics are not necessary, disable this feature to ensure device performance.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable Layer 3 packet statistics collection.
   statistics l3-packet enable { **inbound** | **outbound** }
   By default, Layer 3 packet statistics collection is disabled.

Enabling IPv4 local fragment reassembly

About this task

By default, a subordinate in a multichassis IRF fabric delivers received packet fragments to the master for centralized fragment reassembly. To improve fragment reassembly efficiency, use this feature. When a subordinate receives fragments of an IPv4 packet, it reassembles them directly.

Use this feature with caution, because fragment reassembly fails on a subordinate when the fragments of an IPv4 packet are received on different subordinates.

Procedure

1. Enter system view.
   system-view
2. Enable IPv4 local fragment reassembly.
   ip reassemble local enable
   By default, IPv4 local fragment reassembly is disabled.

Enabling processing IP options in IP packets

About this task

IP options are typically used for network path diagnosis or temporary transmission of specific services.

By default, when a packet with IP options arrives at an intermediate device, the device sends the packet to the CPU to process IP options before forwarding it out. In a network with excessive packet exchanges, processing IP options will prevent the intermediate device from processing packets in a timely manner and cause packet loss. To avoid this situation, you can perform either of the following operations:

- Execute the **ip option forward** command. This command disables the device from processing IP options in packets that are not destined for the device. Then, those packets will be forwarded through hardware.
- Execute the **ip option drop** command. This command enables the device to drop IP packets that carry IP options and are not destined for the device.

△ **CAUTION:**
As a best practice, execute this command only when IP options are not used in the network.

When IP options are required and the device does not support hardware forwarding, you can execute the **undo ip option** command. The device will then deliver IP packets carrying IP options to the CPU for processing.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable the device to process IP options in IP packets.
   ```
   ip option { drop | forward }
   ```
   By default, the device delivers IP packets carrying IP options to the CPU for processing.

Enabling IP packet isolation between management port and service port

About this task

With this feature enabled, the device discards IP packets received and sent on different types of ports (management or service), for example, packets received on the management port but sent out of the service port. This isolates management IP traffic and service IP traffic from each other, preventing attacks against the management network through the service network.

In scenarios where the management port forwards IP service traffic, do not enable this feature as a best practice.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable IP packet isolation between management port and service port.
   ```
   management-port isolate enable
   ```
   By default, IP packet isolation between management port and service port is disabled.

Enabling TTL expiry alarm generation

About this task

NOTE:

A TTL expiry packet is an IP packet with a TTL value less than or equal to one.

When the device has a loop or is under TTL expiry attacks, it receives a large number of TTL expiry packets in a short period. The number of TTL expiry packets might grow exponentially. Processing those packets will occupy the resources used for processing service packets.

To avoid the above issue, use this feature to check for loops or TTL expiry attacks. The device periodically obtains the number of packet bytes with TTL expiry errors at the specified intervals. If the number of bytes in TTL expiry packets received during an interval equals or exceeds that during the previous interval multiplied by the specified alarm threshold, the device will generate a TTL expiry alarm. To have the device notify TTL expiry alarm clearance, specify the **no-drop-notify** keyword.

Procedure

1. Enter system view.
   ```
   system-view
   ```

2. Enable the device to generate TTL expiry alarms.

   ip ttl-expired drop-rate alarm enable [**interval** *interval-value*] [**threshold** *threshold-value*] [**no-drop-notify** [**cycles** *cycle-value*]]

   By default, the device supports generating TTL expiry alarms.

Enabling sending ICMP error messages

About sending ICMP error messages

ICMP messages are used by network layer and transport layer protocols to communicate updates and errors with other devices, facilitating network management.

Sending excessive ICMP messages increases network traffic. The device performance degrades if it receives a lot of malicious ICMP messages that cause it to respond with ICMP error messages. To prevent such problems, the sending of ICMP error messages is disabled by default. You can enable sending ICMP error messages of different types as needed.

ICMP error messages include redirect messages, time exceeded messages, and destination unreachable messages.

Enabling sending ICMP redirect messages

About this task

A host that has only one default route sends all packets to the default gateway. The default gateway sends an ICMP redirect message to inform the host of a correct next hop when the following conditions are met:

- The receiving and sending interfaces are the same.
- The packet source IP address and the IP address of the packet receiving interface are on the same segment.
- There is no source route option in the received packet.

ICMP redirect messages simplify host management and enable hosts to gradually optimize their routing table.

Procedure

1. Enter system view.

   system-view

2. Enable sending ICMP redirect messages.
3. **ip redirects enable**

   By default, the device does not send ICMP redirect messages.

Enabling sending ICMP time exceeded messages

About this task

A device sends ICMP time exceeded messages by following these rules:

- The device sends the source an ICMP TTL exceeded in transit message when the following conditions are met:
  - The received packet is not destined for the device.
  - The TTL field of the packet is 1.

- When the device receives the first fragment of an IP datagram destined for it, it starts a timer. If the timer expires before all the fragments of the datagram are received, the device sends an ICMP fragment reassembly time exceeded message to the source.

Restrictions and guidelines

If the ICMP time exceeded message sending is disabled, the device does not send ICMP TTL exceeded in transit messages. However, it can still send ICMP fragment reassembly time exceeded messages.

Procedure

1. Enter system view.

   `system-view`
2. Enable sending ICMP time exceeded messages.
3. **`ip ttl-expires enable`**

   By default, the device does not send ICMP time exceeded messages.

Enable sending ICMP destination unreachable messages

About this task

A device sends ICMP destination unreachable messages by following these rules:

- The device sends the source an ICMP network unreachable message when the following conditions are met:
  - The packet does not match any route.
  - No default route exists in the routing table.
- The device sends the source an ICMP protocol unreachable message when the following conditions are met:
  - The packet is destined for the device.
  - The transport layer protocol of the packet is not supported by the device.
- The device sends the source an ICMP port unreachable message when the following conditions are met:
  - The UDP packet is destined for the device.
  - The packet's port number does not match the corresponding process.
- The device sends the source an ICMP source route failed message when the following conditions are met:
  - The source uses Strict Source Routing to send packets.
  - The intermediate device finds that the next hop specified by the source is not directly connected.
- The device sends the source an ICMP fragmentation needed and DF set message when the following conditions are met:
  - The MTU of the sending interface is smaller than the packet.
  - The packet has DF set.

Restrictions and guidelines

If a DHCP-enabled device receives an ICMP echo reply without sending any ICMP echo requests, the device does not send any ICMP protocol unreachable messages to the source. To enable DHCP, use the **`dhcp enable`** command. For more information about this command, see DHCP commands in *Layer 3—IP Services Command Reference*.

Procedure

1. Enter system view.

system-view

2. Enable sending ICMP destination unreachable messages.
3. **ip unreachables enable**

   By default, the device does not send ICMP destination unreachable messages.

Configuring rate limit for ICMP error messages

About this task

To avoid sending excessive ICMP error messages within a short period that might cause network congestion, you can limit the rate at which ICMP error messages are sent. A token bucket algorithm is used with one token representing one ICMP error message.

A token is placed in the bucket at intervals until the maximum number of tokens that the bucket can hold is reached.

A token is removed from the bucket when an ICMP error message is sent. When the bucket is empty, ICMP error messages are not sent until a new token is placed in the bucket.

Procedure

1. Enter system view.

   system-view
2. Set the interval for tokens to arrive in the bucket and the bucket size for ICMP error messages.

   ip icmp error-interval *interval* [*bucketsize*]

   By default, a token is placed in the bucket at intervals of 100 milliseconds and the bucket allows a maximum of 10 tokens.

   To disable the ICMP rate limit, set the interval to 0 milliseconds.

Disabling forwarding ICMP fragments

Restrictions and guidelines

Disabling forwarding ICMP fragments can protect your device from ICMP fragment attacks.

Procedure

1. Enter system view.

   system-view
2. Disable forwarding ICMP fragments.

   ip icmp fragment discarding

   By default, forwarding ICMP fragments is enabled.

Specifying the source address for ICMP packets

About this task

Specifying the source IP address for outgoing ping echo requests and ICMP error messages helps users to locate the sending device easily. As a best practice, specify the IP address of the loopback interface as the source IP address.

Restrictions and guidelines

If you specify an IP address in the **ping** command, ping echo requests use the specified address as the source IP address rather than the IP address specified by the **ip icmp source** command.

Procedure

1. Enter system view.
   system-view
2. Specify the source address for outgoing ICMP packets.
   ip icmp source [**vpn-instance** *vpn-instance-name*] *ip-address*
   By default, no source address is specified for outgoing ICMP packets. The default source IP addresses for different types of ICMP packets vary as follows:
   - For an ICMP error message, the source IP address is the IP address of the receiving interface of the packet that triggers the ICMP error message. ICMP error messages include Time Exceeded, Port Unreachable, and Parameter Problem messages.
   - For an ICMP echo request, the source IP address is the IP address of the sending interface.
   - For an ICMP echo reply, the source IP address is the destination IP address of the ICMP echo request specific to this reply.

Disabling response to broadcast echo requests

About this task

When you use the **ping** command to ping a broadcast address, all devices that have received the ICMP echo request must respond to the request. Attackers might exploit this mechanism to launch an ICMP flood attack. The victims will respond to ICMP echo requests frequently, which degrades their forwarding performance. To resolve this issue, perform this task to disable the device from responding to broadcast echo requests.

You can also disable response to broadcast echo requests in the following scenarios:

- The device has received too many broadcast packets.
- The CPU usage of the device is too high.

Procedure

1. Enter system view.
   system-view
2. Disable response to broadcast echo requests.
   undo ip icmp broadcast-echo-reply enable
   By default, the device responds to broadcast echo requests.

Disabling sending a specific type of ICMP messages

About this task

By default, the device sends all types of ICMP messages except Destination Unreachable, Time Exceeded, and Redirect messages. Attackers might obtain information from specific types of ICMP messages, causing security issues.

For security purposes, you can perform this task disable sending ICMP messages of specific types.

Restrictions and guidelines

Disabling sending ICMP messages of a specific type might affect network operation. Please use this feature with caution.

To enable sending Destination Unreachable, Time Exceeded, or Redirect messages, you can perform one of the following tasks:

- Execute the **ip icmp send enable** command.
- Execute one of the following commands as needed:
  - **ip unreachables enable**
  - **ip ttl-expires enable**
  - **ip redirects enable**

Procedure

1. Enter system view.

   system-view
2. Disable the device from sending a specific type of ICMP messages.

   undo ip icmp { **name** *icmp-name* | **type** *icmp-type* **code** *icmp-code* } **send enable**

   By default, the device sends all types of ICMP messages except Destination Unreachable, Time Exceeded, and Redirect messages.

Disabling receiving a specific type of ICMP messages

About this task

By default, the device receives all types of ICMP messages. Such a setting might affect device performance if a large number of ICMP responses are received within a short time. To resolve this issue, you can perform this task to disable the device from receiving a specific type of ICMP messages.

Restrictions and guidelines

Disabling receiving ICMP messages of a specific type might affect network operation. Please use this feature with caution.

Procedure

1. Enter system view.

   system-view
2. Disable the device from receiving a specific type of ICMP messages.

   undo ip icmp { **name** *icmp-name* | **type** *icmp-type* **code** *icmp-code* } **receive enable**

   By default, the device receives all types of ICMP messages.

Enable SNMP notifications for attack events on ports

About this task

This feature enables the port attack module to generate SNMP notifications for critical events, such as ICMP packet reception overspeeding on a port. The SNMP notifications are sent to the SNMP module. For the SNMP notifications to be sent correctly, you must also configure SNMP. For more information about SNMP configuration, see SNMP configuration in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable SNMP notifications for attack events on ports.
   ```
   snmp-agent trap enable port-attack
   ```
   By default, SNMP notifications are disabled for attack events on ports.

Setting TCP MSS for an interface

About this task

The maximum segment size (MSS) option informs the receiver of the largest segment that the sender can accept. Each end announces its MSS during TCP connection establishment. If the size of a TCP segment is smaller than the MSS of the receiver, TCP sends the TCP segment without fragmentation. If not, it fragments the segment according to the receiver's MSS.

Restrictions and guidelines

- If you set the TCP MSS on an interface, the size of each TCP segment received or sent on the interface cannot exceed the MSS value.
- This configuration takes effect only for TCP connections established after the configuration rather than the TCP connections that already exist.
- This configuration is effective only for IP packets.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the TCP MSS for the interface.
   tcp mss *value*
   By default, the TCP MSS is not set.

Configuring TCP path MTU discovery

About this task

TCP path MTU discovery (in RFC 1191) discovers the path MTU between the source and destination ends of a TCP connection. The device uses the path MTU to calculate the MSS to avoid IP fragmentation. The path MTU uses an aging mechanism to ensure that the source device can increase the path MTU when the minimum link MTU on the path increases.

TCP path MTU discovery works as follows:

1. A TCP source device sends a packet with the Don't Fragment (DF) bit set.
2. A router discards the packet that exceeds the MTU of the outgoing interface and returns an ICMP error message. The error message contains the MTU of the outgoing interface.
3. Upon receiving the ICMP message, the TCP source device calculates the current path MTU of the TCP connection.
4. The TCP source device sends subsequent TCP segments that are smaller than the MSS (MSS = path MTU – IP header length – TCP header length).

If the TCP source device still receives ICMP error messages when the MSS is smaller than 32 bytes, the TCP source device will fragment packets.

An ICMP error message received from a router that does not support RFC 1191 has the MTU of the outgoing interface set to 0. Upon receiving the ICMP message, the TCP source device selects the path MTU smaller than the current path MTU from the MTU table as described in RFC 1191. Based on the selected path MTU, the TCP source device calculates the TCP MSS. The MTU table contains MTUs of 68, 296, 508, 1006, 1280, 1492, 2002, 4352, 8166, 17914, 32000, and 65535 bytes. Because the minimum TCP MSS specified by the system is 32 bytes, the actual minimum MTU is 72 bytes.

The aging mechanism of the path MTU is as follows:

- When the TCP source device receives an ICMP error message, it reduces the path MTU and starts an aging timer for the path MTU.
- After the aging timer expires, the source device uses a larger MSS in the MTU table, as described in RFC 1191.
- If no ICMP error message is received within two minutes, the source device increases the MSS again until the MSS negotiated during TCP three-way handshake is reached.

Prerequisites

Make sure all devices on a TCP connection are enabled to send ICMP error messages by using the **ip unreachables enable** command.

Procedure

1. Enter system view.

   system-view

2. Enable TCP path MTU discovery.

   tcp path-mtu-discovery [**aging** *age-time* | **no-aging**]

   By default, TCP path MTU discovery is disabled.

Enabling SYN Cookie

About this task

A TCP connection is established through a three-way handshake. An attacker can exploit this mechanism to mount SYN Flood attacks. The attacker sends a large number of SYN packets, but does not respond to the SYN ACK packets from the server. As a result, the server establishes a large number of TCP semi-connections and can no longer handle normal services.

SYN Cookie can protect the server from SYN Flood attacks. When the server receives a SYN packet, it responds with a SYN ACK packet without establishing a TCP semi-connection. The server establishes a TCP connection and enters ESTABLISHED state only when it receives an ACK packet from the client.

Procedure

1. Enter system view.

   system-view

2. Enable SYN Cookie.

   tcp syn-cookie enable

   By default, SYN Cookie is disabled.

Setting the TCP buffer size

1. Enter system view.
   system-view
2. Set the size of TCP receive/send buffer.
   tcp window *window-size*
   The default buffer size is 63 KB.

Setting TCP timers

About this task

You can set the following TCP timers:

- **SYN wait timer**—TCP starts the SYN wait timer after sending a SYN packet. Within the SYN wait timer if no response is received or the upper limit on TCP connection tries is reached, TCP fails to establish the connection.
- **FIN wait timer**—TCP starts the FIN wait timer when TCP changes the connection state to FIN_WAIT_2. If no FIN packet is received within the timer interval, TCP terminates the connection. If a FIN packet is received, TCP changes the connection state to TIME_WAIT. If a non-FIN packet is received, TCP restarts the timer, and tears down the connection when the timer expires.

Procedure

1. Enter system view.
   system-view
2. Set the TCP SYN wait timer.
3. **tcp timer syn-timeout** *time-value*
   - By default, the TCP SYN wait timer is 75 seconds.
4. Set the TCP FIN wait timer.
5. **tcp timer fin-timeout** *time-value*
   By default, the TCP FIN wait timer is 675 seconds.

Enabling the Timestamps option encapsulation in outgoing TCP packets

About this task

Devices at each end of the TCP connection can calculate the RTT value by using the TCP Timestamps option carried in TCP packets. For security purpose in some networks, you can disable this feature at one end of the TCP connection to prevent intermediate devices from obtaining the Timestamps option information.

Procedure

1. Enter system view.
   system-view
2. Enable the device to encapsulate the TCP Timestamps option in outgoing TCP packets.
   tcp timestamps enable
   By default, the TCP timestamps option is encapsulated in outgoing TCP packets.

Enabling SNMP notifications for TCP events

About this task

This feature enables the TCP module to generate SNMP notifications for critical TCP events. The SNMP notifications are sent to the SNMP module. For the SNMP notifications to be sent correctly, you must also configure SNMP. For more information about SNMP configuration, see SNMP configuration in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   `system-view`
2. Enable SNMP notifications for TCP events.
   `snmp-agent trap enable tcp`
   By default, SNMP notifications for TCP events are enabled.

Display and maintenance commands for IP performance optimization

Execute **`display`** commands in any view and **`reset`** commands in user view.

Task	Command
Display ICMP statistics.	**`display icmp statistics`** [**`slot`** *`slot-number`*]

Configuring UDP helper

About UDP helper

UDP helper can provide the following packet conversion services for packets with specific UDP destination port numbers:

- Convert broadcast to unicast, and forward the unicast packets to specific destinations.
- Convert broadcast to multicast, and forward the multicast packets.

Configuring UDP helper to convert broadcast to unicast

About this task

You can configure UDP helper to convert broadcast packets with specific UDP port numbers to unicast packets.

Upon receiving a UDP broadcast packet, UDP helper uses the configured UDP ports to match the UDP destination port number of the packet.

- If a match is found, UDP helper duplicates the packet and modifies the destination IP address of the copy to the configured unicast address. Then UDP helper forwards the unicast packet to the unicast address.
- If no match is found, UDP helper does not process the packet.

Procedure

1. Enter system view.

   system-view

2. Enable UDP helper.

   udp-helper enable

   By default, UDP helper is disabled.

3. Specify a UDP port number for UDP helper.

   udp-helper port { *port-number* | **dns** | **netbios-ds** | **netbios-ns** | **tacacs** | **tftp** | **time** }

   By default, no UDP port numbers are specified for UDP helper.

   Do not set UDP ports 67 and 68 for UDP helper, because UDP helper cannot forward DHCP broadcast packets.

   You can specify a maximum of 256 UDP ports for UDP helper.

4. Enter interface view.

   interface *interface-type interface-number*

5. Specify a destination server for UDP helper to convert broadcast to unicast.

   udp-helper server *ip-address* [**global** | **vpn-instance** *vpn-instance-name*]

   By default, no destination servers are specified.

   Use this command on the interface that receives broadcast packets.

Configuring UDP helper to convert broadcast to multicast

About this task

You can configure UDP helper to convert broadcast packets with specific UDP port numbers to multicast packets.

Upon receiving a UDP broadcast packet, UDP helper uses the configured UDP ports to match the UDP destination port number of the packet.

- If a match is found, UDP helper duplicates the packet and modifies the destination IP address of the copy to the configured multicast address. Then UDP helper forwards the packet to the multicast group.
- If no match is found, UDP helper does not process the packet.

Procedure

1. Enter system view.

   system-view
2. Enable UDP helper.

   udp-helper enable

   By default, UDP helper is disabled.
3. Specify a UDP port number for UDP helper.

   udp-helper port { *port-number* | **dns** | **netbios-ds** | **netbios-ns** | **tacacs** | **tftp** | **time** }

   By default, no UDP port numbers are specified for UDP helper.

   Do not set UDP ports 67 and 68 for UDP helper, because UDP helper cannot forward DHCP broadcast packets.

   You can specify a maximum of 256 UDP ports for UDP helper.
4. Enter interface view.

   interface *interface-type interface-number*
5. Specify a destination multicast address for UDP helper to convert broadcast to multicast.

   udp-helper broadcast-map *multicast-address* [**acl** *acl-number*]

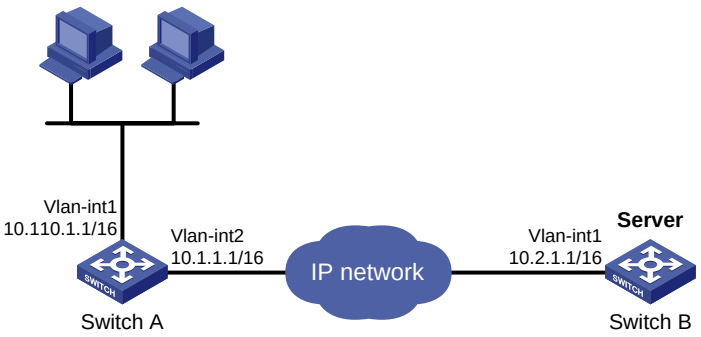
   By default, no destination multicast addresses are specified for UDP helper.

   Use this command on the interface that receives broadcast packets.

Display and maintenance commands for UDP helper

Execute **display** command in any view and **reset** commands in user view.

Task	Command
Display information about broadcast to unicast conversion by UDP helper on an interface.	**display udp-helper interface** *interface-type interface-number*
Clear packet statistics for UDP helper.	**reset udp-helper statistics**



UDP helper configuration examples

Example: Configuring UDP helper to convert broadcast to unicast

Network configuration

As shown in Figure 1, configure UDP helper to convert broadcast to unicast on VLAN-interface 1 of Switch A. This feature enables Switch A to forward broadcast packets with UDP destination port number 55 to the destination server 10.2.1.1/16.

Figure 1 Network diagram

Procedure

Make sure Switch A can reach the subnet 10.2.0.0/16.

Enable UDP helper.

```
[SwitchA] System-view
[SwitchA] udp-helper enable
```

Enable the UDP port 55 for UDP helper.

```
[SwitchA] udp-helper port 55
```

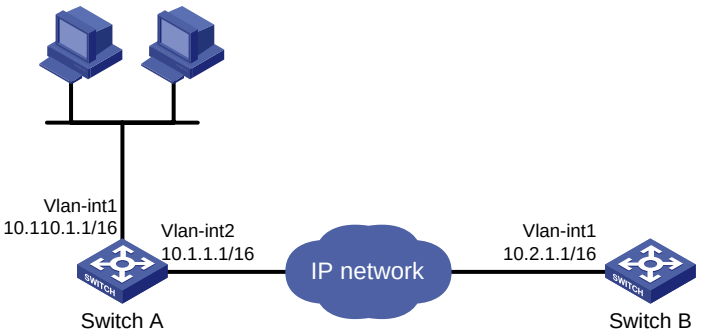
Specify the destination server 10.2.1.1 for UDP helper to convert broadcast to unicast on VLAN-interface 1.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ip address 10.110.1.1 16
[SwitchA-Vlan-interface1] udp-helper server 10.2.1.1
```

Verifying the configuration

Display information about broadcast to unicast conversion by UDP helper on VLAN-interface 1.

```
[SwitchA-Vlan-interface1] display udp-helper interface vlan-interface 1
Interface                Server VPN instance          Server address Packets sent
Vlan-interface1          N/A                          10.2.1.1       5
```



Example: Configuring UDP helper to convert broadcast to multicast

Network configuration

As shown in Figure 2, VLAN-interface 1 of Switch B can receive multicast packets destined to 225.1.1.1.

Configure UDP helper to convert broadcast to multicast on VLAN-interface 1 of Switch A. This feature enables Switch A to forward broadcast packets with UDP destination port number 55 to the multicast group 225.1.1.1.

Figure 2 Network diagram

Procedure

Make sure Switch A can reach the subnet 10.2.0.0/16.

1. Configure Switch A:

Enable UDP helper.

```
<SwitchA> system-view
[SwitchA] udp-helper enable
```

Enable the UDP port 55 for UDP helper.

```
[SwitchA] udp-helper port 55
```

Configure UDP helper to convert broadcast packets to multicast packets destined for 225.1.1.1.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ip address 10.110.1.1 16
[SwitchA-Vlan-interface1] udp-helper broadcast-map 225.1.1.1
[SwitchA-Vlan-interface1] quit
```

Enable IP multicast routing globally.

```
[SwitchA] multicast routing
[SwitchA-mrib] quit
```

Enable PIM-DM on VLAN-interface 1.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] pim dm
[SwitchA-Vlan-interface1] quit
```

Enable PIM-DM and IGMP on VLAN-interface 2.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] pim dm
[SwitchA-Vlan-interface2] igmp enable
```

Configure VLAN-interface 2 as a static member of multicast group 225.1.1.1.

```
[SwitchA-Vlan-interface2] igmp static-group 225.1.1.1
```

2. Configure Switch B:

Enable IP multicast routing globally.

```
<SwitchB> system-view
[SwitchB] multicast routing
[SwitchB-mrib] quit
```

Enable PIM-DM and IGMP on VLAN-interface 1.

```
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] pim dm
[SwitchB-Vlan-interface1] igmp enable
```

Configure VLAN-interface 1 as a static member of multicast group 225.1.1.1.

```
[SwitchB-Vlan-interface1] igmp static-group 225.1.1.1
```

Verifying the configuration

Verify that you can capture multicast packets from Switch A on Switch B.

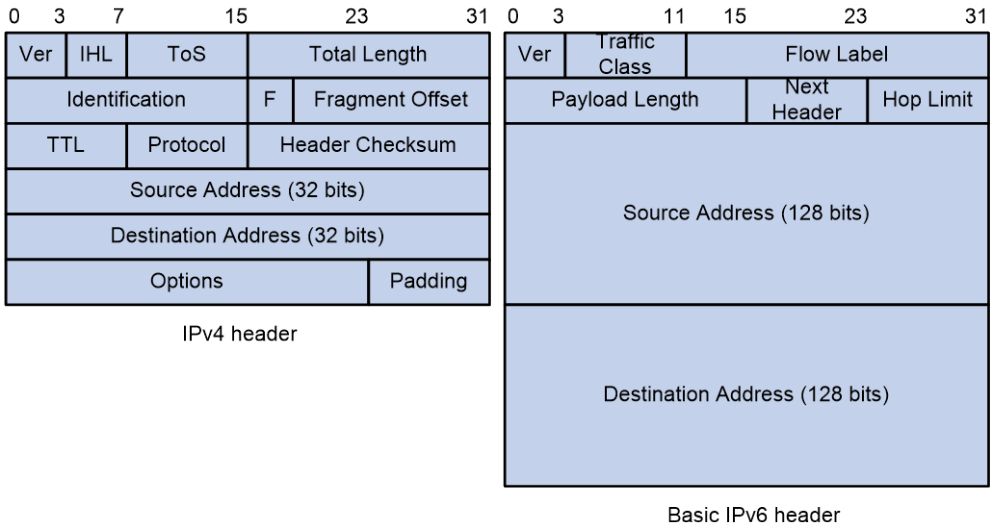
Configuring basic IPv6 settings

About IPv6



IPv6, also called IP next generation (IPng), was designed by the IETF as the successor to IPv4. One significant difference between IPv6 and IPv4 is that IPv6 increases the IP address size from 32 bits to 128 bits.

IPv6 features

Simplified header format

IPv6 removes several IPv4 header fields or moves them to the IPv6 extension headers to reduce the length of the basic IPv6 packet header. The basic IPv6 packet header has a fixed length of 40 bytes to simplify IPv6 packet handling and improve forwarding efficiency. Although the IPv6 address size is four times the IPv4 address size, the basic IPv6 packet header size is only twice the size of the option-less IPv4 packet header.

Figure 1 IPv4 packet header format and basic IPv6 packet header format

Larger address space

IPv6 can provide 3.4 x 10^{38} addresses to meet the requirements of hierarchical address assignment for both public and private networks.

Hierarchical address structure

IPv6 uses a hierarchical address structure to speed up route lookup and reduce the IPv6 routing table size through route aggregation.

Address autoconfiguration

To simplify host configuration, IPv6 supports stateful and stateless address autoconfiguration.

- Stateful address autoconfiguration enables a host to acquire an IPv6 address and other configuration information from a server (for example, a DHCPv6 server). For more information about DHCPv6 server, see "Configuring the DHCPv6 server."

- Stateless address autoconfiguration enables a host to automatically generate an IPv6 address and other configuration information by using its link-layer address and the prefix information advertised by a router.

To communicate with other hosts on the same link, a host automatically generates a link-local address based on its link-layer address and the link-local address prefix (FE80::/10).

Built-in security

IPv6 defines extension headers to support IPsec. IPsec provides end-to-end security and enhances interoperability among different IPv6 applications.

QoS support

The Flow Label field in the IPv6 header allows the device to label the packets of a specific flow for special handling.

Enhanced neighbor discovery mechanism

The IPv6 neighbor discovery protocol uses a group of ICMPv6 messages to manage information exchange among neighboring nodes on the same link. The group of ICMPv6 messages replaces ARP messages, ICMPv4 router discovery messages, and ICMPv4 redirect messages and provides a series of other functions.

Flexible extension headers

IPv6 eliminates the Options field in the header and introduces optional extension headers to provide scalability and improve efficiency. The Options field in the IPv4 packet header contains a maximum of 40 bytes, whereas the IPv6 extension headers are restricted to the maximum size of IPv6 packets.

IPv6 addresses

IPv6 address format

An IPv6 address is represented as a set of 16-bit hexadecimals separated by colons (:). An IPv6 address is divided into eight groups, and each 16-bit group is represented by four hexadecimal numbers, for example, 2001:0000:130F:0000:0000:09C0:876A:130B.

To simplify the representation of IPv6 addresses, you can handle zeros in IPv6 addresses by using the following methods:

- The leading zeros in each group can be removed. For example, the above address can be represented in a shorter format as 2001:0:130F:0:0:9C0:876A:130B.
- If an IPv6 address contains one or more consecutive groups of zeros, they can be replaced by a double colon (::). For example, the above address can be represented in the shortest format as 2001:0:130F::9C0:876A:130B.

IMPORTANT:

A double colon can appear once or not at all in an IPv6 address. This limit allows the device to determine how many zeros the double colon represents and correctly convert it to zeros to restore a 128-bit IPv6 address.

An IPv6 address consists of an address prefix and an interface ID, which are equivalent to the network ID and the host ID of an IPv4 address.

An IPv6 address prefix is written in IPv6-address/prefix-length notation. The prefix-length is a decimal number indicating how many leftmost bits of the IPv6 address are in the address prefix.

IPv6 address types

IPv6 addresses include the following types:

- **Unicast address**—An identifier for a single interface, similar to an IPv4 unicast address. A packet sent to a unicast address is delivered to the interface identified by that address.
- **Multicast address**—An identifier for a set of interfaces (typically belonging to different nodes), similar to an IPv4 multicast address. A packet sent to a multicast address is delivered to all interfaces identified by that address.

  Broadcast addresses are replaced by multicast addresses in IPv6.
- **Anycast address**—An identifier for a set of interfaces (typically belonging to different nodes). A packet sent to an anycast address is delivered to the nearest interface among the interfaces identified by that address. The nearest interface is chosen according to the routing protocol's measure of distance.

The type of an IPv6 address is designated by the first several bits, called the format prefix.

Table 1 Mappings between address types and format prefixes

Type		Format prefix (binary)	IPv6 prefix ID
Unicast address	Unspecified address	00...0 (128 bits)	::/128
	Loopback address	00...1 (128 bits)	::1/128
	Link-local address	1111111010	FE80::/10
	Global unicast address	Other forms	N/A
Multicast address		11111111	FF00::/8
Anycast address		Anycast addresses use the unicast address space and have the identical structure of unicast addresses.	

Unicast addresses

Unicast addresses include global unicast addresses, link-local unicast addresses, the loopback address, and the unspecified address.

- **Global unicast addresses**—Equivalent to public IPv4 addresses, global unicast addresses are provided for Internet service providers. This type of address allows for prefix aggregation to restrict the number of global routing entries.
- **Link-local addresses**—Used for communication among link-local nodes for neighbor discovery and stateless autoconfiguration. Packets with link-local source or destination addresses are not forwarded to other links.
- **A loopback address**—0:0:0:0:0:0:0:1 (or ::1). It has the same function as the loopback address in IPv4. It cannot be assigned to any physical interface. A node uses this address to send an IPv6 packet to itself.
- **An unspecified address**—0:0:0:0:0:0:0:0 (or ::). It cannot be assigned to any node. Before acquiring a valid IPv6 address, a node fills this address in the source address field of IPv6 packets. The unspecified address cannot be used as a destination IPv6 address.

Multicast addresses

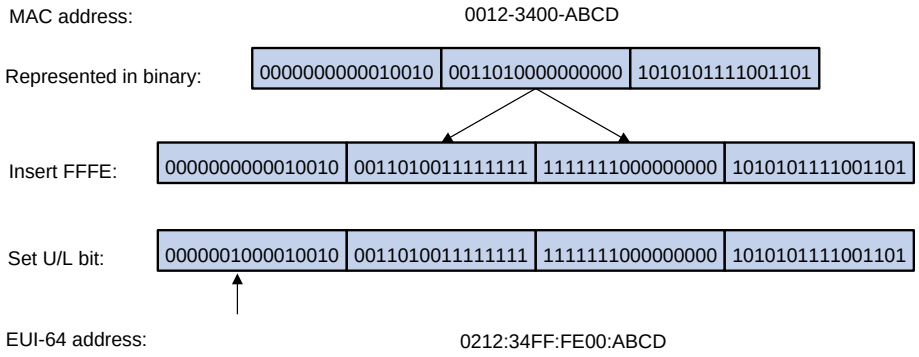
IPv6 multicast addresses listed in Table 2 are reserved for special purposes.

Table 2 Reserved IPv6 multicast addresses

Address	Application
FF01::1	Node-local scope all-nodes multicast address.
FF02::1	Link-local scope all-nodes multicast address.
FF01::2	Node-local scope all-routers multicast address.
FF02::2	Link-local scope all-routers multicast address.

Multicast addresses also include solicited-node addresses. A node uses a solicited-node multicast address to acquire the link-layer address of a neighboring node on the same link and to detect duplicate addresses. Each IPv6 unicast or anycast address has a corresponding solicited-node address. The format of a solicited-node multicast address is FF02:0:0:0:0:1:FFXX:XXXX. FF02:0:0:0:0:1:FF is fixed and consists of 104 bits, and XX:XXXX is the last 24 bits of an IPv6 unicast address or anycast address.

EUI-64 address-based interface identifiers



An interface identifier is 64 bits long and uniquely identifies an interface on a link.

On an IEEE 802 interface (such as a VLAN interface), the interface identifier is derived from the link-layer address (typically a MAC address) of the interface. The MAC address is 48 bits long.

To obtain an EUI-64 address-based interface identifier, follow these steps:

1. Insert the 16-bit binary number 1111111111111110 (hexadecimal value of FFFE) behind the 24th high-order bit of the MAC address.
2. Invert the universal/local (U/L) bit (the seventh high-order bit). This operation makes the interface identifier have the same local or global significance as the MAC address.

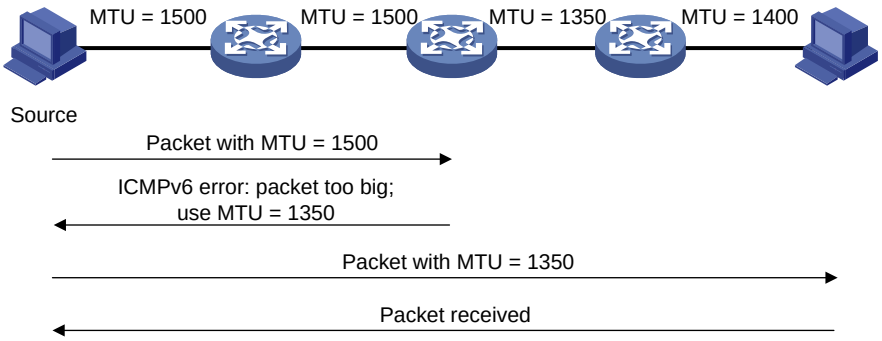
Figure 2 Converting a MAC address into an EUI-64 address-based interface identifier

On a tunnel interface, the lower 32 bits of the EUI-64 address-based interface identifier are the source IPv4 address of the tunnel interface. The higher 32 bits of the EUI-64 address-based interface identifier of an ISATAP tunnel interface are 0000:5EFE, whereas those of other tunnel interfaces are all zeros. For more information about tunnels, see "Configuring tunneling."

On an interface of another type (such as a serial interface), the EUI-64 address-based interface identifier is generated randomly by the device.

IPv6 path MTU discovery

The links that a packet passes from a source to a destination can have different MTUs, among which the minimum MTU is the path MTU. If a packet exceeds the path MTU, the source end fragments the packet to reduce the processing pressure on intermediate devices and to use network resources effectively.



A source end uses path MTU discovery to find the path MTU to a destination, as shown in Figure 3.

1. The source host sends a packet no larger than its MTU to the destination host.
2. If the MTU of an intermediate device's output interface is smaller than the packet, the device performs the following operations:
   - Discards the packet.
   - Returns an ICMPv6 error message containing the interface MTU to the source host.
3. Upon receiving the ICMPv6 error message, the source host performs the following operations:
   - Uses the returned MTU to limit the packet size.

- Performs fragmentation.
- Sends the fragments to the destination host.

4. Step 2 and step 3 are repeated until the destination host receives the packet. In this way, the source host finds the minimum MTU of all links in the path to the destination host.

Figure 3 Path MTU discovery process

IPv6 transition technologies

IPv6 transition technologies enable communication between IPv4 and IPv6 networks.

Dual stack

Dual stack is the most direct transition approach. A network node that supports both IPv4 and IPv6 is a dual-stack node. A dual-stack node configured with an IPv4 address and an IPv6 address can forward both IPv4 and IPv6 packets. An application that supports both IPv4 and IPv6 prefers IPv6 at the network layer.

Dual stack is suitable for communication between IPv4 nodes or between IPv6 nodes. It is the basis of all transition technologies. However, it does not solve the IPv4 address depletion issue because each dual-stack node must have a globally unique IPv4 address.

Tunneling

Tunneling uses one network protocol to encapsulate the packets of another network protocol and transfers them over the network. For more information about tunneling, see "Configuring tunneling."

IPv6 basics tasks at a glance

To configure basic IPv6 settings, perform the following tasks:

1. Configuring an IPv6 address

   Choose the following tasks as needed:

   - Configuring an IPv6 global unicast address
   - Configuring an IPv6 link-local address
   - Configuring an IPv6 anycast address
2. (Optional.)Configuring path MTU discovery
   - Setting the interface MTU for IPv6 packets
   - Setting a static path MTU for an IPv6 address
   - Setting the aging time for dynamic path MTUs
3. (Optional.) Setting the IPv6 TCP MSS for an interface
4. (Optional.) Controlling sending ICMPv6 messages
   - Disabling receiving a specific type of ICMPv6 messages
   - Disabling sending a specific type of ICMPv6 messages
   - Configuring the rate limit for ICMPv6 error messages
   - Enabling replying to multicast echo requests
   - Enabling sending ICMPv6 destination unreachable messages
   - Enabling sending ICMPv6 time exceeded messages
   - Enabling sending ICMPv6 redirect messages
   - Specifying the source address for unsolicited ICMPv6 packets
   - Specifying the source IPv6 address for outgoing ICMPv6 replies
5. (Optional.) Enabling Layer 3 packet statistics collection
6. (Optional.) Enabling IPv6 local fragment reassembly
7. (Optional.) Enabling discarding IPv6 packets that contain extension headers
8. (Optional.) Enabling IPv6 fast traffic migration
9. (Optional.) Enabling IPv6 FIB entry consistency check
10. (Optional.) Enabling source MAC unknown IPv6 packets to trigger ND snooping
11. (Optional.) Enabling HopLimit expiry alarm generation
12. (Optional.) Enabling SNMP notifications for the IPv6 basics module
13. (Optional.) Enabling SNMP notifications for the IPv6 forwarding module

Configuring an IPv6 global unicast address

About IPv6 global unicast address

Use one of the following methods to configure an IPv6 global unicast address for an interface:

- **EUI-64 IPv6 address**—The IPv6 address prefix of the interface is manually configured, and the interface ID is generated automatically by the interface.
- **Manual configuration**—The IPv6 global unicast address is manually configured.
- **Stateless address autoconfiguration**—The IPv6 global unicast address is generated automatically based on the address prefix information contained in the RA message.

- **Prefix-specific address autoconfiguration**—The IPv6 global unicast address is generated automatically based on the prefix specified by its ID. The prefix can be manually configured or obtained through DHCPv6.

You can configure multiple IPv6 global unicast addresses on an interface.

Manually configured global unicast addresses (including EUI-64 IPv6 addresses) take precedence over automatically generated ones. If you manually configure a global unicast address with the same address prefix as an existing global unicast address on an interface, the manually configured one takes effect. However, it does not overwrite the automatically generated address. If you delete the manually configured global unicast address, the device uses the automatically generated one.

Restrictions and guidelines

An interface ID is used in EUI-64 IPv6 address configuration and stateless address autoconfiguration. The interface ID is derived from the MAC address of the interface. If the MAC address changes, the interface ID, global unicast address, and link-local address will also change. This will cause the entry table to rebuild for some protocols, such as MLD, IPv6 PIM, and OSPFv3. If you do not want this situation to occur, use other IPv6 address configuration methods that do not use MAC addresses, for example, manually specify an IPv6 address.

Generating an EUI-64 IPv6 address

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure an EUI-64 IPv6 address on the interface.
   ipv6 address { *ipv6-address prefix-length* | *ipv6-address*/*prefix-length* } **eui-64**
   By default, no EUI-64 IPv6 address is configured on an interface.

Manually assigning an IPv6 global unicast address

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Assign an IPv6 global unicast address to the interface.
   ipv6 address { *ipv6-address prefix-length* | *ipv6-address*/*prefix-length* }
   By default, no IPv6 global unicast address is configured on an interface.

Stateless address autoconfiguration

About this task

Stateless address autoconfiguration enables an interface to automatically generate an IPv6 global unicast address by using the address prefix in the received RA message and the interface ID. On an IEEE 802 interface (such as an Ethernet interface or a VLAN interface), the interface ID is generated based on the interface's MAC address and is globally unique. An attacker can exploit this rule to identify the sending device easily.

To fix the vulnerability, you can configure the temporary address feature. With this feature, an IEEE 802 interface generates the following addresses:

- **Public IPv6 address**—Includes the address prefix in the RA message and a fixed interface ID generated based on the MAC address of the interface.
- **Temporary IPv6 address**—Includes the address prefix in the RA message and a random interface ID generated through MD5.

You can also configure the interface to preferentially use the temporary IPv6 address as the source address of sent packets. When the valid lifetime of the temporary IPv6 address expires, the interface deletes the address and generates a new one. This feature enables the system to send packets with different source addresses through the same interface. If the temporary IPv6 address cannot be used because of a DAD conflict, the public IPv6 address is used.

The preferred lifetime and valid lifetime for a temporary IPv6 address are determined as follows:

- The preferred lifetime of a temporary IPv6 address takes the smaller of the following values:
  - The preferred lifetime of the address prefix in the RA message.
  - The preferred lifetime configured for temporary IPv6 addresses minus DESYNC_FACTOR (a random number in the range of 0 to 600 seconds).
- The valid lifetime of a temporary IPv6 address takes the smaller of the following values:
  - The valid lifetime of the address prefix.
  - The valid lifetime configured for temporary IPv6 addresses.

Restrictions and guidelines

If the IPv6 prefix in the RA message is not 64 bits long, stateless address autoconfiguration fails to generate an IPv6 global unicast address.

To generate a temporary address, an interface must be enabled with stateless address autoconfiguration. Temporary IPv6 addresses do not overwrite public IPv6 addresses, so an interface can have multiple IPv6 addresses with the same address prefix but different interface IDs.

If an interface fails to generate a public IPv6 address because of a prefix conflict or other reasons, it does not generate any temporary IPv6 address.

Executing the **undo ipv6 address auto** command on an interface deletes all IPv6 global unicast addresses and link-local addresses that are automatically generated on the interface.

Enabling stateless address autoconfiguration

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable stateless address autoconfiguration on an interface, so that the interface can automatically generate a global unicast address.

   ipv6 address auto

   By default, the stateless address autoconfiguration feature is disabled on an interface.

Configuring the temporary address feature and preferentially using the temporary IPv6 address as the source address of outgoing packets

1. Enter system view.

   system-view
2. Enable the temporary IPv6 address feature.

   ipv6 temporary-address [*valid-lifetime preferred-lifetime*]

   By default, the temporary IPv6 address feature is disabled.

3. Enable the system to preferentially use the temporary IPv6 address as the source address of the outgoing packets.

   ipv6 prefer temporary-address

   By default, the system does not preferentially use the temporary IPv6 address as the source address of the outgoing packets.

Configuring prefix-specific address autoconfiguration

1. Enter system view.

   system-view

2. Configure an IPv6 prefix.

   Choose one option as needed:

   - Configure a static IPv6 prefix.

     ipv6 prefix *prefix-number ipv6-prefix*/*prefix-length*

     By default, no static IPv6 prefixes exist.

   - Use DHCPv6 to obtain a dynamic IPv6 prefix.

     For more information about IPv6 prefix acquisition, see "Configuring the DHCPv6 client."

3. Enter interface view.

   interface *interface-type interface-number*

4. Specify an IPv6 prefix for an interface to automatically generate an IPv6 global unicast address and advertise the prefix.

   ipv6 address *prefix-number sub-prefix/prefix-length*

   By default, no IPv6 prefix is specified for the interface to automatically generate an IPv6 global unicast address.

Configuring an IPv6 link-local address

About IPv6 link-local address

Configure IPv6 link-local addresses using one of the following methods:

- **Automatic generation**—The device automatically generates a link-local address for an interface according to the link-local address prefix (FE80::/10) and the link-layer address of the interface.
- **Manual assignment**—Manually configure an IPv6 link-local address for an interface.

Restrictions and guidelines

After you configure an IPv6 global unicast address for an interface, the interface automatically generates a link-local address. This link-local address is the same as the one generated by using the **ipv6 address auto link-local** command. If a link-local address is manually assigned to an interface, this manual assigned link-local address takes effect. If the manually assigned link-local address is deleted, the automatically generated link-local address takes effect.

Using the **undo ipv6 address auto link-local** command on an interface deletes only the link-local address generated by the **ipv6 address auto link-local** command. If the interface has an IPv6 global unicast address, it still has a link-local address. If the interface has no IPv6 global unicast address, it has no link-local address.

An interface can have only one link-local address. As a best practice, use the automatic generation method to avoid link-local address conflicts. If both the automatic generation and manual assignment methods are used, the manual assignment takes precedence.

- If you first use automatic generation and then manual assignment, the manually assigned link-local address overwrites the automatically generated one.
- If you first use manual assignment and then automatic generation, both of the following occur:
  - The link-local address is still the manually assigned one.
  - The automatically generated link-local address does not take effect. If you delete the manually assigned address, the automatically generated link-local address takes effect.

An interface ID is used for generating the link-local address for an interface. On an IEEE 802 interface (such as an Ethernet interface or a VLAN interface), the interface ID is derived from the MAC address of the interface. If the MAC address changes, the interface ID, global unicast address, and link-local address will also change. This will cause the entry table to rebuild for some protocols, such as MLD, IPv6 PIM, and OSPFv3. If you do not want this situation to occur, use other IPv6 address configuration methods that do not use MAC addresses, for example, manually specify a link-local address.

Configuring automatic generation of an IPv6 link-local address for an interface

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Configure the interface to automatically generate an IPv6 link-local address.

   ipv6 address auto link-local

   By default, no link-local address is configured on an interface.

   After an IPv6 global unicast address is configured on the interface, a link-local address is generated automatically.

Manually assigning an IPv6 link-local address to an interface

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Manually assign an IPv6 link-local address to the interface.

   ipv6 address { *ipv6-address* [*prefix-length*] | *ipv6-address/prefix-length* } **link-local**

   By default, no link-local address is configured on an interface.

Configuring an IPv6 anycast address

4. Enter system view.

   system-view
5. Enter interface view.

   interface *interface-type interface-number*

6. Configure an IPv6 anycast address.

   ipv6 address { *ipv6-address prefix-length* | *ipv6-address*/*prefix-length* } **anycast**

   By default, no IPv6 anycast address is configured on an interface.

Configuring path MTU discovery

Setting the interface MTU for IPv6 packets

About this task

If the size of a packet exceeds the MTU of the sending interface, the device discards the packet. If the device is an intermediate device, it also sends the source host an ICMPv6 Packet Too Big message with the MTU of the sending interface. The source host fragments the packets according to the MTU. To avoid this situation, set a proper interface MTU.

Restrictions and guidelines

When you configure the MTU of an interface, the system prompts configuration failure but the MTU configuration actually takes effect on the interface. If the size of a packet exceeds the specified MTU, the device fragments the packet.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the interface MTU for IPv6 packets.

   ipv6 mtu *size*

   By default, no interface MTU is set.

Setting a static path MTU for an IPv6 address

About this task

You can set a static path MTU for an IPv6 address. Before sending a packet to the IPv6 address, the device compares the output interface MTU with the static path MTU. If the packet size exceeds the smaller one of the two values, the device fragments the packet according to the smaller value. After sending the fragmented packets, the device dynamically finds the path MTU to a destination host (see "IPv6 path MTU discovery").

Procedure

1. Enter system view.

   system-view

2. Set a static path MTU for an IPv6 address.

   ipv6 pathmtu [**vpn-instance** *vpn-instance-name*] *ipv6-address value*

   By default, no path MTU is set for any IPv6 address.

Setting the aging time for dynamic path MTUs

About this task

After the device dynamically discovers the path MTU to a destination host (see "IPv6 path MTU discovery"), it performs the following operations:

- Sends packets to the destination host based on this path MTU.
- Starts the aging timer for this path MTU.

When the aging timer expires, the device removes the dynamic path MTU and discovers the path MTU again.

Restrictions and guidelines

The aging time is invalid for a static path MTU.

Procedure

1. Enter system view.
   system-view
2. Set the aging time for dynamic path MTUs.
   ipv6 pathmtu age *age-time*
   The default setting is 10 minutes.

Setting the IPv6 TCP MSS for an interface

About this task

The maximum segment size (MSS) option informs the receiver of the largest segment that the sender can accept. Each end announces its MSS during TCP connection establishment. If the size of a TCP segment does not exceed the MSS value of the receiver, TCP sends the TCP segment without fragmentation. If not, it fragments the segment according to the receiver's MSS.

Restrictions and guidelines

- If you set the TCP MSS on an interface, the size of each TCP segment received or sent on the interface cannot exceed the MSS value.
- This configuration takes effect only for TCP connections established after the configuration rather than the TCP connections that already exist.
- This configuration is effective only for IPv6 packets. If MPLS is enabled on the interface, do not set the TCP MSS on the interface.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the IPv6 TCP MSS for the interface.
   ipv6 tcp mss *value*
   By default, the IPv6 TCP MSS is not set.

Controlling sending ICMPv6 messages

Disabling receiving a specific type of ICMPv6 messages

About this task

By default, the device receives all types of ICMPv6 messages. Such a setting might affect device performance if a large number of ICMPv6 responses are received within a short time. To resolve this issue, you can perform this task to disable the device from receiving a specific type of ICMPv6 messages.

Restrictions and guidelines

Disabling receiving ICMPv6 messages of a specific type might affect network operation. Please use this feature with caution.

Procedure

1. Enter system view.

   system-view

2. Disable the device from receiving a specific type of ICMPv6 messages.

   undo ipv6 icmpv6 { **name** *name* | **type** *type* **code** *code* } **receive enable**

   By default, the device receives all types of ICMPv6 messages.

Disabling sending a specific type of ICMPv6 messages

About this task

By default, the device sends all types of ICMPv6 messages except Destination Unreachable and Redirect messages. Attackers might obtain device information from specific types of ICMPv6 messages, causing security issues.

For security purposes, you can perform this task to disable the device from sending specific types of ICMPv6 messages.

Restrictions and guidelines

Disabling sending ICMPv6 messages of a specific type might affect network operation. Please use this feature with caution.

To enable sending Destination Unreachable, Time Exceeded, or Redirect messages, you can perform one of the following tasks:

- Execute the **ipv6 icmpv6 send enable** command.
- Execute one of the following commands as needed:
  - **ipv6 unreachables enable**
  - **ipv6 hoplimit-expires enable**
  - **ipv6 redirects enable**

Procedure

1. Enter system view.

   system-view

2. Disable the device from sending a specific type of ICMPv6 messages.

   undo ipv6 icmpv6 { **name** *name* | **type** *type* **code** *code* } **send enable**

   By default, the device can send all types of ICMPv6 messages except Destination Unreachable and Redirect messages.

Configuring the rate limit for ICMPv6 error messages

About this task

To avoid sending excessive ICMPv6 error messages within a short period that might cause network congestion, you can limit the rate at which ICMPv6 error messages are sent. A token bucket algorithm is used with one token representing one ICMPv6 error message.

A token is placed in the bucket at intervals until the maximum number of tokens that the bucket can hold is reached.

A token is removed from the bucket when an ICMPv6 error message is sent. When the bucket is empty, ICMPv6 error messages are not sent until a new token is placed in the bucket.

Procedure

1. Enter system view.

   `system-view`
2. Set the bucket size and the interval for tokens to arrive in the bucket for ICMPv6 error messages.

   `ipv6 icmpv6 error-interval` *`interval`* [*`bucketsize`*]

   By default, the bucket allows a maximum of 10 tokens. A token is placed in the bucket at an interval of 100 milliseconds.

   To disable the ICMPv6 rate limit, set the interval to 0 milliseconds.

Enabling replying to multicast echo requests

1. Enter system view.

   `system-view`
2. Enable replying to multicast echo requests.

   `ipv6 icmpv6 multicast-echo-reply enable`

   By default, this feature is disabled.

Enabling sending ICMPv6 destination unreachable messages

About this task

The device sends the source the following ICMPv6 destination unreachable messages:

- **ICMPv6 No Route to Destination message**—A packet to be forwarded does not match any route.
- **ICMPv6 Communication with Destination Administratively Prohibited message**—An administrative prohibition is preventing successful communication with the destination. This is typically caused by a firewall or an ACL on the device.
- **ICMPv6 Beyond Scope of Source Address message**—The destination is beyond the scope of the source IPv6 address. For example, a packet's source IPv6 address is a link-local address, and its destination IPv6 address is a global unicast address.
- **ICMPv6 Address Unreachable message**—The device fails to resolve the link layer address for the destination IPv6 address of a packet.
- **ICMPv6 Port Unreachable message**—No port process on the destination device exists for a received UDP packet.

Restrictions and guidelines

An ICMPv6 destination unreachable message indicates that the destination is not reachable from the source device. Attackers can launch malicious attacks to make the device generate incorrect ICMPv6 destination unreachable messages, which will affect the function of the network. To protect the network from malicious attacks and decrease unnecessary network traffic, you can disable the sending of ICMPv6 destination unreachable messages.

Procedure

1. Enter system view.

   `system-view`

2. Enable sending ICMPv6 destination unreachable messages.

   `ipv6 unreachables enable`

   By default, the device does not send ICMPv6 destination unreachable messages.

Enabling sending ICMPv6 time exceeded messages

About this task

The device sends the source ICMPv6 time exceeded messages as follows:

- If a received packet is not destined for the device and its hop limit is 1, the device sends an ICMPv6 hop limit exceeded in transit message to the source.
- Upon receiving the first fragment of an IPv6 datagram destined for the device, the device starts a timer. If the timer expires before all fragments arrive, the device sends an ICMPv6 fragment reassembly time exceeded message to the source.

Restrictions and guidelines

If the device receives large numbers of malicious packets, its performance degrades greatly because it must send back ICMP time exceeded messages. To prevent such attacks, disable sending ICMPv6 time exceeded messages.

Procedure

1. Enter system view.

   `system-view`

2. Enable sending ICMPv6 time exceeded messages.

   `ipv6 hoplimit-expires enable`

   By default, sending ICMPv6 time exceeded messages is enabled.

Enabling sending ICMPv6 redirect messages

About this task

Upon receiving a packet from a host, the device sends an ICMPv6 redirect message to inform the host of a better next hop when the following conditions are met:

- The interface receiving the packet is the interface forwarding the packet.
- The selected route is not created or modified by any ICMPv6 redirect messages.
- The selected route is not a default route.
- The forwarded packet does not contain the routing extension header.

The ICMPv6 redirect feature simplifies host management by enabling hosts that hold few routes to optimize their routing table gradually. However, to avoid adding too many routes on hosts, this feature is disabled by default.

Procedure

1. Enter system view.
   system-view
2. Enable sending ICMPv6 redirect messages.
   ipv6 redirects enable
   By default, the device does not send ICMPv6 redirect messages.

Specifying the source address for unsolicited ICMPv6 packets

About this task

Perform this task to specify the source IPv6 address for outgoing ping echo requests and ICMPv6 error messages. It is a good practice to specify the IPv6 address of a loopback interface as the source IPv6 address. This feature helps users easily locate the sending device.

Restrictions and guidelines

For ICMPv6 echo requests, the source IPv6 address specified in the **ping ipv6** command has higher priority than the source IPv6 address specified in the **ipv6 icmpv6 source** command.

Procedure

1. Enter system view.
   system-view
2. Specify a source IPv6 address for unsolicited ICMPv6 packets.
   ipv6 icmpv6 source [**vpn-instance** *vpn-instance-name*] *ipv6-address*
   By default, no source address is specified for unsolicited ICMPv6 packets.

Specifying the source IPv6 address for outgoing ICMPv6 replies

About this task

To help receiver hosts identify sources of ICMPv6 replies, you can specify the IPv6 address of a loopback interface or a local interface as the source IPv6 address for ICMPv6 replies.

Procedure

1. Enter system view.
   system-view
2. Specify a source IPv6 address for ICMPv6 replies.
   ipv6 icmpv6 reply source [**vpn-instance** *vpn-instance-name*] { **address** *ipv6-address* | **interface** *interface-type* [*interface-number*] }
   By default, no source IP address is specified for outgoing ICMPv6 replies.

Enabling Layer 3 packet statistics collection

About this task

With this feature enabled on an interface, the device counts incoming and outgoing IPv6 packets on the interface. To display the collected statistics, execute the **display interface** command.

Restrictions and guidelines

When the interface is processing a large number of packets, Layer 3 packet statistics collection will cause high CPU usage and degrade the forwarding performance. If the statistics are not necessary, disable this feature to ensure the device performance.

Hardware and feature compatibility

The S5200-EI-G switch series does not support this feature.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable Layer 3 packet statistics collection.
   statistics l3-packet enable { **inbound** | **outbound** }
   By default, Layer 3 packet statistics collection is disabled.

Enabling IPv6 local fragment reassembly

About this task

By default, a subordinate in a multichassis IRF fabric delivers received packet fragments to the master for centralized fragment reassembly. To improve fragment reassembly efficiency, use this feature. When a subordinate receives fragments of an IPv6 packet, it reassembles them directly.

Restrictions and guidelines

Use this feature with caution, because fragment reassembly fails on a subordinate when the fragments of an IPv6 packet are received on different subordinates.

Procedure

1. Enter system view.
   system-view
2. Enable IPv6 local fragment reassembly.
   ipv6 reassemble local enable
   By default, IPv6 local fragment reassembly is disabled.

Enabling discarding IPv6 packets that contain extension headers

About this task

This feature enables a device to discard a received IPv6 packet in which the extension headers cannot be processed by the device.

Procedure

1. Enter system view
   system-view
2. Enable the device to discard IPv6 packets that contain extension headers.
   ipv6 extension-header drop enable

By default, the device does not discard IPv6 packets that contain extension headers.

Enabling IPv6 fast traffic migration

About this task

After IPv6 fast traffic migration is enabled on a VLAN interface, the device immediately steers IPv6 traffic forwarded through the VLAN interface to other forwarding paths upon network topology changes or user port migrations. This reduces traffic disruption time to improve overall network response speed and user experience.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable IPv6 fast traffic migration.
   ipv6 forwarding fast-move
   By default, IPv6 fast traffic migration is disabled.

Enabling IPv6 FIB entry consistency check

About this task

Packet drops or incorrect forwarding might occur when the IPv6 FIB entries in hardware are inconsistent with FIB entries configured in software. To prevent these issues, enable IPv6 FIB entry consistency check.

This feature compares all IPv6 FIB entries in software with the IPv6 FIB entries in hardware regularly. If the device detects an inconsistency, the device performs the following tasks:

- Generates a log.
- Updates the IPv6 FIB entry in hardware with the IPv6 FIB entry in software.

Procedure

1. Enter system view.
   system-view
2. Enable IPv6 FIB entry consistency check.
   ipv6 fib consistency-check enable
   By default, IPv6 FIB entry consistency check is disabled.

Enabling source MAC unknown IPv6 packets to trigger ND snooping

About this task

WLANs allow mobile clients to roam from one AP to another with their IPv6 addresses unchanged. The device might receive source MAC unknown packets from a client that has roamed to one of the APs attached to the device.

By default, the device learns the MAC address of an unknown packet, and then forwards the packet. However, it does not generate an ND entry. Packets returned to the client will be unable to reach the device.

To solve this issue, you can enable this feature to send an NS message out the interface on which a source MAC unknown IPv6 packet is received.

The NS message contains the following address information:

- The target IPv6 address is the source IPv6 address of the data packet.
- The destination IPv6 address is the IPv6 address of the multicast group to which the target IPv6 address belongs.
- The destination MAC address is the multicast MAC address for the multicast group.

When the device receives an NA message in response to the NS message, the AP generates an ND entry.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable source MAC unknown IPv6 packets to trigger ND snooping.

   ipv6 nd unknown-source-mac-probing enable

   By default, source MAC unknown IPv6 packets cannot trigger ND snooping.

Enabling HopLimit expiry alarm generation

About this task

NOTE:

A HopLimit expiry packet is an IP packet with a HopLimit value less than or equal to one.

When the device has a loop or is under HopLimit expiry attacks, it receives a large number of HopLimit expiry packets in a short period. The number of HopLimit expiry packets might grow exponentially. Processing those packets will occupy the resources used for processing service packets.

To avoid the above issue, use this feature to check for loops or HopLimit expiry attacks. The device periodically obtains the number of packet bytes with HopLimit expiry errors at the specified intervals. If the number of bytes in HopLimit expiry packets received during an interval equals or exceeds that during the previous interval multiplied by the specified alarm threshold, the device will generate a HopLimit expiry alarm. To have the device notify HopLimit expiry alarm clearance, specify the **no-drop-notify** keyword.

Procedure

1. Enter system view.

   system-view
2. Enable the device to generate HopLimit expiry alarms.

   ipv6 hoplimit-expired drop-rate alarm enable [**interval** *interval-value*] [**threshold** *threshold-value*] [**no-drop-notify** [**cycles** *resume-value*]]

   By default, the device supports generating HopLimit expiry alarms.

Enabling SNMP notifications for the IPv6 basics module

About this task

This feature enables the IPv6 basics module to generate SNMP notifications for critical events. The SNMP notifications will be sent to the SNMP module. For the SNMP notifications to be sent correctly, you must also configure SNMP. For more information about SNMP configuration, see SNMP configuration in *Network Management and Monitoring Configuration Guide*.

- If you specify the **interface-state-change** keyword, the IPv6 basics module will send SNMP notifications for IPv6 interface state changes. When an IPv6 interface has a state change, the device sends information about the interface and status of the interface in SNMP notifications to the SNMP module.
- If you specify the **protocol-enable-failure** keyword, the IPv6 basics module will send SNMP notifications for interface-level IPv6 enabling failures. When an IPv6 interface has an IPv6 enabling failure, the device sends the name, chassis number, and slot number of the interface in SNMP notifications to the SNMP module.

Restrictions and guidelines

To enable or disable all SNMP notifications for the IPv6 basics module, do not specify any parameters when you use the **snmp-agent trap enable ipv6 address** command.

After you disable SNMP notifications for the IPv6 basics module, the IPv6 basics module will not send any SNMP notifications to the SNMP module. The device can report the critical events of the IPv6 basics module only by sending log messages to the information center. For log messages to be sent correctly, configure the information center to set log message filtering and output rules, including output destinations. For information about the log destination and output rule configuration in the information center, see information center configuration in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for the IPv6 basics module.

   snmp-agent trap enable ipv6 address [**interface-state-change** | **protocol-enable-failure**] *

   By default, SNMP notifications are enabled for the IPv6 basics module.

   To enable all SNMP notifications for the IPv6 basics module, do not specify any parameters.

Enabling SNMP notifications for the IPv6 forwarding module

About this task

This feature enables the IPv6 forwarding module to generate SNMP notifications for critical events. The SNMP notifications are delivered to the SNMP module. For the SNMP notifications to be sent correctly, you must also configure SNMP. For more information about SNMP configuration, see SNMP configuration in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

system-view

2. Enable SNMP notifications for the IPv6 forwarding module.

   snmp-agent trap enable ipv6-forwarding

   By default, SNMP notifications are enabled for the IPv6 forwarding module.

Display and maintenance commands for IPv6 basics

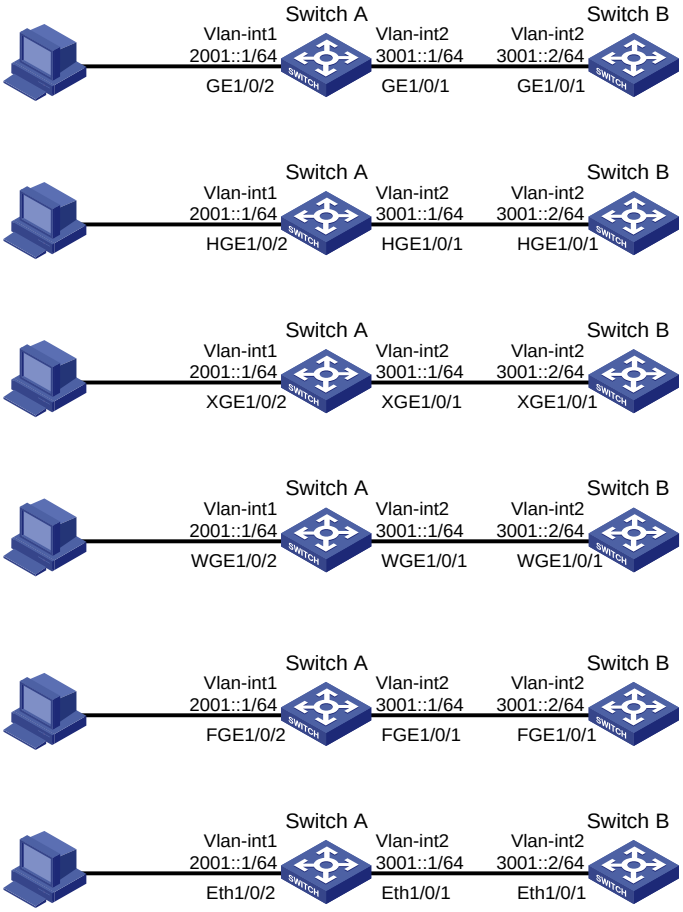
Execute **display** commands in any view and **reset** commands in user view.

For information about the **display tcp statistics**, **display udp statistics**, **reset tcp statistics**, and **reset udp statistics** command, see the IP performance commands in *Layer 3—IP Services Command Reference*.

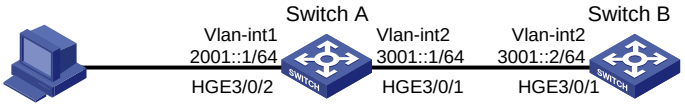
Task	Command
Display IPv6 FIB entries.	**display ipv6 fib** [**vpn-instance** *vpn-instance-name*] [*ipv6-address* [*prefix-length*]]
Display the IPv6 FIB table usage.	**display ipv6 fib usage**
Display ICMPv6 traffic statistics.	**display ipv6 icmp statistics** [**slot** *slot-number*]
Display IPv6 information about the interface.	**display ipv6 interface** [*interface-type* [*interface-number*]] [**brief** [**description**]]
Display IPv6 prefix information about the interface.	**display ipv6 interface** *interface-type interface-number* **prefix**
Display the IPv6 path MTU information.	**display ipv6 pathmtu** [**vpn-instance** *vpn-instance-name*] { *ipv6-address* | { **all** | **dynamic** | **static** } [**count**] }
Display the IPv6 prefix information.	**display ipv6 prefix** [*prefix-number*]
Display brief information about IPv6 RawIP connections.	**display ipv6 rawip** [**slot** *slot-number*]
Display detailed information about IPv6 RawIP connections.	**display ipv6 rawip verbose** [**slot** *slot-number* [**pcb** *pcb-index*]]
Display IPv6 and ICMPv6 packet statistics.	**display ipv6 statistics** [**slot** *slot-number*]
Display brief information about IPv6 TCP connections.	**display ipv6 tcp** [**slot** *slot-number*]
Display detailed information about IPv6 TCP connections.	**display ipv6 tcp verbose** [**slot** *slot-number* [**pcb** *pcb-index*]]
Display brief information about IPv6 UDP connections.	**display ipv6 udp** [**slot** *slot-number*]
Display detailed information about IPv6 UDP connections.	**display ipv6 udp verbose** [**slot** *slot-number* [**pcb** *pcb-index*]]
Display IPv6 TCP traffic statistics.	**display tcp statistics** [**slot** *slot-number*]

Task	Command
Display IPv6 UDP traffic statistics.	**display udp statistics** [**slot** *slot-number*]
Clear path MTUs.	**reset ipv6 pathmtu** { **all** | **dynamic** | **static** }
Clear IPv6 and ICMPv6 packet statistics.	**reset ipv6 statistics** [**slot** *slot-number*]
Clear IPv6 TCP traffic statistics.	**reset tcp statistics**
Clear IPv6 UDP traffic statistics.	**reset udp statistics**

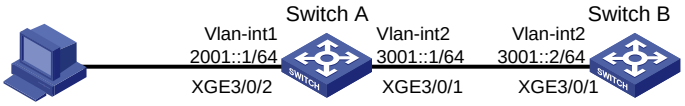
Basic IPv6 settings configuration examples



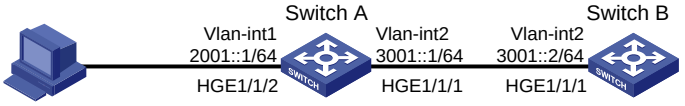
Example: Configuring basic IPv6 settings



Network configuration



As shown in Figure 4, a host, Switch A, and Switch B are connected through Ethernet ports. Add the Ethernet ports to corresponding VLANs. Configure IPv6 addresses for the VLAN interfaces and verify that they are connected. Switch B can reach the host.



Enable IPv6 on the host to automatically obtain an IPv6 address through IPv6 ND.

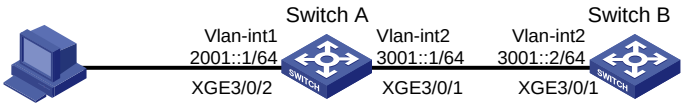


Figure 4 Network diagram

Procedure

This example assumes that the VLAN interfaces have been created on the switches.

1. Configure Switch A:

Specify a global unicast address for VLAN-interface 2.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ipv6 address 3001::1/64
[SwitchA-Vlan-interface2] quit
```

Specify a global unicast address for VLAN-interface 1, and allow it to advertise RA messages (no interface advertises RA messages by default).

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ipv6 address 2001::1/64
[SwitchA-Vlan-interface1] undo ipv6 nd ra halt
[SwitchA-Vlan-interface1] quit
```

2. Configure Switch B:

Configure a global unicast address for VLAN-interface 2.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ipv6 address 3001::2/64
[SwitchB-Vlan-interface2] quit
```

Configure an IPv6 static route with destination IPv6 address 2001::/64 and next hop address 3001::1.

```
[SwitchB] ipv6 route-static 2001:: 64 3001::1
```

3. Configure the host:

Enable IPv6 for the host to automatically obtain an IPv6 address through IPv6 ND.

Display neighbor information for GigabitEthernet 1/0/2 on Switch A.

```
[SwitchA] display ipv6 neighbors interface gigabitethernet 1/0/2
Type: S-Static    D-Dynamic    O-Openflow     R-Rule    IS-Invalid static

2001::15B:E0EA:3524:E791  0015-e9a6-7d14 1          GE1/0/2       STALE D  1248
FE80::215:E9FF:FEA6:7D14  0015-e9a6-7d14 1          XGE3/0/2      STALE D  1238
2001::15B:E0EA:3524:E791  0015-e9a6-7d14 1          XGE3/0/2      STALE D  1248
FE80::215:E9FF:FEA6:7D14  0015-e9a6-7d14 1          XGE3/0/2      STALE D  1238
2001::15B:E0EA:3524:E791  0015-e9a6-7d14 1          XGE3/0/2      STALE D  1248
```

The output shows that the IPv6 global unicast address that Host obtained is 2001::15B:E0EA:3524:E791.

Verifying the configuration

Display the IPv6 interface settings on Switch A. All IPv6 global unicast addresses configured on the interface are displayed.

```
[SwitchA] display ipv6 interface vlan-interface 2
Vlan-interface2 current state: UP
Line protocol current state: UP
IPv6 is enabled, link-local address is FE80::20F:E2FF:FE00:2
  Global unicast address(es):
    3001::1, subnet is 3001::/64
  Joined group address(es):
    FF02::1
    FF02::2
    FF02::1:FF00:1
    FF02::1:FF00:2
  MTU is 1500 bytes
  ND DAD is enabled, number of DAD attempts: 1
  ND reachable time is 1200000 milliseconds
  ND retransmit interval is 1000 milliseconds
  Hosts use stateless autoconfig for addresses
IPv6 Packet statistics:
  InReceives:                   25829
  InTooShorts:                  0

Ping Switch A and Switch B on the host, and ping Switch A and the host on Switch B to verify that they are connected.

NOTE:

When you ping a link-local address, use the **-i** parameter to specify an interface for the link-local address.

```
[SwitchB] ping ipv6 -c 1 3001::1
Ping6(56 data bytes) 3001::2 --> 3001::1, press CTRL+C to break
56 bytes from 3001::1, icmp_seq=0 hlim=64 time=4.404 ms

--- Ping6 statistics for 3001::1 ---
1 packet(s) transmitted, 1 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 4.404/4.404/4.404/0.000 ms
[SwitchB] ping ipv6 -c 1 2001::15B:E0EA:3524:E791
Ping6(56 data bytes) 3001::2 --> 2001::15B:E0EA:3524:E791, press CTRL+C to break
56 bytes from 2001::15B:E0EA:3524:E791, icmp_seq=0 hlim=64 time=5.404 ms

--- Ping6 statistics for 2001::15B:E0EA:3524:E791 ---
1 packet(s) transmitted, 1 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 5.404/5.404/5.404/0.000 ms
```

The output shows that Switch B can ping Switch A and the host. The host can also ping Switch B and Switch A.

Configuring IPv6 neighbor discovery

About IPv6 neighbor discovery

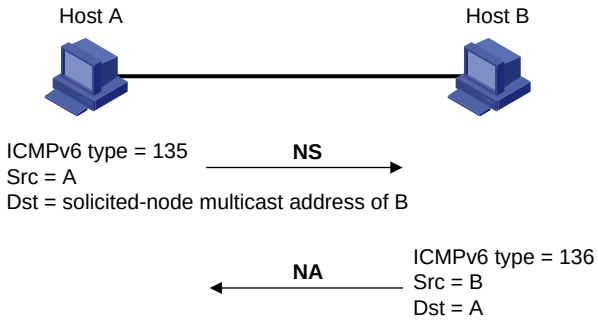
ICMPv6 messages used by IPv6 neighbor discovery

The IPv6 neighbor discovery (ND) process uses ICMP messages for address resolution, neighbor reachability verification, and neighboring device tracking.

Table 3 describes the ICMPv6 messages used by the IPv6 ND protocol.

Table 3 ICMPv6 messages used by ND

ICMPv6 message	Type	Function
Neighbor Solicitation (NS)	135	Acquires the link-layer address of a neighbor on the local link.
		Verifies the reachability of a neighbor.
		Detects duplicate addresses.
Neighbor Advertisement (NA)	136	Responds to an NS message.
		Notifies the neighboring nodes of link layer changes.
Router Solicitation (RS)	133	Requests an address prefix and other configuration information for autoconfiguration after startup.
Router Advertisement (RA)	134	Responds to an RS message.
		Advertises information, such as the Prefix Information options and flag bits.
Redirect	137	Informs the source host of a better next hop on the path to a particular destination when certain conditions are met.



Address resolution

This function is similar to ARP in IPv4. An IPv6 node acquires the link-layer addresses of neighboring nodes on the same link through NS and NA messages.

Figure 5 shows how Host A acquires the link-layer address of Host B on the same link. The address resolution procedure is as follows:

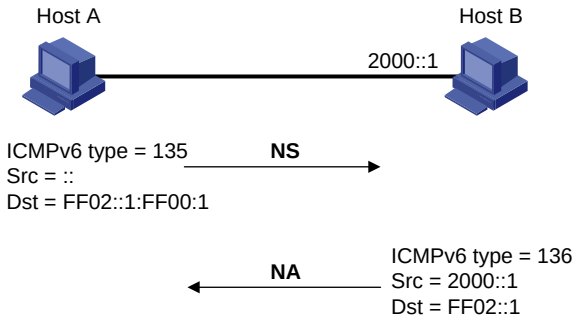
1. Host A multicasts an NS message. The source address of the NS message is the IPv6 address of the sending interface of Host A. The destination address is the solicited-node multicast address of Host B. The NS message body contains the link-layer address of Host A and the target IPv6 address.
2. After receiving the NS message, Host B determines whether the target address of the packet is its IPv6 address. If it is, Host B learns the link-layer address of Host A, and then unicasts an NA message containing its link-layer address.
3. Host A acquires the link-layer address of Host B from the NA message.

Figure 5 Address resolution

Neighbor reachability detection

After Host A acquires the link-layer address of its neighbor Host B, Host A can use NS and NA messages to test the reachability of Host B as follows:

1. Host A sends an NS message whose destination address is the IPv6 address of Host B.
2. If Host A receives an NA message from Host B, Host A decides that Host B is reachable. Otherwise, Host B is unreachable.



Duplicate address detection

After Host A acquires an IPv6 address, it performs Duplicate Address Detection (DAD) to check whether the address is being used by any other node. This is similar to gratuitous ARP in IPv4. DAD is accomplished through NS and NA messages.

The DAD procedure is as follows:

1. Host A sends an NS message. The source address is the unspecified address and the destination address is the corresponding solicited-node multicast address of the IPv6 address to be detected. The NS message body contains the detected IPv6 address.
2. If Host B uses this IPv6 address, Host B returns an NA message that contains its IPv6 address.
3. Host A knows that the IPv6 address is being used by Host B after receiving the NA message from Host B. If receiving no NA message, Host A decides that the IPv6 address is not in use and uses this address.

Figure 6 Duplicate address detection

Router/prefix discovery and stateless address autoconfiguration

Router/prefix discovery allows an IPv6 node to find the neighboring routers and learn the prefix and network configuration parameters of the network from receiving RA messages.

Stateless address autoconfiguration allows an IPv6 node to automatically generate an IPv6 address based on the information learned through router/prefix discovery.

A node performs router/prefix discovery and stateless address autoconfiguration as follows:

1. At startup, a node sends an RS message to request configuration information from a router.
2. The router returns an RA message containing the Prefix Information option and other configuration information. (The router also periodically sends an RA message.)
3. The node automatically generates an IPv6 address and other configuration parameters according to the configuration information in the RA message.

The Prefix Information option contains an address prefix and the preferred lifetime and valid lifetime of the address prefix. A node updates the preferred lifetime and valid lifetime upon receiving a periodic RA message.

The generated IPv6 address is valid within the valid lifetime and becomes invalid when the valid lifetime expires.

After the preferred lifetime expires, the node cannot use the generated IPv6 address to establish new connections, but can receive packets destined for the IPv6 address. The preferred lifetime cannot be greater than the valid lifetime.

Redirection

Upon receiving a packet from a host, the gateway sends an ICMPv6 redirect message to inform the host of a better next hop when the following conditions are met:

- The interface receiving the packet is the same as the interface forwarding the packet.
- The selected route is not created or modified by an ICMPv6 redirect message.
- The selected route is not a default route on the device.
- The forwarded IPv6 packet does not contain the routing extension header.

Protocols and standards

- RFC 4861, *Neighbor Discovery for IP Version 6 (IPv6)*
- RFC 8106, *IPv6 Router Advertisement Options for DNS Configuration*

IPv6 neighbor discovery tasks at a glance

All IPv6 neighbor discovery tasks are optional.

- Configuring ND entry related features
  - Configuring a static neighbor entry
  - Setting the dynamic neighbor learning limit
  - Enabling unsolicited NA learning
  - Setting the aging timer for ND entries in stale state
  - Setting ND entry probing parameters
  - Minimizing link-local ND entries

- Setting the hop limit
- Configuring RA message sending and parameters
- Setting the maximum number of attempts to send an NS message for DAD
- Enabling duplicate address detection
- Configuring ND snooping
  - Configuring ND snooping in a VLAN
- Enabling ND proxy
- Configuring IPv6 ND direct route advertisement
- Enabling ND direct route advertisement for single-homing interfaces in M-LAG MAD DOWN state
- Adding prefix information advertised through RA messages to IPSG binding entries
- Configuring user information recording
  - Enabling recording user IPv6 address conflicts
  - Enabling recording user port migrations
  - Enabling ND logging for user online and offline events
- Logging ND entry deployment events
- Enabling ND entry consistency check
- Disabling the device from aging or deleting ND entries in response to network topology changes
- Enabling recording ND entry learning events
- Disabling sending NS messages when data packets trigger ND resolution
- Performing ND-ping

Configuring a static neighbor entry

About this task

A neighbor entry stores information about a link-local node. The entry can be created dynamically through NS and NA messages, or configured statically.

The device uniquely identifies a static neighbor entry by using the neighbor's IPv6 address and the number of the Layer 3 interface that connects to the neighbor. You can configure a static neighbor entry by using one of the following methods:

- **Method 1**—Associate a neighbor's IPv6 address and link-layer address with the local Layer 3 interface.
- **Method 2**—Associate a neighbor's IPv6 address and link-layer address with a Layer 2 port in a VLAN.

Restrictions and guidelines

To configure a static neighbor entry for a VLAN interface, use Method 1 or Method 2.

- If you use Method 1, the device is required to resolve the Layer 2 port in the related VLAN.
- If you use Method 2, make sure the Layer 2 port belongs to the specified VLAN and the corresponding VLAN interface already exists. After the configuration, the device associates the VLAN interface with the neighbor IPv6 address to identify the static neighbor entry.

To delete a static neighbor entry for a VLAN interface, specify only the VLAN interface.

You can use the **`undo ipv6 neighbor`** command to delete both static and dynamic neighbor entries.

Procedure

1. Enter system view.

   system-view

2. Configure a static neighbor entry.

   ipv6 neighbor *ipv6-address mac-address* { *vlan-id port-type port-number* | **interface** *interface-type interface-number* } [**vpn-instance** *vpn-instance-name*]

   By default, no static neighbor entries exist.

Setting the dynamic neighbor learning limit

About this task

The device can dynamically acquire the link-layer address of a neighboring node through NS and NA messages and add it into the neighbor table. A large neighbor table degrades the forwarding performance. To avoid excessive resource consumption by neighbor entries, use one of the following methods:

- Set the maximum number of dynamic neighbor entries that an interface can learn. When the number of dynamic neighbor entries reaches the limit, the interface stops learning neighbor information.
- Set the maximum number of dynamic neighbor entries that the device can learn. When the number of dynamic neighbor entries reaches the limit, the device stops learning neighbor information.

The number of dynamic neighbor entries learnt by the interfaces on a device cannot exceed the maximum number of dynamic neighbor entries that the device can learn.

Setting the maximum number of dynamic neighbor entries on an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the dynamic neighbor learning limit on the interface.

   ipv6 neighbors max-learning-num *max-number*

   By default, an interface can learn a maximum of 12288 dynamic neighbor entries.

Setting the maximum number of dynamic neighbor entries on the device

1. Enter system view.

   system-view

2. Set the dynamic neighbor learning limit on the device.

   ipv6 neighbors max-learning-number *max-number* **slot** *slot-number* [**cpu** *cpu-number*]

   By default, the device can learn a maximum of 12288 dynamic neighbor entries.

   To disable the device from learning dynamic neighbor entries, set the value for the *max-number* argument to 0.

Enabling unsolicited NA learning

About this task

On some networks, a server multicasts NA messages to two peer devices for link backup. The peer devices cannot learn ND entry for the server from these NA messages by default. If no ND learning is triggered by data exchange between the server and peer devices, the peer devices learn the entry for the server only when the server unicasts messages to them.

This feature enables an interface to learn ND entries from unsolicited NA messages. The ND entries generated by using this method are in stale state.

Restrictions and guidelines

To ensure that the device learns ND entries from trusted NA messages, enable this feature only on a secure network.

This feature might cause the device to learn excessive ND entries that consume too many system resources. As a best practice, execute the **ipv6 neighbor stale-aging** command to set a smaller aging timer before you enable this feature. The smaller aging timer accelerates the aging of ND entries in stale state.

This feature is available only on Layer 3 interfaces.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Enable unsolicited NA learning.
   ipv6 nd unsolicited-na-learning enable
   By default, unsolicited NA learning is disabled.

Setting the aging timer for ND entries in stale state

About this task

ND entries in stale state have an aging timer. If an ND entry in stale state is not refreshed before the timer expires, the ND entry changes to the delay state. If it is still not refreshed in 5 seconds, the ND entry changes to the probe state, and the device sends an NS message three times. If no response is received, the device deletes the ND entry.

Restrictions and guidelines

You can set the aging timer for ND entries in stale state in system view and interface view. For ND entries in stale state on an interface, the aging timer in interface view has higher priority than the aging timer in system view.

Procedure

1. Enter system view.
   system-view
2. Set the aging timer for ND entries in stale state.
   - Set the aging timer for ND entries in stale state in system view.
     ipv6 neighbor stale-aging { *aging-minutes* | **second** *aging-seconds* }
     The default setting is 240 minutes.
   - Execute the following commands in sequence to set the aging timer in interface view.

interface *interface-type interface-number*

ipv6 neighbor timer stale-aging { *aging-minutes* | **second** *aging-seconds* }

By default, the aging timer of ND entries in stale state is not configured on an interface. The aging timer is determined by the configuration of the **ipv6 neighbor stale-aging** command in system view.

Setting ND entry probing parameters

About this task

After an ND entry changes to PROBE state, the device sends an NS message to test the reachability of the neighbor in the ND entry. A maximum of three attempts is allowed by default. The device handles the ND entry as follows:

- If the device does not receive an NA message from the neighbor, it deletes the ND entry.
- If the device receives an NA message from the neighbor, it sets the ND entry state to REACHABLE.

Perform this task to set the maximum number of probes and the probe interval for ND entries.

Restrictions and guidelines

When you modify the probe count, the modification does not take effect on ND entries in PROBE state. Neighbor entries in DELAY state will adopt this setting when they enter into the PROBE state.

When you modify the probe interval, the modification takes effect immediately.

Procedure

1. Enter system view.

   system-view

   system-view

2. Set the maximum number of probes to test the reachability of neighbors in ND entries.

   ipv6 neighbor aging probe-count *count*

   By default, the device performs a maximum of three probes to test the reachability of neighbors in ND entries.

3. Set the interval for testing the reachability of neighbors in ND entries.

   ipv6 neighbor aging probe-interval *interval*

   By default, the interval for testing the reachability of neighbors in ND entries is the same as the interval for retransmitting an NS message.

Minimizing link-local ND entries

About this task

Perform this task to minimize link-local ND entries assigned to the hardware. Link-local ND entries refer to ND entries that contain link-local addresses.

By default, the device assigns all ND entries to the hardware. With this feature enabled, the newly learned link-local ND entries are not assigned to the hardware if the link-local addresses of the entries are not the next hops of any routes. This feature saves hardware resources.

This feature takes effect only on newly learned link-local ND entries.

Procedure

1. Enter system view.

system-view

2. Minimize link-local ND entries.
   ipv6 neighbor link-local minimize
   By default, the device assigns all ND entries to the hardware.

Setting the hop limit

About this task

You can set the hop limit value to fill in the Hop Limit field for IPv6 packets to be sent.

Procedure

1. Enter system view.
   system-view
2. Set the value for the Hop Limit field in the IP header.
   ipv6 hop-limit *value*
   The default setting is 64.

Configuring RA message sending and parameters

About RA message parameters

You can enable an interface to send RA messages, and configure the interval for sending RA messages and parameters in RA messages. After receiving an RA message, a host can use these parameters to perform corresponding operations. Table 4 describes the configurable parameters in an RA message.

Table 4 Parameters in an RA message and their descriptions

Parameter	Description
Hop Limit	Maximum number of hops in RA messages. A host receiving the RA message fills the value in the Hop Limit field of sent IPv6 packets.
Prefix information	After receiving the prefix information, the hosts on the same link can perform stateless autoconfiguration.
MTU	Guarantees that all nodes on the link use the same MTU.
Boot file URL	Specifies the URL address for downloading the boot file in RA messages. The device can use the ND protocol to obtain both the IPv6 address and the boot file URL for automatic configuration instead of using DHCPv6.
M flag	Determines whether a host uses stateful autoconfiguration to obtain an IPv6 address. If the M flag is set to 1, the host uses stateful autoconfiguration (for example, from a DHCPv6 server) to obtain an IPv6 address. Otherwise, the host uses stateless autoconfiguration to generate an IPv6 address according to its link-layer address and the prefix information in the RA message.
O flag	Determines whether a host uses stateful autoconfiguration to obtain configuration information other than the IPv6 address. If the O flag is set to 1, the host uses stateful autoconfiguration (for example, from a DHCPv6 server) to obtain configuration information other than the IPv6 address. Otherwise, the host uses stateless autoconfiguration.
Router Lifetime	Tells the receiving hosts how long the advertising router can live. If the lifetime of

Parameter	Description
	a router is 0, the router cannot be used as the default gateway.
Retrans Timer	If the device does not receive a response message within the specified time after sending an NS message, it retransmits the NS message.
Reachable Time	If the neighbor reachability detection shows that a neighbor is reachable, the device considers the neighbor reachable within the specified reachable time. If the device needs to send a packet to the neighbor after the specified reachable time expires, the device reconfirms whether the neighbor is reachable.
Router Preference	Specifies the router preference in an RA message. A host selects a router as the default gateway according to the router preference. If router preferences are the same, the host selects the router from which the first RA message is received.
DNS server option	DNS server information for IPv6 hosts. Hosts can obtain DNS server information from received RA messages instead of using DHCPv6.
DNS suffix information in DNS Search List (DNSSL) option	DNS suffix information for IPv6 hosts. Hosts can obtain DNS suffix information from received RA messages instead of using DHCPv6.

Restrictions and guidelines

The maximum interval for sending RA messages should be less than (or equal to) the router lifetime in RA messages. In this way, the router can be updated by an RA message before expiration.

The values of the NS retransmission timer and the reachable time configured for an interface are sent in RA messages to hosts. This interface sends NS messages at the interval of the NS retransmission timer and considers a neighbor reachable within the reachable time.

Enabling the sending of RA messages

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable the sending of RA messages.

   undo ipv6 nd ra halt

   The default setting is disabled.
4. Set the maximum and minimum intervals for sending RA messages.

   ipv6 nd ra interval *max-interval min-interval*

   By default, the maximum interval for sending RA messages is 600 seconds, and the minimum interval is 200 seconds.

   The device sends RA messages at random intervals between the maximum interval and the minimum interval.

   The minimum interval should be less than or equal to 0.75 times the maximum interval.

Configuring parameters for RA messages

1. Enter system view.

   system-view
2. Enter interface view.

interface *interface-type interface-number*

3. Configure the prefix information in RA messages.

   ipv6 nd ra prefix { *ipv6-prefix prefix-length* | *ipv6-prefix*/*prefix-length* } [*valid-lifetime preferred-lifetime* [**no-autoconfig** | **off-link** | **prefix-preference** *level*] * | **no-advertise**]

   By default, no prefix information is configured for RA messages, and the IPv6 address of the interface sending RA messages is used as the prefix information. If the IPv6 address is manually configured, the prefix uses a fixed valid lifetime of 2592000 seconds (30 days) and a preferred lifetime of 604800 seconds (7 days). If the IPv6 address is automatically obtained, the prefix uses the valid lifetime and preferred lifetime configured for the IPv6 address.

4. Configure the default settings for prefixes advertised in RA messages.

   ipv6 nd ra prefix default [*valid-lifetime preferred-lifetime* [**no-autoconfig** | **off-link**] * | **no-advertise**]

   By default, no default settings are configured for prefixes advertised in RA messages.

5. Turn off the MTU option in RA messages.

   ipv6 nd ra no-advlinkmtu

   By default, RA messages contain the MTU option.

6. Specify unlimited hops in RA messages.

   ipv6 nd ra hop-limit unspecified

   By default, the maximum number of hops in RA messages is 64.

7. Specify the URL of the boot file in RA messages.

   ipv6 nd ra boot-file-url *url-string*

   By default, RA messages do not contain the URL of the boot file.

8. Set the M flag bit to 1.

   ipv6 nd autoconfig managed-address-flag

   By default, the M flag bit is set to 0 in RA advertisements. Hosts receiving the advertisements will obtain IPv6 addresses through stateless autoconfiguration.

9. Set the O flag bit to 1.

   ipv6 nd autoconfig other-flag

   By default, the O flag bit is set to 0 in RA advertisements. Hosts receiving the advertisements will acquire other configuration information through stateless autoconfiguration.

10. Set the router lifetime in RA messages.

    ipv6 nd ra router-lifetime *time*

    By default, the router lifetime is three times as long as the maximum interval for advertising RA messages.

11. Set the NS retransmission timer.

    ipv6 nd ns retrans-timer *value*

    By default, an interface sends NS messages every 1000 milliseconds, and the value of the Retrans Timer field in RA messages is 0.

12. Set the router preference in RA messages.

    ipv6 nd router-preference { **high** | **low** | **medium** }

    By default, the router preference is medium.

13. Set the reachable time.

    ipv6 nd nud reachable-time *time*

    By default, the neighbor reachable time is 1200000 milliseconds, and the value of the Reachable Time field in sent RA messages is 0.

Specifying DNS server information in RA messages

About this task

The DNS server options in RA messages provide DNS server information for IPv6 hosts. The RA messages allow hosts to obtain their IPv6 addresses and the DNS server through stateless autoconfiguration. This method is useful in a network where DHCPv6 infrastructure is not provided.

One DNS server option contains one DNS server. All DNS server options are sorted in ascending order of the DNS server sequence number.

After you execute the **ipv6 nd ra dns server** command, the device immediately sends an RA message with the existing and newly specified DNS server information.

After you execute the **undo ipv6 nd ra dns server** command, the device immediately sends two RA messages.

- The first RA message contains information about all DNS servers, including the DNS servers specified in the **undo** command with their lifetime set to 0 seconds.
- The second RA message contains information about remaining DNS servers.

Each time the device sends an RA message from an interface, it immediately refreshes the RA message advertisement interval for that interface.

Restrictions and guidelines

You can configure a maximum of eight DNS servers on an interface.

The default lifetime of a DNS server is three times the maximum interval for advertising RA messages. To set the maximum interval, use the **ipv6 nd ra interval** command.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Specify DNS server information to be advertised in RA messages.

   ipv6 nd ra dns server *ipv6-address* [*seconds* | **infinite**] **sequence** *seqno*

   By default, no DNS server information is specified and RA messages do not contain DNS server options.

Specifying DNS suffix information in RA messages

About this task

The DNSSL option in RA messages provides suffix information for IPv6 hosts. The RA messages allow hosts to obtain their IPv6 addresses and the DNS suffix through stateless autoconfiguration. This method is useful in a network where DHCPv6 infrastructure is not provided.

One DNSSL option contains one DNS suffix. All DNSSL options are sorted in ascending order of the sequence number of the DNS suffix.

After you execute the **ipv6 nd ra dns search-list** command, the device immediately sends an RA message with the existing and newly specified DNS suffix information.

After you execute the **undo ipv6 nd ra dns search-list** command, the device immediately sends two RA messages.

- The first RA message contains information about all DNS suffixes, including DNS suffixes specified in the **undo** command with their lifetime set to 0 seconds.
- The second RA message contains information about remaining DNS suffixes.

Each time the device sends an RA message from an interface, it immediately refreshes the RA message advertisement interval for that interface.

Restrictions and guidelines

You can configure a maximum of eight DNS suffixes on an interface.

The default lifetime of a DNS suffix is three times the maximum interval for advertising RA messages. To set the maximum interval, use the **ipv6 nd ra interval** command.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Specify DNS suffix information to be advertised in RA messages.

   ipv6 nd ra dns search-list *domain-name* [*seconds* | **infinite**] **sequence** *seqno*

   By default, no DNS suffix information is specified and RA messages do not contain DNS suffix options.

Suppressing advertising DNS information in RA messages

About this task

Perform this task to suppress the device from advertising information about DNS server addresses and DNS suffixes in RA messages.

Whether enabling this feature on an interface will trigger sending RA message immediately depends on the interface configuration:

- If the interface has DNS server information configured or has obtained an AAA-authorized DNS server address, the device immediately sends two RA messages. In the first message, the lifetime for DNS server addresses is 0 seconds. The second RA message does not contain any DNS server options.
- If the interface has no DNS server information specified or no AAA-authorized DNS server address assigned, no RA messages are triggered.

If you specify a new DNS server or remove a DNS server on the interface after enabling DNS server suppression, the device immediately sends an RA message without any DNS server options.

Whether disabling this feature on an interface will trigger sending RA message immediately depends on the interface configuration:

- If the interface has DNS server information configured or has obtained an AAA-authorized DNS server address, the device immediately sends an RA message containing the DNS server information.
- If the interface has no DNS server information specified or no AAA-authorized DNS server address assigned, no RA messages are triggered.

Each time the device sends an RA message from an interface, it immediately refreshes the RA message advertisement interval for that interface.

The same suppression mechanism applies when you enable or disable DNS suffix suppression in RA messages.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable DNS server suppression in RA messages.
   ipv6 nd ra dns server suppress
   By default, DNS server suppression in RA messages is disabled.
4. Enable DNS suffix suppression in RA messages.
   ipv6 nd ra dns search-list suppress
   By default, DNS suffix suppression in RA messages is disabled.

Setting the maximum number of attempts to send an NS message for DAD

About this task

An interface sends an NS message for DAD for an obtained IPv6 address. The interface resends the NS message if it does not receive a response within the time specified by the **ipv6 nd ns retrans-timer** command. If the interface receives no response after making the maximum attempts specified by the **ipv6 nd dad attempts** command, the interface uses the IPv6 address.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the number of attempts to send an NS message for DAD.
   ipv6 nd dad attempts *times*
   The default setting is 1. When the *times* argument is set to 0, DAD is disabled.

Enabling duplicate address detection

About this task

If the device detects that an IPv6 address on an interface has been used on the network, the device marks that IPv6 address as duplicate. The interface cannot use the address for communication.

By default, an interface does not perform duplicate address detection. Once an IPv6 address is marked as duplicate on an interface, it will be unusable even after it becomes unique on the link later.

To resolve this issue, enable duplicate address detection. This feature sends NS messages to the duplicate address at random intervals until it does not receive an NA response message from that address or until duplicate detection is disabled for duplicate addresses. For more information about the detection process, see "Duplicate address detection."

You can set the maximum duplicate detection interval for duplicate addresses. After the device marks a detected address as duplicate, it waits for a random amount of time between 1 and the maximum detection interval. Then, the device resends an NS message to the solicited-node multicast address of the duplicate address. This mechanism helps reduce the risk of congestion that results from the NS messages sent for duplicate detection.

Procedure

1. Enter system view.
   system-view
2. Enable duplicate address detection.
   ipv6 address duplicate-detect enable
   By default, duplicate address detection is disabled.
3. (Optional.) Set the maximum duplicate detection interval for duplicate addresses.
   ipv6 address duplicate-detect interval *interval*
   The default maximum interval is 5 seconds.

Configuring ND snooping in a VLAN

About ND snooping in a VLAN

The ND snooping feature is used in Layer 2 switching networks. It learns the source MAC addresses, source IPv6 addresses, input interfaces, and VLANs of arriving ND messages and data packets to build the ND snooping table.

ND snooping entries can be used by ND detection to prevent spoofing attacks.

ND detection processes the ND messages received on ND trusted and untrusted interfaces as follows:

- ND detection forwards all ND messages received on an ND trusted interface.
- ND detection compares all ND messages received on an ND untrusted interface with the ND snooping entries except for RA and redirect messages.

You can use the **ipv6 nd detection trust** command to specify a Layer 2 Ethernet or aggregate port as an ND trusted interface. For more information about the **ipv6 nd detection trust** command, see *Security Command Reference*.

ND snooping entries can be used by IPv6 source guard to prevent spoofing attacks. For more information about IPv6 source guard, see *Security Configuration Guide*.

ND snooping provides device liveness tracking so that the ND snooping table can be updated in a timely manner. After ND snooping is enabled for a VLAN, the device uses the following mechanisms to create, update, and delete ND snooping entries. The following example uses ND messages for illustration.

Creation of ND snooping entries

Upon receiving an ND message or data packet from an unknown source, the device creates an ND snooping entry in INVALID status and performs DAD for the source IPv6 address. The device sends NS messages out of the ND trusted interfaces in the receiving VLAN twice. The sending interval is set by the **ipv6 nd snooping dad retrans-timer** command.

- If the device does not receive an NA message within the invalid entry lifetime (set by the **ipv6 nd snooping lifetime invalid** command), the entry becomes valid.
- If the device receives an NA message within the invalid entry lifetime, it deletes this entry.

Updating of ND snooping entries

When the ND untrusted interface that receives an ND message is different from that in the entry for an IPv6 address, the device performs DAD for the entry. It sends NS messages twice. The sending interval is set by the **ipv6 nd snooping dad retrans-timer** command.

- If the device does not receive an NA message within the invalid entry lifetime, it updates the entry with the new receiving interface.

- If the device receives an NA message within the invalid entry lifetime, the ND snooping entry remains unchanged.

Deletion of ND snooping entries

- When an ND trusted interface in the VLAN receives an ND message from the IPv6 address in a learned ND snooping entry, it performs DAD for the entry. The device sends NS messages twice. The sending interval is set by the **ipv6 nd snooping dad retrans-timer** command.
  - If the device does not receive an NA message within the invalid entry lifetime, it deletes the entry.
  - If the device receives an NA message within the invalid entry lifetime, the ND snooping entry remains unchanged.
- If an ND snooping entry has no matching ND messages within the valid entry lifetime (set by the **ipv6 nd snooping lifetime valid** command), the entry becomes invalid. The device then performs DAD for the entry by sending NS messages out of the interface in the entry. The device sends NS messages twice by default. You can use the **ipv6 nd snooping aging** command to set the sending interval and probe times.
  - If the device does not receive an NA message within the invalid entry lifetime, it deletes the entry.
  - If the device receives an NA message within the invalid entry lifetime, the ND snooping entry remains unchanged and becomes valid.

Enabling ND snooping

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable ND snooping for IPv6 addresses. Choose the options to configure as needed:
   - Enable ND snooping for global unicast addresses.
     ipv6 nd snooping enable global
   - Enable ND snooping for link-local addresses.
     ipv6 nd snooping enable link-local

   By default, ND snooping is disabled for IPv6 global unicast addresses and link-local addresses.
4. (Optional.) Enable ND snooping for data packets from unknown sources.
   ipv6 nd snooping glean source

   By default, ND snooping is disabled for data packets from unknown sources.

   After executing this command for a VLAN, you must configure IPv6 source guard on all untrusted interfaces in the VLAN to ensure correct forwarding of the data packets received on these interfaces.

Specifying an ACL for ND snooping entry filtering

About this task

ND snooping is used in networks deployed with a Layer 2 switch. The device creates ND snooping entries by listening to ND or IPv6 messages. To control network traffic and ensure the effective use of network resources, you can specify an ACL to filter ND snooping entries.

When the device creates an ND snooping entry, it matches the specified ACL against the source IPv6 address in the related ND or IPv6 message.

- If the source IPv6 address hits a permit rule in the ACL, the device continues to create that ND snooping entry.
- If the source IPv6 address cannot hit a permit rule in the ACL, the device does not create that ND snooping entry.

Restrictions and guidelines

After you specify a new ACL for ND snooping entry filtering in a VLAN, the device will match the new ACL against all existing ND snooping entries in that VLAN:

- If the source IPv6 address in an ND snooping entry hits a permit rule in the ACL, the device will retain the ND snooping entry.
- If the source IPv6 address in an ND snooping entry cannot hit a permit rule in the ACL, the device will mark the ND snooping entry stale and delete it immediately.
- If the ACL specified in a VLAN does not exist or does not have rules, the device will delete all ND snooping entries from that VLAN.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Specify an ACL for ND snooping entry filtering.
   ipv6 nd snooping match acl { *ipv6-acl-number* | **name** *ipv6-acl-name* }
   By default, no ACL is specified for ND snooping entry filtering.

Setting the ND snooping entry learning limit

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. (Optional.) Set the ND snooping entry learning limit on the interface.
   ipv6 nd snooping max-learning-num *max-number*
   By default, an interface can learn a maximum of 6144 ND snooping entries.

Configuring ND snooping entry related parameters

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. (Optional.) Configure the port as an ND snooping uplink port. The ND snooping uplink port cannot learn ND snooping entries.
   ipv6 nd snooping uplink
   By default, the port is not an ND snooping uplink port. After ND snooping is enabled, the port can learn ND snooping entries.
4. Return to system view.
   quit
5. (Optional.) Set timeout timers for ND snooping entries.

ipv6 nd snooping lifetime { **invalid** *invalid-lifetime* | **valid** *valid-lifetime* }

The default settings are as follows:

- The timeout timer for ND snooping entries in INVALID status (TENTATIVE, TESTING_TPLT, or TESTING_VP) is 500 milliseconds.
- The timeout timer for ND snooping entries in VALID status is 300 seconds.

6. (Optional.) Set the DAD NS message retransmission interval for ND snooping entry creation or update.

   ipv6 nd snooping dad retrans-timer *interval*

   The default value is 250 milliseconds.

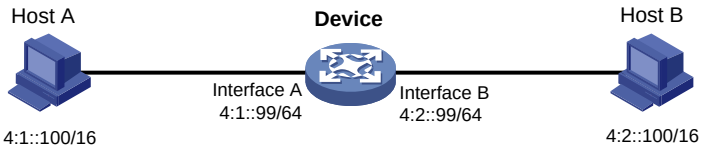
7. (Optional.) Set the probe times and interval for the device to send NS messages for aging ND snooping entries.

   ipv6 nd snooping aging { *probe-count count* | *probe-interval interval* }

   By default, the device sends two NS messages at an interval of 250 milliseconds for aging ND snooping entries.

Enabling ND proxy

About ND proxy



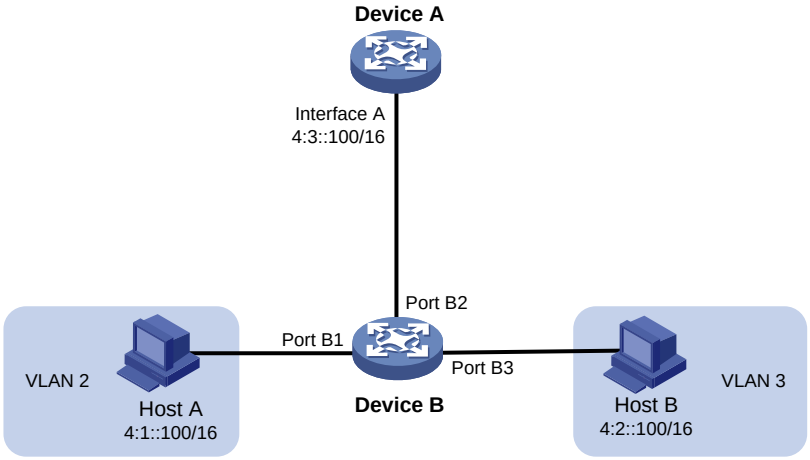
ND proxy enables a device to answer an NS message requesting the hardware address of a host on another network. With ND proxy, hosts in different broadcast domains can communicate with each other as they would on the same network.

ND proxy includes common ND proxy and local ND proxy.

Common ND proxy

As shown in Figure 7, Interface A with IPv6 address 4:1::99/64 and Interface B with IPv6 address 4:2::99/64 belong to different subnets. Host A and Host B reside on the same network but in different broadcast domains.

Figure 7 Application environment of ND proxy



Because Host A's IPv6 address is on the same subnet as Host B's, Host A directly sends an NS message to obtain Host B's MAC address. However, Host B cannot receive the NS message because they belong to different broadcast domains.

To solve this problem, enable common ND proxy on Interface A and Interface B of the device. The device replies to the NS message from Host A, and forwards packets from other hosts to Host B.

Local ND proxy

As shown in Figure 8, Host A belongs to VLAN 2 and Host B belongs to VLAN 3. Host A and Host B connect to Port B1 and Port B3, respectively.

Figure 8 Application environment of local ND proxy

Because Host A's IPv6 address is on the same subnet as Host B's, Host A directly sends an NS message to obtain Host B's MAC address. However, Host B cannot receive the NS message because they belong to different VLANs.

To solve this problem, enable local ND proxy on Interface A of Device A so that Device A can forward messages between Host A and Host B.

Local ND proxy implements Layer 3 communication for four hosts in the following cases:

Local ND proxy implements Layer 3 communication for two hosts in the following cases:

Local ND proxy implements Layer 3 communication for two hosts in the following cases:

- The two hosts connect to ports of the same device and the ports must be in different VLANs.
- The two hosts connect to isolated Layer 2 ports in the same isolation group of a VLAN.

Enabling common ND proxy

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
3. Enable common ND proxy.
   `proxy-nd enable`
   By default, common ND proxy is disabled.

Enabling local ND proxy

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
3. Enable local ND proxy.
   `local-proxy-nd enable`
   By default, local ND proxy is disabled.

Configuring IPv6 ND direct route advertisement

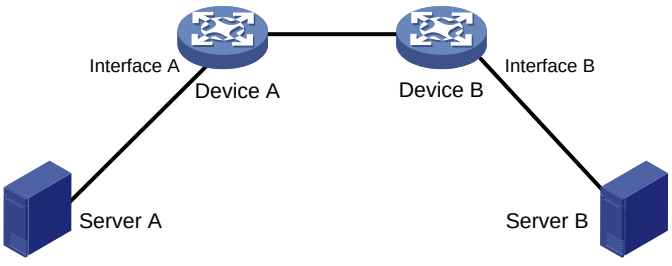
About IPv6 ND direct route advertisement

This feature generates 128-bit host routes based on ND entries for packet forwarding and route advertisement. The route preference value determines the match order of a route. Dynamic routing protocols use the tag value as the route identifier when redistributing the route.

After you enable this feature, the routing table might be populated with excessive host routes. To reduce the routing table size, execute the **ipv6 nd route-direct prefix convert-length** command for the device to generate network routes for identified ND entries instead of host routes.

After you enable ND direct route advertisement by using the **ipv6 nd route-direct advertise** command, the device uses ND entries to generate direct routes and adjacency entries. If the direct routes are generated earlier than the adjacency entries, packet loss will occur due to lack of Layer 2 information during packet encapsulation. To avoid such an issue, use the **ipv6 nd route-direct advertise delay** command to set the delay time for ND direct route generation.

After you enable ND direct route advertisement and set the delay time for ND direct route generation, the device starts a timer after it has learned an ND entry. Then, it generates an ND direct route when the timer value reaches the delay time. If you edit the direct route advertisement configuration within the delay time, the device immediately advertises the direct route with the new configuration.



Restrictions and guidelines

The **ipv6 nd route-direct advertise** command is mutually exclusive with the **ipv6 nd route-direct advertise mad-down-single-homed** command. If you execute both of them on the same interface, the most recent command takes effect.

Application in Layer 3 access networks

As shown in Figure 9, ND direct route advertisement is enabled on Interface A and Interface B. This feature generates a host route to Server A and a host route to Server B for the routing protocols to advertise. Therefore, each device forwards only the traffic destined to the server within the network, which saves bandwidth.

Figure 9 Application in a Layer 3 access network

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*

3. (Optional.) Set the delay time for ND direct route generation.

   ipv6 nd route-direct advertise delay *delay-time*

   By default, the device does not delay ND direct route generation.

4. Enable ND direct route advertisement.

   ipv6 nd route-direct advertise [**preference** *preference-value* | **tag** *tag-value*] *

   By default, ND direct route advertisement is disabled.

5. (Optional.) Specify a prefix length for generating a network route for identified ND entries.

   ipv6 nd route-direct prefix *ipv6-prefix prefix-length* **convert-length** *convert-length*

   By default, no prefix length is specified for generating a network route for identified ND entries, and the device generates 128-bit host routes based on ND entries.

   Make sure the IPv6 prefix is consistent with the prefix of the IPv6 address configured for the interface.

Enabling ND direct route advertisement for single-homing interfaces in M-LAG MAD DOWN state

About this task

If the peer link of an M-LAG system fails, M-LAG Multi-Active Detection (MAD) will shut down all interfaces on the secondary member device upon M-LAG system split, except for the interfaces excluded from the shutdown action by IRF MAD or M-LAG MAD. An interface in M-LAG MAD DOWN state cannot forward traffic. As a result, traffic cannot be forwarded for the devices single-homed to the secondary member device.

To ensure traffic forwarding for single-homed devices, enable ND direct route advertisement for single-homing interfaces in M-LAG MAD DOWN state. When the peer link fails, the ND module on the secondary member device will send ND entries to the routing management module, and the routing management module will generate direct routes based on the ND entries. The direct routes are used to direct traffic forwarding or are advertised by routing protocols to the single-homed devices.

Restrictions and guidelines

The **ipv6 nd route-direct advertise mad-down-single-homed** and **ipv6 nd route-direct advertise** commands are mutually exclusive. If you execute both of them on the same interface, the most recent command takes effect.

Procedure

1. Enter system view.

   system-view

2. Enter VLAN interface view.

   interface vlan-interface *interface-number*

3. Enable ND direct route advertisement for single-homing interfaces in M-LAG MAD DOWN state.

   ipv6 nd route-direct advertise mad-down-single-homed

   By default, ND direct route advertisement is disabled for single-homing interfaces in M-LAG MAD DOWN state.

Adding prefix information advertised through RA messages to IPSG binding entries

About this task

This feature enables a VLAN interface to add prefix information advertised through RA messages to IP Source Guard (IPSG) binding entries. IPSG can then filter incoming IPv6 packets by IPv6 prefix information in the related IPSG binding entries.

This feature also supports collaboration with the ND detection feature to validate access users.

Procedure

1. Enter system view.

   system-view

2. Enter VLAN interface view.

   interface vlan-interface *interface-number*

3. Add prefix information advertised through RA messages to IP Source Guard (IPSG) binding entries.

   ipv6 nd ra prefix source binding

   By default, the VLAN interface does not add prefix information advertised through RA messages to IPSG binding entries.

Enabling recording user IPv6 address conflicts

About this task

This feature detects and records user IPv6 address conflicts. A conflict occurs if an incoming NA packet has the same source IP address as an existing ND entry but a different source MAC address. The device generates a user IPv6 address conflict record, logs the conflict, and sends the log to the information center. For information about the log destination and output rule configuration in the information center, see the information center in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable recording user IPv6 address conflicts.

   ipv6 nd user-ip-conflict record enable

   By default, recording user IPv6 address conflicts is disabled.

Enabling recording user port migrations

About this task

This feature enables the device to detect and record user port migrations. A user port migrates if an incoming NA packet has the same source IPv6 address and source MAC address as an existing ND entry but a different ingress port. The device generates a user port migration record, logs the migration event, and sends the log to the information center. For information about the log destination and output rule configuration in the information center, see the information center in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enable recording user port migrations.
   ipv6 nd user-move record enable
   By default, recording user port migrations is disabled.

Enabling ND logging for user online and offline events

About this task

This feature enables the device to generate user online or offline logs upon such events and send these logs to the information center. For information about the log destination and output rule configuration in the information center, see the information center in *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

A higher log output rate consumes more CPU resources. Adjust the log output rate based the CPU performance and usage.

Procedure

1. Enter system view.
   system-view
2. Enable ND logging for user online and offline events.
   ipv6 nd online-offline-log enable [**rate** *rate*]
   By default, ND logging for user online and offline events is disabled.

Logging ND entry deployment events

About this task

After learning an ND entry, the device deploys that ND entry to hardware for packet forwarding. To record the events that occur during ND entry deployment to hardware, you can enable this feature. This feature enables the device to generate log messages for ND deployment events and deliver such log messages to the information center.

For log messages to be sent correctly, configure the information center to set log message filtering and output rules, including output destinations. For information about information center configuration, see information center configuration in *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

Log generation consumes memory resources. To save device memory, enable this feature only when you need to troubleshoot traffic forwarding issues.

If the number of log messages generated by the device per second reaches the limit, the device will not generate any log message for a new ND deployment event.

Procedure

1. Enter system view.
   system-view

2. Enable logging ND entry deployment events.
   ipv6 nd hardware log enable [**count-limit** *count-limit-value*]
   By default, the device does not log ND entry deployment events.

Enabling ND entry consistency check

About this task

Packet drops or incorrect forwarding might occur when the ND entries in hardware are inconsistent with ND entries configured in software. To prevent these issues, enable ND entry consistency check.

This feature compares all ND entries in software with the ND entries in hardware regularly. If the device detects an inconsistency, the device performs the following tasks:

- Generates a log.
- Updates the ND entry in hardware with the ND entry in software.

Procedure

1. Enter system view.
   system-view
2. Enable ND entry consistency check.
   ipv6 nd consistency-check enable
   By default, ND entry consistency check is disabled.

Disabling the device from aging or deleting ND entries in response to network topology changes

About this task

After you configure STP for the device in a tree-shaped network topology, the system notifies the ND module to age or delete the learned ND entries when the loop protocol detects a network topology change. Then, the device must learn ND entries again to obtain the latest ND entry information. If the network topology changes frequently, a large number of ND messages might occur when the device relearns ND entries, which occupies too many system resources and affects the normal operation of other services. To avoid such an issue, you can execute the **undo ipv6 nd topology-change enable** command. The device will not age or delete ND entries even if the network topology changes.

Restrictions and guidelines

After you execute the **undo ipv6 nd topology-change enable** command, the ND entries saved by the device might not be the latest ones, which causes user traffic interruption. As a best practice, use this command only when necessary.

Procedure

1. Enter system view.
   system-view
2. Disable the device from aging or deleting ND entries in response to network topology changes.
   undo ipv6 nd topology-change enable
   By default, the device ages or deletes ND entries in response to network topology changes.

Enabling recording ND entry learning events

About this task

An ND entry learning event occurs when the number of ND entries that an IRF member device or an interface has learnt exceeds the threshold or drops below the threshold.

After you enable this feature, the ND module logs ND entry learning events and sends them to the information center. For log messages to be sent correctly, configure the information center to set log message filtering and output rules, including output destinations. For information about the log destination and output rule configuration in the information center, see information center configuration in *Network Management and Monitoring Configuration Guide*.

If you enable ND entry limit notifications for the ND module, the device sends a notification to the SNMP module when the number of ND entries exceeds the alarm threshold. For ND entry limit notifications to be sent correctly, you must also configure SNMP on the device.

For more information about SNMP configuration, see SNMP configuration in *Network Management and Monitoring Configuration Guide*. For more information about ND entry limit notifications, see ND attack defense configuration in *Security Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`

2. (Optional.) Enable SNMP notifications for the ND module.

   `snmp-agent trap enable nd` [**`entry-limit`**]

   By default, SNMP notifications are disabled for the ND module.

   If you do not specify a keyword, this command enables all types of SNMP notifications for the ND module. If you specify the **`entry-limit`** keyword, this command enables only ND entry limit notifications for the ND module.

3. Enable recording ND entry learning events.

   `ipv6 nd entry-limit record enable`

   By default, the ND module does not record ND entry learning events.

Disabling sending NS messages when data packets trigger ND resolution

About this task

By default, when the device receives a data packet not destined for it and cannot find a match for the next hop in the ND table, it performs the following tasks:

1. Multicasts an NS message to obtain the MAC address of the next hop.
2. Generates an ND entry based on the obtained MAC address.

A large number of NS messages consume too many network resources, affecting normal service operation. To resolve the issue, use this command to disable the device from sending NS messages for ND entry learning when IPv6 data packets trigger ND resolution. This suppresses ND flooding by reducing ND packets on the network.

Restrictions and guidelines

With this feature configured on an interface, the device does not multicast an NS message for ND entry learning when the interface attempts to send a data packet that triggers ND resolution. As a best practice, configure this feature only when the network is under ND flood attacks.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Disable the device from sending NS messages for ND entry learning when IPv6 data packets trigger ND resolution.

   ipv6 nd fib-miss drop

   By default, the device sends NS messages for ND entry learning when IPv6 data packets trigger ND resolution.

Performing ND-ping

Using ND-ping to verify the availability of an IPv6 address

About this task

This feature allows users to verify if an IPv6 address is being used by another device in the LAN.

After you perform this task, the device sends an NS packet to the specified IPv6 address. If no NA packet is received within the timeout time, the device retransmits the NS packet. If no NA packet is received after the maximum number of transmission attempts is reached, the device considers that the IPv6 address is not being used.

You can also use the **ping ipv6** command to verify the IPv6 address availability. However, the test result might be inaccurate, because the peer device cannot respond if a firewall is configured to forbid the device from responding to ICMPv6 packets. Compared with ping operations, ND-ping uses Layer 2 packets (ND packets), which are not blocked by firewalls in most cases, and NS packets are shorter than ICMPv6 packets and require less network resources.

Prerequisites

To test the address availability by specifying a host name, configure DNS for the device to translate the host name to an IPv6 address. For more information about DNS, see "Configuring DNS."

Restrictions and guidelines

If multiple devices exist in the LAN, executing the **ping nd ipv6** command might take a long time. To stop the command execution, press **Ctrl+C**.

Procedure

Execute the command in any view to verify the availability of an IPv6 address in the LAN.

ping nd ipv6 *host* [**interface** *interface-type interface-number* [**vlan** *vlan-id*]] [**timeout** *timeout*] [**count** *count*]

Using ND-Ping to obtain the IPv6 address for a MAC address

About this task

Perform this task to obtain the IPv6 address of the device that uses the specified MAC address in a specific subnet.

After you perform this task, the device broadcasts a Layer 3 ICMPv6 packet. If no ICMPv6 response is received within the timeout time, the device resends the broadcast packet. If no ICMPv6 response is received after the number of maximum transmission attempts is received, the device considers that the MAC address does not exist in the subnet.

Restrictions and guidelines

If multiple devices exist in the subnet, executing the **ping nd mac** command might take a long time. To stop the command execution, press **Ctrl+C**.

Procedure

Execute the command in any view to obtain the IPv6 address of the device that uses the specified MAC address in a specific subnet.

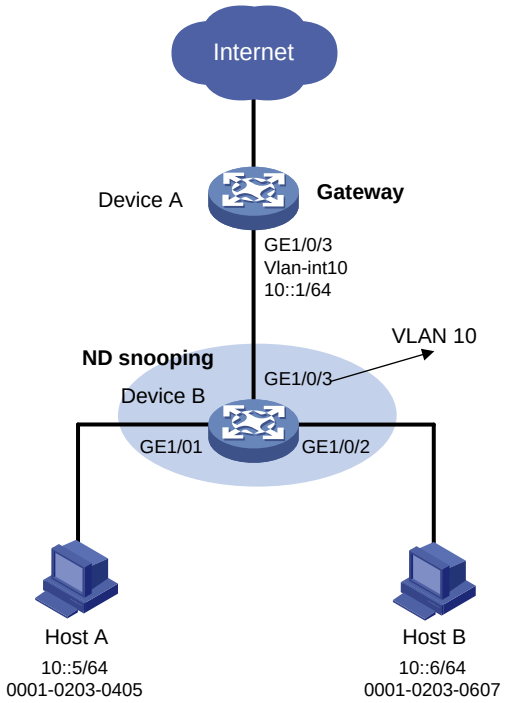
ping nd mac *mac-address* { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*] } [**timeout** *timeout*] [**count** *count*]

Display and maintenance commands for IPv6 ND

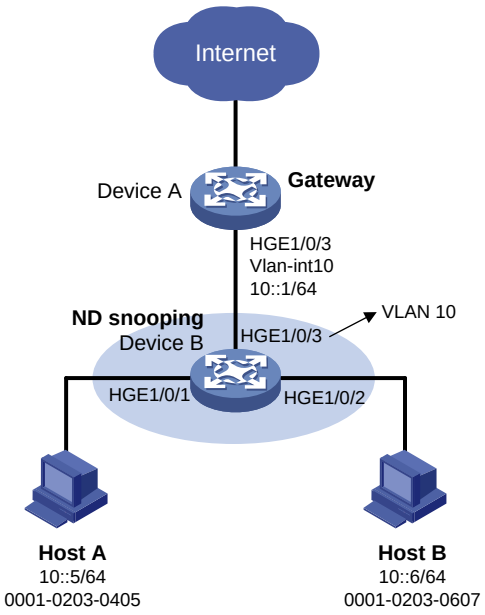
Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display statistics for ND proxy reply packets.	**display ipv6 nd proxy statistics**
Display information about direct routes generated advertised by the ND module.	**display ipv6 nd route-direct advertise interface** *interface-type interface-number*
Display the number of IPv6 ND snooping entries in VLANs.	**display ipv6 nd snooping count vlan** [**interface** *interface-type interface-number*]
Display IPv6 ND snooping entries in VLANs.	**display ipv6 nd snooping vlan** [[*vlan-id* | **interface** *interface-type interface-number*] [**global** | **link-local**] | *ipv6-address*] [**verbose**]
Display user IPv6 address conflict records.	**display ipv6 nd user-ip-conflict record** [**slot** *slot-number*]
Display user port migration records.	**display ipv6 nd user-move record** [**slot** *slot-number*]
Display the total number of neighbor entries.	**display ipv6 neighbors** { { **all** | **dynamic** | **static** } [**slot** *slot-number*] | **interface** *interface-type interface-number* | **vlan** *vlan-id* } **count**
Display neighbor information.	**display ipv6 neighbors** { { *ipv6-address* | **all** | **dynamic** | **static** } [**slot** *slot-number*] | **interface** *interface-type interface-number* | **vlan** *vlan-id* } [**verbose**]
Display the maximum number of ND entries that a device supports.	**display ipv6 neighbors entry-limit**
Display ND entry statistics.	**display ipv6 neighbors statistics** { [**by-slot**] **all** | **interface** { *interface-name* | *interface-type interface-number* } | **slot** *slot-number* }
Display the ND table usage.	**display ipv6 neighbors usage**
Display neighbor information for a VPN.	**display ipv6 neighbors vpn-instance** *vpn-instance-name* [**count**]

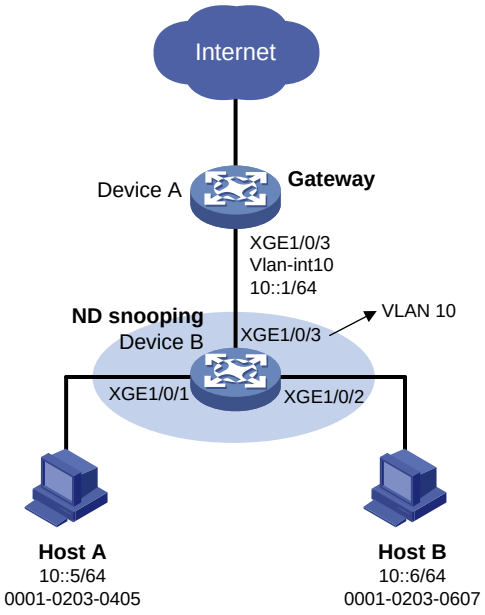
Clear IPv6 ND snooping entries in a VLAN.	**reset ipv6 nd snooping vlan** { [*vlan-id*] [**global** | **link-local**] | *vlan-id ipv6-address* }
Clear IPv6 neighbor information.	**reset ipv6 neighbors** { **all** | **dynamic** | **interface** *interface-type interface-number* | **slot** *slot-number* | **static** }



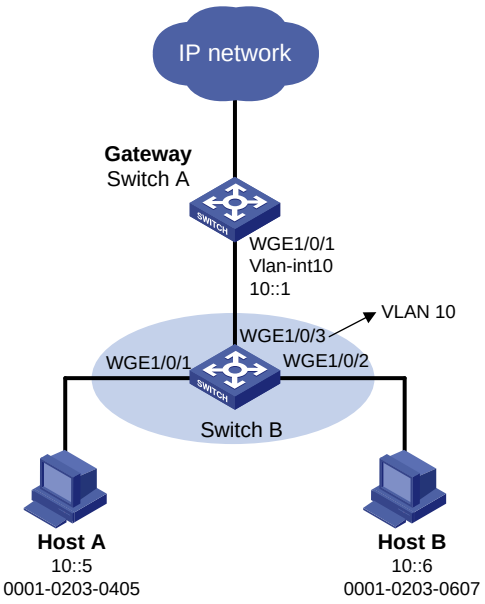
IPv6 ND configuration examples



Example: Configuring ND snooping



Network configuration



As shown in Figure 10, Host A and Host B are connected to the gateway through Device B. Enable ND snooping on Device B to learn ND snooping entries about Host A and Host B.

Procedure

1. Configure Device A:

   # Create VLAN 10.

   ```
   <DeviceA> system-view
   [DeviceA] vlan 10
   [DeviceA-vlan10] quit
   ```

   # Configure GigabitEthernet 1/0/3 to trunk VLAN 10.

   ```
   [DeviceA] interface gigabitethernet 1/0/3
   [DeviceA-GigabitEthernet1/0/3] port link-type trunk
   [DeviceA-GigabitEthernet1/0/3] port trunk permit vlan 10
   [DeviceA-GigabitEthernet1/0/3] quit
   ```

   # Assign IPv6 address 10::1/64 to VLAN-interface 10.

   ```
   [DeviceA] interface vlan-interface 10
   ```

```
[DeviceA-Vlan-interface10] ipv6 address 10::1/64
[DeviceA-Vlan-interface10] quit
```

2. Configure Device B:

Create VLAN 10.

```
[DeviceB] vlan 10
[DeviceB-vlan10] quit
```

Configure GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 to trunk VLAN 10.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type access
[DeviceB-GigabitEthernet1/0/1] port access vlan 10
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type access
[DeviceB-GigabitEthernet1/0/2] port access vlan 10
[DeviceB-GigabitEthernet1/0/2] quit
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan 10
[DeviceB-GigabitEthernet1/0/3] quit
```

Enable ND snooping for global unicast addresses and link-local addresses in VLAN 10.

```
[DeviceB] vlan 10
[DeviceB-vlan10] ipv6 nd snooping enable global
[DeviceB-vlan10] ipv6 nd snooping enable link-local
```

Enable ND snooping for data packets from unknown sources in VLAN 10.

```
[DeviceB-vlan10] ipv6 nd snooping glean source
[DeviceB-vlan10] quit
```

Configure GigabitEthernet 1/0/3 as ND trusted interface.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] ipv6 nd detection trust
[DeviceB-GigabitEthernet1/0/3] quit
```

Configure GigabitEthernet 1/0/1 to learn a maximum number of 200 ND snooping entries.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ipv6 nd snooping max-learning-num 200
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 to learn a maximum number of 200 ND snooping entries.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] ipv6 nd snooping max-learning-num 200
[DeviceB-GigabitEthernet1/0/2] quit
[DeviceB] commit
```

Verifying the configuration

Verify that Device B has learned ND snooping entries for Host A and Host B.

```
[DeviceB] display ipv6 nd snooping vlan 10

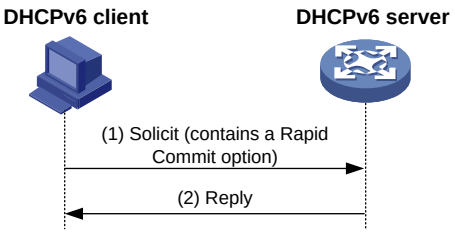
DHCPv6 overview

DHCPv6 provides a framework to assign IPv6 prefixes, IPv6 addresses, and other configuration parameters to hosts.

DHCPv6 address/prefix assignment



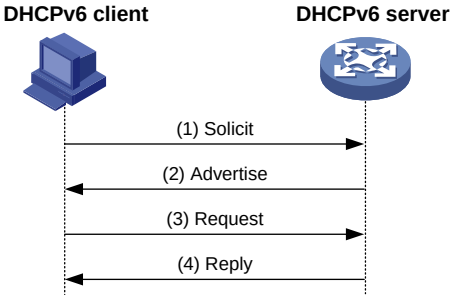
An address/prefix assignment process involves two or four messages.

Rapid assignment involving two messages

As shown in Figure 1, rapid assignment operates in the following steps:

1. The DHCPv6 client sends to the DHCPv6 server a Solicit message that contains a Rapid Commit option to prefer rapid assignment.
2. If the DHCPv6 server supports rapid assignment, it responds with a Reply message containing the assigned IPv6 address/prefix and other configuration parameters. If the DHCPv6 server does not support rapid assignment, Assignment involving four messages is performed.

Figure 1 Rapid assignment involving two messages



Assignment involving four messages

As shown in Figure 2, four-message assignment operates using the following steps:

1. The DHCPv6 client sends a Solicit message to request an IPv6 address/prefix and other configuration parameters.
2. The DHCPv6 server responds with an Advertise message that contains the assignable address/prefix and other configuration parameters if either of the following conditions exists:
   - The Solicit message does not contain a Rapid Commit option.
   - The DHCPv6 server does not support rapid assignment even though the Solicit message contains a Rapid Commit option.
3. The DHCPv6 client might receive multiple Advertise messages offered by different DHCPv6 servers. It selects an offer according to the receiving sequence and server priority, and sends a Request message to the selected server for confirmation.
4. The DHCPv6 server sends a Reply message to the client, confirming that the address/prefix and other configuration parameters are assigned to the client.

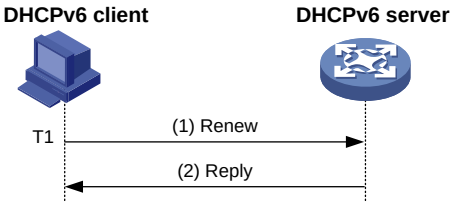


Figure 2 Assignment involving four messages

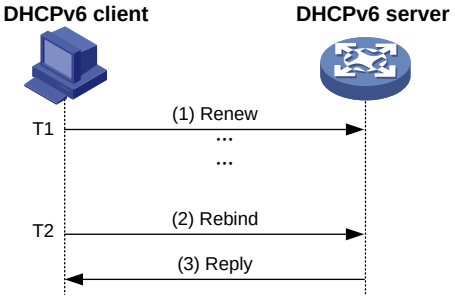
Address/prefix lease renewal



An IPv6 address/prefix assigned by a DHCPv6 server has a valid lifetime. After the valid lifetime expires, the DHCPv6 client cannot use the IPv6 address/prefix. To use the IPv6 address/prefix, the DHCPv6 client must renew the lease time.

Figure 3 Using the Renew message for address/prefix lease renewal

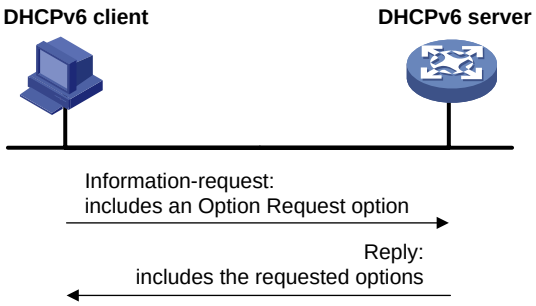
As shown in Figure 3, at T1, the DHCPv6 client sends a Renew message to the DHCPv6 server. The recommended value of T1 is half the preferred lifetime. The DHCPv6 server responds with a Reply message, informing the client whether the lease is renewed.

Figure 4 Using the Rebind message for address/prefix lease renewal

As shown in Figure 4:

- If the DHCPv6 client does not receive a response from the DHCPv6 server after sending a Renew message at T1, it multicasts a Rebind message to all DHCPv6 servers at T2. Typically, the value of T2 is 0.8 times the preferred lifetime.
- The DHCPv6 server responds with a Reply message, informing the client whether the lease is renewed.
- If the DHCPv6 client does not receive a response from any DHCPv6 server before the valid lifetime expires, the client stops using the address/prefix.

For more information about the valid lifetime and the preferred lifetime, see "Configuring basic IPv6 settings."



Stateless DHCPv6

Stateless DHCPv6 enables a device that has obtained an IPv6 address/prefix to get other configuration parameters from a DHCPv6 server.

The device performs stateless DHCPv6 if an RA message with the following flags is received from the router during stateless address autoconfiguration:

- The managed address configuration flag (M flag) is set to 0.
- The other stateful configuration flag (O flag) is set to 1.

Figure 5 Stateless DHCPv6 operation

As shown in Figure 5, stateless DHCPv6 operates in the following steps:

2. The DHCPv6 client sends an Information-request message to the multicast address of all DHCPv6 servers and DHCPv6 relay agents. The Information-request message contains an Option Request option that specifies the requested configuration parameters.
3. The DHCPv6 server returns to the client a Reply message containing the requested configuration parameters.
4. The client checks the Reply message. If the obtained configuration parameters match those requested in the Information-request message, the client uses these parameters to complete configuration. If not, the client ignores the configuration parameters. If the client receives multiple replies with configuration parameters matching those requested in the Information-request message, it uses the first received reply.

DHCPv6 options

Option 18

Option 18, also called the interface-ID option, is used by the DHCPv6 relay agent to determine the interface to use to forward RELAY-REPLY message.

The DHCPv6 snooping device adds Option 18 to the received DHCPv6 request message before forwarding it to the DHCPv6 server. The server then assigns IP address to the client based on the client information in Option 18.

Figure 6 Option 18 format

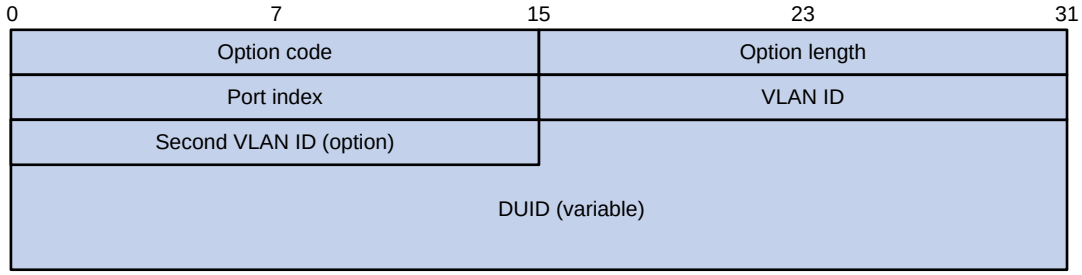


Figure 6 shows the Option 18 format, which includes the following fields:

- **Option code**—Option code. The value is 18.
- **Option length**—Size of the option data.
- **Port index**—Port that receives the DHCPv6 request from the client.
- **VLAN ID**—ID of the outer VLAN.
- **Second VLAN ID**—ID of the inner VLAN. This field is optional. If the received DHCPv6 request does not contain a second VLAN, Option 18 also does not contain it.
- **DUID**—DUID of the DHCPv6 client.

Option 37

Option 37, also called the remote-ID option, is used to identify the client.

The DHCPv6 snooping device adds Option 37 to the received DHCPv6 request message before forwarding it to the DHCPv6 server. This option provides client information about address allocation.

Figure 7 Option 37 format

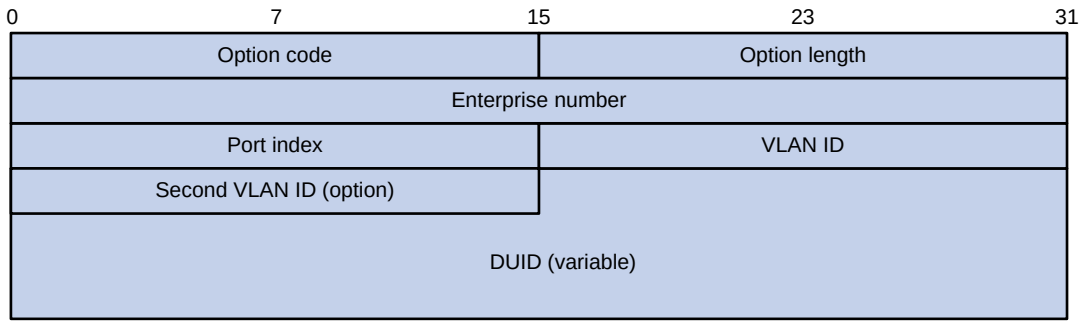

Figure 7 shows the Option 37 format, which includes the following fields:

- **Option code**—Option code. The value is 37.
- **Option length**—Size of the option data.
- **Enterprise number**—Enterprise number.
- **Port index**—Port to which the client is attached.
- **VLAN ID**—ID of the outer VLAN.
- **Second VLAN ID**—ID of the inner VLAN. This field is optional. Option 37 does not contain this information if the received DHCPv6 request does not contain a second VLAN ID.
- **DUID**—DUID information to be sent to DHCP servers. This information is configurable with the **`ipv6 dhcp relay remote-id duid`** command.

Option 79

Option 79, also called the client link-layer address option, is used to record the MAC address of the DHCPv6 client. The first relay agent that a DHCPv6 request passes learns the MAC address of the client and encapsulates this address into Option 79 in the Relay-Forward message for the request. The DHCPv6 server verifies the client or assigns IPv6 address/prefix to the client based on the MAC address of the client.

Figure 8 Option 79 format

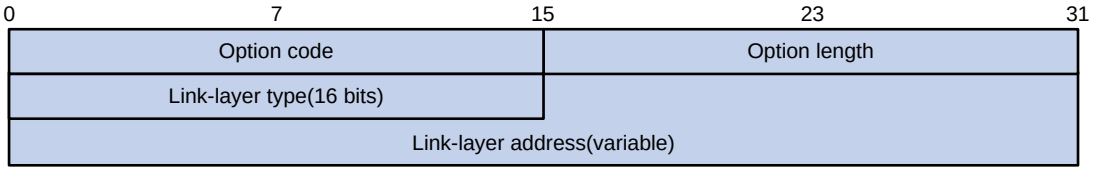

Figure 8 shows the Option 79 format, which includes the following fields:

- **Option code**—Option code. The value is 79.
- **Option length**—Size of the option data.
- **Link-layer type**—Link-layer address type of the client.
- **Link-layer address**—Link-layer address of the client.

Option 65253

As a vendor-specific DHCP option, Option 65253 contains the IPv6 domain name of a cloud server. After a DHCP client receives a DHCPv6 server reply that contains Option 65253, it automatically obtains the cloud server's domain name by parsing Option 65253. Then, the client can remotely log in to the cloud server for management purposes. For more information about cloud servers, see cloud connection configuration in *Network Management and Monitoring Configuration Guide*.

To have the device correctly obtain the IPv6 domain name in Option 65253, make sure the value in Option 65253 uses one of the following formats:

- Domain name with a port number specified:
  - **Domain name format**: *domain name:port number*, for example, example.com:17443.
  - **IPv4 address format**: *X.X.X.X:port number*, for example, 192.168.1.1:17443.
  - **IPv6 address format**: *[X:X::X:X]:port number*, for example, [1::1]:64.
- Domain name without a port number specified (the default port number is used):
  - **Domain name format**: *domain name*, for example, example.com.
  - **IPv4 address format**: *X.X.X.X*, for example, 192.168.1.1.
  - **IPv6 address format**: *X:X::X:X* or *[X:X::X:X]*, for example, 1::1 or [1::1].

Protocols and standards

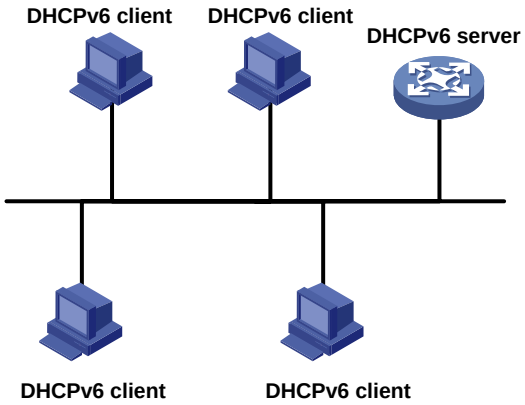
- RFC 6939, *Client Link-Layer Address Option in DHCPv6*

Configuring the DHCPv6 server

About DHCPv6 server

A DHCPv6 server can assign IPv6 addresses, IPv6 prefixes, and other configuration parameters to DHCPv6 clients.



IPv6 address assignment

As shown in Figure 9, the DHCPv6 server assigns IPv6 addresses, domain name suffixes, DNS server addresses, and other configuration parameters to DHCPv6 clients.

The IPv6 addresses assigned to the clients include the following types:

- **Temporary IPv6 addresses**—Frequently changed without lease renewal.
- **Non-temporary IPv6 addresses**—Correctly used by DHCPv6 clients, with lease renewal.

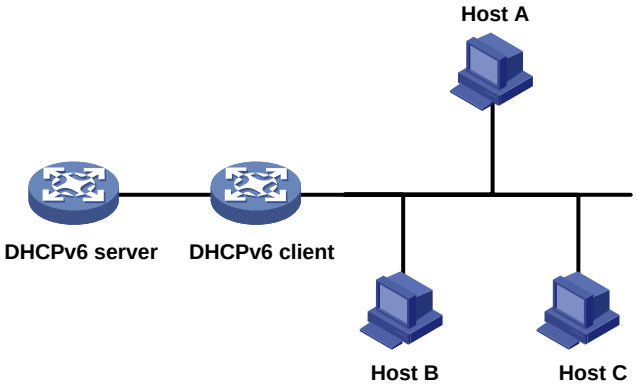


Figure 9 IPv6 address assignment

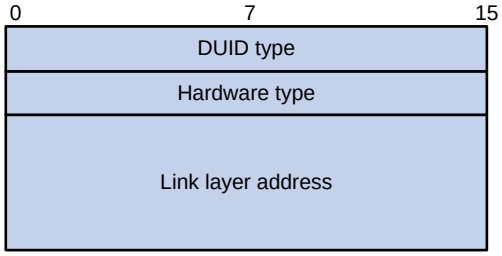
IPv6 prefix assignment

As shown in Figure 10, the DHCPv6 server assigns an IPv6 prefix to the DHCPv6 client. The client advertises the prefix information in a multicast RA message so that hosts on the subnet can automatically configure their IPv6 addresses by using the prefix.

Figure 10 IPv6 prefix assignment

Concepts



Multicast addresses used by DHCPv6

DHCPv6 uses the multicast address FF05::1:3 to identify all site-local DHCPv6 servers. It uses the multicast address FF02::1:2 to identify all link-local DHCPv6 servers and relay agents.

DUID

A DHCP unique identifier (DUID) uniquely identifies a DHCPv6 device (DHCPv6 client, server, or relay agent). A DHCPv6 device adds its DUID in a sent packet.

Figure 11 DUID-LL format

The device supports the DUID format based on link-layer address (DUID-LL) defined in RFC 3315. Figure 11 shows the DUID-LL format, which includes the following fields:

- **DUID type**—The device supports the DUID type of DUID-LL with the value of 0x0003.
- **Hardware type**—The device supports the hardware type of Ethernet with the value of 0x0001.
- **Link layer address**—Takes the value of the bridge MAC address of the device.

IA

Identified by an IAID, an identity association (IA) provides a construct through which a client manages the obtained addresses, prefixes, and other configuration parameters. A client can have multiple IAs, for example, one for each of its interfaces.

IAID

An IAID uniquely identifies an IA. It is chosen by the client and must be unique on the client.

PD

The DHCPv6 server creates a prefix delegation (PD) for each assigned prefix to record the following details:

- IPv6 prefix.
- Client DUID.
- IAID.
- Valid lifetime.
- Preferred lifetime.
- Lease expiration time.
- IPv6 address of the requesting client.

DHCPv6 address pool

The DHCP server selects IPv6 addresses, IPv6 prefixes, and other parameters from an address pool, and assigns them to the DHCP clients.

Address allocation mechanisms

DHCPv6 supports the following address allocation mechanisms:

- **Static address allocation**—To implement static address allocation for a client, create a DHCPv6 address pool, and manually bind the DUID and IAID of the client to an IPv6 address in the DHCPv6 address pool. When the client requests an IPv6 address, the DHCPv6 server assigns the IPv6 address in the static binding to the client.
- **Dynamic address allocation**—To implement dynamic address allocation for clients, create a DHCPv6 address pool, specify a subnet for the pool, and divide the subnet into temporary and non-temporary IPv6 address ranges. Upon receiving a DHCP request, the DHCPv6 server selects an IPv6 address from the temporary or non-temporary IPv6 address range based on the address type in the client request.

Prefix allocation mechanisms

DHCPv6 supports the following prefix allocation mechanisms:

- **Static prefix allocation**—To implement static prefix allocation for a client, create a DHCPv6 address pool, and manually bind the DUID and IAID of the client to an IPv6 prefix in the DHCPv6 address pool. When the client requests an IPv6 prefix, the DHCPv6 server assigns the IPv6 prefix in the static binding to the client.
- **Dynamic prefix allocation**—To implement dynamic prefix allocation for clients, create a DHCPv6 address pool and a prefix pool, specify a subnet for the address pool, and apply the prefix pool to the address pool. Upon receiving a DHCP request, the DHCPv6 server dynamically selects an IPv6 prefix from the prefix pool in the address pool.

Address pool selection

The DHCPv6 server observes the following principles when selecting an IPv6 address or prefix for a client:

1. If there is an address pool where an IPv6 address is statically bound to the DUID or IAID of the client, the DHCPv6 server selects this address pool. It assigns the statically bound IPv6 address or prefix and other configuration parameters to the client.
2. If the receiving interface has a DHCP policy and the DHCP client matches a user class, the DHCP server selects the address pool that is bound to the matching user class. If no matching user class is found, the server assigns an IP address and other parameters from the default DHCP address pool. If no default address pool is specified or the default address pool does not have assignable IP addresses, the address assignment fails.
3. If the receiving interface has an address pool applied, the DHCP server selects an IPv6 address or prefix and other configuration parameters from this address pool.
4. If the above conditions are not met, the DHCPv6 server selects an address pool depending on the client location.
    - **Client on the same subnet as the server**—The DHCPv6 server compares the IPv6 address of the receiving interface with the subnets of all address pools. It selects the address pool with the longest-matching subnet.
    - **Client on a different subnet than the server**—The DHCPv6 server compares the IPv6 address of the DHCPv6 relay agent interface closest to the client with the subnets of all address pools. It also selects the address pool with the longest-matching subnet.

    To make sure IPv6 address allocation functions correctly, keep the subnet used for dynamic assignment consistent with the subnet where the interface of the DHCPv6 server or DHCPv6 relay agent resides.

IPv6 address/prefix allocation sequence

The DHCPv6 server selects an IPv6 address/prefix for a client in the following sequence:

1. IPv6 address/prefix statically bound to the client's DUID and IAID and expected by the client.

2. IPv6 address/prefix statically bound to the client's DUID and IAID.
3. IPv6 address/prefix statically bound to the client's DUID and expected by the client.
4. IPv6 address/prefix statically bound to the client's DUID.
5. EUI-64 IPv6 address generated based on the client MAC address if EUI-64 address allocation is enabled.
6. Assignable IPv6 address/prefix in the address pool/prefix pool expected by the client.
7. IPv6 address/prefix that was ever assigned to the client.
8. Assignable IPv6 address/prefix in the address pool/prefix pool.
9. IPv6 address/prefix that was a conflict or passed its lease duration. If no IPv6 address/prefix is assignable, the server does not respond.

If a client moves to another subnet, the DHCPv6 server selects an IPv6 address/prefix from the address pool that matches the new subnet.

Conflicted IPv6 addresses can be assigned to other DHCPv6 clients only after the addresses are in conflict for one hour.

DHCPv6 server tasks at a glance

To configure the DHCPv6 server, perform the following tasks:

1. Configuring the DHCPv6 server to assign IPv6 prefixes, IPv6 addresses, and other network parameters

   Choose the following tasks as needed:
   - Configuring IPv6 prefix assignment
   - Configuring IPv6 address assignment
   - Configuring network parameters assignment
2. Modifying the address pool selection method on the DHCPv6 server

   Choose the following tasks as needed:
   - Configuring the DHCPv6 server on an interface
   - Configuring a DHCPv6 policy for IPv6 address and prefix assignment
3. (Optional.) Setting the DSCP value for DHCPv6 packets sent by the DHCPv6 server
4. (Optional.) Configuring DHCPv6 binding auto backup
5. (Optional.) Advertising subnets assigned to clients
6. (Optional.) Enabling the DHCPv6 server to advertise IPv6 prefixes
7. (Optional.) Configuring DHCPv6 vendor-specific options
8. (Optional.) Applying a DHCPv6 address pool to a VPN instance
9. (Optional.) Enabling IPv6 address binding conversion for IP source guard
10. (Optional.) Configuring SNMP notifications for the DHCPv6 server
11. (Optional.) Enabling DHCPv6 logging on the DHCPv6 server
12. (Optional.) Enabling IPv6 resource exhaustion logging

Configuring IPv6 prefix assignment

About this task

Use the following methods to configure IPv6 prefix assignment:

- **Configure a static IPv6 prefix binding in an address pool**—If you bind a DUID and an IAID to an IPv6 prefix, the DUID and IAID in a request must match those in the binding before the

DHCPv6 server can assign the IPv6 prefix to the DHCPv6 client. If you only bind a DUID to an IPv6 prefix, the DUID in the request must match the DUID in the binding before the DHCPv6 server can assign the IPv6 prefix to the DHCPv6 client.

- **Apply a prefix pool to an address pool**—The DHCPv6 server dynamically assigns an IPv6 prefix from the prefix pool in the address pool to a DHCPv6 client.

Restrictions and guidelines

When you configure IPv6 prefix assignment, follow these restrictions and guidelines:

- An IPv6 prefix can be bound to only one DHCPv6 client. You cannot modify bindings that have been created. To change the binding for a DHCPv6 client, you must delete the existing binding first.
- One address pool can have only one prefix pool applied. You cannot modify prefix pools that have been applied. To change the prefix pool for an address pool, you must remove the prefix pool application first.
- You can apply a prefix pool that has not been created to an address pool. The setting takes effect after the prefix pool is created.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Specify the IPv6 prefixes excluded from dynamic assignment.

   ipv6 dhcp server forbidden-prefix *start-prefix*/*prefix-len* [*end-prefix*/*prefix-len*] [**vpn-instance** *vpn-instance-name*]

   By default, no IPv6 prefixes in the prefix pool are excluded from dynamic assignment.

   If the excluded IPv6 prefix is in a static binding, the prefix still can be assigned to the client.

3. Create a prefix pool.

   ipv6 dhcp prefix-pool *prefix-pool-number* **prefix** { *prefix-number* | *prefix*/*prefix-len* } **assign-len** *assign-len* [**vpn-instance** *vpn-instance-name*]

   This step is required for dynamic prefix assignment.

   If you specify an IPv6 prefix by its ID, make sure the IPv6 prefix is in effect. Otherwise, the configuration does not take effect.

4. Enter DHCP address pool view.

   ipv6 dhcp pool *pool-name*

5. Specify an IPv6 subnet for dynamic assignment.

   network { *prefix/prefix-length* | **prefix** *prefix-number* [*sub-prefix/sub-prefix-length*] } [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*]

   By default, no IPv6 subnet is specified for dynamic assignment.

   The IPv6 subnets cannot be the same in different address pools.

   If you specify an IPv6 prefix by its ID, make sure the IPv6 prefix is in effect. Otherwise, the configuration does not take effect.

6. Configure the prefix assignment. Choose the options to configure as needed:

   - Configure a static prefix binding:

     static-bind prefix *prefix*/*prefix-len* **duid** *duid* [**iaid** *iaid*] [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*]

     By default, no static prefix binding is configured.

     To add multiple static IPv6 prefix bindings, repeat this step.

- Apply the prefix pool to the address pool:

  prefix-pool *prefix-pool-number* [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*]

  By default, static or dynamic prefix assignment is not configured for an address pool.

Configuring IPv6 address assignment

About this task

Use one of the following methods to configure IPv6 address assignment:

- Configure a static IPv6 address binding in an address pool.

  If you bind a DUID and an IAID to an IPv6 address, the DUID and IAID in a request must match those in the binding before the DHCPv6 server can assign the IPv6 address to the requesting client. If you only bind a DUID to an IPv6 address, the DUID in a request must match the DUID in the binding before the DHCPv6 server can assign the IPv6 address to the requesting client.
- Specify a subnet and address ranges in an address pool.
  - **Non-temporary address assignment**—The server selects addresses from the non-temporary address range specified by the **address range** command. If no non-temporary address range is specified, the server selects addresses on the subnet specified by the **network** command.
  - **Temporary address assignment**—The server selects addresses from the temporary address range specified by the **temporary address range** command. If no temporary address range is specified in the address pool, the DHCPv6 server cannot assign temporary addresses to clients.

Restrictions and guidelines

- You can specify only one non-temporary address range and one temporary address range in an address pool.
- The address ranges specified by the **address range** and **temporary address range** commands must be on the subnet specified by the **network** command. Otherwise, the addresses are unassignable.
- An IPv6 address can be bound to only one DHCPv6 client. You cannot modify bindings that have been created. To change the binding for a DHCPv6 client, you must delete the existing binding first.
- Only one subnet can be specified in an address pool. If you use the **network** command multiple times in a DHCPv6 address pool, the most recent configuration takes effect. If you use this command to specify only new lifetimes, the settings do not affect existing leases. The IPv6 addresses assigned after the modification will use the new lifetimes.

Procedure

1. Enter system view.

   system-view
2. (Optional.) Specify the IPv6 addresses excluded from dynamic assignment.

   ipv6 dhcp server forbidden-address *start-ipv6-address* [*end-ipv6-address*] [**vpn-instance** *vpn-instance-name*]

   By default, all IPv6 addresses except for the DHCPv6 server's IP address in a DHCPv6 address pool are assignable.

   If the excluded IPv6 address is in a static binding, the address still can be assigned to the client.
3. Enter DHCPv6 address pool view.

   ipv6 dhcp pool *pool-name*

4. Specify an IPv6 subnet for dynamic assignment.

   network { *prefix/prefix-length* | **prefix** *prefix-number* [*sub-prefix/sub-prefix-length*] } [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*]

   By default, no IPv6 address subnet is specified.

   The IPv6 subnets cannot be the same in different address pools.

   If you specify an IPv6 prefix by its ID, make sure the IPv6 prefix is in effect. Otherwise, the configuration does not take effect.

5. (Optional.) Specify a non-temporary IPv6 address range.

   address range *start-ipv6-address end-ipv6-address* [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*]

   By default, no non-temporary IPv6 address range is specified, and all unicast addresses on the subnet are assignable.

6. (Optional.) Specify a temporary IPv6 address range.

   temporary address range *start-ipv6-address end-ipv6-address* [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*]

   By default, no temporary IPv6 address range is specified, and the DHCPv6 server cannot assign temporary IPv6 addresses.

7. (Optional.) Enable EUI-64 address allocation mode.

   address-alloc-mode eui-64

   By default, EUI-64 address allocation mode is disabled.

   This feature enables the DHCPv6 server to obtain the client MAC address in the DHCP request and generates an EUI-64 IPv6 address to assign to the client.

8. (Optional.) Create a static binding.

   static-bind address *ipv6-address*/*addr-prefix-length* **duid** *duid* [**iaid** *iaid*] [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*]

   By default, no static binding is configured.

   To add more static bindings, repeat this step.

Configuring network parameters assignment

About network parameters assignment

In addition to IPv6 prefixes and IPv6 addresses, you can configure the following network parameters in an address pool:

- A maximum of eight DNS server addresses.
- One domain name.
- A maximum of eight SIP server addresses.
- A maximum of eight SIP server domain names.

You can configure network parameters on a DHCPv6 server by using one of the following methods:

- Configure network parameters in a DHCPv6 address pool.
- Configure network parameters in a DHCPv6 option group, and specify the option group for a DHCPv6 address pool.

Network parameters configured in a DHCPv6 address pool take precedence over those configured in a DHCPv6 option group.

Configuring network parameters in a DHCPv6 address pool

1. Enter system view.

   system-view

2. Enter DHCPv6 address pool view.

   ipv6 dhcp pool *pool-name*

3. Specify an IPv6 subnet for dynamic assignment.

   network { *prefix/prefix-length* | **prefix** *prefix-number* [*sub-prefix/sub-prefix-length*] } [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*]

   By default, no IPv6 subnet is specified.

   The IPv6 subnets cannot be the same in different address pools.

   If you specify an IPv6 prefix by its ID, make sure the IPv6 prefix is in effect. Otherwise, the configuration does not take effect.

4. Specify a DNS server address.

   dns-server *ipv6-address*

   By default, no DNS server address is specified.

5. Specify a domain name.

   domain-name *domain-name*

   By default, no domain name is specified.

6. Specify a SIP server address or domain name.

   sip-server { **address** *ipv6-address* | **domain-name** *domain-name* }

   By default, no SIP server address or domain name is specified.

7. Configure a self-defined DHCPv6 option.

   option *code* **hex** *hex-string*

   By default, no self-defined DHCPv6 option is configured.

Configuring network parameters in a DHCPv6 option group

About this task

A DHCPv6 option group can be created by using the following methods:

- Create a static DHCPv6 option group by using the **ipv6 dhcp option-group** command. The static DHCPv6 option group takes precedence over the dynamic DHCPv6 option group.
- When the device acts as a DHCPv6 client, it automatically creates a dynamic DHCPv6 option group for saving the obtained parameters. For more information about creating a dynamic DHCPv6 option group, see "Configuring the DHCPv6 client."

Procedure

1. Enter system view.

   system-view

2. Create a static DHCPv6 option group and enter its view.

   ipv6 dhcp option-group *option-group-number*

3. Specify a DNS server address.

dns-server *ipv6-address*

By default, no DNS server address is specified.

4. Specify a domain name suffix.

domain-name *domain-name*

By default, no domain name suffix is specified.

5. Specify a SIP server address or domain name.

sip-server { **address** *ipv6-address* | **domain-name** *domain-name* }

By default, no SIP server address or domain name is specified.

6. Configure a self-defined DHCPv6 option.

option *code* **hex** *hex-string*

By default, no self-defined DHCPv6 option is configured.

7. Return to system view.

quit

8. Enter DHCPv6 address pool view.

ipv6 dhcp pool *pool-name*

9. Specify a DHCPv6 option group.

option-group *option-group-number*

By default, no DHCPv6 option group is specified.

Configuring the DHCPv6 server on an interface

About this task

Enable the DHCP server and configure one of the following address/prefix assignment methods on an interface:

- **Apply an address pool on the interface**—The DHCPv6 server selects an IPv6 address/prefix from the applied address pool for a requesting client. If there is no assignable IPv6 address/prefix in the address pool, the DHCPv6 server cannot assign an IPv6 address/prefix to a client.
- **Configure global address assignment on the interface**—The DHCPv6 server selects an IPv6 address/prefix in the global DHCPv6 address pool that matches the server interface address or the DHCPv6 relay agent address for a requesting client.

If you configure both methods on an interface, the DHCPv6 server uses the specified address pool for address assignment without performing global address assignment.

Restrictions and guidelines

- An interface cannot act as a DHCPv6 server and DHCPv6 relay agent at the same time.
- Do not enable DHCPv6 server and DHCPv6 client on the same interface.
- You can apply an address pool that has not been created to an interface. The setting takes effect after the address pool is created.

Procedure

1. Enter system view.

system-view

2. Enter interface view.

interface *interface-type interface-number*

3. Enable the DHCPv6 server on the interface.

ipv6 dhcp select server

By default, the interface does not act as a DHCP server or a DHCP relay agent, and discards DHCPv6 packets from DHCPv6 clients.

4. Configure an assignment method.
   - Configure global address assignment.

     ipv6 dhcp server { **allow-hint** | **preference** *preference-value* | **rapid-commit** } *

     By default, the DHCP server supports global address assignment, but it does not support desired address/prefix assignment or rapid assignment. The default preference is 0.
   - Apply a DHCPv6 address pool to the interface.

     ipv6 dhcp server apply pool *pool-name* [**allow-hint** | **preference** *preference-value* | **rapid-commit**] *

Configuring a DHCPv6 policy for IPv6 address and prefix assignment

About this task

In a DHCPv6 policy, each DHCPv6 user class has a bound DHCPv6 address pool. Clients matching different user classes obtain IPv6 addresses, IPv6 prefixes, and other parameters from different address pools. When receiving a DHCPv6 request, the DHCPv6 server compares the packet against the user classes in the order that they are configured.

If a match is found and the bound address pool has assignable IPv6 addresses or prefixes, the server uses the address pool for assignment. If the bound address pool does not have assignable IPv6 addresses or prefixes, the assignment fails.

If no match is found, the server uses the default DHCPv6 address pool for assignment. If no default address pool is specified or the default address pool does not have assignable IPv6 addresses or prefixes, the assignment fails.

For successful assignment, make sure the applied DHCPv6 policy and the bound address pools exist.

A match rule cannot match an option added by the DHCPv6 device, for example, Option 18 or Option 37.

Procedure

1. Enter system view.

   system-view
2. Create a DHCPv6 user class and enter DHCPv6 user class view.

   ipv6 dhcp class *class-name*
3. Configure a match rule for the DHCPv6 user class.

   if-match rule *rule-number* { **option** *option-code* [**ascii** *ascii-string* [**offset** *offset* | **partial**] | **hex** *hex-string* [**mask** *mask* | **offset** *offset* **length** *length* | **partial**]] | **relay-agent** *gateway-ipv6-address* }

   By default, no match rule is configured for a DHCPv6 user class.
4. Return to system view.

   quit
5. Create a DHCPv6 policy and enter DHCPv6 policy view.

   ipv6 dhcp policy *policy-name*

   The DHCPv6 policy takes effect only after it is applied to the interface that acts as the DHCPv6 server.

6. Specify a DHCPv6 address pool for a DHCPv6 user class.
   class *class-name* **pool** *pool-name*
   By default, no address pool is specified for a user class.
7. (Optional.) Specify the default DHCPv6 address pool.
   default pool *pool-name*
   By default, the default address pool is not specified.
8. Return to system view.
   quit
9. Enter interface view.
   interface *interface-type interface-number*
10. Apply the DHCPv6 policy to the interface.
    ipv6 dhcp apply-policy *policy-name*
    By default, no DHCPv6 policy is applied to an interface.

Setting the DSCP value for DHCPv6 packets sent by the DHCPv6 server

About this task

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet.

Procedure

1. Enter system view.
   system-view
2. Set the DSCP value for DHCPv6 packets sent by the DHCPv6 server.
   ipv6 dhcp dscp *dscp-value*
   By default, the DSCP value in DHCPv6 packets sent by the DHCPv6 server is 56.

Configuring DHCPv6 binding auto backup

About this task

The auto backup feature saves DHCPv6 bindings to a backup file, and allows the DHCPv6 server to download the bindings from the backup file at the server reboot. The bindings include the lease bindings and conflicted IPv6 addresses. They cannot survive a reboot on the DHCPv6 server.

The DHCPv6 server does not provide services during the download process. If a connection error occurs during the process and cannot be repaired in a short amount of time, you can terminate the download operation. Manual interruption allows the DHCPv6 server to provide services without waiting for the connection to be repaired.

Procedure

1. Enter system view.
   system-view
2. Configure the DHCPv6 server to back up the bindings to a file.
   ipv6 dhcp server database filename { *filename* | **url** *url* [**username** *username* [**password** { **cipher** | **simple** } *string*]] }
   By default, the DHCPv6 server does not back up the DHCPv6 bindings.

With this command executed, the DHCPv6 server backs up its bindings immediately and runs auto backup.

3. (Optional.) Manually save the DHCPv6 bindings to the backup file.

   ipv6 dhcp server database update now

4. (Optional.) Set the waiting time after a DHCPv6 binding change for the DHCPv6 server to update the backup file.

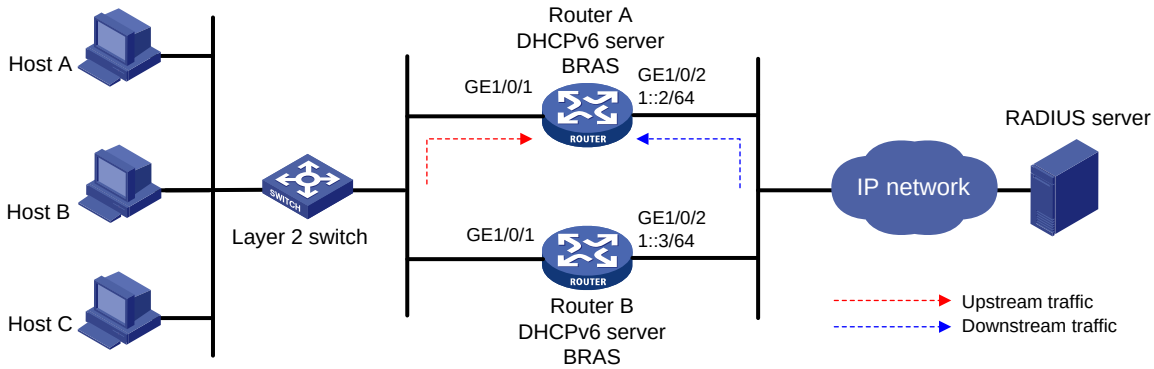
   ipv6 dhcp server database update interval *interval*

   By default, the DHCP server waits 300 seconds to update the backup file after a DHCP binding change. If no DHCP binding changes, the backup file is not updated.

5. (Optional.) Terminate the download of DHCPv6 bindings from the backup file.

   ipv6 dhcp server database update stop

   This command only triggers one termination.



Advertising subnets assigned to clients

About this task

This feature enables the route management module to advertise subnets assigned to DHCPv6 clients. Use this feature in a node redundancy scenario to make sure the bidirectional traffic of each DHCPv6 client traverses the same node for purposes such as traffic accounting.

Figure 12 shows a typical scenario in which Router A and Router B act as both DHCPv6 servers and BRAS devices. The BRAS devices send accounting packets to the RADIUS server for each client. Upon receipt of the accounting packets, the RADIUS server overwrites the previous traffic statistics for that client with the new statistics in the received packets. If the upstream and downstream traffic of a client traverses different BRAS devices, the RADIUS server will be unable to collect complete traffic statistics for that client. To make sure the RADIUS server collect complete traffic statistics for each client from the BRAS devices, configure the DHCPv6 servers to advertise subnets assigned to clients. This configuration makes sure the upstream and downstream traffic of a client traverses the same BRAS device.

Figure 12 Network diagram

Restrictions and guidelines

If the address pool is bound to a VPN instance, you must make sure the VPN instance already exists for the subnet advertisement feature to take effect.

Procedure

1. Enter system view.

   system-view

2. Enter DHCP address pool view.

ipv6 dhcp pool *pool-name*

3. Advertise the subnet that is assigned to DHCPv6 clients.

   network { *prefix/prefix-length* | **prefix** *prefix-number* [*sub-prefix/sub-prefix-length*] } [**preferred-lifetime** *preferred-lifetime* **valid-lifetime** *valid-lifetime*] **export-route**

   By default, the subnet assigned to DHCPv6 clients is not advertised.

Enabling the DHCPv6 server to advertise IPv6 prefixes

About this task

A DHCPv6 client can obtain an IPv6 prefix through DHCPv6 and use this IPv6 prefix to assign IPv6 addresses for clients in a downstream network. If the IPv6 prefix is in a different subnet than the IPv6 address of the DHCPv6 client's upstream interface, the clients in the downstream network cannot access the external network. If the DHCPv6 server is on the same link as the DHCPv6 client, enable the DHCPv6 server to advertise the IPv6 prefix.

Procedure

1. Enter system view.

   system-view

2. Enable the DHCPv6 server to advertise IPv6 prefixes.

   ipv6 dhcp advertise pd-route

   By default, the DHCPv6 server does not advertise IPv6 prefixes.

Configuring DHCPv6 vendor-specific options

About this task

In addition to the options defined by RFC, the DHCPv6 server also supports a group of options that require manual configuration. These options are known as vendor-specific options.

The DHCPv6 server can use vendor-specific options to assign additional network settings to a DHCPv6 client. These network settings include TFTP server information and the client's configuration file name. After receiving a DHCPv6 reply that carries vendor-specific options, the DHCPv6 client can parse these options to obtain related information.

Procedure

1. Enter system view.

   system-view

2. Enter IPv6 address pool view.

   ipv6 dhcp pool *pool-name*

3. Configure a vendor-specific option and enter its view.

   vendor-specific *vendor-id*

   By default, no vendor-specific options are configured.

4. Configure a DHCPv6 vendor-specific suboption.

   suboption *suboption-code* { **address** *ipv6-address*&<1-4> | **ascii** *ascii-string* | **hex** *hex-string* }

   By default, no vendor-specific suboptions are configured.

Applying a DHCPv6 address pool to a VPN instance

About this task

If a DHCPv6 address pool is applied to a VPN instance, the DHCPv6 server assigns IPv6 addresses in this address pool to clients in the VPN instance. Addresses in this address pool will not be assigned to clients on the public network.

The DHCPv6 server can obtain the VPN instance to which a DHCPv6 client belongs from the following information:

- The client's VPN information stored in authentication modules.
- The VPN information of the DHCPv6 server's interface that receives DHCPv6 packets from the client.

The VPN information from authentication modules takes priority over the VPN information of the receiving interface.

An MCE acting as the DHCP server can assign IP addresses not only to clients on public networks, but also to clients on private networks. The IP address ranges of public and private networks or those of private networks on the DHCP server cannot overlap. For more information about MCE, see *MCE Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter DHCP address pool view.
   ipv6 dhcp pool *pool-name*
3. Apply the address pool to a VPN instance.
   vpn-instance *vpn-instance-name*
   By default, the address pool is not applied to any VPN instance.

Enabling IPv6 address binding conversion for IP source guard

About this task

In some networks, the gateway acts as the DHCPv6 server to assign IPv6 addresses to users and reports user information to the controller. The user information report supports only IP source guard entries based on which the controller manages and monitors users. For the DHCPv6 server to report information about all online DHCP users, use this feature to convert user IPv6 address bindings to dynamic IP source guard bindings.

For more information about IP source guard, see *Security Configuration Guide*.

Restrictions and guidelines

If the device does not have enough storage space, execute the **undo ipv6 dhcp server entry-convert enable** command to disable this feature. The system does not delete IP source guard bindings that have been converted before you disable this feature.

Procedure

1. Enter system view.
   system-view

2. Enable IPv6 address binding conversion for IP source guard.
   ipv6 dhcp server entry-convert enable
   By default, IPv6 address binding conversion for IP source guard is disabled.

Configuring SNMP notifications for the DHCPv6 server

About SNMP DHCPv6 server notifications

Perform this task to configure the DHCPv6 module to send SNMP notifications to report DHCPv6 server events, including:

- Resource exhaustion events or recoveries from resource exhaustion conditions in an IPv6 address pool.
- Resource usage threshold violations or recoveries from threshold violation conditions in an IPv6 pool.

The SNMP notifications are sent to the SNMP module. For the SNMP notifications to be sent correctly, you must also configure SNMP. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*.

Enabling IPv6 resource exhaustion notifications

1. Enter system view.
   system-view
2. Enable IPv6 resource exhaustion notifications.
   snmp-agent trap enable ipv6 dhcp server address-exhaust pd-exhaust
   By default, IPv6 resource exhaustion notifications are enabled.
3. Enter IPv6 address pool view.
   ipv6 dhcp pool *pool-name*
4. (Optional.) Enable IPv6 resource exhaustion alarming for an IPv6 pool.
   exhaustion trap enable
   By default, IPv6 resource exhaustion alarming is enabled for an IPv6 pool.

Enabling IPv6 address usage alarm notifications

1. Enter system view.
   system-view
2. Enable IPv6 address usage alarm notifications.
   snmp-agent trap enable ipv6 dhcp server ip-in-use
   By default, IPv6 address usage alarm notifications are enabled.
3. Enter IPv6 address pool view.
   ipv6 dhcp pool *pool-name*
4. (Optional.) Set the IPv6 address usage threshold.
   ip-in-use threshold *threshold-value*
   The default threshold is 100%.

Enabling IPv6 prefix usage alarm notifications

1. Enter system view.
   system-view
2. Enable IPv6 prefix usage alarm notifications.
   snmp-agent trap enable ipv6 dhcp server pd-in-use
   By default, IPv6 prefix usage alarm notifications are enabled.
3. Enter IPv6 address pool view.
   ipv6 dhcp pool *pool-name*
4. (Optional.) Set the IPv6 prefix usage threshold.
   pd-in-use threshold *threshold-value*
   The default threshold is 100%.

Enabling DHCPv6 logging on the DHCPv6 server

About this task

The DHCPv6 logging feature enables the DHCPv6 server to generate DHCPv6 logs and send them to the information center. The information helps administrators locate and solve problems. For information about the log destination and output rule configuration in the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

As a best practice, disable this feature if the log generation affects the device performance or reduces the address and prefix allocation efficiency. For example, this situation might occur when a large number of clients frequently come online or go offline.

Procedure

1. Enter system view.
   system-view
2. Enable DHCPv6 logging.
   ipv6 dhcp log enable
   By default, DHCPv6 logging is disabled.

Enabling IPv6 resource exhaustion logging

About this task

This feature enables the DHCPv6 module to send IPv6 resource exhaustion log messages to the information center. For log messages to be sent correctly, configure the information center to set log message filtering and output rules, including output destinations. For information about the information center configuration, see *Network Management and Monitoring Configuration Guide*.

The DHCPv6 module generates an IPv6 resource exhaustion log message when the IPv6 address pool encounters one of the following events:

NOTE:

If the IPv6 address usage or prefix usage threshold for the pool is 100%, the DHCPv6 module generates an alarm message instead of a log message for one of the following events.

To set the IPv6 address usage threshold for an IPv6 address pool, use the **ip-in-use**

threshold command. To set the IPv6 prefix usage threshold for an IPv6 address pool, use the **pd-in-use threshold** command.

- The pool does not have assignable address resources or prefix resources.
- The IPv6 address usage or prefix usage of the pool drops to or below 90% after exhaustion.

You can use the following formulas to calculate the IPv6 resource usage of an IPv6 address pool:

- *IPv6 address usage = (total number of IPv6 addresses – number of assignable IPv6 addresses)/total number of IPv6 addresses*
- *IPv6 prefix usage = (total number of IPv6 prefixes – number of assignable IPv6 prefixes)/total number of IPv6 prefixes*

Restrictions and guidelines

This feature is not affected if DHCPv6 logging is disabled.

Procedure

1. Enter system view.
   system-view
2. Enter IPv6 address pool view.
   ipv6 dhcp pool *pool-name*
3. Enable IPv6 resource exhaustion logging.
   exhaustion log enable
   By default, IPv6 resource exhaustion logging is disabled.

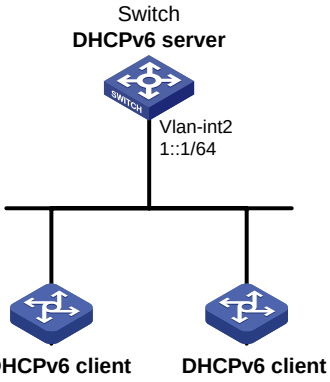
Display and maintenance commands for DHCPv6 server

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the DUID of the local device.	**display ipv6 dhcp duid**
Display information about a DHCPv6 option group.	**display ipv6 dhcp option-group** [*option-group-number*]
Display DHCPv6 address pool information.	**display ipv6 dhcp pool** [*pool-name* | **vpn-instance** *vpn-instance-name*]
Display prefix pool information.	**display ipv6 dhcp prefix-pool** [*prefix-pool-number*] [**vpn-instance** *vpn-instance-name*]
Display DHCPv6 server information on an interface.	**display ipv6 dhcp server** [**interface** *interface-type interface-number*]
Display information about IPv6 address conflicts.	**display ipv6 dhcp server conflict** [**address** *ipv6-address*] [**vpn-instance** *vpn-instance-name*]
Display information about DHCPv6 binding auto backup	**display ipv6 dhcp server database**
Display information about expired IPv6 addresses.	**display ipv6 dhcp server expired** [[**address** *ipv6-address*] [**vpn-instance**

Task	Command
	vpn-instance-name] | **pool** *pool-name*]
Display information about IPv6 address bindings.	**display ipv6 dhcp server ip-in-use** [[**address** *ipv6-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]
Display information about IPv6 prefix bindings.	**display ipv6 dhcp server pd-in-use** [**pool** *pool-name* | [**prefix** *prefix/prefix-len*] [**vpn-instance** *vpn-instance-name*]]
Display packet statistics on the DHCPv6 server.	**display ipv6 dhcp server statistics** [**pool** *pool-name* | **vpn-instance** *vpn-instance-name*]
Clear information about IPv6 address conflicts.	**reset ipv6 dhcp server conflict** [**address** *ipv6-address*] [**vpn-instance** *vpn-instance-name*]
Clear information about expired IPv6 address bindings.	**reset ipv6 dhcp server expired** [[**address** *ipv6-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]
Clear information about IPv6 address bindings.	**reset ipv6 dhcp server ip-in-use** [[**address** *ipv6-address*] [**vpn-instance** *vpn-instance-name*] | **pool** *pool-name*]
Clear information about IPv6 prefix bindings.	**reset ipv6 dhcp server pd-in-use** [**pool** *pool-name* | [**prefix** *prefix/prefix-len*] [**vpn-instance** *vpn-instance-name*]]
Clear packets statistics on the DHCPv6 server.	**reset ipv6 dhcp server statistics** [**vpn-instance** *vpn-instance-name*]

DHCPv6 server configuration examples



Example: Configuring dynamic IPv6 prefix assignment

Network configuration

As shown in Figure 13, the switch acts as a DHCPv6 server to assign an IPv6 prefix, a DNS server address, a domain name, a SIP server address, and a SIP server name to each DHCPv6 client.

The switch assigns prefix 2001:0410:0201::/48 to the client whose DUID is 00030001CA0006A40000, and assigns prefixes in the range of 2001:0410::/48 to 2001:0410:FFFF::/48 (excluding 2001:0410:0201::/48) to other clients. The DNS server address is 2::2:3. The DHCPv6 clients reside in the domain **aaa.example.com**. The SIP server address is 2:2::4, and the SIP server name is **bbb.example.com**.

Figure 13 Network diagram

Procedure

Specify an IPv6 address for VLAN-interface 2.

```
<Switch> system-view
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ipv6 address 1::1/64
```

Disable RA message suppression on VLAN-interface 2.

```
[Switch-Vlan-interface2] undo ipv6 nd ra halt
```

Set the M flag to 1 in RA advertisements to be sent on VLAN-interface 2. Hosts that receive the RA advertisements will obtain IPv6 addresses through DHCPv6.

```
[Switch-Vlan-interface2] ipv6 nd autoconfig managed-address-flag
```

Set the O flag to 1 in RA advertisements to be sent on VLAN-interface 2. Hosts that receive the RA advertisements will obtain information other than IPv6 address through DHCPv6.

```
[Switch-Vlan-interface2] ipv6 nd autoconfig other-flag
[Switch-Vlan-interface2] quit
```

Create prefix pool 1, and specify the prefix 2001:0410::/32 with the assigned prefix length 48.

```
[Switch] ipv6 dhcp prefix-pool 1 prefix 2001:0410::/32 assign-len 48
```

Create address pool 1.

```
[Switch] ipv6 dhcp pool 1
```

In address pool 1, configure subnet 1::/64 where VLAN interface-2 resides.

```
[Switch-dhcp6-pool-1] network 1::/64
```

Apply prefix pool 1 to address pool 1, and set the preferred lifetime to one day, and the valid lifetime to three days.

```
[Switch-dhcp6-pool-1] prefix-pool 1 preferred-lifetime 86400 valid-lifetime 259200
```

In address pool 1, bind prefix 2001:0410:0201::/48 to the client DUID 00030001CA0006A40000, and set the preferred lifetime to one day, and the valid lifetime to three days.

```
[Switch-dhcp6-pool-1] static-bind prefix 2001:0410:0201::/48 duid 00030001CA0006A40000
preferred-lifetime 86400 valid-lifetime 259200
```

Configure the DNS server address 2:2::3.

```
[Switch-dhcp6-pool-1] dns-server 2:2::3
```

Configure the domain name as **aaa.example.com**.

```
[Switch-dhcp6-pool-1] domain-name aaa.example.com
```

Configure the SIP server address as 2:2::4, and the SIP server name as **bbb.example.com**.

```
[Switch-dhcp6-pool-1] sip-server address 2:2::4
```

```
[Switch-dhcp6-pool-1] sip-server domain-name bbb.example.com
[Switch-dhcp6-pool-1] quit
```

Enable the DHCPv6 server on VLAN-interface 2, enable desired prefix assignment and rapid prefix assignment, and set the preference to the highest.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ipv6 dhcp select server
[Switch-Vlan-interface2] ipv6 dhcp server allow-hint preference 255 rapid-commit
```

Verifying the configuration

Display DHCPv6 server configuration on VLAN-interface 2.

```
[Switch-Vlan-interface2] display ipv6 dhcp server interface vlan-interface 2
Using pool: global
Preference value: 255
Allow-hint: Enabled
Rapid-commit: Enabled
```

Display information about address pool 1.

```
[Switch-Vlan-interface2] display ipv6 dhcp pool 1
DHCPv6 pool: 1
  Network: 1::/64
    Preferred lifetime 604800 seconds, valid lifetime 2592000 seconds
  Prefix pool: 1
    Preferred lifetime 86400 seconds, valid lifetime 259200 seconds
  Static bindings:
    DUID: 00030001ca0006a40000
    IAID: Not configured
    Prefix: 2001:410:201::/48
      Preferred lifetime 86400 seconds, valid lifetime 259200 seconds
  DNS server addresses:
    2:2::3
  Domain name:
    aaa.example.com
  SIP server addresses:
    2:2::4
  SIP server domain names:
    bbb.example.com
  undo exhaustion log enable
  IP-in-use threshold: 100
  PD-in-use threshold: 100
  exhaustion trap enable
```

Display information about prefix pool 1.

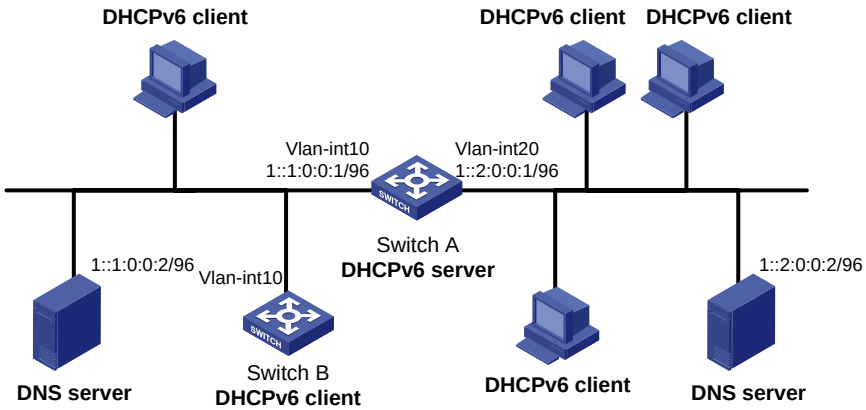
```
[Switch-Vlan-interface2] display ipv6 dhcp prefix-pool 1
Prefix: 2001:410::/32
Assigned length: 48
Total prefix number: 65536
Available: 65535
In-use: 0
Static: 1
```

After the client with the DUID 00030001CA0006A40000 obtains an IPv6 prefix, display the binding information on the DHCPv6 server.

```
[Switch-Vlan-interface2] display ipv6 dhcp server pd-in-use
Pool: 1
 IPv6 prefix                                Type      Lease expiration
 2001:410:201::/48                          Static(C) Jul 10 19:45:01 2019
```

After the other client obtains an IPv6 prefix, display binding information on the DHCPv6 server.

```
[Switch-Vlan-interface2] display ipv6 dhcp server pd-in-use
Pool: 1
 IPv6 prefix                                Type      Lease expiration
 2001:410:201::/48                          Static(C) Jul 10 19:45:01 2019
 2001:410::/48                              Auto(C)   Jul 10 20:44:05 2019
```



Example: Configuring dynamic IPv6 address assignment

Network configuration

As shown in Figure 14, Switch A acts as a DHCPv6 server to assign IPv6 addresses to the clients on subnets 1::1:0:0:0/96 and 1::2:0:0:0/96.

On Switch A, configure the IPv6 address 1::1:0:0:1/96 for VLAN-interface 10 and 1::2:0:0:1/96 for VLAN-interface 20. The lease duration of the addresses on subnet 1::1:0:0:0/96 is 172800 seconds (two days), the valid time is 345600 seconds (four days), the domain name suffix is aabbcc.com, and the DNS server address is 1::1:0:0:2/96. The lease duration of the addresses on subnet 1::2:0:0:0/96 is 432000 seconds (five days), the valid time is 864000 seconds (ten days), the domain name is aabbcc.com, and the DNS server address is 1::2:0:0:2/96.

Figure 14 Network diagram

Procedure

1. Configure the interfaces on the DHCPv6 server:

   # Specify an IPv6 address for VLAN-interface 10.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 10
   [SwitchA-Vlan-interface10] ipv6 address 1::1:0:0:1/96
   ```

   # Disable RA message suppression on VLAN-interface 10.

   ```
   [SwitchA-Vlan-interface10] undo ipv6 nd ra halt
   ```

   # Set the M flag to 1 in RA advertisements to be sent on VLAN-interface 10. Hosts that receive the RA advertisements will obtain IPv6 addresses through DHCPv6.

```
[SwitchA-Vlan-interface10] ipv6 nd autoconfig managed-address-flag
```

Set the O flag to 1 in RA advertisements to be sent on VLAN-interface 10. Hosts that receive the RA advertisements will obtain information other than IPv6 address through DHCPv6.

```
[SwitchA-Vlan-interface10] ipv6 nd autoconfig other-flag
[SwitchA-Vlan-interface10] quit
```

Specify an IPv6 address for VLAN-interface 20.

```
[SwitchA] interface vlan-interface 20
[SwitchA-Vlan-interface20] ipv6 address 1::2:0:0:1/96
```

Disable RA message suppression on VLAN-interface 20.

```
[SwitchA-Vlan-interface20] undo ipv6 nd ra halt
```

Set the M flag to 1 in RA advertisements to be sent on VLAN-interface 20. Hosts that receive the RA advertisements will obtain IPv6 addresses through DHCPv6.

```
[SwitchA-Vlan-interface20] ipv6 nd autoconfig managed-address-flag
```

Set the O flag to 1 in RA advertisements to be sent on VLAN-interface 20. Hosts that receive the RA advertisements will obtain information other than IPv6 address through DHCPv6.

```
[SwitchA-Vlan-interface20] ipv6 nd autoconfig other-flag
[SwitchA-Vlan-interface20] quit
```

2. Enable DHCPv6:

Enable DHCPv6 server on VLAN-interface 10 and VLAN-interface 20.

```
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] ipv6 dhcp select server
[SwitchA-Vlan-interface10] quit
[SwitchA] interface vlan-interface 20
[SwitchA-Vlan-interface20] ipv6 dhcp select server
[SwitchA-Vlan-interface20] quit
```

Exclude the DNS server addresses from dynamic assignment.

```
[SwitchA] ipv6 dhcp server forbidden-address 1::1:0:0:2
[SwitchA] ipv6 dhcp server forbidden-address 1::2:0:0:2
```

Configure the DHCPv6 address pool 1 to assign IPv6 addresses and other configuration parameters to clients on subnet 1::1:0:0:0/96.

```
[SwitchA] ipv6 dhcp pool 1
[SwitchA-dhcp6-pool-1] network 1::1:0:0:0/96 preferred-lifetime 172800
valid-lifetime 345600
[SwitchA-dhcp6-pool-1] domain-name aabbcc.com
[SwitchA-dhcp6-pool-1] dns-server 1::1:0:0:2
[SwitchA-dhcp6-pool-1] quit
```

Configure the DHCPv6 address pool 2 to assign IPv6 addresses and other configuration parameters to clients on subnet 1::2:0:0:0/96.

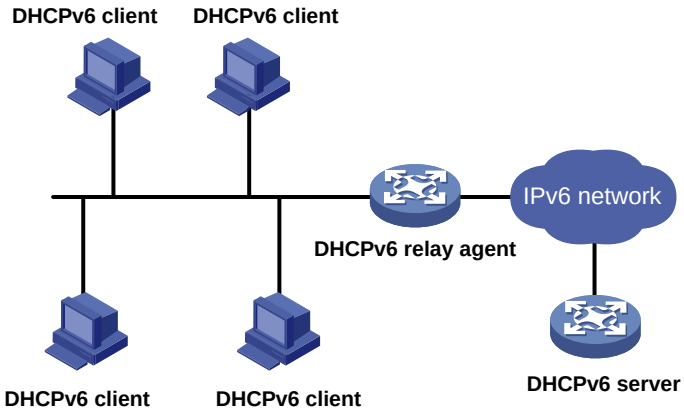
```
[SwitchA] ipv6 dhcp pool 2
[SwitchA-dhcp6-pool-2] network 1::2:0:0:0/96 preferred-lifetime 432000
valid-lifetime 864000
[SwitchA-dhcp6-pool-2] domain-name aabbcc.com
[SwitchA-dhcp6-pool-2] dns-server 1::2:0:0:2
[SwitchA-dhcp6-pool-2] quit
```

Verifying the configuration

Verify that the clients on subnets 1::1:0:0:0/96 and 1::2:0:0:0/96 can obtain IPv6 addresses and all other configuration parameters from the DHCPv6 server (Switch A). (Details not shown.)

On the DHCPv6 server, display IPv6 addresses assigned to the DHCPv6 clients.

```
[SwitchA] display ipv6 dhcp server ip-in-use
```



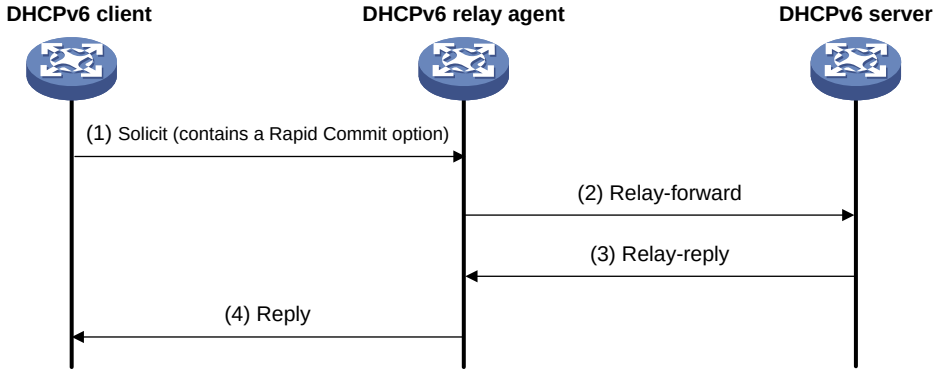
Configuring the DHCPv6 relay agent

About DHCPv6 relay agent

Typical application

A DHCPv6 client usually uses a multicast address to contact the DHCPv6 server on the local link to obtain an IPv6 address and other configuration parameters. As shown in Figure 15, if the DHCPv6 server resides on another subnet, the DHCPv6 clients need a DHCPv6 relay agent to contact the server. The relay agent feature avoids deploying a DHCPv6 server on each subnet.

Figure 15 Typical DHCPv6 relay agent application



DHCPv6 relay agent operating process

As shown in Figure 16, a DHCPv6 client obtains an IPv6 address and other network configuration parameters from a DHCPv6 server through a DHCPv6 relay agent. The following example uses rapid assignment to describe the process:

- The DHCPv6 client sends a Solicit message containing the Rapid Commit option to the multicast address FF02::1:2 of all the DHCPv6 servers and relay agents.
- After receiving the Solicit message, the DHCPv6 relay agent encapsulates the message into the Relay Message option of a Relay-forward message, and sends the message to the DHCPv6 server.
- After obtaining the Solicit message from the Relay-forward message, the DHCPv6 server performs the following tasks:
  - Selects an IPv6 address and other required parameters.
  - Adds them to a reply that is encapsulated within the Relay Message option of a Relay-reply message.
  - Sends the Relay-reply message to the DHCPv6 relay agent.
- The DHCPv6 relay agent obtains the reply from the Relay-reply message and sends the reply to the DHCPv6 client.
- The DHCPv6 client uses the IPv6 address and other network parameters assigned by the DHCPv6 server to complete network configuration.

Figure 16 Operating process of a DHCPv6 relay agent

DHCPv6 relay agent tasks at a glance

To configure a DHCPv6 relay agent, perform the following tasks:

1. Enabling the DHCPv6 relay agent on an interface
2. Specifying DHCPv6 servers on the relay agent
3. (Optional.) Specifying a gateway address for DHCPv6 clients
4. (Optional.) Setting the DUID entry aging timer for smart relay
5. (Optional.) Configuring DHCPv6 smart relay for address acquisition from different IPv6 subnets for a client
6. (Optional.) Setting the DSCP value for DHCPv6 packets sent by the DHCPv6 relay agent
7. (Optional.) Specifying a padding mode for the Interface-ID option
8. (Optional.) Configuring the DHCPv6 relay agent to add Option 37 in Relay-forward messages
9. (Optional.) Enabling the DHCPv6 relay agent to support Option 79
10. (Optional.) Enabling the DHCPv6 relay agent to advertise IPv6 prefixes
11. (Optional.) Enabling advertising host routes for assigned IPv6 addresses
12. (Optional.) Specifying the source IPv6 address for relayed DHCPv6 requests
13. (Optional.) Configuring DHCPv6 relay security features
14. (Optional.) Enabling checking the Reply messages in response to Confirm messages
15. (Optional.) Configuring support for forwarding DHCPv6 replies based on MAC address table

Enabling the DHCPv6 relay agent on an interface

Restrictions and guidelines

As a best practice, do not enable DHCPv6 relay agent and DHCPv6 client on the same interface.

Procedure

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
3. Enable DHCPv6 relay agent on the interface.
   `ipv6 dhcp select relay`

By default, the DHCPv6 relay agent is disabled on the interface.

Specifying DHCPv6 servers on the relay agent

Specifying DHCPv6 server IP addresses

Restrictions and guidelines

- You can use the **ipv6 dhcp relay server-address** command to specify a maximum of eight DHCPv6 servers on the DHCPv6 relay agent interface. The DHCPv6 relay agent forwards DHCP requests to all the specified DHCPv6 servers.
- If a DHCPv6 server address is a link-local address or multicast address, you must specify an outgoing interface by using the **interface** keyword in this command. Otherwise, DHCPv6 packets might fail to reach the DHCPv6 server.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify a DHCPv6 server.
   ipv6 dhcp relay server-address *ipv6-address* [**interface** *interface-type interface-number*] [**public** | **vpn-instance** *vpn-instance-name*]
   By default, no DHCPv6 server is specified.

Specifying DHCPv6 servers for a DHCPv6 address pool on the DHCPv6 relay agent

About this task

This feature allows DHCPv6 clients of the same type to obtain IPv6 addresses, IPv6 prefixes, and other configuration parameters from the DHCPv6 servers in the matching DHCPv6 address pool.

It applies to scenarios where the DHCPv6 relay agent connects to clients of the same access type but classified into different types by their locations. In this case, the relay interface typically has no IPv6 address configured. You can use the **gateway-list** command to specify the gateway addresses for clients matching the same DHCPv6 address pool.

Upon receiving a DHCPv6 Solicit or Request from a client that matches a DHCPv6 address pool, the relay agent processes the packet as follows:

- Fills the **link-address** field of the packet with a specified gateway address.
- Forwards the packet to all DHCPv6 servers in the matching DHCPv6 address pool.

The DHCPv6 servers select a DHCPv6 address pool according to the gateway address.

Restrictions and guidelines

- You can specify a maximum of eight DHCPv6 servers for one DHCPv6 address pool for high availability. The relay agent forwards DHCPv6 Solicit and Request packets to all DHCPv6 servers in the DHCPv6 address pool.

Procedure

1. Enter system view.
   system-view

2. Create a DHCPv6 address pool and enter its view.

   ipv6 dhcp pool *pool-name*

3. Specify gateway addresses for the clients matching the DHCPv6 address pool.

   gateway-list *ipv6-address*&<1-8>

   By default, no gateway address is specified.

4. Specify DHCPv6 servers for the DHCPv6 address pool.

   remote-server *ipv6-address* [**interface** *interface-type interface-number*]

   By default, no DHCPv6 server is specified for the DHCPv6 address pool.

Specifying the DHCPv6 server selection algorithm

About this task

The DHCPv6 relay agent supports the **polling** and **master-backup algorithms for** DHCPv6 server selection.

By default, the DHCPv6 relay agent uses the **polling** algorithm. It forwards DHCPv6 requests to all DHCPv6 servers. The DHCPv6 clients select the DHCPv6 server from which the first received DHCP reply comes.

If the DHCPv6 relay agent uses the **master-backup** algorithm, it forwards DHCP requests to the master DHCPv6 server first. If the master DHCPv6 server is not available, the relay agent forwards the subsequent DHCPv6 requests to a backup DHCPv6 server. If the backup DHCPv6 server is not available, the relay agent selects the next backup DHCPv6 server, and so on. If none of the backup DHCPv6 servers are available, it repeats the process, starting from the master DHCPv6 server.

DHCPv6 server selection also supports the following mechanisms:

- **DHCPv6 server response timeout time**—The DHCPv6 relay agent determines that a DHCPv6 server is not available if it does not receive any response from the server within the DHCPv6 server response timeout time. The DHCPv6 server response timeout time is configurable and the default is 30 seconds.
- **DHCPv6 server switchback**—If the DHCPv6 relay agent selects a backup DHCPv6 server, it does not switch back to the master DHCPv6 server by default. You can configure the DHCPv6 relay agent to switch back to the master DHCPv6 server after a delay. If the master DHCPv6 server is available, the DHCPv6 relay agent forwards DHCPv6 requests to the master DHCPv6 server. If the master DHCPv6 server is not available or does not have idle addresses for assignment, the DHCPv6 relay agent still uses the backup DHCP server.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify the DHCPv6 server selection algorithm.

   ipv6 dhcp relay server-address algorithm { **master-backup** | **polling** }

   By default, the polling algorithm is used. The DHCPv6 relay agent forwards DHCPv6 requests to all DHCPv6 servers.

4. (Optional.) Set the DHCPv6 server response timeout time for DHCP server switchover.

   ipv6 dhcp relay dhcp-server timeout *time*

   By default, the DHCPv6 server response timeout time is 30 seconds.

5. (Optional.) Enable the switchback to the master DHCPv6 server and set the delay.

ipv6 dhcp relay master-server switch-delay *delay-time*

By default, the DHCPv6 relay agent does not switch back to the master DHCPv6 server.

Specifying a gateway address for DHCPv6 clients

About this task

By default, the DHCPv6 relay agent fills the **link-address** field of DHCPv6 Solicit and Request packets with the first IPv6 address of the relay interface. You can specify a gateway address on the relay agent for DHCPv6 clients. The DHCPv6 relay agent uses the specified gateway address to fill the **link-address** field of DHCPv6 Solicit and Request packets.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Specify a gateway address for DHCPv6 clients.

   ipv6 dhcp relay gateway *ipv6-address*

   By default, the DHCPv6 relay agent uses the first IPv6 address of the relay interface as the clients' gateway address.

Setting the DUID entry aging timer for smart relay

About this task

This task sets the aging timer for entries in the DUID table for smart relay.

When receiving a Solicit message from a client, DHCPv6 smart relay uses the DUID table to determine the link address set in the Relay-forward message sent to forward the Solicit message.

The DHCPv6 relay DUID entry for a client contains the following information:

- MAC address of the DHCPv6 client.
- Index of the relay interface connected to the client.
- The remaining lifetime of the entry.
- Link address (one of the global unicast addresses on the relay interface).
- Number of Relay-forward messages sent with this link address to forward a Solicit message from the client.
- The amount of time that has elapsed since the first Relay-forward message was sent with that link address to forward a Solicit message from the client.

To avoid smart relay failure, make sure the aging timer for DUID entries is greater than the time-based link address change trigger set by using the **ipv6 dhcp smart-relay** command. For more information about DHCPv6 smart relay, see "Configuring DHCPv6 smart relay for address acquisition from different IPv6 subnets for a client."

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Set the aging timer for DUID entries on the DHCPv6 relay interface.

ipv6 dhcp relay duid aging-time *seconds*

By default, the aging timer for DUID entries is 60 seconds on the DHCPv6 relay agent.

Configuring DHCPv6 smart relay for address acquisition from different IPv6 subnets for a client

About this task

DHCPv6 smart relay enables a client to obtain an IPv6 address or prefix from one of the subnets to which the relay interface is attached in the following situations:

- The DHCPv6 server does not have free IPv6 addresses or prefixes in one subnet.
- The DHCPv6 server does not respond.

When receiving a Solicit message from a client on a relay interface, DHCPv6 smart relay forwards that message in a Relay-forward message to DHCPv6 servers. In the Relay-forward message, DHCPv6 smart relay sets the lowest global unicast address on the relay interface in the **link-address** field.

When a DHCPv6 server receives the Relay-forward message, it searches for free IPv6 address or prefix resources on the same subnet as the received link address.

- If free resources are available, the DHCPv6 server replies with a free address or prefix.
- If no free resources are available, the DHCPv6 server returns a NOADDRS-AVAIL or NOPREIFIX-AVAIL message.

Upon receipt of the NOADDRS-AVAIL or NOPREIFIX-AVAIL message, DHCPv6 smart relay changes the link address of the relay interface to forward the subsequent Solicit message. DHCPv6 smart relay selects one of the global unicast addresses on the relay interface in a round-robin manner to forward Solicit messages from the client until the client obtains an address.

When forwarding the Solicit message from a client, DHCPv6 smart relay agent also changes the link address if the following conditions are met:

- The number of Relay-forward messages sent with that link address for the client has reached the limit.
- The amount of time that has elapsed since the first Relay-forward message was sent with that link address has reached the limit.

Prerequisites

Before you enable DHCPv6 smart relay, you must first enable DHCPv6 relay entry recording by executing the **ipv6 dhcp relay client-information record** command. For more information about DHCPv6 relay entry recording, see "Enabling the DHCPv6 relay agent to record relay entries".

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. (Optional.) Configure smart relay.

   ipv6 dhcp smart-relay { **count** *count* | **time** *seconds* } *

   By default, DHCPv6 smart relay changes the link address if the following conditions are met:

   - That link address has been used in a minimum of three Relay-forward messages sent to forward the Solicit message from a client.

- A minimum of 24 seconds has elapsed since the first Relay-forward message was sent with that link address.

4. Enable DHCPv6 smart relay.

   ipv6 dhcp smart-relay enable

   By default, DHCPv6 smart relay is disabled.

Setting the DSCP value for DHCPv6 packets sent by the DHCPv6 relay agent

About this task

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet.

Procedure

1. Enter system view.

   system-view

2. Set the DSCP value for DHCPv6 packets sent by the DHCPv6 relay agent.

   ipv6 dhcp dscp *dscp-value*

   The default DSCP value is 56.

Specifying a padding mode for the Interface-ID option

About this task

This feature enables the relay agent to fill the Interface-ID option in the specified mode. When receiving a DHCPv6 packet from a client, the relay agent fills the Interface-ID option in the mode and then forwards the packet to the DHCPv6 server.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify a padding mode for the Interface-ID option.

   ipv6 dhcp relay interface-id { **bas** | **interface** | **user-mac** }

   By default, the relay agent fills the Interface-ID option with the interface index of the interface.

Configuring the DHCPv6 relay agent to add Option 37 in Relay-forward messages

About this task

This feature enables the DHCPv6 relay agent to add Option 37 in the Relay-forward message sent to DHCPv6 server for a client. Option 37 provides client location information for DHCPv6 servers to decide the IPv6 address and other settings to be assigned to the requesting client.

For more information about Option 37, see "Option 37".

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable the DHCPv6 relay agent to add Option 37 in Relay-forward messages.
   ipv6 dhcp relay remote-id enable
   By default, the DHCPv6 relay agent does not add Option 37 in Relay-forward messages.
4. (Optional.) Configure the DUID to be set in Option 37.
   ipv6 dhcp relay remote-id duid { **ascii** *ascii-string* | **hex** *hex-string* }
   By default, the DHCPv6 relay agent uses its own DUID in Option 37.

Enabling the DHCPv6 relay agent to support Option 79

About this task

If DHCPv6 relay agents exist in the network, the DHCPv6 server needs the MAC address of the DHCPv6 client for authentication or for IPv6 address or prefix assignment. To meet the requirement, enable the DHCPv6 relay agent that the client first passes to support Option 79. This feature allows the DHCPv6 relay agent to learn the MAC address in the client request. When the relay agent generates a Relay-Forward packet for the request, it fills the MAC address of the client in Option 79. The Relay-Forward packet is then forwarded to the DHCPv6 server.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable the DHCPv6 relay agent to support Option 79.
   ipv6 dhcp relay client-link-address enable
   By default, the DHCPv6 relay agent does not support Option 79.

Enabling the DHCPv6 relay agent to advertise IPv6 prefixes

About this task

A DHCPv6 client can obtain an IPv6 prefix through DHCPv6 and use this IPv6 prefix to assign IPv6 address to clients in a downstream network. If the IPv6 prefix is in a different subnet than the IPv6 address of the DHCPv6 client's upstream interface, the clients in the downstream network cannot access the external network. You can enable the DHCPv6 relay agent that is on the same link as the DHCPv6 client to advertise the IPv6 prefix.

Procedure

1. Enter system view.

```
system-view
```

2. Enable the DHCPv6 relay agent to advertise IPv6 prefixes.

   ```
   ipv6 dhcp advertise pd-route
   ```

   By default, the DHCPv6 relay agent does not advertise IPv6 prefixes.

   Before using this command, make sure the DHCPv6 relay agent is enabled to record DHCPv6 relay entries.

Enabling advertising host routes for assigned IPv6 addresses

About this task

In a network where ND cannot resolve global unicast addresses, network devices cannot generate ND entries for all global unicast addresses. If a DHCPv6 client obtains a global unicast address, the neighboring devices do not have the ND entries for this global unicast address, thus cannot forward the packets destined for the client. To resolve this problem, enable the DHCPv6 relay agent to advertise host routes for assigned IPv6 addresses in DHCPv6 replies. The advertised route information is as follows:

- The destination IP address is the assigned IPv6 address.
- The next hop is the link-local address of the DHCPv6 client.
- The output interface is the interface that forwards the reply.

After the relay agent receives a packet destined for the assigned IPv6 address, the relay agent looks up the routing table for the next hop. ND resolution can succeed because the next hop is the link-local address of the client. The relay agent searches the ND table for the MAC address of the client based on the next hop and then forwards the packet.

Restrictions and guidelines

Before using this feature on the DHCPv6 relay agent, enable the DHCPv6 relay agent to record DHCPv6 relay entries first.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable the DHCPv6 relay agent to advertise host routes for IPv6 addresses assigned to DHCPv6 clients.

   ```
   ipv6 dhcp advertise address-route
   ```

   By default, the DHCPv6 relay agent does not advertise host routes for IPv6 addresses assigned to DHCPv6 clients.

Specifying the source IPv6 address for relayed DHCPv6 requests

About this task

This task is required if a relay interface does not have routes to DHCPv6 servers. You can specify a global unicast address or the IPv6 address of another interface (typically the loopback interface) as the source IPv6 address for DHCPv6 requests. The relay interface inserts the source IPv6 address in the source IPv6 address field of DHCPv6 requests.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify the source IPv6 address for relayed DHCPv6 requests.

   ipv6 dhcp relay source-address { *ipv6-address* | **interface** *interface-type interface-number* }

   By default, the DHCPv6 relay agent uses the IPv6 global unicast address of the interface that connects to the DHCPv6 server as the source IPv6 address for relayed DHCPv6 requests.

   If the specified interface does not have an IPv6 global unicast address, the IPv6 address of the output interface is used as the source address for relayed DHCPv6 requests.

Configuring DHCPv6 relay security features

Enabling the DHCPv6 relay agent to record relay entries

About this task

This feature enables the DHCPv6 relay agent to automatically record DHCPv6 relay entries after DHCPv6 clients obtain IPv6 addresses or prefixes through DHCPv6. A DHCPv6 relay entry contains the binding between a client's hardware address and IPv6 address or prefix.

Some security features, such as IP source guard, use DHCPv6 relay entries to check incoming packets and block packets that do not match any entry. Hosts using manually configured IPv6 addresses are denied to access external networks through the relay agent. For more information about IP source guard, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the recording of DHCPv6 relay entries.

   ipv6 dhcp relay client-information record

   By default, the DHCPv6 relay agent does not record relay entries.

Enabling IPv6 release notification

About this task

This feature enables the DHCPv6 relay agent to send a Release message to the DHCPv6 server after it deletes a DHCPv6 relay entry. After the DHCPv6 server receives the message, it reclaims the IPv6 address or prefix and marks the lease as expired.

If you do not enable this feature, the DHCPv6 relay agent will not send a Release message after it deletes a relay entry.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.
   interface *interface-type interface-number*
3. Enable IPv6 release notification.
   ipv6 dhcp relay release-agent
   By default, IPv6 release notification is disabled.

Enabling client offline detection

About this task

This feature enables the DHCPv6 relay agent to detect the status of ND entries. After an ND entry ages out, the DHCPv6 relay agent considers the client offline and deletes the relay entry for the client. For more information about ND, see "Configuring basic IPv6 settings."

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable client offline detection.
   ipv6 dhcp client-detect
   By default, client offline detection is disabled.

Enabling checking the Reply messages in response to Confirm messages

About this task

Multiple DHCPv6 servers might be deployed on a relay network, for example, DHCPv6 server A and DHCPv6 server B. When DHCPv6 server A receives a Request message from a DHCPv6 client, it assigns an IPv6 address to that client. In this example, the assigned IPv6 address does not belong to any address pool on DHCPv6 server B. Upon receiving the IPv6 address, the client multicasts a Confirm message to all DHCPv6 servers on the network to verify that the IPv6 address is usable. On receipt of the Confirm message, DHCPv6 server A and DHCPv6 server B act differently as follows:

- DHCPv6 server A returns a Reply message to notify the client that the IPv6 address is usable.
- DHCPv6 server B returns a Reply message to notify the client that it fails to assign the IPv6 address.

The DHCPv6 relay agent then forwards the two Reply messages to the client. As a result, the client might fail to obtain the IPv6 address.

To avoid the issue above, enable the DHCPv6 relay agent to check the Reply messages in response to Confirm messages. When the DHCPv6 relay agent receives the first Reply message in response to a client's Confirm message, it performs the following task:

1. Starts a check timer that is fixed at 0.5 seconds.
2. Identifies whether the Reply messages received before the check timer expires confirm successful address allocation.
3. Forwards the Reply messages received after the check timer expires, using the original forwarding mechanism without checking them.

The operating mechanism of this feature is as follows:

- If the first received Reply message confirms successful address allocation to the client, the relay agent forwards that Reply message to the client. The relay agent processes the Reply messages subsequently received for the client within the check timer as follows:
  - Discards the Reply messages that confirm unsuccessful address allocation.
  - Forwards the Reply messages that confirm successful address allocation.
- If the first received Reply message confirms unsuccessful address allocation to the client, the relay agent caches that Reply message and waits for a Reply message of successful address allocation:
  - If the relay agent does not receive such a Reply message for the client within the check timer, it performs the following operations after the check timer expires:
    - Forwards the cached Reply message to the client.
    - Discards the other Reply messages received for the client before the check timer expires.
  - If the relay agent receives such a Reply message for the client within the check timer, it forwards that Reply message to the client and discards the cached Reply message. The relay agent processes the Reply messages received for the client within the check timer as follows:
    - Discards the Reply messages that confirm unsuccessful address allocation.
    - Forwards the Reply messages that confirm successful address allocation.
- If the relay agent receives new DHCP requests (including Confirm messages) from the client, it deletes the cached Reply message and disables the check timer.
- If the relay agent receives a new DHCP request from the client, it determines that the client has initiated a new request. In this situation, the relay agent will directly forward the Reply messages in response to the Confirm message of the client, without checking them.

Procedure

1. Enter system view.

   `system-view`
2. Enable the DHCPv6 relay agent to check the Reply messages in response to Confirm messages.

   `ipv6 dhcp relay confirm-reply-check`

   By default, the DHCPv6 relay agent does not check the Reply messages in response to Confirm messages.

Configuring support for forwarding DHCPv6 replies based on MAC address table

About this task

When a DHCPv6 client sends a request to its gateway enabled with DHCPv6 relay agent, the gateway records the request forwarding information for the client before relaying the request to the DHCPv6 server. The request forwarding information contains the MAC address of the DHCPv6 client and output interface of the request packet. If another gateway receives the reply for this request, the gateway discards the reply by default because it does not have the matching forwarding information for the reply. As a result, the client cannot obtain an IPv6 address or prefix.

To solve this problem, configure the support for forwarding replies based on MAC address table on the relay agent that is connected to the DHCPv6 server. This feature allows the relay agent to look up the MAC address table for the output interface for the replies that do not have the request forwarding information. This feature ensures that DHCPv6 clients receive DHCPv6 reply packets.

If the **broadcast** keyword is specified, the DHCPv6 relay agent broadcasts the DHCPv6 reply out of the interface found in the matching MAC address entry. When the DHCPv6 relay agent connecting to the requesting DHCPv6 client receives the reply, it sends the reply to its CPU before broadcasting the reply. If recording relay entries is enabled on this relay agent, a relay entry is generated for the DHCPv6 client.

If the **broadcast** keyword is not specified, the DHCPv6 relay agent connecting to the requesting client will directly forward the reply based on the MAC address instead of delivering it up to the CPU. In this case, the DHCPv6 relay agent cannot be aware that the packet is a DHCPv6 reply, thus no relay entry is generated for the client even if the recording of relay entries is enabled.

Restrictions and guidelines

This task takes effect only when the replies from the DHCPv6 server to the relay agent carry client MAC address information. To meet this requirement, enable the DHCPv6 relay agent to insert client MAC addresses into Option 18 for DHCPv6 requests by using the **ipv6 dhcp relay interface-id user mac** command.

Procedure

1. Enter system view.

   system-view

2. Enable MAC address table lookup for DHCPv6 replies that do not have request forwarding information.

   ipv6 dhcp relay mac-forward enable [**broadcast**]

   By default, the DHCPv6 relay agent discards a DHCPv6 reply if the relay agent does not have the request forwarding information for the reply.

Display and maintenance commands for DHCPv6 relay agent

Execute **display** commands in any view and **reset** commands in user view.

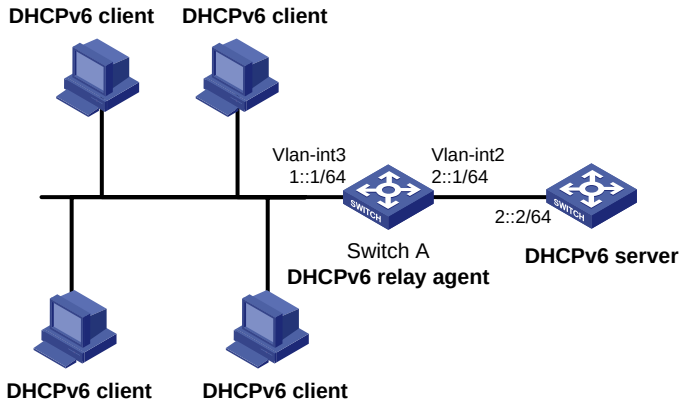
NOTE:

The S5200-EI-G switch series does not support the **display ipv6 dhcp relay m-lag-status** command.

Task	Command
Display the DUID of the local device.	**display ipv6 dhcp duid**
Display DHCPv6 relay entries that record clients' IPv6 address information.	**display ipv6 dhcp relay client-information address** [**interface** *interface-type interface-number* | **ipv6** *ipv6-address*] [**vpn-instance** *vpn-instance-name*]
Display DHCPv6 relay entries that record clients' IPv6 prefix information.	**display ipv6 dhcp relay client-information pd** [**interface** *interface-type interface-number* | **prefix** *prefix/prefix-len*] [**vpn-instance** *vpn-instance-name*]
Display M-LAG status information recorded on the DHCPv6 relay agent.	**display ipv6 dhcp relay m-lag-status**

Task	Command
Display DHCPv6 server addresses specified on a DHCPv6 relay interface.	**display ipv6 dhcp relay server-address** [**interface** *interface-type interface-number*]
Display packet statistics on the DHCPv6 relay agent.	**display ipv6 dhcp relay statistics** [**interface** *interface-type interface-number*]
Clear DHCPv6 relay entries that record clients' IPv6 address information.	**reset ipv6 dhcp relay client-information address** [**interface** *interface-type interface-number* | **ipv6** *ipv6-address*] [**vpn-instance** *vpn-instance-name*]
Clear DHCPv6 relay entries that record clients' IPv6 prefix information.	**reset ipv6 dhcp relay client-information pd** [**interface** *interface-type interface-number* | **prefix** *prefix/prefix-len*] [**vpn-instance** *vpn-instance-name*]
Clear packets statistics on the DHCPv6 relay agent.	**reset ipv6 dhcp relay statistics** [**interface** *interface-type interface-number*]

DHCPv6 relay agent configuration examples



Example: Configuring DHCPv6 relay agent

Network configuration

As shown in Figure 17, configure the DHCPv6 relay agent on Switch A to relay DHCPv6 packets between DHCPv6 clients and the DHCPv6 server.

Switch A acts as the gateway of network 1::/64. It sends RA messages to notify the hosts to obtain IPv6 addresses and other configuration parameters through DHCPv6. For more information about RA messages, see "Configuring basic IPv6 settings."

Figure 17 Network diagram

Procedure

Specify IPv6 addresses for VLAN-interface 2 and VLAN-interface 3.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ipv6 address 2::1 64
[SwitchA-Vlan-interface2] quit
[SwitchA] interface vlan-interface 3
[SwitchA-Vlan-interface3] ipv6 address 1::1 64
```

Disable RA message suppression on VLAN-interface 3.

```
[SwitchA-Vlan-interface3] undo ipv6 nd ra halt
```

Set the M flag to 1 in RA advertisements to be sent on VLAN-interface 3. Hosts that receive the RA advertisements will obtain IPv6 addresses through DHCPv6.

```
[SwitchA-Vlan-interface3] ipv6 nd autoconfig managed-address-flag
```

Set the O flag to 1 in RA advertisements to be sent on VLAN-interface 3. Hosts that receive the RA advertisements will obtain information other than IPv6 address through DHCPv6.

```
[SwitchA-Vlan-interface3] ipv6 nd autoconfig other-flag
```

Enable the DHCPv6 relay agent on VLAN-interface 3 and specify the DHCPv6 server on the relay agent.

```
[SwitchA-Vlan-interface3] ipv6 dhcp select relay
[SwitchA-Vlan-interface3] ipv6 dhcp relay server-address 2::2
```

Verifying the configuration

Display DHCPv6 server address information on Switch A.

```
[SwitchA-Vlan-interface3] display ipv6 dhcp relay server-address
Interface: Vlan-interface3
 Server address      Outgoing Interface         Public/VRF name
 2::2                                           --/--
```

Display packet statistics on the DHCPv6 relay agent.

```
[SwitchA-Vlan-interface3] display ipv6 dhcp relay statistics
Packets dropped               :  0
Packets received              :  14
    Solicit                   :  0
    Request                   :  0
    Confirm                   :  0
    Renew                     :  0
    Rebind                    :  0
    Release                   :  0
    Decline                   :  0
    Information-request       :  7
    Relay-forward             :  0
    Relay-reply               :  7
Packets sent                  :  14
    Advertise                 :  0
    Reconfigure               :  0
    Reply                     :  7
    Relay-forward             :  7
    Relay-reply               :  0
```

Configuring the DHCPv6 client

About the DHCPv6 client

With DHCPv6 client configured, an interface can obtain configuration parameters from the DHCPv6 server.

A DHCPv6 client can use DHCPv6 to complete the following functions:

- Obtain an IPv6 address, an IPv6 prefix, or both, and obtain other configuration parameters. If DHCPv6 server is enabled on the device, the client can automatically save the obtained parameters to a DHCPv6 option group. With the obtained IPv6 prefix, the client can generate its global unicast address.
- Support stateless DHCPv6 to obtain configuration parameters except IPv6 address and IPv6 prefix. The client obtains an IPv6 address through stateless IPv6 address autoconfiguration. If the client receives an RA message with the M flag set to 0 and the O flag set to 1 during address acquisition, stateless DHCPv6 starts.

Restrictions and guidelines: DHCPv6 client configuration

Do not configure the DHCPv6 client on the same interface as the DHCPv6 server or the DHCPv6 relay agent.

DHCPv6 client tasks at a glance

To configure a DHCPv6 client, perform the following tasks:

1. (Optional.) Configuring the DHCPv6 client DUID
2. Configuring the DHCPv6 client to obtain IPv6 addresses, IPv6 prefixes and other network parameters

   Choose the following tasks as needed:

   - Configuring IPv6 address acquisition
   - Configuring IPv6 prefix acquisition
   - Configuring IPv6 address and prefix acquisition
   - Configuring acquisition of configuration parameters except IP addresses and prefixes
3. (Optional.) Setting the DSCP value for DHCPv6 packets sent by the DHCPv6 client

Configuring the DHCPv6 client DUID

About this task

The DUID of a DHCPv6 client is the globally unique identifier of the client. The client pads its DUID into Option 1 of the DHCPv6 packet that it sends to the DHCPv6 server. The DHCPv6 server can assign specific IPv6 addresses or prefixes to DHCPv6 clients with specific DUIDs.

Restrictions and guidelines

Make sure the DUID that you configure is unique.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the DHCPv6 client DUID.
   ipv6 dhcp client duid { **ascii** *ascii-string* | **hex** *hex-string* | **mac** *interface-type interface-number* }
   By default, the interface uses the device bridge MAC address to generate its DHCPv6 client DUID.

Configuring IPv6 address acquisition

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the interface to use DHCPv6 to obtain an IPv6 address and other configuration parameters.
   ipv6 address dhcp-alloc [**option-group** *group-number* | **rapid-commit**] *
   - If the switch starts up with the initial configuration, the default setting of this command takes effect. An interface does not use DHCPv6 to obtain an IPv6 address and other network settings.
   - If the switch starts up with the factory defaults, the factory default setting of this command takes effect. Only VLAN-interface 1 uses DHCPv6 to obtain an IPv6 address and other network settings.

     For more information about initial configuration and factory defaults, see configuration file management configuration in *Fundamentals Configuration Guide*.

Configuring IPv6 prefix acquisition

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the interface to use DHCPv6 to obtain an IPv6 prefix and other configuration parameters.
   ipv6 dhcp client pd *prefix-number* [**option-group** *group-number* | **rapid-commit**] *
   By default, the interface does not use DHCPv6 for IPv6 prefix acquisition.

Configuring IPv6 address and prefix acquisition

1. Enter system view.
   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the interface to use DHCPv6 to obtain an IPv6 address, an IPv6 prefix, and other configuration parameters.

   ipv6 dhcp client stateful prefix *prefix-number* [**option-group** *option-group-number* | **rapid-commit**] *

   By default, the interface does not use DHCPv6 for IPv6 address and prefix acquisition.

Configuring acquisition of configuration parameters except IP addresses and prefixes

About this task

When a DHCPv6 client has obtained an IPv6 address and prefix, you can configure the following methods for the client to obtain other network configuration parameters:

- Execute the **ipv6 address auto** command to enable an interface to automatically generate an IPv6 global unicast address and a link-local address. Then stateless DHCPv6 will be triggered when the M flag is set to 0 and the O flag is set to 1 in a received RA message. For more information about the commands, see *Layer 3—IP services Command Reference*.
- Executing the **ipv6 dhcp client stateless enable** command on an interface to enable the interface to act as a DHCPv6 client to obtain configuration parameters from a DHCPv6 server.

If you execute both the **ip address auto** and **ipv6 dhcp client stateless enable** commands, the interface acts as follows:

- Generate a global unicast address and a link-local address.
- Obtain other configuration parameters from a DHCPv6 server.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the interface to support stateless DHCPv6. Choose the options to configure as needed:
   - Enable stateless IPv6 address autoconfiguration:

     ipv6 address auto
   - Configure the client to obtain network parameters from DHCPv6 servers:

     ipv6 dhcp client stateless enable

   By default, the interface does not support stateless DHCPv6.

Setting the DSCP value for DHCPv6 packets sent by the DHCPv6 client

About this task

The DSCP value of a packet specifies the priority level of the packet and affects the transmission priority of the packet.

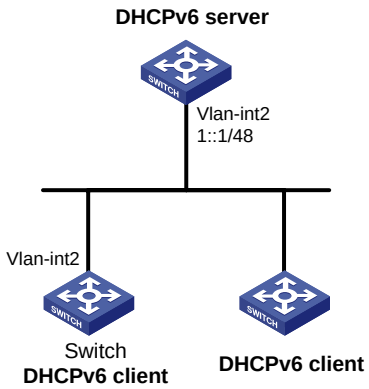
Procedure

1. Enter system view.
   system-view
2. Set the DSCP value for DHCPv6 packets sent by the DHCPv6 client.
   ipv6 dhcp client dscp *dscp-value*
   By default, the DSCP value in DHCPv6 packets sent by the DHCPv6 client is 56.

Display and maintenance commands for DHCPv6 client

Execute the **display** commands in any view, and execute the **reset** command in user view.

Task	Command
Display the DHCPv6 client information.	**display ipv6 dhcp client** [**interface** *interface-type interface-number*]
Display the DHCPv6 client statistics.	**display ipv6 dhcp client statistics** [**interface** *interface-type interface-number*]
Clear the DHCPv6 client statistics.	**reset ipv6 dhcp client statistics** [**interface** *interface-type interface-number*]



DHCPv6 client configuration examples

Example: Configuring IPv6 address acquisition

Network configuration

As shown in Figure 18, configure the switch to use DHCPv6 to obtain configuration parameters from the DHCPv6 server. The parameters include IPv6 address, DNS server address, domain name suffix, SIP server address, and SIP server domain name.

Figure 18 Network diagram

Procedure

You must configure the DHCPv6 server first before configuring the DHCPv6 client. For information about configuring DHCPv6 server, see "Configuring the DHCPv6 server."

Configure VLAN-interface 2 as a DHCPv6 client for IPv6 address acquisition. Configure the DHCPv6 client to support DHCPv6 rapid address assignment. Configure the DHCPv6 client to create a dynamic DHCPv6 option group for saving configuration parameters.

```
<Switch> system-view
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ipv6 address dhcp-alloc rapid-commit option-group 1
[Switch-Vlan-interface2] quit
```

Verifying the configuration

Verify that the client has obtained an IPv6 address and other configuration parameters from the server.

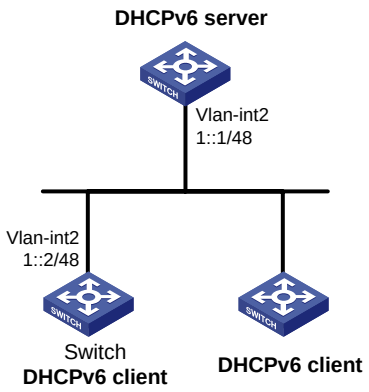
```
[Switch] display ipv6 dhcp client
Vlan-interface2:
  Type: Stateful client requesting address
    State: OPEN
    Client DUID: 0003000100e002000000
    Preferred server:
      Reachable via address: FE80::2E0:1FF:FE00:18
      Server DUID: 0003000100e001000000
    IA_NA: IAID 0x00000642, T1 50 sec, T2 80 sec
      Address: 1:1::2/128
       Preferred lifetime 100 sec, valid lifetime 200 sec
       Will expire on Mar 27 2014 at 08:06:57 (198 seconds left)
    DNS server addresses:
      2000::FF
    Domain name:
      example.com
    SIP server addresses:
      2:2::4
    SIP server domain names:
      bbb.example.com
```

After DHCPv6 server is enabled on the device, verify that configuration parameters are saved in a dynamic DHCPv6 option group.

```
[Switch] display ipv6 dhcp option-group 1
DHCPv6 option group: 1
  DNS server addresses:
    Type: Dynamic (DHCPv6 address allocation)
    Interface: Vlan-interface2
    2000::FF
  Domain name:
    Type: Dynamic (DHCPv6 address allocation)
    Interface: Vlan-interface2
    example.com
  SIP server addresses:
    Type: Dynamic (DHCPv6 address allocation)
    Interface: Vlan-interface2
```

```
    2:2::4
  SIP server domain names:
    Type: Dynamic (DHCPv6 address allocation)
    Interface: Vlan-interface2
    bbb.example.com
```

Verify that the DHCPv6 client has obtained an IPv6 address..



```
[Switch] display ipv6 interface brief
*down: administratively down
(s): spoofing
Interface                              Physical   Protocol   IPv6 Address
Vlan-interface2                        up         up         1:1::2
```

Example: Configuring IPv6 prefix acquisition

Network configuration

As shown in Figure 19, configure the switch to use DHCPv6 to obtain configuration parameters from the DHCPv6 server. The parameters include IPv6 prefix, DNS server address, domain name suffix, SIP server address, and SIP server domain name.

Figure 19 Network diagram

Procedure

You must configure the DHCPv6 server first before configuring the DHCPv6 client. For information about configuring DHCPv6 server, see "Configuring the DHCPv6 server."

Configure an IPv6 address for VLAN-interface 2 that is connected to the DHCPv6 server.

```
<Switch> system-view
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ipv6 address 1::2/48
```

Configure VLAN-interface 2 as a DHCPv6 client for IPv6 prefix acquisition. Configure the DHCPv6 client to support DHCPv6 rapid prefix assignment. Configure the DHCPv6 client to assign an ID to the obtained IPv6 prefix and create a dynamic DHCPv6 option group for saving configuration parameters.

```
[Switch-Vlan-interface2] ipv6 dhcp client pd 1 rapid-commit option-group 1
[Switch-Vlan-interface2] quit
```

Verifying the configuration

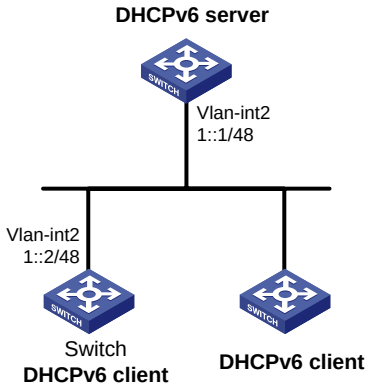
Verify that the DHCPv6 client has obtained an IPv6 prefix and other configuration parameters from the DHCPv6 server.

```
[Switch] display ipv6 dhcp client
Vlan-interface2:
  Type: Stateful client requesting prefix
    State: OPEN
    Client DUID: 0003000100e002000000
    Preferred server:
      Reachable via address: FE80::2E0:1FF:FE00:18
      Server DUID: 0003000100e001000000
    IA_PD: IAID 0x00000642, T1 50 sec, T2 80 sec
      Prefix: 12:34::/48
        Preferred lifetime 100 sec, valid lifetime 200 sec
        Will expire on Feb 4 2014 at 15:37:20(80 seconds left)
    DNS server addresses:
      2000::FF
    Domain name:
      example.com
    SIP server addresses:
      2:2::4
    SIP server domain names:
      bbb.example.com
```

Verify that the client has obtained an IPv6 prefix.

```
[Switch] display ipv6 prefix 1
Number: 1
Type  : Dynamic
Prefix: 12:34::/48
Preferred lifetime 100 sec, valid lifetime 200 sec
```

After DHCPv6 server is enabled on the device, verify that configuration parameters are saved in a dynamic DHCPv6 option group.



```
[Switch] display ipv6 dhcp option-group 1
DHCPv6 option group: 1
  DNS server addresses:
    Type: Dynamic (DHCPv6 prefix allocation)
    Interface: Vlan-interface2
    2000::FF
  Domain name:
    Type: Dynamic (DHCPv6 prefix allocation)
    Interface: Vlan-interface2
    example.com
  SIP server addresses:
    Type: Dynamic (DHCPv6 prefix allocation)
    Interface: Vlan-interface2
    2:2::4
  SIP server domain names:
    Type: Dynamic (DHCPv6 prefix allocation)
    Interface: Vlan-interface2
    bbb.example.com
```

Example: Configuring IPv6 address and prefix acquisition

Network configuration

As shown in Figure 20, configure the switch to use DHCPv6 to obtain configuration parameters from the DHCPv6 server. The parameters include IPv6 address, IPv6 prefix, DNS server address, domain name suffix, SIP server address, and SIP server domain name.

Figure 20 Network diagram

Procedure

You must configure the DHCPv6 server before configuring the DHCPv6 client. For information about configuring the DHCPv6 server, see "Configuring the DHCPv6 server."

Configure an IPv6 address for VLAN-interface 2 that is connected to the DHCPv6 server.

```
<Switch> system-view
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ipv6 address 1::2/48
```

Configure VLAN-interface 2 as a DHCPv6 client for IPv6 address and prefix acquisition. Specify IDs for the dynamic IPv6 prefix and dynamic DHCPv6 option group, and configure the client to support rapid address and prefix assignment.

```
[Switch-Vlan-interface2] ipv6 dhcp client stateful prefix 1 rapid-commit option-group 1
[Switch-Vlan-interface2] quit
```

Verifying the configuration

Verify that the DHCPv6 client has obtained an IPv6 address, an IPv6 prefix, and other configuration parameters from the DHCPv6 server.

```
[Switch] display ipv6 dhcp client
Vlan-interface2:
  Type: Stateful client requesting address and prefix
    State: OPEN
    Client DUID: 0003000100e002000000
    Preferred server:
      Reachable via address: FE80::2E0:1FF:FE00:18
      Server DUID: 0003000100e001000000
    IA_NA: IAID 0x00000642, T1 50 sec, T2 80 sec
      Address: 1:1::2/128
        Preferred lifetime 100 sec, valid lifetime 200 sec
        Will expire on Mar 27 2014 at 08:02:00 (199 seconds left)
    IA_PD: IAID 0x00000642, T1 50 sec, T2 80 sec
```

```
      Prefix: 12:34::/48
        Preferred lifetime 100 sec, valid lifetime 200 sec
        Will expire on Mar 27 2014 at 08:02:00 (199 seconds left)
    DNS server addresses:
      2000::FF
    Domain name:
      example.com
    SIP server addresses:
      2:2::4
    SIP server domain names:
      bbb.example.com
```

Verify that the DHCPv6 client has obtained an IPv6 address.

```
[Switch] display ipv6 interface brief
*down: administratively down
(s): spoofing
Interface                              Physical   Protocol   IPv6 Address
Vlan-interface2                        up         up         1:1::2
```

Verify that the client has obtained an IPv6 prefix.

```
[Switch] display ipv6 prefix 1

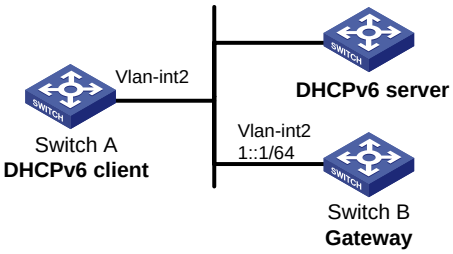
Type  : Dynamic
Prefix: 12:34::/48
Preferred lifetime 100 sec, valid lifetime 200 sec
```

After DHCPv6 server is enabled on the device, verify that configuration parameters are saved in a dynamic DHCPv6 option group.



```
[Switch] display ipv6 dhcp option-group 1
DNS server addresses:
    Type: Dynamic (DHCPv6 address and prefix allocation)
    Interface: Vlan-interface2
    2000::FF
  Domain name:
    Type: Dynamic (DHCPv6 address and prefix allocation)
    Interface: Vlan-interface2
    example.com
  SIP server addresses:
    Type: Dynamic (DHCPv6 address and prefix allocation)
    Interface: Vlan-interface2
    2:2::4
  SIP server domain names:
    Type: Dynamic (DHCPv6 address and prefix allocation)
    Interface: Vlan-interface2
    bbb.example.com
```

Example: Configuring stateless DHCPv6

Network configuration

As shown in Figure 21, configure Switch A to use stateless DHCPv6 to obtain configuration parameters except IPv6 address and IPv6 prefix. Switch B acts as the gateway and advertises RA messages periodically.

Figure 21 Network diagram

Procedure

You must configure the DHCPv6 server first before configuring the DHCPv6 client. For information about configuring DHCPv6 server, see "Configuring the DHCPv6 server."

1. Configure the gateway Switch B.

   # Configure an IPv6 address for VLAN-interface 2.

   ```
   <SwitchB> system-view
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] ipv6 address 1::1 64
   ```

   # Set the O flag to 1 in RA advertisements to be sent on VLAN-interface 2. Hosts that receive the RA advertisements will obtain information other than IPv6 address through DHCPv6.

   ```
   [SwitchB-Vlan-interface2] ipv6 nd autoconfig other-flag
   ```

   # Disable RA message suppression on VLAN-interface 2.

   ```
   [SwitchB-Vlan-interface2] undo ipv6 nd ra halt
   ```

2. Configure the DHCPv6 client Switch A.

   # Enable stateless IPv6 address autoconfiguration on VLAN-interface 2.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ipv6 address auto
   ```

   With stateless IPv6 address autoconfiguration enabled, but no IPv6 address configured for VLAN-interface 2, Switch A automatically generates a link-local address. It sends an RS message to Switch B to request configuration information for IPv6 address generation. Upon receiving the RS message, Switch B sends back an RA message. After receiving an RA message with the M flag set to 0 and the O flag set to 1, Switch A performs stateless DHCPv6 to get other configuration parameters.

Verifying the configuration

Display the DHCPv6 client information.

```
[SwitchA-Vlan-interface2] display ipv6 dhcp client interface vlan-interface 2
Vlan-interface2:
 Type: Stateless client
    State: OPEN
    Client DUID: 00030001000fe2ff0000
    Preferred server:
```

```
      Reachable via address: FE80::213:7FFF:FEF6:C818
      Server DUID: 0003000100137ff6c818
    DNS server addresses:
      1:2:4::5
      1:2:4::7
    Domain name:
      abc.example.com
```

Display the DHCPv6 client statistics.

```
[SwitchA-Vlan-interface2] display ipv6 dhcp client statistics
Interface                    :  Vlan-interface2
Packets received             :  1
        Reply                :  1
        Advertise            :  0
        Reconfigure          :  0
        Invalid              :  0
Packets sent                 :  5
        Solicit              :  0
        Request              :  0
        Renew                :  0
        Rebind               :  0
        Information-request  :  5
        Release              :  0
        Decline              :  0
```

Configuring DHCPv6 snooping

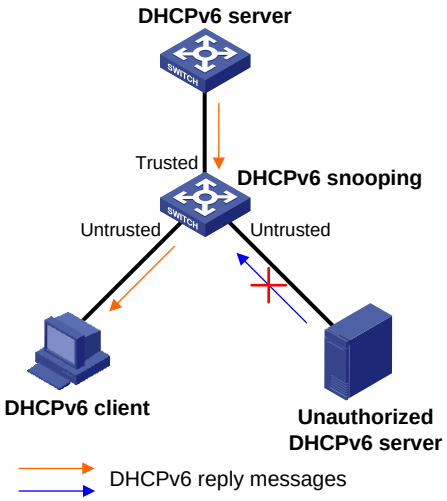
About DHCPv6 snooping

It guarantees that DHCPv6 clients obtain IPv6 addresses or prefixes from authorized DHCPv6 servers. Also, it records IP-to-MAC bindings of DHCPv6 clients (called DHCPv6 snooping address entries) and prefix-to-port bindings of DHCPv6 clients (called DHCPv6 snooping prefix entries) for security purposes.

DHCPv6 snooping defines trusted and untrusted ports to make sure that clients obtain IPv6 addresses only from authorized DHCPv6 servers.

- **Trusted**—A trusted port can forward DHCPv6 messages correctly to make sure the clients get IPv6 addresses from authorized DHCPv6 servers.
- **Untrusted**—An untrusted port discards received messages sent by DHCPv6 servers to prevent unauthorized servers from assigning IPv6 addresses.

DHCPv6 snooping reads DHCP-ACK messages received from trusted ports and DHCP-REQUEST messages to create DHCPv6 snooping entries. A DHCPv6 snooping entry can be an address entry or a prefix entry.



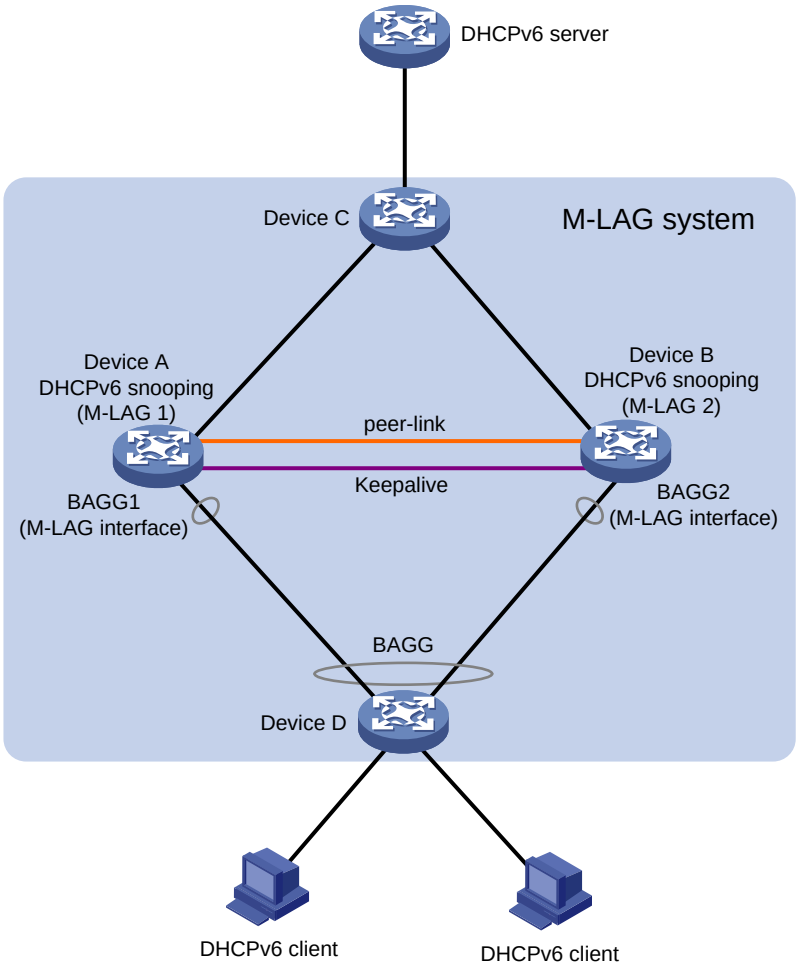
- A DHCPv6 address entry includes the MAC and IP addresses of a client, the port that connects to the DHCPv6 client, and the VLAN. You can use the **`display ipv6 dhcp snooping binding`** command to display the IP addresses of users for management.
- A DHCPv6 prefix entry includes the prefix and lease information assigned to the client, the port that connects to the DHCPv6 client, and the VLAN. You can use the **`display ipv6 dhcp snooping pd binding`** command to display the prefixes of the users for management.

Application of trusted and untrusted ports

Configure ports facing the DHCPv6 server as trusted ports, and configure other ports as untrusted ports.

As shown in Figure 22, configure the DHCPv6 snooping device's port that is connected to the DHCPv6 server as a trusted port. The trusted port forwards response messages from the DHCPv6 server to the client. The untrusted port connected to the unauthorized DHCPv6 server discards incoming DHCPv6 response messages.

Figure 22 Trusted and untrusted ports



DHCPv6 snooping on an M-LAG network

M-LAG can virtualize two DHCPv6 snooping devices into one system through multichassis link aggregation, improving the availability of DHCPv6 snooping devices and facilitating device-level redundancy and load sharing.

To view the M-LAG status information and packet statistics related to DHCPv6 snooping entry synchronization, execute the **display ipv6 dhcp snooping m-lag-status** and **display ipv6 dhcp snooping m-lag-statistics** command, respectively. You can determine whether DHCPv6 snooping operates correctly on an M-LAG network based on the command output.

For more information about M-LAG, see M-LAG configuration in *Layer 2—LAN Switching Configuration Guide*.

Figure 23 DHCPv6 snooping on an M-LAG network

Restrictions and guidelines: DHCPv6 snooping configuration

DHCPv6 snooping works between the DHCPv6 client and server, or between the DHCPv6 client and DHCPv6 relay agent.

DHCPv6 snooping does not work between the DHCPv6 server and DHCPv6 relay agent.

To make sure DHCPv6 clients can obtain valid IPv6 addresses, specify the ports connected to authorized DHCPv6 servers as trusted ports. The trusted ports and the ports connected to DHCPv6 clients must be in the same VLAN.

If you configure DHCPv6 snooping settings on a Layer 2 Ethernet interface that is a member port of a Layer 2 aggregate interface, the settings do not take effect unless the interface is removed from the aggregation group.

After you enable DHCPv6 snooping and configure VLAN mapping on an interface, the interface will generate DHCPv6 snooping entries. The VLAN information in those DHCPv6 snooping entries are original, not processed by VLAN mapping. The device can communicate with a destination IP address in a DHCPv6 snooping entry only if the MAC address associated with the destination IP address matches the MAC address in the DHCPv6 snooping entry. If the MAC entry for the MAC address expires in the MAC address table, the communication will be terminated.

DHCPv6 snooping tasks at a glance

To configure DHCPv6 snooping, perform the following tasks:

1. Configuring basic DHCPv6 snooping features
2. (Optional.) Configuring DHCP snooping support for Option 18
3. (Optional.) Configuring DHCP snooping support for Option 37
4. (Optional.) Configuring DHCPv6 snooping entry auto backup
5. (Optional.) Setting the maximum number of DHCPv6 snooping entries
6. (Optional.) Configuring DHCPv6 packet rate limit
7. (Optional.) Configuring DHCPv6 snooping security features
8. (Optional.) Enabling LDRA on the DHCPv6 snooping device
9. (Optional.) Enabling Relay-Forward packet check
10. (Optional.) Enabling client offline detection on the DHCPv6 snooping device
11. (Optional.) Enabling DHCPv6 snooping logging and alarm
12. (Optional.) Disabling DHCPv6 snooping on an interface

Configuring basic DHCPv6 snooping features

Configuring basic DHCPv6 snooping features in a common network

About this task

Basic DHCPv6 snooping features include enabling DHCPv6 snooping, configuring trusted ports, and enabling recording DHCPv6 snooping entries.

When you enable DHCPv6 snooping globally on a device, DHCPv6 snooping is also enabled in all VLANs on the device. Enable snooping in specific VLANs if you do not need to enable DHCPv6 snooping globally in some networks. You can also other basic DHCP snooping features in these VLANs.

Restrictions and guidelines

If the basic DHCPv6 snooping features are configured globally, you can only use the undo form of the global configuration commands to disable the settings globally. The VLAN-specific configuration commands cannot disable the settings.

If the basic DHCPv6 snooping features are configured in a VLAN, you can only use the undo form of the VLAN-specific configuration commands to disable the settings in the VLAN. The global configuration command cannot disable the settings.

Configuring basic DHCPv6 snooping features globally

1. Enter system view.
   `system-view`
2. Enable DHCPv6 snooping globally.
   `ipv6 dhcp snooping enable`
   By default, DHCPv6 snooping is disabled globally.
3. Enter interface view.
   `interface` *`interface-type interface-number`*
   This interface must connect to the DHCPv6 server.

4. Specify the port as a trusted port.
   ipv6 dhcp snooping trust
   By default, all ports are untrusted ports after DHCPv6 snooping is enabled.
5. Enable recording DHCPv6 snooping entries.
   a. Return to system view.
      quit
   b. Enter interface view.
      interface *interface-type interface-number*
      This interface must connect to the DHCPv6 client.
   c. Enable recording DHCPv6 snooping entries. Choose the following tasks as needed:
      - Enable recording DHCPv6 snooping address entries.
        ipv6 dhcp snooping binding record
        By default, recording of DHCPv6 snooping address entries is disabled.
      - Enable recording DHCPv6 snooping prefix entries.
        ipv6 dhcp snooping pd binding record
        By default, recording of DHCPv6 snooping prefix entries is disabled.

Configuring basic DHCPv6 snooping features for VLANs

1. Enter system view.
   system-view
2. Enable DHCPv6 snooping for VLANs.
   ipv6 dhcp snooping enable vlan *vlan-id-list*
   By default, DHCPv6 snooping is disabled in all VLANs.
3. Enter VLAN view.
   vlan *vlan-id*
   Make sure DHCP snooping is enabled for the VLAN.
4. Specify a port as a trusted port.
   ipv6 dhcp snooping trust interface *interface-type interface-number*
   By default, all ports are untrusted ports after DHCPv6 snooping is enabled.
5. (Optional.) Enable recording DHCPv6 snooping entries in the VLAN. Choose the following tasks as needed:
   - Enable recording DHCPv6 snooping address entries.
     ipv6 dhcp snooping binding record
     By default, recording of DHCPv6 snooping address entries is disabled in a VLAN.
   - Enable recording DHCPv6 snooping prefix entries.
     ipv6 dhcp snooping pd binding record
     By default, recording of DHCPv6 snooping prefix entries is disabled in a VLAN.

Configuring DHCP snooping support for Option 18

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*

3. Enable DHCP snooping support for Option 18.

   ipv6 dhcp snooping option interface-id enable

   By default, DHCP snooping support for Option 18 is disabled.

4. (Optional.) Specify the content as the interface ID for Option 18.

   ipv6 dhcp snooping option interface-id { **bas** | [**vlan** *vlan-id*] **string** *interface-id* }

   By default, the DHCPv6 snooping device uses its DUID as the content for Option 18.

Configuring DHCP snooping support for Option 37

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable DHCP snooping support for Option 37.

   ipv6 dhcp snooping option remote-id enable

   By default, DHCP snooping support for Option 37 is disabled.

4. (Optional.) Specify the content as the remote ID.

   ipv6 dhcp snooping option remote-id [**vlan** *vlan-id*] **string** *remote-id*

   By default, the DHCPv6 snooping device uses its DUID as the content for Option 37.

Configuring DHCPv6 snooping entry auto backup

About this task

The auto backup feature saves DHCPv6 snooping entries to a backup file, and allows the DHCPv6 snooping device to download the entries from the backup file at reboot. The entries on the DHCPv6 snooping device cannot survive a reboot. The auto backup helps the security features provide services if these features (such as IP source guard) must use DHCPv6 snooping entries for user authentication.

Restrictions and guidelines

- If you disable DHCPv6 snooping with the **undo ipv6 dhcp snooping enable** command, the device deletes all DHCPv6 snooping entries, including those stored in the backup file.
- If you execute the **ipv6 dhcp snooping binding database filename** command, the DHCPv6 snooping device backs up DHCPv6 snooping entries immediately and runs auto backup. This command automatically creates the file if you specify a non-existent file.
- The waiting period starts when a DHCPv6 snooping entry is learned, updated, or removed. The DHCPv6 snooping device updates the backup file when the specified waiting period is reached. All changed entries during the period will be saved to the backup file. If no DHCPv6 snooping entry changes, the backup file is not updated.

Procedure

1. Enter system view.

   system-view

2. Configure the DHCPv6 snooping device to back up DHCPv6 snooping entries to a file.

   ipv6 dhcp snooping binding database filename { *filename* | **url** *url* [**username** *username* [**password** { **cipher** | **simple** } *string*]] }

   By default, the DHCPv6 snooping device does not back up the DHCPv6 snooping entries.

3. (Optional.) Manually save DHCPv6 snooping entries to the backup file.

   ipv6 dhcp snooping binding database update now

4. (Optional.) Set the waiting time after a DHCPv6 snooping entry change for the DHCPv6 snooping device to update the backup file.

   ipv6 dhcp snooping binding database update interval *interval*

   By default, the DHCP snooping device waits 300 seconds to update the backup file after a DHCP snooping entry change. If no DHCP snooping entry changes, the backup file is not updated.

Setting the maximum number of DHCPv6 snooping entries

About this task

Perform this task to prevent the system resources from being overused.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the maximum number of DHCPv6 snooping entries for the interface to learn.

   ipv6 dhcp snooping max-learning-num *max-number*

   By default, the number of DHCPv6 snooping entries for an interface to learn is not limited.

Configuring DHCPv6 packet rate limit

About this task

This DHCPv6 packet rate limit feature discards exceeding DHCPv6 packets to prevent attacks that send large numbers of DHCPv6 packets.

Restrictions and guidelines

The rate set on the Layer 2 aggregate interface applies to all members of the aggregate interface. If a member interface leaves the aggregation group, it uses the rate set in its Ethernet interface view.

Hardware and feature compatibility

The S5200-EI-G switch series does not support this feature.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the maximum rate at which an interface can receive DHCPv6 packets.

   ipv6 dhcp snooping rate-limit *rate*

   By default, incoming DHCPv6 packets on an interface are not rate limited.

Configuring DHCPv6 snooping security features

Enabling DHCPv6-REQUEST check

About this task

Perform this task to use the DHCPv6-REQUEST check feature to protect the DHCPv6 server against DHCPv6 client spoofing attacks. Attackers can forge DHCPv6-RENEW messages to renew leases for legitimate DHCPv6 clients that no longer need the IP addresses. The forged messages disable the victim DHCPv6 server from releasing the IP addresses. Attackers can also forge DHCPv6-DECLINE or DHCPv6-RELEASE messages to terminate leases for legitimate DHCPv6 clients that still need the IP addresses.

The DHCPv6-REQUEST check feature enables the DHCPv6 snooping device to check every received DHCPv6-RENEW, DHCPv6-DECLINE, or DHCPv6-RELEASE message against DHCPv6 snooping entries.

- If any criterion in an entry is matched, the device compares the entry with the message information.
  - If they are consistent, the device considers the message valid and forwards it to the DHCPv6 server.
  - If they are different, the device considers the message forged and discards it.
- If no matching entry is found, the device forwards the message to the DHCPv6 server.

Procedure

1. Enter system view.

   `system-view`
2. Enter interface view.

   `interface` *`interface-type interface-number`*
3. Enable DHCPv6-REQUEST check.

   `ipv6 dhcp snooping check request-message`

   By default, DHCPv6-REQUEST check is disabled.

Configuring a DHCPv6 packet blocking port

About this task

Perform this task to configure a port as a DHCPv6 packet blocking port. The DHCPv6 packet blocking port drops all incoming DHCP requests.

Procedure

1. Enter system view.

   `system-view`
2. Enter interface view.

   `interface` *`interface-type interface-number`*
3. Configure the port to block DHCPv6 requests.

   `ipv6 dhcp snooping deny`

   By default, the port does not block DHCPv6 requests.

CAUTION:

To avoid IPv6 address and prefix acquisition failure, make sure no DHCPv6 clients are

connected to the port.

Enabling LDRA on the DHCPv6 snooping device

About this task

Some DHCPv6 servers assign IPv6 addresses or prefixes to DHCPv6 clients only based on the Interface ID option in Relay-Forward packets generated by DHCPv6 relay agents. If no DHCPv6 relay agents exist in the network, these DHCPv6 servers cannot assign IPv6 addresses or prefixes based on the Interface ID option.

To solve this problem, you can enable the lightweight DHCPv6 relay agent (LDRA) on the receiving interface of DHCPv6 requests on the DHCPv6 snooping device. The feature allows the interface to generate a Relay-Forward packet for a received DHCPv6 request and to insert the Interface ID option in the packet. The DHCPv6 server then can assign an IPv6 address or prefix based on the Interface ID option.

Restrictions and guidelines

A network might have multiple cascaded lightweight DHCPv6 relay agents. As a best practice, do not specify the **trust** keyword if illegal Relay-Forward packets exist in the network.

For this feature to take effect, you must first execute the **ipv6 dhcp snooping enable** command to enable DHCPv6 snooping.

If you execute both the **ipv6 dhcp snooping relay-agent enable** and **ipv6 dhcp snooping option interface-id enable** commands, the **ipv6 dhcp snooping relay-agent enable** command does not take effect.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable LDRA on the interface.
   ipv6 dhcp snooping relay-agent enable [**trust**]
   By default, LDRA is disabled on an interface.

Enabling Relay-Forward packet check

About this task

A DHCPv6 snooping device functions between DHCPv6 clients and a DHCPv6 server, or between DHCPv6 clients and a DHCPv6 relay agent. When a DHCPv6 relay agent receives a DHCPv6 request, it generates a Relay-Forward packet, adds client information to Option 79, and then forwards the packet to the DHCPv6 server. If the DHCPv6 snooping device receives a Relay-Forward packet, it indicates that the DHCPv6 snooping device location is not correct. In this case, the DHCPv6 snooping device cannot work correctly.

This feature enables the DHCPv6 snooping device to drop Relay-Forward packets. When the number of dropped Relay-Forward packets reaches or exceeds the threshold, the device generates a log for administrators to adjust locations of the DHCPv6 devices.

Procedure

1. Enter system view.
   system-view

2. Enter interface view.
   interface *interface-type interface-number*
3. Enable the Relay-Forward packet check.
   ipv6 dhcp snooping check relay-forward
   By default, the Relay-Forward packet check is disabled.

Enabling client offline detection on the DHCPv6 snooping device

About this task

When a DHCPv6 client goes offline abnormally, it does not send a message to the DHCPv6 server to release the IPv6 address or prefix. As a result, the DHCPv6 server is not aware of the offline event and cannot release the address or prefix lease of the client in a timely manner.

With this feature enabled, the DHCPv6 snooping device performs the following operations when the ND entry of a client ages out:

1. Deletes the DHCPv6 snooping entry for the client.
2. Sends a release message to the DHCPv6 server to inform the server to release the address or prefix lease of the client.

Procedure

1. Enter system view.
   system-view
2. Enable client offline detection.
   ipv6 dhcp snooping client-detect
   By default, client offline detection is disabled.

Enabling DHCPv6 snooping logging and alarm

Enabling DHCPv6 snooping logging

About this task

The DHCPv6 snooping logging feature enables the DHCPv6 snooping device to generate DHCPv6 snooping logs and send them to the information center. The information helps administrators locate and solve problems. For information about the log destination and output rule configuration in the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

As a best practice, disable this feature if the log generation affects the device performance.

Procedure

1. Enter system view.
   system-view
2. Enable DHCPv6 snooping logging.
   ipv6 dhcp snooping log enable
   By default, DHCPv6 snooping logging is disabled.

Configuring packet drop alarm

About this task

After you enable the packet drop alarm for a feature, the device generates an alarm log when the number of packets dropped by this feature reaches or exceeds the threshold. The alarm log is sent to the information center. For information about the log destination and output rule configuration in the information center, see *Network Management and Monitoring Configuration Guide*.

To set the alarm threshold, use the **ipv6 dhcp snooping alarm threshold** command.

Restrictions and guidelines

For this feature to take effect, you must first execute the **ipv6 dhcp snooping log enable** command to enable DHCPv6 snooping logging.

Procedure

1. Enter system view.
   system-view
2. Enable the packet drop alarm.
   ipv6 dhcp snooping alarm { **relay-forward** | **request-message** } **enable**
   By default, the packet drop alarm is disabled.
3. Set a packet drop alarm threshold.
   ipv6 dhcp snooping alarm { **relay-forward** | **request-message** } **threshold** *threshold*
   By default, the packet drop alarm threshold is 100.

Disabling DHCPv6 snooping on an interface

About this task

This feature allows you to narrow down the interface range where DHCPv6 snooping takes effect. For example, to enable DHCP snooping globally except for a specific interface, you can enable DHCPv6 snooping globally and disable DHCPv6 snooping on the target interface.

Procedure

1. Enter system view.
   system-view
2. Enter interface view
   interface *interface-type interface-number*
3. Disable DHCPv6 snooping on the interface.
   ipv6 dhcp snooping disable
   By default:
   - If you enable DHCPv6 snooping globally or for a VLAN, DHCPv6 snooping is enabled on all interfaces on the device or on all interfaces in the VLAN.
   - If you do not enable DHCPv6 snooping globally or for a VLAN, DHCPv6 snooping is disabled on all interfaces on the device or on all interfaces in the VLAN.

Display and maintenance commands for DHCPv6 snooping

Execute **display** commands in any view, and **reset** commands in user view.

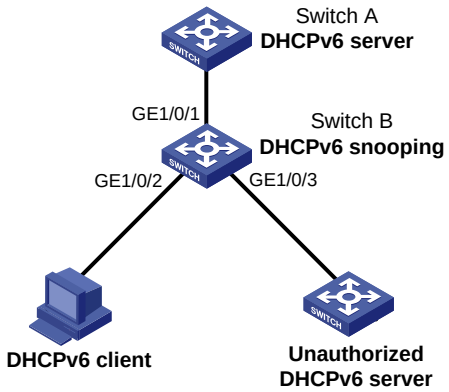
NOTE:

The S5200-EI-G switch series does not support the following commands:

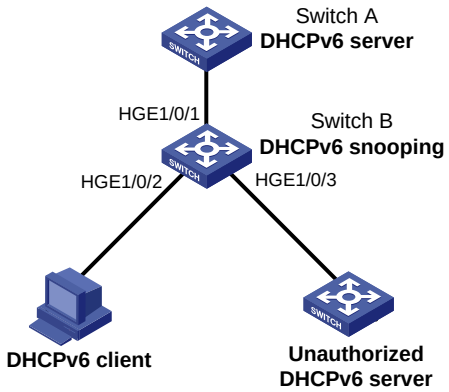
- **display ipv6 dhcp snooping m-lag-statistics**
- **display ipv6 dhcp snooping m-lag-status**
- **reset ipv6 dhcp snooping m-lag-statistics**

Task	Command
Display DHCPv6 snooping address entries.	**display ipv6 dhcp snooping binding** [**address** *ipv6-address* [**vlan** *vlan-id*] | **interface** *interface-type interface-number*]
Display information about the file that stores DHCPv6 snooping entries.	**display ipv6 dhcp snooping binding database**
Display statistics about the packets exchanged between M-LAG member devices for DHCPv6 snooping entry synchronization.	**display ipv6 dhcp snooping m-lag-statistics**
Display M-LAG status information.	**display ipv6 dhcp snooping m-lag-status**
Display DHCPv6 packet statistics for DHCPv6 snooping.	**display ipv6 dhcp snooping packet statistics** [**slot** *slot-number*]
Display DHCPv6 snooping prefix entries.	**display ipv6 dhcp snooping pd binding** [**interface** *interface-type interface-number* | **prefix** *prefix/prefix-length* [**vlan** *vlan-id*]]
Display information about trusted ports.	**display ipv6 dhcp snooping trust**
Clear DHCPv6 snooping address entries.	**reset ipv6 dhcp snooping binding** { **all** | **address** *ipv6-address* [**vlan** *vlan-id*] }
Clear statistics about the packets exchanged between M-LAG member devices for DHCPv6 snooping entry synchronization.	**reset ipv6 dhcp snooping m-lag-statistics**
Clear DHCPv6 packet statistics for DHCPv6 snooping.	**reset ipv6 dhcp snooping packet statistics** [**slot** *slot-number*]
Clear DHCPv6 snooping prefix entries.	**reset ipv6 dhcp snooping pd binding** { **all** | **prefix** *prefix/prefix-length* [**vlan** *vlan-id*] }

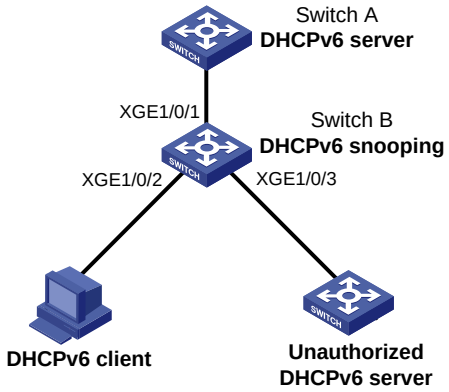
DHCPv6 snooping configuration examples



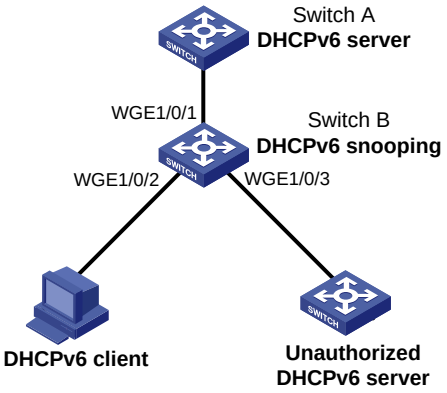
Example: Configuring DHCPv6 snooping globally



Network configuration



As shown in Figure 24, Switch B is connected to the authorized DHCPv6 server through GigabitEthernet 1/0/1, to the unauthorized DHCPv6 server through GigabitEthernet 1/0/3, and to the DHCPv6 client through GigabitEthernet 1/0/2.



Configure only the port connected to the authorized DHCPv6 server to forward the responses from the DHCPv6 server. Enable the DHCPv6 snooping device to record DHCPv6 snooping address entries.

DHCPv6 server

Procedure

Enable DHCPv6 snooping.

```
<SwitchB> system-view
[SwitchB] ipv6 dhcp snooping enable
```

Specify GigabitEthernet 1/0/1 as a trusted port.

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] ipv6 dhcp snooping trust
[SwitchB-GigabitEthernet1/0/1] quit
```

Enable recording DHCPv6 snooping address entries on GigabitEthernet 1/0/2.

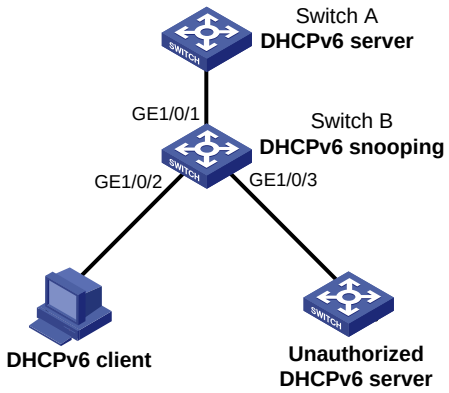
```
[SwitchB]interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] ipv6 dhcp snooping binding record
[SwitchB-GigabitEthernet1/0/2] quit
```

Verifying the configuration

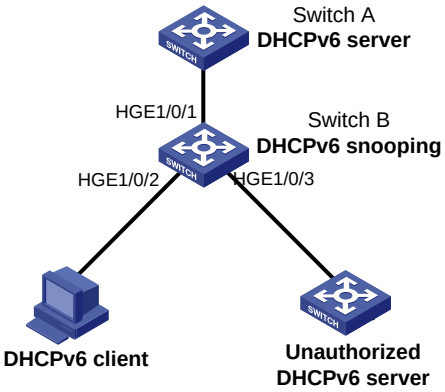
Verify that the DHCPv6 client obtains an IPv6 address and all other configuration parameters only from the authorized DHCPv6 server. (Details not shown.)

Display DHCPv6 snooping address entries on the DHCPv6 snooping device.

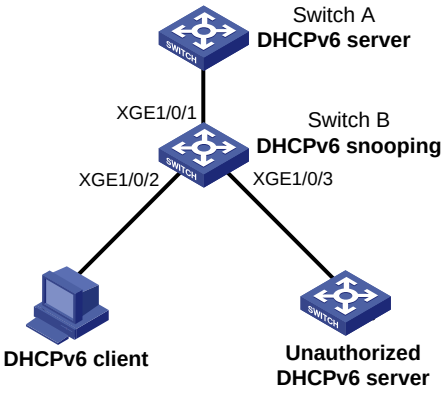
```
[SwitchB] display ipv6 dhcp snooping binding
```



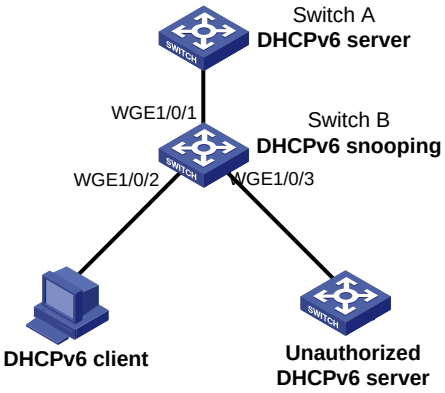
Example: Configuring DHCPv6 snooping for a VLAN



Network configuration



As shown in Figure 25, Switch B is connected to the authorized DHCPv6 server through GigabitEthernet 1/0/1, to the unauthorized DHCPv6 server through GigabitEthernet 1/0/3, and to the DHCPv6 client through GigabitEthernet 1/0/2.



In VLAN 100, configure only the port connected to the authorized DHCPv6 server to forward the responses from the DHCPv6 server. Enable the DHCPv6 snooping device to record DHCPv6 snooping address entries.

Procedure

Assign access ports GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 to VLAN 100.

```
<SwitchB> system-view
[SwitchB] vlan 100
[SwitchB-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/3
[SwitchB-vlan100] quit
```

Enable DHCPv6 snooping for VLAN 100.

```
[SwitchB] ipv6 dhcp snooping enable vlan 100
```

Configure GigabitEthernet 1/0/1 as a trusted port in VLAN 100.

```
[SwitchB] vlan 100
[SwitchB-vlan100] ipv6 dhcp snooping trust interface gigabitethernet 1/0/1
```

Enable recording DHCPv6 snooping entries in VLAN 100.

```
[SwitchB-vlan100] ipv6 dhcp snooping binding record
[SwitchB-vlan100] quit
```

Verifying the configuration

Verify that the DHCPv6 client obtains an IPv6 address and all other configuration parameters only from the authorized DHCPv6 server. (Details not shown.)

Display DHCPv6 snooping address entries on the DHCPv6 snooping device.

```
[SwitchB] display ipv6 dhcp snooping binding
```

Configuring DHCPv6 guard

About DHCPv6 guard

The DHCPv6 guard feature filters DHCPv6 Advertise and Reply messages by using DHCPv6 guard policies to make sure DHCPv6 clients obtain addresses/prefixes from authorized DHCPv6 servers. To provide finer level of filtering granularity, you can specify the following parameters for a DHCPv6 guard policy:

- Device role of the device that attached to the target interface or VLAN. The interface or VLAN to which the DHCPv6 guard policy is applied is called the target interface or VLAN.
- DHCPv6 server match criterion.
- Match criterion for IPv6 addresses/prefixes assigned by DHCPv6 servers.
- Allowed DHCPv6 server preference range.

To meet requirements of DHCPv6 clients in different locations, apply DHCPv6 guard policies to different interfaces or VLANs on the same device.

DHCPv6 guard operating mechanism

Upon receiving a DHCPv6 Solicit or Request message, the DHCPv6 guard device forwards the message without performing the DHCPv6 guard policy check.

When receiving a DHCPv6 reply, the DHCPv6 guard device performs the DHCPv6 guard policy check in the following order:

1. Examines whether the receiving port is a trusted port. The device forwards the message if the message is from the a trusted port.

   Configure trusted ports in a DHCPv6 guard policy only in one of the following conditions:

   - The port to which the DHCPv6 guard policy applies is connected to an authorized server.
   - All ports in the VLAN to which the DHCPv6 guard policy applies are connected to authorized servers.

2. Examines the message based on the device role:

   - If the message is received from the device with the DHCPv6 client device role, the device drops the message.

     If the interface to which the DHCPv6 guard policy applies is not connected to any authorized DHCPv6 servers, set the device role to **client** for the policy, as shown in Figure 26.

     Figure 26 Setting the device role to client

   - If the message is received from the device with the DHCPv6 server device role, the device examines the message as follows:

- For an Advertise message, the message passes the policy check if the source IP address in the message is permitted by the ACL and the server preference is in the match range.
- For a Reply message, the message passes the policy check if the assigned IPv6 addresses/prefixes in the message are permitted by the ACL.

If the interface to which the DHCPv6 guard policy applies is connected to an authorized DHCPv6 server, set the device role to **server** for the policy, as shown in Figure 27.

Figure 27 Setting the device role to server

The device forwards the reply after the message passes the DHCPv6 guard policy check.

Restrictions and guidelines: DHCPv6 guard configuration

The DHCPv6 guard feature operates correctly only when the device is located between the DHCPv6 client and the DHCPv6 server or between the DHCPv6 client and the DHCPv6 relay agent. If the device is located between the DHCPv6 server and the DHCPv6 relay agent, the DHCPv6 guard feature cannot operate correctly.

When the DHCPv6 guard feature is configured on a DHCPv6 snooping device, both features can take effect. The device forwards DHCPv6 reply packets received on a DHCPv6 snooping trusted port only if they pass the DHCPv6 guard check. These packets are dropped if they fail the DHCPv6 guard check.

DHCPv6 guard tasks at a glance

To configure DHCPv6 guard, perform the following tasks:

1. Configuring a DHCPv6 guard policy
2. Applying the DHCPv6 guard policy

   Choose the following tasks as needed:

   - Applying a DHCPv6 guard policy to an interface
   - Applying a DHCPv6 guard policy to a VLAN

   If DHCPv6 guard polices are applied to both an interface and the VLAN of the interface, the interface-specific policy is used on the interface.

Configuring a DHCPv6 guard policy

1. Enter system view.

   ```
   system-view
   ```

2. Create a DHCPv6 guard policy and enter its view.
   ipv6 dhcp guard policy *policy-name*
3. Specify the role of the device attached to the target interface or VLAN.
   device-role { **client** | **server** }
   By default, the device role is DHCPv6 client for the device attached to the target interface or VLAN.
4. Configure a DHCPv6 guard policy.
   - Configure a DHCPv6 server match criterion.
     if-match server acl { *acl-number* | **name** *acl-name* }
     By default, no DHCPv6 server match criterion is configured, and all DHCPv6 servers are authorized.
   - Configure a match criterion for the assigned IPv6 addresses/prefixes.
     if-match reply acl { *acl-number* | **name** *acl-name* }
     By default, no match criterion is configured for the assigned IPv6 addresses/prefixes, and all assigned IPv6 addresses/prefixes can pass the address/prefix check.
   - Configure an allowed DHCPv6 server preference range.
     preference { **max** *max-value* | **min** *min-value* } *
     By default, no DHCPv6 server preference range is configured, and DHCPv6 servers with preferences 1 to 255 can pass the preference check.
   - Configure the port to which the policy applies as a trusted port for the policy.
     trust port
     By default, no trusted port is configured for a DHCPv6 guard policy.

Applying a DHCPv6 guard policy to an interface

1. Enter system view.
   system-view
2. Enter Layer 2 interface view.
   interface *interface-type interface-number*
3. Apply a DHCPv6 guard policy to the interface.
   ipv6 dhcp guard apply policy *policy-name*
   By default, no DHCPv6 guard policy is applied to the interface.

Applying a DHCPv6 guard policy to a VLAN

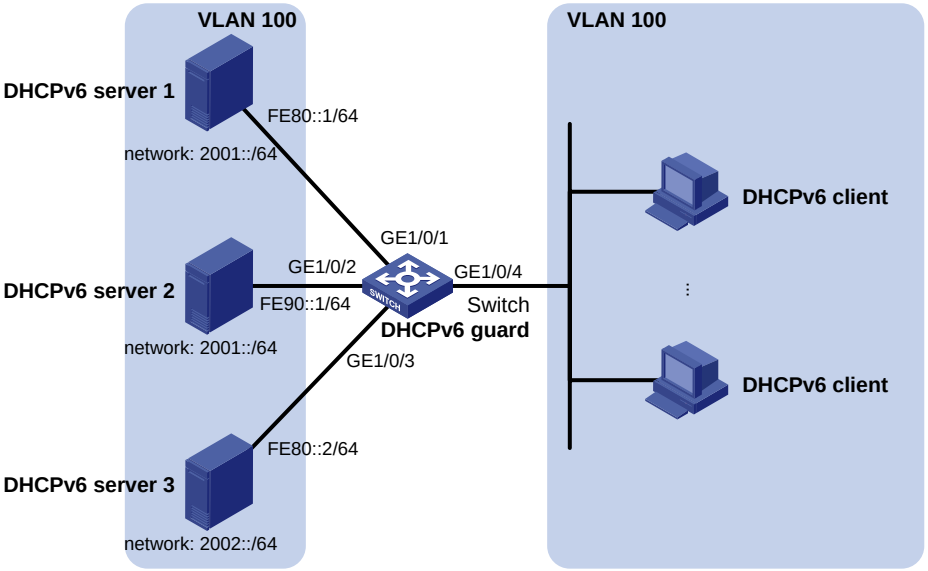
1. Enter system view.
   system-view
2. Create a VLAN and enter its view.
   vlan *vlan-number*
3. Apply a DHCPv6 guard policy to the VLAN.
   ipv6 dhcp guard apply policy *policy-name*
   By default, no DHCPv6 guard policy is applied to the VLAN.

Display and maintenance commands for DHCPv6 guard

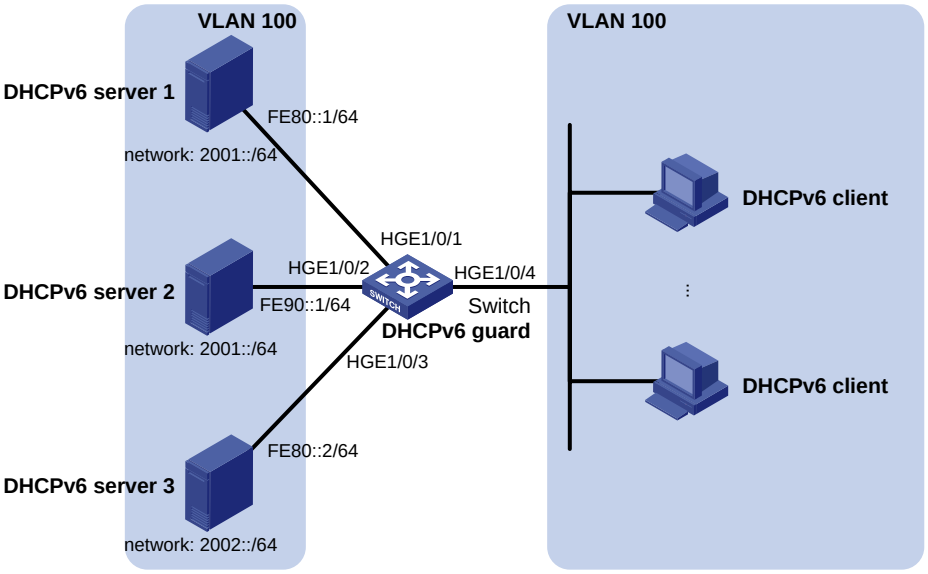
Execute **display** commands in any view.

Task	Command
Display information about DHCPv6 guard policies.	**display ipv6 dhcp guard policy** [*policy-name*]

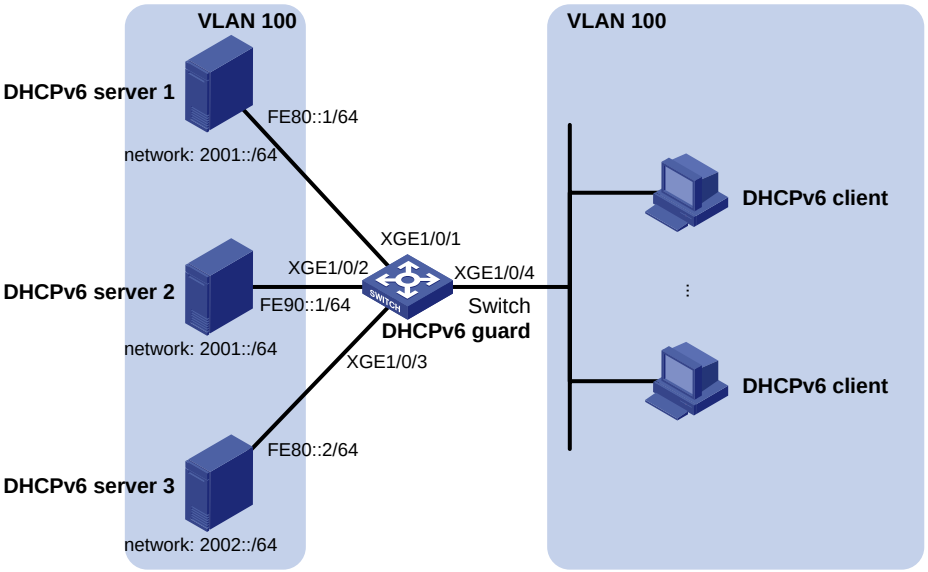
DHCPv6 guard configuration examples



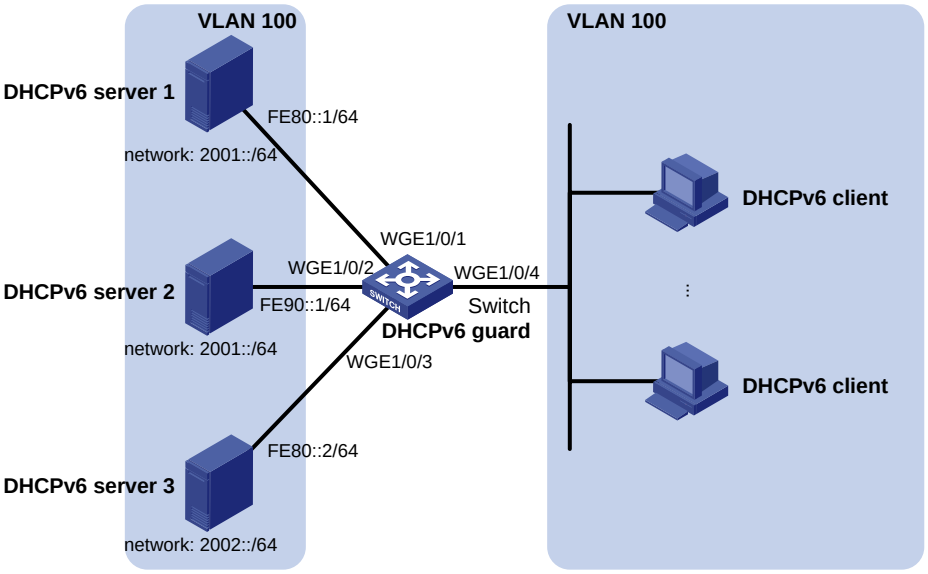
Example: Configuring DHCPv6 guard



Network configuration



As shown in Figure 28, all DHCPv6 servers and clients are in VLAN 100. The assignable IPv6 address ranges on the DHCPv6 server 1, server 2, and server 3 are 2001::/64, 2001::/64, and 2002::/64, respectively.



Configure DHCPv6 guard on the switch, so that the switch forwards only DHCPv6 replies with the source IPv6 address in the range of FE80::/12 and assigned prefixes in the range of 2001::/16.

Procedure

Before you configure DHCPv6 guard, complete the configuration on DHCPv6 servers.

Create VLAN 100, and assign GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, GigabitEthernet 1/0/3, and GigabitEthernet 1/0/4 to VLAN 100.

```
<Switch> system-view
[Switch] vlan 100
[Switch-vlan100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/4
[Switch-vlan100] quit
```

Create an IPv6 basic ACL numbered 2001.

```
[Switch] acl ipv6 number 2001
```

Create rule **1** to permit only packets with source IPv6 addresses in the range of FE80::/12.

```
[Switch-acl-ipv6-basic-2001] rule 1 permit source fe80:: 12
[Switch-acl-ipv6-basic-2001] quit
```

Create an IPv6 basic ACL numbered 2002.

```
[Switch] acl ipv6 number 2002
```

Create rule **1** to permit only packets with source IPv6 addresses in the range of 2001::/16.

```
[Switch-acl-ipv6-basic-2002] rule 1 permit source 2001:: 16
[Switch-acl-ipv6-basic-2002] quit
```

Create DHCPv6 guard policy named **p1**.

```
[Switch] ipv6 dhcp guard policy p1
```

Set the device role to the DHCPv6 server for the device attached to the target VLAN.

```
[Switch-dhcp6-guard-policy-p1] device-role server
```

Specify ACL 2001 to match DHCPv6 servers.

```
[Switch-dhcp6-guard-policy-p1] if-match server acl 2001
```

Specify ACL 2002 to match IPv6 addresses/prefixes assigned by DHCPv6 servers.

```
[Switch-dhcp6-guard-policy-p1] if-match reply acl 2002
[Switch-dhcp6-guard-policy-p1] quit
```

Create DHCPv6 guard policy named **p2**.

```
[Switch] ipv6 dhcp guard policy p2
```

Set the device role to the DHCPv6 client for the device attached to the target interface.

```
[Switch-dhcp6-guard-policy-p2] device-role client
[Switch-dhcp6-guard-policy-p2] quit
```

Apply DHCPv6 guard policy **p1** to VLAN 100.

```
[Switch] vlan 100
[Switch-vlan100] ipv6 dhcp guard apply policy p1
[Switch-vlan100] quit
```

Apply DHCPv6 guard policy **p2** to GigabitEthernet 1/0/4.

```
[Switch]interface gigabitethernet 1/0/4
[Switch-GigabitEthernet1/0/4] ipv6 dhcp guard apply policy p2
[Switch-GigabitEthernet1/0/4] quit
```

Verifying the configuration

Verify that the switch forwards DHCPv6 replies with the source IPv6 address in the range of FE80::/12 and the assigned IPv6 prefixes in the range of 2001::/16. The switch forwards DHCPv6 replies from the DHCPv6 server 1 and drops replies from DHCPv6 server 2 and server 3.

Configuring IPv6 fast forwarding

About IPv6 fast forwarding

Fast forwarding reduces route lookup time and improves packet forwarding efficiency by using a high-speed cache and data-flow-based technology. It identifies a data flow by using the following fields:

- Source IPv6 address.
- Destination IPv6 address.
- Source port number.
- Destination port number.
- Protocol number.

After a flow's first packet is forwarded through the routing table, fast forwarding creates an entry and uses the entry to forward subsequent packets of the flow.

Configuring the aging time for IPv6 software fast forwarding entries

About this task

The IPv6 fast forwarding table uses an aging timer for each forwarding entry. If an entry is not updated before the timer expires, the device deletes the entry. If an entry has a hit within the aging time, the aging timer restarts.

Procedure

1. Enter system view.
   `system-view`
2. Set the aging time for IPv6 fast forwarding entries on the software side.
   `ipv6 fast-forwarding aging-time` *`aging-time`*
   By default, the aging time is 30 seconds for IPv6 fast forwarding entries on the software side.

Configuring IPv6 fast forwarding load sharing for software

About this task

IPv6 software fast forwarding load sharing enables the device to identify a data flow by using the packet information.

If IPv6 fast forwarding load sharing is disabled on the software side, the device identifies a data flow by the packet information and the input interface.

Procedure

1. Enter system view.
   `system-view`
2. Configure IPv6 fast forwarding load sharing on the software side. Choose one option as needed:

- Enable IPv6 fast forwarding load sharing on the software side.
  Ipv6 fast-forwarding load-sharing
- Disable IPv6 fast forwarding load sharing on the software side.
  undo ipv6 fast-forwarding load-sharing

By default, IPv6 fast forwarding load sharing is enabled on the software side.

Display and maintenance commands for IPv6 fast forwarding

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the aging time of the IPv6 fast forwarding entries.	**display ipv6 fast-forwarding aging-time**
Display IPv6 fast forwarding entries.	**display ipv6 fast-forwarding cache** [*ipv6-address*] [**slot** *slot-number*]
Clear the IPv6 fast forwarding table.	**reset ipv6 fast-forwarding cache** [**slot** *slot-number*]

Configuring tunneling

This chapter describes tunnel interface configuration. For information about tunnel modes, see the subsequent chapters.

About tunneling

Tunneling encapsulates the packets of a network protocol within the packets of a second network protocol and transfers them over a virtual point-to-point connection. The virtual connection is called a tunnel. Packets are encapsulated at the tunnel source and de-encapsulated at the tunnel destination.

Restrictions: Hardware compatibility with tunnel configuration

The S5200-EI-G switch series does not support this feature.

Supported tunneling technologies

Tunneling supports the following technologies:

- GRE tunneling. For more information, see "Configuring GRE."
- IPv6 over IPv4 tunneling, IPv4 over IPv4 tunneling, and IPv4/IPv6 over IPv6 tunneling.

Restrictions and guidelines: Tunnel interface configuration

Do not specify the same tunnel source and destination addresses for the tunnel interfaces on the same device.

The S5200-EI-G switch series does not support tunneling features.

Configuring a tunnel interface

About tunnel interface configuration

Configure a tunnel interface (Layer 3 virtual interface) at both ends of a tunnel. The devices use the tunnel interface to identify, process, and send packets for the tunnel.

Tunnel interface configuration tasks at a glance

To configure a tunnel interface, perform the following tasks:

1. Creating a tunnel interface
2. (Optional.) Configuring parameters for tunneled packets
3. (Optional.) Restoring the default settings of the tunnel interface

Creating a tunnel interface

1. Enter system view.

   system-view

2. Create a tunnel interface, specify the tunnel mode, and enter tunnel interface view.

   interface tunnel *number* **[mode** { **gre** [**ipv6**] | **ipv4-ipv4** | **ipv4-ipv6** | **ipv6-ipv4** [**6to4** | **isatap**] | **ipv6-ipv6** } **]**

   For packet tunneling to succeed, the two ends of a tunnel must use the same tunnel mode.

3. Configure a source address or source interface for the tunnel interface.

   source { *ipv4-address* | *ipv6-address* | *interface-type interface-number* }

   By default, no source address or source interface is configured for the tunnel interface.

   If you specify a source address, it is used as the source address of tunneled packets.

   If you specify a source interface, the primary IP address of this interface is used as the source IP address of tunneled packets.

4. Configure a destination address for the tunnel interface.

   destination { *ipv4-address* | *ipv6-address* }

   By default, no destination address is configured for the tunnel interface.

   The tunnel destination address must be the IP address of the receiving interface on the tunnel peer. It is used as the destination IP address of tunneled packets.

5. (Optional.) Configure a description for the interface.

   description *text*

   By default, the description for a tunnel interface is **Tunnel** *number* **Interface**.

6. (Optional.) Set the MTU of the tunnel interface.

   mtu *size*

   The default settings are as follows:

   - If the tunnel interface has never been up, the MTU is 64000 bytes.
   - If the tunnel interface is up, its MTU is identical to the outgoing interface's MTU minus the length of the tunnel headers. The outgoing interface is automatically obtained through routing table lookup based on the tunnel destination address.

   You can use the **ip mtu**, **ipv6 mtu**, or **mtu** command to set the MTU of a tunnel interface.

   - The **mtu** command applies to both IPv4 and IPv6 tunnel interfaces.
   - The **ip mtu** and **ipv6 mtu** commands have higher priority than the **mtu** command on a tunnel interface.
   - If all of the commands are used on a tunnel interface, the **ip mtu** and **ipv6 mtu** commands take effect. After you restore the default settings for the **ip mtu** and **ipv6 mtu** commands, the **mtu** command takes effect.
   - If none of the commands is used on a tunnel interface, the MTU of the tunnel interface is identical to the outgoing interface's MTU minus the length of the tunnel headers. The outgoing interface is automatically obtained through routing table lookup based on the tunnel destination address.

7. (Optional.) Set the expected bandwidth for the tunnel interface.

   bandwidth *bandwidth-value*

   The default expected bandwidth (in kbps) is the interface maximum rate divided by 1000.

   The expected bandwidth is an informational parameter used only by higher-layer protocols for calculation. You cannot adjust the actual bandwidth of an interface by using this command.

8. Bring up the tunnel interface.
   undo shutdown
   By default, a tunnel interface is not administratively down.

Configuring parameters for tunneled packets

1. Enter system view.
   system-view
2. Enter tunnel interface view.
   interface tunnel *number*
3. Set the ToS for tunneled packets.
   tunnel tos *tos-value*
   The default setting is the same as the ToS of the original packets.
4. Set the TTL for tunneled packets.
   tunnel ttl *ttl-value*
   The default TTL for tunneled packets is 255.

Restoring the default settings of the tunnel interface

Restrictions and guidelines

CAUTION:
This operation might interrupt ongoing network services. Make sure you are fully aware of the impact of this operation when you perform it on a live network.

This operation might fail to restore the default settings for some commands for reasons such as command dependencies or system restrictions. Use the **display this** command in interface view to identify these commands. Use their **undo** forms or follow the command reference to restore their default settings. If your restoration attempt still fails, follow the error message instructions to resolve the problem.

Procedure

1. Enter system view.
   system-view
2. Enter tunnel interface view.
   interface tunnel *number*
3. Restore the default settings of the tunnel interface.
   default

Display and maintenance commands for tunnel interface configuration

Execute **display** commands in any view and **reset** commands in user view.

Task	Command	Remarks
Display information about tunnel interfaces.	**display interface** [**tunnel** [*number*]]	N/A

Task	Command	Remarks
	[**brief** [**description** | **down**]]	
Display IPv6 information on tunnel interfaces.	**display ipv6 interface** [**tunnel** [*number*]] [**brief**]	For more information about this command, see IPv6 basics in *Layer 3—IP Services Command Reference*.
Clear statistics on tunnel interfaces.	**reset counters interface** [**tunnel** [*number*]]	N/A
Clear IPv6 statistics on tunnel interfaces.	**reset ipv6 statistics** [**slot** *slot-number*]	For more information about this command, see IPv6 basics in *Layer 3—IP Services Command Reference*.

Troubleshooting tunnel interface configuration

Tunnel interface not up

Symptom

A tunnel interface configured with related parameters such as tunnel source address, tunnel destination address, and tunnel mode cannot come up.

Analysis

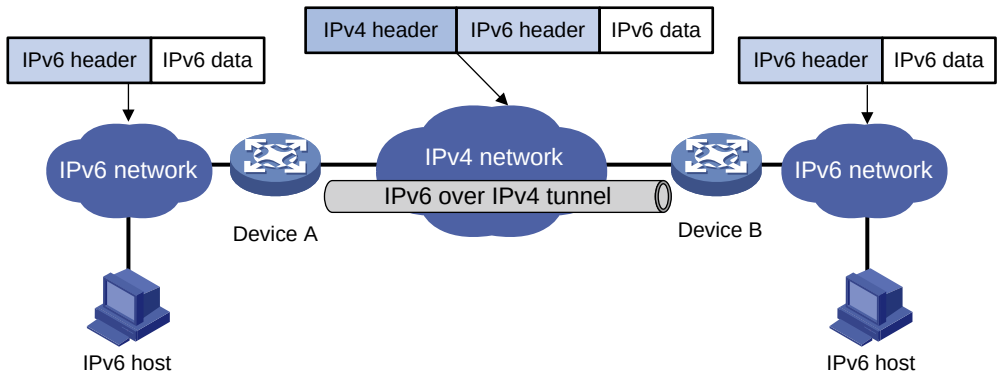
The physical interface of the tunnel does not come up, or the tunnel destination is unreachable.

Solution

1. To resolve the problem:
   - Use the **display interface** or **display ipv6 interface** command to verify that the physical interface of the tunnel is up. If the physical interface is down, check the network connection.
   - Use the **display ipv6 routing-table** or **display ip routing-table** command to verify that the tunnel destination is reachable. If the route is not available, configure a route to reach the tunnel destination.
2. If the problem persists, contact H3C Support.

IPv6 over IPv4 tunneling

About IPv6 over IPv4 tunneling



Implementation

IPv6 over IPv4 tunneling enables isolated IPv6 networks to communicate, as shown in Figure 1.

NOTE:

The devices at both ends of an IPv6 over IPv4 tunnel must support the IPv4/IPv6 dual stack.

Figure 1 IPv6 over IPv4 tunnel

The IPv6 over IPv4 tunnel processes packets by using the following steps:

2. A host in the IPv6 network sends an IPv6 packet to Device A at the tunnel source.
3. After Device A receives the IPv6 packet, it processes the packet as follows:
   a. Searches the routing table to identify the outgoing interface for the IPv6 packet.

      The outgoing interface is the tunnel interface, so Device A knows that the packet needs to be forwarded through the tunnel.

   b. Adds an IPv4 header to the IPv6 packet and forwards the packet through the physical interface of the tunnel.

      In the IPv4 header, the source IPv4 address is the IPv4 address of the tunnel source, and the destination IPv4 address is the IPv4 address of the tunnel destination.
4. Upon receiving the packet, Device B de-encapsulates the packet.
5. If the destination address of the IPv6 packet is itself, Device B forwards it to the upper-layer protocol. If it is not, Device B forwards it according to the routing table.

Tunnel modes

IPv6 over IPv4 tunnels include manually configured tunnels and automatic tunnels, depending on how the IPv4 address of the tunnel destination is obtained.

- **Manually configured tunnel**—The destination IPv4 address of the tunnel cannot be automatically obtained from the destination IPv6 address of an IPv6 packet at the tunnel source. It must be manually configured.

- **Automatic tunnel**—The destination IPv4 address of the tunnel can be automatically obtained from the destination IPv6 address (with an IPv4 address embedded) of an IPv6 packet at the tunnel source.

The source IPv4 addresses for all IPv6 over IPv4 tunnels are manually configured.

According to the way an IPv6 packet is encapsulated, IPv6 over IPv4 tunnels are divided into the modes shown in the following sections.

IPv6 over IPv4 manual tunneling

An IPv6 over IPv4 manual tunnel is a point-to-point link. To establish a manual tunnel, you must manually configure the source and destination addresses of the tunnel at both ends of the tunnel.

Manual tunneling provides the following solutions:

- Connects isolated IPv6 networks over an IPv4 network.
- Connects an IPv6 network and an IPv4/IPv6 dual-stack host over an IPv4 network.

6to4 tunneling

- Ordinary 6to4 tunneling

  A 6to4 tunnel is a point-to-multipoint automatic tunnel. It is used to connect multiple isolated IPv6 networks over an IPv4 network.

  The ends of a 6to4 tunnel are 6to4 addresses. The address format is 2002:abcd:efgh:subnet number::interface ID/48.

  - 2002 is the fixed IPv6 address prefix.
  - abcd:efgh represents a 32-bit globally unique IPv4 address in hexadecimal notation.

    For example, 1.1.1.1 can be represented by 0101:0101. The IPv4 address identifies a 6to4 network (an IPv6 network where all hosts use 6to4 addresses). The border router of a 6to4 network must have the IPv4 address abcd:efgh configured on the interface connected to the IPv4 network.
  - The subnet number identifies a subnet in the 6to4 network.
  - The subnet number::interface ID uniquely identifies a host in the 6to4 network.

  The destination IPv4 address of a 6to4 tunnel is embedded in the destination 6to4 address. This mechanism enables the device to automatically obtain the tunnel destination address.

  6to4 tunneling uses an IPv4 address to identify a 6to4 network. This method overcomes the limitations of automatic IPv4-compatible IPv6 tunneling.

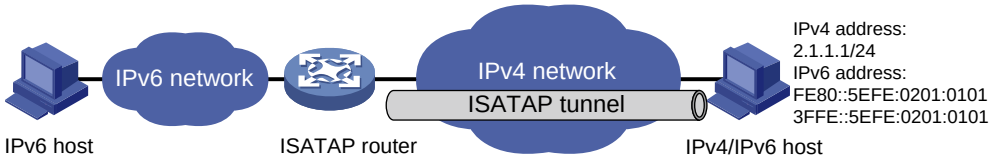
- 6to4 relay

  6to4 relay connects a 6to4 network and an IPv6 network that uses an IP prefix other than 2002::/16. A 6to4 relay router is a gateway that forwards packets from a 6to4 network to an IPv6 network.

  As shown in Figure 2, 6to4 network Site 1 communicates with IPv6 network Site 3 over a 6to4 tunnel. Configure a static route on the border router (Device A) in the 6to4 network. The next hop address must be the 6to4 address of the 6to4 relay router (Device C). Device A forwards all packets destined for the IPv6 network over the 6to4 tunnel, and Device C then forwards them to the IPv6 network.

Figure 2 Principle of 6to4 tunneling and 6to4 relay

ISATAP tunneling



An ISATAP tunnel is a point-to-multipoint automatic tunnel. It provides a solution to connect an IPv6 host and an IPv6 network over an IPv4 network.

The destination address of an ISATAP tunnel is an ISATAP address. The address format is prefix:0:5EFE:abcd:efgh/64.

- The 64-bit prefix is a valid IPv6 unicast address prefix.
- The abcd:efgh/64 segments represent a 32-bit IPv4 address in hexadecimal notation, which identifies the tunnel destination but does not require global uniqueness.

ISATAP tunnels are mainly used for communication between IPv6 routers or between an IPv6 host and an IPv6 router over an IPv4 network.

Figure 3 Principle of ISATAP tunneling

IPv6 over IPv4 tunneling tasks at a glance

To configure IPv6 over IPv4 tunneling, perform the following tasks:

1. Configuring an IPv6 over IPv4 tunnel

   Choose one of the following tasks:

   - Configuring an IPv6 over IPv4 manual tunnel
   - Configuring a 6to4 tunnel
   - Configuring an ISATAP tunnel

Configuring an IPv6 over IPv4 manual tunnel

Restrictions and guidelines

When you perform tasks in this section, follow these restrictions and guidelines:

- The tunnel destination address specified on the local device must be identical with the tunnel source address specified on the tunnel peer device.
- Do not specify the same tunnel source and destination addresses for the tunnel interfaces in the same mode on a device.
- To ensure correct packet forwarding, identify whether the destination IPv6 network and the IPv6 address of the local tunnel interface are on the same subnet. If they are not, configure a route reaching the destination IPv6 network through the tunnel interface. You can configure the route by using one of the following methods:
  - Configure a static route, and specify the local tunnel interface as the egress interface or specify the IPv6 address of the peer tunnel interface as the next hop.
  - Enable a dynamic routing protocol on the tunnel interface.

  The route configuration is required on both ends of the tunnel. For more information about route configuration, see *Layer 3—IP Routing Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Enter IPv6 over IPv4 manual tunnel interface view.

   interface tunnel *number* [**mode ipv6-ipv4**]
3. Specify an IPv6 address for the tunnel interface.

   See "Configuring basic IPv6 settings."
4. Configure a source address or source interface for the tunnel interface.

   source { *ipv4-address* | *interface-type interface-number* }

   By default, no source address or source interface is configured for the tunnel interface.

   If you specify a source address, it is used as the source IP address of tunneled packets.

   If you specify a source interface, the primary IP address of this interface is used as the source IP address of tunneled packets.
5. Configure a destination address for the tunnel interface.

   destination *ipv4-address*

   By default, no destination address is configured for the tunnel interface.

   The tunnel destination address must be the IP address of the receiving interface on the tunnel peer. It is used as the destination IP address of tunneled packets.
6. (Optional.) Set the DF bit for tunneled packets.

   tunnel dfbit enable

   By default, the DF bit is not set for tunneled packets.

Example: Configuring an IPv6 over IPv4 manual tunnel

Network configuration

As shown in Figure 4, configure an IPv6 over IPv4 tunnel between Switch A and Switch B so the two IPv6 networks can reach each other over the IPv4 network. Because the tunnel destination IPv4 address cannot be automatically obtained from the destination IPv6 addresses, configure an IPv6 over IPv4 manual tunnel.

Figure 4 Network diagram

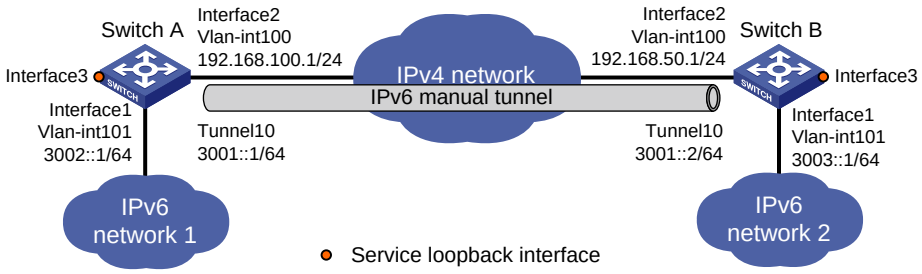


Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

Make sure Switch A and Switch B have the corresponding VLAN interfaces created and can reach each other through IPv4.

1. Configure Switch A:

Add GigabitEthernet 1/0/2 (the physical interface of the tunnel) to VLAN 100.

```
<SwitchA> system-view
[SwitchA] vlan 100
[SwitchA-vlan100] port gigabitethernet 1/0/2
[SwitchA-vlan100] quit
```

Specify an IPv4 address for VLAN-interface 100.

```
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ip address 192.168.100.1 255.255.255.0
[SwitchA-Vlan-interface100] quit
```

Add GigabitEthernet 1/0/1 to VLAN 101.

```
[SwitchA] vlan 101
[SwitchA-vlan101] port gigabitethernet 1/0/1
[SwitchA-vlan101] quit
```

Specify an IPv6 address for VLAN-interface 101.

```
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] ipv6 address 3002::1 64
[SwitchA-Vlan-interface101] quit
```

Create IPv6 over IPv4 manual tunnel interface Tunnel10.

```
[SwitchA] interface tunnel 10 mode ipv6-ipv4
```

Specify an IPv6 address for the tunnel interface.

```
[SwitchA-Tunnel10] ipv6 address 3001::1/64
```

Specify VLAN-interface 100 as the source interface of the tunnel interface.

```
[SwitchA-Tunnel10] source vlan-interface 100
```

Specify the destination address for the tunnel interface as the IP address of the VLAN-interface 100 on Switch B.

```
[SwitchA-Tunnel10] destination 192.168.50.1
```

```
[SwitchA-Tunnel10] quit
```

Configure a static route destined for IPv6 network 2 through Tunnel10.

```
[SwitchA] ipv6 route-static 3003:: 64 tunnel 10
```

2. Configure Switch B:

Add GigabitEthernet 1/0/2 (the physical interface of the tunnel) to VLAN 100.

```
<SwitchB> system-view
[SwitchB] vlan 100
[SwitchB-vlan100] port gigabitethernet 1/0/2
[SwitchB-vlan100] quit
```

Specify an IPv4 address for VLAN-interface 100.

```
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ip address 192.168.50.1 255.255.255.0
[SwitchB-Vlan-interface100] quit
```

Add GigabitEthernet 1/0/1 to VLAN 101.

```
[SwitchB] vlan 101
[SwitchB-vlan101] port gigabitethernet 1/0/1
[SwitchB-vlan101] quit
```

Specify an IPv6 address for VLAN-interface 101.

```
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] ipv6 address 3003::1 64
[SwitchB-Vlan-interface101] quit
```

Create IPv6 over IPv4 manual tunnel interface Tunnel10.

```
[SwitchB] interface tunnel 10 mode ipv6-ipv4
```

Specify an IPv6 address for the tunnel interface.

```
[SwitchB-Tunnel10] ipv6 address 3001::2/64
```

Specify VLAN-interface 100 as the source interface of the tunnel interface.

```
[SwitchB-Tunnel10] source vlan-interface 100
```

Specify the destination address for the tunnel interface as the IP address of VLAN-interface 100 of Switch A.

```
[SwitchB-Tunnel10] destination 192.168.100.1
[SwitchB-Tunnel10] quit
```

Configure a static route destined for IPv6 network 1 through Tunnel10.

```
[SwitchB] ipv6 route-static 3002:: 64 tunnel 10
```

Verifying the configuration

Use the **display ipv6 interface** command to display tunnel interface status on Switch A and Switch B. Verify that the interface Tunnel10 is up. (Details not shown.)

Verify that Switch B and Switch A can ping the IPv6 address of VLAN-interface 101 of each other. This example uses Switch A.

```
[SwitchA] ping ipv6 3003::1
Ping6(56 data bytes) 3001::1 --> 3003::1, press CTRL+C to break
56 bytes from 3003::1, icmp_seq=0 hlim=64 time=45.000 ms
56 bytes from 3003::1, icmp_seq=1 hlim=64 time=10.000 ms
56 bytes from 3003::1, icmp_seq=2 hlim=64 time=4.000 ms
56 bytes from 3003::1, icmp_seq=3 hlim=64 time=10.000 ms
56 bytes from 3003::1, icmp_seq=4 hlim=64 time=11.000 ms

--- Ping6 statistics for 3003::1 ---
```

```
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 4.000/16.000/45.000/14.711 ms
```

Configuring a 6to4 tunnel

Restrictions and guidelines

Follow these guidelines when you configure a 6to4 tunnel:

- You do not need to configure a destination address for a 6to4 tunnel, because the destination IPv4 address is embedded in the 6to4 IPv6 address.
- Do not specify the same source addresses for local tunnel interfaces in the same tunnel mode.
- Automatic tunnels do not support dynamic routing. You must configure a static route destined for the destination IPv6 network if the destination IPv6 network is not in the same subnet as the IPv6 address of the tunnel interface. You can specify the local tunnel interface as the egress interface of the route or specify the IPv6 address of the peer tunnel interface as the next hop of the route. The route configuration is required on both ends of the tunnel. For more information about route configuration, see *Layer 3—IP Routing Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter 6to4 tunnel interface view.
   interface tunnel *number* [**mode ipv6-ipv4 6to4**]
3. Specify an IPv6 address for the tunnel interface.
   See "Configuring basic IPv6 settings."
4. Configure a source address or source interface for the tunnel interface.
   source { *ipv4-address* | *interface-type interface-number* }
   By default, no source address or source interface is configured for the tunnel interface.
   If you specify a source address, it is used as the source IP address of tunneled packets.
   If you specify a source interface, the primary IP address of this interface is used as the source IP address of tunneled packets.
5. (Optional.) Set the DF bit for tunneled packets.
   tunnel dfbit enable
   By default, the DF bit is not set for tunneled packets.

Example: Configuring a 6to4 tunnel

Network configuration

As shown in Figure 5, configure a 6to4 tunnel between 6to4 switches Switch A and Switch B so the two hosts can reach each other over the IPv4 network.

Figure 5 Network diagram

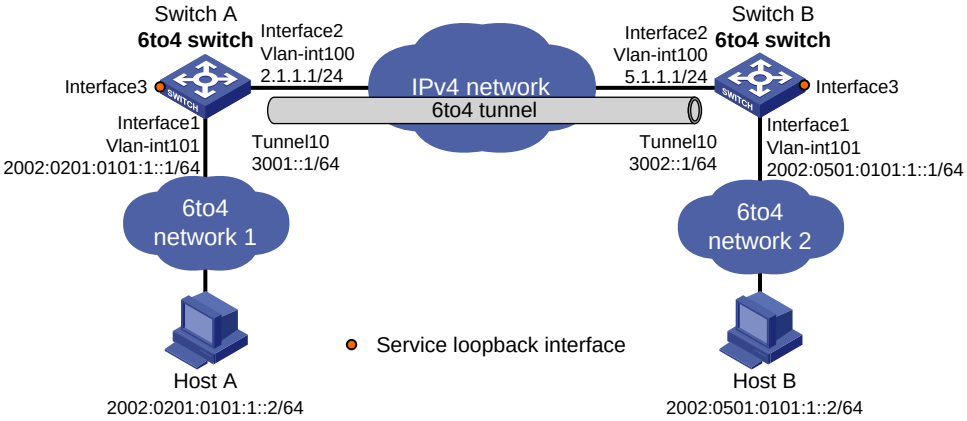

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Requirements analysis

To enable communication between 6to4 networks, configure 6to4 addresses for 6to4 switches and hosts in the 6to4 networks.

- The IPv4 address of VLAN-interface 100 on Switch A is 2.1.1.1/24, and the corresponding 6to4 prefix is 2002:0201:0101::/48. Host A must use this prefix.
- The IPv4 address of VLAN-interface 100 on Switch B is 5.1.1.1/24, and the corresponding 6to4 prefix is 2002:0501:0101::/48. Host B must use this prefix.

Procedure

Make sure Switch A and Switch B have the corresponding VLAN interfaces created and can reach each other through IPv4.

1. Configure Switch A:

Add GigabitEthernet 1/0/2 (the physical interface of the tunnel) to VLAN 100.

```
<SwitchA> system-view
[SwitchA] vlan 100
[SwitchA-vlan100] port gigabitethernet 1/0/2
[SwitchA-vlan100] quit
```

Specify an IPv4 address for VLAN-interface 100.

```
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ip address 2.1.1.1 24
[SwitchA-Vlan-interface100] quit
```

Add GigabitEthernet 1/0/1 to VLAN 101.

```
[SwitchA] vlan 101
[SwitchA-vlan101] port gigabitethernet 1/0/1
[SwitchA-vlan101] quit
```

Specify a 6to4 address for VLAN-interface 101.

```
[SwitchA] interface vlan-interface 101
```

```
[SwitchA-Vlan-interface101] ipv6 address 2002:0201:0101:1::1/64
[SwitchA-Vlan-interface101] quit
```

Create 6to4 tunnel interface Tunnel10.

```
[SwitchA] interface tunnel 10 mode ipv6-ipv4 6to4
```

Specify an IPv6 address for the tunnel interface.

```
[SwitchA-Tunnel10] ipv6 address 3001::1/64
```

Specify the source interface as VLAN-interface 100 for the tunnel interface.

```
[SwitchA-Tunnel10] source vlan-interface 100
[SwitchA-Tunnel10] quit
```

Configure a static route destined for 2002::/16 through the tunnel interface.

```
[SwitchA] ipv6 route-static 2002:: 16 tunnel 10
```

2. Configure Switch B:

Add GigabitEthernet 1/0/2 (the physical interface of the tunnel) to VLAN 100.

```
<SwitchB> system-view
[SwitchB] vlan 100
[SwitchB-vlan100] port gigabitethernet 1/0/2
[SwitchB-vlan100] quit
```

Specify an IPv4 address for VLAN-interface 100.

```
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ip address 5.1.1.1 24
[SwitchB-Vlan-interface100] quit
```

Add GigabitEthernet 1/0/1 to VLAN 101.

```
[SwitchB] vlan 101
[SwitchB-vlan101] port gigabitethernet 1/0/1
[SwitchB-vlan101] quit
```

Specify a 6to4 address for VLAN-interface 101.

```
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] ipv6 address 2002:0501:0101:1::1/64
[SwitchB-Vlan-interface101] quit
```

Create 6to4 tunnel interface Tunnel10.

```
[SwitchB] interface tunnel 10 mode ipv6-ipv4 6to4
```

Specify an IPv6 address for the tunnel interface.

```
[SwitchB-Tunnel10] ipv6 address 3002::1/64
```

Specify the source interface as VLAN-interface 100 for the tunnel interface.

```
[SwitchB-Tunnel10] source vlan-interface 100
[SwitchB-Tunnel10] quit
```

Configure a static route destined for 2002::/16 through the tunnel interface.

```
[SwitchB] ipv6 route-static 2002:: 16 tunnel 10
```

Verifying the configuration

Verify that Host A and Host B can ping each other.

```
D:\>ping6 -s 2002:201:101:1::2 2002:501:101:1::2

Pinging 2002:501:101:1::2
from 2002:201:101:1::2 with 32 bytes of data:

Reply from 2002:501:101:1::2: bytes=32 time=13ms
```

```
Reply from 2002:501:101:1::2: bytes=32 time=1ms
Reply from 2002:501:101:1::2: bytes=32 time=1ms
Reply from 2002:501:101:1::2: bytes=32 time<1ms

Ping statistics for 2002:501:101:1::2:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 0ms, Maximum = 13ms, Average = 3ms
```

Example: Configuring 6to4 relay

Network configuration

As shown in Figure 6, Switch A is a 6to4 switch, and 6to4 addresses are used on the connected IPv6 network. Switch B acts as a 6to4 relay switch and is connected to the IPv6 network (2001::/64). Configure a 6to4 tunnel between Switch A and Switch B to make Host A and Host B reachable to each other.

The configuration on a 6to4 relay switch is similar to that on a 6to4 switch. To enable communication between the 6to4 network and the IPv6 network, configure a route destined for the IPv6 network on the 6to4 switch. The IPv4 address of VLAN-interface 100 on the relay switch is 6.1.1.1/24 and its corresponding 6to4 prefix is 2002:0601:0101::/48. The next hop of the static route must be an address using this prefix.

Figure 6 Network diagram

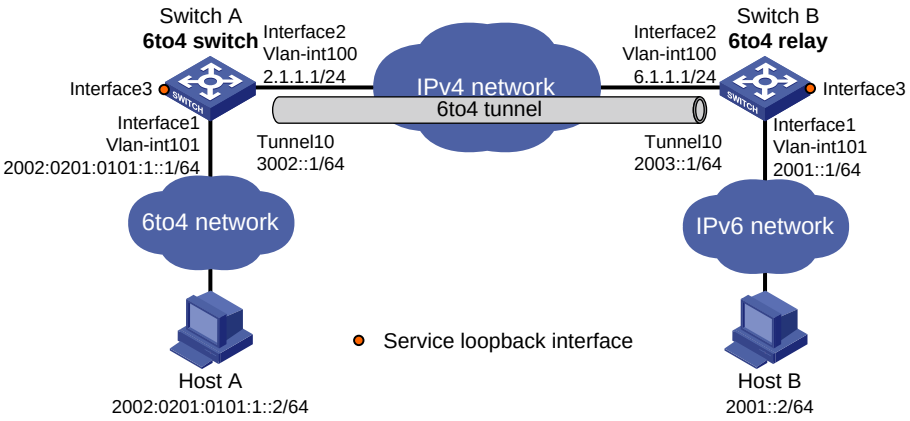

Table 3 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

Make sure Switch A and Switch B have the corresponding VLAN interfaces created and can reach each other through IPv4.

1. Configure Switch A:

   # Add GigabitEthernet 1/0/2 (the physical interface of the tunnel) to VLAN 100.

   ```
   <SwitchA> system-view
   ```

```
[SwitchA] vlan 100
[SwitchA-vlan100] port gigabitethernet 1/0/2
[SwitchA-vlan100] quit
```

Specify an IPv4 address for VLAN-interface 100.

```
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ip address 2.1.1.1 255.255.255.0
[SwitchA-Vlan-interface100] quit
```

Add GigabitEthernet 1/0/1 to VLAN 101.

```
[SwitchA] vlan 101
[SwitchA-vlan101] port gigabitethernet 1/0/1
[SwitchA-vlan101] quit
```

Specify a 6to4 address for VLAN-interface 101.

```
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] ipv6 address 2002:0201:0101:1::1/64
[SwitchA-Vlan-interface101] quit
```

Create 6to4 tunnel interface Tunnel10.

```
[SwitchA] interface tunnel 10 mode ipv6-ipv4 6to4
```

Specify an IPv6 address for the tunnel interface.

```
[SwitchA-Tunnel10] ipv6 address 3002::1/64
```

Specify the source interface as VLAN-interface 100 for the tunnel interface.

```
[SwitchA-Tunnel10] source vlan-interface 100
[SwitchA-Tunnel10] quit
```

Configure a static route destined for the 6to4 relay switch.

```
[SwitchA] ipv6 route-static 2002:0601:0101:: 64 tunnel 10
```

Configure a default route to reach the IPv6 network, which specifies the 6to4 address of the 6to4 relay switch as the next hop.

```
[SwitchA] ipv6 route-static :: 0 2002:0601:0101::1
```

2. Configure Switch B:

Add GigabitEthernet 1/0/2 (the physical interface of the tunnel) to VLAN 100.

```
<SwitchB> system-view
[SwitchB] vlan 100
[SwitchB-vlan100] port gigabitethernet 1/0/2
[SwitchB-vlan100] quit
```

Specify an IPv4 address for VLAN-interface 100.

```
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ip address 6.1.1.1 255.255.255.0
[SwitchB-Vlan-interface100] quit
```

Add GigabitEthernet 1/0/1 to VLAN 101.

```
[SwitchB] vlan 101
[SwitchB-vlan101] port gigabitethernet 1/0/1
[SwitchB-vlan101] quit
```

Specify an IPv6 address for VLAN-interface 101.

```
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] ipv6 address 2001::1/64
[SwitchB-Vlan-interface101] quit
```

Create 6to4 tunnel interface Tunnel10.

```
[SwitchB] interface tunnel 10 mode ipv6-ipv4 6to4
```

Specify an IPv6 address for the tunnel interface.

```
[SwitchB-Tunnel10] ipv6 address 2003::1/64
```

Specify VLAN-interface 100 as the source interface of the tunnel interface.

```
[SwitchB-Tunnel10] source vlan-interface 100
[SwitchB-Tunnel10] quit
```

Configure a static route destined for 2002::/16 through the tunnel interface.

```
[SwitchB] ipv6 route-static 2002:: 16 tunnel 10
```

Verifying the configuration

Verify that Host A and Host B can ping each other.

```
D:\>ping6 -s 2002:201:101:1::2 2001::2

Pinging 2001::2
from 2002:201:101:1::2 with 32 bytes of data:

Reply from 2001::2: bytes=32 time=13ms
Reply from 2001::2: bytes=32 time=1ms
Reply from 2001::2: bytes=32 time=1ms
Reply from 2001::2: bytes=32 time<1ms

Ping statistics for 2001::2:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 0ms, Maximum = 13ms, Average = 3ms
```

Configuring an ISATAP tunnel

Restrictions and guidelines

Follow these guidelines when you configure an ISATAP tunnel:

- You do not need to configure a destination address for an ISATAP tunnel, because the destination IPv4 address is embedded in the ISATAP address.
- Do not specify the same source addresses for local tunnel interfaces in the same tunnel mode.
- Automatic tunnels do not support dynamic routing. You must configure a static route destined for the destination IPv6 network if the destination IPv6 network is not in the same subnet as the IPv6 address of the tunnel interface. You can specify the local tunnel interface as the egress interface of the route or specify the IPv6 address of the peer tunnel interface as the next hop of the route. The route configuration is required on both ends of the tunnel. For more information about route configuration, see *Layer 3—IP Routing Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter ISATAP tunnel interface view.
   interface tunnel *number* [**mode ipv6-ipv4 isatap**]
3. Specify an IPv6 address for the tunnel interface.
   See "Configuring basic IPv6 settings."

4. Configure a source address or source interface for the tunnel interface.

   source { *ipv4-address* | *interface-type interface-number* }

   By default, no source address or source interface is configured for the tunnel interface.

   If you specify a source address, it is used as the source IP address of tunneled packets.

   If you specify a source interface, the primary IP address of this interface is used as the source IP address of tunneled packets.

5. (Optional.) Set the DF bit for tunneled packets.

   tunnel dfbit enable

   By default, the DF bit is not set for tunneled packets.

Example: Configuring an ISATAP tunnel

Network configuration

As shown in Figure 7, configure an ISATAP tunnel between the switch and the ISATAP host so the ISATAP host in the IPv4 network can access the IPv6 network.

Figure 7 Network diagram

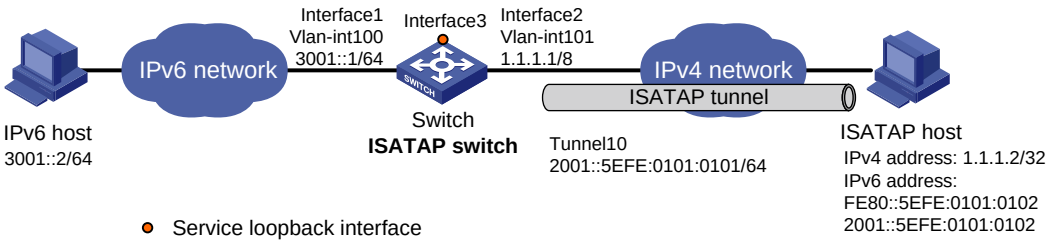

Table 4 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

1. Configure the switch:

   # Add GigabitEthernet 1/0/1 to VLAN 100.

   ```
   <Sysname> system-view
   [Sysname] sysname Switch
   [Switch] vlan 100
   [Switch-vlan100] port gigabitethernet 1/0/1
   [Switch-vlan100] quit
   ```

   # Specify an IPv6 address for VLAN-interface 100.

   ```
   [Switch] interface vlan-interface 100
   [Switch-Vlan-interface100] ipv6 address 3001::1/64
   [Switch-Vlan-interface100] quit
   ```

   # Add GigabitEthernet 1/0/2 (the physical interface of the tunnel) to VLAN 101.

   ```
   [Switch] vlan 101
   [Switch-vlan101] port gigabitethernet 1/0/2
   ```

```
[Switch-vlan101] quit
```

Specify an IPv4 address for VLAN-interface 101.

```
[Switch] interface vlan-interface 101
[Switch-Vlan-interface101] ip address 1.1.1.1 255.0.0.0
[Switch-Vlan-interface101] quit
```

Create ISATAP tunnel interface Tunnel10.

```
[Switch] interface tunnel 10 mode ipv6-ipv4 isatap
```

Specify an EUI-64 IPv6 address for the tunnel interface.

```
[Switch-Tunnel10] ipv6 address 2001:: 64 eui-64
```

Specify VLAN-interface 101 as the source interface of the tunnel interface.

```
[Switch-Tunnel10] source vlan-interface 101
```

Disable RA suppression so that the ISATAP host can acquire information such as the address prefix from the RA message advertised by the ISATAP switch.

```
[Switch-Tunnel10] undo ipv6 nd ra halt
[Switch-Tunnel10] quit
```

2. Configure the ISATAP host:

Configurations on the ISATAP host vary by operating system. The following configuration is performed on Windows 10.

On a Windows 10 host, specify the IPv4 address of the ISATAP switch, for example, 1.1.1.1.

```
C:\>netsh
netsh>interface ipv6 isatap
netsh interface ipv6 isatap>set router 1.1.1.1
netsh interface ipv6 isatap>set state enable
netsh interface ipv6 isatap>exit
```

Display information about the ISATAP interface. In this example, the ISATAP host obtained prefix 2001::/64 and automatically generated global IPv6 unicast address 2001::5efe:1.1.1.2.

```
C:\>ipconfig

Windows IP Configuration

IPv4 over IPv4 tunneling

About IPv4 over IPv4 tunneling

IPv4 over IPv4 tunneling (RFC 1853) enables isolated IPv4 networks to communicate. For example, an IPv4 over IPv4 tunnel can connect isolated private IPv4 networks over a public IPv4 network.

Figure 8 IPv4 over IPv4 tunnel

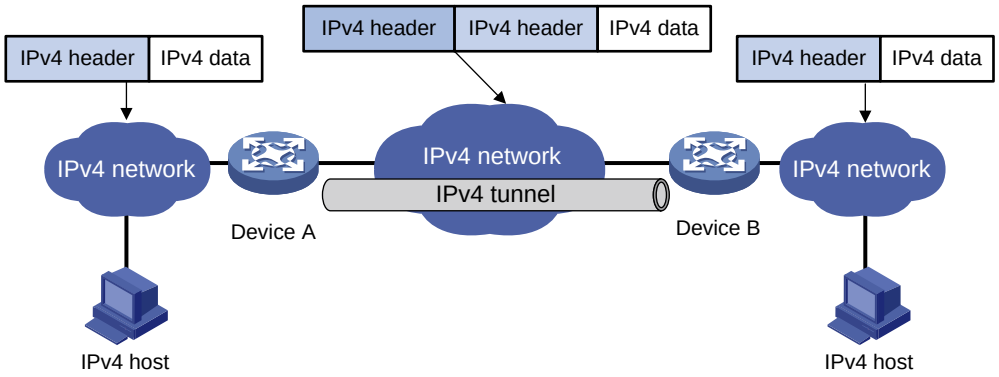

Figure 8 shows the encapsulation and de-encapsulation processes.

- Encapsulation:
  - **a.** Device A receives an IP packet from an IPv4 host and submits it to the IP protocol stack.
  - **b.** The IPv4 protocol stack determines how to forward the packet according to the destination address in the IP header. If the packet is destined for the IPv4 host connected to Device B, Device A delivers the packet to the tunnel interface.
  - **c.** The tunnel interface adds a new IPv4 header to the IPv4 packet and submits it to the IP protocol stack.

    In the new header, the source IP address specifies the tunnel source, and the destination IP address specifies the tunnel destination.
  - **d.** The IP protocol stack uses the destination IP address of the new IP header to look up the routing table, and then sends the packet out.
- De-encapsulation:
  - **e.** After receiving the packet, Device B delivers it to the IP protocol stack.
  - **f.** If the protocol number is 4 (indicating an IPv4 packet is encapsulated within the packet), the IP protocol stack delivers the packet to the tunnel module for de-encapsulation.
  - **g.** The tunnel module de-encapsulates the IP packet and sends it back to the IP protocol stack.
  - **h.** The protocol stack forwards the de-encapsulated packet.

Restrictions and guidelines: IPv4 over IPv4 tunnel configuration

Follow these guidelines when you configure an IPv4 over IPv4 tunnel:

- The tunnel destination address specified on the local device must be identical with the tunnel source address specified on the tunnel peer device.

- Do not specify the same source and destination addresses for local tunnel interfaces in the same tunnel mode.
- The IPv4 address of the local tunnel interface cannot be on the same subnet as the destination address configured on the tunnel interface.
- To ensure correct packet forwarding, identify whether the destination IPv4 network and the IPv4 address of the local tunnel interface are on the same subnet. If they are not, configure a route reaching the destination IPv4 network through the tunnel interface. You can configure the route by using one of the following methods:
  - Configure a static route, and specify the local tunnel interface as the egress interface or specify the IPv4 address of the peer tunnel interface as the next hop.
  - Enable a dynamic routing protocol on the tunnel interface.

  The route configuration is required on both ends of the tunnel. For more information about route configuration, see *Layer 3—IP Routing Configuration Guide*.
- The destination address of the route passing the tunnel interface cannot be on the same subnet as the destination address configured on the tunnel interface.

Configuring an IPv4 over IPv4 tunnel

1. Enter system view.

   system-view
2. Enter IPv4 over IPv4 tunnel interface view.

   interface tunnel *number* [**mode ipv4-ipv4**]
3. Configure an IPv4 address for the tunnel interface.

   ip address *ip-address* { *mask* | *mask-length* } [**sub**]
4. Configure a source address or source interface for the tunnel interface.

   source { *ipv4-address* | *interface-type interface-number* }

   By default, no source address or source interface is configured for the tunnel interface.

   If you specify a source address, it is used as the source IP address of tunneled packets.

   If you specify a source interface, the primary IP address of this interface is used as the source IP address of tunneled packets.
5. Configure a destination address for the tunnel interface.

   destination *ipv4-address*

   By default, no destination address is configured for the tunnel interface.

   The tunnel destination address must be the IP address of the receiving interface on the tunnel peer. It is used as the destination IP address of tunneled packets.
6. (Optional.) Set the DF bit for tunneled packets.

   tunnel dfbit enable

   By default, the DF bit is not set for tunneled packets.

IPv4 over IPv4 tunnel configuration examples

Example: Configuring an IPv4 over IPv4 tunnel

Network configuration

As shown in Figure 9, the two subnets IPv4 group 1 and IPv4 group 2 use private IPv4 addresses. Configure an IPv4 over IPv4 tunnel between Switch A and Switch B to make the two subnets reachable to each other.

Figure 9 Network diagram

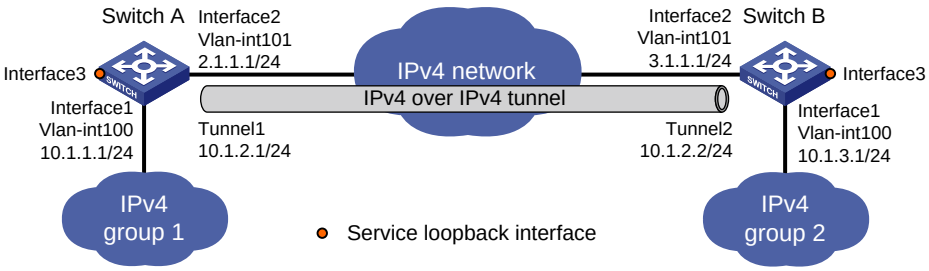

Table 5 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

Make sure Switch A and Switch B have the corresponding VLAN interfaces created and can reach each other through IPv4.

1. Configure Switch A:

   # Add GigabitEthernet 1/0/1 to VLAN 100.

   ```
   <SwitchA> system-view
   [SwitchA] vlan 100
   [SwitchA-vlan100] port gigabitethernet 1/0/1
   [SwitchA-vlan100] quit
   ```

   # Specify an IPv4 address for VLAN-interface 100.

   ```
   [SwitchA] interface vlan-interface 100
   [SwitchA-Vlan-interface100] ip address 10.1.1.1 255.255.255.0
   [SwitchA-Vlan-interface100] quit
   ```

   # Add GigabitEthernet 1/0/2 (the physical interface of the tunnel) to VLAN 101.

   ```
   [SwitchA] vlan 101
   [SwitchA-vlan101] port gigabitethernet 1/0/2
   [SwitchA-vlan101] quit
   ```

   # Specify an IPv4 address for VLAN-interface 101.

   ```
   [SwitchA] interface vlan-interface 101
   [SwitchA-Vlan-interface101] ip address 2.1.1.1 255.255.255.0
   [SwitchA-Vlan-interface101] quit
   ```

Create IPv4 over IPv4 tunnel interface Tunnel 1.

```
[SwitchA] interface tunnel 1 mode ipv4-ipv4
```

Specify an IPv4 address for the tunnel interface.

```
[SwitchA-Tunnel1] ip address 10.1.2.1 255.255.255.0
```

Specify the IP address of VLAN-interface 101 as the source address for the tunnel interface.

```
[SwitchA-Tunnel1] source 2.1.1.1
```

Specify the IP address of VLAN-interface 101 on Switch B as the destination address for the tunnel interface.

```
[SwitchA-Tunnel1] destination 3.1.1.1
[SwitchA-Tunnel1] quit
```

Configure a static route destined for IPv4 group 2 through the tunnel interface.

```
[SwitchA] ip route-static 10.1.3.0 255.255.255.0 tunnel 1
```

2. Configure Switch B:

Add GigabitEthernet 1/0/1 to VLAN 100.

```
<SwitchB> system-view
[SwitchB] vlan 100
[SwitchB-vlan100] port gigabitethernet 1/0/1
[SwitchB-vlan100] quit
```

Specify an IPv4 address for VLAN-interface 100.

```
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ip address 10.1.3.1 255.255.255.0
[SwitchB-Vlan-interface100] quit
```

Add GigabitEthernet 1/0/2 (the physical interface of the tunnel) to VLAN 101.

```
[SwitchB] vlan 101
[SwitchB-vlan101] port gigabitethernet 1/0/2
[SwitchB-vlan101] quit
```

Specify an IPv4 address for VLAN-interface 101.

```
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] ip address 3.1.1.1 255.255.255.0
[SwitchB-Vlan-interface101] quit
```

Create IPv4 over IPv4 tunnel interface Tunnel 2.

```
[SwitchB] interface tunnel 2 mode ipv4-ipv4
```

Specify an IPv4 address for the tunnel interface.

```
[SwitchB-Tunnel2] ip address 10.1.2.2 255.255.255.0
```

Specify the IP address of VLAN-interface 101 as the source address for the tunnel interface.

```
[SwitchB-Tunnel2] source 3.1.1.1
```

Specify the IP address of VLAN-interface 101 on Switch A as the destination address for the tunnel interface.

```
[SwitchB-Tunnel2] destination 2.1.1.1
[SwitchB-Tunnel2] quit
```

Configure a static route destined for IPv4 group 1 through the tunnel interface.

```
[SwitchB] ip route-static 10.1.1.0 255.255.255.0 tunnel 2
```

Verifying the configuration

Use the **`display interface tunnel`** command to display the status of the tunnel interfaces on Switch A and Switch B. Verify that the tunnel interfaces are up. (Details not shown.)

Verify that Switch A and Switch B can ping the IPv4 address of the peer interface VLAN-interface 100. This example uses Switch A.

```
[SwitchA] ping -a 10.1.1.1 10.1.3.1
Ping 10.1.3.1 (10.1.3.1) from 10.1.1.1: 56 data bytes, press CTRL+C to break
56 bytes from 10.1.3.1: icmp_seq=0 ttl=255 time=2.000 ms
56 bytes from 10.1.3.1: icmp_seq=1 ttl=255 time=1.000 ms
56 bytes from 10.1.3.1: icmp_seq=2 ttl=255 time=0.000 ms
56 bytes from 10.1.3.1: icmp_seq=3 ttl=255 time=1.000 ms
56 bytes from 10.1.3.1: icmp_seq=4 ttl=255 time=1.000 ms

--- Ping statistics for 10.1.3.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 0.000/1.000/2.000/0.632 ms
```

IPv4 over IPv6 tunneling

About IPv4 over IPv6 tunneling

Implementation

IPv4 over IPv6 tunneling adds an IPv6 header to IPv4 packets so that the IPv4 packets can pass an IPv6 network through a tunnel to realize interworking between isolated IPv4 networks.

Figure 10 IPv4 over IPv6 tunnel

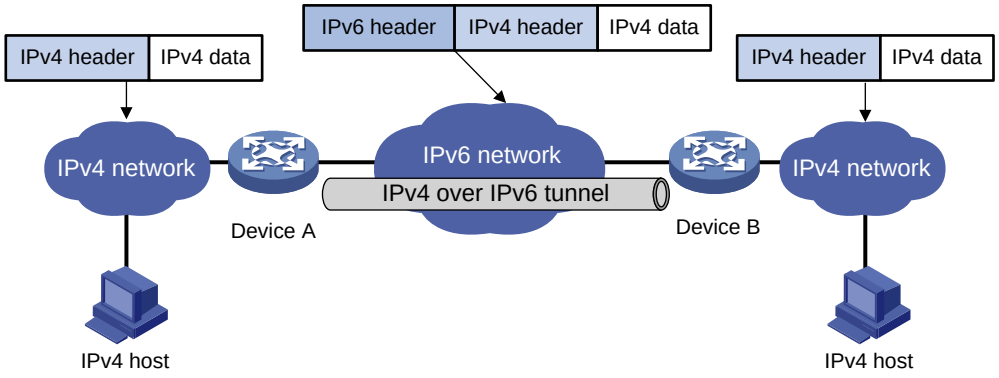

Figure 10 shows the encapsulation and de-encapsulation processes.

- Encapsulation:
  - **a.** Upon receiving an IPv4 packet, Device A delivers it to the IPv4 protocol stack.
  - **b.** The IPv4 protocol stack uses the destination address of the packet to determine the egress interface. If the egress interface is the tunnel interface, the IPv4 protocol stack delivers the packet to the tunnel interface.
  - **c.** The tunnel interface adds an IPv6 header to the original IPv4 packet and delivers the packet to the IPv6 protocol stack.
  - **d.** The IPv6 protocol stack uses the destination IPv6 address of the packet to look up the routing table, and then sends it out.
- De-encapsulation:
  - **e.** Upon receiving the IPv6 packet from the attached IPv6 network, Device B delivers the packet to the IPv6 protocol stack to examine the protocol type encapsulated in the data portion of the packet.
  - **f.** If the protocol type is IPv4, the IPv6 protocol stack delivers the packet to the tunneling module.
  - **g.** The tunneling module removes the IPv6 header and delivers the remaining IPv4 packet to the IPv4 protocol stack.
  - **h.** The IPv4 protocol stack forwards the IPv4 packet.

Configuring an IPv4 over IPv6 tunnel

Restrictions and guidelines

When you perform the tasks in this section, follow these restrictions and guidelines:

- The tunnel destination address specified on the local device must be identical with the tunnel source address specified on the tunnel peer device.
- Do not specify the same source and destination addresses for local tunnel interfaces in the same tunnel mode.
- To ensure correct packet forwarding, identify whether the destination IPv4 network and the IPv4 address of the local tunnel interface are on the same subnet. If they are not, configure a route reaching the destination IPv4 network through the tunnel interface. You can configure the route by using one of the following methods:
  - Configure a static route, and specify the local tunnel interface as the egress interface or specify the IPv6 address of the peer tunnel interface as the next hop.
  - Enable a dynamic routing protocol on the tunnel interface.

  The route configuration is required on both ends of the tunnel. For more information about route configuration, see *Layer 3—IP Routing Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Enter IPv4 over IPv6 tunnel interface view.

   interface tunnel *number* [**mode ipv4-ipv6**]
3. Configure an IPv4 address for the tunnel interface.

   ip address *ip-address* { *mask* | *mask-length* } [**sub**]
4. Configure the source address or interface for the tunnel interface.

   source { *ipv6-address* | *interface-type interface-number* }

   By default, no source address or interface is configured for the tunnel.

   If you specify a source address, it is used as the source IPv6 address of tunneled packets.

   If you specify a source interface, the lowest IPv6 address of this interface is used as the source IPv6 address of tunneled packets.
5. Configure the destination address for the tunnel interface.

   destination *ipv6-address*

   By default, no destination address is configured for the tunnel.

   The tunnel destination address must be the IPv6 address of the receiving interface on the tunnel peer. It is used as the destination IPv6 address of tunneled packets.

Example: Configuring an IPv4 over IPv6 tunnel

Network configuration

As shown in Figure 11, configure an IPv4 over IPv6 manual tunnel between Switch A and Switch B so the two networks can reach each other over the IPv6 network.

Figure 11 Network diagram

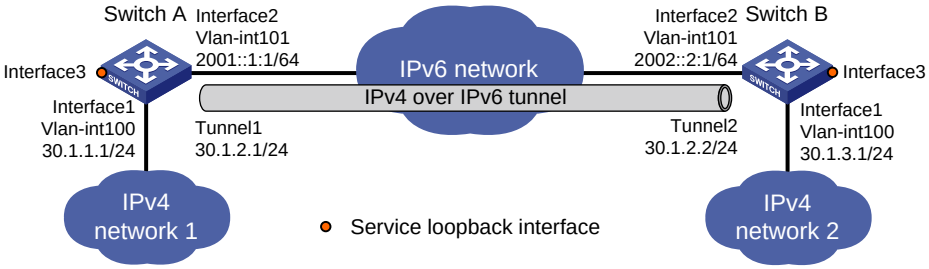

Table 6 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

Make sure Switch A and Switch B have the corresponding VLAN interfaces created and can reach each other through IPv6.

1. Configure Switch A:

Add GigabitEthernet 1/0/1 to VLAN 100.

```
<SwitchA> system-view
[SwitchA] vlan 100
[SwitchA-vlan100] port gigabitethernet 1/0/1
[SwitchA-vlan100] quit
```

Specify an IPv4 address for VLAN-interface 100.

```
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ip address 30.1.1.1 255.255.255.0
[SwitchA-Vlan-interface100] quit
```

Add GigabitEthernet 1/0/2 (the physical interface of the tunnel) to VLAN 101.

```
[SwitchA] vlan 101
[SwitchA-vlan101] port gigabitethernet 1/0/2
[SwitchA-vlan101] quit
```

Specify an IPv6 address for VLAN-interface 101.

```
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] ipv6 address 2001::1:1 64
[SwitchA-Vlan-interface101] quit
```

Create IPv4 over IPv6 tunnel interface Tunnel 1.

```
[SwitchA] interface tunnel 1 mode ipv4-ipv6
```

Specify an IPv4 address for the tunnel interface.

```
[SwitchA-Tunnel1] ip address 30.1.2.1 255.255.255.0
```

Specify the IP address of VLAN-interface 101 as the source address for the tunnel interface.

```
[SwitchA-Tunnel1] source 2001::1:1
```

Specify the IP address of VLAN-interface 101 on Switch B as the destination address for the tunnel interface.

```
[SwitchA-Tunnel1] destination 2003::2:1
```

```
[SwitchA-Tunnel1] quit
```

Configure a static route destined for IPv4 network 2 through the tunnel interface.

```
[SwitchA] ip route-static 30.1.3.0 255.255.255.0 tunnel 1
```

2. Configure Switch B:

Add GigabitEthernet 1/0/1 to VLAN 100.

```
<SwitchB> system-view
[SwitchB] vlan 100
[SwitchB-vlan100] port gigabitethernet 1/0/1
[SwitchB-vlan100] quit
```

Specify an IPv4 address for VLAN-interface 100.

```
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ip address 30.1.3.1 255.255.255.0
[SwitchB-Vlan-interface100] quit
```

Add GigabitEthernet 1/0/2 (the physical interface of the tunnel) to VLAN 101.

```
[SwitchB] vlan 101
[SwitchB-vlan101] port gigabitethernet 1/0/2
[SwitchB-vlan101] quit
```

Specify an IPv6 address for VLAN-interface 101.

```
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] ipv6 address 2003::2:1 64
[SwitchB-Vlan-interface101] quit
```

Create IPv4 over IPv6 tunnel interface Tunnel 2.

```
[SwitchB] interface tunnel 2 mode ipv4-ipv6
```

Specify an IPv4 address for the tunnel interface.

```
[SwitchB-Tunnel2] ip address 30.1.2.2 255.255.255.0
```

Specify the IP address of VLAN-interface 101 as the source address for the tunnel interface (IP address of VLAN-interface 101).

```
[SwitchB-Tunnel2] source 2003::2:1
```

Specify the IP address of VLAN-interface 101 on Switch A as the destination address for the tunnel interface.

```
[SwitchB-Tunnel2] destination 2001::1:1
[SwitchB-Tunnel2] quit
```

Configure a static route destined for IPv4 network 1 through the tunnel interface.

```
[SwitchB] ip route-static 30.1.1.0 255.255.255.0 tunnel 2
```

Verifying the configuration

Use the **`display interface tunnel`** command to display the status of the tunnel interfaces on Switch A and Switch B. Verify that the tunnel interfaces are up. (Details not shown.)

Verify that Switch A and Switch B can ping the IPv4 address of the peer interface. This example uses Switch A.

```
[SwitchA] ping -a 30.1.1.1 30.1.3.1
Ping 30.1.3.1 (30.1.3.1) from 30.1.1.1: 56 data bytes, press CTRL+C to break
56 bytes from 30.1.3.1: icmp_seq=0 ttl=255 time=3.000 ms
56 bytes from 30.1.3.1: icmp_seq=1 ttl=255 time=1.000 ms
56 bytes from 30.1.3.1: icmp_seq=2 ttl=255 time=0.000 ms
56 bytes from 30.1.3.1: icmp_seq=3 ttl=255 time=1.000 ms
56 bytes from 30.1.3.1: icmp_seq=4 ttl=255 time=1.000 ms
```

```
--- Ping statistics for 30.1.3.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 0.000/1.200/3.000/0.980 ms
```

IPv6 over IPv6 tunneling

About IPv6 over IPv6 tunneling

IPv6 over IPv6 tunneling (RFC 2473) enables isolated IPv6 networks to communicate with each other over another IPv6 network. For example, two isolated IPv6 networks that do not want to show their addresses to the Internet can use an IPv6 over IPv6 tunnel to communicate with each other.

Figure 12 Principle of IPv6 over IPv6 tunneling

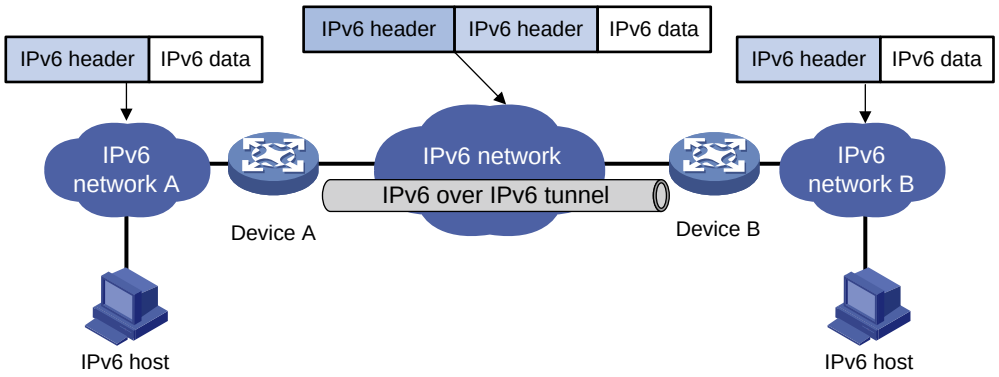

Figure 12 shows the encapsulation and de-encapsulation processes.

- Encapsulation:
  - **a.** After receiving an IPv6 packet, Device A submits it to the IPv6 protocol stack.
  - **b.** The IPv6 protocol stack uses the destination IPv6 address of the packet to find the egress interface. If the egress interface is the tunnel interface, the stack delivers it to the tunnel interface.
  - **c.** After receiving the packet, the tunnel interface adds an IPv6 header to it and submits it to the IPv6 protocol stack.
  - **d.** The IPv6 protocol stack forwards the packet according to its destination IPv6 address.
- De-encapsulation:
  - **e.** Upon receiving the IPv6 packet, Device B delivers it to the IPv6 protocol stack.
  - **f.** The IPv6 protocol stack checks the protocol type of the data portion encapsulated in the IPv6 packet. If the encapsulation protocol is IPv6, the stack delivers the packet to the tunneling module.
  - **g.** The tunneling module de-encapsulates the packet and sends it back to the IPv6 protocol stack.
  - **h.** The IPv6 protocol stack forwards the IPv6 packet.

Restrictions and guidelines: IPv6 over IPv6 tunnel configuration

Follow these guidelines when you configure an IPv6 over IPv6 tunnel:

- The tunnel destination address specified on the local device must be identical with the tunnel source address specified on the tunnel peer device.
- Do not specify the same source and destination addresses for local tunnel interfaces in the same tunnel mode.

- The IPv6 address of the tunnel interface cannot be on the same subnet as the destination address configured for the tunnel interface.
- To ensure correct packet forwarding, identify whether the destination IPv6 network and the IPv6 address of the local tunnel interface are on the same subnet. If they are not, configure a route reaching the destination IPv6 network through the tunnel interface. You can configure the route by using one of the following methods:
  - Configure a static route, and specify the local tunnel interface as the egress interface or specify the IPv6 address of the peer tunnel interface as the next hop.
  - Enable a dynamic routing protocol on the tunnel interface.

  The route configuration is required on both ends of the tunnel. For more information about route configuration, see *Layer 3—IP Routing Configuration Guide*.
- The destination address of the route passing the tunnel interface cannot be on the same subnet as the destination address configured for the tunnel interface.

IPv6 over IPv6 tunnel configuration tasks at a glance

To configure an IPv6 over IPv6 tunnel, perform the following tasks:

1. Configuring an IPv6 over IPv6 tunnel

Configuring an IPv6 over IPv6 tunnel

1. Enter system view.

   system-view
2. Enter IPv6 over IPv6 tunnel interface view.

   interface tunnel *number* [**mode ipv6-ipv6**]
3. Configure an IPv6 address for the tunnel interface.

   See "Configuring basic IPv6 settings."
4. Configure the source address or source interface for the tunnel interface.

   source { *ipv6-address* | *interface-type interface-number* }

   By default, no source address or interface is configured for the tunnel.

   If you specify a source address, it is used as the source IPv6 address of tunneled packets.

   If you specify a source interface, the lowest IPv6 address of this interface is used as the source IPv6 address of tunneled packets.
5. Configure the destination address for the tunnel interface.

   destination *ipv6-address*

   By default, no destination address is configured for the tunnel.

   The tunnel destination address must be the IPv6 address of the receiving interface on the tunnel peer. It is used as the destination IPv6 address of tunneled packets.

IPv6 over IPv6 tunnel configuration examples

Example: Configuring an IPv6 over IPv6 tunnel

Network configuration

As shown in Figure 13, configure an IPv6 over IPv6 tunnel between Switch A and Switch B so the two networks can reach each other without disclosing their IPv6 addresses.

Figure 13 Network diagram

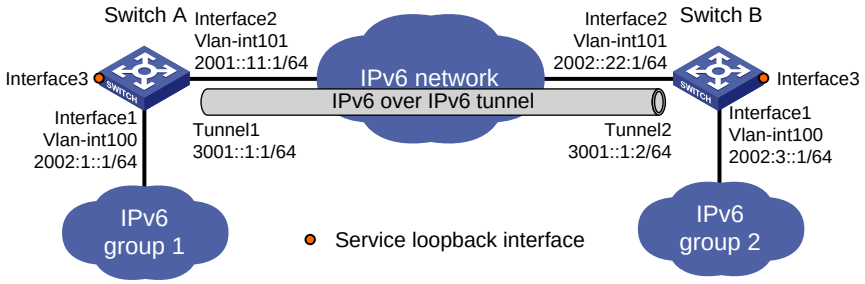

Table 7 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

Make sure Switch A and Switch B have the corresponding VLAN interfaces created and can reach each other through IPv6.

1. Configure Switch A:

   # Add GigabitEthernet 1/0/1 to VLAN 100.

   ```
   <SwitchA> system-view
   [SwitchA] vlan 100
   [SwitchA-vlan100] port gigabitethernet 1/0/1
   [SwitchA-vlan100] quit
   ```

   # Specify an IPv6 address for VLAN-interface 100.

   ```
   [SwitchA] interface vlan-interface 100
   [SwitchA-Vlan-interface100] ipv6 address 2003:1::1 64
   [SwitchA-Vlan-interface100] quit
   ```

   # Add GigabitEthernet 1/0/2 (the physical interface of the tunnel) to VLAN 101.

   ```
   [SwitchA] vlan 101
   [SwitchA-vlan101] port gigabitethernet 1/0/2
   [SwitchA-vlan101] quit
   ```

   # Specify an IPv6 address for VLAN-interface 101.

   ```
   [SwitchA] interface vlan-interface 101
   [SwitchA-Vlan-interface101] ipv6 address 2001::11:1 64
   [SwitchA-Vlan-interface101] quit
   ```

   # Create IPv6 over IPv6 tunnel interface Tunnel 1.

```
[SwitchA] interface tunnel 1 mode ipv6-ipv6
```

Specify an IPv6 address for the tunnel interface.

```
[SwitchA-Tunnel1] ipv6 address 3001::1:1 64
```

Specify the IP address of VLAN-interface 101 as the source address for the tunnel interface.

```
[SwitchA-Tunnel1] source 2001::11:1
```

Specify the IP address of VLAN-interface 101 on Switch B as the destination address for the tunnel interface.

```
[SwitchA-Tunnel1] destination 2003::22:1
[SwitchA-Tunnel1] quit
```

Configure a static route destined for the IPv6 network group 2 through the tunnel interface.

```
[SwitchA] ipv6 route-static 2003:3:: 64 tunnel 1
```

2. Configure Switch B:

Add GigabitEthernet 1/0/1 to VLAN 100.

```
<SwitchB> system-view
[SwitchB] vlan 100
[SwitchB-vlan100] port gigabitethernet 1/0/1
[SwitchB-vlan100] quit
```

Specify an IPv6 address for VLAN-interface 100.

```
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ipv6 address 2003:3::1 64
[SwitchB-Vlan-interface100] quit
```

Add GigabitEthernet 1/0/2 (the physical interface of the tunnel) to VLAN 101.

```
[SwitchB] vlan 101
[SwitchB-vlan101] port gigabitethernet 1/0/2
[SwitchB-vlan101] quit
```

Specify an IPv6 address for VLAN-interface 101.

```
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] ipv6 address 2003::22:1 64
[SwitchB-Vlan-interface101] quit
```

Create IPv6 over IPv6 tunnel interface Tunnel 2.

```
[SwitchB] interface tunnel 2 mode ipv6-ipv6
```

Specify an IPv6 address for the tunnel interface.

```
[SwitchB-Tunnel2] ipv6 address 3001::1:2 64
```

Specify the IP address of VLAN-interface 101 as the source address for the tunnel interface.

```
[SwitchB-Tunnel2] source 2003::22:1
```

Specify the IP address of VLAN-interface 101 on Switch A as the destination address for the tunnel interface.

```
[SwitchB-Tunnel2] destination 2001::11:1
[SwitchB-Tunnel2] quit
```

Configure a static route destined for the IPv6 network group 1 through the tunnel interface.

```
[SwitchB] ipv6 route-static 2003:1:: 64 tunnel 2
```

Verifying the configuration

Use the **display ipv6 interface** command to display the status of the tunnel interfaces on Switch A and Switch B. Verify that the tunnel interfaces are up. (Details not shown.)

Verify that Switch A and Switch B can ping the IPv4 address of the peer interface. This example uses Switch A.

```
[SwitchA] ping ipv6 -a 2003:1::1 2003:3::1
```

```
Ping6(56 data bytes) 2003:1::1 --> 2003:3::1, press CTRL+C to break
56 bytes from 2003:3::1, icmp_seq=0 hlim=64 time=9.000 ms
56 bytes from 2003:3::1, icmp_seq=1 hlim=64 time=1.000 ms
56 bytes from 2003:3::1, icmp_seq=2 hlim=64 time=0.000 ms
56 bytes from 2003:3::1, icmp_seq=3 hlim=64 time=0.000 ms
56 bytes from 2003:3::1, icmp_seq=4 hlim=64 time=0.000 ms

--- Ping6 statistics for 2003:3::1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 0.000/2.000/9.000/3.521 ms
```

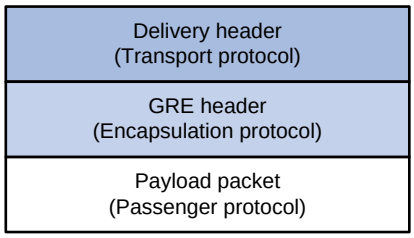
Configuring GRE

About GRE

Generic Routing Encapsulation (GRE) is a tunneling protocol that can encapsulate a protocol (such as IP or Ethernet) into a virtual point-to-point tunnel over a network (such as an IP network). Packets are encapsulated at one tunnel end and de-encapsulated at the other tunnel end. The network layer protocol of the packets before encapsulation and after encapsulation can be the same or different.



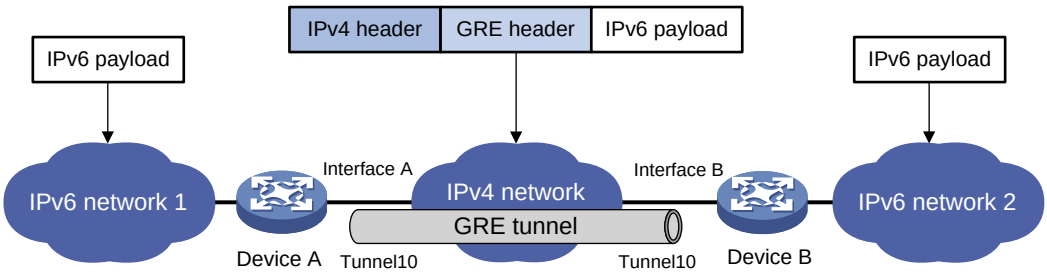
GRE encapsulation format

As shown in Figure 1, a GRE-tunneled packet includes the following parts:

- **Payload packet**—Original packet. The protocol type of the payload packet is called the passenger protocol. The passenger protocol can be any network layer protocol.
- **GRE header**—Header that is added to the payload packet to change the payload packet to a GRE packet. A GRE header includes the number of encapsulations, version, passenger protocol type, checksum, and key. GRE is called the encapsulation protocol.
- **Delivery header**—Header that is added to the GRE packet to deliver it to the tunnel end. The transport protocol (or delivery protocol) is the network layer protocol that transfers GRE packets.

The device supports GRE tunnels with IPv4 and IPv6 as the transport protocols. When the transport protocol is IPv4, the GRE tunnel mode is GRE over IPv4 (GRE/IPv4). When the transport protocol is IPv6, the GRE tunnel mode is GRE over IPv6 (GRE/IPv6).

Figure 1 GRE encapsulation format



GRE tunnel operating principle

As shown in Figure 2, an IPv6 protocol packet traverses an IPv4 network through a GRE tunnel as follows:

1. After receiving an IPv6 packet from the interface connected to IPv6 network 1, Device A processes the packet as follows:
   a. Looks up the routing table to identify the outgoing interface for the IPv6 packet.
   b. Submits the IPv6 packet to the outgoing interface—the GRE tunnel interface Tunnel 10.
2. Upon receiving the packet, the tunnel interface encapsulates the packet with GRE and then with IPv4. In the IPv4 header:
   - The source address is the tunnel's source address (the IP address of Interface A of Device A).
   - The destination address is the tunnel's destination address (the IP address of Interface B of Device B).

3. Device A looks up the routing table according to the destination address in the IPv4 header, and forwards the IPv4 packet out of the physical interface (Interface A) of the GRE tunnel.
4. When the IPv4 arrives at the GRE tunnel destination Device B, Device B checks the destination address. Because the destination is Device B itself and the protocol number in the IP header is 47 (the protocol number for GRE), Device B submits the packet to GRE for de-encapsulation.
5. GRE first removes the IPv4 header, and then checks the GRE key and packet sequence number. After GRE finishes the checking, it removes the GRE header, and submits the payload to the IPv6 protocol for forwarding.

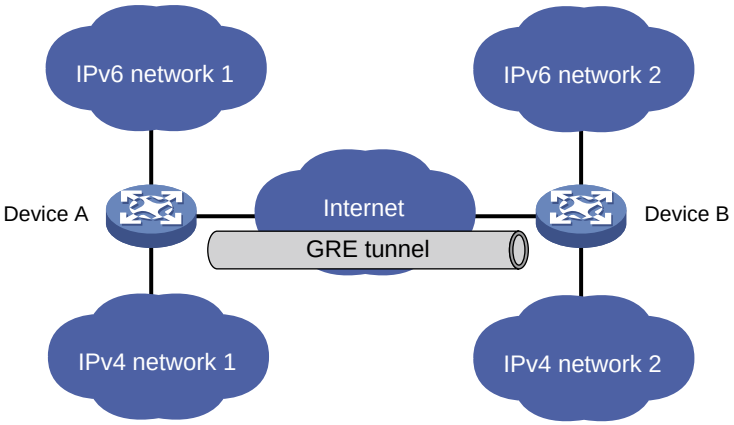
Figure 2 IPv6 networks interconnected through a GRE tunnel

GRE security mechanisms

GRE supports only the GRE key security mechanism.

GRE key

GRE keys ensure packet validity. The sender adds a GRE key into a packet. The receiver compares the GRE key with its own GRE key. If the two keys are the same, the receiver accepts the packet. If the two keys are different, the receiver drops the packet.



GRE application scenarios

The following shows typical GRE application scenarios:

Connecting networks running different protocols over a single backbone

As shown in Figure 3, IPv6 network 1 and IPv6 network 2 are IPv6 networks, and IPv4 network 1 and IPv4 network 2 are IPv4 networks. Through the GRE tunnel between Device A and Device B, IPv6 network 1 can communicate with IPv6 network 2 and IPv4 network 1 can communicate with IPv4 network 2, without affecting each other.

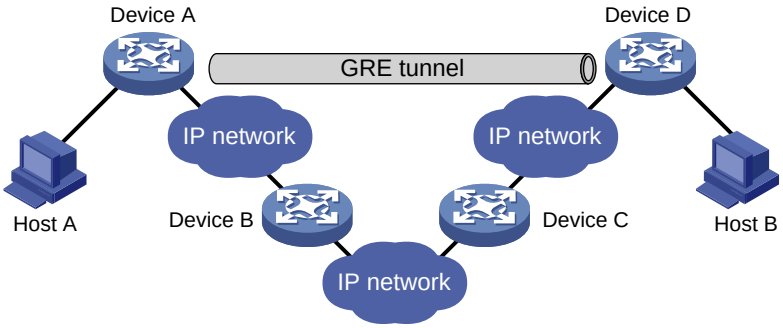


Figure 3 Network diagram

Enlarging network scope

In an IP network, the maximum TTL value of a packet is 255. If two devices have more than 255 hops in between, they cannot communicate with each other. By using a GRE tunnel, you can hide some hops to enlarge the network scope. As shown in Figure 4, only the tunnel-end devices (Device A and Device D) of the GRE tunnel are counted in hop count calculation. Therefore, there are only three hops between Host A and Host B.

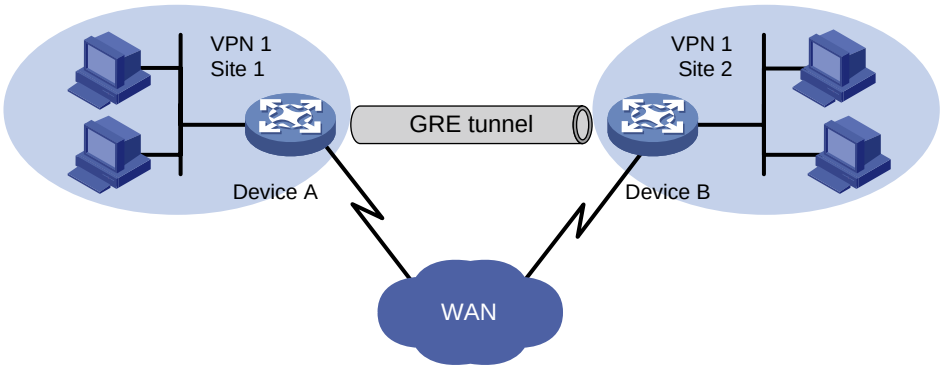

Figure 4 Network diagram

Constructing VPN

As shown in Figure 5, Site 1 and Site 2 both belong to VPN 1 and are located in different cities. Using a GRE tunnel can connect the two VPN sites across the WAN.

Figure 5 Network diagram

Protocols and standards

- RFC 1701, *Generic Routing Encapsulation (GRE)*
- RFC 1702, *Generic Routing Encapsulation over IPv4 networks*
- RFC 2784, *Generic Routing Encapsulation (GRE)*
- RFC 2890, *Key and Sequence Number Extensions to GRE*

Restrictions: Hardware compatibility with GRE configuration

The S5200-EI-G switch series does not support GRE.

Restrictions and guidelines: GRE configuration

When you configure a GRE tunnel, follow these restrictions and guidelines:

- You must configure the tunnel source address and destination address at both ends of a tunnel. The tunnel source or destination address at one end must be the tunnel destination or source address at the other end.
- As a best practice, do not configure the same tunnel source and destination addresses for local tunnel interfaces that use the same tunnel mode.
- To ensure correct packet forwarding, identify whether the destination network of packets and the IP address of the local tunnel interface are on the same subnet. If they are not, configure a route reaching the destination network through the tunnel interface. You can configure the route by using one of the following methods:
  - Configure a static route, using the local tunnel interface as the outgoing interface of the route.
  - Enable a dynamic routing protocol on both the tunnel interface and the interface connecting the private network. This allows the dynamic routing protocol to establish a routing entry with the tunnel interface as the outgoing interface.
- GRE encapsulation and de-encapsulation can decrease the forwarding efficiency of tunnel-end devices.
- The S5200-EI-G switch series does not support GRE.

Configuring a GRE/IPv4 tunnel

Restrictions and guidelines

This task describes only GRE/IPv4 tunnel required tunnel interface commands (the **interface tunnel**, **source**, and **destination** commands). For more tunnel interface commands, see "Configuring tunneling."

Procedure

1. Enter system view.

   system-view

2. Create a GRE tunnel interface, and specify the tunnel mode as GRE/IPv4.

   interface tunnel *number* **mode gre**

   You must configure the same tunnel mode on both ends of a tunnel. Otherwise, packet delivery might fail.

3. Configure an IP address for the tunnel interface based on the passenger protocol.

   IPv4:

   For information about how to assign an IPv4 address to an interface, see "Configuring IP addressing."

   IPv6:

   For information about how to assign an IPv6 address to an interface, see "Configuring basic IPv6 settings."

   By default, no IP address is configured for a tunnel interface.

4. Configure a source address or source interface for the tunnel interface.

   source { *ip-address* | *interface-type interface-number* }

   By default, no source address or interface is configured for a tunnel interface.

   If you configure a source address for a tunnel interface, the tunnel interface uses the source address as the source address of the encapsulated packets.

If you configure a source interface for a tunnel interface, the tunnel interface uses the primary IP address of the source interface as the source address of the encapsulated packets.

5. Configure a destination address for the tunnel interface.

   destination *ip-address*

   By default, no destination address is configured for a tunnel interface.

   The destination address is the address of the physical interface that the tunnel remote end uses to receive packets from the GRE tunnel.

   The tunnel local end uses this address as the destination address of the encapsulated packets.

   The tunnel destination address and the IP address of the tunnel interface must be in different subnets.

6. (Optional.) Enable GRE keepalive, and set the keepalive interval and keepalive number.

   keepalive [*interval* [*times*]]

   By default, GRE keepalive is disabled.

7. (Optional.) Configure GRE security mechanisms.
   - Configure a GRE key for the GRE tunnel interface.

     gre key *key*

     By default, no GRE key is configured for a GRE tunnel interface.

     The two ends of a GRE tunnel must have the same key or both have no key.

8. (Optional.) Set the DF bit for encapsulated packets.

   tunnel dfbit enable

   By default, the DF bit is not set, allowing encapsulated packets to be fragmented.

Configuring a GRE/IPv6 tunnel

Restrictions and guidelines

This task describes only GRE/IPv6 tunnel required tunnel interface commands (the **interface tunnel**, **source**, and **destination** commands). For more tunnel interface commands, see "Configuring tunneling."

Procedure

1. Enter system view.

   system-view

2. Create a GRE tunnel interface, and specify the tunnel mode as GRE/IPv6.

   interface tunnel *number* **mode gre ipv6**

   You must configure the same tunnel mode on both ends of a tunnel. Otherwise, packet delivery might fail.

3. Configure an IP address for the tunnel interface based on the passenger protocol.

   IPv4:

   For information about how to assign an IPv4 address to an interface, see "Configuring IP addressing."

   IPv6:

   For information about how to assign an IPv6 address to an interface, see "Configuring basic IPv6 settings."

   By default, no IP address is configured for a tunnel interface.

4. Configure a source IPv6 address or source interface for the tunnel interface.

   source { *ipv6-address* | *interface-type interface-number* }

By default, no source IPv6 address or interface is configured for a tunnel interface.

If you configure a source IPv6 address for a tunnel interface, the tunnel interface uses the source IPv6 address as the source IPv6 address of the encapsulated packets.

If you configure a source interface for a tunnel interface, the tunnel interface uses the IPv6 address of the source interface as the source IPv6 address of the encapsulated packets.

5. Configure a destination IPv6 address for the tunnel interface.

   destination *ipv6-address*

   By default, no destination IPv6 address is configured for a tunnel interface.

   The destination IPv6 address is the IPv6 address of the physical interface that the tunnel remote end uses to receive packets from the GRE tunnel.

   The tunnel local end uses this address as the destination IPv6 address of the encapsulated packets.

   The tunnel destination address and the IP address of the tunnel interface must be in different subnets.

6. (Optional.) Configure GRE security mechanisms.
   - (Optional.) Configure a GRE key for the tunnel interface.

     gre key *key*

     By default, no GRE key is configured for a GRE tunnel interface.

     The two ends of a GRE tunnel must have the same key or both have no key.

Display and maintenance commands for GRE

Execute **display** commands in any view and **reset** commands in user view.

Task	Command	Remarks
Display information about tunnel interfaces.	**display interface** [**tunnel** [*number*]] [**brief** [**description** | **down**]]	For more information about the commands, see *Layer 3—IP Services Command Reference*.
Display IPv6 information about tunnel interface.	**display ipv6 interface** [**tunnel** [*number*]] [**brief**]	For more information about this command, see *Layer 3—IP Services Command Reference*.
Clear tunnel interface statistics.	**reset counters interface** [**tunnel** [*number*]]	For more information about this command, see *Layer 3—IP Services Command Reference*.
Clear IPv6 statistics on tunnel interfaces.	**reset ipv6 statistics** [**slot** *slot-number*]	For more information about this command, see IPv6 basics in *Layer 3—IP Services Command Reference*.

GRE configuration examples

Example: Configuring an IPv4 over IPv4 GRE tunnel

Network configuration

As shown in Figure 6, Group 1 and Group 2 are two private IPv4 networks. The two networks both use private network addresses on the network segment of 10.0.0.0/8 and belong to the same VPN.

Establish a GRE tunnel between Switch A and Switch B to interconnect the two private IPv4 networks Group 1 and Group 2.

Figure 6 Network diagram

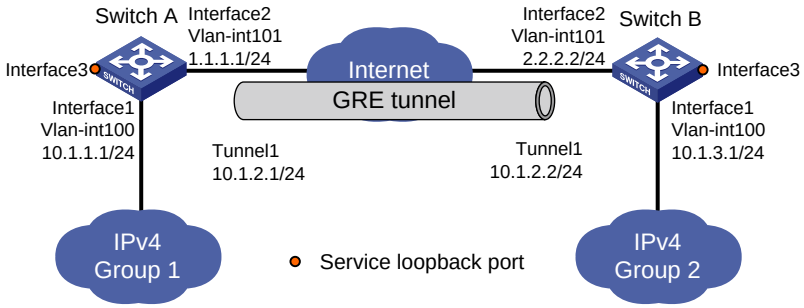

Table 1 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

Before performing the following configuration, configure an IP address for each interface, and make sure Switch A and Switch B can reach each other.

1. Configure Switch A:

Enter system view.

```
<SwitchA> system-view
```

Create a tunnel interface Tunnel 1, and specify the tunnel mode as GRE/IPv4.

```
[SwitchA] interface tunnel 1 mode gre
```

Configure an IP address for the tunnel interface.

```
[SwitchA-Tunnel1] ip address 10.1.2.1 255.255.255.0
```

Configure the source address of tunnel interface as the IP address of VLAN-interface 101 on Switch A.

```
[SwitchA-Tunnel1] source 1.1.1.1
```

Configure the destination address of the tunnel interface as the IP address of VLAN-interface 101 on Switch B.

```
[SwitchA-Tunnel1] destination 2.2.2.2
[SwitchA-Tunnel1] quit
```

Configure a static route from Switch A through the tunnel interface to Group 2.

```
[SwitchA] ip route-static 10.1.3.0 255.255.255.0 tunnel 1
```

2. Configure Switch B:

Enter system view.

```
<SwitchB> system-view
```

Create a tunnel interface Tunnel 1, and specify the tunnel mode as GRE/IPv4.

```
[SwitchB] interface tunnel 1 mode gre
```

Configure an IP address for the tunnel interface.

```
[SwitchB-Tunnel1] ip address 10.1.2.2 255.255.255.0
```

Configure the source address of tunnel interface as the IP address of VLAN-interface 101 on Switch B.

```
[SwitchB-Tunnel1] source 2.2.2.2
```

Configure the destination address of the tunnel interface as the IP address of VLAN-interface 101 on Switch A.

```
[SwitchB-Tunnel1] destination 1.1.1.1
[SwitchB-Tunnel1] quit
```

Configure a static route from Switch B through the tunnel interface to Group 1.

```
[SwitchB] ip route-static 10.1.1.0 255.255.255.0 Tunnel 1
```

Verifying the configuration

Display tunnel interface information on Switch A.

```
[SwitchA] display interface tunnel 1
Tunnel1
Current state: UP
Line protocol state: UP
Description: Tunnel1 Interface
Bandwidth: 64kbps
Maximum transmission unit: 1476
Internet address: 10.1.2.1/24 (primary)
Tunnel source 1.1.1.1, destination 2.2.2.2
Tunnel keepalive disabled
Tunnel TTL 255
Tunnel protocol/transport GRE/IP
    GRE key disabled
    Checksumming of GRE packets disabled
Last clearing of counters: Never
Last 300 seconds input rate: 0 bytes/sec, 0 bits/sec, 0 packets/sec
Last 300 seconds output rate: 0 bytes/sec, 0 bits/sec, 0 packets/sec
Input: 0 packets, 0 bytes, 0 drops
Output: 0 packets, 0 bytes, 0 drops
```

Display tunnel interface information on Switch B.

```
[SwitchB] display interface tunnel 1
Tunnel1
Current state: UP
Line protocol state: UP
Description: Tunnel1 Interface
Bandwidth: 64kbps
Maximum transmission unit: 1476
Internet address: 10.1.2.2/24 (primary)
Tunnel source 2.2.2.2, destination 1.1.1.1
Tunnel keepalive disabled
Tunnel TTL 255
Tunnel protocol/transport GRE/IP
    GRE key disabled
    Checksumming of GRE packets disabled
Last clearing of counters: Never
Last 300 seconds input rate: 0 bytes/sec, 0 bits/sec, 0 packets/sec
Last 300 seconds output rate: 0 bytes/sec, 0 bits/sec, 0 packets/sec
```

```
Input: 0 packets, 0 bytes, 0 drops
Output: 0 packets, 0 bytes, 0 drops
```

From Switch B, ping the IP address of VLAN-interface 100 on Switch A.

```
[SwitchB] ping -a 10.1.3.1 10.1.1.1
Ping 10.1.1.1 (10.1.1.1) from 10.1.3.1: 56 data bytes, press CTRL+C to break
56 bytes from 10.1.1.1: icmp_seq=0 ttl=255 time=11.000 ms
56 bytes from 10.1.1.1: icmp_seq=1 ttl=255 time=1.000 ms
56 bytes from 10.1.1.1: icmp_seq=2 ttl=255 time=0.000 ms
56 bytes from 10.1.1.1: icmp_seq=3 ttl=255 time=0.000 ms
56 bytes from 10.1.1.1: icmp_seq=4 ttl=255 time=0.000 ms

--- Ping statistics for 10.1.1.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 0.000/2.400/11.000/4.317 ms
```

The output shows that Switch B can successfully ping Switch A.

Example: Configuring an IPv4 over IPv6 GRE tunnel

Network configuration

As shown in Figure 7, two IPv4 subnets Group 1 and Group 2 are connected to an IPv6 network. Create a GRE/IPv6 tunnel between Switch A and Switch B, so the two IPv4 subnets can communicate with each other through the GRE tunnel over the IPv6 network.

Figure 7 Network diagram

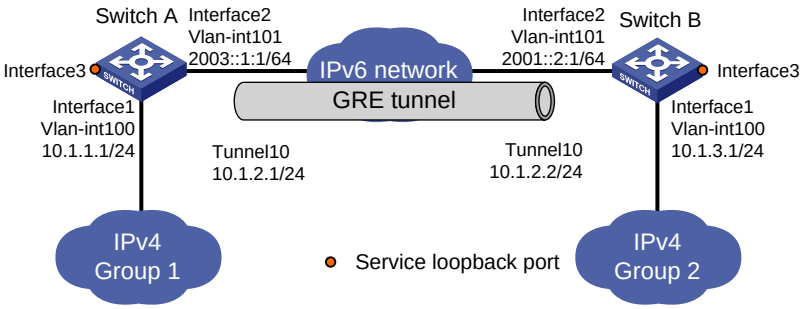

Table 2 Interface label and interface name mappings

Interface label	Interface name
Interface1	GigabitEthernet1/0/1
Interface2	GigabitEthernet1/0/2
Interface3	GigabitEthernet1/0/3

Procedure

Before performing the following configuration, configure an IP address for each interface, and make sure Switch A and Switch B can reach each other.

1. Configure Switch A:

   # Enter system view.

   ```
   <SwitchA> system-view
   ```

   # Create a tunnel interface Tunnel 10, and specify the tunnel mode as GRE/ IPv6.

```
[SwitchA] interface tunnel 10 mode gre ipv6
```

Configure an IP address for the tunnel interface.

```
[SwitchA-Tunnel10] ip address 10.1.2.1 255.255.255.0
```

Configure the source address of the tunnel interface as the IPv6 address of VLAN-interface 101 on Switch A.

```
[SwitchA-Tunnel10] source 2003::1:1
```

Configure the destination address of the tunnel interface as the IPv6 address of VLAN-interface 101 on Switch B.

```
[SwitchA-Tunnel10] destination 2001::2:1
[SwitchA-Tunnel10] quit
```

Configure a static route from Switch A through the tunnel interface to Group 2.

```
[SwitchA] ip route-static 10.1.3.0 255.255.255.0 tunnel 10
```

2. Configure Switch B:

Enter system view.

```
<SwitchB> system-view
```

Create a tunnel interface Tunnel 10, and specify the tunnel mode as GRE/IPv6.

```
[SwitchB] interface tunnel 10 mode gre ipv6
```

Configure an IP address for the tunnel interface.

```
[SwitchB-Tunnel10] ip address 10.1.2.2 255.255.255.0
```

Configure the source address of tunnel interface as the IPv6 address of VLAN-interface 101 on Switch B.

```
[SwitchB-Tunnel10] source 2001::2:1
```

Configure the destination address of the tunnel interface as the IPv6 address of VLAN-interface 101 on Switch A.

```
[SwitchB-Tunnel10] destination 2003::1:1
[SwitchB-Tunnel10] quit
```

Configure a static route from Switch B through the tunnel interface to Group 1.

```
[SwitchB] ip route-static 10.1.1.0 255.255.255.0 tunnel 10
```

Verifying the configuration

Display tunnel interface information on Switch A.

```
[SwitchA] display interface tunnel 10
Tunnel10
Current state: UP
Line protocol state: UP
Description: Tunnel10 Interface
Bandwidth: 64kbps
Maximum transmission unit: 1456
Internet address: 10.1.2.1/24 (primary)
Tunnel source 2003::1:1, destination 2001::2:1
Tunnel TTL 255
Tunnel protocol/transport GRE/IPv6
    GRE key disabled
    Checksumming of GRE packets disabled
Last clearing of counters: Never
Last 300 seconds input rate: 0 bytes/sec, 0 bits/sec, 0 packets/sec
Last 300 seconds output rate: 0 bytes/sec, 0 bits/sec, 0 packets/sec
Input: 0 packets, 0 bytes, 0 drops
```

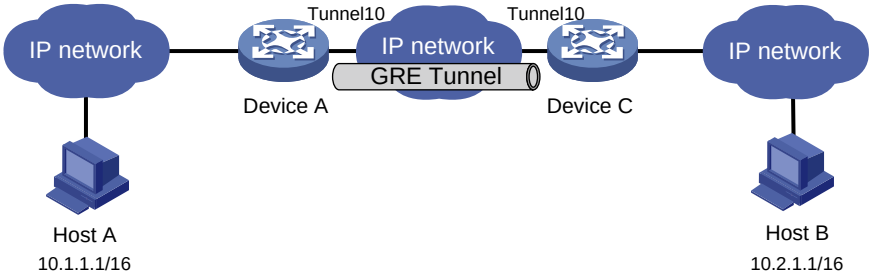
```
Output: 0 packets, 0 bytes, 0 drops
```

Display tunnel interface information on Switch B.

```
[SwitchB] display interface tunnel 10
Tunnel10
Current state: UP
Line protocol state: UP
Description: Tunnel10 Interface
Bandwidth: 64kbps
Maximum transmission unit: 1456
Internet address: 10.1.2.2/24 (primary)
Tunnel source 2001::2:1, destination 2003::1:1
Tunnel TTL 255
Tunnel protocol/transport GRE/IPv6
    GRE key disabled
    Checksumming of GRE packets disabled
Last clearing of counters: Never
Last 300 seconds input rate: 0 bytes/sec, 0 bits/sec, 0 packets/sec
Last 300 seconds output rate: 0 bytes/sec, 0 bits/sec, 0 packets/sec
Input: 0 packets, 0 bytes, 0 drops
Output: 0 packets, 0 bytes, 0 drops
```

From Switch B, ping the IP address of VLAN-interface 100 on Switch A.

```
[SwitchB] ping -a 10.1.3.1 10.1.1.1
Ping 10.1.1.1 (10.1.1.1) from 10.1.3.1: 56 data bytes, press CTRL+C to break
56 bytes from 10.1.1.1: icmp_seq=0 ttl=255 time=2.000 ms
56 bytes from 10.1.1.1: icmp_seq=1 ttl=255 time=1.000 ms
56 bytes from 10.1.1.1: icmp_seq=2 ttl=255 time=1.000 ms
56 bytes from 10.1.1.1: icmp_seq=3 ttl=255 time=0.000 ms
56 bytes from 10.1.1.1: icmp_seq=4 ttl=255 time=1.000 ms



--- Ping statistics for 10.1.1.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 0.000/1.000/2.000/0.632 ms
```

The output shows that Switch B can successfully ping Switch A.

Troubleshooting GRE

The key to configuring GRE is to keep the configuration consistent. Most faults can be located by using the **debugging gre** or **debugging tunnel** command. This section analyzes one type of fault for illustration, with the scenario shown in Figure 8.

Figure 8 Network diagram

Hosts at both ends of a GRE tunnel cannot ping each other

Symptom

The interfaces at both ends of the tunnel are configured correctly and can ping each other, but Host A and Host B cannot ping each other.

Solution

To resolve the issue:

1. Execute the **`display ip routing-table`** command on Device A and Device C to view whether Device A has a route over tunnel 0 to 10.2.0.0/16 and whether Device C has a route over tunnel 0 to 10.1.0.0/16.
2. If such a route does not exist, execute the **`ip route-static`** command in system view to add the route. Take Device A as an example:

   ```
   [DeviceA] ip route-static 10.2.0.0 255.255.0.0 tunnel 0
   ```
3. If the issue persists, contact Technical Support.

Configuring HTTP redirect 1

About HTTP redirect 1
Restrictions: Hardware compatibility with HTTP redirect 1
HTTP redirect tasks at a glance 1
Specifying the HTTPS redirect listening port number 1
Associating an SSL server policy with the HTTPS redirect service 2
Enabling the endpoint denylist feature for HTTP redirect 2
Display and maintenance commands for HTTP redirect 3

Configuring HTTP redirect

About HTTP redirect

HTTP redirect is a method to redirect users' HTTP or HTTPS requests to a specific URL.

It is used in the following features:

- Redirect URL assignment in 802.1X authentication, MAC authentication, and port security.
- EAD assistant URL redirection in 802.1X authentication.
- URL redirection services in portal.

Restrictions: Hardware compatibility with HTTP redirect

The S5200-EI-G switch series does not support HTTP redirect.

HTTP redirect tasks at a glance

No configuration is required to redirect HTTP requests.

To redirect HTTPS requests, perform the following tasks:

1. Specifying the HTTPS redirect listening port number
2. (Optional.) Associating an SSL server policy with the HTTPS redirect service
3. (Optional.) Enabling the endpoint denylist feature for HTTP redirect

Specifying the HTTPS redirect listening port number

About this task

The device can redirect HTTPS requests only after you specify the TCP port number on which the HTTPS redirect service listens for HTTPS requests.

Restrictions and guidelines

To avoid service unavailability caused by port conflict, do not specify a TCP port number used by a well-known protocol or used by any other TCP-based service. To display TCP port numbers that have been used by services, use the **display tcp** command. For more information about this command, see IP performance optimization commands in *Layer 3—IP Services Command Reference*.

If you perform this task multiple times, the most recent configuration takes effect.

Procedure

1. Enter system view.
   system-view
2. Specify the HTTPS redirect listening port number.
   http-redirect https-port *port-number*

By default, the HTTPS redirect listening port number is 6654.

Associating an SSL server policy with the HTTPS redirect service

About this task

An SSL server policy is a set of SSL parameters used by the device when the device acts as the SSL server. You can configure parameters such as supported cipher suites and whether to perform digital certificate-based authentication on SSL clients for the SSL server policy.

You can use one of the following local certificates for HTTPS redirect service according to the security requirements and the configuration complexity:

- **Self-signed certificate**—Using this type of certificate is simple in configuration but has low security. You do not need to associate an SSL server policy with the HTTPS redirect service and the default SSL parameters are used. However, a self-signed certificate is not trusted by the browser. When the device redirects HTTPS requests to the specified URL, a certificate security warning prompt might appear on the browser. If you accept the security risks stated in the prompt, you can ignore the prompt to browse the page.
- **CA-signed certificate**—Using this type of certificate is complex in configuration but has high security. You must obtain a CA certificate, request a local certificate from the CA, create an SSL server policy, and associate the SSL server policy with the HTTPS redirect service.

For more information about digital certificates, see PKI in *Security Configuration Guide*. For more information about the SSL server policy configuration, see SSL in *Security Configuration Guide*.

Restrictions and guidelines

HTTPS redirect is unavailable if the associated SSL server policy does not exist. You can first associate a nonexistent SSL server policy with the HTTPS redirect service and then configure the SSL server policy.

If you change the SSL server policy associated with the HTTPS redirect service, the new policy takes effect immediately.

If you perform this task multiple times, the most recent configuration takes effect.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Associate an SSL server policy with the HTTPS redirect service.

   ```
   http-redirect ssl-server-policy policy-name
   ```

   By default, no SSL server policy is associated with the HTTPS redirect service. The HTTPS redirect service uses the self-assigned certificate and the default SSL parameters.

Enabling the endpoint denylist feature for HTTP redirect

About this task

In portal authentication scenarios, the device redirects HTTP/HTTPS requests of users to the portal authentication page. When users frequently initiate HTTP/HTTPS requests and trigger redirection to the authentication page, the device processes many HTTP/HTTPS packets. This causes high CPU usage, which affects normal services. To avoid this issue, you can enable the endpoint denylist feature for HTTP redirect.

This feature enables the device to use the configured denylist parameters to uniquely identify endpoint entries by IP or MAC address and collect statistics on the received users' HTTP redirect packets. When the device detects that the number of HTTP redirect packets sent by a user reaches the threshold for adding an endpoint denylsit entry during the statistics period, the device will add the user's IP or MAC address to the endpoint denylist entry.

After a user's IP or MAC address is added to an endpoint denylist entry, the device stops redirecting HTTP packets from that user until the entry expires or the administrator removes the entry.

Restrictions and guidelines

After you enable this feature, if you edit the endpoint denylist parameters again, the device clears the existing endpoint denylist entries and restarts collecting statistics on users' HTTP redirect packets.

Procedures

1. Enter system view.

   system-view

2. Enable the endpoint denylist feature for HTTP redirect.

   http-redirect endpoint-denylist enable [**packet** *packet-count*] [**period** *period*] [**aging-time** *aging-time*] [**ipbase** | **macbase**]

   By default, the endpoint denylist feature is disabled for HTTP redirect.

Display and maintenance commands for HTTP redirect

Execute **display** commands in any view and execute **reset** commands in user view.

Task	Command
Display endpoint denylist entries for HTTP redirect.	**display http-redirect endpoint-denylist** [**interface** *interface-type interface-number*] [**ip** *ipv4-address* | **ipv6** *ipv6-address* | **mac** *mac-address*] [**slot** *slot-number*]
Delete endpoint denylist entries for HTTP redirect.	**reset http-redirect endpoint-denylist** [**ip** *ipv4-address* | **ipv6** *ipv6-address* | **mac** *mac-address*]

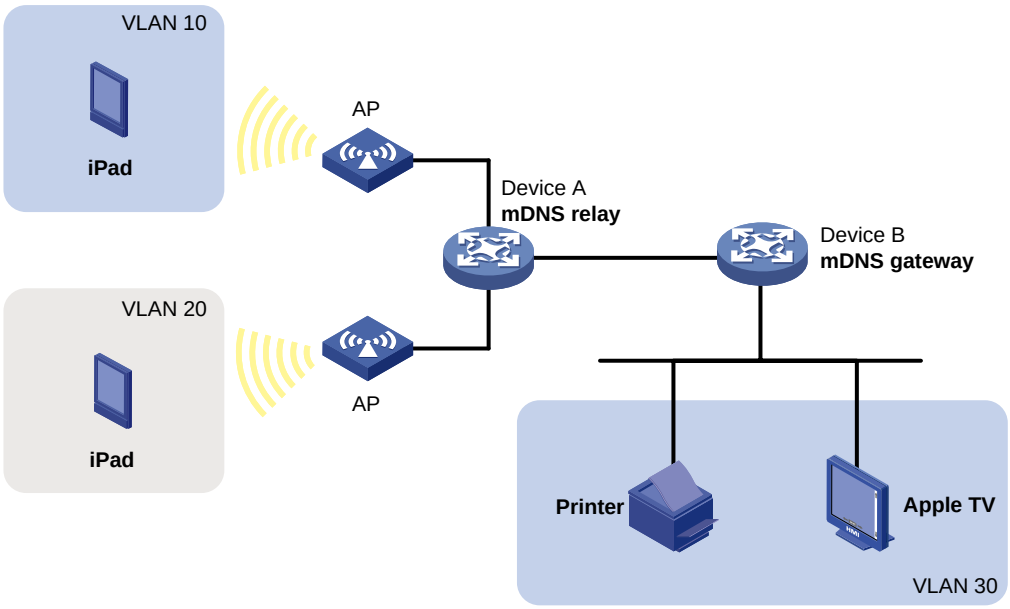
Configuring mDNS gateway



About mDNS gateway

A Multicast Domain Name System (mDNS) gateway can be deployed in a large-scale network to enable inter-VLAN mDNS service discovery. It records a list of available services in the network, responds to service queries from mDNS clients, and performs active mDNS service discovery as well as access control.

mDNS network model

As shown in Figure 1, an mDNS network contains mDNS endpoint devices, mDNS service providers, the mDNS gateway, and mDNS relays.

Figure 1 mDNS networking model

mDNS endpoint device

An mDNS endpoint device obtains services from mDNS service providers. Examples are iPhones and iPads.

mDNS service provider

An mDNS service provider provides services for mDNS endpoint devices. Examples are mDNS-capable printers and Apple TVs.

mDNS gateway

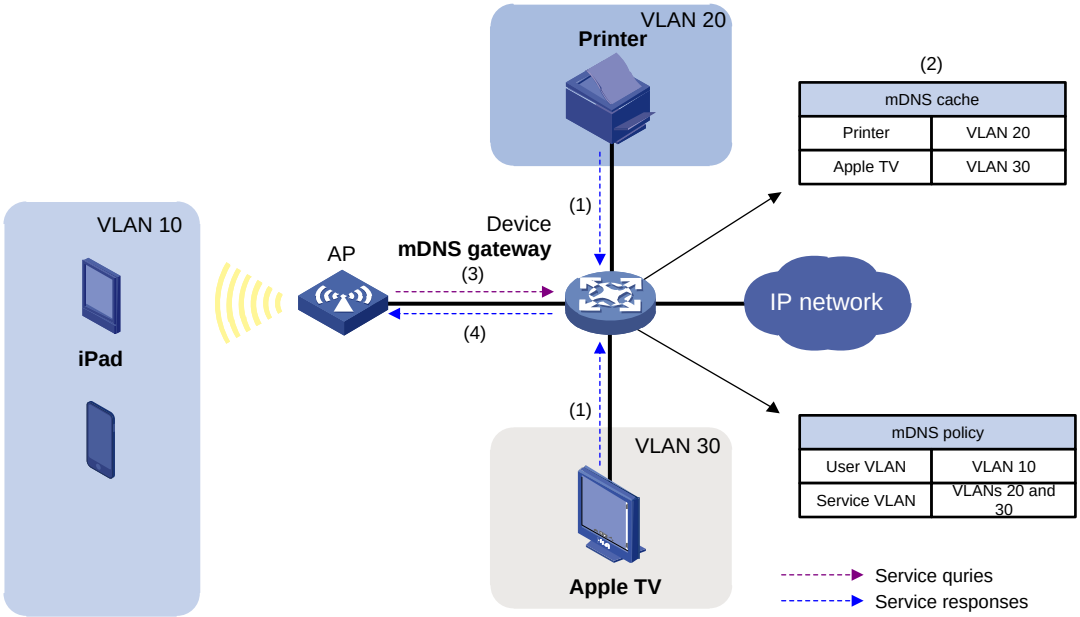
The mDNS gateway records available services advertised by mDNS service providers and responds to queries from mDNS endpoint devices. With mDNS gateway enabled, Device B in Figure 1 can act as the mDNS gateway to help mDNS endpoint devices discover mDNS service providers in a different VLAN from the endpoint devices.

mDNS relay

An mDNS relay ensures successful mDNS communication when mDNS endpoint devices and mDNS service providers are in different subnets.

mDNS gateway functionalities

The mDNS gateway provides the following functionalities based on mDNS policies:



- **Reply mDNS queries.**
- **Discover mDNS services.**

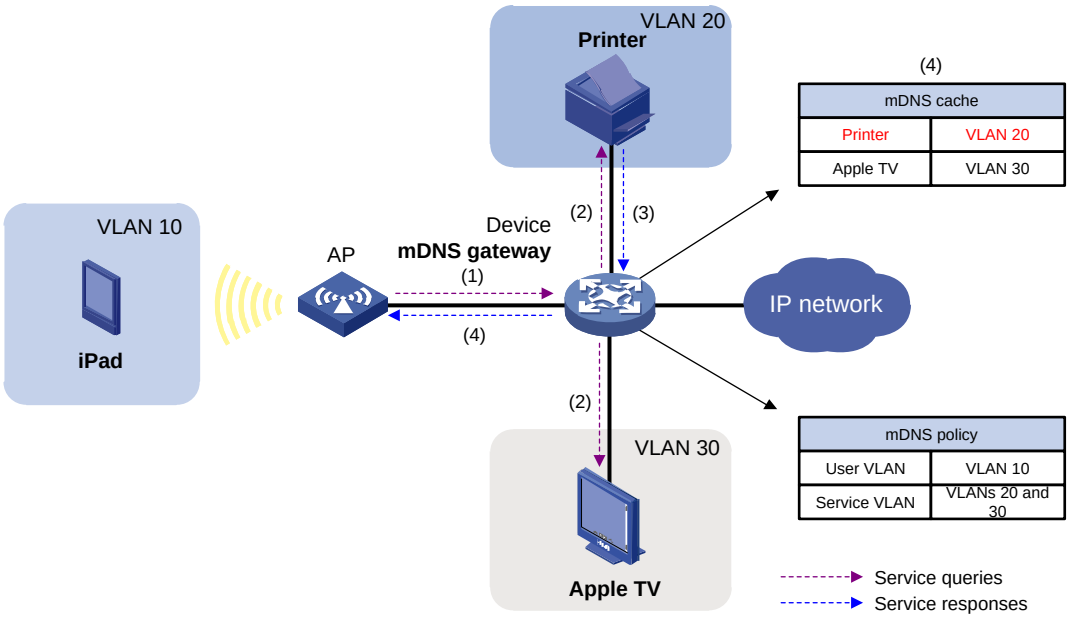
An mDNS gateway policy defines user VLAN and service VLAN mappings to ensure that endpoint devices in specific VLANs can access only service providers in specific service VLANs.

Replying mDNS queries

Upon receiving mDNS queries from mDNS endpoint devices, the gateway checks its service list and sends responses that carry service information to the endpoint devices if matches are found.

Figure 2 Replying mDNS queries

As shown in Figure 2, the mDNS gateway replies mDNS queries in a VLAN-separated network as follows:



1. mDNS service providers broadcast mDNS service responses to notify services.
2. Upon receiving the responses, the mDNS gateway creates an mDNS service entry that records information such as service instance name and service type.
3. The mDNS endpoint device sends an mDNS query to the mDNS gateway.
4. The mDNS gateway searches its service list for the requested service.
   - If a match is found, the mDNS gateway sends a response to the endpoint device directly.
   - If no match is found, the mDNS gateway starts service discovery in the corresponding service VLANs of the user VLAN in which the endpoint device resides.
5. The mDNS endpoint device obtains information about the service provider from the response.

Discovering mDNS services

The mDNS gateway discovers mDNS services by listening to mDNS service responses sent by mDNS service providers and then records information about the services as entries. Service providers can broadcast service responses actively or reply service responses upon requests.

After receiving a query to a service that is not in the service list, the mDNS gateway forwards the query in the corresponding service VLANs of the user VLAN. Upon receiving the query, service providers that provide the service will send responses.

Figure 3 Discovering mDNS services

As shown in Figure 3, the mDNS gateway discovers services as follows:

1. The mDNS gateway receives a query for the printing service from the mDNS endpoint device (iPad).
2. The mDNS gateway searches its service list for the printing service and no match is found.
3. The mDNS gateway forwards the mDNS query to the corresponding service VLANs.
4. Upon receiving the query, the printer sends an mDNS response.
5. Upon receiving the response, the mDNS gateway records information about the service and sends a response to the mDNS endpoint device.

Protocols and standards

RFC 6762, *Multicast DNS*

mDNS gateway tasks at a glance

To configure the mDNS gateway, perform the following tasks:

1. Enabling mDNS gateway
2. (Optional.) Configuring an mDNS gateway policy
3. (Optional.) Specifying the permitted service types for entry learning
4. (Optional.) Specifying trusted mDNS devices
5. (Optional.) Specifying the source address for mDNS packets
6. (Optional.) Enabling mDNS gateway periodic probing
7. (Optional.) Enabling mDNS gateway proxy forwarding
8. (Optional.) Enabling the mDNS gateway to forward mDNS queries on the receiving port in a VLAN
9. (Optional.) Configuring the mDNS gateway to support QinQ

Enabling mDNS gateway

1. Enter system view.
   system-view
2. Enable mDNS gateway.
   mdns gateway enable
   By default, mDNS gateway is disabled.

Configuring an mDNS gateway policy

Restrictions and guidelines

With mDNS gateway policies configured, the mDNS gateway processes only the queries of mDNS endpoint devices in user VLANs configured in the policies.

Procedure

1. Enter system view.
   system-view
2. Create an mDNS gateway policy and enter its view.
   mdns gateway policy *policy-name*
3. Specify service VLANs.
   service vlan *vlan-id-list*
   By default, no service VLAN is specified.
4. Specify user VLANs.
   user vlan *vlan-id-list*
   By default, no user VLAN is specified.

Specifying the permitted service types for entry learning

About this task

By default, the mDNS gateway can learn all mDNS services of a predefined type, which can be memory-consuming if a large number of service providers exist. You can perform this task to specify the permitted service types that can be learned by the mDNS gateway for the gateway to learn only required services.

Procedure

1. Enter system view.
   system-view
2. Specify a permitted service type for entry learning.
   mdns gateway permit service-type { *predefined-service-type* | **user-defined** *user-defined-service-type* } [**max-entry-count** *count*]
   By default, the mDNS gateway can learn all mDNS services of a pre-defined type.

Specifying trusted mDNS devices

About this task

To prevent security issues and resource waste caused by attacks performed by rogue mDNS devices, you can specify trustworthy mDNS relays as trusted mDNS devices. With trusted devices specified, the mDNS gateway processes only unicast queries from the trusted mDNS devices.

Procedure

1. Enter system view.

   system-view

2. Specify a trusted mDNS device.

   mdns gateway trust device-ip *ip-address* [**vpn-instance** *vpn-instance-name*]

   By default, no trusted device is specified.

Specifying the source address for mDNS packets

About specifying the source address for mDNS packets

For responses destined for endpoint devices and mDNS queries and probe queries sent within a VLAN, the default source IP address is the primary IP address of the VLAN interface. If no IP address is configured for the VLAN interface, the mDNS gateway cannot send out the queries.

If the mDNS gateway is connected to a large number of VLANs, configuring an IP address to each VLAN interface wastes IP address resources. You can use this command to specify a specific IP address for the mDNS gateway to use.

Restrictions and guidelines

When you configure the same source address for mDNS packets configured in different views, the configuration in the following views is in descending order of priority: VLAN view > system view.

Specifying the source address for mDNS packets in a VLAN

1. Enter system view.

   system-view

2. Enable mDNS gateway.

   mdns gateway enable

   By default, mDNS gateway is disabled.

3. Enter VLAN view.

   vlan *vlan-id*

4. Specify the source address for mDNS packets.

   mdns gateway source ip { **interface** *interface-type interface-number* | *ip-address* }

   By default, the source IP address is the primary IP address of the VLAN interface.

   You can specify only one source address for a VLAN. If you execute this command multiple times, the most recent configuration takes effect.

Specifying the source address for mDNS packets in system view

1. Enter system view.

   system-view

2. Enable mDNS gateway.

   mdns gateway enable

   By default, mDNS gateway is disabled.

3. Specify the source address for mDNS packets.

   mdns gateway source ip { **interface** *interface-type interface-number* | *ip-address* }

   By default, the mDNS gateway uses the primary IP address of the VLAN interface for packet output as the source IP address of mDNS packets.

   In QinQ scenarios, as a best practice to simplify configuration and prevent the mDNS gateway from sending multiple mDNS probe queries, configure this command in system view.

Enabling mDNS gateway periodic probing

About mDNS gateway periodic probing

mDNS service providers broadcast their services at network association. For the mDNS gateway to discover services offered by service providers that accessed the network earlier than the gateway, enable mDNS gateway periodic probing.

This feature enables the mDNS gateway to send mDNS probe queries at intervals. Each mDNS service provider sends a response to the gateway after receiving the query. The mDNS gateway can learn the latest service information of all mDNS service providers in the network in a timely manner.

Restrictions and guidelines

For an mDNS device, you can enable periodic probing on its directly connected mDNS gateway or mDNS relay.

If you execute the **mdns gateway probe interval** command in both mDNS gateway policy view or VLAN view, the mDNS gateway will send two probe queries. As a best practice, execute the command in either of the views.

As a best practice to control periodic probing in different VLANs, configure multiple mDNS gateway policies and execute the **mdns gateway probe interval** command in the view of each mDNS gateway policy.

In a QinQ scenario, to avoid any impact on the device service networking capabilities due to too many mDNS multicast packets sent within a short period, configure the inner VLANs as accurately as possible.

Enabling mDNS gateway periodic probing in a VLAN

1. Enter system view.

   system-view

2. Enable mDNS gateway.

mdns gateway enable

By default, mDNS gateway is disabled.

3. Enter VLAN view.

vlan *vlan-id*

4. Enable mDNS gateway periodic probing.

mdns gateway probe interval *interval*

By default, mDNS gateway periodic probing is disabled.

If you execute this command multiple times, the most recent configuration takes effect.

Enabling mDNS gateway periodic probing in a mDNS gateway policy

1. Enter system view.

system-view

2. Enable mDNS gateway.

mdns gateway enable

By default, mDNS gateway is disabled.

3. Enter mDNS gateway policy view.

mdns gateway policy *policy-name*

4. Enable mDNS gateway periodic probing.

mdns gateway probe interval *interval*

By default, mDNS gateway periodic probing is disabled.

If you execute this command multiple times, the most recent configuration takes effect.

Enabling mDNS gateway proxy forwarding

About this task

By default, mDNS gateway proxy forwarding is enabled. The mDNS gateway can send probe queries to discover mDNS service providers on the network. If you enable both mDNS gateway proxy forwarding and periodic probing, the mDNS gateway will send two probe queries. In this case, disable mDNS gateway proxy forwarding.

Restrictions and guidelines

As a best practice to control proxy forwarding in different VLANs, configure multiple mDNS gateway policies and execute the **mdns gateway probe interval** command in the view of each mDNS gateway policy.

In QinQ scenarios or scenarios with a lot of services VLANs, enable periodic probing on the mDNS gateway and disable mDNS gateway proxy forwarding.

Procedure

1. Enter system view.

system-view

2. Enable mDNS gateway policy view.

mdns gateway policy *policy-name*

3. Enable mDNS gateway proxy forwarding.

mdns gateway proxy-forward enable

By default, mDNS gateway proxy forwarding **is enabled**.

Enabling the mDNS gateway to forward mDNS queries on the receiving port in a VLAN

About this task

Use this feature in scenarios where the mDNS gateway must receive and forward mDNS queries on the same port.

Procedure

1. Enter system view.

   system-view

2. Enable the mDNS gateway to forward mDNS queries on the receiving port in a VLAN.

   mdns gateway permit source-port-forward enable

   By default, the mDNS gateway does not forward mDNS queries on the receiving port in a VLAN.

Configuring the mDNS gateway to support QinQ

About this task

On a QinQ network, packets sent from both the client and server to the mDNS gateway carry two layers of VLAN tags. The inner VLAN tag (also called CVLAN tag) identifies the VLAN to which the frame belongs when it is transmitted in the customer network. The outer VLAN tag (also called SVLAN tag) identifies the VLAN to which the QinQ frame belongs when it is transmitted in the service provider network. The mDNS gateway identifies the two layers of VLAN tags and implements service discovery as follows:

1. You specify service VLANs and users VLANs for an mDNS gateway policy and specify inner VLANs and outer VLANs.
2. Upon receiving an mDNS query, the mDNS gateway identifies whether the outer and inner VLAN tags of the packet matches the mDNS gateway policy.
   - If a match is found, the mDNS gateway forwards the query to the corresponding service VLANs in the mDNS gateway policy.
   - If no match is found, the mDNS gateway drops the query.

Restrictions and guidelines

In a QinQ scenario, to avoid any impact on the device service networking capabilities due to too many mDNS multicast packets sent within a short period, configure the inner VLANs as accurately as possible.

Procedure

1. Enter system view.

   system-view

2. Enable mDNS gateway.

   mdns gateway enable

   By default, mDNS gateway is disabled.

3. (Optional.) Specify the source address for mDNS packets.

   mdns gateway source ip { **interface** *interface-type interface-number* | *ip-address* }

By default, the mDNS gateway uses the primary IP address of the VLAN interface for packet output as the source IP address of mDNS packets.

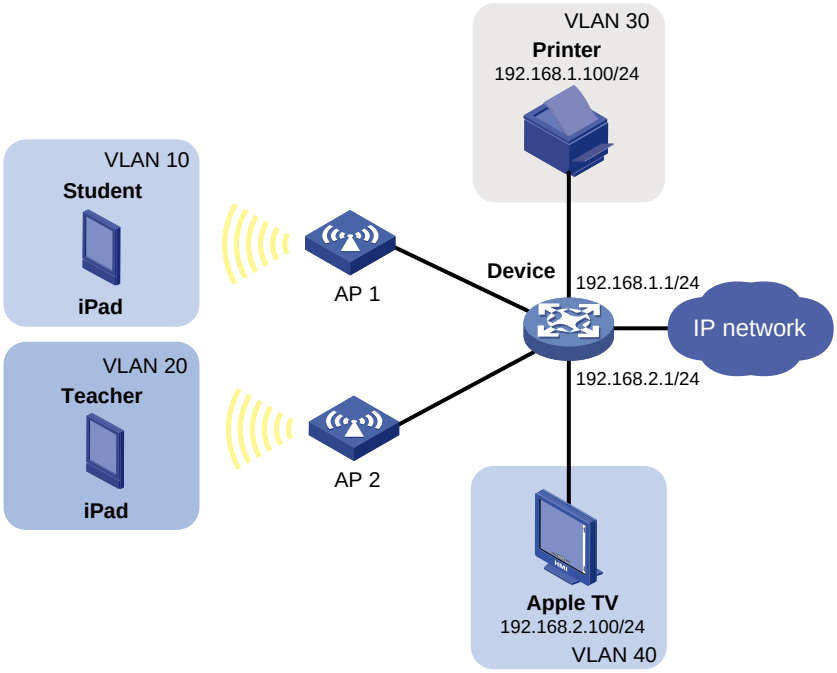
4. Enter mDNS gateway policy view.
   mdns gateway policy *policy-name*
5. Specify service VLANs for the mDNS gateway policy.
   service vlan *vlan-id-list* **second-vlan** *vlan-id-list*
   By default, no service VLAN is specified for an mDNS gateway policy.
6. Specify user VLANs for the mDNS gateway policy.
   user vlan *vlan-id-list* **second-vlan** *vlan-id-list*
   By default, no user VLAN is specified for an mDNS gateway policy.

Display and maintenance commands for mDNS relay

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display mDNS gateway configuration.	**display mdns gateway**
Display mDNS gateway policy information.	**display mdns gateway policy** [*policy-name*]
Display information about services learned by the mDNS gateway.	**display mdns gateway service** { **all** | *predefined-service-type* | **user-defined** *user-defined-service-type* | **vlan** *vlan-id* [**second-vlan** *vlan-id*] } [**verbose**]
Display mDNS gateway packet statistics.	**display mdns gateway statistics**
Clear information about services learned by the mDNS gateway.	**reset mdns gateway service** { **all** | *predefined-service-type* | **user-defined** *user-defined-service-type* | **vlan** *vlan-id* }
Clear mDNS gateway packet statistics.	**reset mdns gateway statistics**

mDNS gateway configuration examples



Example: Configuring mDNS gateway

Network configuration

As shown in Figure 4, a campus network uses mDNS to provide services to both teachers and students. Configure mDNS gateway to allow students to access only the printer and allow teachers to access both the Apple TV and the printer.

Enable mDNS gateway periodic probing for the gateway to update mDNS services in time.

Figure 4 Network diagram

Procedure

1. Enable mDNS gateway.

```
<Device> system-view
[Device] mdns gateway enable
```

2. Create an mDNS gateway policy named **student**.

```
[Device] mdns gateway policy student
```

3. Specify VLAN 10 as a user VLAN and VLAN 30 as a service VLAN.

```
[Device-mdns-gateway-policy-student] user vlan 10
[Device-mdns-gateway-policy-student] service vlan 30
[Device-mdns-gateway-policy-student] quit
```

4. Create an mDNS gateway policy named **teacher**.

```
[Device] mdns gateway policy teacher
```

5. Specify VLAN 20 as a user VLAN and VLANs 30 and 40 as service VLANs.

```
[Device-mdns-gateway-policy-teacher] user vlan 20
[Device-mdns-gateway-policy-teacher] service vlan 30 40
[Device-mdns-gateway-policy-teacher] quit
```

6. Permit service types **airplay**, **raop**, and **printer** in entry learning.

```
[Device] mdns gateway permit service-type airplay
[Device] mdns gateway permit service-type raop
[Device] mdns gateway permit service-type printer
```

7. Specify the source address for mDNS packets in VLAN 10.

```
[Device] vlan 10
[Device-vlan10] mdns gateway source ip 192.168.1.1
[Device-vlan10] quit
```

8. Specify the source address for mDNS packets in VLAN 20.

```
[Device] vlan 20
[Device-vlan20] mdns gateway source ip 192.168.2.1
```

```
[Device-vlan20] quit
```

9. Enable mDNS gateway periodic probing in VLAN 30 and set the probing interval to 600 seconds.

```
[Device] vlan 30
[Device-vlan30] mdns gateway probe interval 600
[Device-vlan30] quit
```

10. Enable mDNS gateway periodic probing in VLAN 40 and set the probing interval to 600 seconds.

```
[Device] vlan 40
[Device-vlan40] mdns gateway probe interval 600
[Device-vlan40] quit
```

Verifying the configuration

Display mDNS gateway configuration.

```
[Device] display mdns gateway
mDNS gateway status: Enabled
mDNS gateway source IP:
  VLAN 10: 192.168.1.1
  VLAN 20: 192.168.2.1
mDNS gateway probe is enabled in the following VLANs: 30, 40
mDNS gateway probe is enabled in the following VSIs:
mDNS gateway probe is enabled in the following Policys:
```

Display information about services learned by the mDNS gateway.

```
[Device] display mdns gateway service all
Instance name        Service type VLAN/VSI name TTL      Pro IP
Apple TV             airplay      40           120       TCP
192.168.2.100
Apple TV             raop         40           120       TCP 192.168.2.100
Printer              printer      30           120       TCP
192.168.1.100

Total mDNS gateway services: 3
```

Verify that students can access only the printer and teachers can access both the Apple TV and the printer.

Troubleshooting mDNS gateway

Failure to receive packets from an mDNS relay

Symptom

The mDNS gateway cannot receive mDNS packets from an mDNS relay.

Analysis

Possible reasons are:

- The mDNS gateway feature is not enabled.
- Trusted mDNS devices are configured, but the mDNS relay is not a trusted device.

Solution

To resolve this issue:

1. Execute the **display mdns gateway** command to view current configuration. If mDNS gateway is not enabled, execute the **mdns gateway enable** command to enable this feature.
2. Execute the **display current-configuration** command to view trusted mDNS devices. If the mDNS relay is not in the list, execute the **mdns gateway trust device-ip** command to specify the mDNS relay as a trusted device.

Configuring mDNS relay

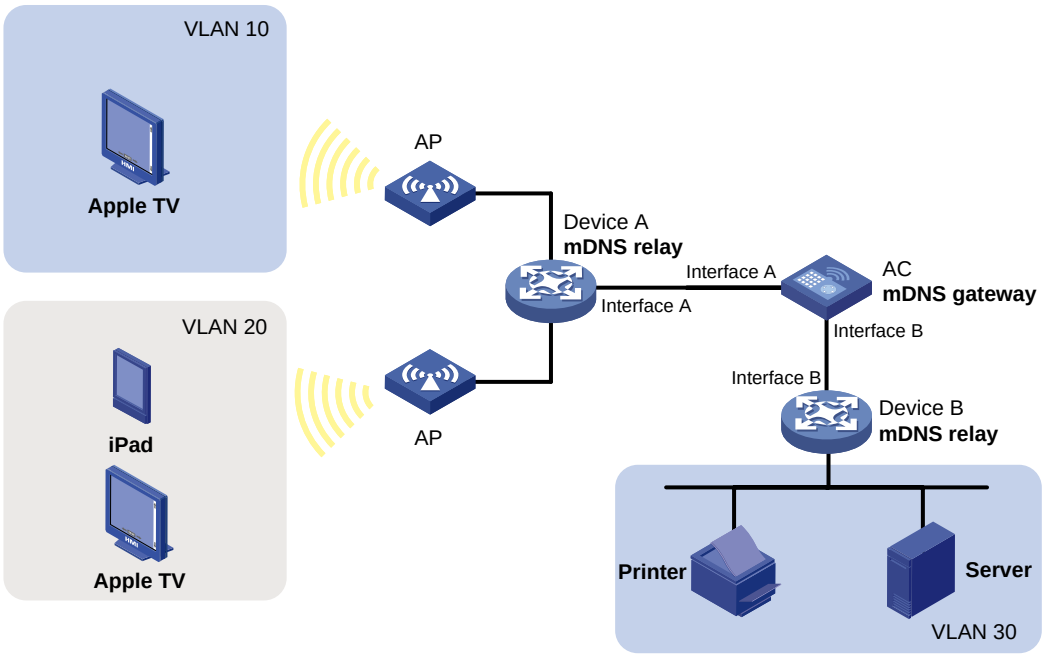
About mDNS relay

The multicast Domain Name Service (mDNS) protocol is a zero configuration networking protocol for mDNS service discovery. In a LAN network, endpoint devices can automatically discover available services advertised by mDNS service providers without knowing these service providers.

The mDNS relay supports mDNS packet transmission across subnets and expands the use of the mDNS protocol to large-scale networks. Without the mDNS relay, mDNS packets can only be transmitted within a subnet.

mDNS network device types

An mDNS network contains the following device types:



- **mDNS endpoint device**—Obtains services from mDNS service providers. Examples are iPhones and iPads.
- **mDNS service provider**—Provides services for mDNS endpoint devices. Examples are printers and video servers.
- **mDNS gateway**—Records available services advertised by mDNS service providers and responds to queries from mDNS endpoint devices. For more information about the mDNS gateway, see "Configuring mDNS gateway."
- **mDNS relay**—Ensures successful mDNS communication when mDNS endpoint devices and mDNS service providers are in different subnets. The mDNS relay supports periodically probing mDNS service providers in the network.

mDNS network model

As shown in Figure 1, mDNS endpoint devices (Apple TVs and iPad) and mDNS service providers (printer and server) are in different VLANs. APs and the AC require inter-subnet Layer 3 communication. The AC acts as the mDNS gateway and cannot receive multicast mDNS packets sent from the endpoint devices and service providers.

To resolve this problem, enable mDNS relay on Device A and Device B and specify the mDNS gateway address on them. After receiving an mDNS packet from an endpoint device, Device A changes the packet destination IP address to the mDNS gateway address and unicasts it to the gateway. After receiving an mDNS packet from an mDNS service provider, Device B changes the packet destination IP address to the mDNS gateway address and unicasts it to the gateway.

Figure 1 mDNS network model

mDNS relay functionalities

The mDNS relay provides the following functionalities:

- **Relaying mDNS service advertisements**—After receiving advertisements from an mDNS service provider, the relay changes the packet destination IP address to the mDNS gateway address and unicasts them to the gateway.
- **Relaying mDNS queries**—After receiving mDNS queries from endpoint devices, the relay changes the query destination IP address to the mDNS gateway address and unicasts them to the gateway.
- **Periodic probing**—The mDNS relay supports periodically sending mDNS queries to probe mDNS service providers in a subnet and forwarding the responses to the mDNS gateway for service update.

Relaying mDNS service advertisements

An mDNS service provider advertises its service to the mDNS gateway when it is attached to the network. The host name identifies the mDNS service provider and the service name identifies service type and other information provided by the service provider.

As shown in Figure 2, an mDNS service provider probes and advertises the host name and service name in the following workflow:

1. Host name probe.
   a. The mDNS service provider automatically generates a host name after it is attached to the network. To detect the uniqueness of the host name, the service provider sends an mDNS query with multicast destination address 224.0.0.251 and starts the probe timer.
   b. After receiving the query, the mDNS relay replaces the destination IP address with the mDNS gateway address and unicasts it to the mDNS gateway.
   c. The mDNS gateway examines whether the host name conflicts with host names of existing mDNS service entries. If a conflict exists, the mDNS gateway sends the mDNS relay an mDNS response to announce the conflict. The mDNS relay changes the destination IP

address of the response to multicast address 224.0.0.251 and forwards it to the mDNS service provider.

d. After receiving the conflict announcement, the mDNS service provider generates another host name and starts probing again.

2. Host name advertisement.

a. The mDNS service provider advertises its host name if it does not receive any host name conflict announcement within the probe period. The destination of the advertisement packet is 224.0.0.251.

b. After receiving the packet, the mDNS relay changes the packet destination IP address to the mDNS gateway address and unicasts it to the mDNS gateway.

c. The mDNS gateway records the host name and IP address in the received packet.

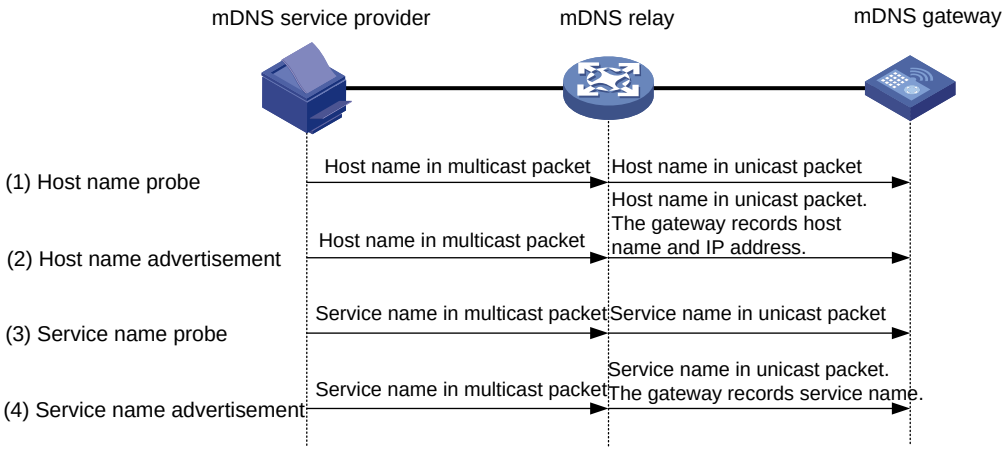
3. Service name probe.

a. The mDNS service provider sends an mDNS query with destination address 224.0.0.251 to detect the uniqueness of the service name and starts the probe timer.

b. After receiving the query, the mDNS relay replaces the destination IP address with the mDNS gateway address and unicasts it to the mDNS gateway.

c. The mDNS gateway examines whether the service name conflicts with service names of existing mDNS service entries. If a conflict exists, the mDNS gateway sends the mDNS relay an mDNS response to announce the conflict. The mDNS relay changes the destination IP address of the response to multicast address 224.0.0.251 and forwards it to the mDNS service provider.

d. After receiving the conflict announcement, the mDNS service provider generates another service name and starts probing again.



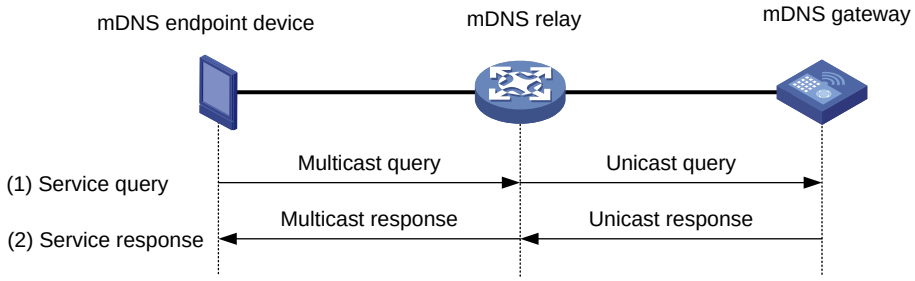
4. Service name advertisement.

a. The mDNS service provider advertises its service name if it does not receive any service name conflict announcement within the probe period. The destination of the advertisement packet is 224.0.0.251.

b. After receiving the packet, the mDNS relay changes the packet destination IP address to the mDNS gateway address and unicasts it to the mDNS gateway.

c. The mDNS gateway records the service name information in the received packet.

Figure 2 Relaying mDNS service advertisements



Relaying mDNS queries

As shown in Figure 3, an mDNS query originated from the mDNS endpoint device is relayed as follows:

1. Before accessing a service, the mDNS endpoint device first sends an mDNS query with multicast address 224.0.0.251 to detect whether this service is available.
2. Upon receiving the query, the mDNS relay changes the query destination IP address to the mDNS gateway address and unicasts the query to the gateway.
3. The mDNS gateway looks for a matching service after receiving the query. If the matching service exists, the mDNS gateway encapsulates the host name and IP address of the service provider into the response and unicasts it to the mDNS relay.
4. The mDNS relay changes the response destination IP address to 224.0.0.251 and multicasts the response.
5. After receiving the response, the mDNS endpoint device can access the service provider based on the IP address in the response. Other mDNS endpoints that receive the response will also record information about the service provider for future use.

Figure 3 Relaying mDNS queries

Periodic probing

When an mDNS service provider connects to the network, it unsolicitly sends an advertisement to the mDNS gateway. The mDNS gateway creates a service entry based on the advertisement information. When a new mDNS gateway joins the network where the mDNS service providers already exist, the mDNS service providers do not send advertisements. Therefore, the new mDNS gateway does not know existing mDNS services in the network.

The mDNS gateway creates and maintains service entries for mDNS services. If the mDNS gateway receives an update message for a service before the service entry ages out, the mDNS gateway resets the service entry timer. If the mDNS gateway does not receives any update message for a service before the service entry ages out, the mDNS gateway deletes the entry. In a large-sized network where mDNS service providers exists in many VLANs, the mDNS gateway cannot receive update messages timely and might delete service entries mistakenly.

To resolve these issues, enable periodic probing on the mDNS relay and set a probe interval. The mDNS relay sends mDNS queries at intervals to VLANs where mDNS relay is enabled. Each mDNS service provider that receives the query sends back an mDNS response. The mDNS relay then unicasts the response to the mDNS gateway, so that the mDNS gateway can quickly learn the latest services provided by all mDNS service providers.

Protocols and standards

RFC 6762, *Multicast DNS*

mDNS relay tasks at a glance

To configure the mDNS relay, perform the following tasks:

1. Specifying the mDNS gateway address

2. Enabling mDNS relay
3. (Optional.) Specifying the source IP address for mDNS packets
4. (Optional.) Enabling mDNS relay periodic probing

Specifying the mDNS gateway address

About this task

After receiving an mDNS query from an mDNS endpoint device, the mDNS relay replaces the multicast destination address with the specified mDNS gateway address and unicasts the query to the mDNS gateway. When receiving the response from the gateway, the mDNS relay multicasts it in the VLAN where the requesting mDNS endpoint resides. The requesting endpoint device can then receive the response and other mDNS endpoint devices can learn and update the service information.

Procedure

1. Enter system view.
   system-view
2. Specify the IP address of the mDNS gateway.
   mdns relay gateway ip *ip-address* [**vpn-instance** *vpn-instance-name*]
   By default, no mDNS gateway address is specified on the mDNS relay.

Enabling mDNS relay

Restrictions and guidelines for enabling mDNS relay

The mDNS relay feature takes effect only after you specify the mDNS gateway address on the mDNS relay.

Enabling mDNS relay for a VLAN

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable mDNS relay.
   mdns relay enable
   By default, mDNS relay is disabled.

Specifying the source IP address for mDNS packets

About specifying source IP address for mDNS packets

For responses destined for endpoint devices and probe queries sent within a VLAN, the default source IP address is the IP address of the VLAN interface. If no IP address is configured for the VLAN interface, the mDNS relay cannot send out the queries.

If the mDNS relay is connected to a large number of VLANs, configuring an IP address to each VLAN interface wastes IP address resources. You can use this command to specify a specific IP address for the mDNS relay to use.

Restrictions and guidelines for specifying the source IP address for mDNS packets

Make sure the specified source address is on the relay and has a reachable route to the mDNS gateway. If these requirements are not met, the mDNS relay cannot receive responses for the queries or forwarded packets.

As a best practice, specify the interface connecting to the mDNS gateway in the **mdns relay source ip** command.

Specifying the source IP address for mDNS packets in a VLAN

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Specify source IP address for mDNS packets.
   mdns relay source ip { *ip-address* | **interface** *interface-type interface-number* }
   By default, the mDNS relay encapsulates source IP addresses for packets as follows:
   - For responses destined for endpoint devices and VLAN-specific probe queries, the default source IP address is the IP address of the VLAN interface.
   - For multicast packets destined for the gateway, the default source IP address is the IP address of the packet output interface on the mDNS relay.

Enabling mDNS relay periodic probing

About mDNS relay periodic probing

This feature enables the mDNS relay to send mDNS probe queries within an mDNS relay-enabled VLAN at intervals. Each mDNS service provider sends a response to the mDNS relay after receiving the query. The mDNS relay then unicasts the responses to the mDNS gateway. The mDNS gateway can learn the latest service information of all mDNS service providers in the network in a timely manner.

Enabling mDNS relay periodic probing in a VLAN

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable mDNS relay periodic probing.
   mdns relay probe interval *interval*

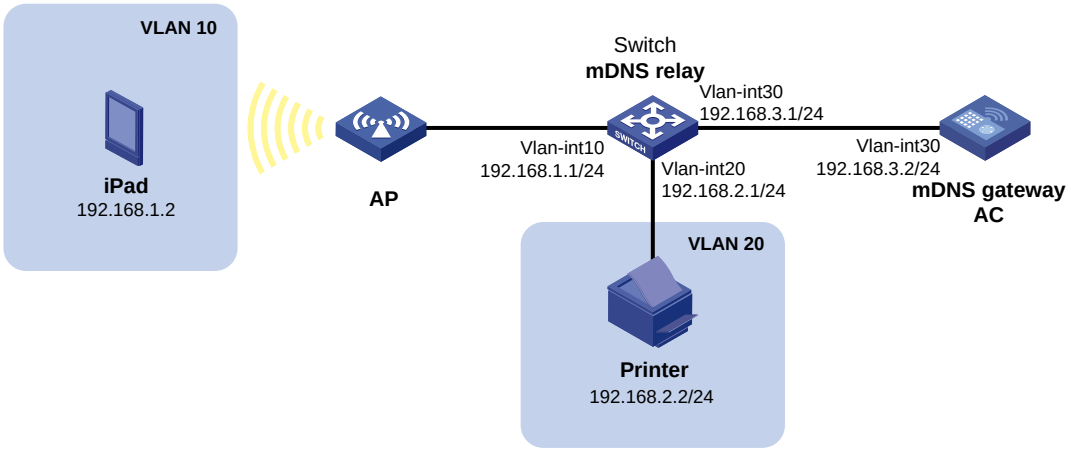
By default, mDNS relay periodic probing is disabled.

Display and maintenance commands for mDNS relay

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display mDNS relay configuration.	**display mdns relay**
Display packet statistics on the mDNS relay.	**display mdns relay statistics**
Clear packet statistics on the mDNS relay.	**reset mdns relay statistics**

mDNS relay configuration examples



Example: Configuring mDNS relay

Network configuration

As shown in Figure 4, an enterprise network uses mDNS for communication. The working area is in VLAN 10 and uses subnet 192.168.1.0. The service area is in VLAN 20 and uses subnet 192.168.2.0. Subnet 192.168.3.0 runs between the mDNS relay and the mDNS gateway.

Configure mDNS relay on the switch to allow employers in the working area to access the printer in the service area.

Figure 4 Network diagram

Procedure

1. Configure the mDNS gateway and make sure route among the AP, the mDNS relay, and the mDNS gateway is reachable. (Details not shown.)
2. Configure the mDNS relay.

   # Specify 192.168.3.2 as the mDNS gateway address.

   ```
   <Switch> system-view
   ```

```
[Switch] mdns relay gateway ip 192.168.3.2
```

Enable mDNS relay in VLAN 10.

```
[Switch] vlan 10
[Switch-vlan10] mdns relay enable
```

Specify 192.168.3.1 as the source IP address for mDNS packets.

```
[Switch-vlan10] mdns relay source ip 192.168.3.1
[Switch-vlan10] quit
```

Enable mDNS relay in VLAN 20.

```
[Switch] vlan 20
[Switch-vlan20] mdns relay enable
```

Specify 192.168.3.1 as the source IP address for mDNS packets.

```
[Switch-vlan20] mdns relay source ip 192.168.3.1
[Switch-vlan20] quit
```

Verifying the configuration

Display mDNS relay configuration.

```
[Switch] display mdns relay
mDNS relay configuration:
mDNS gateway IP: 192.168.3.2
mDNS relay configuration in VLANs:
VLAN ID  Source IP address          Probe interval (sec)
10       192.168.3.1                --
20       192.168.3.1                --
```

Verify that the user in VLAN 10 can use the iPad to access the printer in VLAN 20. (Details not shown.)

Troubleshooting mDNS relay

mDNS packet receiving failure

Symptom

The mDNS relay cannot receive mDNS packets.

Analysis

Possible reasons are:

- The mDNS relay is not enabled.
- The IP address of the mDNS gateway is not specified on the mDNS relay.

Solution

To resolve this issue:

1. Execute the **`display mdns relay`** command to view current configuration.
2. Perform one of the following tasks:
   - If mDNS relay is not enabled, execute the **`mdns relay enable`** command to enable this feature.
   - If the IP address of the mDNS gateway is not specified on the mDNS relay, execute the **`mdns relay gateway ip`** command to specify the mDNS gateway address.

Preface

This configuration guide describes the routing fundamentals and configuration procedures. It covers the mainstream routing protocols for IPv4 and IPv6 networks, and describes how to use policies to filter routes and affect routing decisions.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** >

Convention	Description
	Folder.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Configuring basic IP routing

This chapter focuses on unicast routing protocols. For more information about multicast routing protocols, see *IP Multicast Configuration Guide*.

About IP routing

IP routing directs IP packet forwarding on routers. Based on the destination IP address in the packet, a router looks up a route for the packet in a routing table and forwards the packet to the next hop. Routes are path information used to direct IP packets.

Routing table

A RIB contains the global routing information and related information, including route recursion, route redistribution, and route extension information. The router selects optimal routes from the routing table and puts them into the FIB table. It uses the FIB table to forward packets. For more information about the FIB table, see *Layer 3—IP Services Configuration Guide*.

Route categories

Table 1 categorizes routes by different criteria.

Table 1 Route categories

Criterion	Categories
Origin	• **Direct route**—A direct route is discovered by the data link protocol on an interface, and is also called an interface route. • **Static route**—A static route is manually configured by an administrator. • **Dynamic route**—A dynamic route is dynamically discovered by a routing protocol.
Destination	• **Network route**—The destination is a network. The subnet mask is less than 32 bits. • **Host route**—The destination is a host. The subnet mask is 32 bits.
Whether the destination is directly connected	• **Direct route**—The destination is directly connected. • **Indirect route**—The destination is indirectly connected.

Dynamic routing protocols

Static routes work well in small, stable networks. They are easy to configure and require fewer system resources. However, in networks where topology changes occur frequently, a typical practice is to configure a dynamic routing protocol. Compared with static routing, a dynamic routing protocol is complicated to configure, requires more router resources, and consumes more network resources.

Dynamic routing protocols dynamically collect and report reachability information to adapt to topology changes. They are suitable for large networks.

Dynamic routing protocols can be classified by different criteria, as shown in Table 2.

Table 2 Categories of dynamic routing protocols

Criterion	Categories
Operation scope	• **IGPs**—Work within an AS. Examples include RIP, OSPF, and IS-IS. • **EGPs**—Work between ASs. The most popular EGP is BGP.
Routing algorithm	• **Distance-vector protocols**—Examples include RIP and BGP. BGP is also considered a path-vector protocol. • **Link-state protocols**—Examples include OSPF and IS-IS.
Destination address type	• **Unicast routing protocols**—Examples include RIP, OSPF, BGP, and IS-IS. • **Multicast routing protocols**—Examples include PIM-SM and PIM-DM.
IP version	• **IPv4 routing protocols**—Examples include RIP, OSPF, BGP, and IS-IS. • **IPv6 routing protocols**—Examples include RIPng, OSPFv3, IPv6 BGP, and IPv6 IS-IS.

An AS refers to a group of routers that use the same routing policy and work under the same administration.

Route preference

Routing protocols, including static and direct routing, each by default have a preference. If they find multiple routes to the same destination, the router selects the route with the highest preference as the optimal route.

The preference of a direct route is always 0 and cannot be changed. You can configure a preference for each static route and each dynamic routing protocol. The following table lists the route types and default preferences. The smaller the value, the higher the preference.

Table 3 Route types and default route preferences

Route type	Preference
Direct route	0
Multicast static route	1
OSPF	10
IS-IS	15
Unicast static route	60
RIP	100
OSPF ASE	150
OSPF NSSA	150
IBGP	255
EBGP	255
Unknown (route from an untrusted source)	256

Load sharing

A routing protocol might find multiple optimal equal-cost routes to the same destination. You can use these routes to implement equal-cost multi-path (ECMP) load sharing.

Static routing, IPv6 static routing, RIP, RIPng, OSPF, OSPFv3, BGP, IPv6 BGP, IS-IS, and IPv6 IS-IS support ECMP load sharing.

Route backup

Route backup can improve network availability. Among multiple routes to the same destination, the route with the highest priority is the primary route and others are secondary routes.

The router forwards matching packets through the primary route. When the primary route fails, the route with the highest preference among the secondary routes is selected to forward packets. When the primary route recovers, the router uses it to forward packets.

Route recursion

To use a static, BGP, or RIP route that has an indirectly connected next hop, a router must perform route recursion to find the output interface to reach the next hop.

Link-state routing protocols, such as OSPF and IS-IS, do not need route recursion, because they obtain directly connected next hops through route calculation.

The RIB records and saves route recursion information, including brief information about related routes, recursive paths, and recursion depth.

Route redistribution

Route redistribution enables routing protocols to learn routing information from each other. A dynamic routing protocol can redistribute routes from other routing protocols, including direct and static routing. For more information, see the respective chapters on those routing protocols in this configuration guide.

The RIB records redistribution relationships of routing protocols.

Extension attribute redistribution

Extension attribute redistribution enables routing protocols to learn route extension attributes from each other, including BGP extended community attributes, OSPF area IDs, route types, and router IDs.

The RIB records extended attributes of each routing protocol and redistribution relationships of different routing protocol extended attributes.

Setting the maximum lifetime for routes and labels in the RIB

About this task

Perform this task to prevent routes and labels of a certain protocol from being aged out due to slow protocol convergence resulting from a large number of route entries or long GR period.

Restrictions and guidelines

The configuration takes effect at the next protocol or RIB process switchover.

Procedure (IPv4)

1. Enter system view.

   ```
   system-view
   ```

2. Enter RIB view.
   rib
3. Create the RIB IPv4 address family and enter its view.
   address-family ipv4
4. Set the maximum lifetime for IPv4 routes and labels in the RIB.
   protocol *protocol* [**instance** *instance-name*] **lifetime** *seconds*
   By default, the maximum lifetime for routes and labels in the RIB is 900 seconds.

Procedure (IPv6)

1. Enter system view.
   system-view
2. Enter RIB view.
   rib
3. Create the RIB IPv6 address family and enter its view.
   address-family ipv6
4. Set the maximum lifetime for IPv6 routes and labels in the RIB.
   protocol *protocol* [**instance** *instance-name*] **lifetime** *seconds*
   By default, the maximum lifetime for routes and labels in the RIB is 900 seconds.

Setting the maximum lifetime for routes in the FIB

About this task

When GR or NSR is disabled, FIB entries must be retained for some time after a protocol process switchover or RIB process switchover. When GR or NSR is enabled, FIB entries must be removed immediately after a protocol or RIB process switchover to avoid routing issues. Perform this task to meet such requirements.

Procedure (IPv4)

1. Enter system view.
   system-view
2. Enter RIB view.
   rib
3. Create the RIB IPv4 address family and enter its view.
   address-family ipv4
4. Set the maximum lifetime for IPv4 routes in the FIB.
   fib lifetime *seconds*
   By default, the maximum lifetime for routes in the FIB is 600 seconds.

Procedure (IPv6)

1. Enter system view.
   system-view
2. Enter RIB view.
   rib
3. Create the RIB IPv6 address family and enter its view.
   address-family ipv6
4. Set the maximum lifetime for IPv6 routes in the FIB.

fib lifetime *seconds*

By default, the maximum lifetime for routes in the FIB is 600 seconds.

Enabling the RIB to flush route attribute information to the FIB

1. Enter system view.
   system-view
2. Enter RIB view.
   rib
3. Create the RIB IPv4 address family and enter its view.
   address-family ipv4
4. Enable the RIB to flush route attribute information to the FIB.
   flush route-attribute *protocol*

   By default, the RIB does not flush route attribute information to the FIB.

Setting the maximum number of ECMP routes

Restrictions and guidelines

IMPORTANT:

This task is used only for version rollback in an IRF network environment and must be performed under the guidance of H3C technical support.

This configuration takes effect at reboot. Make sure the reboot does not impact your network.

Procedure

1. Enter system view.
   system-view
2. Set the maximum number of ECMP routes.
   max-ecmp-num *number*

   By default, the maximum number of ECMP routes is 64.

Configuring the ECMP mode

About this task

An ECMP route group contains ECMP routes to the same destination. The following ECMP modes are supported:

- **Normal mode**—When one or multiple ECMP routes in an ECMP group fail, this mode enables the device to reallocate all traffic to the remaining routes in the ECMP group.
- **Enhanced mode**—When one or multiple ECMP routes in an ECMP group fail, this mode enables the device to reallocate only the traffic of the failed routes to the remaining routes.

Restrictions and guidelines

Only the S5200-HI-G switch series supports this configuration.

The task applies to both IPv4 and IPv6 ECMP routes.

Procedure

1. Enter system view.
   system-view
2. Configure the ECMP mode.
   ecmp mode enhanced
   By default, the normal ECMP mode is used.

Configuring RIB NSR

About this task

When an active/standby switchover occurs, nonstop routing (NSR) backs up routing information from the active process to the standby process to avoid routing flapping and ensure forwarding continuity.

RIB NSR provides faster route convergence than protocol NSR during an active/standby switchover.

Restrictions and guidelines

Use this feature with protocol GR or NSR to avoid route timeouts and traffic interruption.

Procedure (IPv4)

1. Enter system view.
   system-view
2. Enter RIB view.
   rib
3. Create the RIB IPv4 address family and enter its view.
   address-family ipv4
4. Enable IPv4 RIB NSR.
   non-stop-routing
   By default, RIB NSR is disabled.

Procedure (IPv6)

1. Enter system view.
   system-view
2. Enter RIB view.
   rib
3. Create the RIB IPv6 address family and enter its view.
   address-family ipv6
4. Enable IPv6 RIB NSR.
   non-stop-routing
   By default, RIB NSR is disabled.

Configuring inter-protocol FRR

About this task

This feature is applicable to services that are sensitive to packet loss and latency. Inter-protocol fast reroute (FRR) enables fast rerouting between routes of different protocols. A backup next hop is

automatically selected to reduce the service interruption time caused by unreachable next hops. When the next hop of the primary link fails, the traffic is redirected to the backup next hop.

Among the routes to the same destination in the RIB, a router adds the route with the highest preference to the FIB table. After you configure this feature, the device will select a route of another routing protocol as the backup route. When the next hop of the primary route is unreachable, the device forwards packets through the backup route.

Restrictions and guidelines

This feature uses the next hop of a route from a different protocol as the backup next hop, which might cause loops.

If you configure both inter-protocol FRR and FRR for the specified routing protocol, FRR for the specified routing protocol takes effect.

Procedure (IPv4)

1. Enter system view.
   system-view
2. Enter RIB view.
   rib
3. Create the RIB IPv4 address family and enter its view.
   address-family ipv4
4. Enable IPv4 RIB inter-protocol FRR.
   inter-protocol fast-reroute [**vpn-instance** *vpn-instance-name*]
   By default, inter-protocol FRR is disabled.
   If you do not specify a VPN instance, inter-protocol FRR is enabled for the public network.

Procedure (IPv6)

1. Enter system view.
   system-view
2. Enter RIB view.
   rib
3. Create the RIB IPv6 address family and enter its view.
   address-family ipv6
4. Enable IPv6 RIB inter-protocol FRR.
   inter-protocol fast-reroute [**vpn-instance** *vpn-instance-name*]
   By default, inter-protocol FRR is disabled.
   If you do not specify a VPN instance, inter-protocol FRR is enabled for the public network.

Configuring BFD for primary route next hop availability detection

About configuring BFD for primary route next hop detection

This feature uses BFD to detect the availability of the primary route next hop for inter-protocol FRR or ECMP routes. When the primary route next hop unreachable, this feature enables the upper layer routing protocol to reallocate service traffic to the backup next hops or to the remaining ECMP next hops.

For inter-protocol FRR, the primary route is the route with the highest preference among the routes to the same destination. If BFD detects that the next hop of the primary route is unreachable, it notifies the FIB of the issue. The FIB will use the backup next hops to guide traffic forwarding.

For ECMP routes of a routing protocol, the primary route is each ECMP route. If BFD detects that the next hop of an ECMP route is unreachable, it notifies the routing protocol of the issue. The routing protocol will reallocate the service traffic to the remaining ECMP next hops. When BFD detects that the next hops of all ECMP routes are invalid, BFD notifies the routing protocol to withdraw the routes. In addition, the device reselects optimal routes for the service traffic.

For more information about BFD, see *High Availability Configuration Guide*.

Restrictions and guidelines for configuring BFD for primary route next hop availability detection

If you specify the **ecmp-shared** keyword when configuring FRR for a routing protocol, the device will use the LFA algorithm to calculate backup next hops for each ECMP route. The routes destined for the backup next hops are also added to the routing table as ECMP routes and the state of these routes is backup. BFD does not detect these backup ECMP routes.

The source IPv6 address of packets for an echo-packet-mode BFD session can only be a global unicast address. If the IPv6 next hop address of the primary link is not a global unicast address, as a best practice, use a control-packet-mode BFD session to detect next hop reachability for the primary link.

Configuring BFD control packet mode

About this task

This mode uses BFD control packets to detect the status of a link bidirectionally at a millisecond level.

Restrictions and guidelines for BFD control packet mode

A control-packet-mode BFD session can be successfully established through negotiation between the two ends. To use a control-packet-mode BFD session to detect the primary route next hop availability, you must create a static BFD session that meets the following requirements on the next hop device:

- Create a single-hop BFD session in control packet mode.
- The source IP address of the BFD session is the destination IP address of the BFD session automatically created by the local end.
- The destination IP address of the BFD session is the source IP address of the BFD session automatically created by the local end.
- The remote discriminator of the BFD session is the local discriminator of the BFD session automatically created by the local end.

The local device can use a control-packet-mode BFD session to detect the primary route next hop only after you create the static BFD session on the primary route next hop device.

Procedure

1. Enter system view.

   system-view
2. Enter RIB view.

   rib
3. Create RIB IPv4 or IPv6 address family view and enter the view.

   IPv4:

address-family ipv4

IPv6:

address-family ipv6

4. Enable BFD for primary link availability detection.

   primary-path-detect bfd ctrl [**inter-protocol-frr** | **protocol-ecmp** *protocol*]

   By default, BFD is disabled for primary link availability detection.

Configuring BFD echo packet mode

About this task

With BFD echo packet mode enabled, the output interface sends BFD echo packets to the destination device, and the device sends the packets back to test the link reachability.

Restrictions and guidelines

You do not need to configure BFD echo packet mode at the peer end.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Configure the source IP address of echo packets.

   IPv4:

   bfd echo-source-ip *ip-address*

   By default, the source IPv4 address of echo packets is not configured.

   As a best practice to avoid network congestion caused by excessive ICMP redirect packets from the peer, use this command. Make sure the source IPv4 address is not on the subnet of any interfaces on the device.

   For more information about this command, see BFD in *High Availability Command Reference*.

   IPv6:

   bfd echo-source-ipv6 *ipv6-address*

   By default, the source IPv6 address of echo packets is not configured.

   As a best practice to avoid network congestion caused by excessive ICMPv6 redirect packets from the peer, use this command. Make sure the source IPv6 address is not on the subnet of any interfaces on the device.

   You must specify a global unicast address as the source IPv6 address of BFD echo packets.

   For more information about this command, see BFD in *High Availability Command Reference*.

3. Enter RIB view.

   rib

4. Create RIB IPv4 or IPv6 address family view and enter the view.

   IPv4:

   address-family ipv4

   IPv6:

   address-family ipv6

5. Enable BFD for primary link availability detection.

   primary-path-detect bfd echo [**inter-protocol-frr** | **protocol-ecmp** *protocol*]

   By default, BFD is disabled for primary link availability detection.

Enabling route fast switchover

About this task

This feature applies to a device that provides the same physical output interface for large numbers of routes, including ECMP routes and primary/secondary routes. When a link failure occurs on the interface, the device must perform the following tasks before switching the traffic to another route:

1. Deletes all ARP or ND entries for the link.
2. Instructs the FIB to delete the associated FIB entries.

This procedure is time consuming and interrupts traffic for a long time. To resolve this problem, you can enable route fast switchover. This feature allows the device to instruct the FIB to delete the invalid FIB entries for route switchover first.

Procedure (IPv4)

1. Enter system view.
   `system-view`
2. Enable IPv4 route fast switchover.
   `ip route fast-switchover enable`
   By default, IPv4 route fast switchover is disabled.

Procedure (IPv6)

1. Enter system view.
   `system-view`
2. Enable IPv6 route fast switchover.
   `ipv6 route fast-switchover enable`
   By default, IPv6 route fast switchover is disabled.

Configuring routing policy-based recursive lookup

About this task

Configure routing policy-based recursive lookup to control route recursion results. For example, when a route changes, the routing protocol has to perform a route recursion if the next hop is indirectly connected. The routing protocol might select an incorrect path, which can cause traffic loss. To prevent this problem, you can use a routing policy to filter out incorrect routes. The routes that pass the filtering of the routing policy will be used for route recursion.

Restrictions and guidelines

The **`apply`** clauses in the specified routing policy cannot take effect.

Make sure a minimum of one related route can match the routing policy for correct traffic forwarding.

Procedure (IPv4)

1. Enter system view.
   `system-view`
2. Enter RIB view.
   `rib`
3. Create the RIB IPv4 address family and enter its view.
   `address-family ipv4`
4. Configure routing policy-based recursive lookup.

protocol *protocol* **nexthop recursive-lookup route-policy** *route-policy-name*

By default, routing policy-based recursive lookup is not configured.

Procedure (IPv6)

1. Enter system view.

   system-view
2. Enter RIB view.

   rib
3. Create the RIB IPv6 address family and enter its view.

   address-family ipv6
4. Configure routing policy-based recursive lookup.

   protocol *protocol* **nexthop recursive-lookup route-policy** *route-policy-name*

   By default, routing policy-based recursive lookup is not configured.

Setting the maximum number of active routes supported by the device

About this task

To perform this task:

- You can use the **routing-table limit** *number warn-threshold* command to specify an alarm threshold. When the percentage of active routes exceeds the alarm threshold, the system generates a system log message but still accepts active routes. You can take relevant actions based on the message to save system resources. If the number of active routes reaches the maximum number, no more routes can be added and new routes are discarded.
- You can use the **routing-table limit** *number* **simply-alert** command to specify an alarm threshold. When the maximum number of active IPv4/IPv6 routes is exceeded, the device still accepts new active routes but generates a system log message. You can take relevant actions based on the message to save system resources.

Procedure (IPv4)

1. Enter system view.

   system-view
2. Enter RIB view.

   rib
3. Create the RIB IPv4 address family and enter its view.

   address-family ipv4
4. Set the maximum number of active IPv4 routes supported by the device.

   routing-table limit *number* { *warn-threshold* | **simply-alert** }

   By default, the maximum number of active IPv4 routes is not set for the device.

   Configuration in RIB IPv4 address family view limits the number of active IPv4 routes for the public network and all VPN instances.

Procedure (IPv6)

1. Enter system view.

   system-view

2. Enter RIB view.

   rib

3. Create the RIB IPv6 address family and enter its view.

   address-family ipv6

4. Set the maximum number of active IPv6 routes supported by the device.

   routing-table limit *number* { *warn-threshold* | **simply-alert** }

   By default, the maximum number of active IPv6 routes is not set for the device.

   Configuration in RIB IPv6 address family view limits the number of active IPv6 routes for the public network and all VPN instances.

Configuring RIB SNMP notifications

About this task

To report critical RIB events to an NMS, enable SNMP notifications for RIB. For SNMP notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

Procedure (IPv4)

1. Enter system view.

   system-view

2. Enable IPv4 RIB SNMP notifications.

   snmp-agent trap enable rib [**prefix-exceed** | **prefix-exceed-clear** | **prefix-threshold-exceed** | **prefix-thresholdexceed-clear** | **public-prefix-exceed** | **public-prefixexceed-clear** | **public-prefixthreshold-exceed** | **public-prefixthresholdexceed-clear** | **vrf-prefix-exceed** | **vrf-prefixexceed-clear** | **vrf-prefixthreshold-exceed** | **vrf-prefixthresholdexceed-clear**] *

   By default, IPv4 RIB SNMP notifications are enabled.

Procedure (IPv6)

1. Enter system view.

   system-view

2. Enable IPv6 RIB SNMP notifications.

   snmp-agent trap enable ipv6 rib [**prefix-exceed** | **prefix-exceed-clear** | **prefix-threshold-exceed** | **prefix-thresholdexceed-clear** | **public-prefix-exceed** | **public-prefixexceed-clear** | **public-prefixthreshold-exceed** | **public-prefixthresholdexceed-clear** | **vrf-prefix-exceed** | **vrf-prefixexceed-clear** | **vrf-prefixthreshold-exceed** | **vrf-prefixthresholdexceed-clear**] *

   By default, IPv6 RIB SNMP notifications are enabled.

Display and maintenance commands for basic IP routing

Execute **display** commands in any view and **reset** commands in user view.

IMPORTANT:

The **display max-ecmp-num** command is used only for version rollback in an IRF network environment and must be used under the guidance of H3C technical support.

Task	Command
Display the ECMP mode.	**display ecmp mode**
Display routing table information.	**display ip routing-table** [**all-vpn-instance** | **vpn-instance** *vpn-instance-name*] [**verbose**] **display ip routing-table all-routes**
Display information about routes permitted by an IPv4 basic ACL.	**display ip routing-table** [**vpn-instance** *vpn-instance-name*] **acl** *ipv4-acl-number* [**verbose**]
Display information about routes to a specific destination address.	**display ip routing-table** [**vpn-instance** *vpn-instance-name*] *ip-address* [*mask-length* | *mask*] [**longer-match**] [**verbose**]
Display information about routes to a range of destination addresses.	**display ip routing-table** [**vpn-instance** *vpn-instance-name*] *ip-address1* **to** *ip-address2* [**verbose**]
Display information about routes permitted by an IP prefix list.	**display ip routing-table** [**vpn-instance** *vpn-instance-name*] **prefix-list** *prefix-list-name* [**verbose**]
Display information about routes installed by a protocol.	**display ip routing-table** [**vpn-instance** *vpn-instance-name*] **protocol** *protocol* [**inactive** | **verbose**]
Display IPv4 route statistics.	**display ip routing-table** [**all-routes** | **all-vpn-instance** | **vpn-instance** *vpn-instance-name*] **statistics**
Display brief IPv4 routing table information.	**display ip routing-table** [**vpn-instance** *vpn-instance-name*] **summary**
Display route attribute information in the IPv6 RIB.	**display ipv6 rib attribute** [*attribute-id*]
Display IPv6 RIB GR state information.	**display ipv6 rib graceful-restart**
Display next hop information in the IPv6 RIB.	**display ipv6 rib nib** [**self-originated**] [*nib-id*] [**verbose**] **display ipv6 rib nib protocol** *protocol* [**verbose**]
Display next hop information for IPv6 direct routes.	**display ipv6 route-direct nib** [*nib-id*] [**verbose**]
Display IPv6 routing table information.	**display ipv6 routing-table** [**all-vpn-instance** | **vpn-instance** *vpn-instance-name*] [**verbose**] **display ipv6 routing-table all-routes**
Display information about routes permitted by an IPv6 basic ACL.	**display ipv6 routing-table** [**vpn-instance** *vpn-instance-name*] **acl** *ipv6-acl-number* [**verbose**]

Task	Command
Display information about routes to an IPv6 destination address.	**display ipv6 routing-table** [**vpn-instance** *vpn-instance-name*] *ipv6-address* [*prefix-length*] [**longer-match**] [**verbose**]
Display information about routes to a range of IPv6 destination addresses.	**display ipv6 routing-table** [**vpn-instance** *vpn-instance-name*] *ipv6-address1* **to** *ipv6-address2* [**verbose**]
Display information about routes permitted by an IPv6 prefix list.	**display ipv6 routing-table** [**vpn-instance** *vpn-instance-name*] **prefix-list** *prefix-list-name* [**verbose**]
Display information about routes installed by an IPv6 protocol.	**display ipv6 routing-table** [**vpn-instance** *vpn-instance-name*] **protocol** *protocol* [**inactive** | **verbose**]
Display IPv6 route statistics.	**display ipv6 routing-table** [**all-routes** | **all-vpn-instance** | **vpn-instance** *vpn-instance-name*] **statistics**
Display brief IPv6 routing table information.	**display ipv6 routing-table** [**vpn-instance** *vpn-instance-name*] **summary**
Display the maximum number of ECMP routes.	**display max-ecmp-num**
Display route attribute information in the RIB.	**display rib attribute** [*attribute-id*]
Display RIB GR state information.	**display rib graceful-restart**
Display next hop information in the RIB.	**display rib nib** [**self-originated**] [*nib-id*] [**verbose**] **display rib nib protocol** *protocol* [**verbose**]
Display next hop information for direct routes.	**display route-direct nib** [*nib-id*] [**verbose**]
Clear IPv4 route statistics.	**reset ip routing-table statistics protocol** [**vpn-instance** *vpn-instance-name*] { *protocol* | **all** } **reset ip routing-table** [**all-routes** | **all-vpn-instance**] **statistics protocol** { *protocol* | **all** }
Clear IPv6 route statistics.	**reset ipv6 routing-table statistics protocol** [**vpn-instance** *vpn-instance-name*] { *protocol* | **all** } **reset ipv6 routing-table** [**all-routes** | **all-vpn-instance**] **statistics protocol** { *protocol* | **all** }

Configuring static routing

About static routes

Static routes are manually configured. If a network's topology is simple, you only need to configure static routes for the network to work correctly.

Static routes cannot adapt to network topology changes. If a fault or a topological change occurs in the network, the network administrator must modify the static routes manually.

Configuring a static route

1. Enter system view.

   system-view

2. Configure a static route.

   Public network:

   ip route-static *dest-address* { *mask-length* | *mask* } *interface-type interface-number* [*next-hop-address* [**nexthop-index** *index-string*]] [**permanent** | **track** *track-entry-number*] [**preference** *preference*] [**tag** *tag-value*] [**recursive-lookup**] [**description** *text*]

   ip route-static *dest-address* { *mask-length* | *mask* } { *next-hop-address* [**nexthop-index** *index-string*] [**recursive-lookup** { **host-route** | **longest-match** }] | **vpn-instance** *d-vpn-instance-name next-hop-address* [**nexthop-index** *index-string*] [**recursive-lookup** { **host-route** | **longest-match** }] } [**permanent** | **track** *track-entry-number*] [**preference** *preference*] [**tag** *tag-value*] [**recursive-lookup**] [**description** *text*]

   ip route-static *dest-address* { *mask-length* | *mask* } *interface-type interface-number next-hop-address* [**nexthop-index** *index-string*] **track-arp** [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, no static route is configured.

   You can associate Track with a static route to monitor the reachability of the next hops. For more information about Track, see *High Availability Configuration Guide*.

   The **recursive-lookup host-route**, **recursive-lookup longest-match**, and **recursive-lookup** keywords are mutually exclusive. You cannot specify the keywords at the same time.

3. (Optional.) Enable periodic sending of ARP requests to the next hops of static routes.

   ip route-static arp-request interval *interval*

   By default, the device does not send ARP requests to the next hops of static routes.

4. (Optional.) Configure the default preference for static routes.

   ip route-static default-preference *default-preference*

   The default setting is 60.

Configuring a static route group

About this task

This task allows you to batch create static routes with different prefixes but the same output interface and next hop.

You can create a static route group, and specify the static group in the **ip route-static** command. All prefixes in the static route group will be assigned the next hop and output interface specified in the **ip route-static** command.

Procedure

1. Enter system view.

   system-view

2. Create a static route group and enter its view.

   ip route-static-group *group-name*

   By default, no static route group is configured.

3. Add a static route prefix to the static route group.

   prefix *dest-address* { *mask-length* | *mask* }

   By default, no static route prefix is added to the static route group.

4. Return to system view.

   quit

5. Configure a static route.

   Public network:

   ip route-static group *group-name interface-type interface-number* [*next-hop-address*] [**permanent** | **track** *track-entry-number*] [**preference** *preference*] [**tag** *tag-value*] [**recursive-lookup**] [**description** *text*]

   ip route-static group *group-name* { *next-hop-address* [**recursive-lookup** { **host-route** | **longest-match** }] | **vpn-instance** *d-vpn-instance-name next-hop-address* [**recursive-lookup** { **host-route** | **longest-match** }] } [**permanent** | **track** *track-entry-number*] [**preference** *preference*] [**tag** *tag-value*] [**recursive-lookup**] [**description** *text*]

   ip route-static group *group-name interface-type interface-number next-hop-address* **track-arp** [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   The **recursive-lookup host-route**, **recursive-lookup longest-match**, and **recursive-lookup** keywords are mutually exclusive. You cannot specify the keywords at the same time.

   VPN:

   ip route-static vpn-instance *s-vpn-instance-name* **group** *group-name interface-type interface-number* [*next-hop-address*] [**permanent** | **track** *track-entry-number*] [**preference** *preference*] [**tag** *tag-value*] [**recursive-lookup**] [**description** *text*]

   ip route-static vpn-instance *s-vpn-instance-name* **group** *group-name* { *next-hop-address* [**recursive-lookup** { **host-route** | **longest-match** }] [**public**] | **vpn-instance** *d-vpn-instance-name next-hop-address* [**recursive-lookup** { **host-route** | **longest-match** }] } [**permanent** | **track** *track-entry-number*] [**preference** *preference*] [**tag** *tag-value*] [**recursive-lookup**] [**description** *text*]

ip route-static vpn-instance *s-vpn-instance-name* **group** *group-name interface-type interface-number next-hop-address* **track-arp** [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

The **recursive-lookup host-route**, **recursive-lookup longest-match**, and **recursive-lookup** keywords are mutually exclusive. You cannot specify the keywords at the same time.

By default, no static route is configured.

Configuring floating static routes

Perform this task to configure route backup to improve network reliability.

When a static or dynamic route to a destination address already exists on the device, you configure another static route with a lower priority as the backup route to improve the network reliability. This backup static route is called a floating static route and is activated only when the primary route fails. After the primary route recovers from failure, the floating static route becomes inactive and data forwarding switches back to the primary route.

A floating static route can be configured in either of the following ways

- Configure different priorities for multiple static routes to the same destination address. The route with the lower priority automatically becomes the floating static route.
- When a route to a destination address already exists on the device, configure a static route with a lower priority to the same destination address.

When you configure a floating static route, the priority value of the route must be larger than then priority value of the primary route. For more information, see "Configuring a static route."

Deleting static routes

About this task

To delete a static route, use the **undo ip route-static** command. To delete all static routes including the default route, use the **delete static-routes all** command.

Procedure

1. Enter system view.

   system-view

2. Delete all static routes.

   Public network:

   delete static-routes all

   VPN:

   delete vpn-instance *vpn-instance-name* **static-routes all**

CAUTION:

Deleting all static routes with caution. This operation might cause network connectivity failure and packet forwarding failure.

Configuring BFD for static routes

IMPORTANT:

Enabling BFD for a flapping route could worsen the situation.

About BFD

BFD provides a general-purpose, standard, medium-, and protocol-independent fast failure detection mechanism. It can uniformly and quickly detect the failures of the bidirectional forwarding paths between two routers for protocols, such as routing protocols.

For more information about BFD, see *High Availability Configuration Guide*.

Configuring BFD control packet mode

About this task

This mode uses BFD control packets to detect the status of a link bidirectionally at a millisecond level.

BFD control packet mode can be applied to static routes with a direct next hop or with an indirect next hop.

Restrictions and guidelines for BFD control packet mode

If you use BFD control packet mode at the local end, you must use this mode also at the peer end.

Configuring BFD control packet mode for a static route (direct next hop)

1. Enter system view.

   system-view

2. Configure BFD control packet mode for a static route.

   Public network:

   ip route-static *dest-address* { *mask-length* | *mask* } *interface-type interface-number next-hop-address* **bfd control-packet** [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   VPN:

   ip route-static vpn-instance *s-vpn-instance-name dest-address* { *mask-length* | *mask* } *interface-type interface-number next-hop-address* **bfd control-packet** [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, BFD control packet mode for a static route is not configured.

Configuring BFD control packet mode for a static route (indirect next hop)

1. Enter system view.

   system-view

2. Configure BFD control packet mode for a static route.

   Public network:

   ip route-static *dest-address* { *mask-length* | *mask* } { *next-hop-address* **bfd control-packet bfd-source** *ip-address* | **vpn-instance** *d-vpn-instance-name next-hop-address* **bfd control-packet bfd-source** *ip-address* } [**preference** *preference*] [**tag tag-value**] [**description** *text*]

VPN:

ip route-static vpn-instance *s-vpn-instance-name dest-address* { *mask-length* | *mask* } { *next-hop-address* **bfd control-packet bfd-source** *ip-address* | **vpn-instance** *d-vpn-instance-name next-hop-address* **bfd control-packet bfd-source** *ip-address* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

By default, BFD control packet mode for a static route is not configured.

Configuring BFD echo packet mode

About this task

With BFD echo packet mode enabled for a static route, the output interface sends BFD echo packets to the destination device, which loops the packets back to test the link reachability.

Restrictions and guidelines

You do not need to configure BFD echo packet mode at the peer end.

Do not use BFD for a static route with the output interface in spoofing state.

Procedure

1. Enter system view.

   system-view

2. Configure the source address of echo packets.

   bfd echo-source-ip *ip-address*

   By default, the source address of echo packets is not configured.

   As a best practice to avoid network congestion caused by excessive ICMP redirect packets from the peer, use this command. Make sure the source IPv4 address is not on the subnet of any interfaces on the device.

   For more information about this command, see *High Availability Command Reference*.

3. Configure BFD echo packet mode for a static route.

   Public network:

   ip route-static *dest-address* { *mask-length* | *mask* } *interface-type interface-number next-hop-address* **bfd echo-packet** [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   VPN:

   ip route-static vpn-instance *s-vpn-instance-name dest-address* { *mask-length* | *mask* } *interface-type interface-number next-hop-address* **bfd echo-packet** [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, BFD echo packet mode for a static route is not configured.

Configuring static route FRR

About static route FRR

A link or router failure on a path can cause packet loss. Static route fast reroute (FRR) enables fast rerouting to minimize the impact of link or node failures.

Figure 1 Network diagram

As shown in Figure 1, upon a link failure, packets are directed to the backup next hop to avoid traffic interruption. You can either specify a backup next hop for FRR or enable FRR to automatically select a backup next hop (which must be configured in advance).

Restrictions and guidelines for static route FRR

- Do not use static route FRR and BFD (for a static route) at the same time.
- Equal-cost routes do not support static route FRR.
- Besides the configured static route for FRR, the device must have another route to reach the destination.

  When the state of the primary link (with Layer 3 interfaces staying up) changes from bidirectional to unidirectional or down, static route FRR quickly redirects traffic to the backup next hop. When the Layer 3 interfaces of the primary link are down, static route FRR temporarily redirects traffic to the backup next hop. In addition, the device searches for another route to reach the destination and redirects traffic to the new path if a route is found. If no route is found, traffic interruption occurs.

Configuring static route FRR by specifying a backup next hop

Restrictions and guidelines

A static route does not take effect when the backup output interface is unavailable.

To change the backup output interface or next hop, you must first remove the current setting. The backup output interface and next hop must be different from the primary output interface and next hop.

Procedure

1. Enter system view.

   system-view

2. Configure static route FRR.

   Public network:

   ip route-static *dest-address* { *mask-length* | *mask* } *interface-type interface-number* [*next-hop-address* [**backup-interface** *interface-type interface-number* [**backup-nexthop** *backup-nexthop-address*]]] [**permanent**] [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   VPN:

   ip route-static vpn-instance *s-vpn-instance-name dest-address* { *mask-length* | *mask* } *interface-type interface-number* [*next-hop-address* [**backup-interface** *interface-type interface-number* [**backup-nexthop** *backup-nexthop-address*]]] [**permanent**] [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

By default, static route FRR is disabled.

Configuring static route FRR to automatically select a backup next hop

1. Enter system view.
   system-view
2. Configure static route FRR to automatically select a backup next hop.
   ip route-static fast-reroute auto
   By default, static route FRR is disabled from automatically selecting a backup next hop.

Enabling BFD echo packet mode for static route FRR

About this task

By default, static route FRR uses ARP to detect primary link failures. Perform this task to enable static route FRR to use BFD echo packet mode for fast failure detection on the primary link.

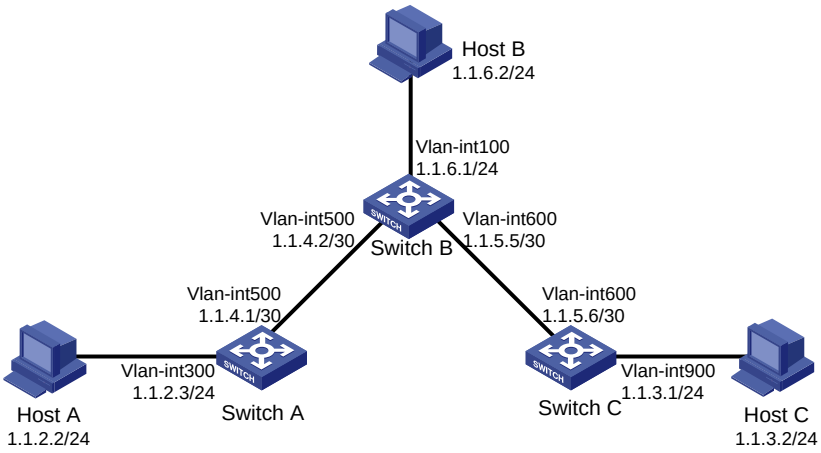
Procedure

1. Enter system view.
   system-view
2. Configure the source IP address of BFD echo packets.
   bfd echo-source-ip *ip-address*
   By default, the source IP address of BFD echo packets is not configured.
   As a best practice to avoid network congestion caused by excessive ICMP redirect packets from the peer, use this command. Make sure the source IPv4 address is not on the subnet of any interfaces on the device.
   For more information about this command, see *High Availability Command Reference*.
3. Enable BFD echo packet mode for static route FRR.
   ip route-static primary-path-detect bfd echo
   By default, BFD echo packet mode for static route FRR is disabled.

Display and maintenance commands for static routing

Execute **display** commands in any view.

Task	Command
Display static route information.	**display ip routing-table protocol static** [**inactive** | **verbose**]
Display static route next hop information.	**display route-static nib** [*nib-id*] [**verbose**]
Display static routing table information.	**display route-static routing-table** [**vpn-instance** *vpn-instance-name*] [*ip-address* { *mask-length* | *mask* }]



Static route configuration examples

Example: Configuring basic static routes

Network configuration

As shown in Figure 2, configure static routes on the switches for interconnections between any two hosts.

Figure 2 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure static routes:

   # Configure a default route on Switch A.

   ```
   <SwitchA> system-view
   [SwitchA] ip route-static 0.0.0.0 0.0.0.0 1.1.4.2
   ```

   # Configure two static routes on Switch B.

   ```
   <SwitchB> system-view
   [SwitchB] ip route-static 1.1.2.0 255.255.255.0 1.1.4.1
   [SwitchB] ip route-static 1.1.3.0 255.255.255.0 1.1.5.6
   ```

   # Configure a default route on Switch C.

   ```
   <SwitchC> system-view
   [SwitchC] ip route-static 0.0.0.0 0.0.0.0 1.1.5.5
   ```
3. Configure the default gateways of Host A, Host B, and Host C as 1.1.2.3, 1.1.6.1, and 1.1.3.1. (Details not shown.)

Verifying the configuration

Display static routes on Switch A.

```
[SwitchA] display ip routing-table protocol static

Summary count : 1

Static Routing table status : <Active>
Summary count : 1
```

```
Destination/Mask    Proto  Pre  Cost         NextHop         Interface
0.0.0.0/0           Static 60   0            1.1.4.2         Vlan500

Static Routing table status : <Inactive>
Summary count : 0
```

Display static routes on Switch B.

```
[SwitchB] display ip routing-table protocol static

Summary count : 2

Static Routing table status : <Active>
Summary count : 2

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
1.1.2.0/24          Static 60   0            1.1.4.1         Vlan500

Static Routing table status : <Inactive>
Summary count : 0
```

Use the **`ping`** command on Host B to test the reachability of Host A (Windows XP runs on the two hosts).

```
C:\Documents and Settings\Administrator>ping 1.1.2.2

Pinging 1.1.2.2 with 32 bytes of data:

Reply from 1.1.2.2: bytes=32 time=1ms TTL=126
Reply from 1.1.2.2: bytes=32 time=1ms TTL=126
Reply from 1.1.2.2: bytes=32 time=1ms TTL=126
Reply from 1.1.2.2: bytes=32 time=1ms TTL=126

Ping statistics for 1.1.2.2:
    Packets: Sent = 4, Received = 4, Lost = 0 (0% loss),
Approximate round trip times in milli-seconds:
    Minimum = 1ms, Maximum = 1ms, Average = 1ms
```

Use the **`tracert`** command on Host B to test the reachability of Host A.

```
C:\Documents and Settings\Administrator>tracert 1.1.2.2

Tracing route to 1.1.2.2 over a maximum of 30 hops

  1    <1 ms    <1 ms    <1 ms  1.1.6.1
  2    <1 ms    <1 ms    <1 ms  1.1.4.1
  3     1 ms    <1 ms    <1 ms  1.1.2.2

Trace complete.
```

Example: Configuring BFD for static routes (direct next hop)

Network configuration

Configure the following, as shown in Figure 3:

- Configure a static route to subnet 120.1.1.0/24 on Switch A.
- Configure a static route to subnet 121.1.1.0/24 on Switch B.
- Enable BFD for both routes.
- Configure a static route to subnet 120.1.1.0/24 and a static route to subnet 121.1.1.0/24 on Switch C.

When the link between Switch A and Switch B through the Layer 2 switch fails, BFD can detect the failure immediately. Switch A then communicates with Switch B through Switch C.

Figure 3 Network diagram

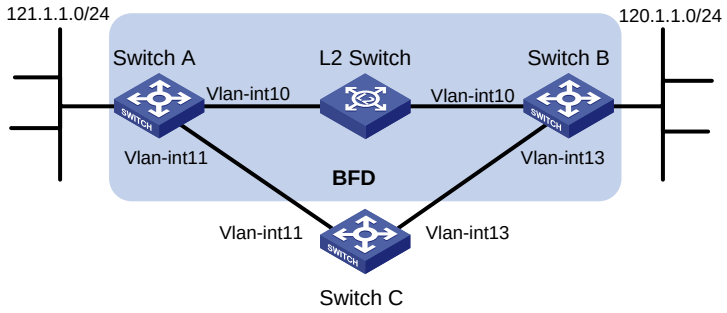


Table 1 Interface and IP address assignment

Device	Interface	IP address
Switch A	VLAN-interface 10	12.1.1.1/24
Switch A	VLAN-interface 11	10.1.1.102/24
Switch B	VLAN-interface 10	12.1.1.2/24
Switch B	VLAN-interface 13	13.1.1.1/24
Switch C	VLAN-interface 11	10.1.1.100/24
Switch C	VLAN-interface 13	13.1.1.2/24

Procedure

1. Configure IP addresses for the interfaces. (Details not shown.)
2. Configure static routes and BFD:

   # Configure static routes on Switch A and enable BFD control packet mode for the static route that traverses the Layer 2 switch.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 10
[SwitchA-vlan-interface10] bfd min-control-interval 500
[SwitchA-vlan-interface10] bfd detect-multiplier 9
[SwitchA-vlan-interface10] quit
[SwitchA] ip route-static 120.1.1.0 24 vlan-interface 10 12.1.1.2 bfd control-packet
[SwitchA] ip route-static 120.1.1.0 24 vlan-interface 11 10.1.1.100 preference 65
[SwitchA] quit
```

Configure static routes on Switch B and enable BFD control packet mode for the static route that traverses the Layer 2 switch.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 10
[SwitchB-vlan-interface10] bfd min-control-interval 500
[SwitchB-vlan-interface10] bfd detect-multiplier 9
[SwitchB-vlan-interface10] quit
[SwitchB] ip route-static 121.1.1.0 24 vlan-interface 10 12.1.1.1 bfd control-packet
[SwitchB] ip route-static 121.1.1.0 24 vlan-interface 13 13.1.1.2 preference 65
[SwitchB] quit
```

Configure static routes on Switch C.

```
<SwitchC> system-view
[SwitchC] ip route-static 120.1.1.0 24 13.1.1.1
[SwitchC] ip route-static 121.1.1.0 24 10.1.1.102
```

Verifying the configuration

Display BFD sessions on Switch A.

```
<SwitchA> display bfd session
 Total sessions: 1        Up sessions: 1        Init mode: Active

 IPv4 session working in control packet mode:

 LD/RD            SourceAddr      DestAddr        State  Holdtime    Interface
 4/7              12.1.1.1        12.1.1.2        Up     2000ms      Vlan10
```

The output shows that the BFD session has been created.

Display the static routes on Switch A.

```
<SwitchA> display ip routing-table protocol static

Summary count : 1

Static Routing table status : <Active>
Summary count : 1

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
120.1.1.0/24        Static 60   0            12.1.1.2        Vlan10

Static Routing table status : <Inactive>
Summary count : 0
```

The output shows that Switch A communicates with Switch B through VLAN-interface 10. Then the link over VLAN-interface 10 fails.

Display static routes on Switch A.

```
<SwitchA> display ip routing-table protocol static

Summary count : 1

Static Routing table status : <Active>
Summary count : 1
```

```
Destination/Mask    Proto  Pre  Cost         NextHop         Interface
120.1.1.0/24        Static 65   0            10.1.1.100      Vlan11

Static Routing table status : <Inactive>
Summary count : 0
```

The output shows that Switch A communicates with Switch B through VLAN-interface 11.

Example: Configuring BFD for static routes (indirect next hop)

Network configuration

Figure 4 shows the network topology as follows:

- Switch A has a route to interface Loopback 1 (2.2.2.9/32) on Switch B, with the output interface VLAN-interface 10.
- Switch B has a route to interface Loopback 1 (1.1.1.9/32) on Switch A, with the output interface VLAN-interface 12.
- Switch D has a route to 1.1.1.9/32, with the output interface VLAN-interface 10, and a route to 2.2.2.9/32, with the output interface VLAN-interface 12.

Configure the following:

- Configure a static route to subnet 120.1.1.0/24 on Switch A.
- Configure a static route to subnet 121.1.1.0/24 on Switch B.
- Enable BFD for both routes.
- Configure a static route to subnet 120.1.1.0/24 and a static route to subnet 121.1.1.0/24 on both Switch C and Switch D.

When the link between Switch A and Switch B through Switch D fails, BFD can detect the failure immediately. Switch A then communicates with Switch B through Switch C.

Figure 4 Network diagram

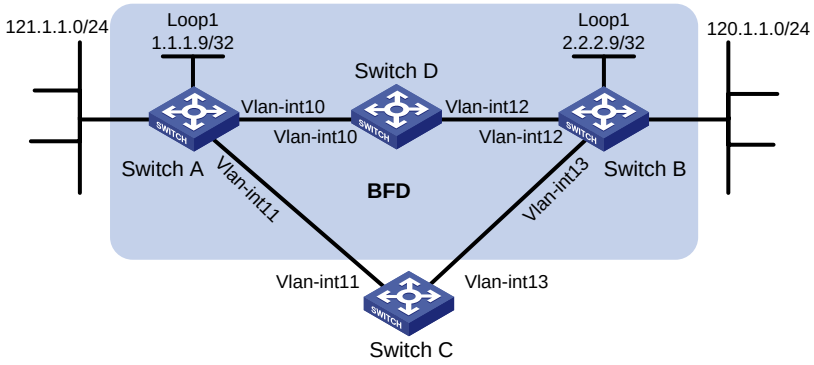

Table 2 Interface and IP address assignment

Device	Interface	IP address
Switch A	VLAN-interface 10	12.1.1.1/24
Switch A	VLAN-interface 11	10.1.1.102/24
Switch A	Loopback 1	1.1.1.9/32
Switch B	VLAN-interface 12	11.1.1.1/24

Device	Interface	IP address
Switch B	VLAN-interface 13	13.1.1.1/24
Switch B	Loopback 1	2.2.2.9/32
Switch C	VLAN-interface 11	10.1.1.100/24
Switch C	VLAN-interface 13	13.1.1.2/24
Switch D	VLAN-interface 10	12.1.1.2/24
Switch D	VLAN-interface 12	11.1.1.2/24

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure static routes and BFD:

   # Configure static routes on Switch A and enable BFD control packet mode for the static route that traverses Switch D.

```
<SwitchA> system-view
[SwitchA] bfd multi-hop min-control-interval 500
[SwitchA] bfd multi-hop detect-multiplier 9
[SwitchA] ip route-static 2.2.2.9 32 12.1.1.2
[SwitchA] ip route-static 120.1.1.0 24 2.2.2.9 bfd control-packet bfd-source 1.1.1.9
[SwitchA] ip route-static 120.1.1.0 24 vlan-interface 11 10.1.1.100 preference 65
[SwitchA] quit
```

   # Configure static routes on Switch B and enable BFD control packet mode for the static route that traverses Switch D.

```
<SwitchB> system-view
[SwitchB] bfd multi-hop min-control-interval 500
[SwitchB] bfd multi-hop detect-multiplier 9
[SwitchB] ip route-static 1.1.1.9 32 11.1.1.2
[SwitchB] ip route-static 121.1.1.0 24 1.1.1.9 bfd control-packet bfd-source 2.2.2.9
[SwitchB] ip route-static 121.1.1.0 24 vlan-interface 13 13.1.1.2 preference 65
[SwitchB] quit
```

   # Configure static routes on Switch C.

```
<SwitchC> system-view
[SwitchC] ip route-static 120.1.1.0 24 13.1.1.1
[SwitchC] ip route-static 121.1.1.0 24 10.1.1.102
```

   # Configure static routes on Switch D.

```
<SwitchD> system-view
[SwitchD] ip route-static 120.1.1.0 24 11.1.1.1
[SwitchD] ip route-static 121.1.1.0 24 12.1.1.1
```

Verifying the configuration

Display BFD sessions on Switch A.

```
<SwitchA> display bfd session
 Total sessions: 1        Up sessions: 1        Init mode: Active

 IPv4 session working in control packet mode:

 LD/RD           SourceAddr      DestAddr        State  Holdtime    Interface
```

```
 4/7                1.1.1.9          2.2.2.9          Up      2000ms      N/A
```

The output shows that the BFD session has been created.

Display the static routes on Switch A.

```
<SwitchA> display ip routing-table protocol static

Summary count : 1

Static Routing table status : <Active>
Summary count : 1

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
120.1.1.0/24        Static 60   0            12.1.1.2        Vlan10

Static Routing table status : <Inactive>
Summary count : 0
```

The output shows that Switch A communicates with Switch B through VLAN-interface 10. Then the link over VLAN-interface 10 fails.

Display static routes on Switch A.

```
<SwitchA> display ip routing-table protocol static

Summary count : 1

Static Routing table status : <Active>
Summary count : 1

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
120.1.1.0/24        Static 65   0            10.1.1.100      Vlan11

Static Routing table status : <Inactive>
Summary count : 0
```

The output shows that Switch A communicates with Switch B through VLAN-interface 11.

Example: Configuring static route FRR

Network configuration

As shown in Figure 5, configure static routes on Switch A, Switch B, and Switch C, and configure static route FRR. When Link A becomes unidirectional, traffic can be switched to Link B immediately.

Figure 5 Network diagram

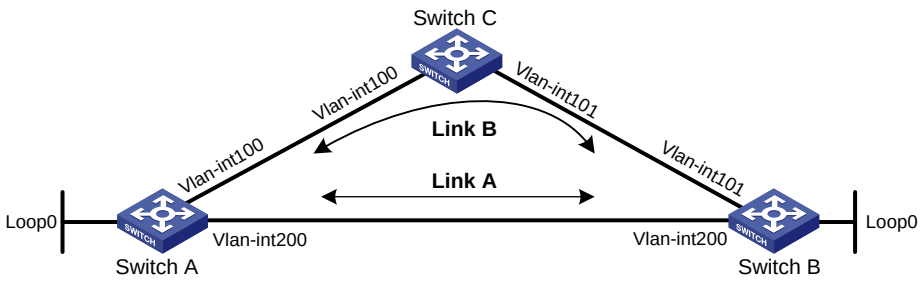

Table 3 Interface and IP address assignment

Device	Interface	IP address
Switch A	VLAN-interface 100	12.12.12.1/24
Switch A	VLAN-interface 200	13.13.13.1/24
Switch A	Loopback 0	1.1.1.1/32
Switch B	VLAN-interface 101	24.24.24.4/24
Switch B	VLAN-interface 200	13.13.13.2/24
Switch B	Loopback 0	4.4.4.4/32
Switch C	VLAN-interface 100	12.12.12.2/24
Switch C	VLAN-interface 101	24.24.24.2/24

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure static route FRR on link A:

   Use one of the following methods:

   - (Method 1.) Specify a backup next hop for static route FRR:

     # Configure a static route on Switch A, and specify VLAN-interface 100 as the backup output interface and 12.12.12.2 as the backup next hop.

     ```
     <SwitchA> system-view
     [SwitchA] ip route-static 4.4.4.4 32 vlan-interface 200 13.13.13.2
     backup-interface vlan-interface 100 backup-nexthop 12.12.12.2
     ```

     # Configure a static route on Switch B, and specify VLAN-interface 101 as the backup output interface and 24.24.24.2 as the backup next hop.

     ```
     <SwitchB> system-view
     [SwitchB] ip route-static 1.1.1.1 32 vlan-interface 200 13.13.13.1
     backup-interface vlan-interface 101 backup-nexthop 24.24.24.2
     ```

   - (Method 2.) Configure static route FRR to automatically select a backup next hop:

     # Configure static routes on Switch A, and enable static route FRR.

     ```
     <SwitchA> system-view
     [SwitchA] ip route-static 4.4.4.4 32 vlan-interface 200 13.13.13.2
     [SwitchA] ip route-static 4.4.4.4 32 vlan-interface 100 12.12.12.2 preference 70
     [SwitchA] ip route-static fast-reroute auto
     ```

     # Configure static routes on Switch B, and enable static route FRR.

     ```
     <SwitchB> system-view
     [SwitchB] ip route-static 1.1.1.1 32 vlan-interface 200 13.13.13.1
     [SwitchB] ip route-static 1.1.1.1 32 vlan-interface 101 24.24.24.2 preference 70
     [SwitchB] ip route-static fast-reroute auto
     ```

3. Configure static routes on Switch C.

   ```
   <SwitchC> system-view
   [SwitchC] ip route-static 4.4.4.4 32 vlan-interface 101 24.24.24.4
   [SwitchC] ip route-static 1.1.1.1 32 vlan-interface 100 12.12.12.1
   ```

Verifying the configuration

Display route 4.4.4.4/32 on Switch A to view the backup next hop information.

```
[SwitchA] display ip routing-table 4.4.4.4 verbose
```

```
Summary count : 1

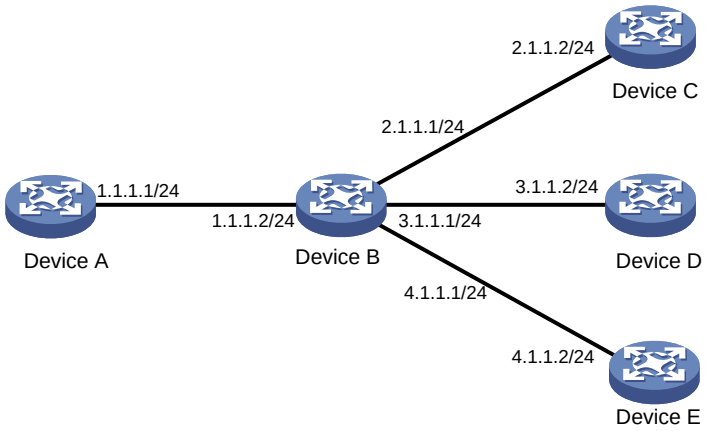
Configuring a default route

A default route is used to forward packets that do not match any specific routing entry in the routing table. Without a default route, packets that do not match any routing entries are discarded and an ICMP destination-unreachable packet is sent to the source.



A default route can be configured in either of the following ways:

- The network administrator can configure a default route with both destination and mask being 0.0.0.0. For more information, see "Configuring static routing."
- Some dynamic routing protocols (such as OSPF, IS-IS, and RIP) can generate a default route. For example, an upstream router running OSPF can generate a default route and advertise it to other routers. These routers install the default route with the next hop being the upstream router. For more information, see the respective chapters on these routing protocols in this configuration guide.

As shown in Figure 6, Device B is the next hop for packets from Device A to Device C, Device D, and Device E. You can configure a default route on Device A to replace the three static routes from Device A to Device C, Device D, and Device E, respectively. Then, packets that do not match any other routes will be forwarded based on the default route.

The next hop address, destination address, and subnet mask of the default route configured on Device A are 1.1.1.2, 0.0.0.0, and 0.0.0.0, respectively.

Configuring RIP

About RIP

Routing Information Protocol (RIP) is a distance-vector IGP suited to small-sized networks. It employs UDP to exchange route information through port 520.

RIP routing metrics

RIP uses a hop count to measure the distance to a destination. The hop count from a router to a directly connected network is 0. The hop count from a router to a directly connected router is 1. To limit convergence time, RIP restricts the value range of the metric from 0 to 15. A destination with a metric value of 16 (or greater) is considered unreachable. For this reason, RIP is not suitable for large-sized networks.

RIP route entries

RIP stores routing entries in a database. Each routing entry contains the following elements:

- **Destination address**—IP address of a destination host or a network.
- **Next hop**—IP address of the next hop.
- **Egress interface**—Egress interface of the route.
- **Metric**—Cost from the local router to the destination.
- **Route time**—Time elapsed since the last update. The time is reset to 0 when the routing entry is updated.
- **Route tag**—Used for route control. For more information, see "Configuring routing policies."

RIP operation

RIP works as follows:

1. RIP sends request messages to neighboring routers. Neighboring routers return response messages that contain their routing tables.
2. RIP uses the received responses to update the local routing table and sends triggered update messages to its neighbors. All RIP routers on the network do this to learn latest routing information.
3. RIP periodically sends the local routing table to its neighbors. After a RIP neighbor receives the message, it updates its routing table, selects optimal routes, and sends an update to other neighbors. RIP ages routes to keep only valid routes.

Routing loop prevention

RIP uses the following mechanisms to prevent routing loops:

- **Counting to infinity**—A destination with a metric value of 16 is considered unreachable. When a routing loop occurs, the metric value of a route will increment to 16 to avoid endless looping.
- **Triggered updates**—RIP immediately advertises triggered updates for topology changes to reduce the possibility of routing loops and to speed up convergence.
- **Split horizon**—Disables RIP from sending routes through the interface where the routes were learned to prevent routing loops and save bandwidth.

- **Poison reverse**—Enables RIP to set the metric of routes received from a neighbor to 16 and sends these routes back to the neighbor. The neighbor can delete such information from its routing table to prevent routing loops.

RIP versions

There are two RIP versions, RIPv1 and RIPv2.

RIPv1 is a classful routing protocol. It advertises messages only through broadcast. RIPv1 messages do not carry mask information, so RIPv1 can only recognize natural networks such as Class A, B, and C. For this reason, RIPv1 does not support discontiguous subnets.

RIPv2 is a classless routing protocol. It has the following advantages over RIPv1:

- Supports route tags to implement flexible route control through routing policies.
- Supports masks, route summarization, and CIDR.
- Supports designated next hops to select the best ones on broadcast networks.
- Supports multicasting route updates so only RIPv2 routers can receive these updates to reduce resource consumption.
- Supports plain text authentication and MD5 authentication to enhance security.

RIPv2 supports two transmission modes: broadcast and multicast. Multicast is the default mode using 224.0.0.9 as the multicast address. An interface operating in RIPv2 broadcast mode can also receive RIPv1 messages.

Protocols and standards

- RFC 1058, *Routing Information Protocol*
- RFC 1723, *RIP Version 2 - Carrying Additional Information*
- RFC 1721, *RIP Version 2 Protocol Analysis*
- RFC 1722, *RIP Version 2 Protocol Applicability Statement*
- RFC 1724, *RIP Version 2 MIB Extension*
- RFC 2082, *RIPv2 MD5 Authentication*
- RFC 2091, *Triggered Extensions to RIP to Support Demand Circuits*
- RFC 2453, *RIP Version 2*

RIP tasks at a glance

To configure RIP, perform the following tasks:

1. Configuring basic RIP
   a. Enabling RIP
   b. (Optional.) Controlling RIP reception and advertisement on interfaces
   c. (Optional.) Configuring a RIP version
   d. Specifying a RIP neighbor

      To enable RIP on a link that does not support broadcast or multicast, you must manually specify a RIP neighbor.
2. (Optional.) Configuring RIP route control
   - Configuring an additional routing metric
   - Configuring RIPv2 route summarization
   - Disabling host route reception

- Advertising a default route
- Configuring received/redistributed route filtering
- Setting a preference for RIP
- Configuring RIP route redistribution

3. (Optional.) Tuning and optimizing RIP networks
   - Setting RIP timers
   - Enabling split horizon and poison reverse
   - Setting the maximum number of RIP ECMP routes
   - Setting the RIP triggered update interval
   - Configuring the RIP packet sending rate
   - Setting the maximum length of RIP packets
   - Setting the DSCP value for outgoing RIP packets
4. (Optional.) Configuring RIP network management
5. Enhancing RIP availability
   - Configuring RIP GR
   - Enabling RIP NSR
   - Configuring BFD for RIP
   - Configuring RIP FRR
6. (Optional.) Enhancing RIP security
   - Enabling zero field check for incoming RIPv1 messages
   - Enabling source IP address check for incoming RIP updates
   - Configuring RIPv2 message authentication

Configuring basic RIP

Restrictions and guidelines for configuring basic RIP

To enable multiple RIP processes on a router, you must specify an ID for each process. A RIP process ID has only local significance. Two RIP routers having different process IDs can also exchange RIP packets.

Enabling RIP

About this task

You can enable RIP on a network and specify a wildcard mask for the network. After that, only the interface attached to the network runs RIP.

Restrictions and guidelines

If you configure RIP settings in interface view before enabling RIP, the settings do not take effect until RIP is enabled.

If a physical interface is attached to multiple networks, you cannot advertise these networks in different RIP processes.

You cannot enable multiple RIP processes on a physical interface.

The **`rip enable`** command takes precedence over the **`network`** command.

Enabling RIP on a network

1. Enter system view.
   system-view
2. Enable RIP and enter RIP view.
   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]
   By default, RIP is disabled.
3. Enable RIP on a network.
   network *network-address* [*wildcard-mask*]
   By default, RIP is disabled on a network.
   The **network** 0.0.0.0 command can enable RIP on all interfaces in a single process, but does not apply to multiple RIP processes.

Enabling RIP on an interface

1. Enter system view.
   system-view
2. Enable RIP and enter RIP view.
   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]
   By default, RIP is disabled.
3. Return to system view.
   quit
4. Enter interface view.
   interface *interface-type interface-number*
5. Enable RIP on the interface.
   rip *process-id* **enable** [**exclude-subip**]
   By default, RIP is disabled on an interface.

Controlling RIP reception and advertisement on interfaces

About this task

You can perform this task to configure the following features:

- Suppressing an interface. The suppressed interface can receive RIP messages but cannot send RIP messages.
- Disabling an interface from sending RIP messages.
- Disabling an interface from receiving RIP messages.

Restrictions and guidelines for RIP reception and advertisement control on interfaces

An interface suppressed by using the **silent-interface** command can only receive RIP messages. It cannot send RIP messages. You can use the **silent-interface all** command to suppress all interfaces. The **silent-interface** command takes precedence over the **rip input** and **rip output** commands.

Suppressing an interface

1. Enter system view.
   system-view
2. Enter RIP view.
   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Suppress an interface.

   silent-interface { *interface-type interface-number* | **all** }

   By default, all RIP-enabled interfaces can send RIP messages.

   The suppressed interface can still receive RIP messages and respond to unicast requests containing unknown ports.

Disabling an interface from receiving RIP messages

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Disable an interface from receiving RIP messages.

   undo rip input

   By default, a RIP-enabled interface can receive RIP messages.

Disabling an interface from sending RIP messages

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Disable an interface from sending RIP messages.

   undo rip output

   By default, a RIP-enabled interface can send RIP messages.

Configuring a RIP version

About this task

You can configure a global RIP version in RIP view or an interface-specific RIP version in interface view.

An interface preferentially uses the interface-specific RIP version. If no interface-specific version is specified, the interface uses the global RIP version. If neither a global nor interface-specific RIP version is configured, the interface sends RIPv1 broadcasts and can receive the following:

- RIPv1 broadcasts and unicasts.
- RIPv2 broadcasts, multicasts, and unicasts.

Procedure

1. Enter system view.

   system-view

2. Specify a RIP version.

   - Execute the following commands in sequence to specify a global RIP version:

     rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

     version { **1** | **2** }

     By default, no global version is specified. An interface sends RIPv1 broadcasts, and can receive RIPv1 broadcasts and unicasts, and RIPv2 broadcasts, multicasts, and unicasts.

   - Execute the following commands in sequence to specify a RIP version on an interface:

     interface *interface-type interface-number*

     rip version { **1** | **2** [**broadcast** | **multicast**] }

By default, no interface-specific RIP version is specified. The interface sends RIPv1 broadcasts, and can receive RIPv1 broadcasts and unicasts, and RIPv2 broadcasts, multicasts, and unicasts.

Specifying a RIP neighbor

About this task

Typically RIP messages are sent in broadcast or multicast. To enable RIP on a link that does not support broadcast or multicast, you must manually specify a RIP neighbor.

Restrictions and guidelines

As a best practice, do not use the **peer** *ip-address* command to specify a directly connected neighbor. The neighbor might receive a route update in both unicast and multicast (or broadcast) messages from the device.

Procedure

1. Enter system view.

   system-view
2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Specify a RIP neighbor.

   peer *ip-address*

   By default, RIP does not unicast updates to any peer.
4. Disable source IP address check on inbound RIP updates.

   undo validate-source-address

   By default, source IP address check is enabled on inbound RIP updates.

   If the specified neighbor is not directly connected, disable source address check on incoming updates.

Configuring RIP route control

Configuring an additional routing metric

About this task

An additional routing metric (hop count) can be added to the metric of an inbound or outbound RIP route.

- An outbound additional metric is added to the metric of a sent route, and it does not change the route's metric in the routing table.
- An inbound additional metric is added to the metric of a received route before the route is added into the routing table, and the route's metric is changed. If the sum of the additional metric and the original metric is greater than 16, the metric of the route is 16.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Specify an inbound additional routing metric.

rip metricin [**route-policy** *route-policy-name*] *value*

By default, the additional metric of an inbound route is 0.

4. Specify an outbound additional routing metric.

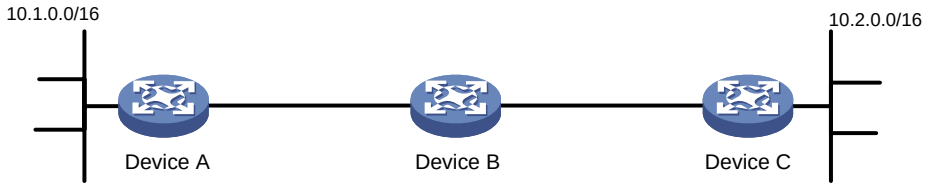
rip metricout [**route-policy** *route-policy-name*] *value*

By default, the additional metric of an outbound route is 1.

Configuring RIPv2 route summarization

About this task

Perform this task to summarize contiguous subnets into a summary network and sends the network to neighbors. The smallest metric among all summarized routes is used as the metric of the summary route.



You can use the following methods to summarize routes in RIPv2:

- **Automatic summarization**—Configure RIPv2 to generate a natural network for contiguous subnets. For example, suppose there are three subnet routes 10.1.1.0/24, 10.1.2.0/24, and 10.1.3.0/24. Automatic summarization automatically creates and advertises a summary route 10.0.0.0/8 instead of the more specific routes.
- **Manual summarization**—Manually configure a summary route. RIPv2 advertises the summary route rather than more specific routes. For example, suppose contiguous subnets routes 10.1.1.0/24, 10.1.2.0/24, and 10.1.3.0/24 exist in the routing table. You can create a summary route 10.1.0.0/16 on GigabitEthernet 1/0/1 to advertise the summary route instead of the more specific routes. By default, natural masks are used to advertise summary routes. To manually configure a summary route on an interface, you must first disable RIPv2 automatic route summarization.

In certain cases, route summarization might result in incorrect route calculation because it disables subnet route advertisement. If the routing table contains non-contiguous subnets, disable automatic route summarization so that RIPv2 can advertise subnet routes and host routes for correct route calculation.

As shown in Figure 1, RIPv2 is enabled on all interfaces on Device A, Device B, and Device C. If automatic route summarization is enabled (default setting), both Device A and Device C will send 10.1.0.0/8 to Device B. To ensure correct route calculation on Device B based on subnets 10.1.0.0/16 and 10.2.0.0/16, disable RIPv2 automatic route summarization.

Figure 1 Disabling RIPv2 automatic route summarization

Restrictions and guidelines

To prevent loops caused by route summarization, create a black hole route by specifying interface NULL 0 as the output interface of the summary route. Packets that match the black hole route are dropped.

Enabling RIPv2 automatic route summarization

1. Enter system view.

system-view

2. Enter RIP view.

rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enable RIPv2 automatic route summarization.

   summary

   By default, RIPv2 automatic route summarization is enabled.

   If subnets in the routing table are not contiguous, disable automatic route summarization to advertise more specific routes.

Advertising a summary route

1. Enter system view.

   system-view

2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Disable RIPv2 automatic route summarization.

   undo summary

   By default, RIPv2 automatic route summarization is enabled.

4. Return to system view.

   quit

5. Enter interface view.

   interface *interface-type interface-number*

6. Configure a summary route.

   rip summary-address *ip-address* { *mask-length* | *mask* }

   By default, no summary route is configured.

Disabling host route reception

About this task

This task disables RIPv2 from receiving host routes from the same network to save network resources. This feature does not apply to RIPv1.

Procedure

1. Enter system view.

   system-view

2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Disable RIP from receiving host routes.

   undo host-route

   By default, RIP receives host routes.

Advertising a default route

About this task

You can advertise a default route on all RIP interfaces in RIP view or on a specific RIP interface in interface view. The interface view setting takes precedence over the RIP view settings.

To disable an interface from advertising a default route, use the **rip default-route no-originate** command on the interface.

The router enabled to advertise a default route does not accept default routes from RIP neighbors.

Procedure

1. Enter system view.

   system-view

2. Advertise a default route.
   - Execute the following commands in sequence to configure RIP to advertise a default route:

     rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

     default-route { **only** | **originate** } [**cost** *cost-value* | **route-policy** *route-policy-name*] *

     By default, RIP does not advertise a default route.
   - Execute the following commands in sequence to configure a RIP interface to advertise a default route:

     interface *interface-type interface-number*

     rip default-route { { **only** | **originate** } [**cost** *cost-value* | **route-policy** *route-policy-name*] * | **no-originate** }

     By default, a RIP interface can advertise a default route if the RIP process is enabled to advertise a default route.

Configuring received/redistributed route filtering

About this task

This task allows you to create a policy to filter received or redistributed routes that match specific criteria such as an ACL, IP prefix list, or routing policy.

Procedure

1. Enter system view.

   system-view

2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Configure the filtering of received routes.

   filter-policy { *ipv4-acl-number* | **gateway** *prefix-list-name* | **prefix-list** *prefix-list-name* [**gateway** *prefix-list-name*] | **route-policy** *route-policy-name* } **import** [*interface-type interface-number*]

   By default, the filtering of received routes is not configured.

   This command filters received routes. Filtered routes are not installed into the routing table or advertised to neighbors.

4. Configure the filtering of redistributed routes.

   filter-policy { *ipv4-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } **export** [*protocol* [*process-id*] | *interface-type interface-number*]

   By default, the filtering of redistributed routes is not configured.

   This command filters redistributed routes, including routes redistributed with the **import-route** command.

Setting a preference for RIP

About this task

If multiple IGPs find routes to the same destination, the route found by the IGP that has the highest priority is selected as the optimal route. Perform this task to assign a preference to RIP. The smaller the preference value, the higher the priority.

Procedure

1. Enter system view.

   system-view
2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Set a preference for RIP.

   preference { *preference* | **route-policy** *route-policy-name* } *

   The default preference for RIP is 100.

Configuring RIP route redistribution

About this task

Perform this task to configure RIP to redistribute routes from other routing protocols, including OSPF, IS-IS, BGP, static, and direct.

Restrictions and guidelines

Only the S5200-HI-G switch series supports the BGP and IS-IS related commands and parameters.

Procedure

1. Enter system view.

   system-view
2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Configure route redistribution.
   - Redistribute routes from BGP.

     import-route bgp [*as-number*] [**allow-ibgp**] [**cost** *cost-value* | **route-policy** *route-policy-name* | **tag** *tag*] *
   - Redistribute direct or static routes.

     import-route { **direct** | **static** } [**cost** *cost-value* | **route-policy** *route-policy-name* | **tag** *tag*] *
   - Redistribute routes from OSPF, IS-IS, or other RIP processes.

     import-route { **isis** | **ospf** | **rip** } [*process-id* | **all-processes**] [**allow-direct** | **cost** *cost-value* | **route-policy** *route-policy-name* | **tag** *tag*] *

   By default, RIP does not redistribute routes.

   This command can redistribute only active routes. To view active routes, use the **display ip routing-table protocol** command.
4. (Optional.) Set a default cost for redistributed routes.

   default cost *cost-value*

   The default cost for redistributed routes is 0.

Tuning and optimizing RIP networks

Setting RIP timers

About this task

You can change the RIP network convergence speed by adjusting the following RIP timers:

- **Update timer**—Specifies the interval between route updates.
- **Timeout timer**—Specifies the route aging time. If no update for a route is received within the aging time, the metric of the route is set to 16.
- **Suppress timer**—Specifies how long a RIP route stays in suppressed state. When the metric of a route is 16, the route enters the suppressed state. A suppressed route can be replaced by an updated route that is received from the same neighbor before the suppress timer expires and has a metric less than 16.
- **Garbage-collect timer**—Specifies the interval from when the metric of a route becomes 16 to when it is deleted from the routing table. RIP advertises the route with a metric of 16. If no update is announced for that route before the garbage-collect timer expires, the route is deleted from the routing table.

Restrictions and guidelines

To avoid unnecessary traffic or route flapping, configure identical RIP timer settings on RIP routers.

Procedure

1. Enter system view.

   system-view

2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Set RIP timers.

   timers { **garbage-collect** *garbage-collect-value* | **suppress** *suppress-value* | **timeout** *timeout-value* | **update** *update-value* } *

   The default settings are as follows:

   - The garbage-collect timer is 120 seconds.
   - The suppress timer is 120 seconds.
   - The timeout timer is 180 seconds.
   - The update timer is 30 seconds.

Enabling split horizon and poison reverse

About this task

The split horizon and poison reverse features can prevent routing loops.

- Split horizon disables RIP from sending routes through the interface where the routes were learned to prevent routing loops between adjacent routers.
- Poison reverse allows RIP to send routes through the interface where the routes were learned. The metric of these routes is always set to 16 (unreachable) to avoid routing loops between neighbors.

Restrictions and guidelines

If both split horizon and poison reverse are configured, only the poison reverse feature takes effect.

Enabling split horizon

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable split horizon.
   rip split-horizon
   By default, split horizon is enabled.

Enabling poison reverse

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable poison reverse.
   rip poison-reverse
   By default, poison reverse is disabled.

Setting the maximum number of RIP ECMP routes

About this task

Perform this task to use ECMP routes to share the load of the RIP network.

Procedure

1. Enter system view.
   system-view
2. Enter RIP view.
   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Set the maximum number of RIP ECMP routes.
   maximum load-balancing *number*
   By default, the maximum number of RIP ECMP routes equals the maximum number of ECMP routes, which is configurable by using the **max-ecmp-num** command.

Setting the RIP triggered update interval

About this task

Perform this task to avoid network overhead and reduce system resource consumption caused by frequent RIP triggered updates.

You can use the **timer triggered** command to set the maximum interval, minimum interval, and incremental interval for sending RIP triggered updates.

- For a stable network, the *minimum-interval* is used.
- If network changes become frequent, the incremental interval *incremental-interval* is used to extend the triggered update sending interval until the *maximum-interval* is reached.

Procedure

1. Enter system view.

system-view

2. Enter RIP view.

   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Set the RIP triggered update interval.

   timer triggered *maximum-interval* [*minimum-interval* [*incremental-interval*]]

   The default settings are as follows:

   - The maximum interval is 5 seconds.
   - The minimum interval is 50 milliseconds.
   - The incremental interval is 200 milliseconds.

Configuring the RIP packet sending rate

About this task

Perform this task to set the interval for sending RIP packets and the maximum number of RIP packets that can be sent at each interval. This feature can avoid excessive RIP packets from affecting system performance and consuming too much bandwidth.

Procedure

1. Enter system view.

   system-view

2. Configure the RIP packet sending rate.

   - Execute the following commands in sequence to configure the RIP packet sending rate for all interfaces:

     rip [*process-id*] [**vpn-instance** *vpn-instance-name*]

     output-delay *time* **count** *count*

     By default, an interface sends up to three RIP packets every 20 milliseconds.

   - Execute the following commands in sequence to configure the RIP packet sending rate for an interface:

     interface *interface-type interface-number*

     rip output-delay *time* **count** *count*

     By default, the interface uses the RIP packet sending rate configured for the RIP process that the interface runs.

Setting the maximum length of RIP packets

About this task

The packet length of RIP packets determines how many routes can be carried in a RIP packet. Set the maximum length of RIP packets to make good use of link bandwidth.

When authentication is enabled, follow these guidelines to ensure packet forwarding:

- For simple authentication, the maximum length of RIP packets must be no less than 52 bytes.
- For MD5 authentication (with packet format defined in RFC 2453), the maximum length of RIP packets must be no less than 56 bytes.
- For MD5 authentication (with packet format defined in RFC 2082), the maximum length of RIP packets must be no less than 72 bytes.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the maximum length of RIP packets.
   rip max-packet-length *value*
   By default, the maximum length of RIP packets is 512 bytes.

Setting the DSCP value for outgoing RIP packets

About this task

The DSCP value specifies the precedence of outgoing packets.

Procedure

1. Enter system view.
   system-view
2. Enter RIP view.
   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Set the DSCP value for outgoing RIP packets.
   dscp *dscp-value*
   By default, the DSCP value for outgoing RIP packets is 48.

Configuring RIP network management

About this task

You can use network management software to manage the RIP process to which MIB is bound.

Procedure

1. Enter system view.
   system-view
2. Bind MIB to a RIP process.
   rip mib-binding *process-id*
   By default, MIB is bound to the RIP process with the smallest process ID.

Configuring RIP GR

About this task

GR ensures forwarding continuity when a routing protocol restarts or an active/standby switchover occurs.

Two routers are required to complete a GR process. The following are router roles in a GR process:

- **GR restarter**—Graceful restarting router. It must have GR capability.
- **GR helper**—A neighbor of the GR restarter. It helps the GR restarter to complete the GR process.

After RIP restarts on a router, the router must learn RIP routes again and update its FIB table, which causes network disconnections and route reconvergence.

With the GR feature, the restarting router (known as the GR restarter) can notify the event to its GR capable neighbors. GR capable neighbors (known as GR helpers) maintain their adjacencies with the router within a GR interval. During this process, the FIB table of the router does not change. After the restart, the router contacts its neighbors to retrieve its FIB.

By default, a RIP-enabled device acts as the GR helper. Perform this task on the GR restarter.

Procedure

1. Enter system view.
   system-view
2. Enter RIP view.
   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enable GR for RIP.
   graceful-restart
   By default, RIP GR is disabled.
4. (Optional.) Set the GR interval.
   graceful-restart interval *interval*
   By default, the GR interval is 60 seconds.

Enabling RIP NSR

About this task

Nonstop Routing (NSR) allows the device to back up the routing information from the active RIP process to the standby RIP process. After an active/standby switchover, NSR can complete route regeneration without tearing down adjacencies or impacting forwarding services.

To use RIP NSR, the system must have a minimum of two IRF member devices. NSR ensures nonstop services when RIP has redundant processes on multiple IRF member devices.

In contrast to GR, NSR does not require a neighbor device to recover routing information.

Restrictions and guidelines

When both GR and NSR are configured for RIP, the following rules apply:

- NSR has a higher priority than GR. When the active RIP process goes down, the device does not act as the GR restarter and performs RIP NSR to ensure nonstop forwarding.
- The device can participate in a GR process only when it acts as the GR helper. If it performs an active/standby RIP process switchover before the GR process finishes, the GR process might fail even if RIP NSR is enabled on the device.

Procedure

1. Enter system view.
   system-view
2. Enter RIP view.
   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enable RIP NSR.
   non-stop-routing
   By default, RIP NSR is disabled.
   RIP NSR enabled for a RIP process takes effect only on that process. As a best practice, enable RIP NSR for each process if multiple RIP processes exist.

Configuring BFD for RIP

About BFD for RIP

RIP detects route failures by periodically sending requests. If it receives no response for a route within a certain time, RIP considers the route unreachable. To speed up convergence, perform this task to enable BFD for RIP. For more information about BFD, see *High Availability Configuration Guide*.

RIP supports the following BFD detection modes:

- **Single-hop echo detection**—Detection mode for a directly connected neighbor. In this mode, a BFD session is established only when the directly connected neighbor has route information to send.
- **Single-hop echo detection for a specific destination**—Detection mode for a directly connected neighbor. In this mode, a BFD session is established to the specified RIP neighbor when RIP is enabled on the local interface. When BFD detects a unidirectional link, the local device will not receive or send any RIP packets through the interface to improve convergence speed. When the link recovers, the interface can send RIP packets again.
- **Bidirectional control detection**—Detection mode for both directly and indirectly connected neighbors. In this mode, a BFD session is established only when both ends have routes to send and BFD is enabled on the receiving interface.

Restrictions and guidelines

The **rip bfd enable** and **rip bfd enable destination** commands are mutually exclusive.

Configuring single-hop echo detection (for a directly connected RIP neighbor)

1. Enter system view.

   system-view
2. Configure the source IP address of BFD echo packets.

   bfd echo-source-ip *ip-address*

   By default, the source IP address of BFD echo packets is not configured.

   As a best practice, configure this command and do not specify a source IP address on the same network segment as any local interfaces. This can avoid network congestion caused by a large number of ICMP redirect packets sent from the peer.

   For more information about this command, see *High Availability Command Reference*.
3. Enter interface view.

   interface *interface-type interface-number*
4. Enable BFD for RIP.

   rip bfd enable

   By default, BFD for RIP is disabled.

Configuring single-hop echo detection (for a specific destination)

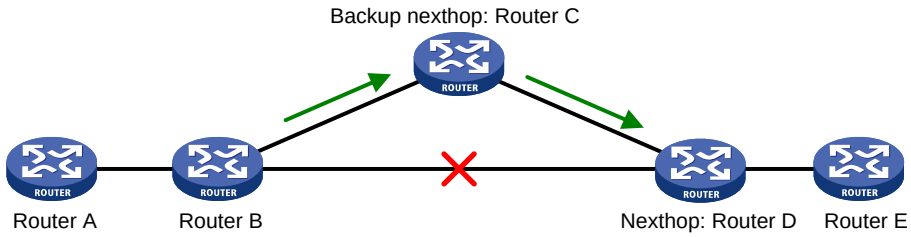
Restrictions and guidelines

This feature applies only to RIP neighbors that are directly connected.

Procedure

1. Enter system view.
   system-view
2. Configure the source IP address of BFD echo packets.
   bfd echo-source-ip *ip-address*
   By default, no source IP address is configured for BFD echo packets.
   As a best practice, configure this command and do not specify a source IP address on the same network segment as any local interfaces. This can avoid network congestion caused by a large number of ICMP redirect packets sent from the peer.
   For more information about this command, see *High Availability Command Reference*.
3. Enter interface view.
   interface *interface-type interface-number*
4. Enable BFD for RIP.
   rip bfd enable destination *ip-address*
   By default, BFD for RIP is disabled.

Configuring bidirectional control detection



1. Enter system view.
   system-view
2. Enter RIP view.
   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Specify a RIP neighbor.
   peer *ip-address*
   By default, RIP does not unicast updates to any peer.
   Because the **undo peer** command does not remove the neighbor relationship immediately, executing the command cannot bring down the BFD session immediately.
4. Enter interface view.
   interface *interface-type interface-number*
5. Enable BFD for RIP.
   rip bfd enable [**ctrl**]
   By default, BFD for RIP is disabled.

Configuring RIP FRR

About RIP FRR

A link or router failure on a path can cause packet loss and even routing loop until RIP completes routing convergence based on the new network topology. FRR enables fast rerouting to minimize the impact of link or node failures.

Figure 2 Network diagram for RIP FRR

As shown in Figure 2, configure FRR on Router B by using a routing policy to specify a backup next hop. When the primary link fails, RIP directs packets to the backup next hop. At the same time, RIP calculates the shortest path based on the new network topology, and forwards packets over that path after network convergence.

Restrictions and guidelines for RIP FRR

RIP FRR takes effect only for RIP routes learned from directly connected neighbors.

RIP FRR is available only when the state of primary link (with Layer 3 interfaces staying up) changes from bidirectional to unidirectional or down.

Equal-cost routes do not support RIP FRR.

Enabling RIP FRR

1. Enter system view.
   `system-view`
2. Configure a routing policy for FRR.
   You must specify a next hop by using the **`apply fast-reroute backup-interface`** command in the routing policy.
   For more information about routing policy configuration, see "Configuring routing policies."
3. Enter RIP view.
   `rip` [*`process-id`*] [**`vpn-instance`** *`vpn-instance-name`*]
4. Enable RIP FRR.
   `fast-reroute route-policy` *`route-policy-name`*
   By default, RIP FRR is disabled.

Enabling BFD for RIP FRR

About this task

By default, RIP FRR does not use BFD to detect primary link failures. For quicker RIP FRR, use BFD single-hop echo detection on the primary link of redundant links to detect link failure.

Procedure

1. Enter system view.
   system-view
2. Configure the source IP address of BFD echo packets.
   bfd echo-source-ip *ip-address*
   By default, the source IP address of BFD echo packets is not configured.
   As a best practice, configure this command and do not specify a source IP address on the same network segment as any local interfaces. This can avoid network congestion caused by a large number of ICMP redirect packets sent from the peer.
   Execute this command only when configuring echo-packet-mode BFD sessions.
   For more information about this command, see *High Availability Command Reference*.
3. Enter interface view.
   interface *interface-type interface-number*
4. Enable BFD for RIP FRR.
   rip primary-path-detect bfd { **ctrl** | **echo** }
   By default, BFD for RIP FRR is disabled.

Enhancing RIP security

Enabling zero field check for incoming RIPv1 messages

About this task

Some fields in the RIPv1 message must be set to zero. These fields are called "zero fields." You can enable zero field check for incoming RIPv1 messages. If a zero field of a message contains a non-zero value, RIP does not process the message. If you are certain that all messages are trustworthy, disable zero field check to save CPU resources.

This feature does not apply to RIPv2 packets, because they have no zero fields.

Procedure

1. Enter system view.
   system-view
2. Enter RIP view.
   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enable zero field check for incoming RIPv1 messages.
   checkzero
   By default, zero field check is disabled for incoming RIPv1 messages.

Enabling source IP address check for incoming RIP updates

About this task

Perform this task to enable source IP address check for incoming RIP updates.

Upon receiving a message on an Ethernet interface, RIP compares the source IP address of the message with the IP address of the interface. If they are not in the same network segment, RIP discards the message.

Upon receiving a message on a PPP interface, RIP checks whether the source address of the message is the IP address of the peer interface. If not, RIP discards the message.

Procedure

1. Enter system view.
   system-view
2. Enter RIP view.
   rip [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enable source IP address check for incoming RIP messages.
   validate-source-address
   By default, source IP address check is disabled for incoming RIP updates.

Configuring RIPv2 message authentication

About this task

Perform this task to enable authentication on RIPv2 messages.

RIPv2 supports simple authentication, MD5 authentication, and keychain authentication.

- **Simple authentication**—As a best practice, do not configure the simple authentication mode in network requirements with high security requirements, because the passwords are sent with authentication packets.
- **MD5 authentication**—Uses MD5 passwords to perform packet encryption and decryption. This authentication method is securer than the simple authentication mode.
- **Keychain authentication**—Uses keychains to perform dynamic authentication. For more information about keychains, see keychain configuration in *Security Configuration Guide*.

Procedure

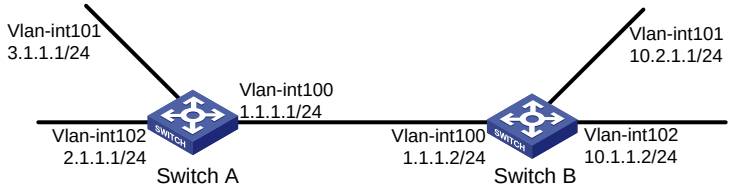
1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure RIPv2 authentication.
   rip authentication-mode { **keychain** *keychain-name* { **rfc2453** | **rfc4822** } | **md5** { **rfc2082** { **cipher** | **plain** } *string key-id* | **rfc2453** { **cipher** | **plain** } *string* } | **simple** { **cipher** | **plain** } *string* }
   By default, RIPv2 authentication is not configured.
   RIPv1 does not support authentication. Although you can specify an authentication mode for RIPv1 in interface view, the configuration does not take effect.
   For more information about keychains, see keychain configuration in *Security Configuration Guide*.

Display and maintenance commands for RIP

Execute **display** commands in any view and execute **reset** commands in user view.

Task	Command
Display RIP current status and configuration information.	**display rip** [*process-id*]
Display RIP GR information.	**display rip** [*process-id*] **graceful-restart**

Task	Command
Display RIP NSR information.	**display rip** [*process-id*] **non-stop-routing**
Display active routes in the RIP database.	**display rip** *process-id* **database** [*ip-address* { *mask-length* | *mask* }]
Display RIP interface information.	**display rip** *process-id* **interface** [*interface-type interface-number*]
Display neighbor information for a RIP process.	**display rip** *process-id* **neighbor** [*interface-type interface-number*]
Display routing information for a RIP process.	**display rip** *process-id* **route** [*ip-address* { *mask-length* | *mask* } [**verbose**] | **peer** *ip-address* | **statistics**]
Reset a RIP process.	**reset rip** *process-id* **process**
Clear the statistics for a RIP process.	**reset rip** *process-id* **statistics**



RIP configuration examples

Example: Configuring basic RIP

Network configuration

As shown in Figure 3, enable RIPv2 on all interfaces on Switch A and Switch B. Configure Switch B to not advertise route 10.2.1.0/24 to Switch A, and to accept only route 2.1.1.0/24 from Switch A.

Figure 3 Network diagram

Procedure

1. Configure IP addresses for the interfaces. (Details not shown.)
2. Enable RIP.

   # Enable RIP on the specified networks on Switch A.

```
<SwitchA> system-view
[SwitchA] rip
[SwitchA-rip-1] network 1.0.0.0
[SwitchA-rip-1] network 2.0.0.0
[SwitchA-rip-1] network 3.0.0.0
[SwitchA-rip-1] quit
```

   # Enable RIP on the specified interfaces on Switch B.

```
<SwitchB> system-view
[SwitchB] rip
```

```
[SwitchB-rip-1] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] rip 1 enable
[SwitchB-Vlan-interface100] quit
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] rip 1 enable
[SwitchB-Vlan-interface101] quit
[SwitchB] interface vlan-interface 102
[SwitchB-Vlan-interface102] rip 1 enable
[SwitchB-Vlan-interface102] quit
```

Display the RIP routing table of Switch A.

```
[SwitchA] display rip 1 route
 Route Flags: R - RIP, T - TRIP
              P - Permanent, A - Aging, S - Suppressed, G - Garbage-collect
              D - Direct, O - Optimal, F - Flush to RIB
------------------------------------------------------------------------------
 Peer 1.1.1.2 on Vlan-interface100
      Destination/Mask        Nexthop          Cost    Tag     Flags   Sec
      10.0.0.0/8              1.1.1.2          1       0       RAOF    11
 Local route
      Destination/Mask        Nexthop          Cost    Tag     Flags   Sec
      1.1.1.0/24              0.0.0.0          0       0       RDOF    -
      2.1.1.0/24              0.0.0.0          0       0       RDOF    -
      3.1.1.0/24              0.0.0.0          0       0       RDOF    -
```

The output shows that RIPv1 uses a natural mask.

3. Configure a RIP version:

Configure RIPv2 on Switch A.

```
[SwitchA] rip
[SwitchA-rip-1] version 2
[SwitchA-rip-1] undo summary
[SwitchA-rip-1] quit
```

Configure RIPv2 on Switch B.

```
[SwitchB] rip
[SwitchB-rip-1] version 2
[SwitchB-rip-1] undo summary
[SwitchB-rip-1] quit
```

Display the RIP routing table on Switch A.

```
[SwitchA] display rip 1 route
 Route Flags: R - RIP, T - TRIP
              P - Permanent, A - Aging, S - Suppressed, G - Garbage-collect
              D - Direct, O - Optimal, F - Flush to RIB
------------------------------------------------------------------------------

 Peer 1.1.1.2 on Vlan-interface100
      Destination/Mask        Nexthop          Cost    Tag     Flags   Sec
      10.0.0.0/8              1.1.1.2          1       0       RAOF    50
      10.2.1.0/24             1.1.1.2          1       0       RAOF    16
      10.1.1.0/24             1.1.1.2          1       0       RAOF    16
```

```
 Local route
      Destination/Mask        Nexthop          Cost    Tag     Flags   Sec
      1.1.1.0/24              0.0.0.0          0       0       RDOF    -
      2.1.1.0/24              0.0.0.0          0       0       RDOF    -
      3.1.1.0/24              0.0.0.0          0       0       RDOF    -
```

The output shows that RIPv2 uses classless subnet masks.

NOTE:

After RIPv2 is configured, RIPv1 routes might still exist in the routing table until they are aged out.

Display the RIP routing table on Switch B.

```
[SwitchB] display rip 1 route
 Route Flags: R - RIP, T - TRIP
              P - Permanent, A - Aging, S - Suppressed, G - Garbage-collect
              D - Direct, O - Optimal, F - Flush to RIB
------------------------------------------------------------------------------
 Peer 1.1.1.1 on Vlan-interface100
      Destination/Mask        Nexthop          Cost    Tag     Flags   Sec
      2.1.1.0/24              1.1.1.1          1       0       RAOF    19
      3.1.1.0/24              1.1.1.1          1       0       RAOF    19
 Local route
      Destination/Mask        Nexthop          Cost    Tag     Flags   Sec
      1.1.1.0/24              0.0.0.0          0       0       RDOF    -
      10.1.1.0/24             0.0.0.0          0       0       RDOF    -
      10.2.1.0/24             0.0.0.0          0       0       RDOF    -
```

4. Configure route filtering:

Reference IP prefix lists on Switch B to filter received and redistributed routes.

```
[SwitchB] ip prefix-list aaa index 10 permit 2.1.1.0 24
[SwitchB] ip prefix-list bbb index 10 deny 10.2.1.0 24
[SwitchB] ip prefix-list bbb index 11 permit 0.0.0.0 0 less-equal 32
[SwitchB] rip 1
[SwitchB-rip-1] filter-policy prefix-list aaa import
[SwitchB-rip-1] filter-policy prefix-list bbb export
[SwitchB-rip-1] quit
```

Display the RIP routing table on Switch A.

```
[SwitchA] display rip 100 route
 Route Flags: R - RIP, T - TRIP

```

Example: Configuring RIP route redistribution

Network configuration

As shown in Figure 4, Switch B communicates with Switch A through RIP 100 and with Switch C through RIP 200.

Configure RIP 200 to redistribute direct routes and routes from RIP 100 on Switch B so Switch C can learn routes destined for 10.2.1.0/24 and 11.1.1.0/24. Switch A cannot learn routes destined for 12.3.1.0/24 and 16.4.1.0/24.

Figure 4 Network diagram

Procedure

1. Configure IP addresses for the interfaces. (Details not shown.)
2. Configure basic RIP settings:

   # Enable RIP 100, and configure RIPv2 on Switch A.

   ```
   <SwitchA> system-view
   [SwitchA] rip 100
   [SwitchA-rip-100] network 10.0.0.0
   [SwitchA-rip-100] network 11.0.0.0
   [SwitchA-rip-100] version 2
   [SwitchA-rip-100] undo summary
   [SwitchA-rip-100] quit
   ```

   # Enable RIP 100 and RIP 200, and configure RIPv2 on Switch B.

   ```
   <SwitchB> system-view
   [SwitchB] rip 100
   [SwitchB-rip-100] network 11.0.0.0
   ```

```
[SwitchB-rip-100] version 2
[SwitchB-rip-100] undo summary
[SwitchB-rip-100] quit
[SwitchB] rip 200
[SwitchB-rip-200] network 12.0.0.0
[SwitchB-rip-200] version 2
[SwitchB-rip-200] undo summary
[SwitchB-rip-200] quit
```

Enable RIP 200, and configure RIPv2 on Switch C.

```
<SwitchC> system-view
[SwitchC] rip 200
[SwitchC-rip-200] network 12.0.0.0
[SwitchC-rip-200] network 16.0.0.0
[SwitchC-rip-200] version 2
[SwitchC-rip-200] undo summary
[SwitchC-rip-200] quit
```

Display the IP routing table on Switch C.

```
[SwitchC] display ip routing-table

Destinations : 13        Routes : 13

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
0.0.0.0/32          Direct 0    0            127.0.0.1       InLoop0

12.3.1.255/32       Direct 0    0            12.3.1.2        Vlan200
16.4.1.0/24         Direct 0    0            16.4.1.1        Vlan400
16.4.1.0/32         Direct 0    0            16.4.1.1        Vlan400
16.4.1.1/32         Direct 0    0            127.0.0.1       InLoop0
16.4.1.255/32       Direct 0    0            16.4.1.1        Vlan400
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.0/32        Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
127.255.255.255/32  Direct 0    0            127.0.0.1       InLoop0
```

3. Configure route redistribution:

Configure RIP 200 to redistribute routes from RIP 100 and direct routes on Switch B.

```
[SwitchB] rip 200
[SwitchB-rip-200] import-route rip 100
[SwitchB-rip-200] import-route direct
[SwitchB-rip-200] quit
```

Display the IP routing table on Switch C.

```
[SwitchC] display ip routing-table

Destinations : 15        Routes : 15

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
0.0.0.0/32          Direct 0    0            127.0.0.1       InLoop0
```

```
10.2.1.0/24         RIP    100  1           12.3.1.1        Vlan200
11.1.1.0/24         RIP    100  1           12.3.1.1        Vlan200

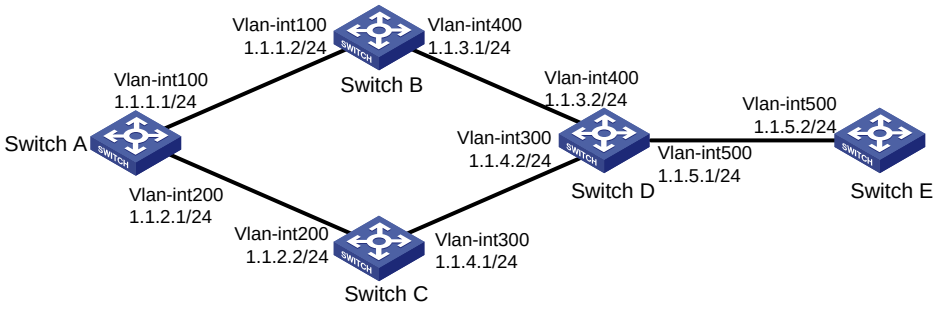
12.3.1.2/32         Direct 0    0           127.0.0.1       InLoop0
12.3.1.255/32       Direct 0    0           12.3.1.2        Vlan200
16.4.1.0/24         Direct 0    0           16.4.1.1        Vlan400
16.4.1.0/32         Direct 0    0           16.4.1.1        Vlan400
16.4.1.1/32         Direct 0    0           127.0.0.1       InLoop0
16.4.1.255/32       Direct 0    0           16.4.1.1        Vlan400
127.0.0.0/8         Direct 0    0           127.0.0.1       InLoop0
127.0.0.0/32        Direct 0    0           127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0           127.0.0.1       InLoop0
127.255.255.255/32  Direct 0    0           127.0.0.1       InLoop0
```



Example: Configuring an additional metric for a RIP interface

Network configuration

As shown in Figure 5, run RIPv2 on all the interfaces of Switch A, Switch B, Switch C, Switch D, and Switch E.

Switch A has two links to Switch D. The link from Switch B to Switch D is more stable than that from Switch C to Switch D. Configure an additional metric for RIP routes received from VLAN-interface 200 on Switch A so Switch A prefers route 1.1.5.0/24 learned from Switch B.

Figure 5 Network diagram

Procedure

1. Configure IP addresses for the interfaces. (Details not shown.)
2. Configure basic RIP settings:

   # Configure Switch A.

   ```
   <SwitchA> system-view
   [SwitchA] rip 1
   [SwitchA-rip-1] network 1.0.0.0
   [SwitchA-rip-1] version 2
   [SwitchA-rip-1] undo summary
   [SwitchA-rip-1] quit
   ```

   # Configure Switch B.

   ```
   <SwitchB> system-view
   [SwitchB] rip 1
   [SwitchB-rip-1] network 1.0.0.0
   ```

```
[SwitchB-rip-1] version 2
[SwitchB-rip-1] undo summary
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchB] rip 1
[SwitchC-rip-1] network 1.0.0.0
[SwitchC-rip-1] version 2
[SwitchC-rip-1] undo summary
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] rip 1
[SwitchD-rip-1] network 1.0.0.0
[SwitchD-rip-1] version 2
[SwitchD-rip-1] undo summary
```

Configure Switch E.

```
<SwitchE> system-view
[SwitchE] rip 1
[SwitchE-rip-1] network 1.0.0.0
[SwitchE-rip-1] version 2
[SwitchE-rip-1] undo summary
```

Display all active routes in the RIP database on Switch A.

```
[SwitchA] display rip 1 database
   1.0.0.0/8, auto-summary
       1.1.1.0/24, cost 0, nexthop 1.1.1.1, RIP-interface
       1.1.2.0/24, cost 0, nexthop 1.1.2.1, RIP-interface
       1.1.3.0/24, cost 1, nexthop 1.1.1.2
       1.1.4.0/24, cost 1, nexthop 1.1.2.2
       1.1.5.0/24, cost 2, nexthop 1.1.1.2
       1.1.5.0/24, cost 2, nexthop 1.1.2.2
```

The output shows two RIP routes destined for network 1.1.5.0/24, with the next hops as Switch B (1.1.1.2) and Switch C (1.1.2.2), and with the same cost of 2.

3. Configure an additional metric for a RIP interface:

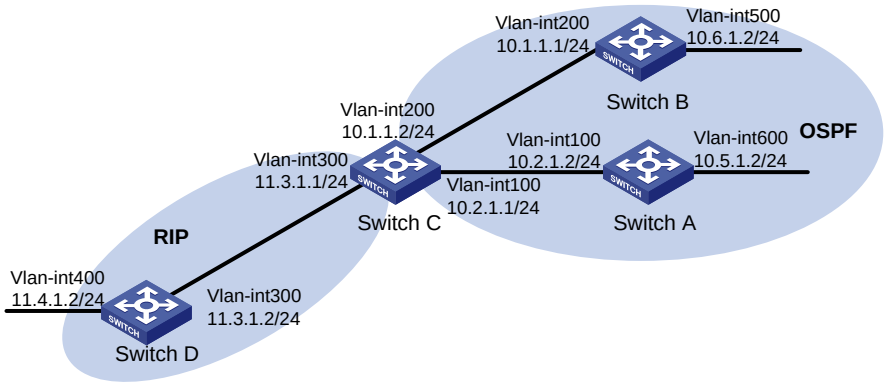
Configure an inbound additional metric of 3 for RIP-enabled interface VLAN-interface 200 on Switch A.

```
[SwitchA] interface vlan-interface 200
[SwitchA-Vlan-interface200] rip metricin 3
```

Display all active routes in the RIP database on Switch A.

```
[SwitchA-Vlan-interface200] display rip 1 database
   1.0.0.0/8, auto-summary
       1.1.1.0/24, cost 0, nexthop 1.1.1.1, RIP-interface
       1.1.2.0/24, cost 0, nexthop 1.1.2.1, RIP-interface
       1.1.3.0/24, cost 1, nexthop 1.1.1.2
       1.1.4.0/24, cost 2, nexthop 1.1.1.2
       1.1.5.0/24, cost 2, nexthop 1.1.1.2
```

The output shows that only one RIP route reaches network 1.1.5.0/24, with the next hop as Switch B (1.1.1.2) and a cost of 2.



Example: Configuring RIP to advertise a summary route

Network configuration

As shown in Figure 6, Switch A and Switch B run OSPF, Switch D runs RIP, and Switch C runs OSPF and RIP. Configure RIP to redistribute OSPF routes on Switch C so Switch D can learn routes destined for networks 10.1.1.0/24, 10.2.1.0/24, 10.5.1.0/24, and 10.6.1.0/24.

To reduce the routing table size of Switch D, configure route summarization on Switch C to advertise only the summary route 10.0.0.0/8 to Switch D.

Figure 6 Network diagram

Procedure

1. Configure IP addresses for the interfaces. (Details not shown.)
2. Configure basic OSPF settings:

   # Configure Switch A.

   ```
   <SwitchA> system-view
   [SwitchA] ospf
   [SwitchA-ospf-1] area 0
   [SwitchA-ospf-1-area-0.0.0.0] network 10.5.1.0 0.0.0.255
   [SwitchA-ospf-1-area-0.0.0.0] network 10.2.1.0 0.0.0.255
   [SwitchA-ospf-1-area-0.0.0.0] quit
   ```

   # Configure Switch B.

   ```
   <SwitchB> system-view
   [SwitchB] ospf
   [SwitchB-ospf-1] area 0
   [SwitchB-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
   [SwitchB-ospf-1-area-0.0.0.0] network 10.6.1.0 0.0.0.255
   [SwitchB-ospf-1-area-0.0.0.0] quit
   ```

   # Configure Switch C.

   ```
   <SwitchC> system-view
   [SwitchC] ospf
   [SwitchC-ospf-1] area 0
   [SwitchC-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
   [SwitchC-ospf-1-area-0.0.0.0] network 10.2.1.0 0.0.0.255
   [SwitchC-ospf-1-area-0.0.0.0] quit
   [SwitchC-ospf-1] quit
   ```

3. Configure basic RIP settings:

Configure Switch C.

```
[SwitchC] rip 1
[SwitchC-rip-1] network 11.3.1.0
[SwitchC-rip-1] version 2
[SwitchC-rip-1] undo summary
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] rip 1
[SwitchD-rip-1] network 11.0.0.0
[SwitchD-rip-1] version 2
[SwitchD-rip-1] undo summary
[SwitchD-rip-1] quit
```

Configure RIP to redistribute routes from OSPF process 1 and direct routes on Switch C.

```
[SwitchC-rip-1] import-route direct
[SwitchC-rip-1] import-route ospf 1
[SwitchC-rip-1] quit
```

Display the IP routing table on Switch D.

```
[SwitchD] display ip routing-table

Destinations : 15        Routes : 15

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
0.0.0.0/32          Direct 0    0            127.0.0.1       InLoop0
10.1.1.0/24         RIP    100  1            11.3.1.1        Vlan300

```

Example: Configuring RIP GR

Network configuration

As shown in Figure 7, Switch A, Switch B, and Switch C all run RIPv2.

- Enable GR on Switch A. Switch A acts as the GR restarter.
- Switch B and Switch C act as GR helpers to synchronize their routing tables with Switch A by using GR.

Figure 7 Network diagram

Procedure

1. Configure IP addresses and subnet masks for the interfaces on the switches. (Details not shown.)
2. Configure RIPv2 on the switches to ensure the following: (Details not shown.)
   - Switch A, Switch B, and Switch C can communicate with each other at Layer 3.
   - Dynamic route update can be implemented among them with RIPv2.
3. Enable RIP GR on Switch A.

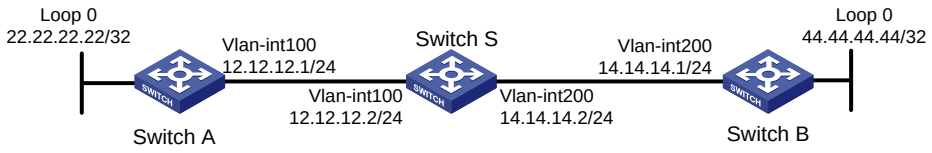
```
<SwitchA> system-view
[SwitchA] rip
[SwitchA-rip-1] graceful-restart
```

Verifying the configuration

Restart RIP or trigger an active/standby switchover, and then display GR status on Switch A.

```
<SwitchA> display rip graceful-restart
 RIP process: 1
 Graceful Restart capability     : Enabled
```

```
Current GR state                : Normal
Graceful Restart period         : 60  seconds
Graceful Restart remaining time : 0   seconds
```



Example: Configuring RIP NSR

Network configuration

As shown in Figure 8, Switch A, Switch B, and Switch S all run RIPv2.

Enable RIP NSR on Switch S to ensure correct routing when an active/standby switchover occurs on Switch S.

Figure 8 Network diagram

Procedure

1. Configure IP addresses and subnet masks for the interfaces on the switches. (Details not shown.)
2. Configure RIPv2 on the switches to ensure the following: (Details not shown.)
   - Switch A, Switch B, and Switch S can communicate with each other at Layer 3.
   - Dynamic route update can be implemented among them with RIPv2.
3. Enable RIP NSR.

   # Enable RIP NSR on Switch S.

   ```
   <SwitchS> system-view
   [SwitchS] rip 100
   [SwitchS-rip-100] non-stop-routing
   [SwitchS-rip-100] quit
   ```

Verifying the configuration

Perform an active/standby switchover on Switch S.

```

```

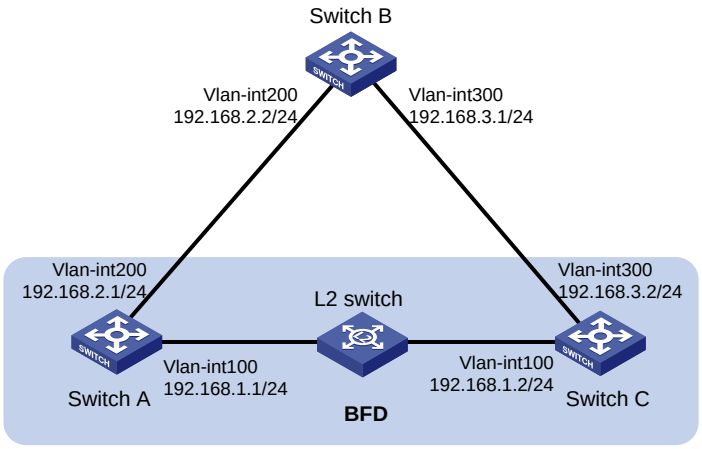
The output shows that the neighbor and route information on Switch A and Switch B keep unchanged during the active/standby switchover on Switch S. The traffic from Switch A to Switch B has not been impacted.



Example: Configuring BFD for RIP (single-hop echo detection for a directly connected neighbor)

Network configuration

As shown in Figure 9, VLAN-interface 100 of Switch A and Switch C runs RIP process 1. VLAN-interface 200 of Switch A runs RIP process 2. VLAN-interface 300 of Switch C and VLAN-interface 200 and VLAN-interface 300 of Switch B run RIP process 1.

- Configure a static route destined for 100.1.1.1/24 and enable static route redistribution into RIP on Switch C. This allows Switch A to learn two routes destined for 100.1.1.1/24 through VLAN-interface 100 and VLAN-interface 200 respectively, and uses the one through VLAN-interface 100.
- Enable BFD for RIP on VLAN-interface 100 of Switch A. When the link over VLAN-interface 100 fails, BFD can quickly detect the failure and notify RIP. RIP deletes the neighbor relationship and route information learned on VLAN-interface 100, and uses the route destined for 100.1.1.1 24 through VLAN-interface 200.

Figure 9 Network diagram

Procedure

1. Configure IP addresses for the interfaces. (Details not shown.)
2. Configure basic RIP settings:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] rip 1
[SwitchA-rip-1] version 2
[SwitchA-rip-1] undo summary
[SwitchA-rip-1] network 192.168.1.0
[SwitchA-rip-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] rip bfd enable
[SwitchA-Vlan-interface100] quit
[SwitchA] rip 2
[SwitchA-rip-2] version 2
[SwitchA-rip-2] undo summary
[SwitchA-rip-2] network 192.168.2.0
[SwitchA-rip-2] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] rip 1
[SwitchB-rip-1] version 2
[SwitchB-rip-1] undo summary
[SwitchB-rip-1] network 192.168.2.0
[SwitchB-rip-1] network 192.168.3.0
[SwitchB-rip-1] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] rip 1
[SwitchC-rip-1] version 2
[SwitchC-rip-1] undo summary
[SwitchC-rip-1] network 192.168.1.0
[SwitchC-rip-1] network 192.168.3.0
[SwitchC-rip-1] import-route static
[SwitchC-rip-1] quit
```

3. Configure BFD parameters on VLAN-interface 100 of Switch A.

```
[SwitchA] bfd echo-source-ip 11.11.11.11
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] bfd min-echo-receive-interval 500
[SwitchA-Vlan-interface100] bfd detect-multiplier 7
[SwitchA-Vlan-interface100] quit
```

4. Configure a static route on Switch C.

```
[SwitchC] ip route-static 120.1.1.0 24 null 0
```

Verifying the configuration

Display the BFD session information on Switch A.

```
<SwitchA> display bfd session
 Total sessions: 1        Up sessions: 1        Init mode: Active

 IPv4 session working in echo mode:

 LD               SourceAddr      DestAddr        State  Holdtime    Interface
 4                192.168.1.1     192.168.1.2     Up     2000ms      Vlan100
```

Display RIP routes destined for 120.1.1.0/24 on Switch A.

```
<SwitchA> display ip routing-table 120.1.1.0 24

Summary count : 1

Destination/Mask   Proto   Pre Cost        NextHop         Interface
120.1.1.0/24       RIP     100 1           192.168.1.2     Vlan-interface100
```

The output shows that Switch A communicates with Switch C through VLAN-interface 100. Then the link over VLAN-interface 100 fails.

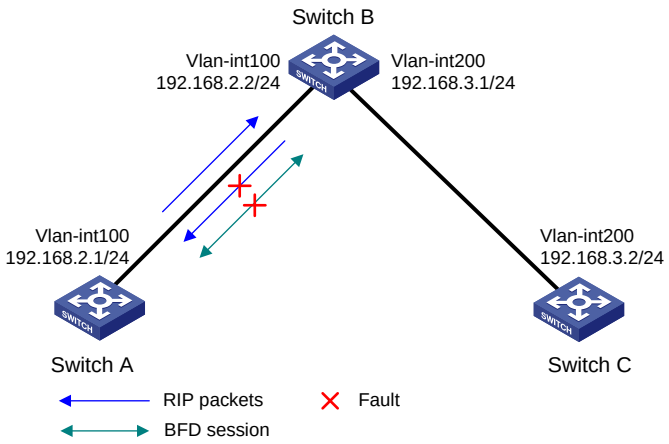
Display RIP routes destined for 120.1.1.0/24 on Switch A.

```
<SwitchA> display ip routing-table 120.1.1.0 24

Summary count : 1
```

```
Destination/Mask    Proto   Pre Cost        NextHop         Interface
120.1.1.0/24        RIP     100 1           192.168.2.2     Vlan-interface200
```

The output shows that Switch A communicates with Switch C through VLAN-interface 200.



Example: Configuring BFD for RIP (single hop echo detection for a specific destination)

Network configuration

As shown in Figure 10, VLAN-interface 100 of Switch A and Switch B runs RIP process 1. VLAN-interface 200 of Switch B and Switch C runs RIP process 1.

- Configure a static route destined for 100.1.1.0/24 and enable static route redistribution into RIP on both Switch A and Switch C. This allows Switch B to learn two routes destined for 100.1.1.0/24 through VLAN-interface 100 and VLAN-interface 200. The route redistributed from Switch A has a smaller cost than that redistributed from Switch C, so Switch B uses the route through VLAN-interface 200.
- Enable BFD for RIP on VLAN-interface 100 of Switch A, and specify VLAN-interface 100 of Switch B as the destination. When a unidirectional link occurs between Switch A and Switch B, BFD can quickly detect the link failure and notify RIP. Switch B then deletes the neighbor relationship and the route information learned on VLAN-interface 100. It does not receive or send any packets from VLAN-interface 100. When the route learned from Switch A ages out, Switch B uses the route destined for 100.1.1.1 24 through VLAN-interface 200.

Figure 10 Network diagram

Procedure

1. Configure IP addresses for the interfaces. (Details not shown.)
2. Configure basic RIP settings and enable BFD on the interfaces:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] rip 1
[SwitchA-rip-1] network 192.168.2.0
[SwitchA-rip-1] import-route static
[SwitchA-rip-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] rip bfd enable destination 192.168.2.2
```

```
[SwitchA-Vlan-interface100] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] rip 1
[SwitchB-rip-1] network 192.168.2.0
[SwitchB-rip-1] network 192.168.3.0
[SwitchB-rip-1] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] rip 1
[SwitchC-rip-1] network 192.168.3.0
[SwitchC-rip-1] import-route static cost 3
[SwitchC-rip-1] quit
```

3. Configure BFD parameters on VLAN-interface 100 of Switch A.

```
[SwitchA] bfd echo-source-ip 11.11.11.11
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] bfd min-echo-receive-interval 500
[SwitchA-Vlan-interface100] return
```

4. Configure static routes:

Configure a static route on Switch A.

```
[SwitchA] ip route-static 100.1.1.0 24 null 0
```

Configure a static route on Switch C.

```
[SwitchA] ip route-static 100.1.1.0 24 null 0
```

Verifying the configuration

Display BFD session information on Switch A.

```
<SwitchA> display bfd session
 Total sessions: 1        Up sessions: 1        Init mode: Active

 IPv4 session working in echo mode:

 LD               SourceAddr      DestAddr        State  Holdtime    Interface
 3                192.168.2.1     192.168.2.2     Up     2000ms      vlan100
```

Display routes destined for 100.1.1.0/24 on Switch B.

```
<SwitchB> display ip routing-table 100.1.1.0 24 verbose

Summary Count : 1

RealFIRType: Normal           RealThres: 0
```

Example: Configuring BFD for RIP (bidirectional detection in BFD control packet mode)

Network configuration

As shown in Figure 11, VLAN-interface 100 of Switch A and VLAN-interface 200 of Switch C run RIP process 1.

VLAN-interface 300 of Switch A runs RIP process 2. VLAN-interface 400 of Switch C, and VLAN-interface 300 and VLAN-interface 400 of Switch D run RIP process 1.

- Configure a static route destined for 100.1.1.0/24 on Switch A.
- Configure a static route destined for 101.1.1.0/24 on Switch C.
- Enable static route redistribution into RIP on Switch A and Switch C. This allows Switch A to learn two routes destined for 100.1.1.0/24 through VLAN-interface 100 and VLAN-interface 300. It uses the route through VLAN-interface 100.
- Enable BFD on VLAN-interface 100 of Switch A and VLAN-interface 200 of Switch C.

When the link over VLAN-interface 100 fails, BFD can quickly detect the link failure and notify RIP. RIP deletes the neighbor relationship and the route information received learned on VLAN-interface 100. It uses the route destined for 100.1.1.0/24 through VLAN-interface 300.

Figure 11 Network diagram

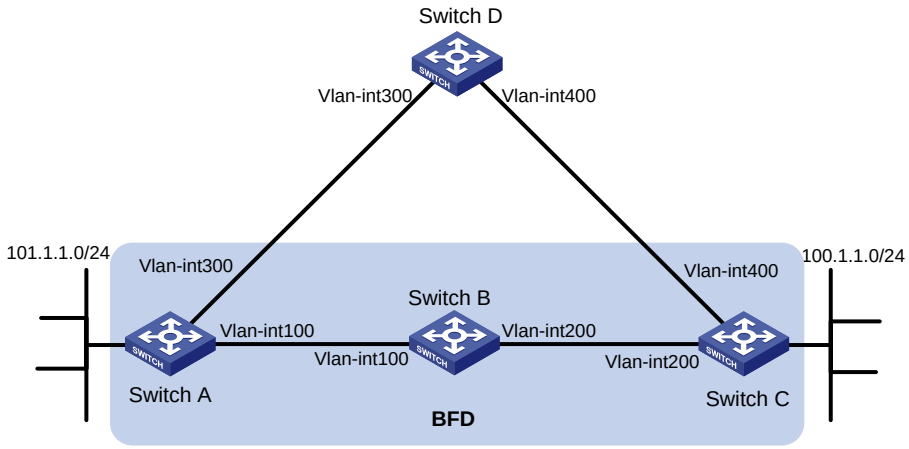

Table 1 Interface and IP address assignment

Device	Interface	IP address
Switch A	VLAN-interface 300	192.168.3.1/24
Switch A	VLAN-interface 100	192.168.1.1/24
Switch B	VLAN-interface 100	192.168.1.2/24
Switch B	VLAN-interface 200	192.168.2.1/24
Switch C	VLAN-interface 200	192.168.2.2/24
Switch C	VLAN-interface 400	192.168.4.2/24
Switch D	VLAN-interface 300	192.168.3.2/24
Switch D	VLAN-interface 400	192.168.4.1/24

Procedure

1. Configure IP addresses for the interfaces. (Details not shown.)
2. Configure basic RIP settings and enable static route redistribution into RIP so Switch A and Switch C have routes to send to each other:

   # Configure Switch A.

   ```
   <SwitchA> system-view
   [SwitchA] rip 1
   [SwitchA-rip-1] version 2
   ```

```
[SwitchA-rip-1] undo summary
[SwitchA-rip-1] network 192.168.1.0
[SwitchA-rip-1] network 101.1.1.0
[SwitchA-rip-1] peer 192.168.2.2
[SwitchA-rip-1] undo validate-source-address
[SwitchA-rip-1] import-route static
[SwitchA-rip-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] rip bfd enable
[SwitchA-Vlan-interface100] quit
[SwitchA] rip 2
[SwitchA-rip-2] version 2
[SwitchA-rip-2] undo summary
[SwitchA-rip-2] network 192.168.3.0
[SwitchA-rip-2] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] rip 1
[SwitchC-rip-1] version 2
[SwitchC-rip-1] undo summary
[SwitchC-rip-1] network 192.168.2.0
[SwitchC-rip-1] network 192.168.4.0
[SwitchC-rip-1] network 100.1.1.0
[SwitchC-rip-1] peer 192.168.1.1
[SwitchC-rip-1] undo validate-source-address
[SwitchC-rip-1] import-route static
[SwitchC-rip-1] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] rip bfd enable
[SwitchC-Vlan-interface200] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] rip 1
[SwitchD-rip-1] version 2
[SwitchD-rip-1] undo summary
[SwitchD-rip-1] network 192.168.3.0
[SwitchD-rip-1] network 192.168.4.0
```

3. Configure BFD parameters:

Configure Switch A.

```
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] bfd min-transmit-interval 500
[SwitchA-Vlan-interface100] bfd min-receive-interval 500
[SwitchA-Vlan-interface100] bfd detect-multiplier 7
[SwitchA-Vlan-interface100] quit
```

Configure Switch C.

```
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] bfd min-transmit-interval 500
[SwitchC-Vlan-interface200] bfd min-receive-interval 500
```

```
[SwitchC-Vlan-interface200] bfd detect-multiplier 7
[SwitchC-Vlan-interface200] quit
```

4. Configure static routes:

   # Configure a static route to Switch C on Switch A.

   ```
   [SwitchA] ip route-static 192.168.2.0 24 vlan-interface 100 192.168.1.2
   ```

   # Configure a static route to Switch A on Switch C.

   ```
   [SwitchC] ip route-static 192.168.1.0 24 vlan-interface 200 192.168.2.1
   ```

Verifying the configuration

Display the BFD session information on Switch A.

```
<SwitchA> display bfd session
 Total sessions: 1        Up sessions: 1        Init mode: Active

 IPv4 session working in control packet mode:

 LD/RD            SourceAddr      DestAddr        State  Holdtime    Interface
 513/513          192.168.1.1     192.168.2.2     Up     1700ms      vlan100
```

Display RIP routes destined for 100.1.1.0/24 on Switch A.

```
<SwitchA> display ip routing-table 100.1.1.0 24

Summary count : 1

Destination/Mask   Proto   Pre Cost        NextHop         Interface
100.1.1.0/24       RIP     100 1           192.168.2.2     vlan-interface 100
```

The output shows that Switch A communicates with Switch C through VLAN-interface 100. Then the link over VLAN-interface 100 fails.

Display RIP routes destined for 100.1.1.0/24 on Switch A.

```
<SwitchA> display ip routing-table 100.1.1.0 24

Summary count : 1

Destination/Mask   Proto   Pre Cost        NextHop         Interface
100.1.1.0/24       RIP     100 2           192.168.3.2     vlan-interface 300
```

The output shows that Switch A communicates with Switch C through VLAN-interface 300.

Example: Configuring RIP FRR

Network configuration

As shown in Figure 12, Switch A, Switch B, and Switch C run RIPv2. Configure RIP FRR so that when Link A becomes unidirectional, services can be switched to Link B immediately.

Figure 12 Network diagram

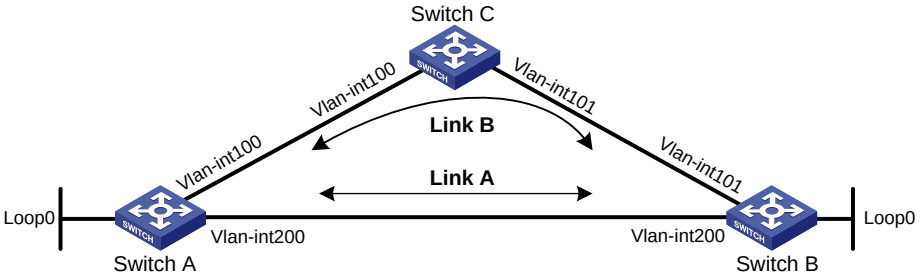

Table 2 Interface and IP address assignment

Device	Interface	IP address
Switch A	VLAN-interface 100	12.12.12.1/24
Switch A	VLAN-interface 200	13.13.13.1/24
Switch A	Loopback 0	1.1.1.1/32
Switch B	VLAN-interface 101	24.24.24.4/24
Switch B	VLAN-interface 200	13.13.13.2/24
Switch B	Loopback 0	4.4.4.4/32
Switch C	VLAN-interface 100	12.12.12.2/24
Switch C	VLAN-interface 101	24.24.24.2/24

Procedure

1. Configure IP addresses and subnet masks for the interfaces on the switches. (Details not shown.)
2. Configure RIPv2 on the switches to make sure Switch A, Switch B, and Switch C can communicate with each other at Layer 3. (Details not shown.)
3. Configure RIP FRR:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ip prefix-list abc index 10 permit 4.4.4.4 32
[SwitchA] route-policy frr permit node 10
[SwitchA-route-policy-frr-10] if-match ip address prefix-list abc
[SwitchA-route-policy-frr-10] apply fast-reroute backup-interface vlan-interface
100 backup-nexthop 12.12.12.2
[SwitchA-route-policy-frr-10] quit
[SwitchA] rip 1
[SwitchA-rip-1] fast-reroute route-policy frr
[SwitchA-rip-1] quit
```

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ip prefix-list abc index 10 permit 1.1.1.1 32
[SwitchB] route-policy frr permit node 10
[SwitchB-route-policy-frr-10] if-match ip address prefix-list abc
[SwitchB-route-policy-frr-10] apply fast-reroute backup-interface vlan-interface
101 backup-nexthop 24.24.24.2
```

```
[SwitchB-route-policy-frr-10] quit
[SwitchB] rip 1
[SwitchB-rip-1] fast-reroute route-policy frr
[SwitchB-rip-1] quit
```

Verifying the configuration

Display route 4.4.4.4/32 on Switch A to view the backup next hop information.

```
[SwitchA] display ip routing-table 4.4.4.4 verbose

Configuring OSPF

About OSPF

Open Shortest Path First (OSPF) is a link-state IGP developed by the OSPF working group of the IETF. OSPF version 2 is used for IPv4. OSPF refers to OSPFv2 throughout this chapter.

OSPF features

OSPF has the following features:

- **Wide scope**—Supports multiple network sizes and several hundred routers in an OSPF routing domain.
- **Fast convergence**—Advertises routing updates instantly upon network topology changes.
- **Loop free**—Computes routes with the SPF algorithm to avoid routing loops.
- **Area-based network partition**—Splits an AS into multiple areas to facilitate management. This feature reduces the LSDB size on routers to save memory and CPU resources, and reduces route updates transmitted between areas to save bandwidth.
- **ECMP routing**—Supports multiple equal-cost routes to a destination.
- **Routing hierarchy**—Supports a 4-level routing hierarchy that prioritizes routes into intra-area, inter-area, external Type-1, and external Type-2 routes.
- **Authentication**—Supports area- and interface-based packet authentication to ensure secure packet exchange.
- **Support for multicasting**—Multicasts protocol packets on some types of links to avoid impacting other devices.

OSPF packets

OSPF messages are carried directly over IP. The protocol number is 89.

OSPF uses the following packet types:

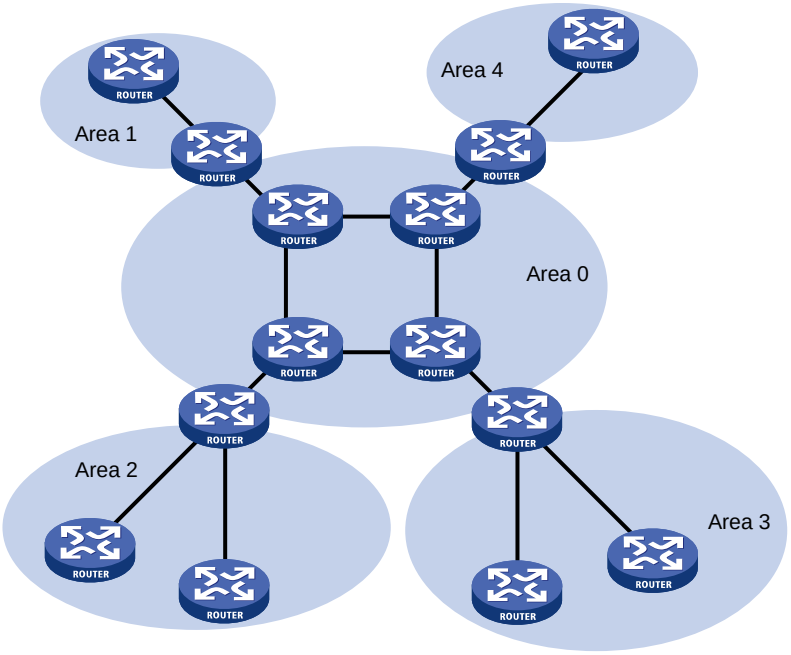
- **Hello**—Periodically sent to find and maintain neighbors, containing timer values, information about the DR, BDR, and known neighbors.
- **Database description (DD)**—Describes the digest of each LSA in the LSDB, exchanged between two routers for data synchronization.
- **Link state request (LSR)**—Requests needed LSAs from a neighbor. After exchanging the DD packets, the two routers know which LSAs of the neighbor are missing from their LSDBs. They then exchange LSR packets requesting the missing LSAs. LSR packets contain the digest of the missing LSAs.
- **Link state update (LSU)**—Transmits the requested LSAs to the neighbor.
- **Link state acknowledgment (LSAck)**—Acknowledges received LSU packets. It contains the headers of received LSAs (an LSAck packet can acknowledge multiple LSAs).

LSA types

OSPF advertises routing information in Link State Advertisements (LSAs). The following LSAs are commonly used:

- **Router LSA**—Type-1 LSA, originated by all routers and flooded throughout a single area only. This LSA describes the collected states of the router's interfaces to an area.
- **Network LSA**—Type-2 LSA, originated for broadcast and NBMA networks by the designated router, and flooded throughout a single area only. This LSA contains the list of routers connected to the network.
- **Network Summary LSA**—Type-3 LSA, originated by Area Border Routers (ABRs), and flooded throughout the LSA's associated area. Each summary-LSA describes a route to a destination outside the area, yet still inside the AS (an inter-area route).
- **ASBR Summary LSA**—Type-4 LSA, originated by ABRs and flooded throughout the LSA's associated area. Type 4 summary-LSAs describe routes to Autonomous System Boundary Router (ASBR).
- **AS External LSA**—Type-5 LSA, originated by ASBRs, and flooded throughout the AS (except stub and NSSA areas). Each AS-external-LSA describes a route to another AS.
- **NSSA LSA**—Type-7 LSA, as defined in RFC 1587, originated by ASBRs in NSSAs and flooded throughout a single NSSA. NSSA LSAs describe routes to other ASs.
- **Opaque LSA**—LSA for OSPF extensions. Its format consists of a standard LSA header and application specific information. The opaque LSA includes Type 9, Type 10, and Type 11. The Type 9 opaque LSA is flooded into the local subnet. Grace LSA, used by graceful restart, is Type 9 LSA. The Type 10 is flooded into the local area. The Type 11 is flooded throughout the AS.

OSPF areas



Area-based OSPF network partition

In large OSPF routing domains, SPF route computations consume too many storage and CPU resources, and enormous OSPF packets generated for route synchronization occupy excessive bandwidth.

To resolve these issues, OSPF splits an AS into multiple areas. Each area is identified by an area ID. The boundaries between areas are routers rather than links. A network segment (or a link) can only reside in one area as shown in Figure 1.

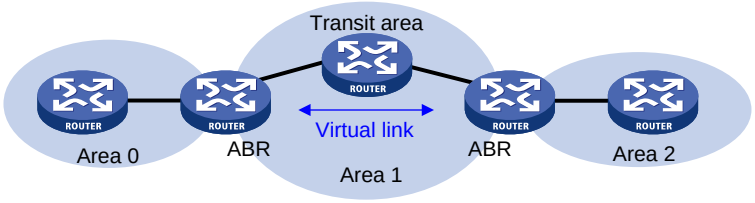
You can configure route summarization on ABRs to reduce the number of LSAs advertised to other areas and minimize the effect of topology changes.

Figure 1 Area-based OSPF network partition

Backbone area

Each AS has a backbone area that distributes routing information between non-backbone areas. Routing information between non-backbone areas must be forwarded by the backbone area. OSPF has the following requirements:

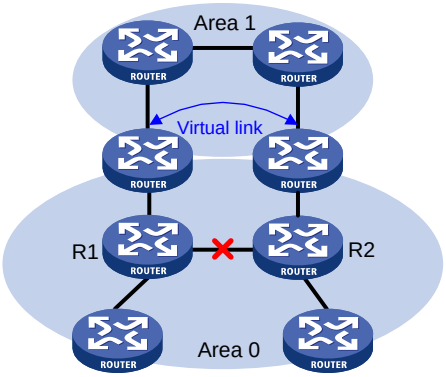
- All non-backbone areas must maintain connectivity to the backbone area.
- The backbone area must maintain connectivity within itself.



In practice, these requirements might not be met due to lack of physical links. OSPF virtual links can solve this issue.

Virtual links

A virtual link is established between two ABRs through a non-backbone area. It must be configured on both ABRs to take effect. The non-backbone area is called a transit area.



As shown in Figure 2, Area 2 has no direct physical link to the backbone Area 0. You can configure a virtual link between the two ABRs to connect Area 2 to the backbone area.

Figure 2 Virtual link application 1

Virtual links can also be used as redundant links. If a physical link failure breaks the internal connectivity of the backbone area, you can configure a virtual link to replace the failed physical link, as shown in Figure 3.

Figure 3 Virtual link application 2

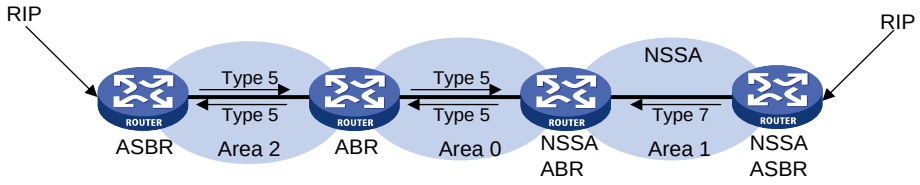
The virtual link between the two ABRs acts as a point-to-point connection. You can configure interface parameters, such as hello interval, on the virtual link as they are configured on a physical interface.

The two ABRs on the virtual link unicast OSPF packets to each other, and the OSPF routers in between convey these OSPF packets as normal IP packets.

Stub area and totally stub area

A stub area does not distribute Type-5 LSAs to reduce the routing table size and LSAs advertised within the area. The ABR of the stub area advertises a default route in a Type-3 LSA so that the routers in the area can reach external networks through the default route.

To further reduce the routing table size and advertised LSAs, you can configure the stub area as a totally stub area. The ABR of a totally stub area does not advertise inter-area routes or external routes. It advertises a default route in a Type-3 LSA so that the routers in the area can reach external networks through the default route.



NSSA area and totally NSSA area

An NSSA area does not import AS external LSAs (Type-5 LSAs) but can import Type-7 LSAs generated by the NSSA ASBR. The NSSA ABR translates Type-7 LSAs into Type-5 LSAs and advertises the Type-5 LSAs to other areas.

As shown in Figure 4, the OSPF AS contains Area 1, Area 2, and Area 0. The other two ASs run RIP. Area 1 is an NSSA area where the ASBR redistributes RIP routes in Type-7 LSAs into Area 1. Upon receiving the Type-7 LSAs, the NSSA ABR translates them to Type-5 LSAs, and advertises the Type-5 LSAs to Area 0.

The ASBR of Area 2 redistributes RIP routes in Type-5 LSAs into the OSPF routing domain. However, Area 1 does not receive Type-5 LSAs because it is an NSSA area.

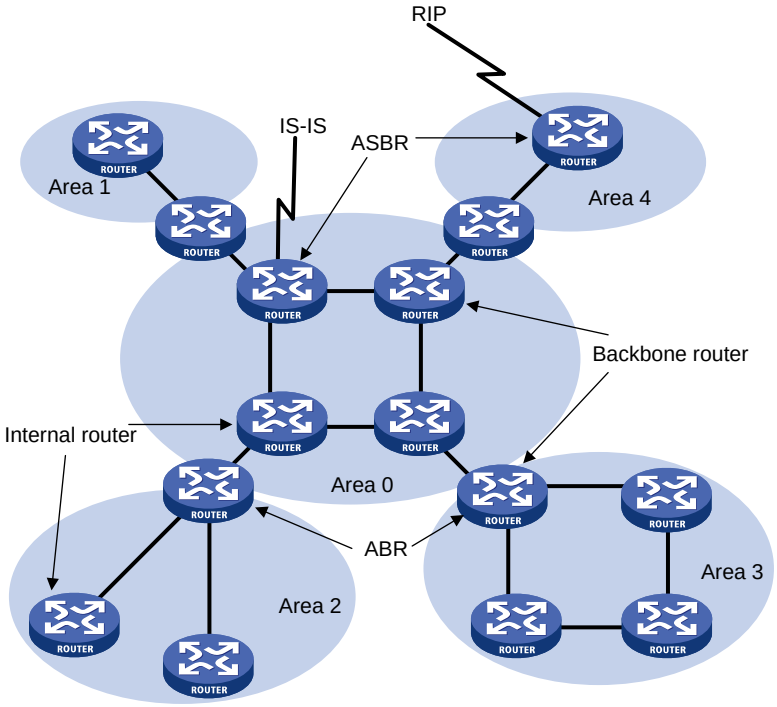


Figure 4 NSSA area

Router types

As shown in Figure 5, OSPF routers are classified into different types, including internal routers, ABRs, backbone routers, and ASBRs.

Figure 5 OSPF router types

Internal router

All interfaces on an internal router belong to one OSPF area.

ABR

An ABR belongs to more than two areas, one of which must be the backbone area. ABR connects the backbone area to a non-backbone area. An ABR and the backbone area can be connected through a physical or logical link.

Backbone router

No less than one interface of a backbone router must reside in the backbone area. All ABRs and internal routers in Area 0 are backbone routers.

ASBR

An ASBR exchanges routing information with another AS. An ASBR might not reside on the border of the AS. It can be an internal router or an ABR.

Route types

OSPF prioritizes routes into the following route levels:

- Intra-area route.
- Inter-area route.
- Type-1 external route.
- Type-2 external route.

The intra-area and inter-area routes describe the network topology of the AS. The external routes describe routes to external ASs.

A Type-1 external route has high credibility. The cost of a Type-1 external route = the cost from the router to the corresponding ASBR + the cost from the ASBR to the destination of the external route.

A Type-2 external route has low credibility. OSPF considers that the cost from the ASBR to the destination of a Type-2 external route is much greater than the cost from the ASBR to an OSPF internal router. The cost of a Type-2 external route = the cost from the ASBR to the destination of the Type-2 external route. If two Type-2 routes to the same destination have the same cost, OSPF takes the cost from the router to the ASBR into consideration to determine the best route.

Router ID

A router ID uniquely identifies a router in an AS. For a router to run OSPF, it must have a router ID. You can choose to manually specify a router ID or use the global router ID for an OSPF process.

Manual configuration

When you create an OSPF process, you can manually specify a router ID. To make sure the router ID is unique in the AS, you can specify the IP address of an interface on the router as the router ID.

Using the global router ID

If you do not specify a router ID when creating an OSPF process, the global router ID is used. As a best practice, manually specify a router ID or enable the OSPF process to automatically obtain a router ID when you create the OSPF process.

Route calculation

OSPF computes routes in an area as follows:

- Each router generates LSAs based on the network topology around itself, and sends them to other routers in update packets.
- Each OSPF router collects LSAs from other routers to compose an LSDB. An LSA describes the network topology around a router, and the LSDB describes the entire network topology of the area.
- Each router transforms the LSDB to a weighted directed graph that shows the topology of the area. All the routers within the area have the same graph.
- Each router uses the SPF algorithm to compute a shortest path tree that shows the routes to the nodes in the area. The router itself is the root of the tree.

OSPF network types

OSPF classifies networks into the following types, depending on different link layer protocols:

- **Broadcast**—If the link layer protocol is Ethernet or FDDI, OSPF considers the network type as broadcast by default. On a broadcast network, hello, LSU, and LSAck packets are multicast to 224.0.0.5 that identifies all OSPF routers or to 224.0.0.6 that identifies the DR and BDR. DD packets and LSR packets are unicast.
- **NBMA**—If the link layer protocol is Frame Relay, ATM, or X.25, OSPF considers the network type as NBMA by default. OSPF packets are unicast on an NBMA network.
- **P2MP**—No link is P2MP type by default. P2MP must be a conversion from other network types such as NBMA. On a P2MP network, OSPF packets are multicast to 224.0.0.5.
- **P2P**—If the link layer protocol is PPP or HDLC, OSPF considers the network type as P2P. On a P2P network, DD packets are unicast and other OSPF packets are multicast to 224.0.0.5.

The following are the differences between NBMA and P2MP networks:

- NBMA networks are fully meshed. P2MP networks are not required to be fully meshed.
- NBMA networks require DR and BDR election. P2MP networks do not have DR or BDR.

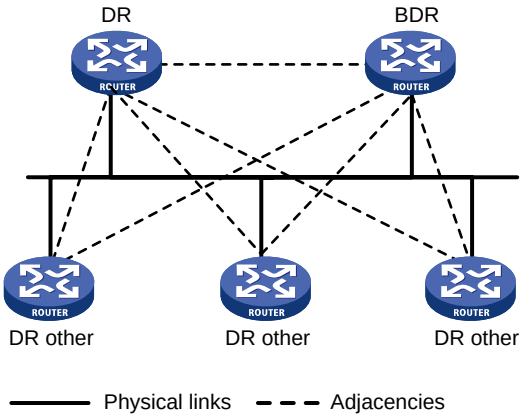
- On an NBMA network, OSPF packets are unicast, and neighbors are manually configured. On a P2MP network, OSPF packets are multicast by default, and you can configure OSPF to unicast protocol packets.

DR and BDR

DR and BDR mechanism

On a broadcast or NBMA network, any two routers must establish an adjacency to exchange routing information with each other. If n routers are present on the network, n(n-1)/2 adjacencies are established. Any topology change on the network results in an increase in traffic for route synchronization, which consumes a large amount of system and bandwidth resources.

Using the DR and BDR mechanisms can solve this problem.



- **DR**—Elected to advertise routing information among other routers. If the DR fails, routers on the network must elect another DR and synchronize information with the new DR. Using this mechanism without BDR is time-consuming and is prone to route calculation errors.
- **BDR**—Elected along with the DR to establish adjacencies with all other routers. If the DR fails, the BDR immediately becomes the new DR, and other routers elect a new BDR.

Routers other than the DR and BDR are called DR Others. They do not establish adjacencies with one another, so the number of adjacencies is reduced.

The role of a router is subnet (or interface) specific. It might be a DR on one interface and a BDR or DR Other on another interface.

As shown in Figure 6, solid lines are Ethernet physical links, and dashed lines represent OSPF adjacencies. With the DR and BDR, only seven adjacencies are established.

Figure 6 DR and BDR in a network

NOTE:

In OSPF, neighbor and adjacency are different concepts. After startup, OSPF sends a hello packet on each OSPF interface. A receiving router checks parameters in the packet. If the parameters match its own, the receiving router considers the sending router an OSPF neighbor. Two OSPF neighbors establish an adjacency relationship after they synchronize their LSDBs through exchange of DD packets and LSAs.

DR and BDR election

DR election is performed on broadcast or NBMA networks but not on P2P and P2MP networks.

Routers in a broadcast or NBMA network elect the DR and BDR by router priority and ID. Routers with a router priority value higher than 0 are candidates for DR and BDR election.

The election votes are hello packets. Each router sends the DR elected by itself in a hello packet to all the other routers. If two routers on the network declare themselves as the DR, the router with the higher router priority wins. If router priorities are the same, the router with the higher router ID wins.

If a router with a higher router priority becomes active after DR and BDR election, the router cannot replace the DR or BDR until a new election is performed. Therefore, the DR of a network might not be the router with the highest priority, and the BDR might not be the router with the second highest priority.

OSPF state machines

Interface state machine

On receipt of link state information, OSPF establishes adjacency relationships with neighboring devices, and then exchanges LSAs with them. The state of an OSPF interface indicates the role of the device in an OSPF link. Two neighboring devices can correctly form an adjacency relationship by checking each other's interface state.

The interface state machine involves the following interface states:

- **Down**—Initial interface state.

  An OSPF interface in this state cannot be used for traffic sending or receiving.
- **Loopback**—The network-attached interface is looped back on the device.

  A loopback interface is not available for regular data transmission. However, to obtain link quality information on the interface, you might either send ICMP ping packets to the loopback interface. To meet this potential requirement, each OSPF device advertises loopback interface information in Router LSAs.
- **Waiting**—The device is determining the DR and BDR for the network.

  When the device does not run for the DR or BDR, the interface starts a wait timer. The hello packets sent by the device does not contain any DR or BDR information unless the wait timer expires. The device cannot be elected as the DR or BDR on the network until it exits from **Waiting** state. The wait timer mechanism prevents unnecessary DR and BDR changes.

  This interface state is supported only on NBMA networks and broadcast networks.
- **Point-to-point**—The interface is connected to a physical P2P network or to a virtual link.

  If an interface enters this state, it attempts to establish an adjacency relationship with the neighboring device.

  This interface state is supported only on P2P networks and P2MP networks.
- **DR Other**—The interface is connected to a broadcast or NBMA network on which another device has been elected as the DR.

  A device in **DR Other** state is neither elected as the DR nor the BDR. When DR and BDR election is complete on the network, each DR Other device establishes adjacencies with both the DR and the BDR.
- **BDR**—The device is the BDR on the attached network.

  As the BDR, the device establishes adjacencies with all other devices on the attached network. It will immediately become the new DR if the existing DR fails.
- **DR**—The device is the DR on the attached network.

  As the DR, the device establishes adjacencies with all other devices on the attached network.

A number of input events (IE) can cause OSPF interface state changes. As shown in Figure 7, the relationships between IEs and state changes form the OSPF interface state machine.

Figure 7 OSPF interface state machine

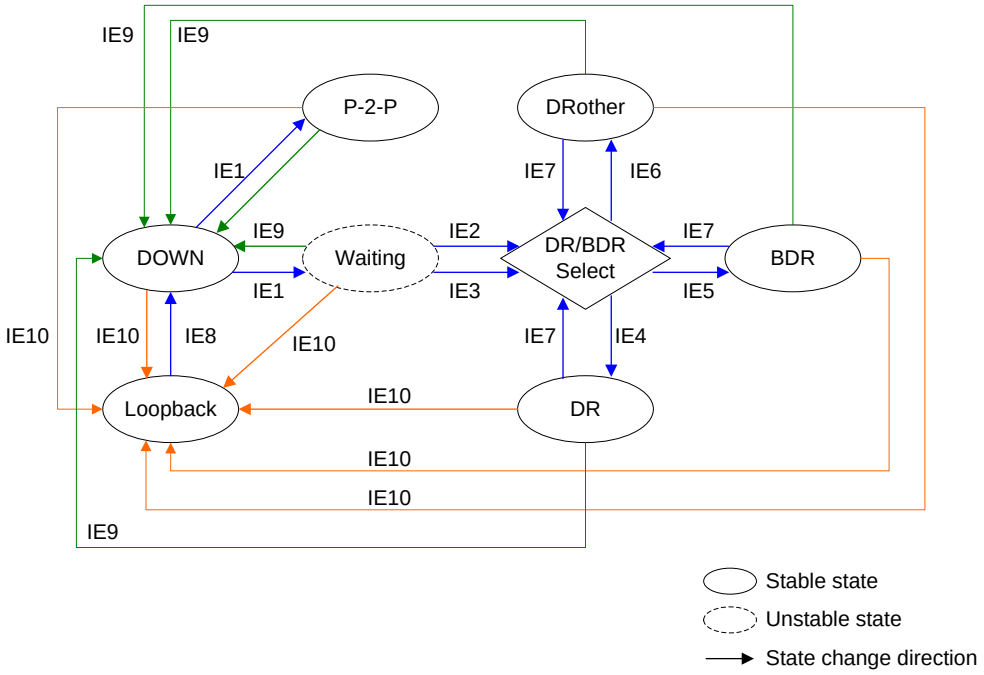


Table 1 shows the IEs that can cause interface state changes.

Table 1 Input events

Input event	Description
IE1	InterfaceUp event: Lower-level protocols have indicated that the interface is operational.
IE2	WaitTimer event: The wait timer has expired and the device can run for the DR or the BDR.
IE3	BackupSeen event: The device has detected the existence or non-existence of a BDR on the attached network through one of the following methods: • The interface receives a hello packet from a neighbor that claims itself to be the BDR. • The interface receives a hello packet from a neighbor that claims itself to be the DR. The hello packet also indicates that there is no BDR. This event marks an end to **Waiting** state and indicates that the device and the neighbor can have bidirectional communication.
IE4	The interface is elected as the DR.
IE5	The interface is elected as the BDR.
IE6	The interface is neither elected as the DR nor the BDR.
IE7	NeighborChange event: A neighbor associated with the interface has a change. The DR and BDR need to be re-elected. The following neighbor changes might lead to the re-election of DR and BDR: • The device can have bidirectional communication with a neighbor. • The device no longer has bidirectional communication with a neighbor. • A neighbor claims itself as DR or BDR. The device detects this event again by examining the hello packets from the neighbor. • A neighbor no longer claims itself as DR or BDR. The device detects this event again by examining the hello packets from the neighbor. • The DR priority for a neighbor has changed. The device detects this event again by

	examining the hello packets from the neighbor.
IE8	UnloopInd event: Network management or lower-level protocols has indicated that the interface is no longer looped back.
IE9	InterfaceDown event: Lower-level protocols has indicated that the interface is not operational. If this event occurs, the interface state might change to Down.
IE10	LoopInd event: Network management or lower-level protocols has indicated that the interface is looped back. If this event occurs, the interface state might change to Loopback.

Neighbor state machine

The process of OSPF adjacency establishment involves a series of neighbor state changes that transition from **Down** state to **Full** state.

The neighbor state machine involves the following neighbor states:

- **Down**—Initial state of a neighbor conversation.

  This state indicates that the local device does not receive any hello packets from the neighbor within the neighbor dead interval. An OSPF device sends hello packets at intervals of PollInterval.

  Whether an OSPF device sends hello packets to neighbors in **Down** state depends on its network type. The device sends hello packets to neighbors in **Down** state only when its network type is NBMA.
- **Attempt**—In this state, the local device attempts to establish neighbor relationships with the manually specified neighbors by sending hello packets at intervals of HelloInterval.

  This state is valid only for the neighbors on NBMA networks.
- **Init**—This state indicates that the local device has received a hello packet from a neighbor before the neighbor dead interval elapses. However, the local device has not established bidirectional communication with the neighbor, because the received hello packet does not contain the local device's router ID.
- **2-Way**—This state indicates that the local device has established a neighbor relationship with a neighboring device. Each of the two devices has received a hello packet from another and has seen its own router ID in the received hello packet.

  If the neighbor relationship between two devices does not prompt to an adjacency, the neighbor state will remain 2-Way.

  DR and BDR election starts only when the neighbor state is 2-Way or greater.
- **ExStart**—This state indicates that the local device and the neighbor is deciding which is the master. This step is to determine the sequence number for initial DD packets. The devices can then exchange DD packets in order.
- **Exchange**—This state indicates that the local device is exchanging DD packets with the neighbor. The local device describes its LSDB information in DD packets and sends them to the neighbor.
- **Loading**—This state indicates that the local device and the neighbor are having bidirectional LSDB synchronization. They send LSRs to each other to request the most recent LSAs, and then synchronize their LSDBs through exchanges of LSUs and LSAcks.
- **Full**—This state indicates that the local device and the neighbor has completed bidirectional LSDB synchronization and they are fully adjacent.

As shown in Figure 8, the relationships between IEs and state changes form the OSPF neighbor state machine.

Figure 8 OSPF neighbor state machine

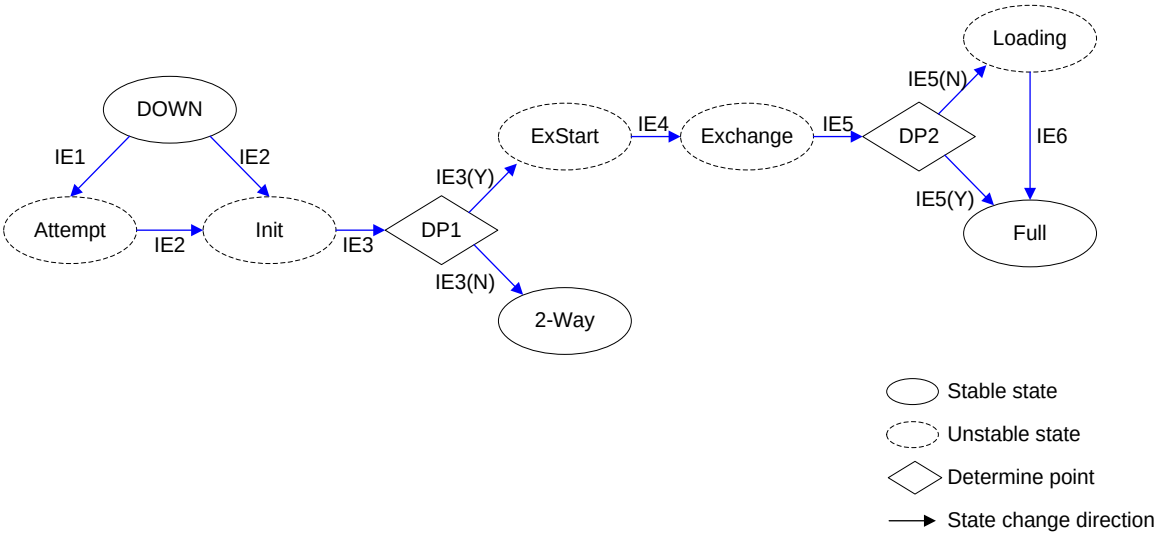

Table 2 shows the IEs that can cause neighbor state changes.

Table 2 Input events

Input event	Description
IE1	Start event: The OSPF device attempts to establish a neighbor relationship with the neighbor by sending hello packets at intervals of HelloInterval. This event is supported only on NBMA networks.
IE2	HelloReceived event: The OSPF device has received a hello packet from the neighbor.
IE3	2-WayReceived event: The OSPF device has received a hello packet from the neighbor and has seen its router ID in the received hello packet. The two neighboring devices have established bidirectional communication. The OSPF device then performs the following task: • If the OSPF device needs to form an adjacency with the neighbor, it changes the neighbor state to ExStart. • If the OSPF device should not form an adjacency with the neighbor, it changes the neighbor state to 2-Way.
IE4	NegotiationDone event: The OSPF device and the neighbor have completed master/secondary relationship negotiation and have determined the sequence number for initial DD packets.
IE5	ExchangeDone event: The OSPF device have exchanged DD packets with the neighbor. The OSPF device then performs the following task: • If the LSR list is empty, the device changes the neighbor state to Full. This neighbor state indicates that bidirectional LSDB synchronization is complete and the device has established an adjacency with the neighbor. • If the LSR list is not empty, the device changes the neighbor state to Loading, and then sends LSRs to the neighbor to request missing link state information.
IE6	LoadingDone event: The LSR list is already empty.

Restrictions and guidelines: OSPF configuration

To run OSPF, you must first enable OSPF on the router. Make a proper configuration plan to avoid incorrect settings that can result in route blocking and routing loops.

OSPF tasks at a glance

To configure OSPF, perform the following tasks:

1. Configuring basic OSPF functions
   - Enabling an OSPF process
   - Creating an OSPF area
   - Enabling OSPF
   - (Optional.) Enabling OSPF to establish neighbor relationships through the secondary IP addresses of an interface
2. (Optional.) Configuring OSPF stub and NSSA areas
   - Configuring a stub area
   - Configuring an NSSA area
   - Configuring a virtual link
3. (Optional.) Configuring OSPF network types
   - Configuring the broadcast network type for an interface

- Configuring the NBMA network type for an interface
- Configuring the P2MP network type for an interface
- Configuring the P2P network type for an interface

4. (Optional.) Configuring OSPF route control
   - Configuring OSPF inter-area route summarization
   - Configuring redistributed route summarization
   - Configuring received OSPF route filtering
   - Configuring Type-3 LSA filtering
   - Setting an OSPF cost for an interface
   - Enabling OSPF to advertise the maximum link cost to neighbors
   - Associating OSPF with Track
   - Setting the maximum number of ECMP routes
   - Setting OSPF preference
   - Configuring discard routes for summary networks
   - Redistributing routes from another routing protocol
   - Redistributing a default route
   - Advertising a host route
   - Advertising OSPF link state information to BGP
5. (Optional.) Setting OSPF timers
   - Configuring OSPF packet timers
   - Setting the LSA transmission delay
   - Setting the OSPF route calculation interval
   - Setting the minimum LSA arrival interval
   - Setting the LSA update interval
   - Setting the OSPF exit overflow interval
6. (Optional.) Configuring OSPF packet parameters
   - Disabling interfaces from receiving and sending OSPF packets
   - Adding the interface MTU into DD packets
   - Setting the DSCP value for outgoing OSPF packets
   - Setting the maximum length of OSPF packets that can be sent by an interface
   - Setting the LSU transmit rate
7. (Optional.) Controlling LSA generation, advertisement, and reception
   - Setting the maximum number of external LSAs in LSDB
   - Filtering outbound LSAs on an interface
   - Filtering LSAs for the specified neighbor
8. (Optional.) Accelerating OSPF convergence speed
   - Enabling OSPF ISPF
   - Configuring prefix suppression
   - Configuring prefix prioritization
   - Configuring OSPF PIC
9. (Optional.) Configuring advanced OSPF features
   - Configuring stub routers
   - Configuring OSPF isolation
   - Configuring OSPF shutdown

- Enabling compatibility with RFC 1583

10. (Optional.) Enhancing OSPF availability
    - Configuring OSPF GR
    - Configuring OSPF NSR
    - Configuring BFD for OSPF
    - Configuring OSPF FRR
11. (Optional.) Configuring OSPF security features
    - Configuring OSPF authentication
    - Configuring GTSM for OSPF
12. (Optional.) Configuring OSPF logging, SNMP notifications, and troubleshooting
    - Logging neighbor state changes
    - Configuring the OSPF logging feature
    - Configuring OSPF network management
    - Setting the maximum number of OSPF neighbor relationship troubleshooting entries

Configuring basic OSPF functions

Enabling an OSPF process

1. Enter system view.
   system-view
2. (Optional.) Configure a global router ID.
   router id *router-id*
   By default, no global router ID is configured.
   If no global router ID is configured, the highest loopback interface IP address, if any, is used as the router ID. If no loopback interface IP address is available, the highest physical interface IP address is used, regardless of the interface status (up or down).
3. Enter OSPF view.
   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
   By default, OSPF is disabled.
4. (Optional.) Configure a description for the OSPF process.
   description *text*
   By default, no description is configured for the OSPF process.
   As a best practice, configure a description for each OSPF process.

Creating an OSPF area

1. Enter system view.
   system-view
2. (Optional.) Configure a global router ID.
   router id *router-id*
   By default, no global router ID is configured.
3. Enter OSPF view.

ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

By default, OSPF is disabled.

4. (Optional.) Configure a description for the OSPF process.

description *text*

By default, no description is configured for the OSPF process.

As a best practice, configure a description for each OSPF process.

5. Create an OSPF area and enter OSPF area view.

area *area-id*

6. (Optional.) Configure a description for the area.

description *text*

By default, no description is configured for the area.

As a best practice, configure a description for each OSPF area.

7. (Optional.) Exclude interfaces in the OSPF area from the base topology:

capability default-exclusion

By default, interfaces in an OSPF area belong to the base topology.

For correct neighbor relationship establishment, perform this task on both the local device and the neighbor device.

Enabling OSPF

About this task

To enable OSPF on a router, you must perform the following tasks:

1. Create an OSPF process.
2. Create an OSPF area for the process.
3. Specify a network in the area.

The interface attached to the network will run the OSPF process in the area. OSPF advertises direct routes of the interface.

OSPF supports multiple processes. To run multiple OSPF processes, you must specify an ID for each process. The process IDs take effect locally and has no influence on packet exchange between routers. Two routers with different process IDs can exchange packets.

OSPF supports multiple VPNs. You can configure an OSPF process to run in a VPN instance. An OSPF process with no VPN instance specified runs on the public network. For more information about VPN, see MCE configuration in *MCE Configuration Guide.*

Restrictions and guidelines for enabling OSPF

When you configure OSPF on an interface, follow these restrictions and guidelines:

- You can enable OSPF on the network where the interface resides or directly enable OSPF on that interface. If you configure both, the latter takes precedence.
- If the specified OSPF process and area do not exist, the operation creates an OSPF process and area for the interface. Disabling an OSPF process on an interface does not delete the OSPF process or the area.

Enabling OSPF on a network

1. Enter system view.

system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Enter OSPF area view.

   area *area-id*

4. Specify a network to enable the interface attached to the network to run the OSPF process in the area.

   network *ip-address wildcard-mask*

   By default, no network is specified to enable OSPF on the interface attached to the network.

   A network can be added to only one area.

Enabling OSPF on an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable an OSPF process on the interface.

   ospf *process-id* **area** *area-id* [**exclude-subip**]

   By default, OSPF is disabled on an interface.

Enabling OSPF to establish neighbor relationships through the secondary IP addresses of an interface

About this task

By default, OSPF uses only the primary IP address of an interface to establish neighbor relationships. This feature enables OSPF to establish neighbor relationships through the secondary IP addresses of an interface.

Restrictions and guidelines

- For an interface with both primary and secondary addresses, if you have advertised only the primary address in an area of an OSPF process, OSPF uses only the primary address to establish neighbor relationships. For OSPF to establish neighbor relationships through the secondary IP addresses, you must also advertise the secondary IP addresses in the same area of the same OSPF process.
- If an interface does not have a primary address but has multiple secondary addresses, OSPF uses the lowest secondary address to establish neighbor relationships. For OSPF to establish neighbor relationships through the other secondary addresses, you must advertise these addresses in the same area of the same OSPF process.
- After you execute the **ospf peer sub-address enable** command on a P2P OSPF interface, the device automatically checks the local and remote interface IP addresses before neighbor establishment. If the IP addresses belong to different networks, they cannot establish a neighbor relationship.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable OSPF to establish neighbor relationships through the secondary IP addresses of the interface.

   ospf peer sub-address enable

   By default, OSPF cannot establish neighbor relationships through the secondary IP addresses of an interface.

Configuring OSPF stub and NSSA areas

About OSPF stub and NSSA area configuration

This task allows you to configure an OSPF area as a stub area or NSSA area. It also allows you to create a virtual link if no connectivity can be achieved between a non-backbone area and backbone area, or in the backbone area.

Configuring a stub area

About this task

You can configure a non-backbone area at an AS edge as a stub area. To do so, execute the **stub** command on all routers attached to the area. The routing table size is reduced because Type-5 LSAs will not be flooded within the stub area. The ABR generates a default route into the stub area so all packets destined outside of the AS are sent through the default route.

To further reduce the routing table size and routing information exchanged in the stub area, configure a totally stub area by using the **stub no-summary** command on the ABR. AS external routes and inter-area routes will not be distributed into the area. All the packets destined for outside of the AS or area will be sent to the ABR for forwarding.

A stub or totally stub area cannot have an ASBR because external routes cannot be distributed into the area.

Restrictions and guidelines

Do not configure the backbone area as a stub area or totally stub area.

To configure an area as a stub area, execute the **stub** command on all routers attached to the area.

To configure an area as a totally stub area, execute the **stub** command on all routers attached to the area, and execute the **stub no-summary** command on the ABR.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Enter area view.

   area *area-id*

4. Configure the area as a stub area.

   stub [**default-route-advertise-always** | **no-summary**] *

   By default, no stub area is configured.

5. (Optional.) Set a cost for the default route advertised to the stub area.

   default-cost *cost-value*

   By default, the cost for the default route advertised to the stub area is 1.

This command takes effect only on the ABR of a stub area or totally stub area.

Configuring an NSSA area

About this task

A stub area cannot import external routes, but an NSSA area can import external routes into the OSPF routing domain while retaining other stub area characteristics.

To configure an area as a totally NSSA area, use the **nssa no-summary** command. The ABR of the area does not advertise inter-area routes into the area.

Restrictions and guidelines

Do not configure the backbone area as an NSSA area or totally NSSA area.

To configure an NSSA area, configure the **nssa** command on all the routers attached to the area.

To configure a totally NSSA area, configure the **nssa** command on all the routers attached to the area and configure the **nssa no-summary** command on the ABR.

Procedure

1. Enter system view.

   system-view
2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Enter area view.

   area *area-id*
4. Configure the area as an NSSA area.

   nssa [**default-route-advertise** [**cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **type** *type*] * | **no-import-route** | **no-summary** | **suppress-fa** | [[[**translate-always**] [**translate-ignore-checking-backbone**]] | **translate-never**] | **translator-stability-interval** *value*] *

   By default, no area is configured as an NSSA area.
5. (Optional.) Set a cost for the default route advertised to the NSSA area.

   default-cost *cost-value*

   By default, the cost for the default route advertised to the NSSA area is 1.

   This command takes effect only on the ABR/ASBR on an NSSA area or totally NSSA area.

Configuring a virtual link

About this task

You can configure a virtual link to maintain connectivity between a non-backbone area and the backbone, or in the backbone itself.

Restrictions and guidelines

A virtual link cannot traverse a stub area, totally stub area, NSSA area, or totally NSSA area.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Enter OSPF area view.

   area *area-id*

4. Configure a virtual link.

   vlink-peer *router-id* [**dead** *seconds* | **hello** *seconds* | { **authentication-none** | { **hmac-md5** | **hmac-sha-256** | **hmac-sm3** | **md5** } [*key-id* { **cipher** | **plain** } *string*] | **keychain** *keychain-name* | **simple** [{ **cipher** | **plain** } *string*] } | **retransmit** *seconds* | **trans-delay** *seconds*] *

   Configure this command on both ends of a virtual link. The **hello** and **dead** intervals must be identical on both ends of the virtual link.

Configuring OSPF network types

Based on the link layer protocol, OSPF classifies networks into different types, including broadcast, NBMA, P2MP, and P2P.

Restrictions and guidelines for configuring OSPF network types

If any routers in a broadcast network do not support multicasting, change the network type to NBMA.

If only two routers running OSPF exist on a network segment, you can change the network type to P2P to save costs.

Two broadcast-, NBMA-, and P2MP-interfaces can establish a neighbor relationship only when they are on the same network segment.

Configuring the broadcast network type for an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the OSPF network type for the interface as broadcast.

   ospf network-type broadcast

   By default, the network type of an interface depends on the encapsulated link layer protocol.

4. (Optional.) Set a router priority for the interface.

   ospf dr-priority *priority*

   The default router priority is 1.

Configuring the NBMA network type for an interface

Restrictions and guidelines

After you configure the network type as NBMA, you must specify neighbors and their router priorities because NBMA interfaces cannot find neighbors by broadcasting hello packets.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the OSPF network type for the interface as NBMA.
   ospf network-type nbma
   By default, the network type of an interface depends on the encapsulated link layer protocol.
4. (Optional.) Set a router priority for the interface.
   ospf dr-priority *priority*
   The default router priority for an interface is 1.
   The router priority configured with this command is for DR election.
5. Return to system view.
   quit
6. Enter OSPF view.
   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
7. Specify an NBMA neighbor.
   peer *ip-address* [**dr-priority** *priority*]
   By default, no neighbor is specified.
   The priority configured with this command indicates whether a neighbor has the election right or not. If you configure the router priority for a neighbor as 0, the local router determines the neighbor has no election right. It does not send hello packets to this neighbor. However, if the local router is the DR or BDR, it still sends hello packets to the neighbor for neighbor relationship establishment.

Configuring the P2MP network type for an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the OSPF network type for the interface as P2MP.
   ospf network-type p2mp [**unicast**]
   By default, the network type of an interface depends on the encapsulated link layer protocol.
   After you configure the OSPF network type for an interface as P2MP unicast, all packets are unicast over the interface. The interface cannot broadcast hello packets to discover neighbors, so you must manually specify the neighbors.
4. Return to system view.
   quit
5. Enter OSPF view.
   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
6. Specify a P2MP neighbor.
   peer *ip-address* [**cost** *cost-value*]
   By default, no neighbor is specified

This step is required if the interface network type is P2MP unicast.

Configuring the P2P network type for an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the OSPF network type for the interface as P2P.
   ospf network-type p2p [**multicast** | **peer-address-check**] *
   By default, the network type of an interface depends on the encapsulated link layer protocol.

Configuring OSPF route control

This section describes how to control the advertisement and reception of OSPF routing information, as well as route redistribution from other protocols.

Configuring OSPF inter-area route summarization

About this task

OSPF inter-area route summarization reduces the routing information exchanged between areas and the size of routing tables, and improves routing performance.

OSPF inter-area route summarization enables an ABR to summarize contiguous networks into a single network and advertise the network to other areas. For example, three internal networks 19.1.1.0/24, 19.1.2.0/24, and 19.1.3.0/24 are available within an area. You can configure the ABR to summarize the three networks into network 19.1.0.0/16, and advertise the summary network to other areas in a Type-3 LSA. This configuration reduces the scale of LSDBs on routers in other areas and the influence of topology changes.

Procedure

1. Enter system view.
   system-view
2. Enter OSPF view.
   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Enter OSPF area view.
   area *area-id*
4. Configure ABR route summarization.
   abr-summary *ip-address* { *mask-length* | *mask* } [**advertise** | **not-advertise**] [**cost** *cost-value*]
   By default, route summarization is not configured on an ABR.

Configuring redistributed route summarization

About this task

Perform this task to enable an ASBR to summarize external routes within the specified address range into a single route. The ASBR advertises only Type-5 LSAs to reduce the number of LSAs in the LSDB.

An ASBR can summarize routes in the following LSAs:

- Type-5 LSAs.
- Type-7 LSAs in an NSSA area.

Restrictions and guidelines

If an ASBR (also an ABR) is a translator in an NSSA area, it summarizes routes in Type-5 LSAs translated from Type-7 LSAs. If it is not a translator, it does not summarize routes in in Type-5 LSAs translated from Type-7 LSAs.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Configure ASBR route summarization.

   asbr-summary *ip-address* { *mask-length* | *mask* } [**cost** *cost-value* | **not-advertise** | **nssa-only** | **tag** *tag*] *

   By default, route summarization is not configured on an ASBR.

Configuring received OSPF route filtering

About this task

Perform this task to filter routes calculated using received LSAs.

The following filtering methods are available:

- Use an ACL or IP prefix list to filter routing information by destination address.
- Use the **gateway** *prefix-list-name* option to filter routing information by next hop.
- Use an ACL or IP prefix list to filter routing information by destination address. At the same time use the **gateway** *prefix-list-name* option to filter routing information by next hop.
- Use the **route-policy** *route-policy-name* option to filter routing information.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Configure OSPF to filter routes calculated using received LSAs.

   filter-policy { *ipv4-acl-number* [**gateway** *prefix-list-name*] | **gateway** *prefix-list-name* | **prefix-list** *prefix-list-name* [**gateway** *prefix-list-name*] | **route-policy** *route-policy-name* } **import**

   By default, OSPF accepts all routes calculated by using received LSAs.

Configuring Type-3 LSA filtering

About this task

Perform this task to filter Type-3 LSAs advertised into the local area or other areas on an ABR.

Procedure

1. Enter system view.
   system-view
2. Enter OSPF view.
   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Enter OSPF area view.
   area *area-id*
4. Configure Type-3 LSA filtering.
   filter { *ipv4-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } { **export** | **import** }
   By default, the ABR does not filter Type-3 LSAs.

Setting an OSPF cost for an interface

About this task

Set an OSPF cost for an interface by using either of the following methods:

- Set the cost value in interface view.
- Set a bandwidth reference value for the interface. OSPF computes the cost with this formula: Interface OSPF cost = Bandwidth reference value (100 Mbps) / Expected interface bandwidth (Mbps). The expected bandwidth of an interface is configured with the **bandwidth** command (see *Interface Command Reference*).
  - If the calculated cost is greater than 65535, the value of 65535 is used. If the calculated cost is less than 1, the value of 1 is used.
  - If no cost or bandwidth reference value is configured for an interface, OSPF computes the interface cost based on the interface bandwidth and default bandwidth reference value.

Setting an OSPF cost for an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set an OSPF cost for the interface.
   ospf cost *cost-value*
   By default, the OSPF cost is calculated according to the interface bandwidth. For a loopback interface, the OSPF cost is 0 by default.

Setting a bandwidth reference value

1. Enter system view.
   system-view
2. Enter OSPF view.
   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Set a bandwidth reference value.
   bandwidth-reference *value*
   The default setting is 100 Mbps.

Enabling OSPF to advertise the maximum link cost to neighbors

About this task

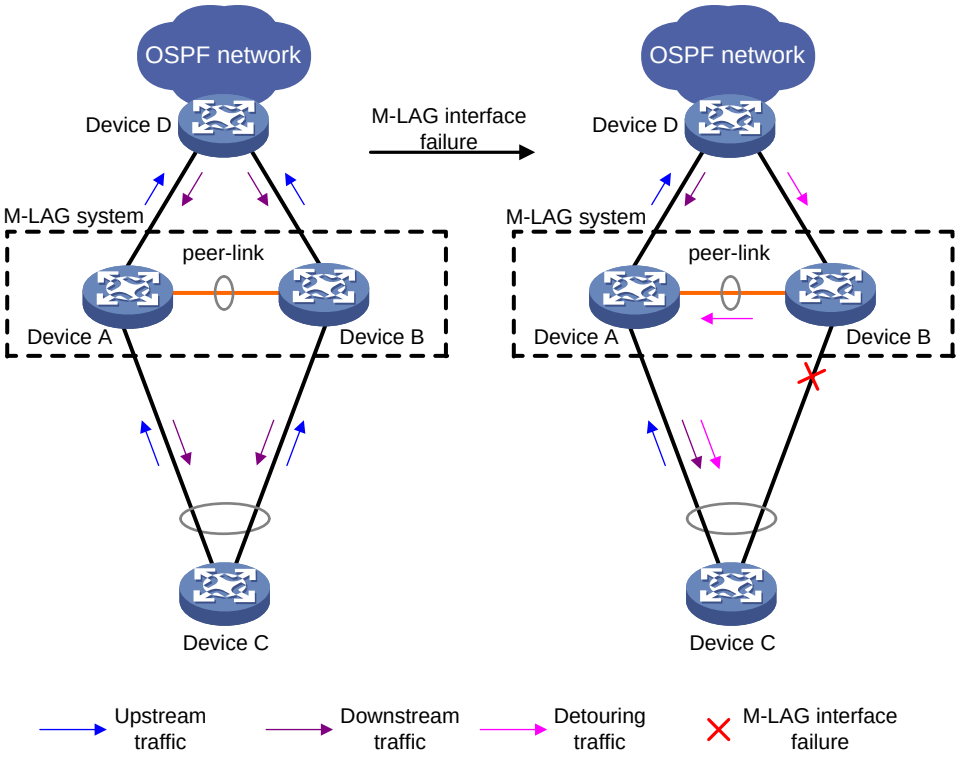
On an OSPF network, when a link recovers from failures or the state of an interface changes, OSPF will re-establish neighbor relationships and perform route convergence. During the route convergence process, routing loops and traffic loss might occur because the convergence speeds of the nodes are different. To address this issue, enable OSPF to advertise the maximum link cost to neighbors within the specified period, so the traffic forwarding path remains unchanged. After the specified period, OSPF advertises the original link cost to neighbors and performs optimal route selection again.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable OSPF to advertise the maximum link cost to neighbors within the specified period.
   ospf peer hold-max-cost duration *time*
   By default, OSPF advertises the original link cost to neighbors during a route convergence.

Associating OSPF with Track

About this task



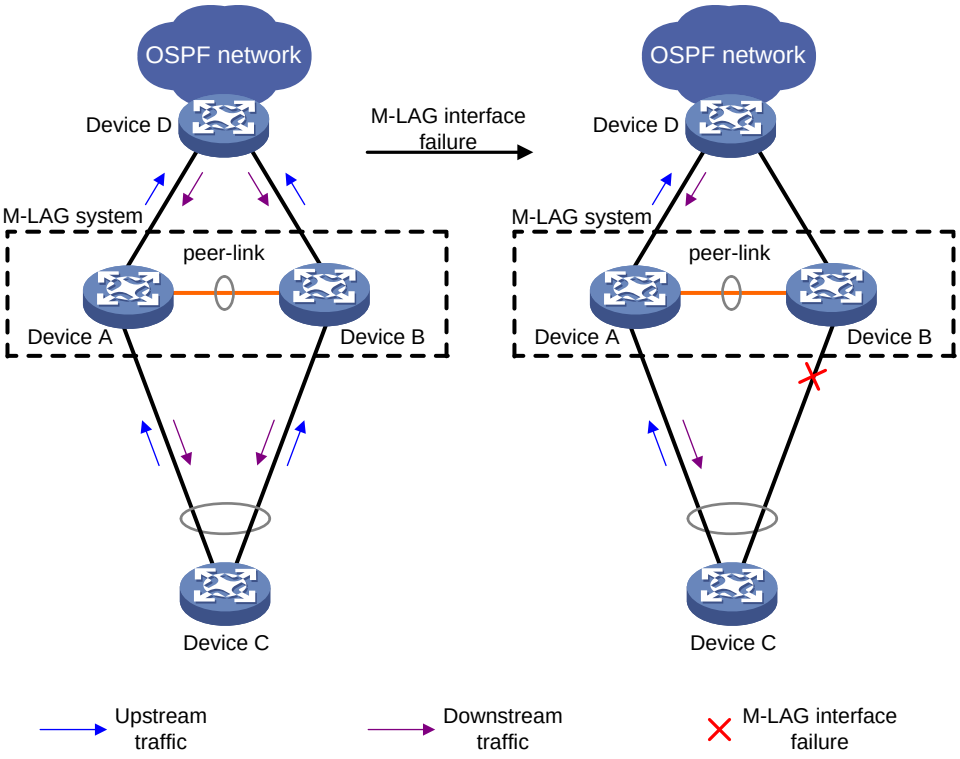
Perform this task to associate an OSPF interface with a track entry to adjust the cost of the interface as follows:

- When the track entry state becomes negative, OSPF increases the cost of the interface.
- When the track entry state becomes positive, OSPF restores the cost of the interface to the original value.

When a customer side device is dual-homed to an OSPF network through M-LAG, you can configure this feature to prevent the traffic from detouring through the M-LAG peer link. As shown in Figure 9, customer-side device Device C is dual-homed to the OSPF network through an M-LAG system formed by Device A and Device B. Device A and Device B share the traffic load between Device D and Device C. When the DR interface that connects Device B to Device C fails, the upstream traffic and downstream traffic are forwarded as follows:

- Device C detects the M-LAG interface failure, and traffic from Device C to Device D is switched from path Device C->Device B->Device D to path Device C->Device A->Device D.
- Device D cannot detect the M-LAG interface failure and still forwards traffic through Device B. Because the link between Device B and Device C fails, traffic from Device D to Device C is switched from path Device D->Device B->Device C to path Device D->Device B->Device A->Device C.

Figure 9 Traffic forwarding path after M-LAG interface failure



To prevent the downstream traffic from detouring through the M-LAG peer link, perform the following tasks on Device B:

1. Execute the **track interface** command to create a track entry and associate it with the link state of the M-LAG interface. For more information about the **track interface** command, see track commands in *High Availability Command Reference*.
2. Execute the **ospf track adjust-cost** command to associate the gateway interface with the track entry.

Then, Device B adjusts the cost of the gateway interface based on the state of the associated track entry:

- When the M-LAG interface fails, the track entry state becomes negative, and OSPF increases the cost of the gateway interface. Then, traffic from Device D to Device C is switched to path Device D->Device A->Device C.
- When the M-LAG interface recovers, the track entry state becomes positive, and OSPF restores the cost of the gateway interface to the original value. Then, traffic from Device D to Device C is switched back to path Device D->Device B->Device C.

Figure 10 Traffic forwarding path after associating OSPF with Track

Restrictions and guidelines

The S5200-EI-G switch series does not support M-LAG.

Procedure

1. Enter system view.

   system-view

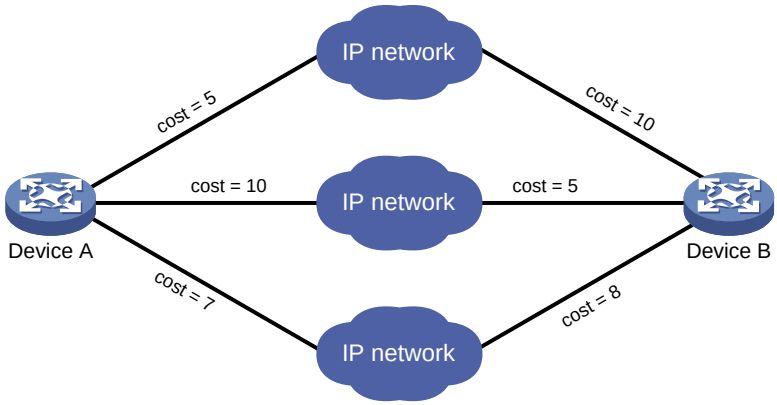
2. Enter interface view.

   interface *interface-type interface-number*

3. Associate the OSPF interface with a track entry to adjust the cost of the interface based on the track entry state.

   ospf track *track-entry-number* **adjust-cost** { *cost-offset* | **max** }

   By default, an OSPF interface is not associated with any track entry.



Setting the maximum number of ECMP routes

About this task

OSPF might find multiple optimal equal-cost routes to the same destination, which can be used to share the traffic load. This task allows you to set the maximum number of ECMP routes for OSPF.

As shown in Figure 11, Device A and Device B run OSPF. There are three equal-cost routes between Device A and Device B. You can use these routes to implement load sharing.

Figure 11 Equal-cost routes

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Set the maximum number of ECMP routes.

   maximum load-balancing *number*

   By default, the maximum number of ECMP routes equals the maximum number of ECMP routes supported by the system.

Setting OSPF preference

About this task

A router can run multiple routing protocols, and each protocol is assigned a preference. If multiple routes are available to the same destination, the one with the highest protocol preference is selected as the best route.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Set a preference for OSPF.

   preference [**ase**] { *preference* | **route-policy** *route-policy-name* } *

   By default, the preference of OSPF internal routes is 10 and the preference of OSPF external routes is 150.

Configuring discard routes for summary networks

About this task

Perform this task on an ABR or ASBR to specify whether to generate discard routes for summary networks. You can also specify a preference for the discard routes.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Configure discard routes for summary networks.

   discard-route { **external** { *preference* | **suppression** } | **internal** { *preference* | **suppression** } } *

   By default, the ABR or ASBR generates discard routes for summary networks and the default preference of discard routes is 255.

Redistributing routes from another routing protocol

About this task

When an OSPF device does not have routes from a non-OSPF routing protocol, it cannot access any devices that run the non-OSPF routing protocol. To resolve this issue, you can configure OSPF to redistribute routes from other protocols, such as IS-IS and BGP. OSPF can then advertise the routes in Type-5 LSAs or Type-7 LSAs.

In addition, you can configure OSPF to filter redistributed routes so that OSPF advertises only permitted routes.

Restrictions and guidelines

Although OSPF is a dynamic routing protocol that provides loop-free intra-area/inter-area routes, this protocol is not good at guarding against the routing loops caused by redistributed external routes. When you configure route redistribution for OSPF, make sure you have understood the potential impact.

OSPF redistributes only active routes. To view route status information, use the **display ip routing-table protocol** command.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Configure route redistribution.

   import-route bgp [*as-number*] [**allow-ibgp**] [[**cost** *cost-value* | **inherit-cost**] | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

   import-route { **direct** | **static** } [[**cost** *cost-value* | **inherit-cost**] | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

   import-route { **isis** | **ospf** | **rip** } [*process-id* | **all-processes**] [**allow-direct** | [**cost** *cost-value* | **inherit-cost**] | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

   By default, OSPF does not redistribute routes.

   The **import-route bgp** command redistributes only EBGP routes. The **import-route bgp allow-ibgp** command redistributes both EBGP and IBGP routes, which might cause routing loops. Therefore, use it with caution.

4. (Optional.) Configure OSPF to filter redistributed routes.

   filter-policy { *ipv4-acl-number* | **prefix-list** *prefix-list-name* } **export** [*protocol* [*process-id*]]

   By default, OSPF accepts all redistributed routes.

5. Configure the default parameters for redistributed routes (cost, tag, and type).

   default { **cost** *cost-value* | **tag** *tag* | **type** *type* } *

   By default, the cost is 1, the tag is 1, and the route type is 2

Redistributing a default route

About this task

On a OSPF network, multiple ABRs and ASBRs work together to implement multi-egress redundancy or load balancing. To ease the service burden on these devices and save routing table capacity, you can configure default routes.

OSPF default routes are mostly used in the following scenarios:

- After receiving a Type 3 LSA that describes a default route from the ABR, the intra-area router can use the route for packet forwarding to another area in the same AS.
- After receiving a Type 5 or 7 LSA that describes a default route from the ASBR, the intra-area router can use the route for packet forwarding to another AS.

When a router cannot find a exactly matching route, it can use the default route for packet forwarding. The default route originated from a Type 3 LSA takes precedence over that originated from a Type 5 LSA.

As shown in Table 3, the advertisement method for a redistributed default route varies by its area type.

Table 3 Advertisement of redistributed default routes

Area type	Route redistribution condition	Advertiser	LSA type	LSA flooding scope
Common area	Use the **default-route-advertise** command.	ASBR	Type 5 LSA	Common area
Stub area	Automatic route redistribution.	ABR	Type 3 LSA	Stub area
NSSA area	Use the **nssa** [**default-route-advertise**] command.	ASBR	Type 7 LSA	NSSA area
Totally NSSA area	Automatic route redistribution.	ABR	Type 3 LSA	NSSA area

The **import-route** command cannot redistribute a default route from an external routing protocol. To resolve this issue, perform this task on the ASBR to redistribute a default route.

Restrictions and guidelines

After receiving a default route from the ASBR, the device can add the default route to its routing table in one of the following scenarios:

- The device does not have a static route.
- The device has a static route, but the priority value for the default route is higher than that for the static route.

Procedure

1. Enter system view.
   system-view
2. Enter OSPF view.
   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Redistribute a default route.
   default-route-advertise [[**always** | **permit-calculate-other**] | **cost** *cost-value* | **route-policy** *route-policy-name* | **type** *type*] *
   default-route-advertise [**summary cost** *cost-value*]
   By default, no default route is redistributed.
   This command is applicable only to VPNs. The PE router advertises a default route in a Type-3 LSA to a CE router.
4. Configure the default parameters for redistributed routes (cost, tag, and type).
   default { **cost** *cost-value* | **tag** *tag* | **type** *type* } *
   By default, the cost is 1, the tag is 1, and the route type is 2.

Advertising a host route

1. Enter system view.
   system-view
2. Enter OSPF view.
   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Enter area view.
   area *area-id*
4. Advertise a host route.
   host-advertise *ip-address cost-value*
   By default, OSPF does not advertise host routes that are not in the area.

Advertising OSPF link state information to BGP

About this task

After the device advertises OSPF link state information to BGP, BGP can advertise the information for intended applications. For more information about BGP LS, see "Configuring BGP."

Hardware and feature compatibility

The S5200-EI-G switch series does not support this feature.

Procedure

1. Enter system view.
   system-view
2. Enter OSPF view.
   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Advertise OSPF link state information to BGP.
   distribute bgp-ls [**strict-link-checking**]

By default, the device does not advertise OSPF link state information to BGP.

Setting OSPF timers

About setting OSPF timers

This task allows you to change OSPF packet timers to adjust the convergence speed and network load and tune the delay time for sending LSAs on low-speed links.

Configuring OSPF packet timers

About this task

An OSPF interface includes the following timers:

- **Hello timer**—Interval for sending hello packets. It must be identical on OSPF neighbors.
- **Poll timer**—Interval for sending hello packets to a neighbor that is down on the NBMA network.
- **Dead timer**—Interval within which if the interface does not receive any hello packet from the neighbor, it declares the neighbor is down.
- **LSA retransmission timer**—Interval within which if the interface does not receive any acknowledgment packets after sending an LSA to the neighbor, it retransmits the LSA.

Restrictions and guidelines

The default value for the hello interval and neighbor dead interval depends on the network type. When the network type for an interface is changed, the default hello interval and neighbor dead interval are restored. Make sure two neighboring interfaces are configured with the same hello interval and neighbor dead interval. Inconsistent settings will affect the OSPF neighbor relationship establishment.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Set the hello interval.

   ospf timer hello *seconds*

   The default hello interval on P2P and broadcast interfaces is 10 seconds. The default hello interval on P2MP and NBMA interfaces is 30 seconds.
4. Set the poll interval.

   ospf timer poll *seconds*

   The default setting is 120 seconds.

   The poll interval is a minimum of four times the hello interval.
5. Set the dead interval.

   ospf timer dead *seconds*

   The default dead interval on P2P and broadcast interfaces is 40 seconds. The default dead interval on P2MP and NBMA interfaces is 120 seconds.

   The dead interval must be a minimum of four times the hello interval on an interface.
6. Set the retransmission interval.

   ospf timer retransmit *interval*

The default retransmission interval is 5 seconds.

A retransmission interval setting that is too small can cause unnecessary LSA retransmissions. Typically set a bigger interval than the round-trip time of a packet between two neighbors.

Setting the LSA transmission delay

About this task

To avoid LSAs from aging out during transmission, set an LSA retransmission delay especially for low speed links.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Set the LSA transmission delay.

   ospf trans-delay *seconds*

   The default LSA transmission delay is 1 second.

Setting the OSPF route calculation interval

About this task

LSDB changes result in SPF calculations. When the topology changes frequently, a large amount of network and router resources are occupied by SPF calculation. You can adjust the route calculation interval to reduce the impact.

The default route calculation interval settings are as follows:

- The interval for the first route calculation is 50 milliseconds.
- The interval for the nth (n ≥ 2) route calculation is 50 + (200 x 2^{n-2}) milliseconds, and cannot exceed 5 seconds.

The **spf-schedule-interval** command functions as follows:

- If the **spf-schedule-interval** *maximum-interval* command is executed:
  - The values for the *minimum-interval* and *incremental-interval* arguments are both 0.
  - The route calculation interval is fixed at *maximum-interval*.
- If the **spf-schedule-interval** *maximum-interval minimum-interval* command is executed:
  - The value for the *incremental-interval* argument is 0.
  - The interval for the first route calculation is *minimum-interval*.
  - The interval for subsequent route calculations is *maximum-interval*.
- If the **spf-schedule-interval** *maximum-interval minimum-interval incremental-interval* command is executed:
  - The interval for the first route calculation is *minimum-interval*.
  - The interval for the nth (n ≥ 2) route calculation is *minimum-interval* + *incremental-interval* x 2^{n-2}, and cannot exceed *maximum-interval*.

Procedure

1. Enter system view.
   system-view
2. Enter OSPF view.
   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Set the route calculation interval for OSPF.
   spf-schedule-interval *maximum-interval* [*minimum-interval* [*incremental-interval*]]
   By default, the maximum interval is 5 seconds, the minimum interval is 50 milliseconds, and the incremental interval is 200 milliseconds.

Setting the minimum LSA arrival interval

About this task

OSPF drops any duplicate LSAs (with the same LSA type, LS ID, and router ID) within the minimum LSA arrival interval. This helps avoid overuse of bandwidth and router resources due to frequent network changes.

Restrictions and guidelines

On a stable network, you can set the LSA arrival interval to 0 to fasten route convergence.

Procedure

1. Enter system view.
   system-view
2. Enter OSPF view.
   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Set the minimum LSA arrival interval.
   lsa-arrival-interval *interval*
   By default, the minimum LSA arrival interval is 1000 milliseconds.

Setting the LSA update interval

About this task

If network changes become frequent, bandwidth resources and router resources might be overconsumed. To avoid this issue, use the **lsa-generation-interval** command to adjust the LSA update interval settings for OSPF.

The default LSA update interval settings are as follows:

- The interval for the first LSA update is 50 milliseconds.
- The interval for the nth (n ≥ 2) LSA update is 50 + (200 x 2^{n-2}) milliseconds, and cannot exceed 5 seconds.

The **lsa-generation-interval** command functions as follows:

- If the **lsa-generation**-*interval maximum-interval* command is executed:
  - The values for the *minimum-interval* and *incremental-interval* arguments are both 0.
  - The LSA update interval is fixed at *maximum-interval*.

- If the **lsa-generation-interval** *maximum-interval minimum-interval* command is executed:
  - The value for the *incremental-interval* argument is 0.
  - The interval for the first LSA update is *minimum-interval*.
  - The interval for subsequent LSA updates is *maximum-interval*.
- If the **lsa-generation-interval** *maximum-interval minimum-interval incremental-interval* command is executed:
  - The interval for the first LSA update is *minimum-interval*.
  - The interval for the nth (n ≥ 2) LSA update is *minimum-interval* + *incremental-interval* x 2^{n-2}, and cannot exceed *maximum-interval*.

Procedure

1. Enter system view.

   system-view
2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Set the LSA update interval.

   lsa-generation-interval *maximum-interval* [*minimum-interval* [*incremental-interval*]]

   By default, the maximum interval is 5 seconds, the minimum interval is 50 milliseconds, and the incremental interval is 200 milliseconds.

Setting the OSPF exit overflow interval

About this task

When the number of LSAs in the LSDB exceeds the upper limit, the LSDB is in an overflow state. In this state, OSPF does not receive any external LSAs and deletes the external LSAs generated by itself to save system resources.

This task allows you to configure the interval that OSPF exits overflow state.

Procedure

1. Enter system view.

   system-view
2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Set the interval that OSPF exits overflow state.

   lsdb-overflow-interval *interval*

   By default, the OSPF exit overflow interval is 300 seconds. An interval of 0 means that OSPF does not exit overflow state.

Configuring OSPF packet parameters

Disabling interfaces from receiving and sending OSPF packets

About this task

To enhance OSPF adaptability and reduce resource consumption, you can set an OSPF interface to "silent." A silent OSPF interface blocks OSPF packets and cannot establish any OSPF neighbor relationship. However, other interfaces on the router can still advertise direct routes of the interface in Router LSAs.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Disable interfaces from receiving and sending OSPF packets.

   silent-interface { *interface-type interface-number* | **all** }

   By default, an OSPF interface can receive and send OSPF packets.

   This command disables only the interfaces associated with the current process rather than other processes. Multiple OSPF processes can disable the same interface from receiving and sending OSPF packets.

Adding the interface MTU into DD packets

About this task

By default, an OSPF interface adds a value of 0 into the interface MTU field of a DD packet rather than the actual interface MTU. On receipt of a DD packet, the interface does not check the interface MTU field of that packet. Such a mechanism ensures that two interfaces in different devices can establish a neighbor relationship regardless of the interface MTU. However, the device cannot establish neighbor relationships with the devices from another manufacturer that discard the DD packets whose interface MTU value is 0.

To resolve this issue, perform this task to enable an OSPF interface to add its interface MTU into DD packets and check the interface MTU in received DD packets. If the interface MTU in a received DD packet is higher than the MTU of the local interface, the interface will discard the DD packet. To ensure that two interfaces in different devices can establish a neighbor relationship, set the same MTU for these interfaces.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the interface to add its MTU into DD packets.

   ospf mtu-enable

   By default, the interface adds an MTU value of 0 into DD packets.

Setting the DSCP value for outgoing OSPF packets

About this task

The DSCP value specifies the precedence of outgoing packets.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Set the DSCP value for outgoing OSPF packets.

   dscp *dscp-value*

   By default, the DSCP value for outgoing OSPF packets is 48.

Setting the maximum length of OSPF packets that can be sent by an interface

About this task

This task allows you to limit the length of OSPF packets sent over an interface. In some scenarios, for example, when you establish OSPF neighbors over a tunnel, you can perform this task to prevent OSPF packet fragmentation on the outgoing tunnel interface. Make sure the maximum length of the OSPF packets plus the encapsulated header length is no greater than the outgoing tunnel interface's MTU. For more information about tunnels, see *Layer 3—IP Services Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the maximum length of OSPF packets that can be sent by an interface.

   ospf packet-size *value*

   By default, the maximum length of OSPF packets that an interface can send equals the interface's MTU.

Setting the LSU transmit rate

About this task

During LSDB synchronization, if the local router has multiple neighbors, it must send many LSUs to each neighbor. When a neighbor receives excessive LSUs within a short time period, the following events might occur:

- The neighbor experiences degraded performance because it uses too many system resources to process the received LSU packets.
- The neighbor drops hello packets used for maintaining the neighbor relationship because it is busy dealing with the LSUs. As a result, the neighbor relationship is torn down. To reestablish a relationship to the neighbor, the local router must send more LSUs to the neighbor. This exacerbates the performance degradation.

This task allows you to limit the LSU transmit rate by setting the LSU transmit interval and the maximum number of LSUs that can be sent at each interval.

Procedure

1. Enter system view.

   system-view

2. Enable OSPF to limit the LSU transmit rate.

   ospf lsu-flood-control [*interval count*]

   By default, OSPF does not limit the LSU transmit rate.

   Inappropriate use of this command might cause abnormal routing. As a best practice, execute this command with the default values.

3. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

4. (Optional.) Set the LSU transmit interval and the maximum number of LSUs that can be sent at each interval.

   transmit-pacing interval *interval* **count** *count*

   By default, an OSPF interface sends a maximum of three LSU packets every 20 milliseconds.

Controlling LSA generation, advertisement, and reception

Setting the maximum number of external LSAs in LSDB

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Set the maximum number of external LSAs in the LSDB.

   lsdb-overflow-limit *number*

   By default, the maximum number of external LSAs in the LSDB is not limited.

Filtering outbound LSAs on an interface

About this task

To reduce the LSDB size for the neighbor and save bandwidth, you can perform this task on an interface to filter LSAs to be sent to the neighbor.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Filter outbound LSAs on the interface.

ospf database-filter { **all** | { **ase** [**acl** *ipv4-acl-number*] | **nssa** [**acl** *ipv4-acl-number*] | **summary** [**acl** *ipv4-acl-number*] } * }

By default, the outbound LSAs are not filtered on the interface.

Filtering LSAs for the specified neighbor

About this task

On a P2MP network, a router might have multiple P2MP type OSPF neighbors. Perform this task to prevent the router from sending LSAs to the specified P2MP neighbor.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Filter LSAs for the specified P2MP neighbor.

   database-filter peer *ip-address* { **all** | { **ase** [**acl** *ipv4-acl-number*] | **nssa** [**acl** *ipv4-acl-number*] | **summary** [**acl** *ipv4-acl-number*] } * }

   By default, the LSAs for the specified P2MP neighbor are not filtered.

Accelerating OSPF convergence speed

Enabling OSPF ISPF

About this task

When the topology changes, Incremental Shortest Path First (ISPF) computes only the affected part of the SPT, instead of the entire SPT.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Enable OSPF ISPF.

   ispf enable

   By default, OSPF ISPF is enabled.

Configuring prefix suppression

About this task

By default, an OSPF interface advertises all of its prefixes in LSAs. To speed up OSPF convergence, you can suppress interfaces from advertising all of their prefixes. This feature helps improve network security by preventing IP routing to the suppressed networks.

When prefix suppression is enabled:

- On P2P and P2MP networks, OSPF does not advertise Type-3 links in Type-1 LSAs. Other routing information can still be advertised to ensure traffic forwarding.
- On broadcast and NBMA networks, the DR generates Type-2 LSAs with a mask length of 32 to suppress network routes. Other routing information can still be advertised to ensure traffic forwarding. If no neighbors exist, the DR does not advertise Type-3 links in Type-1 LSAs.

Restrictions and guidelines for prefix suppression

As a best practice, configure prefix suppression on all OSPF routers if you want to use prefix suppression.

Configuring prefix suppression for an OSPF process

1. Enter system view.

   system-view
2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Enable prefix suppression for the OSPF process.

   prefix-suppression

   By default, prefix suppression is disabled for an OSPF process.

   This feature does not suppress the prefixes of secondary IP addresses, loopback interfaces, and passive interfaces.

Configuring prefix suppression for an interface

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable prefix suppression for the interface.

   ospf prefix-suppression [**disable**]

   By default, prefix suppression is disabled on an interface.

   This feature does not suppress prefixes of secondary IP addresses.

Configuring prefix prioritization

About this task

OSPF calculates intra-area routes, inter-area routes, and AS external routes in descending convergence priority order: critical, high, medium, and low. When a route matches multiple prefix priorities, it prefers to use the highest priority.

To prioritize the convergence of specific routes, perform this task to set a higher convergence priority value for those routes.

Procedure

1. Enter system view.

   system-view
2. Configure an IPv4 prefix list.

   ip prefix-list *prefix-list-name* [**index** *index-number*] { **deny** | **permit** } *ip-address mask-length* [**greater-equal** *min-mask-length*] [**less-equal** *max-mask-length*]
3. Configure a routing policy.

route-policy *route-policy-name* { **deny** | **permit** } **node** *node-number*

4. Use the IPv4 prefix list as an IPv4 route filter.

   if-match ip { **address** | **next-hop** | **route-source** } **prefix-list** *prefix-list-name*

   By default, no IPv4 route filters are configured.

5. Set a prefix priority for matching routes.

   apply prefix-priority { **critical** | **high** | **medium** }

   By default, no prefix priority is set.

6. Return to system view.

   quit

7. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

8. Enable prefix prioritization.

   prefix-priority route-policy *route-policy-name*

   By default, prefix prioritization is disabled.

Configuring OSPF PIC

About this task

Prefix Independent Convergence (PIC) enables the device to speed up network convergence by ignoring the number of prefixes.

Restrictions and guidelines for OSPF PIC

When both OSPF PIC and OSPF FRR are configured, OSPF FRR takes effect.

OSPF PIC applies only to inter-area routes and external routes.

Enabling OSPF PIC

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Enable PIC for OSPF.

   pic [**additional-path-always**]

   By default, OSPF PIC is enabled.

Configuring BFD for OSPF PIC

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable BFD control packet mode for OSPF PIC.

   ospf primary-path-detect bfd ctrl

   By default, BFD control packet mode is disabled for OSPF PIC.

   This mode requires BFD configuration on both OSPF routers on the link.

Configuring BFD echo packet mode for OSPF PIC

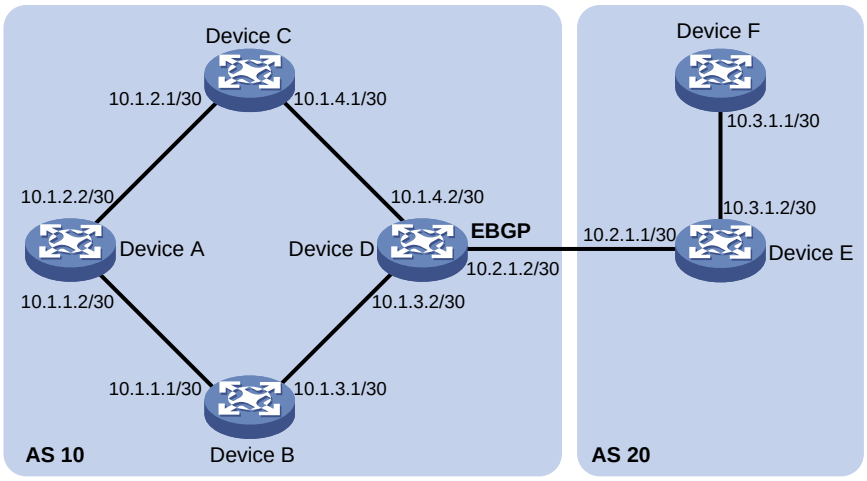
1. Enter system view.
   system-view
2. Configure the source IP address of BFD echo packets.
   bfd echo-source-ip *ip-address*
   By default, the source IP address of BFD echo packets is not configured.
   The source IP address cannot be on the same network segment as any local interfaces.
   For more information about this command, see *High Availability Command Reference*.
3. Enter interface view.
   interface *interface-type interface-number*
4. Enable BFD echo packet mode for OSPF PIC.
   ospf primary-path-detect bfd echo
   By default, BFD echo packet mode is disabled for OSPF PIC.
   This mode requires BFD configuration on one OSPF router on the link.

Configuring advanced OSPF features

Configuring stub routers

About this task

A stub router is used for traffic control. It reports its status as a stub router to neighboring OSPF routers. The neighboring routers can have a route to the stub router, but they do not use the stub router to forward data.



Router LSAs from the stub router might contain different link type values. A value of 3 means a link to a stub network, and the cost of the link will not be changed by default. To set the cost of the link to 65535, specify the **include-stub** keyword in the **stub-router** command. A value of 1, 2 or 4 means a point-to-point link, a link to a transit network, or a virtual link. On such links, a maximum cost value of 65535 is used. Neighbors do not send packets to the stub router as long as they have a route with a smaller cost.

As shown in Figure 12, Device A, Device B, Device C, and Device D run OSPF. Device C is the backup device for Device B. Device A and Device B, Device A and Device C, Device B and Device D, and Device C and Device D are IBGP peers.

When the network is stable, BGP and OSPF can finish route convergence completely. Device A forwards traffic destined for 10.3.1.0/30 to Device B. If Device B fails, Device C will take over to forward the traffic from Device A.

After Device B recovers, Device A immediately forwards the traffic Device B. However, BGP might have not finished route convergence when OSPF has finished route convergence, because OSPF has a higher route convergence speed than BGP. In this situation, Device B does not have a route to 10.3.1.0/30 and will discard the traffic destined for 10.3.1.0/30. To resolve this issue, configure Device B to act as a stub router during BGP route convergence. Device A will forward traffic to Device C instead of Device B until Device B finishes BGP route convergence.

Figure 12 Network diagram

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Configure the router as a stub router.

   stub-router [**external-lsa** [*max-metric-value*] | **include-stub** | **on-startup** { *seconds* | **wait-for-bgp** [*seconds*] } | **summary-lsa** [*max-metric-value*]] *

   By default, the router is not configured as a stub router.

   A stub router is not related to a stub area.

Configuring OSPF isolation

About this task

Isolation is a method used for network device maintenance. It gracefully removes a device from the packet forwarding path for maintenance and gracefully adds the device to the network after maintenance.

To reduce impact on traffic forwarding, you can isolate a device before upgrading it. OSPF isolation works as follows:

1. After OSPF isolation is enabled for a device, OSPF increases the link cost in LSAs advertised by the device based on the following rules:
   - The link cost in Type-1 LSAs (Router LSAs) is increased to 65535.
   - The link cost in the following LSAs is increased to 16711680:
     - Type-3 LSAs (Network summary LSAs).
     - Type-5 LSAs (AS external LSAs).
     - Type-7 LSAs (NSSA external LSAs).
2. Each neighbor of the device reselects an optimal route based on the LSAs and stops forwarding traffic to the device. The device is fully isolated from the network and you can upgrade the device.

3. After the maintenance, disable OSPF isolation on the device to restore its link cost and gracefully add it back to the network.

Restrictions and guidelines

Both the **isolate enable** and **stub-router external-lsa 16711680 summary-lsa 16711680 include-stub** commands can isolate the device from the network.

When you execute both the **isolate enable** and **stub-router** commands, follow these restrictions and guidelines:

- If you specify the **external-lsa** and **summary-lsa** keywords in the **stub-router** command, the higher one of the two link costs provided by the isolation feature and the stub router feature takes effect.
- If the **on-startup** keyword is specified in the **stub-router** command, traffic forwarding path selection is affected only by the isolation feature when the stub router feature does not take effect.

Procedure

1. Enter system view.

   system-view
2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Configure OSPF isolation.
   - Enable OSPF isolation to gracefully isolate the device from the network.

     isolate enable
   - Disable OSPF isolation to gracefully add the device back to the network.

     undo isolate enable

   By default, OSPF isolation is disabled.

Configuring OSPF shutdown

About this task

For maintenance purposes, you can use this feature to shut down OSPF processes on the device with small impact on the network. If you shut down a process, it will perform the following operations:

- Send 1-way hello packets to its neighbors.

  On receipt of the packets, the neighbors disconnect from the OSPF process and use the backup path to forward traffic.
- Stop receiving and sending OSPF packets.
- Clear its neighbor, LSDB, and OSPF route information.

After maintenance, you can use the **undo shutdown process** command to restart the process for neighbor relationship re-establishment.

This feature shuts down an OSPF process while retaining the process-associated settings to facilitate your maintenance.

Procedure

1. Enter system view.

   system-view
2. Enter OSPF view.

ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Configure OSPF shutdown.
   - Shut down an OSPF process to isolate it from the network.

     shutdown process
   - Restart the OSPF process to add it back to the network.

     undo shutdown process

   By default, the OSPF process is not shut down.

Enabling compatibility with RFC 1583

About this task

RFC 1583 specifies a different method than RFC 2328 for selecting the optimal route to a destination in another AS. When multiple routes are available to the ASBR, OSPF selects the optimal route by using the following procedure:

1. Selects the route with the highest preference.
   - If RFC 2328 is compatible with RFC 1583, all these routes have equal preference.
   - If RFC 2328 is not compatible with RFC 1583, the intra-area route in a non-backbone area is preferred to reduce the burden of the backbone area. The inter-area route and intra-area route in the backbone area have equal preference.
2. Selects the route with the lower cost if two routes have equal preference.
3. Selects the route with the larger originating area ID if two routes have equal cost.

Restrictions and guidelines

To avoid routing loops, set identical RFC 1583-compatibility on all routers in a routing domain.

Procedure

1. Enter system view.

   system-view
2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Enable compatibility with RFC 1583.

   rfc1583 compatible

   By default, compatibility with RFC 1583 is enabled.

Configuring OSPF GR

About OSPF GR

GR ensures forwarding continuity when a routing protocol restarts or an active/standby switchover occurs.

Two routers are required to complete a GR process. The following are router roles in a GR process:

- **GR restarter**—Graceful restarting router. It must have GR capability.
- **GR helper**—A neighbor of the GR restarter. It helps the GR restarter to complete the GR process.

OSPF GR has the following types:

- **IETF GR**—Uses Opaque LSAs to implement GR.
- **Non-IETF GR**—Uses link local signaling (LLS) to advertise GR capability and uses out of band synchronization to synchronize the LSDB.

A device can act as a GR restarter and GR helper at the same time.

Configuring OSPF GR restarter

Configuring the IETF OSPF GR restarter

1. Enter system view.
   system-view
2. Enable OSPF and enter its view.
   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Enable opaque LSA reception and advertisement capability.
   opaque-capability enable
   By default, opaque LSA reception and advertisement capability is enabled.
4. Enable the IETF GR.
   graceful-restart ietf [**global** | **planned-only**] *
   By default, the IETF GR capability is disabled.
5. (Optional.) Set the GR interval.
   graceful-restart interval *interval*
   By default, the GR interval is 120 seconds.

Configuring the non-IETF OSPF GR restarter

1. Enter system view.
   system-view
2. Enable OSPF and enter its view.
   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Enable the link-local signaling capability.
   enable link-local-signaling
   By default, the link-local signaling capability is disabled.
4. Enable the out-of-band re-synchronization capability.
   enable out-of-band-resynchronization
   By default, the out-of-band re-synchronization capability is disabled.
5. Enable non-IETF GR.
   graceful-restart [**nonstandard**] [**global** | **planned-only**] *
   By default, non-IETF GR capability is disabled.
6. (Optional.) Set the GR interval.
   graceful-restart interval *interval*
   By default, the GR interval is 120 seconds.

Configuring OSPF GR helper

Configuring the IETF OSPF GR helper

1. Enter system view.

   system-view

2. Enable OSPF and enter its view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Enable opaque LSA reception and advertisement capability.

   opaque-capability enable

   By default, opaque LSA reception and advertisement capability is enabled.

4. Enable GR helper capability.

   graceful-restart helper enable [**planned-only**]

   By default, GR helper capability is enabled.

5. (Optional.) Enable strict LSA checking for the GR helper.

   graceful-restart helper strict-lsa-checking

   By default, strict LSA checking for the GR helper is disabled.

   When an LSA change on the GR helper is detected, the GR helper device exits the GR helper mode.

Configuring the non-IETF OSPF GR helper

1. Enter system view.

   system-view

2. Enable OSPF and enter its view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Enable the link-local signaling capability.

   enable link-local-signaling

   By default, the link-local signaling capability is disabled.

4. Enable the out-of-band re-synchronization capability.

   enable out-of-band-resynchronization

   By default, the out-of-band re-synchronization capability is disabled.

5. Enable GR helper.

   graceful-restart helper enable

   By default, GR helper is enabled.

6. (Optional.) Enable strict LSA checking for the GR helper.

   graceful-restart helper strict-lsa-checking

   By default, strict LSA checking for the GR helper is disabled.

   When an LSA change on the GR helper is detected, the GR helper device exits the GR helper mode.

Triggering OSPF GR

About this task

You can trigger OSPF GR by performing an active/standby switchover or using the **reset ospf process** command.

Procedure

To trigger OSPF GR, execute the **reset ospf** [*process-id*] **process graceful-restart** command in user view.

Configuring OSPF NSR

About this task

Nonstop routing (NSR) backs up OSPF link state information from the active process to the standby process. After an active/standby switchover, NSR can complete link state recovery and route regeneration without tearing down adjacencies or impacting forwarding services.

Choose OSPF NSR or OSPF GR according to the actual situation and make sure data forwarding is not interrupted. The differences between OSPF NSR and OSPF GR as follows:

- **Device requirements**—The active and standby processes of OSPF must run on different IRF member devices. To run OSPF NSR, you must set up an IRF fabric that contains a minimum of two member devices. To run OSPF GR, IRF fabric setup is not required. If an IRF fabric already exists, you can run OSPF GR when the IRF fabric contains only one member device.
- **OSPF neighbor requirements**—When you use OSPF NSR, OSPF neighbors cannot detect process restart or active/standby switchover on the local device. OSPF NSR can recover OSPF route information without requiring the cooperation of OSPF neighbors. OSPF GR requires OSPF neighbors to have the GR helper capability to help the GR restarter complete the GR process.

Restrictions and guidelines

When both GR and NSR are configured for OSPF on a device, the following rules apply:

- OSPF NSR has a higher priority than OSPF GR. When the active process goes down, the device does not act as the GR restarter and performs NSR to ensure nonstop forwarding.
- When the following conditions exist, the GR process might fail even if OSPF NSR is enabled on the GR helper:
  - OSPF is restarted through GR.
  - An active/standby switchover is triggered on the GR helper before the GR process finishes.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Enable OSPF NSR.

   non-stop-routing

   For the S5200-EI-G switch series, OSPF NSR is disabled by default.

   For the S5200-HI-G switch series, OSPF NSR is enabled by default.

   This command takes effect only for the current process. As a best practice, enable OSPF NSR for each process if multiple OSPF processes exist.

Configuring BFD for OSPF

About BFD for OSPF

OSPF sends hello packets to neighbors at specific intervals to detect their state. If OSPF does not receive a hello packet from a neighbor within a specific period, OSPF considers the neighbor down. Such a failure detection method cannot achieve high data reliability, because it takes a long time and causes data loss.

To resolve this issue, configure Bidirectional Forwarding Detection (BFD) for OSPF. This feature improves the route convergence speed against link state changes through fast link state detection. For more information about BFD, see *High Availability Configuration Guide*.

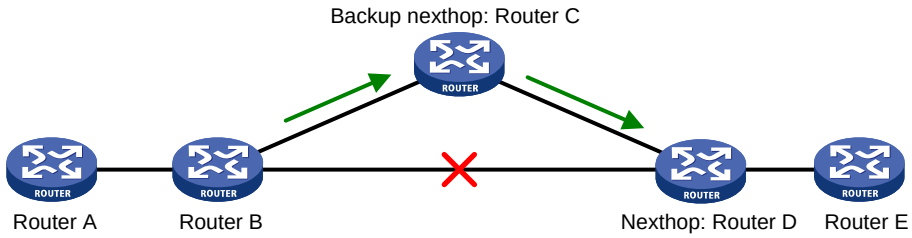
OSPF supports the following BFD detection modes:

- **Bidirectional control detection**—Requires BFD configuration to be made on both OSPF routers on the link.
- **Single-hop echo detection**—Requires BFD configuration to be made on one OSPF router on the link.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable BFD bidirectional control detection.
   ospf bfd enable
   By default, BFD bidirectional control detection is disabled.
   Both ends of a BFD session must be on the same network segment and in the same area.

Configuring single-hop echo detection



1. Enter system view.
   system-view
2. Configure the source address of echo packets.
   bfd echo-source-ip *ip-address*
   By default, the source address of echo packets is not configured.
   The source IP address cannot be on the same network segment as any local interfaces.
   For more information about this command, see *High Availability Command Reference*.
3. Enter interface view.
   interface *interface-type interface-number*
4. Enable BFD single-hop echo detection.
   ospf bfd enable echo
   By default, BFD single-hop echo detection is disabled.

Configuring OSPF FRR

About OSPF FRR

A link or router failure on a path can cause packet loss until OSPF completes routing convergence based on the new network topology. FRR enables fast rerouting to minimize the impact of link or node failures.

Figure 13 Network diagram for OSPF FRR

As shown in Figure 13, configure FRR on Router B by using a routing policy to specify a backup next hop. When the primary link fails, OSPF directs packets to the backup next hop. At the same time, OSPF calculates the shortest path based on the new network topology. It forwards packets over the path after network convergence.

You can configure OSPF FRR to calculate a backup next hop by using the loop free alternate (LFA) algorithm, or specify a backup next hop by using a routing policy.

Restrictions and guidelines for OSPF FRR

When both OSPF PIC and OSPF FRR are configured, OSPF FRR takes effect.

Configuring OSPF FRR to use the LFA algorithm to calculate a backup next hop

Restrictions and guidelines

Do not use the **fast-reroute lfa** command together with the **vlink-peer** command.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. (Optional.) Enable LFA on an interface.
   ospf fast-reroute lfa-backup
   By default, the interface is enabled with LFA and it can be selected as a backup interface.
4. Return to system view.
   quit
5. Enter OSPF view.
   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

6. Enable OSPF FRR to use the LFA algorithm to calculate a backup next hop.

   fast-reroute lfa [**abr-only** | **ecmp-shared**]

   By default, OSPF FRR is disabled.

   If **abr-only** is specified, the route to the ABR is selected as the backup path.

   The S5200-EI-G switch series does not support the **ecmp-shared** keyword.

Configuring OSPF FRR to use a backup next hop specified in a routing policy

About this task

Before you perform this task, use the **apply fast-reroute backup-interface** command to specify a backup next hop in a routing policy for OSPF FRR. For more information about the **apply fast-reroute backup-interface** command and routing policy configuration, see "Configuring routing policies."

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Enable OSPF FRR to use a backup next hop specified in a routing policy.

   fast-reroute route-policy *route-policy-name*

   By default, OSPF FRR is disabled.

Configuring BFD for OSPF FRR

About this task

By default, OSPF FRR does not use BFD to detect primary link failures. To speed up OSPF convergence, enable BFD control packet mode for OSPF FRR to detect primary link failures. This mode requires BFD configuration on both OSPF routers on the link.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable BFD control packet mode for OSPF FRR.

   ospf primary-path-detect bfd ctrl

   By default, BFD control packet mode is disabled for OSPF FRR.

Configuring BFD echo packet mode for OSPF FRR

About this task

By default, OSPF FRR does not use BFD to detect primary link failures. To speed up OSPF convergence, enable BFD echo packet mode for OSPF FRR to detect primary link failures. This mode requires BFD configuration on one OSPF router on the link.

Procedure

1. Enter system view.
   system-view
2. Configure the source IP address of BFD echo packets.
   bfd echo-source-ip *ip-address*
   By default, the source IP address of BFD echo packets is not configured.
   The source IP address cannot be on the same network segment as any local interface's IP address.
   For more information about this command, see *High Availability Command Reference*.
3. Enter interface view.
   interface *interface-type interface-number*
4. Enable BFD echo packet mode for OSPF FRR.
   ospf primary-path-detect bfd echo
   By default, BFD echo packet mode is disabled for OSPF FRR.

Configuring OSPF authentication

About OSPF area and interface authentication

Perform this task to configure OSPF area and interface authentication.

OSPF adds the authentication information into sent packets, and uses the key to authenticate received packets. Only packets that pass the authentication can be received. If a packet fails the authentication, the OSPF neighbor relationship cannot be established.

If you configure OSPF authentication for both an area and an interface in that area, the interface uses the OSPF authentication configured on it.

Restrictions and guidelines for configuring OSPF authentication

OSPF supports the MD5, HMAC-MD5, HMAC-SHA-256, and HMAC-SM3 authentication algorithms.

The ID of keys used for authentication can only be in the range of 0 to 255.

Configuring OSPF area authentication

1. Enter system view.
   system-view
2. Enter OSPF view.
   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Enter area view.
   area *area-id*
4. Configure area authentication mode.
   - Configure HMAC-MD5/HMAC-SHA-256/HMAC-SM3/MD5 authentication.
     authentication-mode { **hmac-md5** | **hmac-sha-256** | **hmac-sm3** | **md5** } [*key-id* { **cipher** | **plain** } *string*]

- Configure simple authentication.
  authentication-mode simple [{ **cipher** | **plain** } *string*]
- Configure keychain authentication.
  authentication-mode keychain *keychain-name*
  For information about keychains, see *Security Configuration Guide*.

By default, no authentication is configured.

All routers in an area must use the same authentication mode. If a key is configured, all routers must be configured with the same key.

Configuring OSPF interface authentication

About this task

To prevent an interface from authenticating OSPF packets, configure the None authentication mode on the interface. Then, the interface will not inherit the authentication configuration of the area.

Restrictions and guidelines

The local interface and its peer interface must use the same authentication mode. If a key is configured, the local and peer interfaces must be configured with the same key.

If you configure the None authentication mode on an interface, make sure its peer interface uses the None authentication mode or is not configured with any authentication modes.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure interface authentication mode.
   - Configure simple authentication.
     ospf authentication-mode simple [{ **cipher** | **plain** } *string*]
   - *Configure* the None authentication mode.
     ospf authentication-mode none
   - Configure HMAC-MD5/HMAC-SHA-256/HMAC-SM3/MD5 authentication.
     ospf authentication-mode { **hmac-md5** | **hmac-sha-256** | **hmac-sm3** | **md5** } [*key-id* { **cipher** | **plain** } *string*]
   - Configure keychain authentication.
     ospf authentication-mode keychain *keychain-name*
     For information about keychains, see *Security Configuration Guide*.

   By default, no authentication is configured.

Configuring GTSM for OSPF

About GTSM

The Generalized TTL Security Mechanism (GTSM) protects the device by comparing the TTL value in the IP header of incoming OSPF packets against a valid TTL range. If the TTL value is within the valid TTL range, the packet is accepted. If not, the packet is discarded.

The valid TTL range is from 255 – the configured hop count + 1 to 255.

When GTSM is configured, the OSPF packets sent by the device have a TTL of 255.

Restrictions and guidelines for GTSM

To use GTSM, you must configure GTSM on both the local and peer devices. You can specify different *hop-count* values for them.

The GTSM configuration in OSPF area view applies to all OSPF interfaces in the area. The GTSM configuration in interface view takes precedence over the configuration in OSPF area view.

Configuring GTSM in OSPF area view

1. Enter system view.

   system-view
2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
3. Enter OSPF area view.

   area *area-id*
4. Enable GTSM for the OSPF area.

   ttl-security [**hops** *hop-count*]

   By default, GTSM is disabled for the OSPF area.

Configuring GTSM in interface view

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Configure GTSM for the interface.
   - Enable GTSM for the interface.

     ospf ttl-security [**hops** *hop-count*]
   - Disable GTSM for the interface.

     ospf ttl-security disable

     Disable GTSM for an interface when the following conditions exist:
     - The area to which the interface belongs is enabled with GTSM.
     - The neighbor of the interface does not support GTSM.

   By default, an interface uses the GTSM configuration of the area to which the interface belongs.

Configuring OSPF logging, SNMP notifications, and troubleshooting

Logging neighbor state changes

About this task

Perform this task to enable output of neighbor state change logs to the information center. The information center processes the logs according to user-defined output rules (whether and where to output logs). For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Enable the logging of neighbor state changes.

   log-peer-change

   By default, this feature of logging neighbor state changes is enabled.

Configuring the OSPF logging feature

About this task

OSPF logs include LSA aging logs, route calculation logs, neighbor logs, OSPF route logs, and self-originated and received LSA logs.

Procedure

1. Enter system view.

   system-view

2. Enter OSPF view.

   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *

3. Set the number of OSPF logs.

   event-log { **hello** { **received** [**abnormal** | **dropped**] | **sent** [**abnormal** | **failed**] } | **lsa-flush** | **peer** | **spf** } **size** *count*

   By default, the device can generate a maximum of 100 OSPF logs for each type.

Configuring OSPF network management

About this task

This task involves the following configurations:

- Bind an OSPF process to MIB so that you can use network management software to manage the specified OSPF process.
- Enable SNMP notifications for OSPF to report important events.

- Configure the SNMP notification output interval and the maximum number of SNMP notifications that can be output at each interval.

To report critical OSPF events to an NMS, enable SNMP notifications for OSPF. For SNMP notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

Procedure

1. Enter system view.
   system-view
2. Bind MIB to an OSPF process.
   ospf mib-binding *process-id*
   By default, MIB is bound to the process with the smallest process ID.
3. Enable SNMP notifications for OSPF.
   snmp-agent trap enable ospf [**authentication-failure** | **bad-packet** | **config-error** | **dr-ip-address-conflict** | **grhelper-status-change** | **grrestarter-status-change** | **if-networktype-mismatch** | **if-state-change** | **inter-area-router-id-conflict** | **intra-area-router-id-conflict** | **lsa-maxage** | **lsa-originate** | **lsdb-approaching-overflow** | **lsdb-overflow** | **neighbor-state-change** | **nssatranslator-status-change** | **retransmit** | **virt-authentication-failure** | **virt-bad-packet** | **virt-config-error** | **virt-retransmit** | **virtgrhelper-status-change** | **virtif-state-change** | **virtneighbor-state-change** | **vlinkid-need-change**] *
   By default, SNMP notifications for OSPF are enabled.
4. Enter OSPF view.
   ospf [*process-id* | **router-id** *router-id* | **vpn-instance** *vpn-instance-name*] *
5. Configure the SNMP notification output interval and the maximum number of SNMP notifications that can be output at each interval.
   snmp trap rate-limit interval *trap-interval* **count** *trap-number*
   By default, OSPF outputs a maximum of seven SNMP notifications within 10 seconds.

Setting the maximum number of OSPF neighbor relationship troubleshooting entries

1. Enter system view.
   system-view
2. Set the maximum number of OSPF neighbor relationship troubleshooting entries.
   ospf troubleshooting max-number *number*
   By default, OSPF can record a maximum of 100 neighbor relationship troubleshooting entries.

Display and maintenance commands for OSPF

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display summary route information	**display ospf** [*process-id*] [**area** *area-id*]

Task	Command
on the OSPF ABR.	**abr-summary** [*ip-address* { *mask-length* | *mask* }] [**verbose**]
Display OSPF FRR backup next hop information.	**display ospf** [*process-id*] [**area** *area-id*] **fast-reroute lfa-candidate**
Display OSPF topology information.	**display ospf** [*process-id*] [**area** *area-id*] **spf-tree** [**verbose**]
Display OSPF process information.	**display ospf** [*process-id*] [**verbose**]
Display OSPF ABR and ASBR information.	**display ospf** [*process-id*] **abr-asbr** [**verbose**]
Display OSPF ASBR route summarization information.	**display ospf** [*process-id*] **asbr-summary** [*ip-address* { *mask-length* | *mask* }]
Display OSPF log information.	**display ospf** [*process-id*] **event-log** { **lsa-flush** | **peer** [*neighbor-id*] [**slot** *slot-number*] | **spf** }
Display OSPF log information about received or sent hello packets.	**display ospf** [*process-id*] **event-log hello** { **received** [**abnormal** | **dropped**] | **sent** } [*neighbor-id*] [**slot** *slot-number*] **display ospf** [*process-id*] **event-log hello sent** { **abnormal** | **failed** } [*neighbor-address*] [**slot** *slot-number*]
Display OSPF GR information.	**display ospf** [*process-id*] **graceful-restart** [**verbose**]
Display OSPF interface information.	**display ospf** [*process-id*] **interface** [*interface-type interface-number* | **verbose**]
Display information about hello packets sent by OSPF interfaces.	**display ospf** [*process-id*] **interface** [*interface-type interface-number*] **hello**
Display OSPF LSDB information.	**display ospf** [*process-id*] [**area** *area-id*] **lsdb** { **asbr** | **network** | **nssa** | **opaque-area** | **opaque-link** | **router** | **summary** } [*link-state-id*] [**originate-router** *advertising-router-id* | **self-originate**] **display ospf** [*process-id*] **lsdb** [**brief** | **originate-router** *advertising-router-id* | **self-originate**] **display ospf** [*process-id*] **lsdb** { **ase** | **opaque-as** } [*link-state-id*] [**originate-router** *advertising-router-id* | **self-originate**]

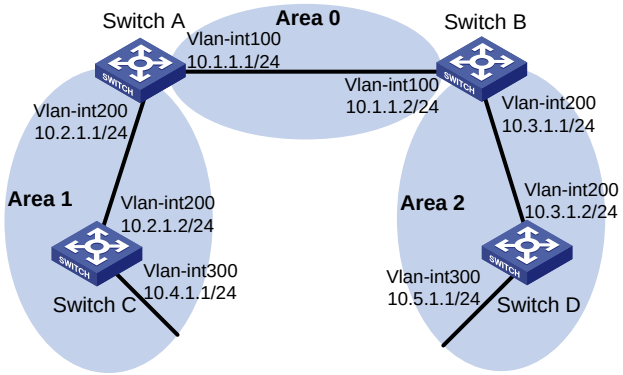
Display OSPF neighbor relationship troubleshooting information.	**display ospf troubleshooting**
Clear OSPF log information.	**reset ospf** [*process-id*] **event-log** [**lsa-flush** | **peer** | **spf**]
Clear OSPF log information about received or sent hello packets.	**reset ospf** [*process-id*] **event-log hello** { **received** [**abnormal** | **dropped**] | **sent** [**abnormal** | **failed**] } [**slot** *slot-number*]
Restart an OSPF process.	**reset ospf** [*process-id*] **process** [**graceful-restart**]
Re-enable OSPF route redistribution.	**reset ospf** [*process-id*] **redistribution**
Clear OSPF statistics.	**reset ospf** [*process-id*] **statistics**
Clear OSPF neighbor relationship troubleshooting information.	**reset ospf troubleshooting**

OSPF configuration examples



Example: Configuring basic OSPF

Network configuration

As shown in Figure 14:

- Enable OSPF on all switches, and split the AS into three areas.
- Configure Switch A and Switch B as ABRs.

Figure 14 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Enable OSPF:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] router id 10.2.1.1
[SwitchA] ospf
[SwitchA-ospf-1] area 0
[SwitchA-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] quit
[SwitchA-ospf-1] area 1
[SwitchA-ospf-1-area-0.0.0.1] network 10.2.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.1] quit
[SwitchA-ospf-1] quit
```

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] router id 10.3.1.1
[SwitchB] ospf
[SwitchB-ospf-1] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] area 2
[SwitchB-ospf-1-area-0.0.0.2] network 10.3.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.2] quit
[SwitchB-ospf-1] quit
```

   # Configure Switch C.

```
<SwitchC> system-view
[SwitchC] router id 10.4.1.1
[SwitchC] ospf
[SwitchC-ospf-1] area 1
[SwitchC-ospf-1-area-0.0.0.1] network 10.2.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.1] network 10.4.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.1] quit
[SwitchC-ospf-1] quit
```

   # Configure Switch D.

```
<SwitchD> system-view
[SwitchD] router id 10.5.1.1
[SwitchD] ospf
[SwitchD-ospf-1] area 2
[SwitchD-ospf-1-area-0.0.0.2] network 10.3.1.0 0.0.0.255
[SwitchD-ospf-1-area-0.0.0.2] network 10.5.1.0 0.0.0.255
[SwitchD-ospf-1-area-0.0.0.2] quit
[SwitchD-ospf-1] quit
```

Verifying the configuration

Display information about neighbors on Switch A.

```
[SwitchA] display ospf peer verbose

          OSPF Process 1 with Router ID 10.2.1.1
                  Neighbors

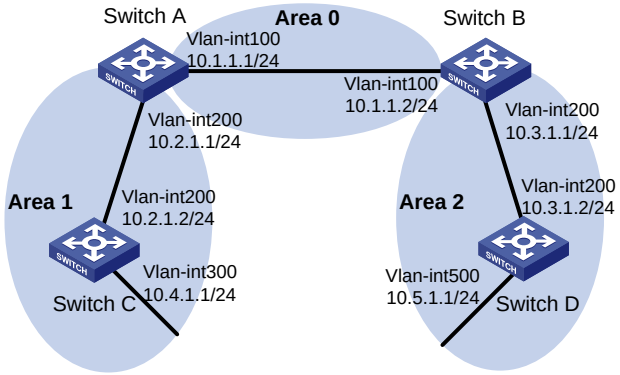
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 0.779/1.408/1.702/0.323 ms
```



Example: Configuring OSPF route redistribution

Network configuration

As shown in Figure 15:

- Enable OSPF on all the switches.
- Split the AS into three areas.
- Configure Switch A and Switch B as ABRs.
- Configure Switch C as an ASBR to redistribute external routes (static routes).

Figure 15 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Enable OSPF (see "Example: Configuring basic OSPF").
3. Configure OSPF to redistribute routes:

   # On Switch C, configure a static route destined for network 3.1.2.0/24.

   ```
   <SwitchC> system-view
   [SwitchC] ip route-static 3.1.2.1 24 10.4.1.2
   ```

   # On Switch C, configure OSPF to redistribute static routes.

   ```
   [SwitchC] ospf 1
   [SwitchC-ospf-1] import-route static
   ```

Verifying the configuration

Display the ABR/ASBR information on Switch D.

```
<SwitchD> display ospf abr-asbr

          OSPF Process 1 with Router ID 10.5.1.1
                  Routing Table to ABR and ASBR

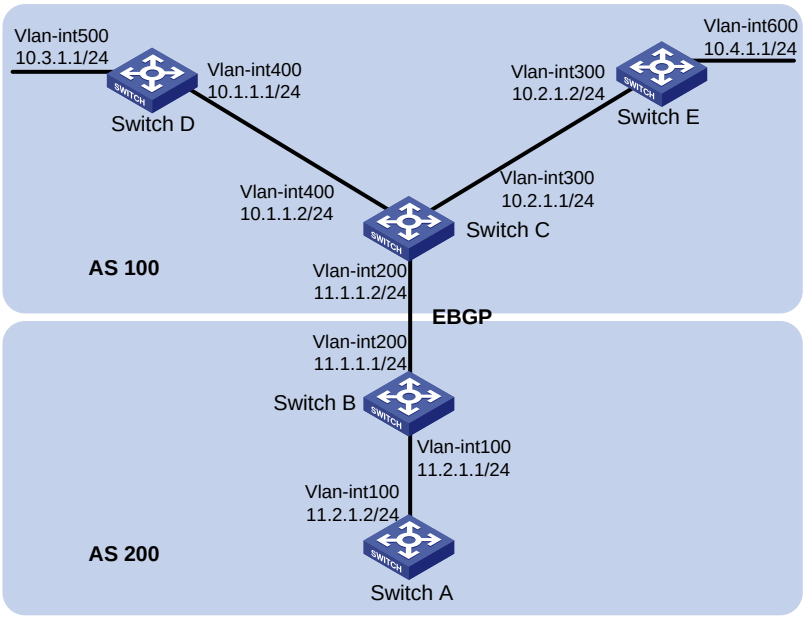
Total nets: 6
Intra area: 2  Inter area: 3  ASE: 1  NSSA: 0
```



Example: Configuring OSPF route summarization

Network configuration

As shown in Figure 16:

- Configure OSPF on Switch A and Switch B in AS 200.
- Configure OSPF on Switch C, Switch D, and Switch E in AS 100.
- Configure an EBGP connection between Switch B and Switch C. Configure Switch B and Switch C to redistribute OSPF routes and direct routes into BGP and BGP routes into OSPF.
- Configure Switch B to advertise only summary route 10.0.0.0/8 to Switch A.

Figure 16 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Enable OSPF:

   # Configure Switch A.

   ```
   <SwitchA> system-view
   [SwitchA] router id 11.2.1.2
   [SwitchA] ospf
   [SwitchA-ospf-1] area 0
   ```

```
[SwitchA-ospf-1-area-0.0.0.0] network 11.2.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] quit
[SwitchA-ospf-1] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] router id 11.2.1.1
[SwitchB] ospf
[SwitchB-ospf-1] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 11.2.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] router id 11.1.1.2
[SwitchC] ospf
[SwitchC-ospf-1] area 0
[SwitchC-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] network 10.2.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] quit
[SwitchC-ospf-1] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] router id 10.3.1.1
[witchD] ospf
[SwitchD-ospf-1] area 0
[SwitchD-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[SwitchD-ospf-1-area-0.0.0.0] network 10.3.1.0 0.0.0.255
[SwitchD-ospf-1-area-0.0.0.0] quit
[SwitchD-ospf-1] quit
```

Configure Switch E.

```
<SwitchE> system-view
[SwitchE] router id 10.4.1.1
[SwitchE] ospf
[SwitchE-ospf-1] area 0
[SwitchE-ospf-1-area-0.0.0.0] network 10.2.1.0 0.0.0.255
[SwitchE-ospf-1-area-0.0.0.0] network 10.4.1.0 0.0.0.255
[SwitchE-ospf-1-area-0.0.0.0] quit
[SwitchE-ospf-1] quit
```

3. Configure BGP to redistribute OSPF routes and direct routes:

Configure Switch B.

```
[SwitchB] bgp 200
[SwitchB-bgp-default] peer 11.1.1.2 as 100
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 11.1.1.2 enable
[SwitchB-bgp-default-ipv4] import-route ospf
[SwitchB-bgp-default-ipv4] import-route direct
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

Configure Switch C.

```
[SwitchC] bgp 100
[SwitchC-bgp-default] peer 11.1.1.1 as 200
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 11.1.1.1 enable
[SwitchC-bgp-default-ipv4] import-route ospf
[SwitchC-bgp-default-ipv4]import-route direct
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

4. Configure Switch B and Switch C to redistribute BGP routes into OSPF:

Configure OSPF to redistribute routes from BGP on Switch B.

```
[SwitchB] ospf
[SwitchB-ospf-1] import-route bgp
```

Configure OSPF to redistribute routes from BGP on Switch C.

```
[SwitchC] ospf
[SwitchC-ospf-1] import-route bgp
```

Display the OSPF routing table on Switch A.

```
[SwitchA] display ip routing-table
         Destinations : 16        Routes : 16
Destination/Mask    Proto  Pre  Cost         NextHop         Interface

127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.0/32        Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
127.255.255.255/32  Direct 0    0            127.0.0.1       InLoop0
224.0.0.0/4         Direct 0    0            0.0.0.0         NULL0
224.0.0.0/24        Direct 0    0            0.0.0.0         NULL0
255.255.255.255/32  Direct 0    0            127.0.0.1       InLoop0
```

5. Configure route summarization:

Configure route summarization on Switch B to advertise a summary route 10.0.0.0/8.

```
[SwitchB-ospf-1] asbr-summary 10.0.0.0 8
```

Display the IP routing table on Switch A.

```
[SwitchA] display ip routing-table
         Destinations : 13        Routes : 13
Destination/Mask    Proto  Pre  Cost         NextHop         Interface
0.0.0.0/32          Direct 0    0            127.0.0.1       InLoop0
10.0.0.0/8          O_ASE2 150  1            11.2.1.1        Vlan100

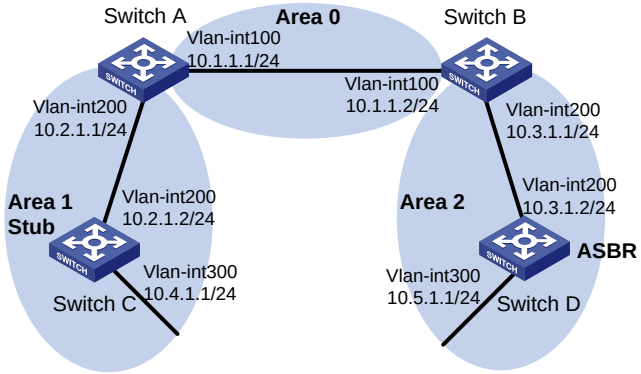
11.2.1.0/32         Direct 0    0            11.2.1.2        Vlan100
11.2.1.2/32         Direct 0    0            127.0.0.1       InLoop0
```

```
11.2.1.255/32       Direct 0    0           11.2.1.2        Vlan100
127.0.0.0/8         Direct 0    0           127.0.0.1       InLoop0
127.0.0.0/32        Direct 0    0           127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0           127.0.0.1       InLoop0
127.255.255.255/32  Direct 0    0           127.0.0.1       InLoop0
224.0.0.0/4         Direct 0    0           0.0.0.0         NULL0
224.0.0.0/24        Direct 0    0           0.0.0.0         NULL0
255.255.255.255/32  Direct 0    0           127.0.0.1       InLoop0
```

The output shows that routes 10.1.1.0/24, 10.2.1.0/24, 10.3.1.0/24 and 10.4.1.0/24 are summarized into a single route 10.0.0.0/8.



Example: Configuring OSPF stub area

Network configuration

As shown in Figure 17:

- Enable OSPF on all switches, and split the AS into three areas.
- Configure Switch A and Switch B as ABRs to forward routing information between areas.
- Configure Switch D as the ASBR to redistribute static routes.
- Configure Area 1 as a stub area to reduce advertised LSAs without influencing reachability.

Figure 17 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Enable OSPF (see "Example: Configuring basic OSPF").
3. Configure route redistribution:

   # Configure Switch D to redistribute static routes.

```
<SwitchD> system-view
[SwitchD] ip route-static 3.1.2.1 24 10.5.1.2
[SwitchD] ospf
[SwitchD-ospf-1] import-route static
[SwitchD-ospf-1] quit
```

   # Display ABR/ASBR information on Switch C.

```
<SwitchC> display ospf abr-asbr

        OSPF Process 1 with Router ID 10.4.1.1
                Routing Table to ABR and ASBR
```

```
                Topology base (MTID 0)
 Type        Destination     Area            Cost  Nexthop         RtType
 Intra       10.2.1.1        0.0.0.1         3     10.2.1.1        ABR
 Inter       10.5.1.1        0.0.0.1         7     10.2.1.1        ASBR
```

Display OSPF routing table on Switch C.

```
<SwitchC> display ospf routing

          OSPF Process 1 with Router ID 10.4.1.1
                  Routing Table

                Topology base (MTID 0)

 Routing for network
 Destination        Cost     Type    NextHop         AdvRouter       Area
 10.2.1.0/24        3        Transit 0.0.0.0         10.2.1.1        0.0.0.1
 10.3.1.0/24        7        Inter   10.2.1.1        10.2.1.1        0.0.0.1
 10.4.1.0/24        3        Stub    10.4.1.1        10.4.1.1        0.0.0.1
 10.5.1.0/24        17       Inter   10.2.1.1        10.2.1.1        0.0.0.1
 10.1.1.0/24        5        Inter   10.2.1.1        10.2.1.1        0.0.0.1

 Routing for ASEs
 Destination        Cost     Type    Tag         NextHop         AdvRouter
3.1.2.0/24          1        Type2   1           10.2.1.1        10.5.1.1

 Total nets: 6
 Intra area: 2  Inter area: 3  ASE: 1  NSSA: 0
```

The output shows that Switch C's routing table contains an AS external route.

4. Configure Area 1 as a stub area:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ospf
[SwitchA-ospf-1] area 1
[SwitchA-ospf-1-area-0.0.0.1] stub
[SwitchA-ospf-1-area-0.0.0.1] quit
[SwitchA-ospf-1] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ospf
[SwitchC-ospf-1] area 1
[SwitchC-ospf-1-area-0.0.0.1] stub
[SwitchC-ospf-1-area-0.0.0.1] quit
[SwitchC-ospf-1] quit
```

Display OSPF routing information on Switch C

```
[SwitchC] display ospf routing

          OSPF Process 1 with Router ID 10.4.1.1
                  Routing Table
```

```
                Topology base (MTID 0)

 Routing for network
 Destination        Cost     Type    NextHop         AdvRouter       Area
 0.0.0.0/0          4        Inter   10.2.1.1        10.2.1.1        0.0.0.1
 10.2.1.0/24        3        Transit 0.0.0.0         10.2.1.1        0.0.0.1
 10.3.1.0/24        7        Inter   10.2.1.1        10.2.1.1        0.0.0.1
 10.4.1.0/24        3        Stub    10.4.1.1        10.4.1.1        0.0.0.1
 10.5.1.0/24        17       Inter   10.2.1.1        10.2.1.1        0.0.0.1
 10.1.1.0/24        5        Inter   10.2.1.1        10.2.1.1        0.0.0.1

 Total nets: 6
 Intra area: 2  Inter area: 4  ASE: 0  NSSA: 0
```

The output shows that a default route replaces the AS external route.

Configure Area 1 as a totally stub area.

```
[SwitchA] ospf
[SwitchA-ospf-1] area 1
[SwitchA-ospf-1-area-0.0.0.1] stub no-summary
[SwitchA-ospf-1-area-0.0.0.1] quit
[SwitchA-ospf-1] quit
```

Display OSPF routing information on Switch C.

```
[SwitchC] display ospf routing

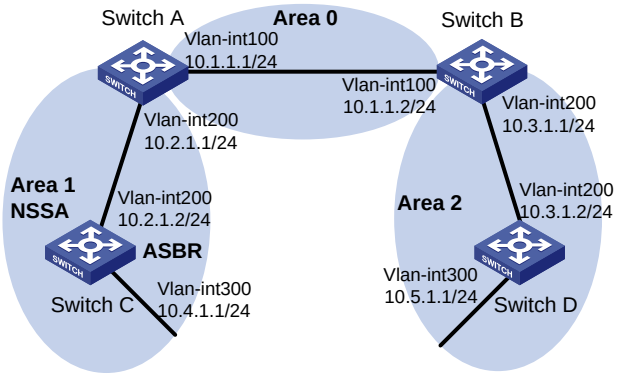
          OSPF Process 1 with Router ID 10.4.1.1
                  Routing Table

                Topology base (MTID 0)

 Routing for network
 Destination        Cost     Type    NextHop         AdvRouter       Area
 0.0.0.0/0          4        Inter   10.2.1.1        10.2.1.1        0.0.0.1
 10.2.1.0/24        3        Transit 0.0.0.0         10.4.1.1        0.0.0.1
 10.4.1.0/24        3        Stub    10.4.1.1        10.4.1.1        0.0.0.1

 Total nets: 3
 Intra area: 2  Inter area: 1  ASE: 0  NSSA: 0
```

The output shows that inter-area routes are removed, and only one external route (a default route) exists on Switch C.



Example: Configuring OSPF NSSA area

Network configuration

As shown in Figure 18:

- Configure OSPF on all switches and split AS into three areas.
- Configure Switch A and Switch B as ABRs to forward routing information between areas.
- Configure Area 1 as an NSSA area and configure Switch C as an ASBR to redistribute static routes into the AS.

Figure 18 Network diagram

Procedure

1. Configure IP addresses for interfaces.
2. Enable OSPF (see "Example: Configuring basic OSPF").
3. Configure Area 1 as an NSSA area:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ospf
[SwitchA-ospf-1] area 1
[SwitchA-ospf-1-area-0.0.0.1] nssa
[SwitchA-ospf-1-area-0.0.0.1] quit
[SwitchA-ospf-1] quit
```

   # Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ospf
[SwitchC-ospf-1] area 1
[SwitchC-ospf-1-area-0.0.0.1] nssa
[SwitchC-ospf-1-area-0.0.0.1] quit
[SwitchC-ospf-1] quit
```

   # Display OSPF routing information on Switch C.

```
[SwitchC] display ospf routing

          OSPF Process 1 with Router ID 10.4.1.1

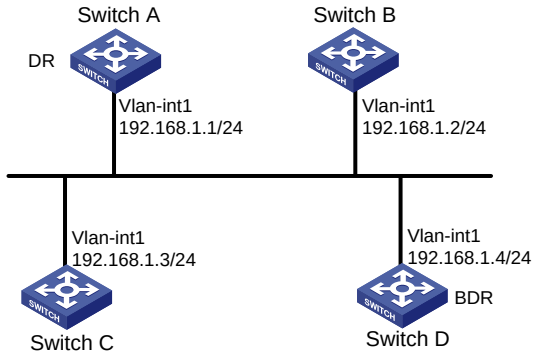
 Destination        Cost     Type    Tag         NextHop         AdvRouter
 3.1.3.0/24         1        Type2   1           10.3.1.1        10.2.1.1
 Total nets: 6
 Intra area: 2  Inter area: 3  ASE: 1  NSSA: 0
```

   The output shows that an external route imported from the NSSA area exists on Switch D.



Example: Configuring OSPF DR election

Network configuration

As shown in Figure 19:

- Enable OSPF on Switches A, B, C, and D on the same network.
- Configure Switch D as the DR, and configure Switch C as the BDR.
- Change the router priorities on the interfaces to configure Switch A as the DR and Switch C as the BDR.

Figure 19 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure basic OSPF settings on all switches. (Details not shown.)
   For more information, see "Example: Configuring basic OSPF."
3. Display OSPF neighbor information on Switch A.

```
[SwitchA] display ospf peer verbose

          OSPF Process 1 with Router ID 1.1.1.1
                  Neighbors

   Authentication Sequence: [ 0 ]
   Neighbor state change count: 6
   BFD status: Disabled

 Router ID: 4.4.4.4          Address: 192.168.1.4      GR State: Normal
   State: Full  Mode: Nbr is master  Priority: 1
   DR: 192.168.1.4  BDR: 192.168.1.3  MTU: 0
   Options is 0x02 (-|-|-|-|-|-|E|-)
   Dead timer due in 31  sec
   Neighbor is up for 00:01:28
   Authentication Sequence: [ 0 ]
   Neighbor state change count: 6
   BFD status: Disabled
```

   The output shows that Switch D is the DR and Switch C is the BDR.
4. Configure router priorities on interfaces:
   # Configure Switch A.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ospf dr-priority 100
[SwitchA-Vlan-interface1] quit
```

   # Configure Switch B.

```
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ospf dr-priority 0
[SwitchB-Vlan-interface1] quit
```

Configure Switch C.

```
[SwitchC] interface vlan-interface 1
[SwitchC-Vlan-interface1] ospf dr-priority 2
[SwitchC-Vlan-interface1] quit
```

Display neighbor information on Switch D.

```
<SwitchD> display ospf peer verbose

          OSPF Process 1 with Router ID 4.4.4.4
                  Neighbors

 Area 0.0.0.0 interface 192.168.1.4(Vlan-interface1)'s neighbors
 Router ID: 1.1.1.1      Address: 192.168.1.1      GR State: Normal
   State: Full  Mode:Nbr is  slave  Priority: 100
   DR: 192.168.1.4  BDR: 192.168.1.3  MTU: 0
   Options is 0x02 (-|-|-|-|-|-|E|-)
   Dead timer due in 31  sec
   Neighbor is up for 00:11:17
   Authentication Sequence: [ 0 ]
   Neighbor state change count: 6
   BFD status: Disabled

 Router ID: 2.2.2.2      Address: 192.168.1.2      GR State: Normal
   State: Full  Mode:Nbr is  slave  Priority: 0
   DR: 192.168.1.4  BDR: 192.168.1.3  MTU: 0
   Options is 0x02 (-|-|-|-|-|-|E|-)
   Dead timer due in 35  sec
   Neighbor is up for 00:11:19
   Authentication Sequence: [ 0 ]
   Neighbor state change count: 6
   BFD status: Disabled

 Router ID: 3.3.3.3      Address: 192.168.1.3      GR State: Normal
   State: Full  Mode:Nbr is  slave  Priority: 2
   DR: 192.168.1.4  BDR: 192.168.1.3  MTU: 0
   Options is 0x02 (-|-|-|-|-|-|E|-)
   Dead timer due in 33  sec
   Neighbor is up for 00:11:15
   Authentication Sequence: [ 0 ]
   Neighbor state change count: 6
   BFD status: Disabled
```

The output shows that the DR and BDR are not changed, because the priority settings do not take effect immediately.

5. Restart OSPF processes:

Restart the OSPF process of Switch A.

```
<SwitchA> reset ospf 1 process
```

```
Reset OSPF process? [Y/N]:y
```

Restart the OSPF process of Switch B.

```
<SwitchB> reset ospf 1 process
Reset OSPF process? [Y/N]:y
```

Restart the OSPF process of Switch C.

```
<SwitchC> reset ospf 1 process
Reset OSPF process? [Y/N]:y
```

Restart the OSPF process of Switch D.

```
<SwitchD> reset ospf 1 process
Reset OSPF process? [Y/N]:y
```

Display neighbor information on Switch D.

```
<SwitchD> display ospf peer verbose

          OSPF Process 1 with Router ID 4.4.4.4
                  Neighbors

   Options is 0x02 (-|-|-|-|-|-|E|-)
   Dead timer due in 39  sec
   Neighbor is up for 00:01:41
   Authentication Sequence: [ 0 ]
   Neighbor state change count: 6
   BFD status: Disabled
```

The output shows that Switch A becomes the DR and Switch C becomes the BDR.

If the neighbor state is *full,* Switch D has established an adjacency with the neighbor. If the neighbor state is *2-way*, the two switches are not the DR or the BDR, and they do not exchange LSAs.

Display OSPF interface information.

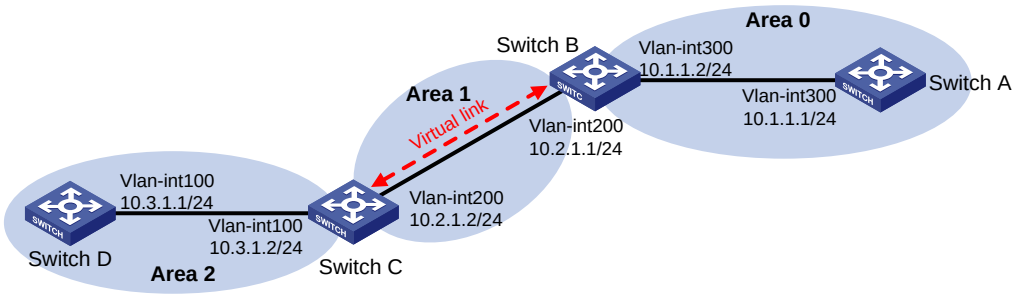
```
<SwitchA> display ospf interface
                 OSPF Process 1 with Router ID 1.1.1.1
                 Interfaces

 Area: 0.0.0.0
 IP Address      Type      State   Cost  Pri   DR             BDR
 192.168.1.1     Broadcast DR      1     100   192.168.1.1    192.168.1.3

<SwitchB> display ospf interface

          OSPF Process 1 with Router ID 2.2.2.2
                 Interfaces

 Area: 0.0.0.0
 IP Address      Type      State    Cost  Pri   DR             BDR
 192.168.1.2     Broadcast DROther  1     0     192.168.1.1    192.168.1.3
```



The interface state *DROther* means the interface is not the DR or BDR.

Example: Configuring OSPF virtual link

Network configuration

As shown in Figure 20, configure a virtual link between Switch B and Switch C to connect Area 2 to the backbone area. After configuration, Switch B can learn routes to Area 2.

Figure 20 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Enable OSPF:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ospf 1 router-id 1.1.1.1
[SwitchA-ospf-1] area 0
[SwitchA-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] quit
[SwitchA-ospf-1] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ospf 1 router-id 2.2.2.2
[SwitchB-ospf-1] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] area 1
[SwitchB–ospf-1-area-0.0.0.1] network 10.2.1.0 0.0.0.255
[SwitchB–ospf-1-area-0.0.0.1] quit
[SwitchB-ospf-1] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ospf 1 router-id 3.3.3.3
[SwitchC-ospf-1] area 1
[SwitchC-ospf-1-area-0.0.0.1] network 10.2.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.1] quit
[SwitchC-ospf-1] area 2
[SwitchC–ospf-1-area-0.0.0.2] network 10.3.1.0 0.0.0.255
[SwitchC–ospf-1-area-0.0.0.2] quit
[SwitchC-ospf-1] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] ospf 1 router-id 4.4.4.4
[SwitchD-ospf-1] area 2
[SwitchD-ospf-1-area-0.0.0.2] network 10.3.1.0 0.0.0.255
[SwitchD-ospf-1-area-0.0.0.2] quit
[SwitchD-ospf-1] quit
```

Display the OSPF routing table on Switch B.

```
[SwitchB] display ospf routing

          OSPF Process 1 with Router ID 2.2.2.2
                  Routing Table

                Topology base (MTID 0)

 Routing for network
 Destination        Cost     Type    NextHop         AdvRouter       Area
 10.2.1.0/24        2        Transit 10.2.1.1        3.3.3.3         0.0.0.1
 10.1.1.0/24        2        Transit 10.1.1.2        2.2.2.2         0.0.0.0
 Total nets: 2
 Intra area: 2  Inter area: 0  ASE: 0  NSSA: 0
```

The output shows that Switch B does not have routes to Area 2 because Area 0 is not directly connected to Area 2.

3. Configure a virtual link:

Configure Switch B.

```
[SwitchB] ospf
[SwitchB-ospf-1] area 1
[SwitchB-ospf-1-area-0.0.0.1] vlink-peer 3.3.3.3
```

```
[SwitchB-ospf-1-area-0.0.0.1] quit
[SwitchB-ospf-1] quit
```

Configure Switch C.

```
[SwitchC] ospf 1
[SwitchC-ospf-1] area 1
[SwitchC-ospf-1-area-0.0.0.1] vlink-peer 2.2.2.2
[SwitchC-ospf-1-area-0.0.0.1] quit
[SwitchC-ospf-1] quit
```

Display the OSPF routing table on Switch B.

```
[SwitchB] display ospf routing

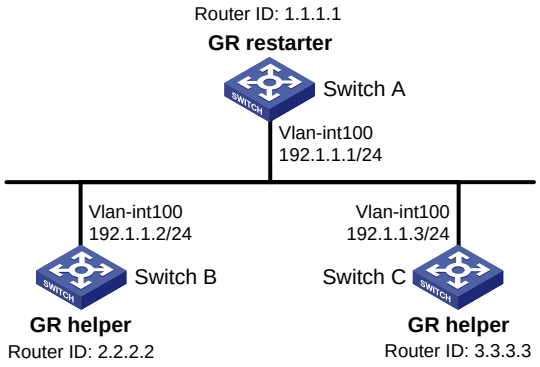
          OSPF Process 1 with Router ID 2.2.2.2
                  Routing Table

                Topology base (MTID 0)

 Routing for network
 Destination        Cost     Type    NextHop         AdvRouter       Area
 10.2.1.0/24        2        Transit 10.2.1.1        3.3.3.3         0.0.0.1
 10.3.1.0/24        5        Inter   10.2.1.2        3.3.3.3         0.0.0.0
 10.1.1.0/24        2        Transit 10.1.1.2        2.2.2.2         0.0.0.0

 Total nets: 3
 Intra area: 2  Inter area: 1  ASE: 0  NSSA: 0
```

The output shows that Switch B has learned the route 10.3.1.0/24 to Area 2.



Example: Configuring OSPF GR

Network configuration

As shown in Figure 21:

- Switch A, Switch B, and Switch C that belong to the same AS and the same OSPF routing domain are GR capable.
- Switch A acts as the non-IETF GR restarter. Switch B and Switch C are the GR helpers, and synchronize their LSDBs with Switch A through OOB communication of GR.

Figure 21 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Enable OSPF:

   # Configure Switch A.

   ```
   SwitchA> system-view
   [SwitchA] router id 1.1.1.1
   [SwitchA] ospf 100
   [SwitchA-ospf-100] area 0
   [SwitchA-ospf-100-area-0.0.0.0] network 192.1.1.0 0.0.0.255
   [SwitchA-ospf-100-area-0.0.0.0] quit
   [SwitchA-ospf-1] quit
   ```

   # Configure Switch B.

   ```
   <SwitchB> system-view
   [SwitchB] router id 2.2.2.2
   [SwitchB] ospf 100
   [SwitchB-ospf-100] area 0
   [SwitchB-ospf-100-area-0.0.0.0] network 192.1.1.0 0.0.0.255
   [SwitchB-ospf-100-area-0.0.0.0] quit
   [SwitchB-ospf-1] quit
   ```

   # Configure Switch C.

   ```
   <SwitchC> system-view
   [SwitchC] router id 3.3.3.3
   [SwitchC] ospf 100
   [SwitchC-ospf-100] area 0
   [SwitchC-ospf-100-area-0.0.0.0] network 192.1.1.0 0.0.0.255
   [SwitchC-ospf-100-area-0.0.0.0] quit
   [SwitchC-ospf-1] quit
   ```

3. Configure OSPF GR:

   # Configure Switch A as the non-IETF OSPF GR restarter: enable the link-local signaling capability, the out-of-band re-synchronization capability, and non-IETF GR capability for OSPF process 100.

   ```
   [SwitchA-ospf-100] enable link-local-signaling
   [SwitchA-ospf-100] enable out-of-band-resynchronization
   [SwitchA-ospf-100] graceful-restart
   [SwitchA-ospf-100] quit
   ```

   # Configure Switch B as the GR helper: enable the link-local signaling capability and the out-of-band re-synchronization capability for OSPF process 100.

   ```
   [SwitchB-ospf-100] enable link-local-signaling
   [SwitchB-ospf-100] enable out-of-band-resynchronization
   ```

   # Configure Switch C as the GR helper: enable the link-local signaling capability and the out-of-band re-synchronization capability for OSPF process 100.

   ```
   [SwitchC-ospf-100] enable link-local-signaling
   [SwitchC-ospf-100] enable out-of-band-resynchronization
   ```

Verifying the configuration

Enable OSPF GR event debugging and restart the OSPF process by using GR on Switch A.

```
<SwitchA> debugging ospf event graceful-restart
<SwitchA> terminal monitor
```

```
<SwitchA> terminal logging level 7
<SwitchA> reset ospf 100 process graceful-restart
Reset OSPF process? [Y/N]:y

192.1.1.2(Vlan-interface100) from Loading to Full.
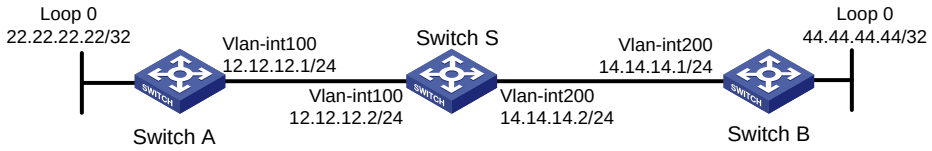
```



The output shows that Switch A completes GR.

Example: Configuring OSPF NSR

Network configuration

As shown in Figure 22, Switch S, Switch A, and Switch B belong to the same OSPF routing domain. Enable OSPF NSR on Switch S to ensure correct routing when an active/standby switchover occurs on Switch S.

Figure 22 Network diagram

Procedure

1. Configure IP addresses and subnet masks for interfaces on the switches. (Details not shown.)
2. Configure OSPF on the switches to ensure the following: (Details not shown.)
   - Switch S, Switch A, and Switch B can communicate with each other at Layer 3.
   - Dynamic route update can be implemented among them with OSPF.
3. Configure OSPF NSR:

   # Enable OSPF NSR on Switch S.

```
<SwitchS> system-view
[SwitchS] ospf 100
[SwitchS-ospf-100] non-stop-routing
[SwitchS-ospf-100] quit
```

Verifying the configuration

Perform an active/standby switchover on Switch S.

```
[SwitchS] placement reoptimize
Predicted changes to the placement
Service Group(instance name)                    Cur location  New location
------------------------------------------------------------------------------
rib                                             0/0           0/0
staticroute                                     0/0           0/0
ospf                                            0/0           1/0
Continue? [y/n]:y
Re-optimization of the placement start. You will be notified on completion.
Re-optimization of the placement complete. Use 'display placement' to view the new
placement.
```

During the switchover period, display OSPF neighbors on Switch A to verify the neighbor relationship between Switch A and Switch S.

```
<SwitchA> display ospf peer

          OSPF Process 1 with Router ID 2.2.2.1

 Total nets: 4
 Intra area: 4  Inter area: 0  ASE: 0  NSSA: 0
```

The output shows the following when an active/standby switchover occurs on Switch S:

- The neighbor relationships and routing information on Switch A and Switch B have not changed.
- The traffic from Switch A to Switch B has not been impacted.

Example: Configuring BFD for OSPF

Network configuration

As shown in Figure 23, run OSPF on Switch A, Switch B, and Switch C so that they are reachable to each other at the network layer.

- When the link over which Switch A and Switch B communicate through a Layer 2 switch fails, BFD can quickly detect the failure and notify OSPF of the failure.
- Switch A and Switch B then communicate through Switch C.

Figure 23 Network diagram

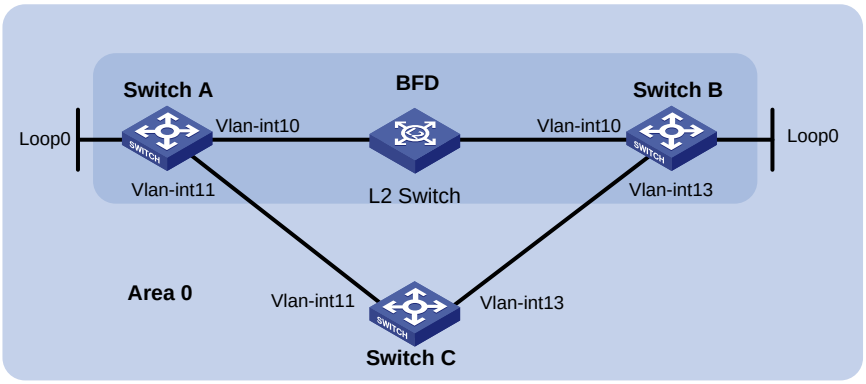

Table 4 Interface and IP address assignment

Device	Interface	IP address
Switch A	Vlan-int10	192.168.0.102/24
Switch A	Vlan-int11	10.1.1.102/24
Switch A	Loop0	121.1.1.1/32
Switch B	Vlan-int10	192.168.0.100/24
Switch B	Vlan-int13	13.1.1.1/24
Switch B	Loop0	120.1.1.1/32
Switch C	Vlan-int11	10.1.1.100/24
Switch C	Vlan-int13	13.1.1.2/24

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Enable OSPF:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ospf
[SwitchA-ospf-1] area 0
[SwitchA-ospf-1-area-0.0.0.0] network 192.168.0.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] network 121.1.1.1 0.0.0.0
[SwitchA-ospf-1-area-0.0.0.0] quit
[SwitchA-ospf-1] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ospf
[SwitchB-ospf-1] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 192.168.0.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] network 13.1.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] network 120.1.1.1 0.0.0.0
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ospf
[SwitchC-ospf-1] area 0
[SwitchC-ospf-1-area-0.0.0.0] network 10.1.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] network 13.1.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] quit
[SwitchC-ospf-1] quit
```

3. Configure BFD:

Enable BFD on Switch A and configure BFD parameters.

```
[SwitchA] bfd session init-mode active
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] ospf bfd enable
[SwitchA-Vlan-interface10] bfd min-transmit-interval 500
[SwitchA-Vlan-interface10] bfd min-receive-interval 500
[SwitchA-Vlan-interface10] bfd detect-multiplier 7
[SwitchA-Vlan-interface10] quit
```

Enable BFD on Switch B and configure BFD parameters.

```
[SwitchB] bfd session init-mode active
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] ospf bfd enable
[SwitchB-Vlan-interface10] bfd min-transmit-interval 500
[SwitchB-Vlan-interface10] bfd min-receive-interval 500
[SwitchB-Vlan-interface10] bfd detect-multiplier 6
[SwitchB-Vlan-interface10] quit
```

Verifying the configuration

Display the BFD information on Switch A.

```
<SwitchA> display bfd session

 Total sessions: 1     Up sessions: 1     Init mode: Active

 IPv4 session working in control packet mode:

 LD/RD            SourceAddr      DestAddr        State  Holdtime    Interface
3/1              192.168.0.102   192.168.0.100   Up     1700ms      Vlan10
```

Display routes destined for 120.1.1.1/32 on Switch A.

```
<SwitchA> display ip routing-table 120.1.1.1 verbose
Summary count : 1
```

```
Destination: 120.1.1.1/32
   Protocol: O_INTRA
 Process ID: 1
  SubProtID: 0x1                  Age: 04h20m37s
       Cost: 1              Preference: 10
      IpPre: N/A            QosLocalID: N/A
        Tag: 0                 State: Active Adv

```

The output shows that Switch A communicates with Switch B through VLAN-interface 11.

Example: Configuring OSPF FRR

Network configuration

As shown in Figure 24, Switch A, Switch B, and Switch C reside in the same OSPF domain. Configure OSPF FRR so that when the link between Switch A and Switch B fails, traffic is immediately switched to Link B.

Figure 24 Network diagram

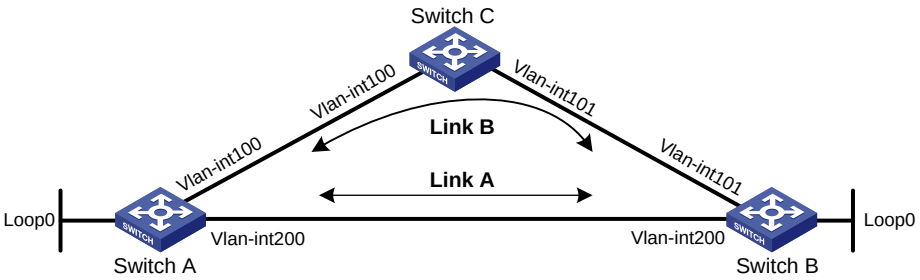

Table 5 Interface and IP address assignment

Device	Interface	IP address
Switch A	Vlan-int100	12.12.12.1/24
Switch A	Vlan-int200	13.13.13.1/24
Switch A	Loop0	1.1.1.1/32
Switch B	Vlan-int101	24.24.24.4/24
Switch B	Vlan-int200	13.13.13.2/24
Switch B	Loop0	4.4.4.4/32
Switch C	Vlan-int100	12.12.12.2/24
Switch C	Vlan-int101	24.24.24.2/24

Procedure

1. Configure IP addresses and subnet masks for interfaces on the switches. (Details not shown.)
2. Configure OSPF on the switches to ensure that Switch A, Switch B, and Switch C can communicate with each other at the network layer. (Details not shown.)
3. Configure OSPF FRR to automatically calculate the backup next hop:

   You can enable OSPF FRR to either calculate a backup next hop by using the LFA algorithm, or specify a backup next hop by using a routing policy.

   - (Method 1.) Enable OSPF FRR to calculate the backup next hop by using the LFA algorithm:

     # Configure Switch A.

     ```
     <SwitchA> system-view
     [SwitchA] ospf 1
     [SwitchA-ospf-1] fast-reroute lfa
     [SwitchA-ospf-1] quit
     ```

     # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ospf 1
[SwitchB-ospf-1] fast-reroute lfa
[SwitchB-ospf-1] quit
```

- (Method 2.) Enable OSPF FRR to designate a backup next hop by using a routing policy.

  # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ip prefix-list abc index 10 permit 4.4.4.4 32
[SwitchA] route-policy frr permit node 10
[SwitchA-route-policy-frr-10] if-match ip address prefix-list abc
[SwitchA-route-policy-frr-10] apply fast-reroute backup-interface vlan-interface
100 backup-nexthop 12.12.12.2
[SwitchA-route-policy-frr-10] quit
[SwitchA] ospf 1
[SwitchA-ospf-1] fast-reroute route-policy frr
[SwitchA-ospf-1] quit
```

  # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ip prefix-list abc index 10 permit 1.1.1.1 32
[SwitchB] route-policy frr permit node 10
[SwitchB-route-policy-frr-10] if-match ip address prefix-list abc
[SwitchB-route-policy-frr-10] apply fast-reroute backup-interface vlan-interface
101 backup-nexthop 24.24.24.2
[SwitchB-route-policy-frr-10] quit
[SwitchB] ospf 1
[SwitchB-ospf-1] fast-reroute route-policy frr
[SwitchB-ospf-1] quit
```

Verifying the configuration

Display route 4.4.4.4/32 on Switch A to view the backup next hop information.

```
[SwitchA] display ip routing-table 4.4.4.4 verbose

Summary count : 1

Destination: 4.4.4.4/32

```

Troubleshooting OSPF configuration

No OSPF neighbor relationship established

Symptom

No OSPF neighbor relationship can be established.

Analysis

If the physical link and lower layer protocols work correctly, verify OSPF parameters configured on interfaces. Two neighbors must have the same parameters, such as the area ID, network segment, and mask. (A P2P or virtual link can have different network segments and masks.)

Solution

To resolve the problem:

1. Use the **display ospf peer** command to verify OSPF neighbor information.
2. Use the **display ospf interface** command to verify OSPF interface information.
3. Ping the neighbor router's IP address to verify that the connectivity is normal.
4. Verify OSPF timers. The dead interval on an interface must be a minimum of four times the hello interval.
5. On an NBMA network, use the **peer ip-address** command to manually specify the neighbor.
6. A minimum of one interface must have a router priority higher than 0 on an NBMA or a broadcast network.
7. If the problem persists, contact H3C Support.

Incorrect routing information

Symptom

OSPF cannot find routes to other areas.

Analysis

The backbone area must maintain connectivity to all other areas. If a router connects to more than one area, a minimum of one area must be connected to the backbone. The backbone cannot be configured as a stub area.

In a stub area, all routers cannot receive external routes, and all interfaces connected to the stub area must belong to the stub area.

Solution

To resolve the problem:

1. Use the **display ospf peer** command to verify neighbor information.
2. Use the **display ospf interface** command to verify OSPF interface information.
3. Use the **display ospf lsdb** command to verify the LSDB.
4. Use the **display current-configuration configuration ospf** command to verify area configuration. If more than two areas are configured, a minimum of one area is connected to the backbone.
5. In a stub area, all routers attached are configured with the **stub** command. In an NSSA area, all routers attached are configured with the **nssa** command.
6. If a virtual link is configured, use the **display ospf vlink** command to verify the state of the virtual link.
7. If the problem persists, contact H3C Support.

Configuring IS-IS

The S5200-EI-G switch series does not support IS-IS.

About IS-IS

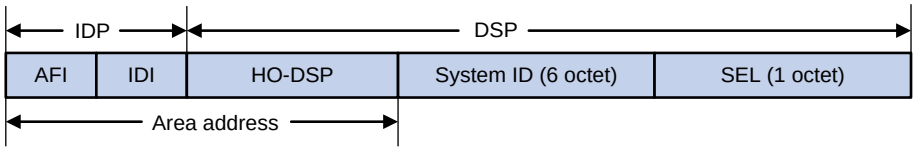
IS-IS is an IGP used within an AS. It uses the SPF algorithm for route calculation.

Terminology

- **Intermediate system**—Similar to a router in TCP/IP, IS is the basic unit used in an IS-IS routing domain to generate and propagate routing information. Throughout this chapter, an IS refers to a router.
- **End system**—Similar to a host in TCP/IP, an ES does not run IS-IS. ISO defines the ES-IS protocol for communication between an ES and an IS.
- **Routing domain**—An RD comprises a group of ISs that exchange routing information with each other by using the same routing protocol.
- **Area**—An IS-IS routing domain can be split into multiple areas.
- **Link State Database**—All link states in the network form the LSDB. Each IS has a minimum of one LSDB. An IS uses the SPF algorithm and LSDB to generate IS-IS routes.
- **Link State Protocol Data Unit or Link State Packet**—An IS advertises link state information in an LSP.
- **Network Protocol Data Unit**—An NPDU is a network layer protocol packet in OSI, similar to an IP packet in TCP/IP.
- **Designated IS**—A DIS is elected on a broadcast network.
- **Network service access point**—An NSAP is an OSI network layer address. The NSAP identifies an abstract network service access point and describes the network address format in the OSI reference model.

IS-IS address

As shown in Figure 1, an NSAP address comprises the Initial Domain Part (IDP) and the Domain Specific Part (DSP). The IDP is analogous to the network ID of an IP address, and the DSP is analogous to the subnet and host ID.



The IDP includes the Authority and Format Identifier (AFI) and the Initial Domain Identifier (IDI).

The DSP includes:

- **High Order Part of DSP (HO-DSP)**—Identifies the area.
- **System ID**—Identifies the host.
- **SEL**—Also known as the N-SEL or the NSAP selector (SEL). It is similar to the protocol identifier in IP and is used to identify the type of service. Different transport layer protocols correspond to different SELs.

The IDP and DSP are variable in length. The length of an NSAP address is in the range of 8 to 20 bytes.

Figure 1 NSAP address format

An IS-IS address contains the following components:

- Area address

  The area address comprises the IDP and the HO-DSP of the DSP, which identify the area and the routing domain. Different routing domains cannot have the same area address.

  Typically, a router only needs one area address, and all nodes in the same area must have the same area address. To support smooth area merging, partitioning, and switching, a router can have a maximum of three area addresses.

- System ID

  A system ID uniquely identifies a host or router. It has a fixed length of 48 bits (6 bytes).

  The system ID of a device can be generated from the router ID. For example, suppose a router uses the IP address 168.10.1.1 of Loopback 0 as the router ID. The system ID can be obtained in the following steps:

  a. Extend each decimal number of the IP address to three digits by adding 0s from the left, such as 168.010.001.001.

  b. Divide the extended IP address into three sections that each has four digits to get the system ID 1680.1000.1001.

  If you use other methods to define a system ID, make sure that it can uniquely identify the host or router.

- SEL

  An SEL is used to identify the type of service. Different transport layer protocols correspond to different SELs. It has a fixed length of 8 bits. All SELs in IP are 00.

NET

A network entity title (NET) identifies the network layer information of an IS. It does not include transport layer information. A NET is a special NSAP address with the SEL being 0. The length of a NET is in the range of 8 to 20 bytes, same as a NSAP address.

A NET includes the following parts:

- **Area ID**—Has a length of 1 to 13 bytes.
- **System ID**—A system ID uniquely identifies a host or router in the area and has a fixed length of 6 bytes.
- **SEL**—Has a value of 0 and a fixed length of 1 byte.

For example, for a NET ab.cdef.1234.5678.9abc.00, the area ID is ab.cdef, the system ID is 1234.5678.9abc, and the SEL is 00.

Typically, a router only needs one NET, but it can have a maximum of three NETs for smooth area merging and partitioning. When you configure multiple NETs, make sure the system IDs are the same.

IS-IS area

IS-IS has a 2-level hierarchy to support large-scale networks. A large-scale routing domain is divided into multiple areas. Typically, a Level-1 router is deployed within an area. A Level-2 router is deployed between areas. A Level-1-2 router is deployed between Level-1 and Level-2 routers.

Level-1 router

A Level-1 router establishes neighbor relationships with Level-1 and Level-1-2 routers in the same area. It maintains an LSDB comprising intra-area routing information. A Level-1 router forwards packets destined for external areas to the nearest Level-1-2 router. Level-1 routers in different areas cannot establish neighbor relationships.

Level-2 router

A Level-2 router establishes neighbor relationships with Level-2 and Level-1-2 routers in the same area or in different areas. It maintains a Level-2 LSDB containing inter-area routing information. All the Level-2 and Level-1-2 routers must be contiguous to form the backbone of the IS-IS routing domain. Level-2 routers can establish neighbor relationships even if they are in different areas.

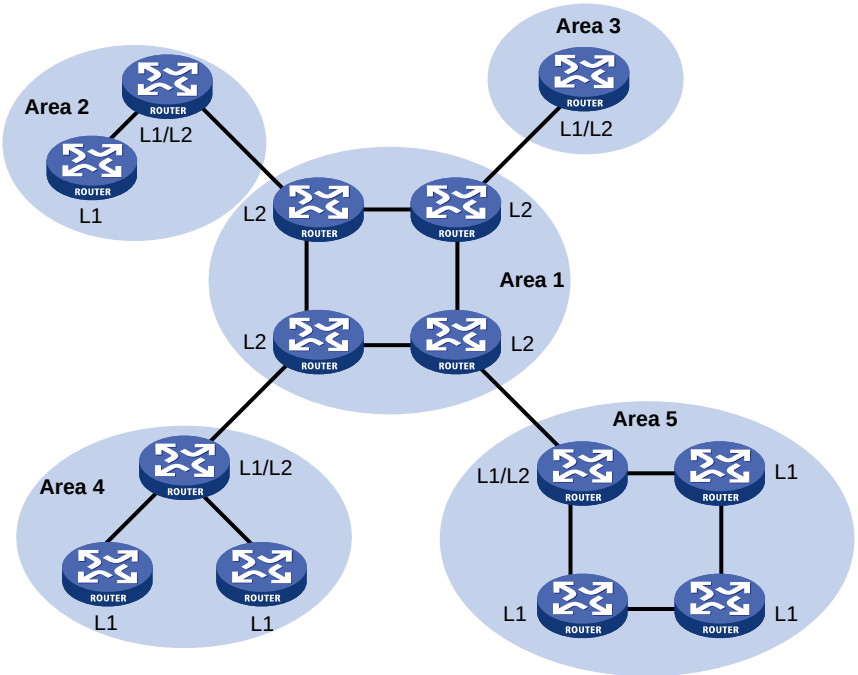
Level-1-2 router

A router with both Level-1 and Level-2 router functions is a Level-1-2 router. It can establish Level-1 neighbor relationships with Level-1 and Level-1-2 routers in the same area. It can establish Level-2 neighbor relationships with Level-2 and Level-1-2 routers in different areas. A Level-1 router can reach other areas only through a Level-1-2 router. The Level-1-2 router maintains two LSDBs, a Level-1 LSDB for intra-area routing and a Level-2 LSDB for inter-area routing.

IS-IS topology

Figure 2 shows one IS-IS network topology. Area 1 is the backbone that comprises a set of Level-2 routers. The other four areas are non-backbone areas connected to the backbone through Level-1-2 routers.

Figure 2 IS-IS topology 1



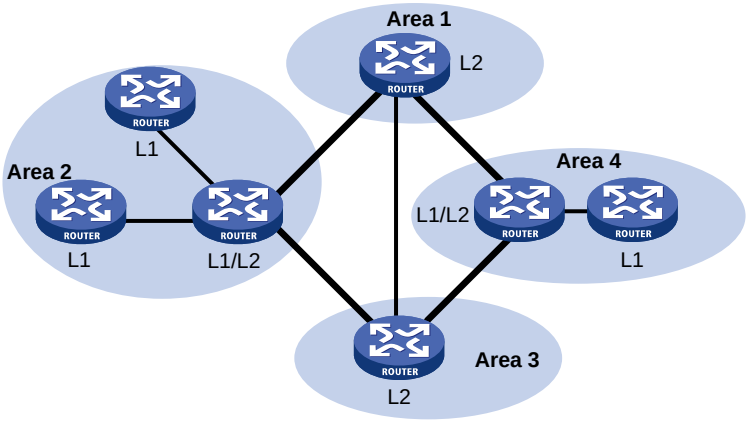


Figure 3 shows another IS-IS topology. No area is defined as the backbone in this topology. The backbone comprises all contiguous Level-2 and Level-1-2 routers in different areas. The IS-IS backbone does not need to be a specific area.

Figure 3 IS-IS topology 2

Both the Level-1 and Level-2 routers use the SPF algorithm to generate the shortest path tree.

Route leaking

Level-2 and Level-1-2 routers form a Level-2 area. An IS-IS routing domain comprises only one Level-2 area and multiple Level-1 areas. A Level-1 area must connect to the Level-1-2 area rather than another Level-1 area.

Level-1-2 routers send the routing information of Level-1 areas to the Level-2 area. Level-2 routers know the routing information of the entire IS-IS routing domain. By default, a Level-2 router does not advertise the routing information of other areas to a Level-1 area. A Level-1 router simply sends packets destined for other areas to the nearest Level-1-2 router. The path passing through the Level-1-2 router might not be the best. To solve this problem, IS-IS provides the route leaking feature.

Route leaking enables a Level-1-2 router to advertise the routes of other areas to the connected Level-1 area so that the Level-1 routers can select the optimal routes.

IS-IS network types

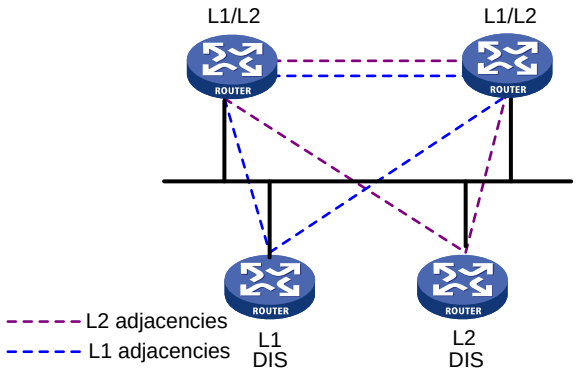
IS-IS supports broadcast networks (for example, Ethernet and Token Ring) and point-to-point networks (for example, PPP and HDLC).

IS-IS cannot run on P2MP links.

DIS and pseudonodes

IS-IS routers on a broadcast network must elect a DIS.

The Level-1 and Level-2 DISs are elected separately. You can assign different priorities to a router for different level DIS elections. The higher the router priority, the more likely the router becomes the DIS. If multiple routers with the same highest DIS priority exist, the one with the highest Subnetwork Point of Attachment (SNPA) address will be elected. On a broadcast network, the SNPA address is the MAC address. A router can be the DIS for different levels.



IS-IS DIS election differs from OSPF DIS election in the following ways:

- A router with priority 0 can also participate in the DIS election.

- When a router with a higher priority is added to the network, an LSP flooding process is performed to elect the router as the new DIS.

As shown in Figure 4, the same level routers on a network, including non-DIS routers, establish adjacency with each other.

Figure 4 DIS in the IS-IS broadcast network

The DIS creates and updates pseudonodes, and generates LSPs for the pseudonodes, to describe all routers on the network.

A pseudonode represents a virtual node on the broadcast network. It is not a real router. In IS-IS, it is identified by the system ID of the DIS and a 1-byte Circuit ID (a non-zero value).

Using pseudonodes simplifies network topology and can reduce the amount of resources consumed by SPF.

NOTE:

On an IS-IS broadcast network, all routers establish adjacency relationships, but they synchronize their LSDBs through the DIS.

On a broadcast network, the device can establish up to 255 neighbor relationships, because the Circuit ID is only one byte long. If the number of broadcast links that require neighbor relationship establishment exceeds 255, the device does not establish IS-IS neighbor relationships on the excess broadcast links.

IS-IS PDUs

PDU

IS-IS PDUs are encapsulated into link layer frames. An IS-IS PDU has two parts, the headers and the variable length fields. The headers comprise the PDU common header and the PDU specific header. All PDUs have the same PDU common header. The specific headers vary by PDU type.

Figure 5 PDU format

Table 1 PDU types

Type	PDU Type	Acronym
15	Level-1 LAN IS-IS hello PDU	L1 LAN IIH
16	Level-2 LAN IS-IS hello PDU	L2 LAN IIH
17	Point-to-Point IS-IS hello PDU	P2P IIH

Type	PDU Type	Acronym
18	Level-1 Link State PDU	L1 LSP
20	Level-2 Link State PDU	L2 LSP
24	Level-1 Complete Sequence Numbers PDU	L1 CSNP
25	Level-2 Complete Sequence Numbers PDU	L2 CSNP
26	Level-1 Partial Sequence Numbers PDU	L1 PSNP
27	Level-2 Partial Sequence Numbers PDU	L2 PSNP

Hello PDU

IS-to-IS hello (IIH) PDUs are used by routers to establish and maintain neighbor relationships. On broadcast networks, Level-1 routers use Level-1 LAN IIHs, and Level-2 routers use Level-2 LAN IIHs. The P2P IIHs are used on point-to-point networks.

LSP

The LSPs carry link state information. LSPs include Level-1 LSPs and Level-2 LSPs. The Level-2 LSPs are sent by the Level-2 routers, and the Level-1 LSPs are sent by the Level-1 routers. The Level-1-2 router can send both types of LSPs.

SNP

A sequence number PDU (SNP) describes the complete or partial LSPs for LSDB synchronization.

SNPs include CSNP and PSNP, which are further divided into Level-1 CSNP, Level-2 CSNP, Level-1 PSNP, and Level-2 PSNP.

A CSNP describes the summary of all LSPs for LSDB synchronization between neighboring routers. On broadcast networks, CSNPs are sent by the DIS periodically (every 10 seconds by default). On point-to-point networks, CSNPs are sent only during the first adjacency establishment.

A PSNP only contains the sequence numbers of one or multiple latest received LSPs. It can acknowledge multiple LSPs at one time. When LSDBs are not synchronized, a PSNP is used to request missing LSPs from a neighbor.

CLV

The variable fields of PDU comprise multiple Code-Length-Value (CLV) triplets.

Figure 6 CLV format

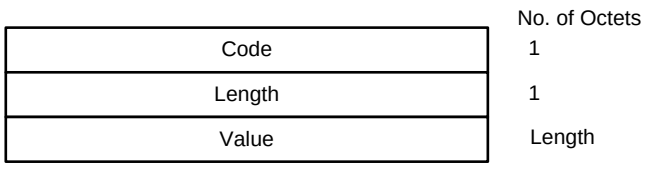


Table 2 shows that different PDUs contain different CLVs. Codes 1 through 10 are defined in ISO 10589 (code 3 and 5 are not shown in the table). Codes 128 through 132 are defined in RFC 1195. Codes 222 through 237 are defined in RFC 5120.

Table 2 CLV codes and PDU types

CLV Code	Name	PDU Type
1	Area Addresses	IIH, LSP
2	IS Neighbors (LSP)	LSP
4	Partition Designated Level 2 IS	L2 LSP

CLV Code	Name	PDU Type
6	IS Neighbors (MAC Address)	LAN IIH
7	IS Neighbors (SNPA Address)	LAN IIH
8	Padding	IIH
9	LSP Entries	SNP
10	Authentication Information	IIH, LSP, SNP
128	IP Internal Reachability Information	LSP
129	Protocols Supported	IIH, LSP
130	IP External Reachability Information	L2 LSP
131	Inter-Domain Routing Protocol Information	L2 LSP
132	IP Interface Address	IIH, LSP
222	MT-ISN	LSP
229	M-Topologies	IIH, LSP
235	MT IP. Reach	LSP
237	MT IPv6 IP. Reach	LSP

IPv6 IS-IS

IS-IS supports multiple network protocols, including IPv6. To support IPv6, the IETF added two type-length-values (TLVs) and a new network layer protocol identifier (NLPID).

The TLVs are as follows:

- **IPv6 Reachability**—Contains routing prefix and metric information to describe network reachability and has a type value of 236 (0xEC).
- **IPv6 Interface Address**—Same as the "IP Interface Address" TLV in IPv4 ISIS, except that the 32-bit IPv4 address is translated to the 128-bit IPv6 address.

The new NLPID is an 8-bit field that identifies which network layer protocol is supported. For IPv6, the NLPID is 142 (0x8E).

IPv4 IS-IS tasks at a glance

To configure IPv4 IS-IS, perform the following tasks:

1. Configuring basic IS-IS
   a. Enabling IPv4 IS-IS
   b. (Optional.) **Enabling a** lightweight IS-IS process
   c. (Optional.) Setting the IS level and circuit level

d. (Optional.) Configuring P2P network type for an interface

2. (Optional.) Configuring IS-IS multi-instance processes
3. (Optional.) Configuring IS-IS route control
   - Configuring IS-IS link cost
   - Specifying a preference for IS-IS
   - Configuring the maximum number of ECMP routes
   - Configuring IS-IS route summarization
   - Advertising a default route
   - Configuring IS-IS route redistribution
   - Filtering routes calculated from received LSPs
   - Filtering redistributed routes
   - Excluding redistributed routes from route calculation
   - Configuring IS-IS route leaking
   - Advertising IS-IS link state information to other protocols
4. (Optional.) Adjusting IS-IS routing convergence speed
   - Specifying the interval for sending IS-IS hello packets
   - Specifying the interval for sending IS-IS CSNP packets
   - Setting the maximum age of LSPs
   - Setting the initial remaining lifetime of IS-IS LSPs in the LSDB
   - Setting the LSP refresh interval and generation interval
   - Setting LSP sending intervals
   - Setting the LSP receiving interval
   - Setting the SPF calculation interval
   - Configuring convergence priorities for specific routes
5. (Optional.) Configuring IS-IS packet-related features
   - Configuring a DIS priority for an interface
   - Configuring the administrative tag value for an interface
   - Specifying the IS-IS hello multiplier
   - Disabling an interface from sending/receiving IS-IS packets
   - Enabling an interface to send small hello packets
   - Setting LSP lengths
   - Enabling LSP flash flooding
   - Enabling LSP fragment extension
6. (Optional.) Limiting LSP flooding
7. (Optional.) Configuring IS-IS route update suppression
8. (Optional.) Configuring advanced IS-IS features
   - Enabling source address check for hello packets on a P2P interface
   - Setting the LSDB overload bit
   - Configuring IS-IS isolation
   - Configuring IS-IS shutdown
   - Configuring the ATT bit
   - Configuring system ID to host name mappings
9. (Optional.) Configuring IS-IS logging and SNMP notifications
   - Enabling the logging of neighbor state changes

- Setting the maximum number of log entries that can be recorded
- Setting the maximum number of advertisement sources that trigger LSP update logging
- Setting the maximum number of IS-IS route change log messages that can be recorded
- Setting the maximum number of IS-IS neighbor relationship troubleshooting entries
- Configuring IS-IS network management

10. (Optional.) Configuring IS-IS fast convergence
    - Enabling ISPF
    - Enabling prefix suppression
    - Configuring IS-IS PIC
11. (Optional.) Enhancing IS-IS network security
    - Configuring neighbor relationship authentication
    - Configuring area authentication
    - Configuring routing domain authentication
12. (Optional.) Enhancing IS-IS network reliability:
    - Configuring IS-IS GR
    - Configuring IS-IS NSR
    - Configuring BFD for IS-IS
    - Configuring IS-IS FRR
    - Configuring IS-IS neighbor flapping suppression
    - Configuring IS-IS member port flapping suppression
    - Setting the priority for FRR backup path selection policies

IPv6 IS-IS tasks at a glance

To configure IPv6 IS-IS, perform the following tasks:

1. Configuring basic IS-IS
   a. Enabling IPv6 IS-IS
   b. (Optional.) **Enabling a** lightweight IS-IS process
   c. (Optional.) Setting the IS level and circuit level
   d. (Optional.) Configuring P2P network type for an interface
2. (Optional.) Configuring IS-IS multi-instance processes
3. (Optional.) Configuring IPv6 IS-IS MTR
4. (Optional.) Configuring IS-IS route control
    - Configuring IS-IS link cost
    - Specifying a preference for IS-IS
    - Configuring the maximum number of ECMP routes
    - Configuring IS-IS route summarization
    - Advertising a default route
    - Configuring IS-IS route redistribution
    - Filtering routes calculated from received LSPs
    - Filtering redistributed routes
    - Excluding redistributed routes from route calculation
    - Configuring IS-IS route leaking
    - Advertising IS-IS link state information to other protocols

5. (Optional.) Adjusting IS-IS routing convergence speed
    - Specifying the interval for sending IS-IS hello packets
    - Specifying the interval for sending IS-IS CSNP packets
    - Setting the maximum age of LSPs
    - Setting the initial remaining lifetime of IS-IS LSPs in the LSDB
    - Setting the LSP refresh interval and generation interval
    - Setting LSP sending intervals
    - Setting the LSP receiving interval
    - Setting the SPF calculation interval
    - Configuring convergence priorities for specific routes
6. (Optional.) Configuring IS-IS packet-related features
7. Configuring a DIS priority for an interface
    - Configuring the administrative tag value for an interface
    - Specifying the IS-IS hello multiplier
    - Disabling an interface from sending/receiving IS-IS packets
    - Enabling an interface to send small hello packets
    - Setting LSP lengths
    - Enabling LSP flash flooding
    - Enabling LSP fragment extension
8. (Optional.) Limiting LSP flooding
9. (Optional.) Configuring IS-IS route update suppression
10. (Optional.) Configuring advanced IS-IS features
    - Enabling source address check for hello packets on a P2P interface
    - Setting the LSDB overload bit
    - Configuring IS-IS isolation
    - Configuring IS-IS shutdown
    - Configuring the ATT bit
    - Configuring system ID to host name mappings
11. (Optional.) Configuring IS-IS logging and SNMP notifications
    - Enabling the logging of neighbor state changes
    - Setting the maximum number of log entries that can be recorded
    - Setting the maximum number of advertisement sources that trigger LSP update logging
    - Setting the maximum number of IS-IS route change log messages that can be recorded
    - Setting the maximum number of IS-IS neighbor relationship troubleshooting entries
    - Configuring IS-IS network management
12. (Optional.) Configuring IS-IS fast convergence
    - Enabling ISPF
    - Enabling prefix suppression
    - Configuring IS-IS PIC
13. (Optional.) Enhancing IS-IS network security
    - Configuring neighbor relationship authentication
    - Configuring area authentication
    - Configuring routing domain authentication
14. (Optional.) Enhancing IS-IS network reliability:

- Configuring IS-IS GR
- Configuring IS-IS NSR
- Configuring BFD for IS-IS
- Configuring IS-IS FRR
- Configuring IS-IS neighbor flapping suppression
- Configuring IS-IS member port flapping suppression

Configuring basic IS-IS

Enabling IPv4 IS-IS

1. Enter system view.
   system-view
2. Enable IS-IS and enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
   By default, IS-IS is disabled.
3. Assign a NET.
   network-entity *net*
   By default, NET is not assigned.

CAUTION:
When you execute the **network-entity** command together with the **cost-style** and **is-level** commands for the same IS-IS process, execute the **network-entity** command at last. Incorrect configuration order might cause data loss because the IS-IS process will restart.

4. Return to system view.
   quit
5. Enter interface view.
   interface *interface-type interface-number*
6. Enable IS-IS on the interface.
   isis enable [*process-id*]
   By default, IS-IS is disabled.

Enabling IPv6 IS-IS

1. Enter system view.
   system-view
2. Enable an IS-IS process and enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
   By default, no IS-IS process is enabled.
3. Configure the NET for the IS-IS process.
   network-entity *net*
   By default, the NET is not configured.

CAUTION:

When you execute the **network-entity** command together with the **cost-style** and **is-level** commands for the same IS-IS process, execute the **network-entity** command at last. Incorrect configuration order might cause data loss because the IS-IS process will restart.

4. Create the IPv6 address family and enter its view.
   address-family ipv6 [**unicast**]
5. Return to IS-IS view.
   quit
6. Return to system view.
   quit
7. Enter interface view.
   interface *interface-type interface-number*
8. Enable IPv6 for IS-IS on the interface.
   isis ipv6 enable [*process-id*]
   By default, IPv6 is disabled for IS-IS on an interface.

Enabling a lightweight IS-IS process

About this task

Enabling multiple IS-IS processes on a device might cause memory insufficiency. To resolve this issue, perform this task to enable lightweight IS-IS processes.

Restrictions and guidelines

Although lightweight processes use less memory resources than traditional processes, device performance might degrade when a large number of neighbors and routes exist. As a best practice, plan the number of lightweight IS-IS processes to be enabled on the basis of the device resource condition.

Procedure

1. Enter system view.
   system-view
2. Enable a lightweight IS-IS process and enter its view.
   isis [*process-id*] **lite** [**vpn-instance** *vpn-instance-name*]

Setting the IS level and circuit level

About this task

Follow these guidelines when you configure the IS level for routers in only one area:

- Set the IS level of all routers to Level-1 or Level-2 rather than different levels because the routers do not need to maintain two identical LSDBs.
- Set the IS level to Level-2 on all routers in an IP network for good scalability.

For an interface of a Level-1 or Level-2 router, the circuit level can only be Level-1 or Level-2. For an interface of a Level-1-2 router, the default circuit level is Level-1-2. If the router only needs to form Level-1 or Level-2 neighbor relationships, set the circuit level for its interfaces to Level-1 or Level-2. This will limit neighbor relationship establishment.

Procedure

1. Enter system view.

system-view

2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Specify the IS level.
   is-level { **level-1** | **level-1-2** | **level-2** }
   By default, the IS level is Level-1-2.
4. Return to system view.
   quit
5. Enter interface view.
   interface *interface-type interface-number*
6. Specify the circuit level.
   isis circuit-level [**level-1** | **level-1-2** | **level-2**]
   By default, an interface can establish either the Level-1 or Level-2 adjacency.

Configuring P2P network type for an interface

About this task

Interfaces with different network types operate differently. For example, broadcast interfaces on a network must elect the DIS and flood CSNP packets to synchronize the LSDBs. However, P2P interfaces on a network do not need to elect the DIS, and have a different LSDB synchronization mechanism.

If only two routers exist on a broadcast network, set the network type of attached interfaces to P2P. This avoids DIS election and CSNP flooding, saving network bandwidth and speeding up network convergence.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure P2P network type for an interface.
   isis [**process-id** *process-id*] **circuit-type p2p**
   By default, the network type of a VLAN interface is broadcast.
   Perform this task only for a broadcast network that has up to two attached routers.

Configuring IS-IS multi-instance processes

About this task

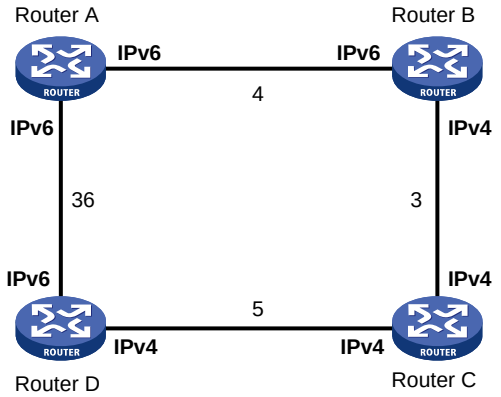
NOTE:

IS-IS processes not enabled with the multi-instance process feature are called traditional IS-IS processes. IS-IS processes enabled with the multi-instance process feature are called IS-IS multi-instance processes.

By default, an interface supports only one IS-IS process. To configure multiple IS-IS processes on a device, you must add more interfaces to the device and configure the interfaces manually. To simplify configuration, use the IS-IS multi-instance process feature to configure multiple IS-IS multi-instance processes as well as a traditional IS-IS process on an interface.

Procedure

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enable the IS-IS multi-instance process and specify an instance ID for the process.
   multi-instance enable iid *iid-value*
   By default, IS-IS multi-instance process is disabled.
4. Configure IS-IS multi-instance processes on an interface:
   a. Return to system view.
      quit
   b. Enter interface view.
      interface *interface-type interface-number*
   c. Enable an IS-IS multi-instance process on the interface:
      IPv4:
      isis enable [*process-id*]
      By default, IPv4 IS-IS is disabled on an interface, and the interface is not enabled with any IS-IS processes.
      IPv6:
      isis ipv6 enable [*process-id*]
      By default, IPv6 IS-IS is disabled on an interface, and the interface is not enabled with any IS-IS processes.



Configuring IPv6 IS-IS MTR

About this task

On a network, IPv4 and IPv6 topologies must be consistent so that both IPv6 IS-IS and IPv4 IS-IS can use the SPF algorithm to perform route calculation. If they are different, routers supporting both IPv4 and IPv6 might send IPv6 packets to routers that do not support IPv6, resulting in packet loss.

To resolve this issue, configure IPv6 IS-IS MTR to perform route calculation separately in IPv4 and IPv6 topologies.

Figure 7 Network diagram

As shown in Figure 7, the numbers refer to the link costs. Router A, Router B, and Router D support both IPv4 and IPv6. Router C supports only IPv4 and cannot forward IPv6 packets.

Enable IPv6 IS-IS MTR on Router A, Router B, Router C, and Router D to make them perform route calculation separately in IPv4 and IPv6 topologies. With this configuration, Router A does not forward IPv6 packets destined to Router D through Router B, avoiding packet loss.

Restrictions and guidelines

As a best practice to avoid route calculation failures, configure this feature when both IPv4 and IPv6 topologies exist in the network.

Procedure

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Specify an IS-IS cost style.
   cost-style { **compatible** | **wide** | **wide-compatible** }
   By default, IS-IS only transmits and receives packets using the **narrow** cost style.
4. Enter IPv6 address family view.
   address-family ipv6 [**unicast**]
5. Enable IPv6 IS-IS MTR.
   multi-topology [**compatible**]
   By default, IPv6 IS-IS MTR is disabled.

Configuring IS-IS route control

Configuring IS-IS link cost

About this task

The IS-IS cost of an interface is determined in the following order:

1. IS-IS cost specified in interface view.
2. IS-IS cost specified in system view.
   The cost is applied to the interfaces associated with the IS-IS process.
3. Automatically calculated cost.
   If the cost style is **wide** or **wide-compatible**, IS-IS automatically calculates the cost using the formula: Interface cost = (Bandwidth reference value / Expected interface bandwidth) × 10, in the range of 1 to 16777214. For other cost styles, Table 3 applies.
   Configure the expected bandwidth of an interface with the **bandwidth** command.

Table 3 Automatic cost calculation scheme for cost styles other than wide and wide-compatible

Interface bandwidth	Interface cost
≤ 10 Mbps	60
≤ 100 Mbps	50
≤ 155 Mbps	40
≤ 622 Mbps	30
≤ 2500 Mbps	20

Interface bandwidth	Interface cost
> 2500 Mbps	10

4. If none of the above costs is used, a default cost of 10 applies.

Configuring an IPv4 IS-IS cost for an interface

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. (Optional.) Specify an IS-IS cost style.
   cost-style { **narrow** | **wide** | **wide-compatible** | { **compatible** | **narrow-compatible** } [**relax-spf-limit**] }
   By default, the IS-IS cost type is **narrow**.
4. Return to system view.
   quit
5. Enter interface view.
   interface *interface-type interface-number*
6. Specify a cost for the IS-IS interface.
   isis [**process-id** *process-id*] **cost** *cost-value* [**level-1** | **level-2**]
   By default, no cost for the interface is specified.

Configuring a global IPv4 IS-IS cost

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Specify a global IS-IS cost.
   circuit-cost *cost-value* [**level-1** | **level-2**]
   By default, no global cost is specified.

Enabling automatic IPv4 IS-IS cost calculation

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enable automatic IS-IS cost calculation.
   auto-cost enable
   By default, automatic IS-IS cost calculation is disabled.
4. (Optional.) Configure a bandwidth reference value for automatic IS-IS cost calculation.
   bandwidth-reference *value*
   The default setting is 100 Mbps.

Configuring an IPv6 IS-IS cost for an interface

1. Enter system view.
   system-view

2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. (Optional.) Specify an IS-IS cost style.
   cost-style { **narrow** | **wide** | **wide-compatible** | { **compatible** | **narrow-compatible** } [**relax-spf-limit**] }
   By default, the IS-IS cost type is **narrow**.
4. Enter IPv6 address family view.
   address-family ipv6 [**unicast**]
5. Return to IS-IS view.
   quit
6. Return to system view.
   quit
7. Enter interface view.
   interface *interface-type interface-number*
8. Enable IPv6 for IS-IS on the interface.
   isis ipv6 enable [*process-id*]
   By default, IPv6 is disabled for IS-IS on an interface.
9. Specify an IPv6 cost for the IS-IS interface.
   isis [**process-id** *process-id*] **ipv6 cost** *cost-value* [**level-1** | **level-2**]
   By default, no IPv6 cost is specified for the interface.

Configuring a global IPv6 IS-IS cost

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enter IPv6 address family view.
   address-family ipv6 [**unicast**]
4. Specify a global IPv6 IS-IS cost.
   circuit-cost *cost-value* [**level-1** | **level-2**]
   By default, no global IPv6 cost is specified.

Enabling automatic IPv6 IS-IS cost calculation

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Specify an IS-IS cost style.
   cost-style { **wide** | **wide-compatible** }
   By default, the IS-IS cost style is **narrow**.
4. Enter IPv6 address family view.
   address-family ipv6 [**unicast**]
5. Enable automatic IPv6 IS-IS cost calculation.
   auto-cost enable

By default, automatic IPv6 IS-IS cost calculation is disabled.

6. (Optional.) Configure a bandwidth reference value for automatic IPv6 IS-IS cost calculation.
   bandwidth-reference *value*

   By default, the bandwidth reference value is 100 Mbps.

Enabling IS-IS to advertise the maximum link cost to neighbors

About this task

On an IS-IS network, when a link recovers from failures or the state of an interface changes, IS-IS will re-establish neighbor relationships and perform route convergence. During the route convergence process, routing loops and traffic loss might occur because the convergence speeds of the nodes are different. To address this issue, enable IS-IS to advertise the maximum link cost to neighbors within the specified period, so the traffic forwarding path remains unchanged. After the specified period, IS-IS advertises the original link cost to neighbors and performs optimal route selection again.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable IS-IS to advertise the maximum link cost to neighbors within the specified period.
   isis peer hold-max-cost duration *time*

   By default, IS-IS advertises the original link cost to neighbors during a route convergence.

Specifying a preference for IS-IS

About this task

If multiple routing protocols find routes to the same destination, the route found by the routing protocol that has the highest preference is selected as the optimal route.

Perform this task to assign a preference to IS-IS directly or by using a routing policy. For more information about the routing policy, see "Configuring routing policies."

Configuring a preference for IPv4 IS-IS

1. Enter system view.
   system-view
2. Enter IS-IS IPv4 unicast address family view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
   address-family ipv4 [**unicast**]
3. Configure a preference for IPv4 IS-IS.
   preference { *preference* | **route-policy** *route-policy-name* } *

   The default setting is 15.

Configuring a preference for IPv6 IS-IS

1. Enter system view.
   system-view
2. Enter IS-IS view.

isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IS-IS IPv6 address family view.
   address-family ipv6 [**unicast**]
4. Configure a preference for IPv6 IS-IS.
   preference { **route-policy** *route-policy-name* | *preference* } *
   The default setting is 15.

Configuring the maximum number of ECMP routes

About this task

Perform this task to implement load sharing over ECMP routes.

Configuring the maximum number of ECMP routes for IPv4 IS-IS

1. Enter system view.
   system-view
2. Enter IS-IS IPv4 unicast address family view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
   address-family ipv4 [**unicast**]
3. Specify the maximum number of ECMP routes.
   maximum load-balancing *number*
   By default, the maximum number of ECMP routes supported by IPv4 IS-IS equals the maximum number of ECMP routes supported by the system.

Configuring the maximum number of ECMP routes for IPv6 IS-IS

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enter IS-IS IPv6 address family view.
   address-family ipv6 [**unicast**]
4. Specify the maximum number of ECMP routes.
   maximum load-balancing *number*
   By default, the maximum number of ECMP routes supported by IPv6 IS-IS equals the maximum number of ECMP routes supported by the system.

Configuring IS-IS route summarization

About this task

Perform this task to summarize specific routes, including IS-IS routes and redistributed routes, into a single route. Route summarization can reduce the routing table size and the LSDB scale.

Route summarization applies only to locally generated LSPs.

Configuring IPv4 IS-IS route summarization

1. Enter system view.
   system-view
2. Enter IS-IS IPv4 unicast address family view.

isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

address-family ipv4 [**unicast**]

3. Configure IPv4 IS-IS route summarization.

   summary *ip-address* { *mask-length* | *mask* } [**avoid-feedback** | **generate_null0_route** | [**level-1** | **level-1-2** | **level-2**] | **tag** *tag*] *

   By default, IPv4 IS-IS route summarization is not configured.

   The cost of the summary route is the lowest one among the costs of the more-specific routes.

Configuring IPv6 IS-IS route summarization

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IS-IS IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Configure IPv6 IS-IS route summarization.

   summary *ipv6-prefix prefix-length* [**avoid-feedback** | **generate_null0_route** | [**level-1** | **level-1-2** | **level-2**] | **tag** *tag*] *

   By default, IPv6 IS-IS route summarization is not configured.

Advertising a default route

About this task

IS-IS cannot redistribute a default route to its neighbors. This task enables IS-IS to advertise a default route of 0.0.0.0/0 in an LSP to the same-level neighbors. Upon receiving the default route, the neighbors add it into their routing table.

When multiple devices exist in an IS-IS network, configuring default route advertisement is more flexible than configuring default static routes. For example, if an IS-IS routing domain has multiple edge devices, you can configure a routing policy on an edge device to control the advertisement of default routes and to prevent routing blackholes.

Advertising an IPv4 IS-IS default route

1. Enter system view.

   system-view

2. Enter IS-IS IPv4 unicast address family view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

   address-family ipv4 [**unicast**]

3. Advertise a Level-1 or Level-2 default route.

   default-route-advertise [[**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name*] *

   By default, IPv4 IS-IS does not advertise a Level-1 or Level-2 default route.

Advertising an IPv6 IS-IS default route

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IS-IS IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Advertise a Level-1 or Level-2 default route.

   default-route-advertise [**avoid-learning** | [**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name* | **tag** *tag*] *

   By default, IPv6 IS-IS does not advertise a Level-1 or Level-2 default route.

Configuring IS-IS route redistribution

About this task

After you enable default route advertisement for an edge device in an IS-IS routing domain, the device acts as a gateway to external routing domains for other devices in the routing domain. The service burden on the edge device will be heavy when it receives a large number of packets from other devices. Besides, selecting the optimal route to an external routing domain might be an issue when multiple edge devices exist in the IS-IS routing domain. To resolve these issues, you can perform this task to redistribute routes from other routing protocols into IS-IS.

You can configure the cost value for redistributed IGP routes and BGP routes. With an ACL, IP prefix list, or routing policy, IS-IS can filter redistributed routes. IS-IS adds only matching routes into its routing table, and then advertises them in LSPs.

To avoid the potential impact on the performance of some network devices, you can specify the maximum number of redistributed routes.

Restrictions and guidelines

This command redistributes only active routes. To display active routes, use the **display ip routing-table protocol** command.

Configuring IPv4 IS-IS route redistribution

1. Enter system view.

   system-view

2. Enter IS-IS IPv4 unicast address family view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

   address-family ipv4 [**unicast**]

3. Redistribute routes from other routing protocols or other IS-IS processes.

   import-route bgp [*as-number*] [**allow-ibgp**] [**cost** *cost-value* | **cost-type** { **external** | **internal** } | [**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name* | **tag** *tag*] *

   import-route bgp [*as-number*] [**allow-ibgp**] **inherit-cost** [[**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name* | **tag** *tag*] *

   import-route { **direct** | **static** } [**cost** *cost-value* | **cost-type** { **external** | **internal** } | [**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name* | **tag** *tag*] *

   import-route { **direct** | **static** } **inherit-cost** [[**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name* | **tag** *tag*] *

   import-route { **isis** | **ospf** | **rip** } [*process-id* | **all-processes**] [**allow-direct** | **cost** *cost-value* | **cost-type** { **external** | **internal** } | [**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name* | **tag** *tag*] *

   import-route { **isis** | **ospf** | **rip** } [*process-id* | **all-processes**] **inherit-cost** [**allow-direct** | [**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name* | **tag** *tag*] *

By default, IS-IS does not redistribute routes.

4. (Optional.) Configure the maximum number of redistributed Level 1/Level 2 IPv4 routes.

   import-route limit *number*

   By default, the maximum number of redistributed Level 1/Level 2 IPv4 routes is 65536.

Configuring IPv6 IS-IS route redistribution

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IS-IS IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Redistribute routes from other routing protocols or other IS-IS processes.

   import-route bgp4+ [*as-number*] [**allow-ibgp**] [[**cost** *cost-value* | **inherit-cost**] | [**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name* | **tag** *tag*] *

   import-route { **direct** | **static** } [[**cost** *cost-value* | **inherit-cost**] | [**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name* | **tag** *tag*] *

   import-route { **isisv6** | **ospfv3** | **ripng** } [*process-id*] [**allow-direct** | [**cost** *cost-value* | **inherit-cost**] | [**level-1** | **level-1-2** | **level-2**] | **route-policy** *route-policy-name* | **tag** *tag*] *

   By default, IPv6 IS-IS does not redistribute routes.

5. (Optional.) Configure the maximum number of redistributed Level 1/Level 2 IPv6 routes.

   import-route limit *number*

   By default, the maximum number of redistributed Level 1/Level 2 IPv6 routes is 32768.

Filtering routes calculated from received LSPs

About this task

IS-IS saves LSPs received from neighbors in the LSDB, and uses the SPF algorithm to calculate the shortest path tree with itself as the root. IS-IS installs the calculated routes to the IS-IS routing table and the optimal routes to the IP routing table.

Perform this task to filter calculated routes. Only routes that are not filtered can be added to the IP routing table. The filtered routes retain in the IS-IS routing table and can be advertised to neighbors.

Filtering IPv4 IS-IS routes calculated from received LSPs

1. Enter system view.

   system-view

2. Enter IS-IS IPv4 unicast address family view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

   address-family ipv4 [**unicast**]

3. Filter routes calculated using received LSPs.

   filter-policy { *ipv4-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } **import**

   By default, IPv4 IS-IS route filtering is not configured.

Filtering IPv6 IS-IS routes calculated from received LSPs

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enter IS-IS IPv6 address family view.
   address-family ipv6 [**unicast**]
4. Filter routes calculated using received LSPs.
   filter-policy { *ipv6-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } **import**

   By default, IPv6 IS-IS route filtering is not configured.

Filtering redistributed routes

About this task

IS-IS can redistribute routes from other routing protocols or other IS-IS processes, add them to the IS-IS routing table, and advertise them in LSPs.

Perform this task to filter redistributed routes. Only routes that are not filtered can be added to the IS-IS routing table and advertised to neighbors.

Restrictions and guidelines

Use this command together with the **import-route** command.

Filtering redistributed IPv4 IS-IS routes

1. Enter system view.
   system-view
2. Enter IS-IS IPv4 unicast address family view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
   address-family ipv4 [**unicast**]
3. Filter routes redistributed from other routing protocols or IS-IS processes.
   filter-policy { *ipv4-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } **export** [*protocol process-id*]

   By default, IPv4 IS-IS route filtering is not configured.

Filtering redistributed IPv6 IS-IS routes

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enter IS-IS IPv6 address family view.
   address-family ipv6 [**unicast**]
4. Filter routes redistributed from other routing protocols or IS-IS processes.
   filter-policy { *ipv6-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } **export** [*protocol process-id*]

   By default, IPv6 IS-IS route filtering is not configured.

Excluding redistributed routes from route calculation

About this task

By default, IS-IS adds only the redistributed route into the routing table if the following conditions exist:

- The redistributed route and the learned route have the same route prefix.
- The redistributed route has a higher preference value than the learned route.

In such a scenario, SR-MPLS and SRv6 cannot run normally because IS-IS does not generate any LSP for the learned route. To resolve this issue, use the **import-route no-route-calculate** command to exclude the redistributed route from route calculation. Then, IS-IS adds only the learned route into the routing table and generates an LSP for the learned route.

Restrictions and guidelines

This feature can take effect on a redistributed route only when this route has the same route prefix as a learned route.

Excluding IPv4 redistributed routes from route calculation

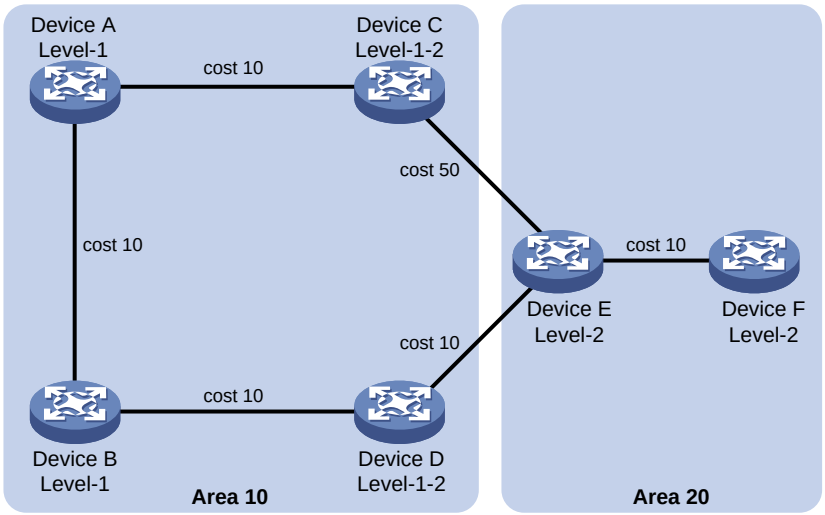
1. Enter system view.
   system-view
2. Enter IS-IS IPv4 unicast address family view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
   address-family ipv4 [**unicast**]
3. Exclude redistributed routes from route calculation
   import-route no-route-calculate
   By default, redistributed routes can participate in route calculation.

Excluding IPv6 redistributed routes from route calculation

1. Enter system view.
   system-view
2. Enter IS-IS IPv6 unicast address family view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
   address-family ipv6 [**unicast**]
3. Exclude redistributed routes from route calculation
   import-route no-route-calculate
   By default, redistributed routes can participate in route calculation.

Configuring IS-IS route leaking

About this task



By default, the Level-2 router does not advertise the routes of the Level-2 area and other Level-1 areas to a Level-1 area. The Level-1 routers in that Level-1 area sends packets destined for other areas to the nearest Level-1-2 router. As a result, IS-IS cannot use the optimal route to forward these packets. To resolve this issue, perform this task to configure IS-IS route leaking.

After you configure route leaking on a Level-1-2 router, this feature functions as follows:

1. Filters routes with the specified criteria.
2. Imports the desired routes from other Level-1 areas and the Level-2 area into the Level-1 area to which the Level-1-2 router belongs.

As shown in Figure 8, the optimal path from Device A to Device F is Device A > Device B > Device D > Device E > Device F and the total cost is 40. By default, the actual path to Device F on Device A is Device A > Device C > Device E > Device F and the total cost is 70. After you configure route leaking on Device C and Device D, IS-IS will use the Device A > Device B > Device D > Device E > Device F path to forward traffic from Device A to Device F.

Figure 8 Route leaking

Perform this task to control route advertisement (route leaking) between Level-1 and Level-2.

You can configure IS-IS to advertise routes from Level-2 to Level-1, and to not advertise routes from Level-1 to Level-2.

Configuring IPv4 IS-IS route leaking

1. Enter system view.

   system-view

2. Enter IS-IS IPv4 unicast address family view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

   address-family ipv4 [**unicast**]

3. Configure route leaking from Level-1 to Level-2.

   import-route isis level-1 into level-2 [**filter-policy** { *ipv4-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } | **tag** *tag*] *

   By default, IS-IS advertises routes from Level-1 to Level-2.

4. Configure route leaking from Level-2 to Level-1.

   import-route isis level-2 into level-1 [**filter-policy** { *ipv4-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } | **tag** *tag*] *

   By default, IS-IS does not advertise routes from Level-2 to Level-1.

Configuring IPv6 IS-IS route leaking

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IS-IS IPv6 address family view.

address-family ipv6 [**unicast**]

4. Configure route leaking from Level-2 to Level-1.

   import-route isisv6 level-2 into level-1 [**filter-policy** { *ipv6-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } | **tag** *tag*] *

   By default, IS-IS does not advertise routes from Level-2 to Level-1.

5. Configure route leaking from Level-1 to Level-2.

   import-route isisv6 level-1 into level-2 [**filter-policy** { *ipv6-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } | **tag** *tag*] *

   By default, IS-IS advertises routes from Level-1 to Level-2.

Advertising IS-IS link state information to other protocols

About this task

After the device advertises IS-IS link state information to other protocols, such as BGP, these protocols can then advertise the information for intended applications.

Restrictions and guidelines

When multiple IS-IS P2P neighbors exist between two devices, use one of the following commands to add the related local interface IP addresses into link state information. This operation ensures that other protocols can distinguish PPP links.

- **advertise link-attributes**
- **router-id** (IS-IS IPv6 address family view)

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Advertise IS-IS link state information to other protocols.

   distribute { **bgp-ls** | **link-state** | **sr-db** } [**instance-id** *id*] [**level-1** | **level-2**]

   By default, the device does not advertise IS-IS link state information to any other protocol.

Adjusting IS-IS routing convergence speed

Specifying the interval for sending IS-IS hello packets

About this task

IS-IS uses hello packets to maintain neighbor relationships. If a neighbor does not receive any hello packets from the router within the advertised hold time, it considers the router down and recalculates the routes. The hold time is the hello multiplier multiplied by the hello interval.

Restrictions and guidelines

The interval between hello packets sent by the DIS is 1/3 the hello interval set with the **isis timer hello** command.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify the interval for sending hello packets.
   isis timer hello *seconds* [**level-1** | **level-2**]
   The default setting is 10 seconds.

Specifying the interval for sending IS-IS CSNP packets

About this task

On a broadcast network, perform this task on the DIS that uses CSNP packets to synchronize LSDBs.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify the interval for sending CSNP packets on the DIS of a broadcast network.
   isis timer csnp *seconds* [**level-1** | **level-2**]
   The default setting is 10 seconds.

Setting the maximum age of LSPs

About this task

Each LSP has an age that decreases in the LSDB. Any LSP with an age of 0 is deleted from the LSDB. You can adjust the age value based on the scale of a network.

Procedure

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Set the maximum LSP age.
   timer lsp-max-age *seconds*
   The default setting is 1200 seconds.

Setting the initial remaining lifetime of IS-IS LSPs in the LSDB

About this task

A large number of LSPs might queue up for flooding in the LSDB of an advertisement source, which inevitably shortens their remaining lifetime. In this situation, the remaining lifetime of some LSPs might be too short when they are flooded. Such LSPs soon expire on the recipient side, causing LSP

flapping or temporary unreachable routes. To resolve this issue, perform this task to set the initial remaining lifetime of IS-IS LSPs in the LSDB.

The **timer lsp-remaining-lifetime refresh**{ *refresh-value* | **lsp-max-age** } command takes effect only when the following requirements are met:

- The local device receives an LSP update from another device.
- The remaining lifetime of the LSP is not 0, and is smaller than that specified by the *refresh-value* argument or the **lsp-max-age** keyword in this command.

Restrictions and guidelines

As a best practice to prevent LSP flapping, execute the **timer lsp-remaining-lifetime refresh**{ *refresh-value* | **lsp-max-age** } command to adjust the remaining lifetime of IS-IS LSPs.

To have the local device use the original remaining lifetime of an updated LSP, execute the **timer lsp-remaining-lifetime refresh disable** command.

Setting the initial remaining lifetime of IS-IS LSPs in the LSDB

1. Enter system view.

   system-view
2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Set the initial remaining lifetime of IS-IS LSPs in the LSDB.

   timer lsp-remaining-lifetime refresh { *refresh-value* | **lsp-max-age** | **disable** }

   By default, when IS-IS receives an updated LSP, it sets the maximum LSP age as the initial remaining lifetime of this LSP.

Disabling configuring the initial remaining lifetime of IS-IS LSPs in the LSDB

1. Enter system view.

   system-view
2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Disable configuring the initial remaining lifetime of IS-IS LSPs in the LSDB.

   timer lsp-remaining-lifetime refresh disable

   By default, when IS-IS receives an updated LSP, it sets the maximum LSP age as the initial remaining lifetime of this LSP.

   After you execute this command, the local device uses the original remaining lifetime of an LSP when it receives an update of that LSP.

Setting the LSP refresh interval and generation interval

About this task

Each router needs to refresh its LSPs at a configurable interval and send them to other routers to prevent valid routes from aging out. A smaller refresh interval speeds up network convergence but consumes more bandwidth.

When network topology changes such as neighbor state, interface metric, system ID, or area ID changes occur, the router generates an LSP after a configurable interval. If such a change occurs frequently, excessive LSPs are generated, consuming a large amount of router resources and bandwidth. To solve the problem, you can adjust the LSP generation interval.

Restrictions and guidelines

Follow these restrictions and guidelines when you configure the **timer lsp-generation** command:

- If you specify only the *maximum-interval* argument, the LSP generation interval is *maximum-interval*.
- If you do not specify the *incremental-interval* argument, the LSP generation interval is in the range of *minimum-interval* to *maximum-interval*.
- If you specify the *incremental-interval* argument, the LSP generation interval is as follows:
  - When network changes are not frequent, the *minimum-interval* is adopted.
  - If network changes are frequent, the LSP generation interval increases by *incremental-interval* × 2^{n-2} (n is the number of calculation times) each time a generation occurs until the *maximum-interval* is reached.

Procedure

1. Enter system view.

   system-view
2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Set the LSP refresh interval.

   timer lsp-refresh *seconds*

   By default, the LSP refresh interval is 900 seconds.
4. Set the LSP generation interval.

   timer lsp-generation *maximum-interval* [*minimum-interval* [*incremental-interval*]] [**level-1** | **level-2**]

   By default:
   - The maximum interval is 5 seconds.
   - The minimum interval is 50 milliseconds.
   - The incremental interval is 200 milliseconds.

Setting LSP sending intervals

About this task

If a change occurs in the LSDB, IS-IS advertises the changed LSP to neighbors. You can specify the minimum interval for sending these LSPs to control the amount of LSPs on the network.

On a P2P link, IS-IS requires an advertised LSP be acknowledged. If no acknowledgment is received within a configurable interval, IS-IS will retransmit the LSP.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Specify the minimum interval for sending LSPs and the maximum LSP number that can be sent at a time.

   isis timer lsp *time* [**count** *count*]

By default, the minimum interval is 33 milliseconds, and the maximum LSP number that can be sent at a time is 5.

4. Specify the LSP retransmission interval on a P2P link.

   isis timer retransmit *seconds*

   By default, the LSP retransmission interval on a P2P link is 5 seconds.

Setting the LSP receiving interval

About this task

When the network is stable, IS-IS uses the minimum receiving interval. When the network changes frequently, the receiving interval increases by the incremental interval each time the same LSP is received until the maximum receiving interval is reached.

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Set the LSP receiving interval.

   timer lsp-arrival *maximum-interval* [*minimum-interval* [*incremental-interval*]] [**level-1** | **level-2**]

   By default, the LSP receiving interval is not set.

Setting the SPF calculation interval

About this task

Based on the LSDB, an IS-IS router uses the SPF algorithm to calculate the shortest path tree with itself being the root, and uses the shortest path tree to determine the next hop to a destination network. By adjusting the SPF calculation interval, you can prevent bandwidth and router resources from being over consumed due to frequent topology changes.

When network changes are not frequent, the *minimum-interval* is adopted. If network changes become frequent, the SPF calculation interval increases by *incremental-interval* × 2^{n-2} (n is the number of calculation times) each time a calculation occurs until the *maximum-interval* is reached.

Setting the IPv4 SPF calculation interval

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Set the SPF calculation interval.

   timer spf { *maximum-interval* [*minimum-interval* [*incremental-interval* [**conservative**]]] | **millisecond** *millisecond-interval* } [**exclude-prc**]

   By default:

   - The maximum interval is 5 seconds.
   - The minimum interval is 50 milliseconds.
   - The incremental interval is 200 milliseconds.

Setting the IPv6 SPF calculation interval

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enter IPv6 address family view.
   address-family ipv6 [**unicast**]
4. Set the SPF calculation interval.
   timer spf { *maximum-interval* [*minimum-interval* [*incremental-interval* [**conservative**]]] | **millisecond** *millisecond-interval* } [**exclude-prc**]

   By default:
   - The maximum interval is 5 seconds.
   - The minimum interval is 50 milliseconds.
   - The incremental interval is 200 milliseconds.

Configuring convergence priorities for specific routes

About this task

A topology change causes IS-IS routing convergence. To improve convergence speed, you can assign convergence priorities to IS-IS routes. Convergence priority levels are critical, high, medium, and low. The higher the convergence priority, the faster the convergence speed.

After you use the **prefix-priority** command, IS-IS sets the convergence priorities for IS-IS routes as follows:

- IS-IS sets the convergence priorities for routes that already exist according to the configuration of the **prefix-priority** command.
- IS-IS sets the convergence priorities for subsequent routes according to the filter result of the **prefix-priority** command.
- When a route matches the rules of multiple convergence priorities, it uses the highest priority.

Configuring convergence priorities for specific IPv4 IS-IS routes

1. Enter system view.
   system-view
2. Enter IS-IS IPv4 unicast address family view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
   address-family ipv4 [**unicast**]
3. Assign convergence priorities to specific IPv4 IS-IS routes.
   - Assign a convergence priority to IPv4 IS-IS routes matching the specified prefix list.
     prefix-priority { **critical** | **high** | **medium** } { **prefix-list** *prefix-list-name* | **tag** *tag-value* }
   - Assign a convergence priority to IPv4 IS-IS routes by using a route policy.
     prefix-priority route-policy *route-policy-name*

   By default, IPv4 IS-IS routes, except IS-IS host routes, have the low convergence priority.

Configuring convergence priorities for specific IPv6 IS-IS routes

1. Enter system view.

system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IPv6 address family view.

   address-family ipv6 [**unicast**]

4. Assign convergence priorities to specific IPv6 IS-IS routes.

   prefix-priority { **critical** | **high** | **medium** } { **prefix-list** *prefix-list-name* | **tag** *tag-value* }

   prefix-priority route-policy *route-policy-name*

   By default, IPv6 IS-IS routes, except IS-IS host routes, have the low convergence priority.

Configuring IS-IS packet-related features

Configuring a DIS priority for an interface

About this task

On a broadcast network, IS-IS must elect a router as the DIS at a routing level. You can specify a DIS priority at a level for an interface. The greater the interface's priority, the more likely it becomes the DIS. If multiple routers in the broadcast network have the same highest DIS priority, the router with the highest MAC address becomes the DIS.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure a DIS priority for the interface.

   isis dis-priority *priority* [**level-1** | **level-2**]

   The default setting is 64.

Configuring the administrative tag value for an interface

About this task

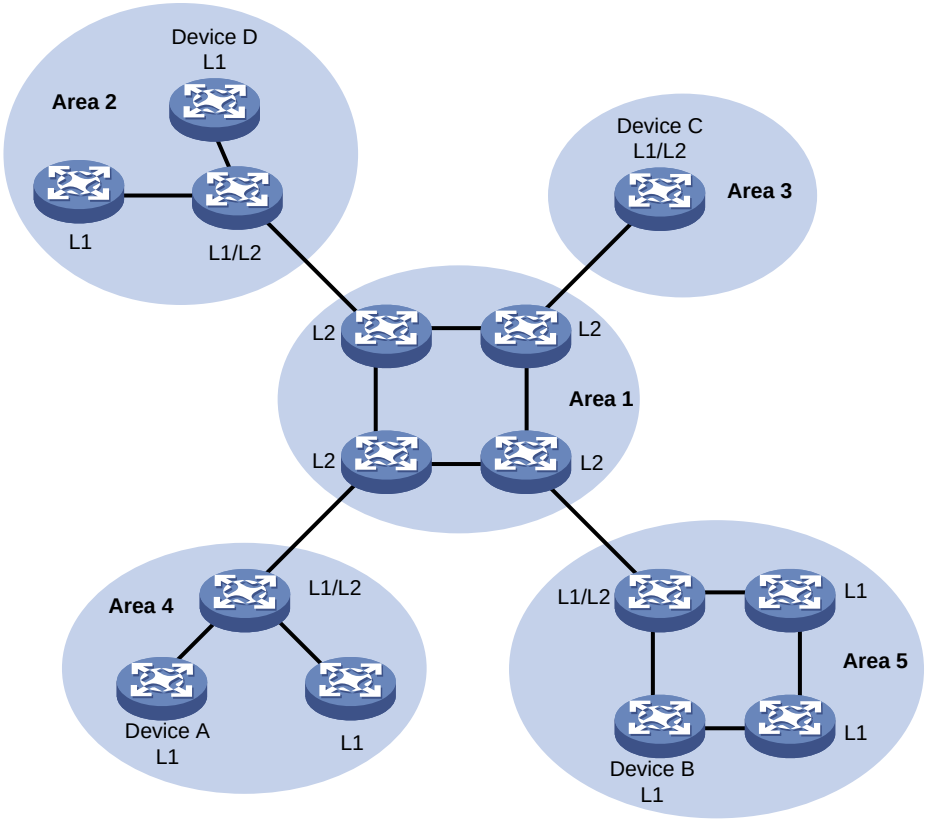
This task simplifies route management by allowing IS-IS to control IP address prefixes with the administrative tag.

As shown in Figure 9, Device A needs to communicate with Device B, Device C, and Device D. For security purposes, other devices in areas 2, 3, and 5 should not receive the packets sent by Device A. To resolve this issue, perform the following task:

1. Configure the same administrative tag value for the IS-IS interfaces on Device B, Device C, and Device D.
2. Configure route leaking from Level-2 to Level-1 on the Level-1-2 device in Area 4 and specify the same tag value as the route filter.

As shown in Figure 10, the IS-IS network topology on Device A is updated after you perform the above task.

Figure 9 IS-IS network diagram without the administrative tag



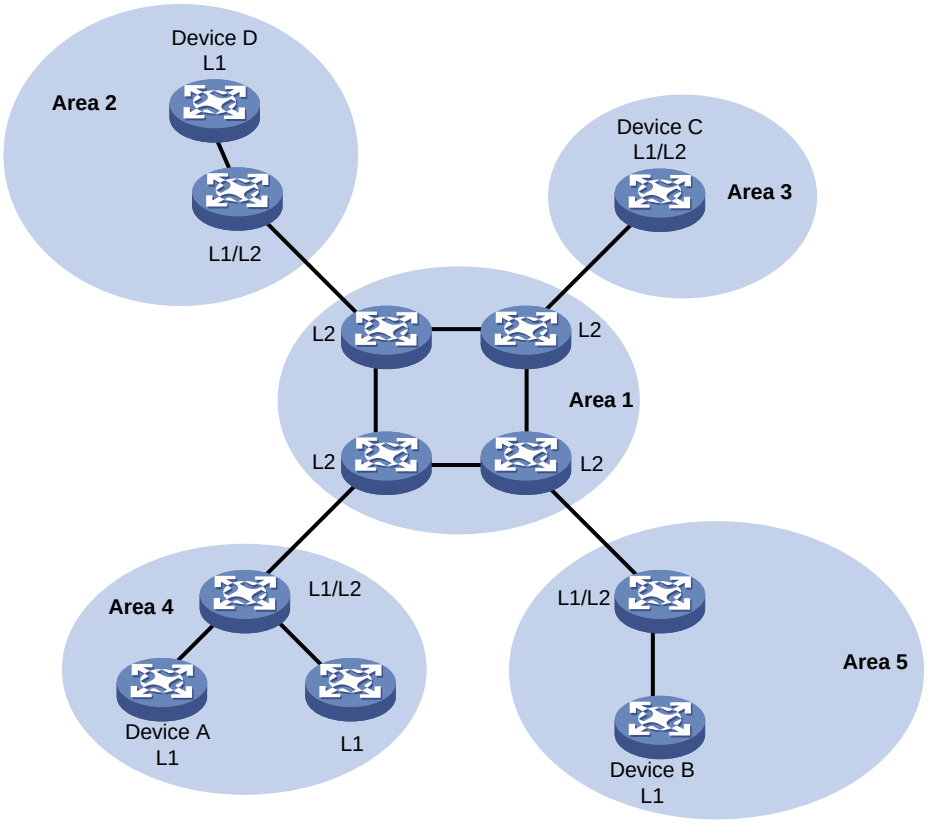


Figure 10 IS-IS network diagram with the administrative tag

Configuring the IPv4 IS-IS administrative tag value for an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the IPv4 IS-IS administrative tag value for the interface.
   isis tag *tag*

   By default, the IPv4 IS-IS administrative tag value of the interface is not configured.

   IS-IS adds the administrative tag to the network address information in LSPs only if the following conditions exist:
   - An administrative tag value is specified.
   - The link cost style is **wide**, **wide-compatible**, or **compatible**.

Configuring the IPv6 IS-IS administrative tag value for an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the IPv6 IS-IS administrative tag value for the interface.
   isis ipv6 tag *tag*

   By default, the IPv6 IS-IS administrative tag value of the interface is not configured.

   After you specify an administrative tag value, IS-IS always adds the specified tag value to the IPv6 prefix information in LSPs, regardless of the link cost style.

Specifying the IS-IS hello multiplier

About this task

The hello multiplier is the number of hello packets a neighbor must miss before it declares that the router is down.

If a neighbor receives no hello packets from the router within the advertised hold time, it considers the router down and recalculates the routes. The hold time is the hello multiplier multiplied by the hello interval.

On a broadcast link, Level-1 and Level-2 hello packets are advertised separately. You must set a hello multiplier for each level.

On a P2P link, Level-1 and Level-2 hello packets are advertised in P2P hello packets. You do not need to specify Level-1 or Level-2.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify the hello multiplier.
   isis timer holding-multiplier *value* [**level-1** | **level-2**]

   The default setting is 3.

Disabling an interface from sending/receiving IS-IS packets

About this task

After being disabled from sending and receiving hello packets, an interface cannot form any neighbor relationship, but can advertise directly connected networks in LSPs through other interfaces. This can save bandwidth and CPU resources, and ensures that other routers know networks directly connected to the interface.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Disable the interface from sending and receiving IS-IS packets.
   isis silent
   By default, the interface can send and receive IS-IS packets.

Enabling an interface to send small hello packets

About this task

IS-IS messages cannot be fragmented at the IP layer because they are directly encapsulated in frames. Any two IS-IS neighboring routers must negotiate a common MTU. To avoid sending big hellos to save bandwidth, enable the interface to send small hello packets without CLVs.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable the interface to send small hello packets without CLVs.
   isis small-hello
   By default, the interface sends standard hello packets.

Setting LSP lengths

About this task

IS-IS messages cannot be fragmented at the IP layer because they are directly encapsulated in frames. IS-IS routers in an area must send LSPs smaller than the smallest interface MTU in the area.

If the IS-IS routers have different interface MTUs, configure the maximum size of generated LSP packets to be smaller than the smallest interface MTU in the area. Without the configuration, the routers must dynamically adjust the LSP packet size to fit the smallest interface MTU, which takes time and affects other services.

Procedure

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Specify the maximum length of generated Level-1 LSPs or Level-2 LSPs.

   lsp-length originate *size* [**level-1** | **level-2**]

   By default, the maximum length of generated Level-1 LSPs or Level-2 LSPs is 1497 bytes.

4. Specify the maximum length of received LSPs.

   lsp-length receive *size*

   By default, the maximum length of received LSPs is 1497 bytes.

Enabling LSP flash flooding

About this task

Changed LSPs can trigger SPF recalculation. To advertise the changed LSPs before the router recalculates routes for faster network convergence, enable LSP flash flooding.

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enable LSP flash flooding.

   flash-flood [**flood-count** *flooding-count* | **max-timer-interval** *flooding-interval* | [**level-1** | **level-2**]] *

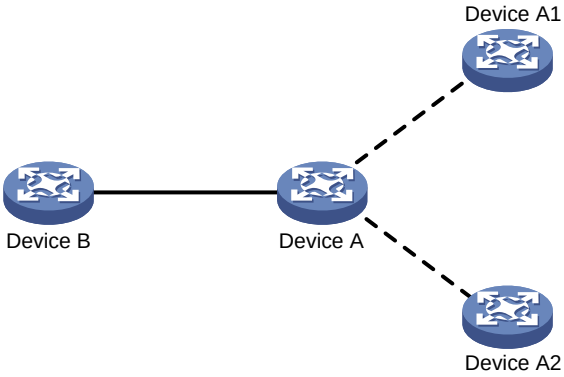
   By default, LSP flash flooding is disabled.

Enabling LSP fragment extension

About this task

When the LSP capacity of a device is insufficient, enable LSP fragment extension to expand the LSP capacity. These LSPs can then carry more IS-IS information, including redistributed routes and TLVs. If IS-IS fails to add some redistributed routes or TLVs into an LSP, it will automatically try to re-add those redistributed routes and TLVs into the LSP after LSP fragment extension.

The LSP fragment extension feature involves the following concepts:



- **Originating System**—IS-IS process.
- **Normal System ID**—System ID of the originating system.
- **Additional System ID**—Unique identifier assigned to a virtual system.
- **Virtual System**—System used to generate extended LSP fragments. Each extended LSP fragment carries the additional system ID of the virtual system in its LSP ID.
- **IS Alias ID TLV**—TLV that describes the relationship between the originating system and the virtual system.

By default, an IS-IS process can generate a maximum of 256 LSP fragments. The number of routes that these LSP fragments can carry is limited. To resolve this issue, the LSP fragment extension feature introduces the concept of additional system ID. Each additional system ID can generate 256 extended LSP fragments. When the LSP capacity of the originating system is insufficient, IS-IS adds the overflowing route information together with the IS Alias ID TLV into the extended LSPs of a virtual system.

As shown in Figure 11, both Device A and Device B support LSP fragment extension. With LSP fragment extension enabled, Device A advertises some route information in the LSPs generated by Device A1 and Device A2. On receipt of these LSPs, Device B reads the IS Alias ID TLVs and determines that Device A is the originating system. The route information received from Device A1

and Device A2 is actually generated by Device A. In this situation, virtual systems do not participate in route calculation.

Figure 11 IS-IS LSP fragment extension

Procedure

2. Enter system view.

   system-view

3. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

4. Enable LSP fragment extension.

   lsp-fragments-extend [**level-1** | **level-1-2** | **level-2**]

   By default, LSP fragment extension is disabled.

   The MTUs of all interfaces running the IS-IS process must not be less than 512. Otherwise, LSP fragment extension does not take effect.

5. Configure a virtual system ID.

   virtual-system *virtual-system-id*

   By default, no virtual system ID is configured.

   Configure a minimum of one virtual system to generate extended LSP fragments.

Limiting LSP flooding

About this task

On a fully meshed network, many P2P links exist. As shown in Figure 12, Devices A, B, C and D run IS-IS. When Device A generates an LSP, it floods the LSP out of VLAN-interface 10, VLAN-interface 20, and VLAN-interface 30. After Device D receives the LSP from VLAN-interface 30, it floods it out of VLAN-interface 10 and VLAN-interface 20 to Device B and Device C. However, Device B and Device C have already received the LSP from Device A. Repeated LSP flooding consumes extra bandwidth.

Figure 12 Network diagram of a fully meshed network

To avoid this problem, you can add interfaces to a mesh group or block some interfaces.

- An interface in a mesh group floods a received LSP only to interfaces not in the mesh group.
- A blocked interface sends LSPs only after receiving LSP requests.

Restrictions and guidelines

Before you configure this task, you must consider redundancy for interfaces in case LSP packets cannot be flooded because of link failures.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Limit LSP flooding.
   - Add the interface to a mesh group.
     isis mesh-group *mesh-group-number*
   - Block the interface.
     isis mesh-group mesh-blocked

   By default, the interface does not belong to any mesh group and is not blocked.

   The commands take effect only on P2P interfaces.

Configuring IS-IS route update suppression

About this task

Perform this task to protect network resources and routers from being overwhelmed by LSPs when route flapping occurs.

Procedure

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Configure IS-IS route update suppression.
   - Suppress LSP generation.

timer lsp-generation suppress-flapping *delay-interval* [**threshold** *threshold-value*] [**level-1** | **level-2**]

By default, IS-IS does not suppress LSP generation.

- Suppress LSP flooding.

  timer lsp-flood suppress-flapping *delay-interval* [**threshold** *threshold-value*] [**level-1** | **level-2**]

  By default, IS-IS does not suppress LSP flooding.

- Suppress route calculation.

  timer route-calculate suppress-flapping *delay-interval* [**threshold** *threshold-value*] [**level-1** | **level-2**]

  By default, IS-IS does not suppress route calculation.

- Suppress route calculation after fragment 0 of a purge LSP is received.

  timer purge-zero-lsp route-calculate-delay *delay-interval* [**level-1** | **level-2**]

  By default, IS-IS suppresses route calculation for 10 seconds after fragment 0 of a purge LSP is received.

Configuring advanced IS-IS features

Enabling source address check for hello packets on a P2P interface

About this task

An IS-IS P2P interface can have a peer on a different network. Perform this task to configure an IS-IS P2P interface to establish neighbor relationship only with a peer on the same network.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

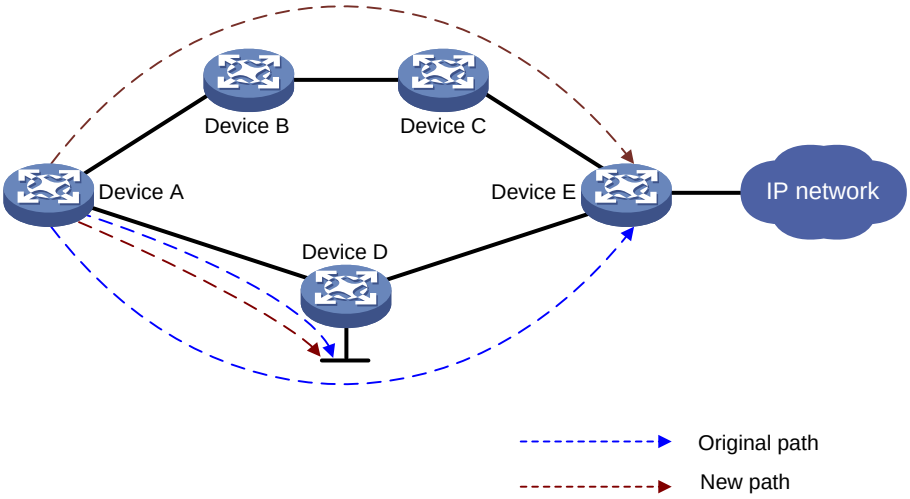
3. Enable source address check for hello packets on a P2P interface.

   isis peer-ip-check

   By default, an IS-IS P2P interface can have a peer on a different network.

Setting the LSDB overload bit

About this task



By setting the overload bit in sent LSPs, an IS-IS device informs other devices of failures that make it unable to select routes and forward packets. The device is then excluded from the SPF calculation by other devices except its direct routes.

When an IS-IS device cannot record the complete LSDB, for example, because of memory insufficiency, it will calculate routes incorrectly. To locate the faulty device, you can temporarily isolate the suspects from the IS-IS network by setting the overload bit.

As shown in Figure 13, the path from Device A to the IP network should be Device A > Device D > Device E > IP network. After you set the overload bit in the LSPs sent by Device D, the path from Device A to the IP network becomes Device A > Device B > Device C > Device E > IP network. If the

packets from Device A are destined for Device D's directly-connected networks, the forwarding path does not change.

Figure 13 Overload bit

Restrictions and guidelines

When both IPv4 and IPv6 topologies exist, the following rules apply to the **set-overload** command and the **multi-topology** command:

- If the **set-overload** command is executed in IS-IS view and the **multi-topology** command is not executed, the **set-overload** command takes effect on both IPv4 IS-IS and IPv6 IS-IS.
- If the following conditions exist, the **set-overload** command does not take effect on IPv6 IS-IS after it is executed in IS-IS IPv6 unicast address family view:
  - The **set-overload** command is not executed in IS-IS view.
  - The **multi-topology** command is not executed.
- If the **set-overload** command is executed in IS-IS view and the **multi-topology** command is executed, the **set-overload** command takes effect only on IPv4 IS-IS. To have the **set-overload** command take effect on IPv6 IS-IS, you must execute it in IS-IS IPv6 unicast address family view.

Setting the LSDB overload bit for IPv4 IS-IS

1. Enter system view.

   system-view
2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Set the overload bit.

   set-overload [**on-startup** [[**start-from-nbr** *system-id* [*timeout1* [*nbr-timeout*]]] | *timeout2* | **wait-for-bgp** [*timeout3*]]] [**allow** { **external** | **interlevel** } *]

   By default, the overload bit is not set.

Setting the LSDB overload bit for IPv6 IS-IS

1. Enter system view.

   system-view
2. Enter IS-IS view.

isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Specify an IS-IS cost style.

   cost-style { **compatible** | **wide** | **wide-compatible** }

   By default, IS-IS only transmits and receives packets using the **narrow** cost style.

4. Enter IPv6 address family view.

   address-family ipv6 [**unicast**]

5. Enable IPv6 IS-IS MTR.

   multi-topology [**compatible**]

   By default, IPv6 IS-IS MTR is disabled.

6. Set the overload bit.

   set-overload [**on-startup** [[**start-from-nbr** *system-id* [*timeout1* [*nbr-timeout*]]] | *timeout2* | **wait-for-bgp4+** [*timeout3*]]] [**allow** { **external** | **interlevel** } *]

   By default, the overload bit is not set.

Configuring IS-IS isolation

About this task

Isolation is a method used for network device maintenance. It gracefully removes a device from the packet forwarding path for maintenance and gracefully adds the device to the network after maintenance.

To reduce impact on traffic forwarding, you can isolate a device before upgrading it. IS-IS isolation works as follows:

1. After IS-IS isolation is enabled for a device, IS-IS sets the overload bit in the LSPs advertised by the device and sets the link cost to the maximum value.
2. Each neighbor of the device reselects an optimal route based on the LSPs and stops forwarding traffic to the device. The device is fully isolated from the network and you can upgrade the device.
3. After the maintenance, disable IS-IS isolation on the device to gracefully add it back to the network by clearing its overload bit and restoring its link cost.

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Configure IS-IS isolation.

   a. Enable IS-IS isolation to gracefully remove the device from the network.

      isolate enable

   b. Disable IS-IS isolation to gracefully add the device to the network.

      undo isolate enable

   By default, IS-IS isolation is disabled.

Configuring IS-IS shutdown

About this task

For maintenance purposes, you can use this feature to shut down IS-IS processes on the device with small impact on the network. If you shut down an IS-IS process, it will perform the following operations:

- Change the state of all neighbors to down.
- Stop receiving and sending IS-IS packets.
- Clear its neighbor, LSDB, and IS-IS route information.

After maintenance, you can use the **undo shutdown process** command to restart the IS-IS process for neighbor relationship re-establishment.

This feature shuts down an IS-IS process while retaining the process-associated settings to facilitate your maintenance.

Procedure

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Configure IS-IS shutdown.
   a. Shut down an IS-IS process to isolate it from the network.
      shutdown process
   b. Restart the IS-IS process to add it back to the network.
      undo shutdown process

   By default, the IS-IS process is not shut down.

Configuring the ATT bit

About this task

The ATT bit is used to identify the connection status between a Level-1 area and other areas. By default, a Level-1-2 router sets the ATT bit for Level-1 LSPs as follows:

- The Level-1-2 router sets the ATT bit in Level-1 LSPs to inform the Level-1 devices that it can reach other areas. After a Level-1 device receives a Level-1 LSP with the ATT bit set, it generates a default route destined for the Level-1-2 router.
- The Level-1-2 router does not set the ATT bit in Level-1 LSPs if it can reach only one area.

To edit the default ATT bit setting rule for a Level-1-2 router, perform the following tasks as needed:

- To enable ATT bit setting for all Level-1 LSPs, execute the **set-att always** command on the Level-1-2 router.
- To disable a Level-1 device from generating a default route upon receiving an ATT-bit-set Level-1 LSP from the Level-1-2 router, you can perform one of the following tasks:
  - Execute the **ignore-att** command on the Level-1 device.
  - Execute the **set-att never** command on the Level-1-2 router.

Configuring IS-IS not to calculate the default route through the ATT bit

1. Enter system view.
   system-view

2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Configure IS-IS not to calculate the default route through the ATT bit.
   ignore-att
   By default, IS-IS uses the ATT bit to calculate the default route.

Setting the ATT bit of IPv4 Level-1 LSPs

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Set the ATT bit of IPv4 Level-1 LSPs.
   set-att { **always** | **never** }
   By default, the Level-1-2 router sets the ATT bit for IPv4 Level-1 LSPs in accordance with the default ATT bit setting rule.

Setting the ATT bit of IPv6 Level-1 LSPs

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enter IPv6 address family view.
   address-family ipv6 [**unicast**]
4. Set the ATT bit of IPv6 Level-1 LSPs.
   set-att { **always** | **never** }
   By default, the Level-1-2 router sets the ATT bit for IPv6 Level-1 LSPs in accordance with the default ATT bit setting rule.

Configuring system ID to host name mappings

About this task

A 6-byte system ID in hexadecimal notation uniquely identifies a router or host in an IS-IS network. To make a system ID easy to read, the system allows you to use host names to identify devices. It also provides mappings between system IDs and host names.

The mappings can be configured manually or dynamically.

- **Static system ID to host name mapping**—You must manually configure a mapping for each router in the network. When a new router is added to the network or a mapping must be modified, you must configure all routers manually.
- **Dynamic system ID to host name mapping**—You only need to configure a host name for each router in the network. Each router advertises the host name in a dynamic host name CLV to other routers so all routers in the network can have all mappings. To help check the origin of LSPs in the LSDB, you can configure a name for the DIS in a broadcast network.

Restrictions and guidelines

Follow these guidelines when you configure the mappings:

- To view host names rather than system IDs by using the **display isis lsdb** command, you must enable dynamic system ID to host name mapping.

- If you configure both dynamic mapping and static mapping on a router, the host name specified for dynamic mapping applies.

Configuring a static system ID to host name mapping

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Configure a system ID to host name mapping for a remote IS.
   is-name map *sys-id map-sys-name*

   By default, no system ID to host name mapping is configured for a remote IS.

   A system ID can correspond to only one host name.

Configuring dynamic system ID to host name mapping

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Specify a host name for the IS and enable dynamic system ID to host name mapping.
   is-name *sys-name*

   By default, dynamic system ID to host name mapping is disabled and no host name is specified for the router.
4. Return to system view.
   quit
5. Enter interface view.
   interface *interface-type interface-number*
6. Configure a DIS name.
   isis dis-name *symbolic-name*

   By default, no DIS name is configured.

   This command takes effect only on a router enabled with dynamic system ID to host name mapping.

   This command is not available on P2P interfaces.

Configuring IS-IS logging and SNMP notifications

Enabling the logging of neighbor state changes

About this task

Neighbor flappings cause a series of issues, such as network instability, unnecessary resource consumption, and even data loss. You can enable the logging of neighbor state changes for fast fault location and troubleshooting.

With this feature enabled, the device delivers logs about neighbor state changes to its information center. The information center processes the logs according to user-defined output rules (whether to output logs and where to output). For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enable the logging of neighbor state changes.
   log-peer-change
   By default, the logging of neighbor state changes is enabled.

Setting the maximum number of log entries that can be recorded

About this task

Perform this task to set the maximum number of log entries that IS-IS can record for each log type.

Procedure

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Set the maximum number of log entries that IS-IS can record.
   event-log { **hello** { **peer-change** | **received-abnormal** | **received-dropped** | **sent-abnormal** | **sent-failed** } | **peer** } **size** *count*
   By default, IS-IS can record 100 log entries for each log type.

Setting the maximum number of advertisement sources that trigger LSP update logging

About this task

After the device starts running, it records LSP-update log information every 15 minutes. By default, it can record LSP-update log information for up to 200 advertisement sources. LSP update logging consumes memory resources. To control the memory usage by LSP update logging, you can perform this task.

Procedure

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Set the maximum number of advertisement sources that trigger LSP update logging.
   event-log updated-lsp size *count*
   By default, a maximum of 200 advertisement sources can trigger LSP update logging.

Setting the maximum number of IS-IS route change log messages that can be recorded

About this task

Supported IS-IS route change log messages include:

- **Route adding**—The device generates a route adding log message when IS-IS adds a route into the IP routing table.
- **Route deletion**—The device generates a route deletion log message when IS-IS deletes a route from the IP routing table.
- **Route update**—The device generates a route update log message when IS-IS updates a route in the IP routing table.

After the device starts running, it records IS-IS route change log messages. This operation consumes memory resources. To save memory resources, perform this task to adjust the maximum number of IS-IS route change log messages that the device can record.

Procedure

1. Enter system view.

   system-view
2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Set the maximum number of IS-IS route change log messages that the device can record.

   event-log route-record { **add** | **delete** | **modify** } **size** *count*

   By default, the device can record up to 5000 IPv4 IS-IS route change log messages for each log type and up to 5000 IPv6 IS-IS route change log messages for each log type.

Setting the maximum number of IS-IS neighbor relationship troubleshooting entries

1. Enter system view.

   system-view
2. Set the maximum number of IS-IS neighbor relationship troubleshooting entries.

   isis troubleshooting max-number *number*

   By default, IS-IS can record a maximum of 100 neighbor relationship troubleshooting entries.

Configuring IS-IS network management

About this task

This task includes the following configurations:

- Bind an IS-IS process to MIB so that you can use network management software to manage the specified IS-IS process.
- Enable IS-IS notifications to report important events.

To report critical IS-IS events to an NMS, enable SNMP notifications for IS-IS. For SNMP notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

Procedure

1. Enter system view.
   system-view
2. Bind MIB to an IS-IS process.
   isis mib-binding *process-id*
   By default, MIB is bound to the IS-IS process with the smallest process ID.
3. Enable IS-IS notification sending.
   snmp-agent trap enable isis [**adjacency-protocol-change** | **adjacency-state-change** | **area-mismatch** | **authentication** | **authentication-type** | **buffsize-mismatch** | **id-length-mismatch** | **lsdboverload-state-change** | **lsp-corrupt** | **lsp-parse-error** | **lsp-size-exceeded** | **manual-address-drop** | **max-seq-exceeded** | **maxarea-mismatch** | **own-lsp-purge** | **protocol-support** | **rejected-adjacency** | **skip-sequence-number** | **version-skew**] *
   By default, IS-IS notification sending is enabled.
4. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
5. Configure the context name for the SNMP object for managing IS-IS.
   snmp context-name *context-name*
   By default, no context name is set for the SNMP object for managing IS-IS.

Configuring IS-IS fast convergence

Enabling ISPF

About this task

When the network topology changes, Incremental Shortest Path First (ISPF) computes only the affected part of the SPT, instead of the entire SPT.

Enabling IPv4 IS-IS ISPF

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enable IPv4 IS-IS ISPF.
   ispf enable
   By default, IPv4 IS-IS ISPF is enabled.

Enabling IPv6 IS-IS ISPF

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enter IPv6 address family view.
   address-family ipv6 [**unicast**]
4. Enable IPv6 IS-IS ISPF.

ispf enable

By default, IPv6 IS-IS ISPF is enabled.

Enabling prefix suppression

About this task

Perform this task to disable an interface from advertising its prefix in LSPs. This enhances network security by preventing IP routing to the interval nodes and speeds up network convergence.

Enabling IPv4 IS-IS prefix suppression

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable IPv4 IS-IS prefix suppression on the interface.
   isis prefix-suppression

   By default, IPv4 IS-IS prefix suppression is disabled on the interface.

   This command is also applicable to the secondary IP address of the interface.

Enabling IPv6 IS-IS prefix suppression

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable IPv6 IS-IS prefix suppression on the interface.
   isis ipv6 prefix-suppression

   By default, IPv6 IS-IS prefix suppression is disabled on the interface.

Configuring IS-IS PIC

About this task

Prefix Independent Convergence (PIC) enables the device to speed up network convergence by ignoring the number of prefixes.

Restrictions and guidelines for IS-IS PIC

Follow these restrictions and guidelines when you configure IS-IS PIC:

- When both IS-IS PIC and IS-IS FRR are configured, IS-IS FRR takes effect.
- IS-IS PIC applies only to LSPs sent by neighbors.

Enabling IS-IS PIC

1. Enter system view.
   system-view
2. Enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enable PIC for IS-IS.
   pic [**additional-path-always**]

By default, IS-IS PIC is enabled.

Enabling BFD for IS-IS PIC

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable BFD control packet mode for IS-IS PIC.

   isis primary-path-detect bfd ctrl

   By default, BFD control packet mode is disabled for IS-IS PIC.

   To use BFD (control packet mode) to detect primary link failures, you must enable BFD control packet mode on both ends of the link.

Enabling BFD echo packet mode for IS-IS PIC

1. Enter system view.

   system-view
2. Configure the source IP address of BFD echo packets.

   bfd echo-source-ip *ip-address*

   By default, the source IP address of BFD echo packets is not configured.

   The source IP address cannot be on the same network segment as any local interface's IP address.

   For more information, see *High Availability Command Reference*.
3. Enter interface view.

   interface *interface-type interface-number*
4. Enable BFD echo packet mode for IS-IS PIC.

   isis primary-path-detect bfd echo

   By default, BFD echo packet mode is disabled for IS-IS PIC.

   To use BFD (echo packet mode) to detect primary link failures, you only need to enable BFD echo packet mode on one end of the link.

Enhancing IS-IS network security

To enhance the security of an IS-IS network, you can configure IS-IS authentication. IS-IS authentication involves neighbor relationship authentication, area authentication, and routing domain authentication.

Configuring neighbor relationship authentication

About this task

With neighbor relationship authentication configured, an interface adds the key in the specified mode into hello packets to the peer and checks the key in the received hello packets. If the authentication succeeds, it forms the neighbor relationship with the peer.

The authentication mode and key at both ends must be identical.

To prevent packet exchange failure in case of an authentication key change, configure the interface not to check the authentication information in the received packets.

Restrictions and guidelines

The authentication mode and key at both ends must be identical.

The keychain authentication mode supports HMAC-MD5 and HMAC-SM3 algorithms.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Specify the authentication mode and key.

   isis [**process-id** *process-id*] **authentication-mode** { { **gca** *key-id* { **hmac-sha-1** | **hmac-sha-224** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** } [**nonstandard**] | **md5** | **simple** } { **cipher** | **plain** } *string* | **keychain** *keychain-name* } [**level-1** | **level-2**] [**ip** | **osi**]

   By default, the authentication mode and key are not configured.

4. (Optional.) Configure the interface not to check the authentication information in the received hello packets.

   isis authentication send-only [**level-1** | **level-2**]

   When the authentication mode and key are configured, the interface checks the authentication information in the received packets by default.

Configuring area authentication

About this task

Area authentication prevents the router from installing routing information from untrusted routers into the Level-1 LSDB. The router encapsulates the authentication key in the specified mode in Level-1 packets (LSP, CSNP, and PSNP). It also checks the key in received Level-1 packets.

To prevent packet exchange failure in case of an authentication key change, configure IS-IS not to check the authentication information in the received packets.

Restrictions and guidelines

Routers in an area must have the same authentication mode and key.

The keychain authentication mode supports HMAC-MD5 and HMAC-SM3 algorithms.

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Specify the area authentication mode and key.

   area-authentication-mode { { **gca** *key-id* { **hmac-sha-1** | **hmac-sha-224** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** } [**nonstandard**] | **md5** | **simple** } { **cipher** | **plain** } *string* | **keychain** *keychain-name* } [**ip** | **osi**]

   By default, the area authentication mode and key are not configured.

4. (Optional.) Configure the interface not to check the authentication information in the received Level-1 packets, including LSPs, CSNPs, and PSNPs.

   area-authentication send-only

   When the authentication mode and key are configured, the interface checks the authentication information in the received packets by default.

Configuring routing domain authentication

About this task

Routing domain authentication prevents untrusted routing information from entering into a routing domain. A router with the authentication configured encapsulates the key in the specified mode into Level-2 packets (LSP, CSNP, and PSNP) and check the key in received Level-2 packets.

To prevent packet exchange failure in case of an authentication key change, configure IS-IS not to check the authentication information in the received packets.

Restrictions and guidelines

A device configured with routing domain authentication can establish adjacencies with other routers that are not configured with routing domain authentication, but it will discard LSPs not carrying the authentication information. In this situation, IS-IS might fail to learn the expected routes. To resolve this issue, configure the same authentication mode and key on all devices in the backbone area.

The keychain authentication mode supports only HMAC-MD5 and HMAC-SM3 algorithms.

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Specify the routing domain authentication mode and key.

   domain-authentication-mode { { **gca** *key-id* { **hmac-sha-1** | **hmac-sha-224** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** } [**nonstandard**] | **md5** | **simple** } { **cipher** | **plain** } *string* | **keychain** *keychain-name* } [**ip** | **osi**]

   By default, the routing domain authentication mode and key are not configured.

4. (Optional.) Configure the interface not to check the authentication information in the received Level-2 packets, including LSPs, CSNPs, and PSNPs.

   domain-authentication send-only

   When the authentication mode and key are configured, the interface checks the authentication information in the received packets by default.

Configuring IS-IS GR

About this task

GR ensures forwarding continuity when a routing protocol restarts or an active/standby switchover occurs.

Two routers are required to complete a GR process. The following are router roles in a GR process.

- **GR restarter**—Graceful restarting router. It must have GR capability.
- **GR helper**—A neighbor of the GR restarter. It assists the GR restarter to complete the GR process. By default, the device acts as the GR helper.

Configure IS-IS GR on the GR restarter.

GR restarter uses the following timers:

- **T1 timer**—Specifies the times that GR restarter can send a Restart TLV with the RR bit set. When rebooted, the GR restarter sends a Restart TLV with the RR bit set to its neighbor. If the GR restarter receives a Restart TLV with the RA set from its neighbor before the T1 timer expires, the GR process starts. Otherwise, the GR process fails.

- **T2 timer**—Specifies the LSDB synchronization interval. Each LSDB has a T2 timer. The Level-1-2 router has a Level-1 timer and a Level-2 timer. If the LSDBs have not synchronized before the two timers expire, the GR process fails.
- **T3 timer**—Specifies the GR interval. The GR interval is set as the holdtime in hello PDUs. Within the interval, the neighbors maintain their adjacency with the GR restarter. If the GR process has not completed within the holdtime, the neighbors tear down the neighbor relationship and the GR process fails.

Restrictions and guidelines

Follow these restrictions and guidelines when you configure IS-IS GR timers:

- The product of the T1 timer and the number of times that the T1 timer can expire must be smaller than the T2 timer.
- The T2 timer must be smaller than the T3 timer.

Procedure

1. Enter system view.
   system-view
2. Enable IS-IS and enter IS-IS view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enable IS-IS GR.
   graceful-restart
   By default, the GR capability for IS-IS is disabled.
4. (Optional.) Suppress the SA bit during restart.
   graceful-restart suppress-sa
   By default, the SA bit is not suppressed.
   By enabling the GR restarter to suppress the Suppress-Advertisement (SA) bit in the hello PDUs, the neighbors will still advertise their adjacency with the GR restarter.
5. (Optional.) Configure the T1 timer.
   graceful-restart t1 *seconds* **count** *count*
   By default, the T1 timer is 3 seconds and can expire 10 times.
6. (Optional.) Configure the T2 timer.
   graceful-restart t2 *seconds*
   By default, the T2 timer is 60 seconds.
7. (Optional.) Configure the T3 timer.
   graceful-restart t3 *seconds*
   By default, the T2 timer is 300 seconds.

Configuring IS-IS NSR

About this task

After an active/standby switchover, the GR restarter obtains routing information from its neighbors, and the IS-IS process must learn all the routes. If the network topology changes during the switchover, removed routes cannot be updated to the device, which can result in blackhole routes.

Nonstop Routing (NSR) solves the problem by backing up IS-IS link state information from the active process to the standby process. After an active/standby switchover, NSR can complete link state recovery and route regeneration without requiring the cooperation of other devices.

Choose IS-IS NSR or IS-IS GR according to the actual situation and make sure data forwarding is not interrupted. The differences between IS-IS NSR and IS-IS GR as follows:

- **Device requirements**—The active and standby processes of IS-IS must run on different IRF member devices. To run IS-IS NSR, you must set up an IRF fabric that contains a minimum of two member devices. To run IS-IS GR, IRF fabric setup is not required. If an IRF fabric already exists, you can run IS-IS GR when the IRF fabric contains only one member device.
- **IS-IS neighbor requirements**—When you use IS-IS NSR, IS-IS neighbors cannot detect process restart or active/standby switchover on the local device. IS-IS NSR can recover IS-IS route information without requiring the cooperation of IS-IS neighbors. IS-IS GR requires IS-IS neighbors to have the GR helper capability to help the GR restarter complete the GR process.

Restrictions and guidelines

When both GR and NSR are configured for IS-IS on a device, the following rules apply:

- IS-IS NSR has a higher priority than IS-IS GR. When the active process goes down, the device does not act as the GR restarter and performs NSR to ensure nonstop forwarding.
- When the following conditions exist, the GR process might fail even if NSR is enabled on the GR helper:
  - IS-IS is restarted through GR.
  - An active/standby switchover is triggered on the GR helper before the GR process finishes.

Procedure

1. Enter system view.

   system-view
2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Enable IS-IS NSR.

   non-stop-routing

   By default, IS-IS NSR is enabled.

   IS-IS NSR takes effect on a per-process basis. As a best practice, enable NSR for each IS-IS process.

Configuring BFD for IS-IS

About this task

BFD provides a single mechanism to quickly detect and monitor the connectivity of links between IS-IS neighbors, reducing network convergence time. For more information about BFD, see *High Availability Configuration Guide*.

Configuring BFD for IPv4 IS-IS

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable BFD on an IPv4 IS-IS interface.

   isis bfd enable

   By default, an IPv4 IS-IS interface is not enabled with BFD.

Configuring BFD for IPv6 IS-IS

1. Enter system view.

   system-view

2. Enter interface view.
   interface *interface-type interface-number*
3. Enable BFD on an IPv6 IS-IS interface.
   isis ipv6 bfd enable
   By default, an IPv6 IS-IS interface is not enabled with BFD.

Configuring IS-IS FRR

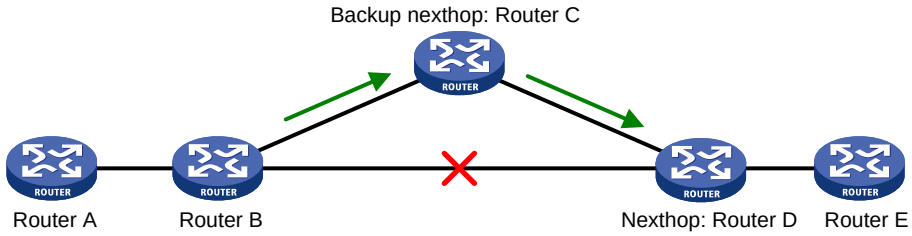
About IS-IS FRR

IS-IS Fast Reroute (FRR) calculates a backup path based on the LSDB and saves the backup path information to the FIB. When the primary path fails, the system immediately switches traffic to the backup path to prevent traffic loss and reduce the route convergence time.

IS-IS supports Loop Free Alternate (LFA) FRR.

The following IS-IS FRR traffic protection types are available:

- **Link protection**—Protects traffic that traverses a specific link.
- **Node protection**—Protects traffic that traverses a specific node.



Node protection takes precedence over link protection.

Configuring IS-IS LFA FRR

About IS-IS LFA FRR

A link or router failure on a path can cause packet loss. IS-IS LFA FRR enables fast rerouting to minimize the failover time.

Figure 14 Network diagram for IS-IS LFA FRR

In Figure 14, after you enable LFA FRR on Router B, IS-IS automatically calculates or designates a backup next hop when a link failure is detected. In this way, packets are directed to the backup next hop to reduce traffic recovery time. Meanwhile, IS-IS calculates the shortest path based on the new network topology, and forwards packets over the path after network convergence.

You can assign a backup next hop for IS-IS FRR through the following ways:

- Enable IS-IS LFA FRR to calculate a backup next hop through LFA calculation.
- Designate a backup next hop with a routing policy for routes matching specific criteria.

Restrictions and guidelines

IS-IS LFA FRR and IS-IS TE are mutually exclusive.

Configuring IPv4 IS-IS LFA FRR to calculate a backup next hop through LFA calculation

1. Enter system view.
   system-view

2. Enter interface view.
   interface *interface-type interface-number*
3. (Optional.) Disable LFA calculation on the interface.
   isis fast-reroute lfa-backup exclude [**level-1** | **level-2**]
   By default, the interface participates in LFA calculation, and can be elected as a backup interface.
4. Return to system view.
   quit
5. Enter IS-IS IPv4 unicast address family view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
   address-family ipv4 [**unicast**]
6. Enable IS-IS LFA FRR to calculate a backup next hop through LFA calculation.
   fast-reroute lfa [**ecmp-shared** | **level-1** | **level-2**]
   By default, IS-IS LFA FRR is disabled.

Configuring IPv4 IS-IS LFA FRR using a routing policy

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. (Optional.) Disable LFA calculation on the interface.
   isis fast-reroute lfa-backup exclude [**level-1** | **level-2**]
   By default, the interface participates in LFA calculation, and can be elected as a backup interface.
4. Return to system view.
   quit
5. Enter IS-IS IPv4 unicast address family view.
   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]
   address-family ipv4 [**unicast**]
6. Enable IPv4 IS-IS LFA FRR using a routing policy.
   - Create a routing policy and specify a backup next hop.
     apply fast-reroute backup-interface
     For more information about the apply fast-reroute backup-interface command and routing policy, see *Layer 3—IP Routing Configuration Guide*.
   - Configure IPv4 IS-IS LFA FRR.
     fast-reroute route-policy *route-policy-name*

   By default, IPv4 IS-IS LFA FRR is disabled.

Enabling BFD for IPv4 IS-IS LFA FRR

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable BFD control packet mode for IPv4 IS-IS FRR.
   isis primary-path-detect bfd ctrl

By default, BFD control packet mode is disabled for IPv4 IS-IS FRR.

To use BFD (control packet mode) to detect primary link failures, you must enable BFD control packet mode on both ends of the link.

Enabling BFD echo packet mode for IPv4 IS-IS LFA FRR

1. Enter system view.

   system-view

2. Configure the source IP address of BFD echo packets.

   bfd echo-source-ip *ip-address*

   By default, the source IP address of BFD echo packets is not configured.

   The source IP address cannot be on the same network segment as any local interface's IP address.

   For more information, see *High Availability Command Reference*.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable BFD echo packet mode for IPv4 IS-IS LFA FRR.

   isis primary-path-detect bfd echo

   By default, BFD echo packet mode is disabled for IPv4 IS-IS LFA FRR.

   To use BFD (echo packet mode) to detect primary link failures, you only need to enable BFD echo packet mode on one end of the link.

Configuring IPv6 IS-IS LFA FRR to calculate a backup next hop through LFA calculation

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. (Optional.) Disable LFA calculation on the interface.

   isis ipv6 fast-reroute lfa-backup exclude [**level-1** | **level-2**]

   By default, the interface participates in LFA calculation, and can be elected as a backup interface.

4. Return to system view.

   quit

5. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

6. Enter IS-IS IPv6 address family view.

   address-family ipv6 [**unicast**]

7. Enable IPv6 IS-IS LFA FRR to calculate a backup next hop through LFA calculation.

   fast-reroute lfa [**level-1** | **level-2**]

   By default, IPv6 IS-IS LFA FRR is disabled.

Configuring IPv6 IS-IS LFA FRR using a routing policy

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. (Optional.) Disable LFA calculation on the interface.

   isis ipv6 fast-reroute lfa-backup exclude [**level-1** | **level-2**]

By default, the interface participates in LFA calculation, and can be elected as a backup interface.

4. Return to system view.

   quit

5. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

6. Enter IS-IS IPv6 address family view.

   address-family ipv6 [**unicast**]

7. Enable IPv6 IS-IS LFA FRR using a routing policy.

   - Create a routing policy and specify a backup next hop.

     apply ipv6 fast-reroute backup-interface

     For more information about the **apply ipv6 fast-reroute backup-interface** command and routing policy, see *Layer 3—IP Routing Configuration Guide*.

   - Configure IPv6 IS-IS LFA FRR.

     fast-reroute route-policy *route-policy-name*

   By default, IPv6 IS-IS LFA FRR is disabled.

Enabling BFD for IPv6 IS-IS LFA FRR

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable BFD control packet mode for IPv6 IS-IS LFA FRR.

   isis ipv6 primary-path-detect bfd ctrl

   By default, BFD control packet mode is disabled for IPv6 IS-IS LFA FRR.

   To use BFD (control packet mode) to detect primary link failures, you must enable BFD control packet mode on both ends of the link.

Enabling BFD echo packet mode for IPv6 IS-IS LFA FRR

1. Enter system view.

   system-view

2. Configure the source IPv6 address of BFD echo packets.

   bfd echo-source-ipv6 *ip-address*

   By default, the source IPv6 address of BFD echo packets is not configured.

   The source IPv6 address cannot be on the same network segment as any local interface's IPv6 address.

   For more information, see *High Availability Command Reference*.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable BFD echo packet mode for IPv6 IS-IS LFA FRR.

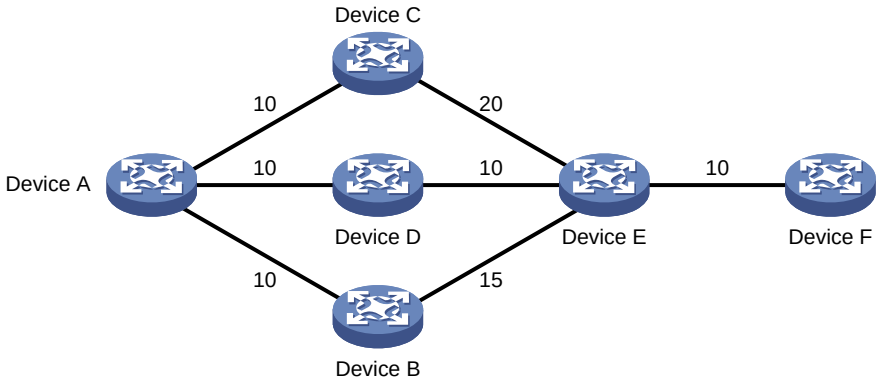
   isis ipv6 primary-path-detect bfd echo

   By default, BFD echo packet mode is disabled for IPv6 IS-IS LFA FRR.

   To use BFD (echo packet mode) to detect primary link failures, you only need to enable BFD echo packet mode on one end of the link.

Setting the priority for FRR backup path selection policies

About this task



IS-IS FRR selects a backup path based on the following policies:

- **Node-protection policy**—Selects the path that involves a specific node.
- **Lowest-cost policy**—Selects the path that has the lowest cost.

As shown in Figure 15, traffic forwarding path **Device A->Device D->Device E->Device F** has two backup paths. Configure this feature as follows to control backup path selection:

- To select path **Device A->Device C->Device E->Device F** that involves Device C, set a higher priority for the node-protection policy than the lowest-cost policy.
- To select path **Device A->Device B->Device E->Device F** that has the lowest cost, set a higher priority for the lowest-cost policy than the node-protection policy.

Figure 15 IS-IS FRR backup path selection

Restrictions and guidelines

If the node-protection policy has a higher priority but the backup path calculation fails, IS-IS uses the lowest-cost policy for further calculation.

If the lowest-cost policy has a higher priority but the backup path calculation fails, IS-IS does not perform further backup path calculation.

Procedure

1. Enter system view.

   system-view

2. Enter IS-IS view.

   isis [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enter IS-IS IPv4 address family view or IS-IS IPv6 address family view.
   - Enter IS-IS IPv4 address family view.

     address-family ipv4 [**unicast**]
   - Enter IS-IS IPv6 address family view.

     address-family ipv6 [**unicast**]

4. Set the priority for the node-protection or lowest-cost backup path selection policy.

   fast-reroute tiebreaker { **lowest-cost** | **node-protecting** | **non-ecmp** | **srlg-disjoint** } **preference** *preference* [**level-1** | **level-2**]

   By default, the priority values of the node-protection and lowest-cost backup path selection policies are 40 and 20, respectively.

Configuring IS-IS neighbor flapping suppression

About this task

When the state of an IS-IS neighbor flaps frequently, IS-IS also frequently performs neighbor relationship re-establishment, LSDB synchronization, and route calculation. Such tasks interrupt IS-IS services and other services that depend on IS-IS, because performing these tasks requires a large number of packet exchanges. To resolve this issue, configure IS-IS neighbor flapping suppression. This feature enables IS-IS to suppress neighbor flapping on an interface by increasing the cost value for the interface. Traffic then does not pass through the interface during neighbor flapping suppression. When the resume timer for neighbor flapping suppression expires, IS-IS restores the cost value to the original for the interface.

IS-IS supports the conservative and non-conservative modes for neighbor flapping suppression.

The conservative mode functions as follows:

1. After you enable neighbor flapping suppression on an interface, the interface starts a flapping event counter to collect statistics about neighbor flapping events. When the time gap between two neighbor down events in a row is shorter than the detection timer, IS-IS increases the number of neighbor flapping events by one.

   IS-IS resets and restarts the flapping event counter when the following conditions exist:

   - The number of neighbor flapping events is less than the threshold that triggers neighbor flapping suppression.
   - The time gap between two neighbor down events in a row is longer than the resume timer.
2. IS-IS compares the number of neighbor flapping events with the threshold that triggers neighbor flapping suppression:
   - If the number of neighbor flapping events is less than the threshold, IS-IS does not suppress neighbor flapping.
   - If the number of neighbor flapping events is not less than the threshold, IS-IS starts neighbor flapping suppression. It increases the cost value for the interface and resets the flapping event counter to zero.
3. The resume timer starts as IS-IS starts neighbor flapping suppression. The suppression duration equals the resume timer.

   If a neighbor down event occurs on the interface during neighbor flapping suppression, IS-IS restarts the resume timer.
4. After the resume timer expires, IS-IS restores the cost value to the original for the interface if no neighbor flapping events occur on the interface before the resume timer expires.

The non-conservative mode functions as follows:

5. After you enable neighbor flapping suppression on an interface, the interface starts a flapping event counter to collect statistics about neighbor flapping events. IS-IS increases the number of neighbor flapping events by one each time a neighbor down event occurs on the interface.

   When a neighbor down event occurs on the interface, IS-IS performs the following tasks:

   a. Record the timestamp of the neighbor down event.

   NOTE:

   For brief description, the following arguments are introduced:

   - The *T* argument represents the timestamp that equals the neighbor down event timestamp minus the detection timer.
   - The *flapping-count* argument represents the number of neighbor flapping events that occur later than *T* and not later than the neighbor down event timestamp.

   b. Compare *flapping-count* with the threshold that triggers neighbor flapping suppression:

- If *flapping-count* is less than the threshold, IS-IS does not suppress neighbor flapping or reset the flapping event counter.
- If *flapping-count* is not less than the threshold, IS-IS starts neighbor flapping suppression. It increases the cost value for the interface and resets the flapping event counter.

6. The resume timer starts as IS-IS starts neighbor flapping suppression. The suppression duration equals the resume timer.

   If a neighbor down event occurs on the interface during neighbor flapping suppression, IS-IS restarts the resume timer.
7. After the resume timer expires, IS-IS restores the cost value to the original for the interface if no neighbor flapping events occur on the interface before the resume timer expires.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable neighbor flapping suppression on the interface and specify the cost adjustment value for the interface.
   - IPv4 IS-IS:

     isis peer suppress-flapping adjust-cost { *cost-offset* | **max** }

     By default, neighbor flapping suppression is disabled on an IPv4 IS-IS interface.
   - IPv6 IS-IS:

     isis ipv6 peer suppress-flapping adjust-cost { *cost-offset* | **max** }

     By default, neighbor flapping suppression is disabled on an IPv6 IS-IS interface.
4. Configure the detection parameters for IS-IS neighbor flapping suppression.
   - IPv4 IS-IS:

     isis peer suppress-flapping { [**detect-interval** *detect-interval* | **threshold** *threshold* | **resume-interval** *resume-interval*] * | **non-conservative** }

     By default, the detection timer is 60 seconds, the threshold is 10, and the resume timer is 120 seconds.
   - IPv6 IS-IS:

     isis ipv6 peer suppress-flapping { [**detect-interval** *detect-interval* | **threshold** *threshold* | **resume-interval** *resume-interval*] * | **non-conservative** }

     By default, the detection timer is 60 seconds, the threshold is 10, and the resume timer is 120 seconds.

Configuring IS-IS member port flapping suppression

About this task

When two IS-IS neighbors are connected by Layer 3 aggregate links and the links between member ports flap frequently, the neighbors perform link switchover frequently for traffic forwarding. To resolve this issue, enable member port flapping suppression on the aggregate interfaces.

This feature enables IS-IS to suppress member port flapping on an aggregate interface by increasing the cost value for the aggregate interface. Traffic then does not pass through the aggregate interface during member port flapping suppression. When the resume timer for member port flapping suppression expires, IS-IS restores the cost value to the original for the aggregate interface.

IS-IS supports the conservative and non-conservative modes for member port flapping suppression.

The conservative mode functions as follows:

1. After you enable member port flapping suppression on an aggregate interface, the aggregate interface starts a flapping event counter to collect statistics about the flapping events that occur on its member ports. When the time gap between two link failures in a row is shorter than the detection timer, IS-IS increases the number of member port flapping events by one.

   IS-IS resets and restarts the flapping event counter when the following conditions exist:

   - The number of member port flapping events is less than the threshold that triggers member port flapping suppression.
   - The time gap between two link failures in a row is longer than the resume timer.

2. IS-IS compares the number of member port flapping events with the threshold that triggers member port flapping suppression:

   - If the number of member port flapping events is less than the threshold, IS-IS does not suppress member port flapping.
   - If the number of member port flapping events is not less than the threshold, IS-IS starts member port flapping suppression. It increases the cost value for the aggregate interface and resets the flapping event counter to zero.

3. The resume timer starts as IS-IS starts member port flapping suppression. The suppression duration equals the resume timer.

   If a link failure occurs on a member port during member port flapping suppression, IS-IS restarts the resume timer.

4. After the resume timer expires, IS-IS restores the cost value to the original for the aggregate interface if no link failures occur on member ports before the resume timer expires.

The non-conservative mode functions as follows:

5. After you enable member port flapping suppression on an aggregate interface, the aggregate interface starts a flapping event counter to collect statistics about the flapping events that occur on its member ports. IS-IS increases the number of member port flapping events by one each time a link failure occurs on a member port.

   When a link failure occurs on a member port, IS-IS performs the following tasks:

   a. Record the timestamp of the link failure.

   NOTE:

   For brief description, the following arguments are introduced:

   - The *T* argument represents the timestamp that equals the link failure timestamp minus the detection timer.
   - The *flapping-count* argument represents the number of member port flapping events that occur later than *T* and not later than the link failure timestamp.

   b. Compare *flapping-count* with the threshold that triggers member port flapping suppression:

      - If *flapping-count* is less than the threshold, IS-IS does not suppress member port flapping or reset the flapping event counter.
      - If *flapping-count* is not less than the threshold, IS-IS starts member port flapping suppression. It increases the cost value for the aggregate interface and resets the flapping event counter to zero.

6. The resume timer starts as IS-IS starts member port flapping suppression. The suppression duration equals the resume timer.

If a link failure occurs on a member port during member port flapping suppression, IS-IS restarts the resume timer.

7. After the resume timer expires, IS-IS restores the cost value to the original for the aggregate interface if no link failures occur on member ports before the resume timer expires.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.
   - Enter Layer 3 aggregate interface view.

     interface route-aggregation *interface-number* [**pex**]
   - Enter Layer 3 aggregate subinterface view.

     interface route-aggregation *interface-number.subnumber*

3. Enable member port flapping suppression on the interface and specify the cost adjustment value for the interface.
   - IPv4 IS-IS:

     isis member-port suppress-flapping adjust-cost { *cost-offset* | **max** }

     By default, member port flapping suppression is disabled on an IPv4 IS-IS aggregate interface.
   - IPv6 IS-IS:

     isis ipv6 member-port suppress-flapping adjust-cost { *cost-offset* | **max** }

     By default, member port flapping suppression is disabled on an IPv6 IS-IS aggregate interface.

4. Configure the detection parameters for IS-IS member port flapping suppression.
   - IPv4 IS-IS:

     isis member-port suppress-flapping { [**detect-interval** *detect-interval* | **threshold** *threshold* | **resume-interval** *resume-interval*] * | **non-conservative** }

     By default, the detection timer is 60 seconds, the threshold is 10, and the resume timer is 120 seconds.
   - IPv6 IS-IS:

     isis ipv6 member-port suppress-flapping { [**detect-interval** *detect-interval* | **threshold** *threshold* | **resume-interval** *resume-interval*] * | **non-conservative** }

     By default, the detection timer is 60 seconds, the threshold is 10, and the resume timer is 120 seconds.

Display and maintenance commands for IS-IS

Execute **display** commands in any view and the **reset** command in user view.

Displaying and maintaining IPv4 IS-IS

Task	Command
Display IS-IS process information.	**display isis** [*process-id*]
Display IS-IS GR log information.	**display isis event-log graceful-restart slot** *slot-number*
Display IS-IS log information about received or sent hello packets.	**display isis event-log hello** { **peer-change** | **received-abnormal** | **received-dropped** | **sent-abnormal** | **sent-failed** } [*process-id*]
Display IS-IS LSP log information.	**display isis event-log lsp** { **purged** [**generated** | **received**] | **refreshed** } [**level-1** | **level-2**] [*process-id*] [**from** *time1 date1* [**to** *time2 date2*]]
Display IS-IS NSR log information.	**display isis event-log non-stop-routing slot** *slot-number*
Display neighbor state change log information.	**display isis event-log peer** [*process-id*]
Display log information about route changes in the IP routing table.	**display isis event-log route-record** { **add** | **delete** | **modify** } [**ipv4** | **ipv6**] [**level-1** | **level-2**] [*process-id*] [**verbose**]
Display IPv4 IS-IS route calculation log information.	**display isis event-log spf** [**ipv4**] [[**level-1** | **level-2**] | **verbose**] * [*process-id*]
Display IS-IS LSP update log information.	**display isis event-log updated-lsp** [**history** [**hour-range** *hour-range1* **to** *hour-range2*]] [**system-id** *system-id*] [**level-1** | **level-2**] [*process-id*]
Display the IS-IS GR status.	**display isis graceful-restart status** [**level-1** | **level-2**] [*process-id*]
Display IS-IS interface information.	**display isis interface** [[*interface-type interface-number*] [**verbose**] | **statistics**] [*process-id*]
Display information about hello packets sent by an interface.	**display isis interface** [*interface-type interface-number*] **hello-sent** [*process-id*]
Display IS-IS LSDB information.	**display isis lsdb** [[**level-1** | **level-2**] | **local** | **lsp-id** *lspid* | [**lsp-name** *lspname*] | **verbose**] * [*process-id*]

Clear OSI connection statistics.	**reset osi statistics**

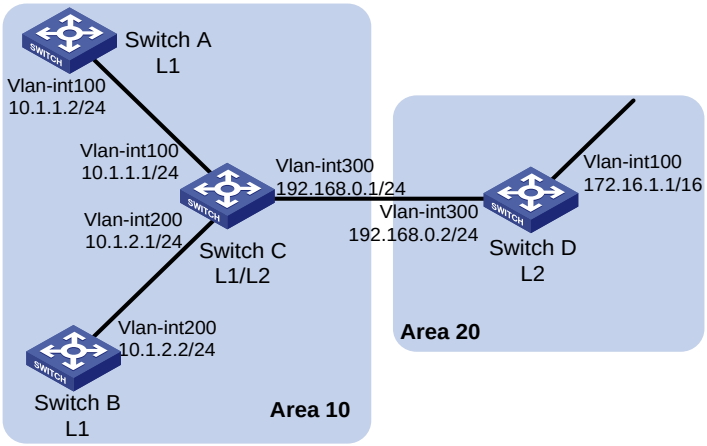
IS-IS configuration examples



Example: Configuring basic IS-IS

Network configuration

As shown in Figure 16, Switch A, Switch B, Switch C, and Switch D reside in an IS-IS AS.

Switch A and B are Level-1 switches, Switch D is a Level-2 switch, and Switch C is a Level-1-2 switch. Switch A, Switch B, and Switch C are in Area 10, and Switch D is in Area 20.

Figure 16 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure IS-IS:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] isis 1
[SwitchA-isis-1] is-level level-1
[SwitchA-isis-1] network-entity 10.0000.0000.0001.00
[SwitchA-isis-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] isis enable 1
[SwitchA-Vlan-interface100] quit
```

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] isis 1
[SwitchB-isis-1] is-level level-1
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] isis enable 1
[SwitchB-Vlan-interface200] quit
```

   # Configure Switch C.

```
<SwitchC> system-view
[SwitchC] isis 1
```

```
[SwitchC-isis-1] network-entity 10.0000.0000.0003.00
[SwitchC-isis-1] quit
[SwitchC] interface vlan-interface 100
[SwitchC-Vlan-interface100] isis enable 1
[SwitchC-Vlan-interface100] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] isis enable 1
[SwitchC-Vlan-interface200] quit
[SwitchC] interface vlan-interface 300
[SwitchC-Vlan-interface300] isis enable 1
[SwitchC-Vlan-interface300] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] isis 1
[SwitchD-isis-1] is-level level-2
[SwitchD-isis-1] network-entity 20.0000.0000.0004.00
[SwitchD-isis-1] quit
[SwitchD] interface vlan-interface 100
[SwitchD-Vlan-interface100] isis enable 1
[SwitchD-Vlan-interface100] quit
[SwitchD] interface vlan-interface 300
[SwitchD-Vlan-interface300] isis enable 1
[SwitchD-Vlan-interface300] quit
```

Verifying the configuration

Display the IS-IS LSDB on each switch to verify the LSPs.

```
[SwitchA] display isis lsdb

[SwitchD] display isis route

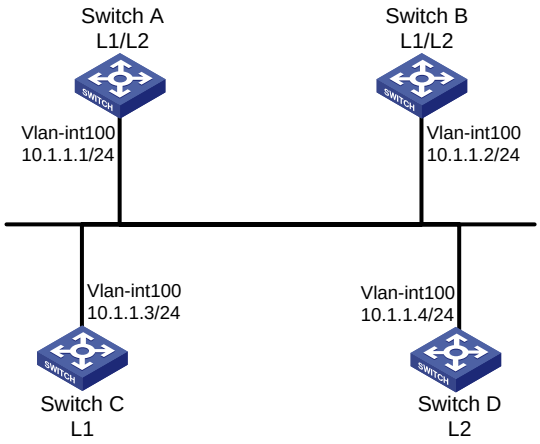
                        Route information for IS-IS(1)
                        ------------------------------

                        Level-2 IPv4 Forwarding Table
                        -----------------------------

 IPv4 Destination     IntCost    ExtCost ExitInterface   NextHop         Flags
-------------------------------------------------------------------------------
 192.168.0.0/24       10         NULL    Vlan300         Direct          D/L/-
 10.1.1.0/24          20         NULL    Vlan300         192.168.0.1     R/-/-
 10.1.2.0/24          20         NULL    Vlan300         192.168.0.1     R/-/-
 172.16.0.0/16        10         NULL    Vlan100         Direct          D/L/-

      Flags: D-Direct, R-Added to Rib, L-Advertised in LSPs, U-Up/Down Bit Set
```

The output shows that the routing table of Level-1 switches contains a default route with the next hop as the Level-1-2 switch. The routing table of Level-2 switch contains both routing information of Level-1 and Level-2.



Example: Configuring DIS election

Network configuration

As shown in Figure 17, Switches A, B, C, and D reside in IS-IS area 10 on a broadcast network (Ethernet). Switch A and Switch B are Level-1-2 switches, Switch C is a Level-1 switch, and Switch D is a Level-2 switch.

Change the DIS priority of Switch A to make it elected as the Level-1-2 DIS router.

Figure 17 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Enable IS-IS:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] isis 1
[SwitchA-isis-1] network-entity 10.0000.0000.0001.00
[SwitchA-isis-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] isis enable 1
[SwitchA-Vlan-interface100] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] isis 1
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] isis enable 1
[SwitchB-Vlan-interface100] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] isis 1
[SwitchC-isis-1] network-entity 10.0000.0000.0003.00
[SwitchC-isis-1] is-level level-1
[SwitchC-isis-1] quit
[SwitchC] interface vlan-interface 100
[SwitchC-Vlan-interface100] isis enable 1
[SwitchC-Vlan-interface100] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] isis 1
[SwitchD-isis-1] network-entity 10.0000.0000.0004.00
[SwitchD-isis-1] is-level level-2
[SwitchD-isis-1] quit
[SwitchD] interface vlan-interface 100
[SwitchD-Vlan-interface100] isis enable 1
[SwitchD-Vlan-interface100] quit
```

Display information about IS-IS neighbors on Switch A.

```
[SwitchA] display isis peer

                      Peer information for IS-IS(1)
                      ------------------------------

 State: Up     HoldTime: 30s       Type: L2          PRI: 64
```

Display information about IS-IS interfaces on Switch A.

```
[SwitchA] display isis interface

                     Interface information for IS-IS(1)
                     ----------------------------------

  Interface:  Vlan-interface100
  Index     IPv4 state      IPv6 state     Circuit ID   MTU   Type   DIS
  00001     Up              Down           1            1497  L1/L2  No/No
```

Display information about IS-IS interfaces on Switch C.

```
[SwitchC] display isis interface

                     Interface information for IS-IS(1)
                     ----------------------------------

  Interface:  Vlan-interface100
  Index     IPv4 state      IPv6 state     Circuit ID   MTU   Type   DIS
  00001     Up              Down           1            1497  L1/L2  Yes/No
```

Display information about IS-IS interfaces on Switch D.

```
[SwitchD] display isis interface

                     Interface information for IS-IS(1)
                     ----------------------------------

  Interface:  Vlan-interface100
  Index     IPv4 state      IPv6 state     Circuit ID   MTU   Type   DIS
  00001     Up              Down           1            1497  L1/L2  No/Yes
```

The output shows that when the default DIS priority is used, Switch C is the DIS for Level-1, and Switch D is the DIS for Level-2. The pseudonodes of Level-1 and Level-2 are 0000.0000.0003.01 and 0000.0000.0004.01.

#Configure the DIS priority of Switch A.

```
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] isis dis-priority 100
[SwitchA-Vlan-interface100] quit
```

Display IS-IS neighbors on Switch A.

```
[SwitchA] display isis peer

                       Peer information for IS-IS(1)
                       ------------------------------

 System ID: 0000.0000.0002
 Interface: Vlan100                Circuit Id: 0000.0000.0001.01
```

```
 State: Up     HoldTime: 21s        Type: L1(L1L2)     PRI: 64

 System ID: 0000.0000.0003
 Interface: Vlan100                 Circuit Id: 0000.0000.0001.01
 State: Up     HoldTime: 27s        Type: L1           PRI: 64

 System ID: 0000.0000.0002

  00001     Up              Down           1            1497  L1/L2  No/No
```

Example: Configuring IS-IS route redistribution

Network configuration

As shown in Figure 18, Switch A, Switch B, Switch C, and Switch D reside in the same AS. They use IS-IS to interconnect. Switch A and Switch B are Level-1 routers, Switch D is a Level-2 router, and Switch C is a Level-1-2 router.

Redistribute RIP routes into IS-IS on Switch D.

Figure 18 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure basic IS-IS:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] isis 1
[SwitchA-isis-1] is-level level-1
[SwitchA-isis-1] network-entity 10.0000.0000.0001.00
```

```
[SwitchA-isis-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] isis enable 1
[SwitchA-Vlan-interface100] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] isis 1
[SwitchB-isis-1] is-level level-1
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] isis enable 1
[SwitchB-Vlan-interface200] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] isis 1
[SwitchC-isis-1] network-entity 10.0000.0000.0003.00
[SwitchC-isis-1] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] isis enable 1
[SwitchC-Vlan-interface200] quit
[SwitchC] interface vlan-interface 100
[SwitchC-Vlan-interface100] isis enable 1
[SwitchC-Vlan-interface100] quit
[SwitchC] interface vlan-interface 300
[SwitchC-Vlan-interface300] isis enable 1
[SwitchC-Vlan-interface300] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] isis 1
[SwitchD-isis-1] is-level level-2
[SwitchD-isis-1] network-entity 20.0000.0000.0004.00
[SwitchD-isis-1] quit
[SwitchD] interface vlan-interface 300
[SwitchD-Vlan-interface300] isis enable 1
[SwitchD-Vlan-interface300] quit
[SwitchD] interface vlan-interface 400
[SwitchD-Vlan-interface400] isis enable 1
[SwitchD-Vlan-interface400] quit
```

Display IS-IS routing information on each switch.

```
[SwitchA] display isis route

                        Route information for IS-IS(1)
                        ------------------------------

-------------------------------------------------------------------------------
 10.1.1.0/24          10         NULL    VLAN100         Direct          D/L/-
 10.1.2.0/24          10         NULL    VLAN200         Direct          D/L/-
 192.168.0.0/24       10         NULL    VLAN300         Direct          D/L/-

      Flags: D-Direct, R-Added to Rib, L-Advertised in LSPs, U-Up/Down Bit Set

                        Level-2 IPv4 Forwarding Table
                        ------------------------------

 IPv4 Destination     IntCost    ExtCost ExitInterface   NextHop         Flags
-------------------------------------------------------------------------------
 10.1.1.0/24          10         NULL                                    D/L/-
 10.1.2.0/24          10         NULL                                    D/L/-
 192.168.0.0/24       10         NULL                                    D/L/-

      Flags: D-Direct, R-Added to Rib, L-Advertised in LSPs, U-Up/Down Bit Set
[SwitchD] display isis route

                        Route information for IS-IS(1)
                        ------------------------------

                        Level-2 IPv4 Forwarding Table
                        ------------------------------

 IPv4 Destination     IntCost    ExtCost ExitInterface   NextHop         Flags
-------------------------------------------------------------------------------
 192.168.0.0/24       10         NULL    VLAN300         Direct          D/L/-
 10.1.1.0/24          20         NULL    VLAN300         192.168.0.1     R/-/-
 10.1.2.0/24          20         NULL    VLAN300         192.168.0.1     R/-/-
```

```
      Flags: D-Direct, R-Added to Rib, L-Advertised in LSPs, U-Up/Down Bit Set
```

3. Run RIPv2 between Switch D and Switch E, and configure IS-IS to redistribute RIP routes on Switch D:

Configure RIPv2 on Switch D.

```
[SwitchD] rip 1
[SwitchD-rip-1] network 10.0.0.0
[SwitchD-rip-1] version 2
[SwitchD-rip-1] undo summary
```

Configure RIPv2 on Switch E.

```
[SwitchE] rip 1

```

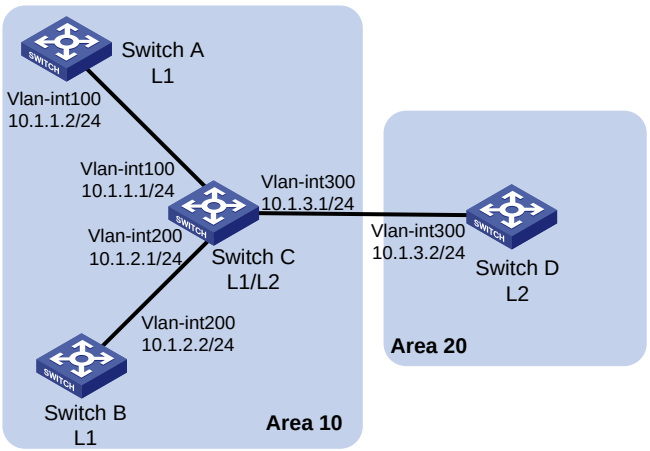
Example: Configuring IS-IS authentication



Network configuration

As shown in Figure 19, Switch A, Switch B, Switch C, and Switch D reside in the same IS-IS routing domain. Run IS-IS among them.

Switch A, Switch B, and Switch C belong to Area 10, and Switch D belongs to Area 20.

- Configure neighbor relationship authentication between neighbors.
- Configure area authentication in Area 10 to prevent untrusted routes from entering into the area.
- Configure routing domain authentication on Switch C and Switch D to prevent untrusted routes from entering the routing domain.

Figure 19 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure basic IS-IS:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] isis 1
[SwitchA-isis-1] network-entity 10.0000.0000.0001.00
[SwitchA-isis-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] isis enable 1
[SwitchA-Vlan-interface100] quit
```

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] isis 1
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] quit
[SwitchB] interface vlan-interface 200
```

```
[SwitchB-Vlan-interface200] isis enable 1
[SwitchB-Vlan-interface200] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] isis 1
[SwitchC-isis-1] network-entity 10.0000.0000.0003.00
[SwitchC-isis-1] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] isis enable 1
[SwitchC-Vlan-interface200] quit
[SwitchC] interface vlan-interface 300
[SwitchC-Vlan-interface300] isis enable 1
[SwitchC-Vlan-interface300] quit
[SwitchC] interface vlan-interface 300
[SwitchC-Vlan-interface300] isis enable 1
[SwitchC-Vlan-interface300] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] isis 1
[SwitchD-isis-1] network-entity 20.0000.0000.0001.00
[SwitchD-isis-1] quit
[SwitchD] interface vlan-interface 300
[SwitchD-Vlan-interface300] isis enable 1
[SwitchD-Vlan-interface300] quit
```

3. Configure neighbor relationship authentication between neighbors:

Set the authentication mode to MD5 and set the plaintext key to **eRq** on VLAN-interface 100 of Switch A and on VLAN-interface 100 of Switch C.

```
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] isis authentication-mode md5 plain eRg
[SwitchA-Vlan-interface100] quit
[SwitchC] interface vlan-interface 100
[SwitchC-Vlan-interface100] isis authentication-mode md5 plain eRg
[SwitchC-Vlan-interface100] quit
```

Set the authentication mode to MD5 and set the plaintext key to **t5Hr** on VLAN-interface 200 of Switch B and on VLAN-interface 200 of Switch C.

```
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] isis authentication-mode md5 plain t5Hr
[SwitchB-Vlan-interface200] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] isis authentication-mode md5 plain t5Hr
[SwitchC-Vlan-interface200] quit
```

Set the authentication mode to MD5 and set the plaintext key to **hSec** on VLAN-interface 300 of Switch D and on VLAN-interface 300 of Switch C.

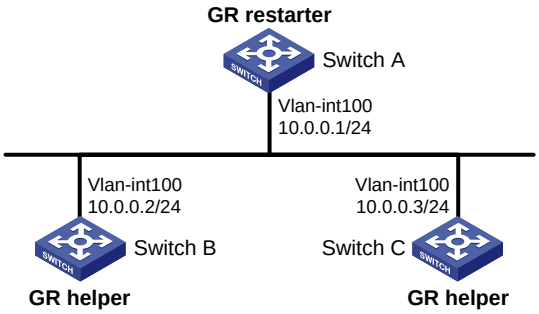
```
[SwitchC] interface vlan-interface 300
[SwitchC-Vlan-interface300] isis authentication-mode md5 plain hSec
[SwitchC-Vlan-interface300] quit
[SwitchD] interface vlan-interface 300
[SwitchD-Vlan-interface300] isis authentication-mode md5 plain hSec
```

```
[SwitchD-Vlan-interface300] quit
```

4. Set the area authentication mode to MD5 and set the plaintext key to **10Sec** on Switch A, Switch B, and Switch C.

```
[SwitchA] isis 1
[SwitchA-isis-1] area-authentication-mode md5 plain 10Sec
[SwitchA-isis-1] quit
[SwitchB] isis 1
[SwitchB-isis-1] area-authentication-mode md5 plain 10Sec
[SwitchB-isis-1] quit
[SwitchC] isis 1
[SwitchC-isis-1] area-authentication-mode md5 plain 10Sec
[SwitchC-isis-1] quit
```

5. Set routing domain authentication mode to MD5 and set the plaintext key to **1020Sec** on Switch C and Switch D.



```
[SwitchC] isis 1
[SwitchC-isis-1] domain-authentication-mode md5 plain 1020Sec
[SwitchC-isis-1] quit
[SwitchD] isis 1
[SwitchD-isis-1] domain-authentication-mode md5 plain 1020Sec
```

Example: Configuring IS-IS GR

Network configuration

As shown in Figure 20, Switch A, Switch B, and Switch C belong to the same IS-IS routing domain.

Figure 20 Network diagram

Procedure

1. Configure IP addresses and subnet masks for interfaces. (Details not shown.)
2. Configure IS-IS on the switches to make sure Switch A, Switch B, and Switch C can communicate with each other at layer 3 and dynamic route update can be implemented among them with IS-IS. (Details not shown.)
3. Enable IS-IS GR on Switch A.

```
<SwitchA> system-view
[SwitchA] isis 1
[SwitchA-isis-1] graceful-restart
[SwitchA-isis-1] quit
[SwitchA] quit
```

Verifying the configuration

Restart the IS-IS process on Switch A.

```
<SwitchA> reset isis all 1 graceful-restart
Reset IS-IS process? [Y/N]:y
```

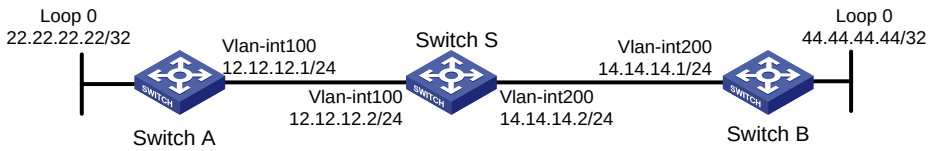
Check the GR state of the IS-IS process on Switch A.

```
<SwitchA> display isis graceful-restart status

                        Restart information for IS-IS(1)
                        --------------------------------
Restart status: COMPLETE
Restart phase: Finish
Restart t1: 3, count 10; Restart t2: 60; Restart t3: 300
SA Bit: supported

                          Level-1 restart information
                          ---------------------------
Total number of interfaces: 1
Number of waiting LSPs: 0

                          Level-2 restart information
                          ---------------------------
Total number of interfaces: 1
Number of waiting LSPs: 0
```



Example: Configuring IS-IS NSR

Network configuration

As shown in Figure 21, Switch S, Switch A, and Switch B belong to the same IS-IS routing domain.

- Run IS-IS on all the switches to interconnect them with each other.
- Enable IS-IS NSR on Switch S to ensure forwarding continuity between Switch A and Switch B when an active/standby switchover occurs on Switch S.

Figure 21 Network diagram

Procedure

1. Configure the IP addresses and subnet masks for interfaces on the switches. (Details not shown.)
2. Configure IS-IS on the switches to make sure Switch S, Switch A, and Switch B can communicate with each other at Layer 3 and dynamic route update can be implemented among them with IS-IS. (Details not shown.)
3. Enable IS-IS NSR on Switch S.

```
<SwitchS> system-view
[SwitchS] isis 1
```

```
[SwitchS-isis-1] non-stop-routing
[SwitchS-isis-1] quit
```

Verifying the configuration

Reoptimize process placement on Switch S to trigger an active/standby switchover.

```
[SwitchS] placement reoptimize
Predicted changes to the placement
Service Group(instance name)                    Cur location  New location
-------------------------------------------------------------------------
rib                                             0/0           0/0
staticroute                                     0/0           0/0
rib6                                            0/0           0/0
staticroute6                                    0/0           0/0
isis                                            0/0           1/0
Continue? [y/n]:y
Re-optimization of the placement start. You will be notified on completion.
Re-optimization of the placement complete. Use 'display placement' to view the new
placement.
```

During the switchover period, display IS-IS neighbor information on Switch A to verify the neighborship between Switch A and Switch S.

```
<SwitchA> display isis peer

                        Peer information for IS-IS(1)
                        ----------------------------

 12.12.12.0/32        10         NULL
 22.22.22.22/32       10         NULL

      Flags: D-Direct, R-Added to Rib, L-Advertised in LSPs, U-Up/Down Bit Set
```

The output shows that the neighbor information and routing information on Switch A and Switch B have not changed during the active/standby switchover on Switch S. The neighbors are unaware of the switchover.

Example: Configuring BFD for IS-IS

Network configuration

- As shown in Figure 22, run IS-IS on Switch A, Switch B and Switch C so that they can reach each other at the network layer.
- After the link over which Switch A and Switch B communicate through the Layer-2 switch fails, BFD can quickly detect the failure and notify IS-IS of the failure. Switch A and Switch B then communicate through Switch C.

Figure 22 Network diagram

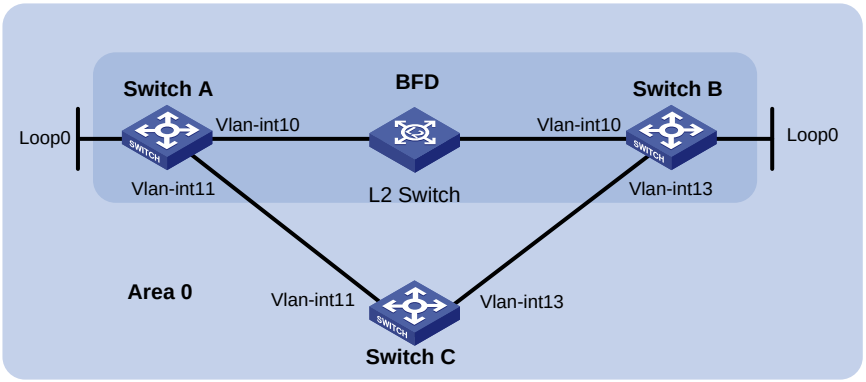

Table 4 Interface and IP address assignment

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int10	10.1.0.102/24	Switch B	Vlan-int10	10.1.0.100/24
	Vlan-int11	11.1.1.1/24		Vlan-int13	13.1.1.1/24
	Loop0	121.1.1.1/32		Loop0	120.1.1.1/32
Switch C	Vlan-int11	11.1.1.2/24			
	Vlan-int13	13.1.1.2/24			

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure basic IS-IS:

   # Configure Switch A.

   ```
   <SwitchA> system-view
   ```

```
[SwitchA] isis
[SwitchA-isis-1] network-entity 10.0000.0000.0001.00
[SwitchA-isis-1] quit
[SwitchA] interface loopback 0
[SwitchA-LoopBack0] isis enable
[SwitchA-LoopBack0] quit
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] isis enable
[SwitchA-Vlan-interface10] quit
[SwitchA] interface vlan-interface 11
[SwitchA-Vlan-interface11] isis enable
[SwitchA-Vlan-interface11] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] isis
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] quit
[SwitchB] interface loopback 0
[SwitchB-LoopBack0] isis enable
[SwitchB-LoopBack0] quit
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] isis enable
[SwitchB-Vlan-interface10] quit
[SwitchB] interface vlan-interface 13
[SwitchB-Vlan-interface13] isis enable
[SwitchB-Vlan-interface13] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] isis
[SwitchC-isis-1] network-entity 10.0000.0000.0003.00
[SwitchC-isis-1] quit
[SwitchC] interface vlan-interface 11
[SwitchC-Vlan-interface11] isis enable
[SwitchC-Vlan-interface11] quit
[SwitchC] interface vlan-interface 13
[SwitchC-Vlan-interface13] isis enable
[SwitchC-Vlan-interface13] quit
```

3. Configure BFD functions:

Enable BFD and configure BFD parameters on Switch A.

```
[SwitchA] bfd session init-mode passive
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] isis bfd enable
[SwitchA-Vlan-interface10] bfd min-receive-interval 500
[SwitchA-Vlan-interface10] bfd min-transmit-interval 500
[SwitchA-Vlan-interface10] bfd detect-multiplier 7
[SwitchA-Vlan-interface10] quit
```

Enable BFD and configure BFD parameters on Switch B.

```
[SwitchB] bfd session init-mode active
```

```
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] isis bfd enable
[SwitchB-Vlan-interface10] bfd min-receive-interval 500
[SwitchB-Vlan-interface10] bfd min-transmit-interval 500
[SwitchB-Vlan-interface10] bfd detect-multiplier 8
[SwitchB-Vlan-interface10] quit
```

Verifying the configuration

Display the BFD session information on Switch A.

```
[SwitchA] display bfd session

 Total sessions: 1     Up sessions: 1     Init mode: Active

 IPv4 session working in control packet mode:

 LD/RD            SourceAddr      DestAddr        State  Holdtime    Interface
 3/1              192.168.0.102   192.168.0.100   Up     1700ms      Vlan10
```

Display routes destined for 120.1.1.1/32 on Switch A.

```
[SwitchA] display ip routing-table 120.1.1.1 verbose

Summary count : 1

Destination: 120.1.1.1/32
   Protocol: IS_L1
 Process ID: 1

   LinkCost: 0               MicroSegID: 0
RealFIRType: Normal           RealThres: 0
```

The output shows that Switch A and Switch B communicate through VLAN-interface 11.

Example: Configuring IS-IS FRR

Network configuration

As shown in Figure 23, Switch A, Switch B, and Switch C belong to the same IS-IS routing domain. Configure IS-IS FRR so that when the Link A fails, traffic can be switched to Link B immediately.

Figure 23 Network diagram

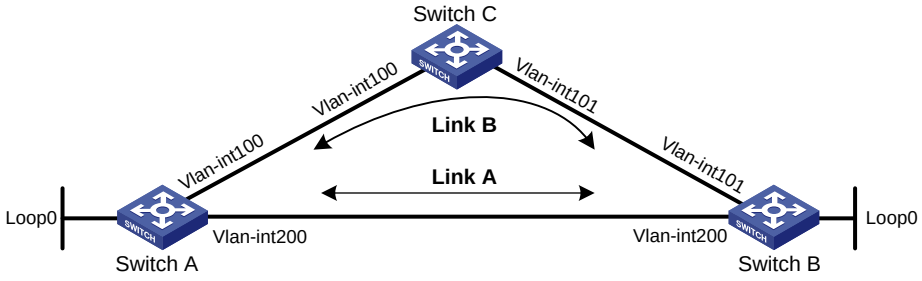

Table 5 Interface and IP address assignment

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int100	12.12.12.1/24	Switch B	Vlan-int101	24.24.24.4/24
	Vlan-int200	13.13.13.1/24		Vlan-int200	13.13.13.2/24

Device	Interface	IP address	Device	Interface	IP address
	Loop0	1.1.1.1/32		Loop0	4.4.4.4/32
Switch C	Vlan-int100	12.12.12.2/24			
	Vlan-int101	24.24.24.2/24			

Procedure

1. Configure IP addresses and subnet masks for interfaces on the switches. (Details not shown.)
2. Configure IS-IS on the switches to make sure Switch A, Switch B, and Switch C can communicate with each other at Layer 3. (Details not shown.)
3. Configure IS-IS FRR:

   Enable IS-IS FRR to calculate a backup next hop through LFA calculation, or designate a backup next hop by using a referenced routing policy.

   - (Method 1.) Enable IS-IS FRR to calculate a backup next hop through LFA calculation:

     # Configure Switch A.

     ```
     <SwitchA> system-view
     [SwitchA] isis 1
     [SwitchA-isis-1] address-family ipv4
     [SwitchA-isis-1-ipv4] fast-reroute lfa
     [SwitchA-isis-1-ipv4] quit
     [SwitchA-isis-1] quit
     ```

     # Configure Switch B.

     ```
     <SwitchB> system-view
     [SwitchB] isis 1
     [SwitchB-isis-1] address-family ipv4
     [SwitchB-isis-1-ipv4] fast-reroute lfa
     [SwitchB-isis-1-ipv4] quit
     [SwitchB-isis-1] quit
     ```

   - (Method 2.) Enable IS-IS FRR to designate a backup next hop by using a referenced routing policy:

     # Configure Switch A.

     ```
     <SwitchA> system-view
     [SwitchA] ip prefix-list abc index 10 permit 4.4.4.4 32
     [SwitchA] route-policy frr permit node 10
     [SwitchA-route-policy-frr-10] if-match ip address prefix-list abc
     [SwitchA-route-policy-frr-10] apply fast-reroute backup-interface vlan-interface
     100 backup-nexthop 12.12.12.2
     [SwitchA-route-policy-frr-10] quit
     [SwitchA] isis 1
     [SwitchA-isis-1] address-family ipv4
     [SwitchA-isis-1-ipv4] fast-reroute route-policy frr
     [SwitchA-isis-1-ipv4] quit
     [SwitchA-isis-1] quit
     ```

     # Configure Switch B.

     ```
     <SwitchB> system-view
     [SwitchB] ip prefix-list abc index 10 permit 1.1.1.1 32
     [SwitchB] route-policy frr permit node 10
     [SwitchB-route-policy-frr-10] if-match ip address prefix-list abc
     ```

```
[SwitchB-route-policy-frr-10] apply fast-reroute backup-interface vlan-interface
101 backup-nexthop 24.24.24.2
[SwitchB-route-policy-frr-10] quit
[SwitchB] isis 1
[SwitchB-isis-1] address-family ipv4
[SwitchB-isis-1-ipv4] fast-reroute route-policy frr
[SwitchB-isis-1-ipv4] quit
[SwitchB-isis-1] quit
```

Verifying the configuration

Display route 4.4.4.4/32 on Switch A to view the backup next hop information.

```
[SwitchA] display ip routing-table 4.4.4.4 verbose

Summary count : 1

Destination: 4.4.4.4/32
   Protocol: IS_L1

RealFIRType: Normal           RealThres: 0
```

Example: Configuring IS-IS multi-instance processes

Network configuration

As shown in Figure 24, the IPv4 and IPv6 costs are different on an interface. Configure IS-IS multi-instance processes to isolate the IPv4 and IPv6 network and avoid IPv6 route calculation errors.

Figure 24 Network diagram

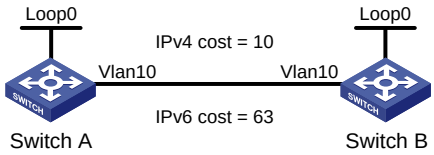

Table 6 Interface and IP address assignment

Device	Interface	IPv4 address	IPv6 address
Switch A	Vlan10	10.1.1.1/24	2001::1/64
	Loop0	1.1.1.1/32	10::1/128
Switch B	Vlan10	10.1.1.2/24	2001::2/64
	Loop0	2.2.2.2/32	20::1/128

Prerequisties

Configure IPv4 and IPv6 addresses for the interfaces. (Details not shown.)

Procedure

1. Configure traditional IPv4 IS-IS processes:

   # Configure Switch A.

   ```
   <SwitchA> system-view
   [SwitchA] isis 1
   [SwitchA-isis-1] network-entity 10.0000.0000.0001.00
   [SwitchA-isis-1] quit
   [SwitchA] interface loopback 0
   ```

```
[SwitchA-LoopBack0] isis enable 1
[SwitchA-LoopBack0] quit
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] isis enable 1
[SwitchA-Vlan-interface10] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] isis 1
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] quit
[SwitchB] interface loopback 0
[SwitchB-LoopBack0] isis enable 1
[SwitchB-LoopBack0] quit
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] isis enable 1
[SwitchB-Vlan-interface10] quit
```

2. Configure IPv6 IS-IS multi-instance processes:

Configure Switch A.

```
[SwitchA] isis 2
[SwitchA-isis-2] network-entity 20.0000.0000.0010.00
[SwitchA-isis-2] multi-instance enable iid 1
[SwitchA-isis-2] address-family ipv6
[SwitchA-isis-2-ipv6] quit
[SwitchA-isis-2] quit
[SwitchA] interface loopback 0
[SwitchA-LoopBack0] isis ipv6 enable 2
[SwitchA-LoopBack0] quit
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] isis ipv6 enable 2
[SwitchA-Vlan-interface10] isis process-id 2 cost 63
[SwitchA-Vlan-interface10] quit
```

Configure Switch B.

```
[SwitchB] isis 2
[SwitchB-isis-2] network-entity 20.0000.0000.0020.00
[SwitchB-isis-2] multi-instance enable iid 1
[SwitchB-isis-2] address-family ipv6
[SwitchB-isis-2-ipv6] quit
[SwitchB-isis-2] quit
[SwitchB] interface loopback 0
[SwitchB-LoopBack0] isis ipv6 enable 2
[SwitchB-LoopBack0] quit
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] isis ipv6 enable 2
[SwitchB-Vlan-interface10] isis process-id 2 cost 63
[SwitchB-Vlan-interface10] quit
```

Verifying the configuration

View information about the IPv4 IS-IS routing table of Switch A.

```
[SwitchA] display isis route ipv4

                        Route information for IS-IS(1)
                        ------------------------------

                        Level-1 IPv4 Forwarding Table
                        ------------------------------

 IPv4 Destination     IntCost    ExtCost ExitInterface   NextHop         Flags
-------------------------------------------------------------------------------
 1.1.1.1/32           0          NULL    Loop0           Direct          D/L/-
 10.1.1.0/24          10         NULL    Vlan10          Direct          D/L/-
 2.2.2.2/32           10         NULL    Vlan10          10.1.1.2        R/L/-

      Flags: D-Direct, R-Added to Rib, L-Advertised in LSPs, U-Up/Down Bit Set

                        Level-2 IPv4 Forwarding Table
                        ------------------------------

 IPv4 Destination     IntCost    ExtCost ExitInterface   NextHop         Flags
-------------------------------------------------------------------------------
 1.1.1.1/32           0          NULL    Loop0           Direct          D/L/-
 10.1.1.0/24          10         NULL    Vlan10          Direct          D/L/-
 2.2.2.2/32           10         NULL

      Flags: D-Direct, R-Added to Rib, L-Advertised in LSPs, U-Up/Down Bit Set
```

The output shows that route calculation results are correct.

View information about the IPv4 IS-IS routing table of Switch B.

```
[SwitchB] display isis route ipv4

                        Route information for IS-IS(1)

 Destination : 10::1                                 PrefixLen: 128
 Flag        : -/-/-                                 Cost     : 63

 Destination : 2001::                                PrefixLen: 64
 Flag        : D/L/-                                 Cost     : 63
 Next hop    : Direct                                Interface: Vlan10

 Destination : 20::1                                 PrefixLen: 128
 Flag        : D/L/-                                 Cost     : 0
 Next hop    : Direct                                Interface: Loop0

      Flags: D-Direct, R-Added to Rib, L-Advertised in LSPs, U-Up/Down Bit Set
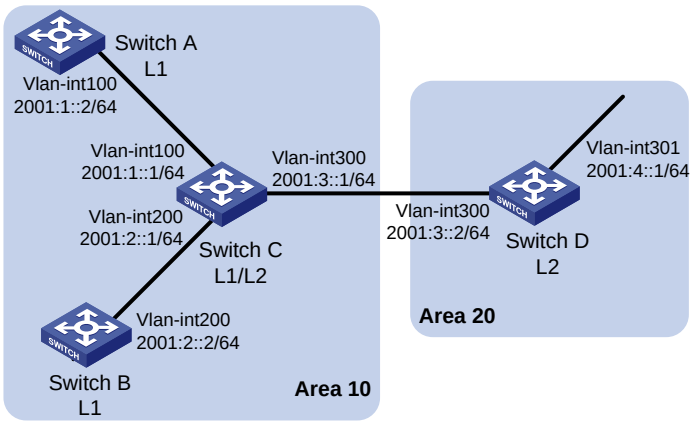
```

The output shows that route calculation results are correct.

IPv6 IS-IS configuration examples



Example: Configuring IPv6 IS-IS basics

Network configuration

As shown in Figure 25, Switch A, Switch B, Switch C, and Switch D, all enabled with IPv6, reside in the same AS. Configure IPv6 IS-IS on the switches so that they can reach each other.

Switch A and Switch B are Level-1 switches, Switch D is a Level-2 switch, and Switch C is a Level-1-2 switch.

Figure 25 Network diagram

Procedure

1. Configure IPv6 addresses for interfaces. (Details not shown.)
2. Configure IPv6 IS-IS:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] isis 1
[SwitchA-isis-1] is-level level-1
[SwitchA-isis-1] network-entity 10.0000.0000.0001.00
[SwitchA-isis-1] address-family ipv6
[SwitchA-isis-1-ipv6] quit
[SwitchA-isis-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] isis ipv6 enable 1
[SwitchA-Vlan-interface100] quit
```

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] isis 1
[SwitchB-isis-1] is-level level-1
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] address-family ipv6
[SwitchB-isis-1-ipv6] quit
[SwitchB-isis-1] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] isis ipv6 enable 1
[SwitchB-Vlan-interface200] quit
```

   # Configure Switch C.

```
<SwitchC> system-view
[SwitchC] isis 1
[SwitchC-isis-1] network-entity 10.0000.0000.0003.00
[SwitchC-isis-1] address-family ipv6
[SwitchC-isis-1-ipv6] quit
[SwitchC-isis-1] quit
```

```
[SwitchC] interface vlan-interface 100
[SwitchC-Vlan-interface100] isis ipv6 enable 1
[SwitchC-Vlan-interface100] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] isis ipv6 enable 1
[SwitchC-Vlan-interface200] quit
[SwitchC] interface vlan-interface 300
[SwitchC-Vlan-interface300] isis ipv6 enable 1
[SwitchC-Vlan-interface300] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] isis 1
[SwitchD-isis-1] is-level level-2
[SwitchD-isis-1] network-entity 20.0000.0000.0004.00
[SwitchD-isis-1] address-family ipv6
[SwitchD-isis-1-ipv6] quit
[SwitchD-isis-1] quit
[SwitchD] interface vlan-interface 300
[SwitchD-Vlan-interface300] isis ipv6 enable 1
[SwitchD-Vlan-interface300] quit
[SwitchD] interface vlan-interface 301
[SwitchD-Vlan-interface301] isis ipv6 enable 1
[SwitchD-Vlan-interface301] quit
```

Verifying the configuration

Display the IPv6 IS-IS routing table on Switch A.

```
[SwitchA] display isis route ipv6

                      Route information for IS-IS(1)
                      ------------------------------

                      Level-1 IPv6 Forwarding Table
                      ------------------------------

 Next Hop    : Direct                                Interface: Vlan300

 Destination : 2001:4::1                             PrefixLen: 64
 Flag        : D/L/-                                 Cost     : 0
 Next Hop    : Direct                                Interface: Loop1
```

```
Flags: D-Direct, R-Added to Rib, L-Advertised in LSPs, U-Up/Down Bit Set
```

Example: Configuring BFD for IPv6 IS-IS

Network configuration

As shown in Figure 26:

- Configure IPv6 IS-IS on Switch A and Switch B so that they can reach other.
- Enable BFD on VLAN-interface 10 of Switch A and Switch B.

After the link between Switch B and the Layer 2 switch fails, BFD can quickly detect the failure and notify IPv6 IS-IS of the failure. Then Switch A and Switch B communicate through Switch C.

Figure 26 Network diagram

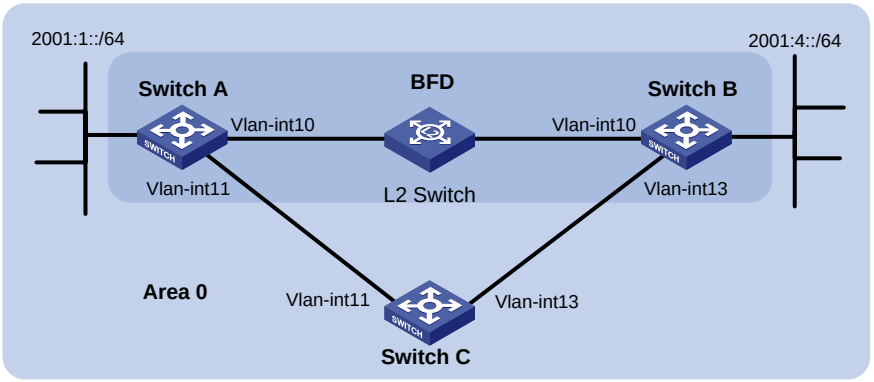

Table 7 Interface and IP address assignment

Device	Interface	IPv6 address	Device	Interface	IPv6 address
Switch A	Vlan-int10	2001::1/64	Switch B	Vlan-int10	2001::2/64
	Vlan-int11	2001:2::1/64		Vlan-int13	2001:3::2/64
Switch C	Vlan-int11	2001:2::2/64			
	Vlan-int13	2001:3::1/64			

Procedure

1. Configure IPv6 addresses for interfaces. (Details not shown.)
2. Configure IPv6 IS-IS:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] isis 1
[SwitchA-isis-1] is-level level-1
[SwitchA-isis-1] network-entity 10.0000.0000.0001.00
[SwitchA-isis-1] address-family ipv6
[SwitchA-isis-1-ipv6] quit
[SwitchA-isis-1] quit
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] isis ipv6 enable 1
[SwitchA-Vlan-interface10] quit
[SwitchA] interface vlan-interface 11
[SwitchA-Vlan-interface11] isis ipv6 enable 1
```

```
[SwitchA-Vlan-interface11] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] isis 1
[SwitchB-isis-1] is-level level-1
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] address-family ipv6
[SwitchB-isis-1-ipv6] quit
[SwitchB-isis-1] quit
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] isis ipv6 enable 1
[SwitchB-Vlan-interface10] quit
[SwitchB] interface vlan-interface 13
[SwitchB-Vlan-interface13] isis ipv6 enable 1
[SwitchB-Vlan-interface13] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] isis 1
[SwitchC-isis-1] network-entity 10.0000.0000.0003.00
[SwitchC-isis-1] address-family ipv6
[SwitchC-isis-1-ipv6] quit
[SwitchC-isis-1] quit
[SwitchC] interface vlan-interface 11
[SwitchC-Vlan-interface11] isis ipv6 enable 1
[SwitchC-Vlan-interface11] quit
[SwitchC] interface vlan-interface 13
[SwitchC-Vlan-interface13] isis ipv6 enable 1
[SwitchC-Vlan-interface13] quit
```

3. Configure BFD functions:

Enable BFD and configure BFD parameters on Switch A.

```
[SwitchA] bfd session init-mode active
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] isis ipv6 bfd enable
[SwitchA-Vlan-interface10] bfd min-transmit-interval 500
[SwitchA-Vlan-interface10] bfd min-receive-interval 500
[SwitchA-Vlan-interface10] bfd detect-multiplier 7
[SwitchA-Vlan-interface10] quit
```

Enable BFD and configure BFD parameters on Switch B.

```
[SwitchB] bfd session init-mode active
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] isis ipv6 bfd enable
[SwitchB-Vlan-interface10] bfd min-transmit-interval 500
[SwitchB-Vlan-interface10] bfd min-receive-interval 500
[SwitchB-Vlan-interface10] bfd detect-multiplier 6
[SwitchB-Vlan-interface10] quit
```

Verifying the configuration

Display BFD session information on Switch A.

```
[SwitchA] display bfd session

 Total sessions: 1     Up sessions: 1     Init mode: Active

 IPv6 session working in control packet mode:

          Local discr: 1441                       Remote discr: 1450
            Source IP: FE80::20F:FF:FE00:1202 (link-local address of Vlan-interface10 on
Switch A)
       Destination IP: FE80::20F:FF:FE00:1200 (link-local address of Vlan-interface10 on
Switch B)
        Session state: Up                            Interface: Vlan10
            Hold time: 2319ms
```

Display routes destined for 2001:4::0/64 on Switch A.

```
[SwitchA] display ipv6 routing-table 2001:4::0 64

Summary count : 1

Destination: 2001:4::/64                                Protocol  : IS_L1
NextHop    : FE80::20F:FF:FE00:1200                     Preference: 15
Interface  : Vlan10                                     Cost      : 10
```

The output shows that Switch A and Switch B communicate through VLAN-interface 10. Then the link over VLAN-interface 10 fails.

Display routes destined for 2001:4::0/64 on Switch A.

```
[SwitchA] display ipv6 routing-table 2001:4::0 64

Summary count : 1

Destination: 2001:4::/64                                Protocol  : IS_L1
NextHop    : FE80::BAAF:67FF:FE27:DCD0                  Preference: 15
Interface  : Vlan11                                     Cost      : 20
```

The output shows that Switch A and Switch B communicate through VLAN-interface 11.

Example: Configuring IPv6 IS-IS FRR

Network configuration

As shown in Figure 27, Switch A, Switch B, and Switch C belong to the same IS-IS routing domain. Configure IPv6 IS-IS FRR so that when the Link A fails, traffic can be switched to Link B immediately.

Figure 27 Network diagram

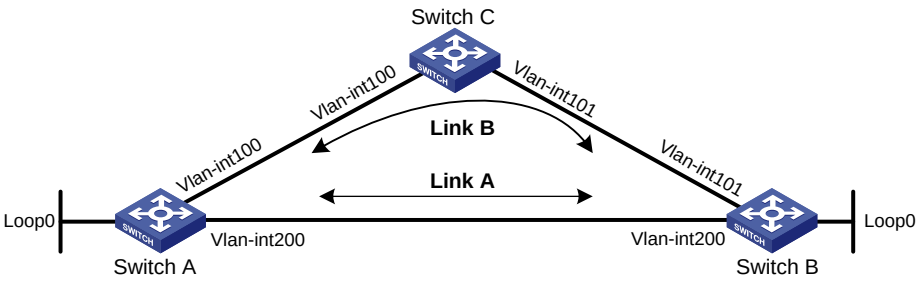

Table 8 Interface and IP address assignment

Device	Interface	IPv6 address	Device	Interface	IPv6 address
Switch A	Vlan-int100	1::1/64	Switch B	Vlan-int101	3::1/64
	Vlan-int200	2::1/64		Vlan-int200	2::2/64
	Loop0	10::1/128		Loop0	20::1/128
Switch C	Vlan-int100	1::2/64			
	Vlan-int101	3::2/64			

Procedure

1. Configure IPv6 addresses for interfaces on the switches. (Details not shown.)
2. Configure IPv6 IS-IS:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] isis 1
[SwitchA-isis-1] is-level level-1
[SwitchA-isis-1] network-entity 10.0000.0000.0001.00
[SwitchA-isis-1] address-family ipv6
[SwitchA-isis-1-ipv6] quit
[SwitchA-isis-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] isis ipv6 enable 1
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 200
[SwitchA-Vlan-interface200] isis ipv6 enable 1
[SwitchA-Vlan-interface200] quit
[SwitchA] interface loopback 0
[SwitchA-LoopBack0] isis ipv6 enable 1
[SwitchA-LoopBack0] quit
```

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] isis 1
[SwitchB-isis-1] is-level level-1
[SwitchB-isis-1] network-entity 10.0000.0000.0002.00
[SwitchB-isis-1] address-family ipv6
[SwitchB-isis-1-ipv6] quit
[SwitchB-isis-1] quit
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] isis ipv6 enable 1
[SwitchB-Vlan-interface101] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] isis ipv6 enable 1
[SwitchB-Vlan-interface200] quit
[SwitchB] interface loopback 0
[SwitchB-LoopBack0] isis ipv6 enable 1
[SwitchB-LoopBack0] quit
```

3. Configure IPv6 IS-IS FRR:

Enable IPv6 IS-IS FRR to calculate a backup next hop through LFA calculation, or designate a backup next hop by using a routing policy.

- (Method 1.) Enable IPv6 IS-IS FRR to calculate a backup next hop through LFA calculation:

  # Configure Switch A.

  ```
  [SwitchA] isis 1
  [SwitchA-isis-1] address-family ipv6
  [SwitchA-isis-1-ipv6] fast-reroute lfa
  [SwitchA-isis-1-ipv6] quit
  [SwitchA-isis-1] quit
  ```

  # Configure Switch B.

  ```
  [SwitchB] isis 1
  [SwitchB-isis-1] address-family ipv6
  [SwitchB-isis-1-ipv6] fast-reroute lfa
  [SwitchB-isis-1-ipv6] quit
  [SwitchB-isis-1] quit
  ```

- (Method 2.) Enable IPv6 IS-IS FRR to designate a backup next hop by using a routing policy:

  # Configure Switch A.

  ```
  [SwitchA] ipv6 prefix-list abc index 10 permit 20::1 128
  [SwitchA] route-policy frr permit node 10
  [SwitchA-route-policy-frr-10] if-match ipv6 address prefix-list abc
  [SwitchA-route-policy-frr-10] apply ipv6 fast-reroute backup-interface
  vlan-interface 100 backup-nexthop fe80::6eab:8bff:fed4:205
  [SwitchA-route-policy-frr-10] quit
  [SwitchA] isis 1
  [SwitchA-isis-1] address-family ipv6
  [SwitchA-isis-1-ipv6] fast-reroute route-policy frr
  [SwitchA-isis-1-ipv6] quit
  [SwitchA-isis-1] quit
  ```

  # Configure Switch B.

  ```
  [SwitchB] ipv6 prefix-list abc index 10 permit 10::1 128
  [SwitchB] route-policy frr permit node 10
  [SwitchB-route-policy-frr-10] if-match ipv6 address prefix-list abc
  [SwitchB-route-policy-frr-10] apply ipv6 fast-reroute backup-interface
  vlan-interface 101 backup-nexthop fe80::6eab:8bff:fed4:206
  [SwitchB-route-policy-frr-10] quit
  [SwitchB] isis 1
  [SwitchB-isis-1] address-family ipv6
  [SwitchB-isis-1-ipv6] fast-reroute route-policy frr
  [SwitchB-isis-1-ipv6] quit
  [SwitchB-isis-1] quit
  ```

Verifying the configuration

Display route 20::1/128 on Switch A to view the backup next hop information.

```
[SwitchA] display ipv6 routing-table 20::1 128 verbose

Summary count : 1

Destination: 20::1/128
```

```

BGP overview

Border Gateway Protocol (BGP) is an exterior gateway protocol (EGP). It is called internal BGP (IBGP) when it runs within an AS and called external BGP (EBGP) when it runs between ASs.

BGP characteristics

BGP has the following characteristics:

- Focuses on route control and selection rather than route discovery and calculation. In addition, it provides rich routing policies, allowing flexible route filtering and selection.
- Uses TCP (port number 179) to enhance reliability. This is because BGP needs to handle a large volume of routing information to implement inter-AS route advertisement and selection. Devices can exchange routing information even if they are not directly connected.
- Has good scalability and can adapt to network developments. An increasing number of new technologies use BGP as their control plane protocol for information transmission.
- Measures the distance of a route by using a list of ASs that the route must travel through to reach the destination. BGP is also called a path-vector protocol.
- Supports CIDR.
- Reduces bandwidth consumption by advertising only incremental updates. BGP is very suitable to advertise large numbers of routes on the Internet.
- Eliminates routing loops by adding AS path information to BGP route updates. A device discards a route when it finds that the route contains the local AS number.

BGP application scenarios

BGP helps an increasing number of emerging technologies establish information pathways. It inserts information of the control plane into BGP routes and transmits the information across networks. BGP is used in the following scenarios:

- The control plane is deployed with BGP and works in conjunction with forwarding-plane technologies to carry services.
  - Scenarios where different users need to unicast packets to each other across ASs in the public network.
  - Scenarios where unicast routing information used for RPF checks and multicast topology setup requires cross-AS advertisement.
  - Scenarios where BGP and MPLS must work together to implement BGP MPLS L3VPN or L2VPN:
    - VPN routing information needs to be transmitted over the public network.
    - Label block information needs to be transmitted.
- The implementation of new features requires BGP extensions:
  - Scenarios where devices need to transmit IPSG bindings.
  - Scenarios where inter-AS paths require SIDs to support SR cross-domain forwarding. These scenarios are based on BGP Egress Peer Engineering (BGP-EPE). For more information about BGP-EPE, see SR-MPLS configuration or SRv6 configuration in *Segment Routing Configuration Guide*.

BGP speaker and BGP peer

A router running BGP is a BGP speaker. A BGP speaker establishes peer relationships with other BGP speakers to exchange routing information over TCP connections.

Based on the AS, a BGP peer can be either of the following types:

- **IBGP peer**—Resides in the same AS as the local router.
- **EBGP peer**—Resides in different ASs from the local router.

Based on the IP version, a BGP peer can be either of the following types:

- **IPv4 peer**—Uses an IPv4 address to establish a peer relationship with the local router.
- **IPv6 peer**—Uses an IPv6 address to establish a peer relationship with the local router.

BGP message types

BGP uses the following message types:

- **OPEN**—After establishing a TCP connection, BGP sends an OPEN message to establish a session to the peer.
- **UPDATE**—BGP sends UPDATE messages to exchange routing information between peers. Each UPDATE message can advertise a group of routes with reachable next hops and identical attributes. An UPDATE message can also contain multiple withdrawn routes. You can identify those routes by their destination addresses in the Network Layer Reachability Information (NLRI) of that update message.
- **KEEPALIVE**—BGP sends KEEPALIVE messages between peers to maintain connectivity.
- **ROUTE-REFRESH**—BGP sends a ROUTE-REFRESH message to request the routing information for a specific address family from a peer. The local device might send a ROUTE-REFRESH message to a peer if both of them are enabled with the ROUTE-REFRESH capability. When the BGP route reception policy changes, the local device sends a ROUTE-REFRESH message to its peers. On receipt of that message, a peer sends its route information to the local device, so the local device can update BGP routes and apply the new reception policy to them.
- **NOTIFICATION**—BGP sends a NOTIFICATION message upon detecting an error and immediately closes the connection.

BGP message formats

A BGP message consists of message header and message content. The five BGP messages have the same message header, but the content of each message differs.

BGP message header

The format of the BGP message header is as shown in Figure 1. For more information about fields in the BGP message header, see Table 1.

Figure 1 BGP message header

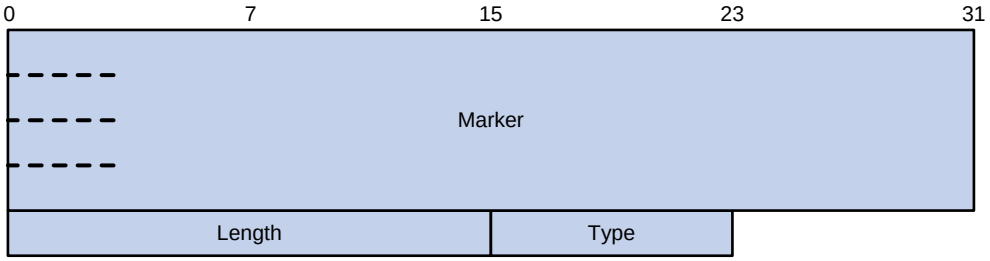

Table 1 Fields in the BGP message header

Field	Length (in bytes)	Description
Marker	16	Synchronization state of the BGP connection. If the value of this field is not a hexadecimal string that contains only Fs, the BGP connection has a synchronization error.
Length	2	Total length of the BGP message, including the message header. The length range is 19 to 4096 bytes.
Type	1	BGP message type: • **1**—OPEN • **2**—UPDATE • **3**—NOTIFICATION • **4**—KEEPALIVE • **5**—ROUTE-REFRESH

OPEN message

OPEN messages are used for BGP connection establishment and BGP capability negotiation. The format of OPEN messages is as shown in Figure 2. For more information about fields in an OPEN message, see Table 2.

Figure 2 OPEN message

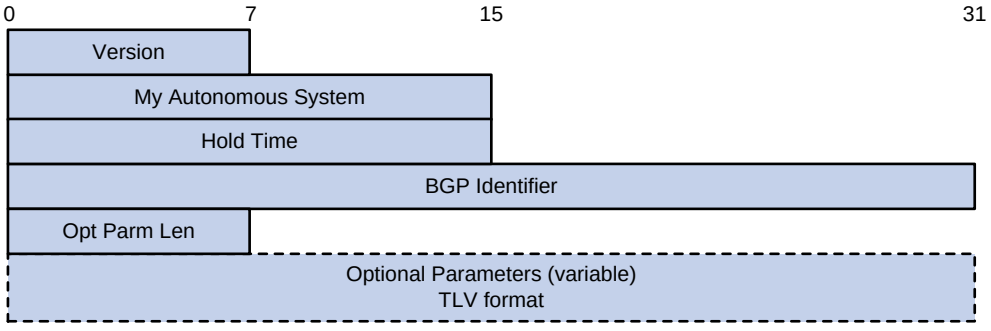

Table 2 Fields in an OPEN message

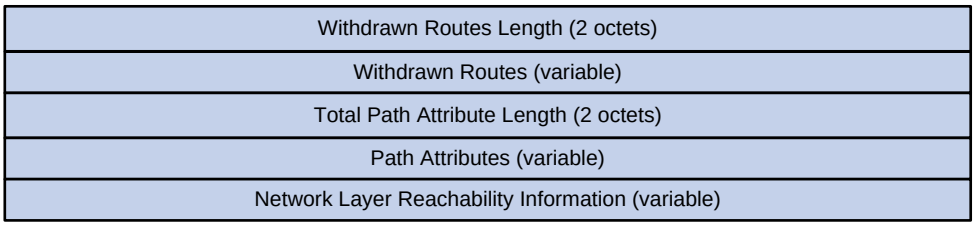
Field	Length (in bytes)	Description
Version	1	BGP version number.
My Autonomous System	2	AS number of the message sender.

Hold Time	2	Hold timer set for the message sender, in seconds. This timer is for peer connection maintenance purposes, and specifies the interval for sending KEEPALIVE or UPDATE messages. After both parties in a BGP session receive the hold timer set for the other, they use the smaller timer.
BGP Identifier	4	Router ID of the message sender.
Opt Parm Len	1	Total length of the **Optional Parameters** field, in bytes. A value of 0 indicates that they message does not contain optional parameters.
Option Parameters	Variable	Optional parameters, each of which is a unit in TLV format. They are typically used to list the capabilities that the message sender can negotiate. For more information about the capabilities supported by the device, see "Tuning and optimizing BGP networks."

UPDATE message

UPDATE messages are used for route advertisement. The format of UPDATE messages is as shown in Figure 3. For more information about fields in an UPDATE message, see Table 3.

Figure 3 UPDATE message



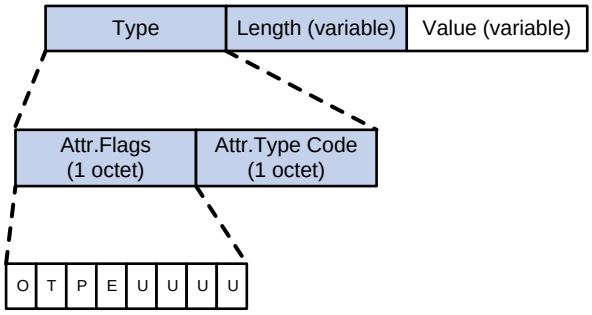


Table 3 Fields in an UPDATE message

Field	Length (in bytes)	Description
Withdrawn Routes Length	2	Total length of the **Withdrawn Routes** field, in bytes. A value of 0 indicates that the message does not contain routes being withdrawn.
Withdrawn Routes	Variable	List of routes being withdrawn. Each route is represented in Length/Prefix format: • **Length**—Length of the IP address prefix. This portion is one byte long. • **Prefix**—IP address prefix of the route. This portion is variable.
Total Path Attribute Length	2	Total length of the **Path Attributes** field, in bytes.
Path Attributes	Variable	List of path attributes carried by routes in the message. Those attributes are listed in ascending order of their type numbers and each of them is encoded in TLV format.

		 The **Type** field indicates the type of a route attribute. It is two bytes long and consists of the **Attr.Flag** and **Attr.Type Code** subfields. • **Attr.Flag**: Type flags of the route attribute: ○ **O**—Indicates whether the route attribute is a well-known attribute. If the route attribute is well-known, this flag is set to 0. If the route attribute is optional, this flag is set to 1. ○ **T**—Indicates whether the route attribute is a transitive attribute. If the route attribute is transitive, this flag is set to 1. If not, this flag is set to 0. ○ **P**—Indicates whether the route attribute is partially effective. If a route attribute has this flag set to 1, it takes effect only within the same AS and will not be transmitted to other ASs. This flag is set to 1 only if the route attribute is an optional transitive attribute and is partially effective . ○ **E**—Indicates whether the **Length** field of the route attribute needs to be extended. If field extension is required, this flag is set to 1, and the **Length** field occupies two bytes. If field extension is not required, this flag is not set, and the **Length** field occupies only one byte. ○ **U**—This flag is reserved and thus set to 0. • **Attr.Type Code**: Type code of the route attribute, which indicates the type of the route attribute. ○ **1**—ORIGIN ○ **2**—AS_PATH ○ **3**—NEXT_HOP ○ **4**—MED ○ **5**—LOCAL_PREF ○ **6**—ATOMIC_AGGREGATE ○ **7**—AGGREGATOR ○ **8**—COMMUNITY ○ **9**—ORIGINATOR_ID ○ **10**—CLUSTER_LIST ○ **14**—MP_REACH_NLRI ○ **15**—MP_UNREACH_NLRI ○ **16**—EXT-COMMUNITY The **Length** field indicates the length of the route attribute, in bytes. The **Value** field indicates the content of the route attribute.
Network Layer Reachability Information (NLRI)	Variable	List of routes to be updated. Each route is represented in Length/Prefix format: • **Length**—Length of the IP address prefix. This portion is one byte long. • **Prefix**—IP address prefix of the route. This portion is

		variable.

NOTIFICATION message

NOTIFICATION messages are used to notify BGP session errors. The format of NOTIFICATION messages is as shown in Figure 4. For more information about fields in a NOTIFICATION message, see Table 4.

Figure 4 NOTIFICATION message

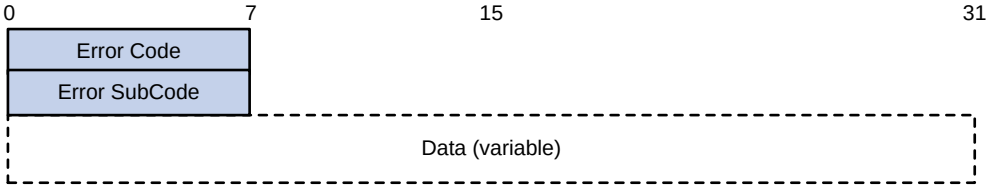

Table 4 Fields in a NOTIFICATION message

Field	Length (in bytes)	Description
Error Code	1	Error code.
Error SubCode	1	Error subcode.
Data	Variable	Detailed error information.

Table 5 introduces supported error codes and subcodes.

Table 5 Error codes and subcodes

Error code/subcode	Reason for peer disconnection	Description
1/1	connection not synchronized	The two ends of the connection were not synchronized. The current implementation is that the first 16 bytes of the received message's header do not contain only Fs.
1/2	bad message length	Invalid message length.
1/3	bad message type	Invalid message type.
3/1	the withdrawn length is too large	The length of routing information to be withdrawn was too long.
	the attribute length is too large	The attribute length was too long.
	one attribute appears more than once	A path attribute appeared multiple times in an UPDATE message.
	the attribute length is too small	The attribute length was less than two bytes.
	exntended length field is less than two octets	The attribute length was extensible, but it was less than two bytes.
	the length field is less than one octet	The attribute length was not extensible, but it was less than one byte.
	link-state attribute error	The link-state attribute was in incorrect form.
3/2	unrecognized well-known attribute	Unknown well-known attribute.

3/3	*attribute-type* attribute missed	The *attribute-type* attribute was lost. The values for the *attribute-type* argument include: • ORIGIN • AS_PATH • LOCAL_PREF • NEXT_HOP
3/4	attribute flags error	Incorrect attribute flags.
3/5	*attribute-type* attribute length error	The length of the *attribute-type* attribute was invalid. The values for the *attribute-type* argument include: • AS_PATH • AS4_PATH • CLUSTER_LIST • AGGREGATOR • AS4_AGGREGATOR • ORIGIN • NEXT_HOP • MED • LOCAL_PREF • ATOMIC_AGGREGATE • ORIGINATOR_ID • MP_REACH_NLRI • COMMUNITIES • EXT-COMMUNITIES
	attribute length exceeds	The attribute length crossed the limit.
3/6	invalid ORIGIN attribute	Invalid ORIGIN attribute.
3/8	invalid NEXT_HOP attribute	Invalid NEXT_HOP attribute.
3/9	invalid nexthop length in MP_REACH_NLRI (*address-family*)	The **Nexthop** length in the MP_REACH_NLRI attribute was invalid for the *address-family* address family. The values for the *address-family* argument include: • **4u**—IPv4 unicast address family. • **MPLS**—MPLS address family. • **VPNv4**—VPNv4 address family. • **6u**—IPv6 unicast address family. • **VPNv6**—VPNv6 address family. • **L2VPN**—L2VPN address family.
	the length of MP_UNREACH_NLRI is too small	The MP_UNREACH_NLRI attribute was shorter than three bytes.
	the MP NLRI attribute length exceeds	The length of the MP_REACH_NLRI or MP_UNREACH_NLRI attribute crossed the limit.
	erroneous MP NLRI attribute end position	The reachable or unreachable prefix and the path attribute ended at different positions.
3/10	invalid network field	Invalid network field.
3/11	malformed AS_PATH	The AS_PATH attribute was malformed.
4/0	Keepalive last triggered time	Most recent time when KEEPALIVE message

		sending was triggered.
	Keepalive last sent time	Most recent time when a KEEPALIVE message was sent.
	Update last sent time	Most recent time when an UPDATE message was sent.
	EPOLLOUT last occurred time	Most recent time when an EPOLLOUT event occurred.
	Keepalive last received time	Most recent time when a KEEPALIVE message was received.
	Update last received time	Most recent time when an UPDATE message was received.
	EPOLLIN last occurred time	Most recent time when an EPOLLIN event occurred.
5/0	connection retry timer expires	The ConnectRetry timer expired.
	TCP_CR_Acked event received	A TCP_CR_Acked event was received.
	TCP_Connection_Confirmed event received	A TCP_Connection_Confirmed event was received.
5/3	open message received	An OPEN message was received.
6/0	manualstop event received	A manualstop event was received.
	physical interface configuration changed	Physical configurations changed, such as interface settings.
	session down event received from BFD	A BFD session down event was received.
6/1	maximum number of prefixes reached	The number of route prefixes has exceeded the upper limit specified by using the **peer route-limit** command.
	maximum number of *address-family* prefixes reached	The number of route prefixes in the *address-family* address family has exceeded the upper limit specified by using the **peer route-limit** command. The values for the *address-family* argument include: • **IPv4 unicast**—IPv4 unicast address family. • **IPv6 unicast**—IPv6 unicast address family. • **VPNv4**—VPNv4 address family. • **VPNv6**—VPNv6 address family.
6/2	configuration of peer ignore changed	The **peer ignore** command was configured.
6/3	address family deleted	An address family was deleted.
	peer disabled	A peer was disabled.
6/4	administrative reset	The BGP session was reset because of the **reset bgp** command or configuration changes.
6/5	connection rejected	The connection request was rejected.
6/6	other configuration change	Other configurations changed.

6/7	connection collision resolution	A connection conflict occurred.
	two connections exist and MD5 authentication is configured for the neighbor	Two connections existed and MD5 authentication was configured for one of them.
6/8	no memory to process the attribute	The memory was insufficient for attribute parsing.
	no memory for the route	Failed to obtain memory resources for route or label block generation.
	no memory to generate unreachable NLRI	Failed to obtain memory resources for MP_UNREACH_NLRI encapsulation.
	no memory to generate a message	Failed to obtain memory resources for message encapsulation.
	can't get the VPN RD	Failed to obtain RDs upon prefix parsing.
	can't get the VPN routing table	Failed to obtain the VPN routing table upon prefix parsing.
	can't get the attributes	Failed to obtain attributes upon prefix parsing.
	entered severe memory state	A severe memory usage alarm was triggered.
	entered critical memory state	A critical memory usage alarm was triggered.

KEEPALIVE message

KEEPALIVE messages are transmitted between BGP peers to maintain connectivity. The format of KEEPALIVE messages is as shown in Figure 5. For more information about fields in a KEEPALIVE message, see Table 6.

Figure 5 KEEPALIVE message

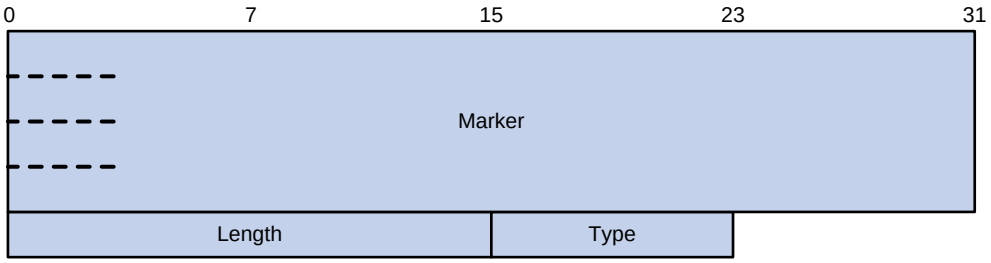

Table 6 Fields in a KEEPALIVE message

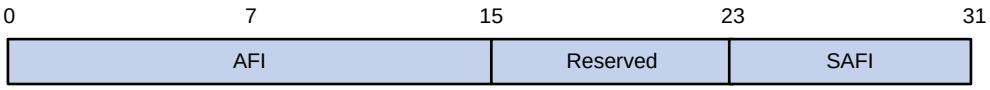
Field	Length (in bytes)	Description
Marker	16	This field indicates the completeness of information synchronization between BGP peers, and can be used for BGP authentication. When BGP authentication is not configured, the value for this field is a hexadecimal string that contains only Fs.
Length	2	Total length of the KEEPALIVE message, in bytes.
Type	1	BGP message type. The type value is 4 for KEEPALIVE messages.

ROUTE-REFRESH message

BGP sends a ROUTE-REFRESH message to request the routing information of a specific address family from a peer. On receipt of the message, the peer re-advertises routes in the specified address family. The format of ROUTE-REFRESH messages is as shown in Figure 6. For more information about fields in a ROUTE-REFRESH message, see Table 7.

Figure 6 ROUTE-REFRESH message



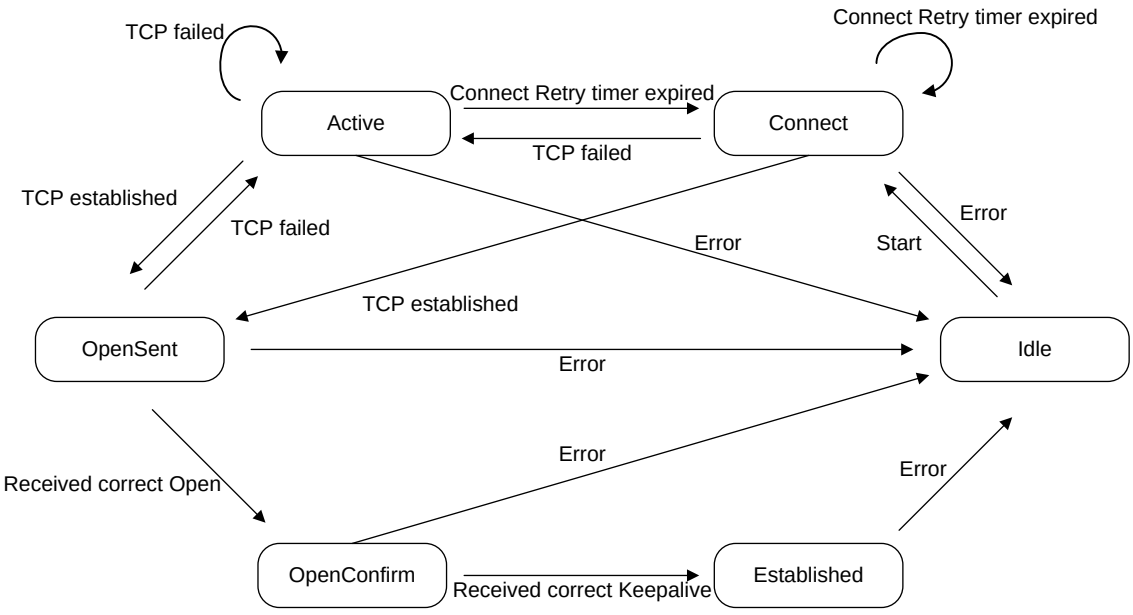


Table 7 Fields in a ROUTE-REFRESH message

Field	Length (in bytes)	Description
AFI	2	Identifier of the address family.
Reserved	1	Reserved field.
SAFI	1	Identifier of the subsequent address family.

BGP finite state machine

During session establishment, the devices at the two ends transition between different BGP states, as shown in Figure 7.

Figure 7 BGP finite state machine

Idle

The idle state is the initial BGP state. In this state, BGP rejects any connection requests. Only upon receiving a Start event, the device assigns resources to BGP, attempts to establish a TCP connection, and transitions to Connect state.

BGP transitions to Idle state from the remaining states upon a TCP disconnection error, packet error, connection closed due to configuration issues, and reception of a NOTIFICATION message.

Connect

In this state, BGP starts a Connect Retry timer and waits for TCP connection establishment to be completed.

- If TCP connection establishment succeeds before the Connect Retry timer expires, BGP closes the Connect Retry timer, sends an OPEN message to the peer, and transitions to OpenSent state.
- If TCP connection establishment fails before the Connect Retry timer expires, BGP transitions to Active state.
- If the Connect Retry timer expires, and no connection response is received, BGP resets the Connect Retry timer, tries to establish a TCP connection with the peer again, and stays in Connect state.

Active

In this state, BGP continuously attempts to establish a TCP connection.

- If TCP connection establishment succeeds, BGP closes the Connect Retry timer, sends an OPEN message to the peer, and transitions to OpenSent state.
- If TCP connection establishment fails, BGP resets the Connect Retry timer and stays in Active state.
- If the Connect Retry timer expires and no connection response is received, BGP resets the Connect Retry timer and transitions to Connect state.

OpenSent

In this state, BGP waits for an OPEN message from the peer, and checks the BGP version number and AS number in the OPEN message.

- If the OPEN message is correct, BGP sends a KEEPALIVE message to the peer, and transitions to OpenConfirm state.
- If the OPEN message is incorrect, BGP sends a NOTIFICATION message to the peer, and transitions to Idle state.

If the TCP connection is disconnected in this state, BGP resets the Connect Retry timer, transitions to Active state, and tries to establish a TCP connection again.

OpenConfirm

In this state, BGP waits for a KEEPALIVE or NOTIFICATION message.

- Upon receiving a KEEPALIVE message, BGP transitions to Established state.
- Upon receiving a NOTIFICATION message, BGP transitions to Idle state.

Established

In this state, BGP can exchange UPDATE, KEEPALIVE, ROUTE-REFRESH, and NOTIFICATION messages with the peer.

- Upon receiving a correct UPDATE or KEEPALIVE message, BGP stays in Established state.
- Upon receiving an incorrect UPDATE or KEEPALIVE message, BGP sends a NOTIFICATION message to the peer and transitions to Idle state.
- Upon receiving a ROUTE-REFRESH message, BGP does not change its state.
- Upon receiving a NOTIFICATION message, BGP transitions to Idle state.

BGP path attributes

BGP path attributes are a set of parameters that are advertised along with routes. They provide further description of specific routes, enabling the route receiver to filter and select routes.

BGP uses a group of path attributes in UPDATE messages for route filtering and selection.

Categories of BGP path attributes

BGP path attributes are categorized as follows:

- **Well-known mandatory**—Attributes that all BGP devices must recognize and UPDATE messages must contain. UPDATE messages lacking these attributes are invalid.
- **Well-known discretionary**—Attributes that all BGP devices must recognize, but UPDATE messages do not need to contain.
- **Optional transitive**—Attributes that BGP devices might not be able to recognize, but can receive and advertise to other BGP devices.
- **Optional non-transitive**—If a BGP device does not support these attributes, the device will ignore them in UPDATE messages and will not forward them to other peers.

ORIGIN

ORIGIN is a well-known mandatory attribute that specifies the origin of BGP routes. This attribute has the following types:

- **IGP**—Has the highest priority. Routes generated in the local AS have the IGP attribute.
- **EGP**—Has the second highest priority. Routes obtained through EGP have the EGP attribute.
- **INCOMPLETE**—Has the lowest priority. The source of routes with this attribute is unknown. Routes redistributed from other routing protocols have the INCOMPLETE attribute.

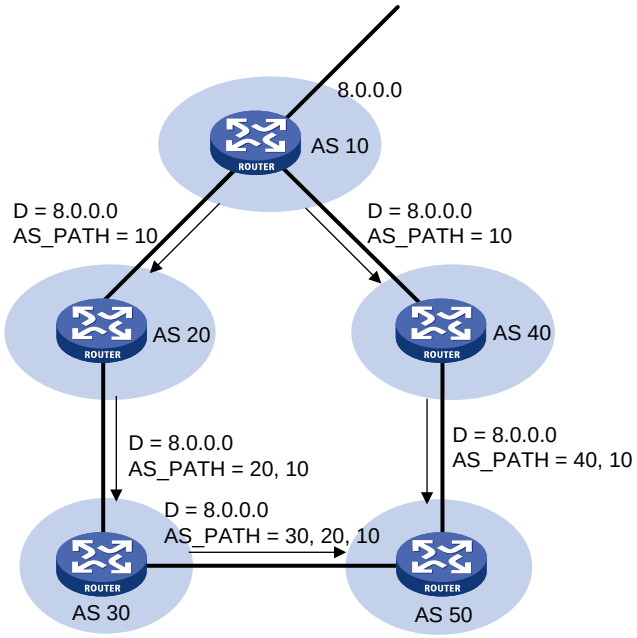
AS_PATH

AS_PATH is a well-known mandatory attribute that records the ASs a route must pass through from the local network to the destination address.The route receiver can then determine the ASs required to route traffic to the destination address based on the AS_PATH attribute.

When a BGP device advertises local routes, it processes them as follows:

- Before advertising routes to EBGP peers, it appends the local AS number to the end of each route's AS_PATH list.
- When it advertises routes to IBGP peers, it does not add any AS number to the AS_PATH list of each route. The AS_PATH list of each advertised route is empty.

When a BGP device forwards routes, it processes them as follows:



- Before forwarding routes to EBGP peers, it appends the local AS number to the head of each route's AS_PATH list.
- Before forwarding routes to IBGP peers, it does not change the AS_PATH list of each route.

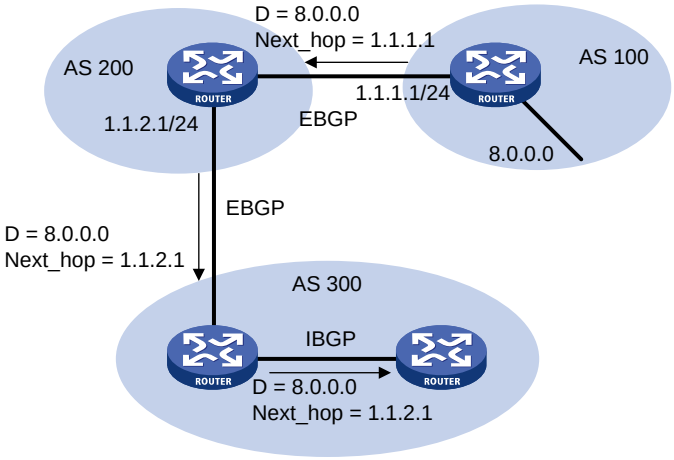
AS numbers in the AS_PATH attribute are arranged in one of the following methods:

- **AS_SEQUENCE**—Arranges AS numbers in sequence. As shown in Figure 8, the number of the AS closest to the receiver's AS is leftmost.
- **AS_SET**—Arranges AS numbers randomly. This method is applicable to route summarization (also called route aggregation) scenarios. After routes are summarized, the system cannot sequentially arrange the AS_PATH attributes of summarized routes. Instead, it records the AS numbers in an unordered manner. When BGP calculates routes, the length of AS_PATH attributes in AS_SET format is counted as one AS number.
- **AS_CONFED_SEQUENCE**—Arranges sub-AS numbers within a confederation in sequence.
- **AS_CONFED_SET**—Arranges sub-AS numbers within a confederation randomly. This method is applicable to intra-confederation route summarization scenarios.

The AS_CONFED_SEQUENCE and AS_CONFED_SET methods are used only in BGP routes forwarded inside a confederation.

Figure 8 AS_PATH attribute

BGP uses the AS_PATH attribute to implement the following functions:



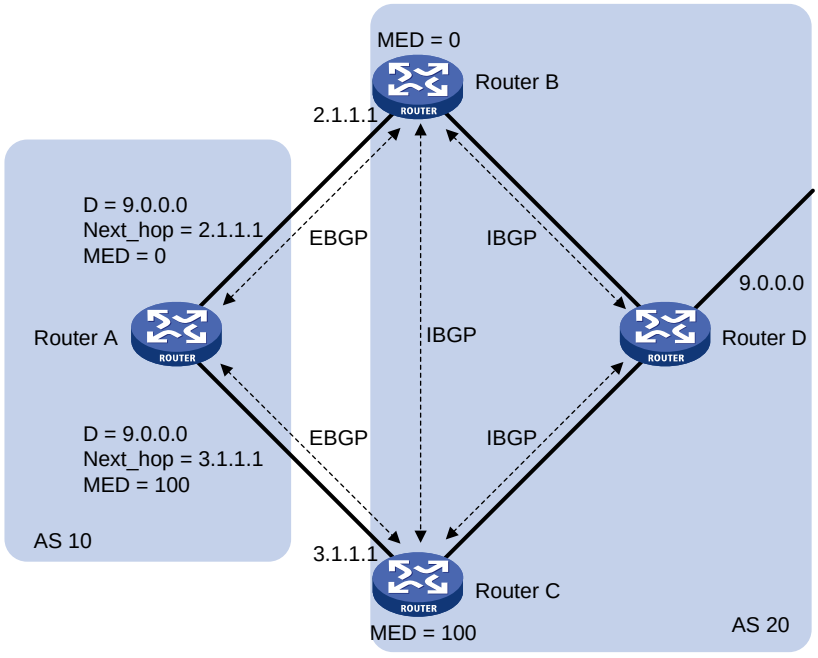
- **Avoid routing loops**—A BGP router does not receive routes containing the local AS number to avoid routing loops.
- **Affect route selection**—BGP gives priority to the route with the shortest AS_PATH length if other factors are the same. As shown in Figure 8, the BGP router in AS 50 gives priority to the route passing AS 40 for sending data to the destination 8.0.0.0. In some applications, you can apply a routing policy to control BGP route selection by modifying the AS_PATH length. For more information about routing policy, see "Configuring routing policies."
- **Filter routes**—By using an AS path list, you can filter routes based on AS numbers contained in the AS_PATH attribute. For more information about AS path list, see "Configuring routing policies."

NEXT_HOP

NEXT_HOP is a well-known mandatory attribute that might not contain the IP address of a directly connected router. Its value is determined as follows:

- When a BGP speaker advertises a self-originated route to a BGP peer, it sets the address of the sending interface as the NEXT_HOP.
- When a BGP speaker sends a received route to an EBGP peer, it sets the address of the sending interface as the NEXT_HOP.
- When a BGP speaker sends a route received from an EBGP peer to an IBGP peer, it does not modify the NEXT_HOP attribute. If load balancing is configured, BGP modifies the NEXT_HOP attribute for the equal-cost routes. For load balancing information, see "BGP load balancing."

Figure 9 NEXT_HOP attribute



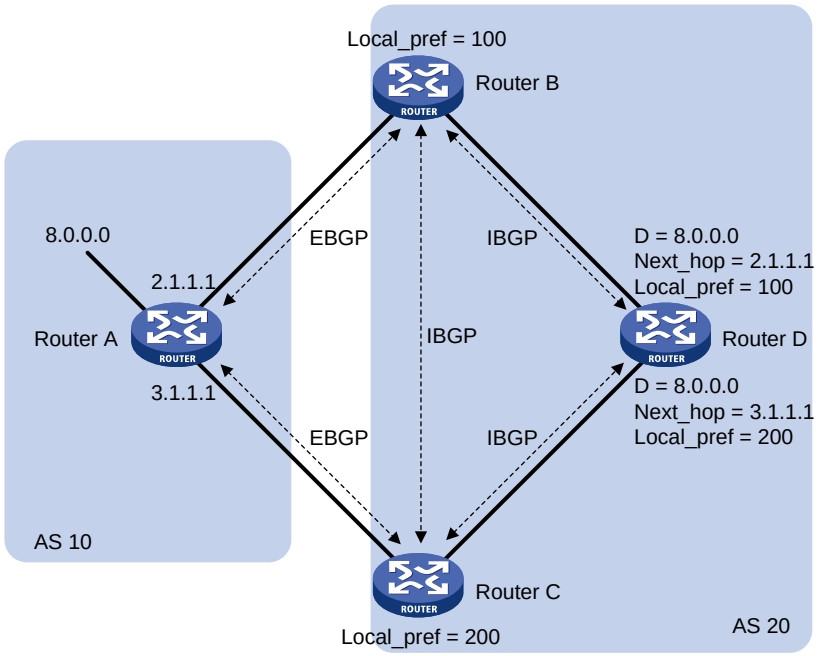
MED (MULTI_EXIT_DISC)

BGP advertises the MED attribute between two neighboring ASs, each of which does not advertise the attribute to any other AS. The MED attribute is an optional non-transitive attribute.

Similar to metrics used by IGPs, MED is used to determine the optimal route for traffic going into an AS. When a BGP router obtains multiple routes to the same destination but with different next hops, it selects the route with the smallest MED value as the optimal route. As shownin Figure 10, traffic from AS 10 to AS 20 travels through Router B that is selected according to MED.

Figure 10 MED attribute

Generally, BGP only compares MEDs of routes received from the same AS. You can also use the **compare-different-as-med** command to force BGP to compare MED values of routes received from different ASs.



LOCAL_PREF

LOCAL_PREF is a well-known discretionary attribute exchanged between IBGP peers only, and is not advertised to any other AS. It indicates the priority of a BGP router.

BGP uses LOCAL_PREF to determine the optimal route for traffic leaving the local AS. When a BGP router obtains multiple routes to the same destination but with different next hops, it selects the route with the highest LOCAL_PREF value as the optimal route. As shown in Figure 11, traffic from AS 20 to AS 10 travels through Router C that is selected according to LOCAL_PREF.

The LOCAL_PREF attribute is transmitted only between IBGP peers, and cannot be advertised to other ASs.

Figure 11 LOCAL_PREF attribute

ATOMIC_AGGREGATE

ATOMIC_AGGREGATE is a well-known discretionary attribute that identifies the aggregation status of a route. A route with the ATOMIC_AGGREGATE attribute is an aggregate route. The route receiver should be aware that the member routes of the aggregate route might be dropped during route advertisement.

AGGREGATOR

AGGREGATOR is an optional transitive attribute supplementary to the ATOMIC_AGGREGATE attribute. It contains the IP address and the AS number of the BGP device that initiated the route aggregation. When a device aggregates BGP routes, it adds both the ATOMIC_AGGREGATE and AGGREGATOR attributes to the aggregate route.

ORIGINATOR_ID

ORIGINATOR_ID is an optional non-transitive attribute that identifies the router ID of the route generator within the local AS. Only route reflectors can add this attribute to routes.

The ORIGINATOR_ID attribute prevents routing loops caused by the introduction of route reflectors. When a BGP route is reflected for the first time, the route reflector adds the ORIGINATOR_ID attribute to the route. The attribute contains the router ID of the device that sent the route to the reflector. When the route reflector receives a route carrying the ORIGINATOR_ID attribute, it does not modify the route. Upon receiving a route with the ORIGINATOR_ID attribute, a device identifies whether the router ID in the ORIGINATOR_ID attribute is the same as its own router ID. If they are the same, a routing loop exists within the current AS, and the receiver discards the route.

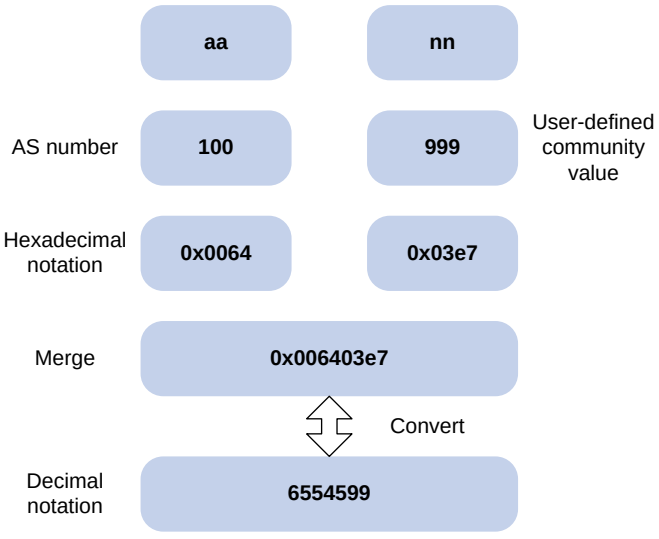
CLUSTER_LIST

CLUSTER_LIST is an optional non-transitive attribute that prevents routing loops by recording the route reflector clusters a route has passed through.

This attribute is generated by route reflectors. When a route reflector a route, it adds the local cluster ID to the CLUSTER_LIST attribute of that route. If the route does not carry a CLUSTER_LIST attribute, the route reflector creates one for the route. When a route reflector receives a BGP route, it identifies whether the route's CLUSTER_LIST attribute contains the local cluster ID. If the local router ID is found, the route will be discarded to prevent routing loops.

COMMUNITY

COMMUNITY is an optional transitive attribute that identifies the communities of BGP routes. A BGP community is a group of routes with the same characteristics. It has no geographical boundaries. Routes of different ASs can belong to the same community.



A route can carry one or more COMMUNITY attribute values (each of which is represented by a 4-byte integer). A router uses the COMMUNITY attribute to determine whether to advertise the route and the advertising scope without using complex filters such as ACLs. This mechanism simplifies routing policy configuration, management, and maintenance.

The COMMUNITY attribute supports the following formats:

- *aa*:*nn*—Both the *aa* and *nn* arguments are in the range of 0 to 65535. The *aa* argument represents the AS number from which the route comes, and the *nn* argument represents the user-defined community value. For example, if the community value of a route from AS 100 is 999, the COMMUNITY attribute of that route is 100:999.
- **Integer**—An integer in the range of 0 to 4294967295.

Figure 12 shows the relationship between the above two formats.

Figure 12 Relationship between the aa:nn and integer formats

Well-known COMMUNITY attributes involve the following:

- **INTERNET**—By default, all routes belong to the Internet community. Routes with this attribute can be advertised to all BGP peers. The value for this attribute is 0.
- **NO_EXPORT**—Routes with this attribute cannot be advertised out of the local AS or out of the local confederation, but can be advertised to other sub-ASs in the confederation. For confederation information, see "Settlements for problems in large-scale BGP networks." The value for this attribute is 4294967041.
- **No_ADVERTISE**—Routes with this attribute cannot be advertised to other BGP peers. The value for this attribute is 4294967042.
- **No_EXPORT_SUBCONFED**—Routes with this attribute cannot be advertised out of the local AS or other sub-ASs in the local confederation. The value for this attribute is 4294967043.

You can configure BGP community lists to filter BGP routes based on the BGP COMMUNITY attribute.

EXT_COMMUNITY

To meet new demands, the EXT_COMMUNITY attribute is introduced, which is an optional non-transitive attribute. This attribute has the following advantages over the COMMUNITY attribute:

- Provides more attribute values by extending the attribute length to eight bytes.
- Allows for using different types of extended community attributes in different scenarios to enhance route filtering and control and simplify configuration and management.

The device supports the link bandwidth extended community attribute, the route target extended community attribute, the tag community attribute, and the Site of Origin (SoO) extended community attribute. For information about route target, see *MCE Configuration Guide*.

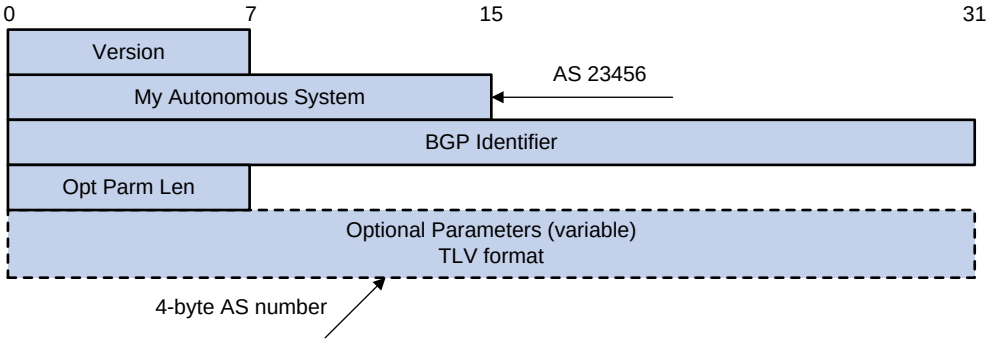
The link bandwidth attribute is used for BGP route-based UCMP load balancing. For information about the link bandwidth attribute, see "Configuring the link bandwidth attribute."

The SoO attribute specifies the site where the route originated. It prevents advertising a route back to the originating site. If the AS-path attribute is lost, the router can use the SoO attribute to avoid routing loops.

The SoO attribute has the following formats:

- *16-bit integer AS number*:*32-bit user-defined number*. For example, 101:3.
- *16-bit dotted AS number*:*32-bit user-defined number*. For example, 0.1:1. The value range is 0.1 to 0.65535 for a dotted AS number.
- *32-bit IP address*:*16-bit user-defined number*. For example, 192.168.122.15:1.
- *32-bit integer AS number*:*16-bit user-defined number*. For example, 65536:1. The minimum integer AS number is 65536.
- *32-bit dotted AS number*:*16-bit user-defined number*. For example, 10.1:1. The minimum dotted AS number is 1.0.

The tag attribute is used to transmit IGP tag information.



4-byte AS numbers

In earlier BGP versions, each AS number was 2 bytes long and was in the range of 1 to 65535. However, as the network size grew, 2-byte AS numbers became insufficient. To avoid AS number exhaustion, AS numbers were lengthened to 4 bytes and their value range became 1 to 4294967295.

Before establishing a session using 4-byte AS numbers, two devices must negotiate with each other about the 4-byte AS number capability through OPEN messages. The session can be established successfully only if both devices support 4-byte AS numbers and the capability negotiation succeeds.

During the capability negotiation, the format of OPEN messages is as shown in Figure 13. The **My Autonomous System** field does not support 4-byte AS numbers because the formats of fields in the OPEN message header are fixed. Therefore, a device using a 4-byte AS number inserts AS number 23456 into the **My Autonomous System** field, and places the real 4-byte AS number in the **Optional Parameters** field. With this approach, two peering devices can determine whether the other supports 4-byte AS numbers and obtain the other's 4-byte AS number during capability negotiation.

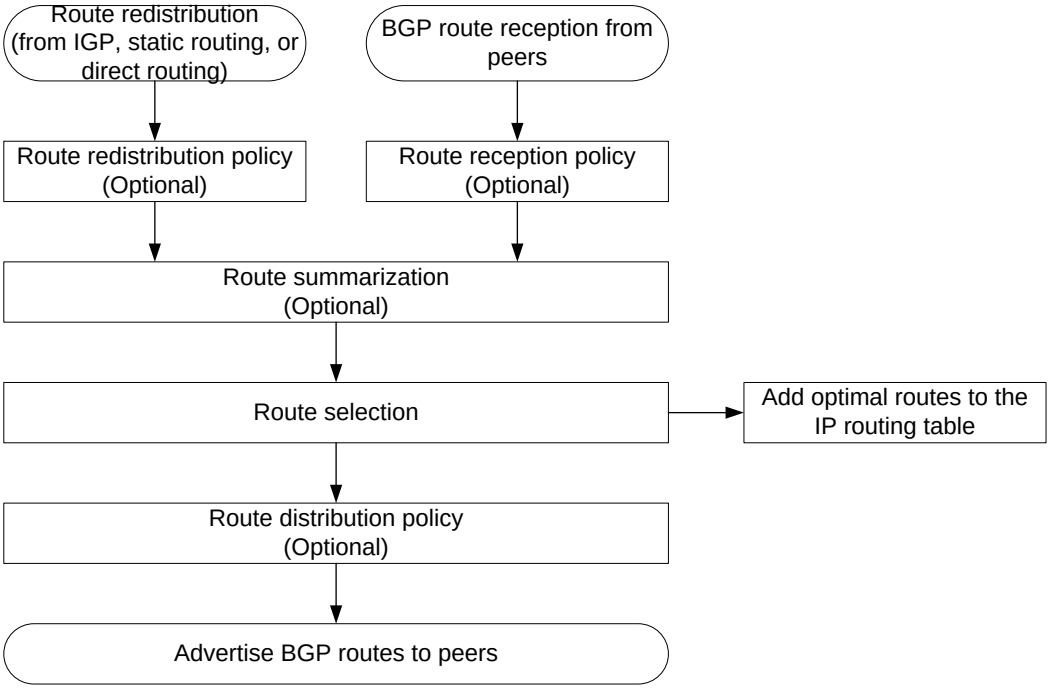


Figure 13 OPEN messages used for 4-byte AS number capability negotiation

BGP route processing mechanism

Figure 14 shows how BGP routes are generated, redistributed, and advertised.

Figure 14 BGP route processing mechanism

Route redistribution

BGP cannot discover routes by itself. To have BGP generate and advertise routes, you must redistribute routes from other protocols into the routing table of BGP. BGP supports the following route redistribution methods:

- **Per-protocol redistribution**—This method redistributes routes in bulk on a per routing protocol basis into the routing table of BGP. The routes that can be redistributed include IGP routes, direct routes, and static routes.
- **Per-route redistribution**—This method can identify a specific route by its prefix and redistribute it into the routing table of BGP.

Route summarization

Route summarization can summarize multiple routes into one summary route. This method can shrink the BGP routing table, because BGP only advertises summary routes rather than summarized routes to peers.

The system supports both manual and automatic route summarization.

- **Automatic summarization**—Summarizes routes redistributed into BGP according to natural network segments. After automatic summarization, BGP suppresses the summarized routes.
- **Manual summarization**—Summarizes BGP routes according to the user-defined summarization settings. This method allows you to determine the attribute of a summary route and whether to advertise the summarized routes.

BGP route selection

BGP discards routes with unreachable next hops and routes without IP-type recursive next hops. If the **bestroute nexthop-resolved none** command is executed, BGP does not discard routes with unreachable next hops. If the **bestroute nexthop-resolved tunnel** command is executed, BGP does not discard routes with only tunnel-type recursive next hops. In this situation, BGP still discards routes with next hops recursed to neither tunnels nor IP addresses.

If multiple routes to the same destination are available, BGP selects the optimal route in the following sequence:

1. The route with the highest-priority RPKI validation result if the **bestroute origin-as-validation** command is executed.

   If the **bestroute origin-as-validation** command is not executed, BGP skips this route selection rule.
2. The route with the highest Preferred_value.
3. The route of the nexthop IP type specified in the **bestroute nexthop-priority preferred** command.

   If the **bestroute nexthop-priority preferred** command is not executed, BGP skips this route selection rule.
4. The route with the highest LOCAL_PREF.
5. The route generated by the **network** command, the route redistributed by the **import-route** command, or the summary route in turn.
6. The route with the shortest AS_PATH.
7. The IGP, EGP, or INCOMPLETE route in turn.
8. The route with the lowest MED value.
9. The route learned from EBGP, confederation EBGP, confederation IBGP, or IBGP in turn.
10. The route of the nexthop IP type specified in the **bestroute nexthop-priority** command.

    If the **bestroute nexthop-priority** command is not executed, BGP skips this route selection rule.
11. The route with the smallest IGP metric.

If the **bestroute igp-metric-ignore** command is executed, BGP skips this route selection rule.

12. The route with the smallest recursion depth.
13. The route of the nexthop type specified in the **bestroute nexthop-type** command.

    If the **bestroute nexthop-type** command is not executed, BGP skips this route selection rule.
14. If a route received from an EBGP peer is the current optimal route, BGP does not change the optimal route when it receives routes from other EBGP peers.
15. The route advertised by the router with the smallest router ID.

    If one of the routes is advertised by a route reflector, BGP compares the ORIGINATOR_ID of the route with the router IDs of other routers. Then, BGP selects the route with the smallest ID as the optimal route.

    If the **bestroute router-id-ignore** command is executed, BGP skips this route selection rule.
16. The route with the shortest CLUSTER_LIST.
17. The route with an IPv6 next hop if the **bestroute ipv6-nexthop** command is executed.

    If the **bestroute ipv6-nexthop** command is not executed, BGP skips this route selection rule.
18. The route with an IPv4 next hop.
19. The route advertised by the peer with the lowest IP address.

The CLUSTER_IDs of route reflectors form a CLUSTER_LIST. If a route reflector receives a route that contains its own CLUSTER ID in the CLUSTER_LIST, the router discards the route to avoid routing loops.

If load balancing is configured, the system selects available routes to implement load balancing.

BGP route advertisement rules

BGP follows these rules for route advertisement:

- When multiple feasible routes to a destination exist, BGP advertises only the optimal route to its peers. If the **advertise-rib-active** command is configured, BGP advertises the optimal route in the IP routing table. If not, BGP advertises the optimal route in the BGP routing table.
- BGP advertises only routes that it uses.
- BGP advertises routes learned from an EBGP peer to all BGP peers, including both EBGP and IBGP peers.
- BGP advertises routes learned from an IBGP peer to EBGP peers, rather than other IBGP peers.
- After establishing a session to a new BGP peer, BGP advertises all the routes matching the above rules to the peer. After that, BGP advertises only incremental updates to the peer.

BGP load balancing

BGP load balancing is applicable between EBGP peers, between IBGP peers, and between confederations.

BGP implements load balancing through route recursion and route selection.

BGP load balancing through route recursion

The next hop of a BGP route might not be directly connected. One of the reasons is that the next hop information exchanged between IBGP peers is not modified. The BGP router must find the directly

connected next hop through IGP. The matching route with the direct next hop is called the recursive route. The process of finding a recursive route is route recursion.

If multiple recursive routes to the same destination are load balanced, BGP generates the same number of next hops to forward packets.

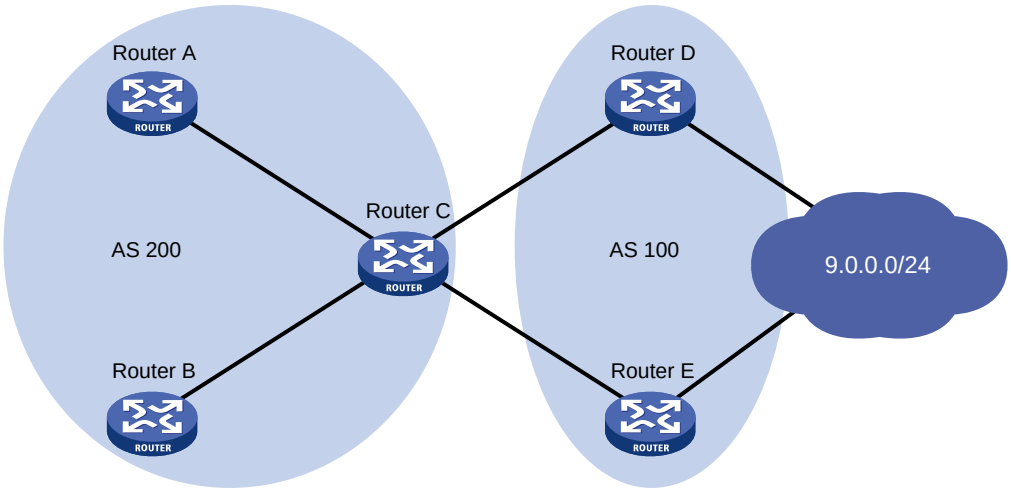
BGP load balancing based on route recursion is always enabled in the system.

BGP load balancing through route selection

IGP routing protocols, such as RIP and OSPF, can use route metrics as criteria to load balance between routes that have the same metric. BGP cannot load balance between routes by route metrics as an IGP protocol does, because BGP does not have a route computation algorithm.

BGP uses the following load balancing criteria to determine load balanced routes:

- The routes have the same ORIGIN, LOCAL_PREF, and MED attributes.
- The routes meet the following requirements on the AS_PATH attribute:
  - If the **balance as-path-neglect** command is configured, the routes can have different AS_PATH attributes.
  - If only the **balance as-path-relax** command is configured, the routes can have different AS_PATH attributes, but the length of the AS_PATH attributes must be the same.
  - If neither the **balance as-path-neglect** nor the **balance as-path-relax** command is configured, the routes must have the same AS_PATH attribute.
- The next hops of the routes meet the following requirements on IGP metrics:
  - If neither the **bestroute igp-metric-ignore** command nor the **balance igp-metric-ignore** command is configured, the next hops of the routes must have the same IGP metric value.
  - If either the **bestroute igp-metric-ignore** command or the **balance igp-metric-ignore** command is configured, the next hops of the routes can have different IGP metric values.



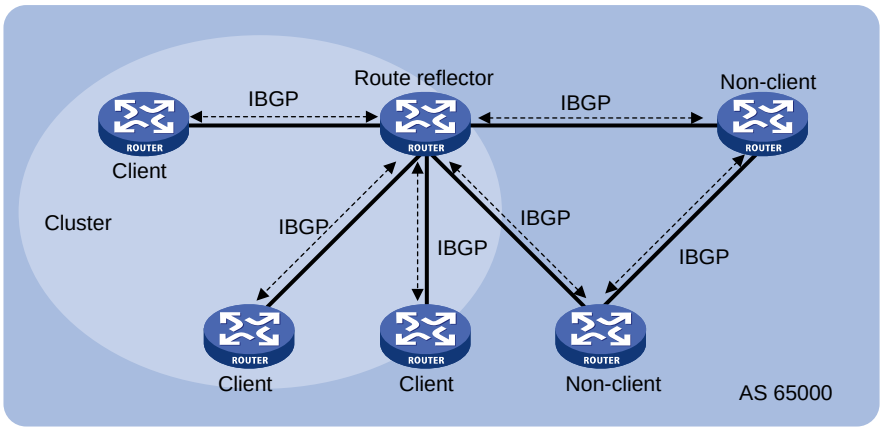
BGP does not use the route selection rules described in "BGP route selection" for load balancing.

As shown in Figure 15, Router A and Router B are IBGP peers of Router C. Router C allows a maximum number of two ECMP routes for load balancing.

Router D and Router E both advertise a route 9.0.0.0 to Router C. Router C installs the two routes to its routing table for load balancing if the routes meet the BGP load balancing criteria. After that, Router C forwards to Router A and Router B a single route whose attributes are changed as follows:

- AS_PATH attribute:
  - If the **balance as-path-neglect** and **balance as-path-relax** commands are not configured, the AS_PATH attribute does not change.
  - If the **balance as-path-neglect** or **balance as-path-relax** command is configured, the AS_PATH attribute is changed to the attribute of the optimal route.
- The NEXT_HOP attribute is changed to the IP address of Router C.
- Other attributes are changed to be the same as the optimal route.

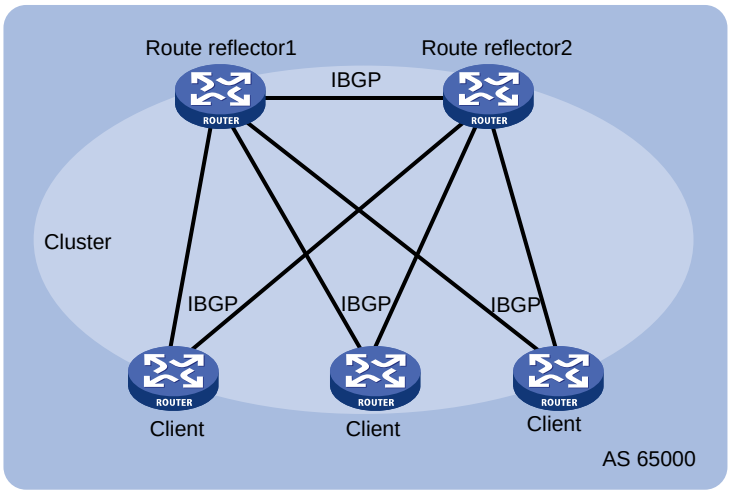
Figure 15 Network diagram



Route reflector

IBGP peers must be fully meshed to maintain connectivity. If n routers exist in an AS, the number of IBGP connections is n(n-1)/2. If a large number of IBGP peers exist, large amounts of network and CPU resources are consumed to maintain sessions.

Using route reflectors can solve this issue. In an AS, a router acts as a route reflector, and other routers act as clients connecting to the route reflector. The route reflector forwards routing information received from a client to other clients. In this way, all clients can receive routing information from one another without establishing BGP sessions.



A router that is neither a route reflector nor a client is a non-client, which, as shown in Figure 16, must establish BGP sessions to the route reflector and other non-clients.

Figure 16 Network diagram for a route reflector

The route reflector and clients form a cluster. Typically a cluster has one route reflector. The ID of the route reflector is the Cluster_ID. You can configure more than one route reflector in a cluster to improve availability, as shown in Figure 17. The configured route reflectors must have the same cluster_ID to avoid routing loops.

Figure 17 Network diagram for route reflectors

When the BGP routers in an AS are fully meshed, route reflection is unnecessary because it consumes more bandwidth resources. You can use commands to disable route reflection between clients instead of modifying the network configuration or changing the network topology.

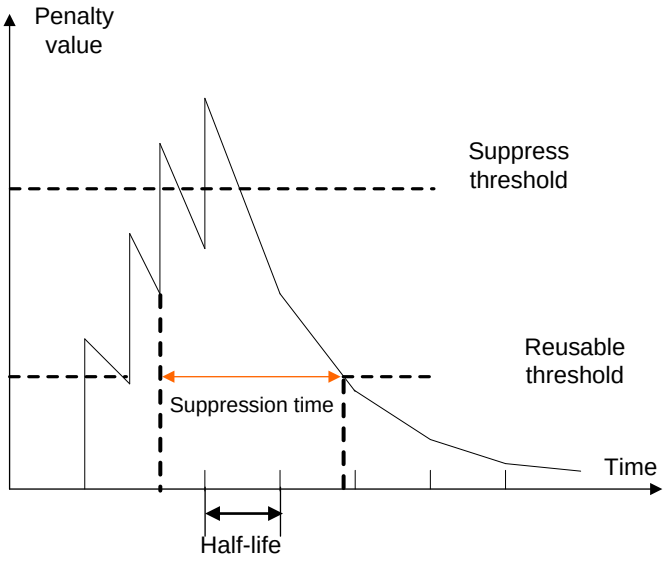
NOTE:

After route reflection is disabled between clients, routes can still be reflected between a client and a non-client.

Settlements for problems in large-scale BGP networks

You can use the following methods to facilitate management and improve route distribution efficiency on a large-scale BGP network.

Route dampening



Route flapping (a route comes up and disappears in the routing table frequently) causes BGP to send many routing updates. It can consume too many resources and affect other operations.

In most cases, BGP runs in complex networks where route changes are more frequent. To solve the problem caused by route flapping, you can use BGP route dampening to suppress unstable routes.

BGP route dampening uses a penalty value to judge the stability of a route. The bigger the value, the less stable the route. Each time a route state changes from reachable to unreachable, or a reachable route's attribute changes, BGP adds a penalty value of 1000 to the route. When the penalty value of the route exceeds the suppress value, the route is suppressed and cannot become the optimal route. When the penalty value reaches the upper limit, no penalty value is added.

If the suppressed route does not flap, its penalty value gradually decreases to half of the suppress value after a period of time. This period is called "Half-life." When the value decreases to the reusable threshold value, the route is usable again.

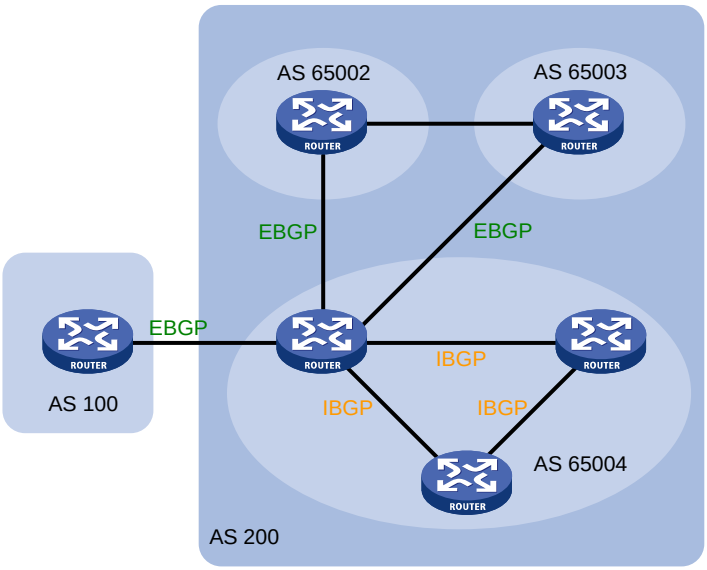
Figure 18 BGP route dampening

Peer group and dynamic peer

You can organize BGP peers with the same attributes into a group to simplify their configurations.

When a peer joins the peer group, the peer obtains the same configuration as the peer group. If the configuration of the peer group is changed, the configuration of group members is changed.

In some BGP networks, peers might change frequently and cause changes to BGP sessions. Using the regular peering method requires frequent BGP configuration adjustments, which is laborious. To resolve this issue, you can configure the neighbors of a device in the same network segment as a dynamic peer. The device accepts the peering request of a device as long as the requesting device is in the configured network segment.



Community

You can apply a community list or an extended community list to a routing policy for route control. For more information, see "BGP path attributes."

Confederation

Confederation is another method to manage growing IBGP connections in an AS. It splits an AS into multiple sub-ASs. In each sub-AS, IBGP peers are fully meshed. As shown in Figure 19, intra-confederation EBGP connections are established between sub-ASs in AS 200.

Figure 19 Confederation network diagram

A non-confederation BGP speaker does not need to know sub-ASs in the confederation. To the BGP speaker, the confederation is one AS and the confederation ID is the AS number. In the above figure, AS 200 is the confederation ID.

Confederation has a deficiency. When you change an AS into a confederation, you must reconfigure the routers, and the topology will be changed.

In large-scale BGP networks, you can use both route reflector and confederation.

BGP update group

In large-scale BGP networks, a device needs to advertise routes to a large number of BGP peers, which requires high performance in bulk packet packaging and advertisement.

To conserve device resources, BGP can treat all peers with the same configurations as an update group. It packages a route only once and advertises that route to all peers in an update group. If the BGP update group feature is not supported, BGP must package routes on a per peer basis. For example, a route reflector has 10 clients and needs to reflect 10000 routes:

- If the route reflector does not support BGP update groups, it must package routes 100000 times.
- If the route reflector supports BGP update groups, it only needs to package routes 10000 times.

In the current software version, the BGP update group feature is supported by default..

MP-BGP

Supported address families

BGP-4 can only advertise IPv4 unicast routing information. Multiprotocol Extensions for BGP-4 (MP-BGP) can advertise routing information for the following address families:

- IPv6 unicast address family.
- IPv4 multicast address family and IPv6 multicast address family.

  PIM uses static and dynamic unicast routes to perform RPF check before creating multicast routing entries. When the multicast and unicast topologies are different, you can use MP-BGP

to advertise the routes for RPF check. MP-BGP stores the routes in the BGP multicast routing table. For more information about PIM and RPF check, see *IP Multicast Configuration Guide*.

MP-BGP extended attributes

Prefixes and next hops are key routing information. BGP-4 uses UPDATE messages to carry the following information:

- Feasible route prefixes in the Network Layer Reachability Information (NLRI) field.
- Unfeasible route prefixes in the withdrawn routes field.
- Next hops in the NEXT_HOP attribute.

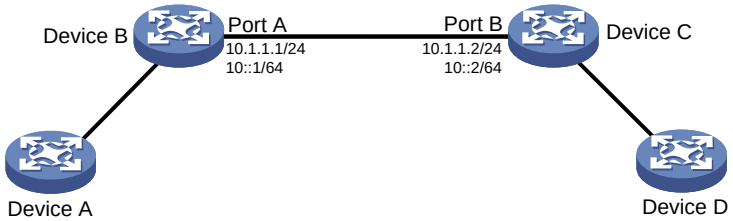
BGP-4 cannot carry routing information for multiple network layer protocols.

To support multiple network layer protocols, MP-BGP defines the following path attributes:

- **MP_REACH_NLRI**—Carries feasible route prefixes and next hops for multiple network layer protocols.
- **MP_UNREACH_NLRI**—Carries unfeasible route prefixes for multiple network layer protocols.

MP-BGP uses these two attributes to advertise feasible and unfeasible routes for different network layer protocols. BGP speakers not supporting MP-BGP ignore updates containing these attributes and do not forward them to its peers.

Address family



MP-BGP uses address families and subsequent address families to identify different network layer protocols for routes contained in the MP_REACH_NLRI and MP_UNREACH_NLRI attributes. For example, an Address Family Identifier (AFI) of 2 and a Subsequent Address Family Identifier (SAFI) of 1 identify IPv6 unicast routing information carried in the MP_REACH_NLRI attribute. For address family values, see RFC 1700.

Exchanging IPv4 and IPv6 routes in both IPv4 and IPv6 address families

MP-BGP supports IPv4 route exchange between IPv6 peers and IPv6 route exchange between IPv4 peers as follows:

- When the next hop of an IPv6 route is an IPv4 address, MP-BGP maps the IPv4 address to an IPv6 address encapsulated in the NEXT_HOP attribute of update messages. In this scenario, you must specify a routing policy to change the next hop of the IPv6 route to the IPv6 address of the peer.
- When the next hop of an IPv4 route is an IPv6 address, BGP negotiates the extended next hop encoding capability with its peer. Then, BGP encapsulates the IPv4 NLRI in the MP_REACH_NLRI attribute of update messages. In this scenario, you must specify a routing policy to change the next hop of the IPv4 route to the IPv4 address of the peer.

Figure 20 Exchanging IPv4 and IPv6 routes in both IPv4 and IPv6 address families

As shown in Figure 20, an IPv6 BGP peer relationship is established between Device A and Device B, between Device B and Device C, and between Device C and Device D. An IPv4 BGP peer relationship is established between Device A and Device B and between Device C and Device D. Device A and Device D can learn both IPv4 and IPv6 routes from each other and traffic is forwarded correctly in both IPv4 and IPv6 address families. For Device C to correctly receive IPv4 routes using the IPv6 address of Device B as the next hop, configure a routing policy on Device C. Use the routing policy to change the next hop of these routes to the IPv4 address of Device B.

BGP route redistribution into local VPN instances

In a private BGP network, BGP sessions might transmit routes that belong to different VPN instances. On receipt of those VPN routes, BGP needs to redistribute them into local VPN instances. During the route redistribution, BGP redistributes routes of non-local VPN instances or routes of another local VPN instance to the BGP routing table of a local VPN instance. Route redistribution into local VPN instances can be divided into local route redistribution and remote route redistribution based on the origins of routes:

- **Local route redistribution**—Redistributes the BGP routes of a local BGP-VPN instance to another local BGP-VPN instance. BGP VPN routes can be redistributed from a local VPN instance to another only if their export RTs equal the import RT of the destination VPN instance.
- **Remote route redistribution**—Redistributes the BGP routes received from remote peers into local VPN instances. BGP VPN routes can be redistributed into a local VPN instance only if their RTs equal the import RT of that VPN instance. If a BGP VPN route matches multiple local VPN instances, BGP will copy the route and redistribute it into those matching VPN instances separately.

In the current software version, only the following routes support route redistribution between VPN instances:

- **Local route redistribution**: BGP-VPN IPv4 unicast routes and BGP-VPN IPv6 unicast routes.
- **Remote route redistribution**: BGP VPNv4 routes, BGP EVPN routes, and BGP VPNv6 routes.

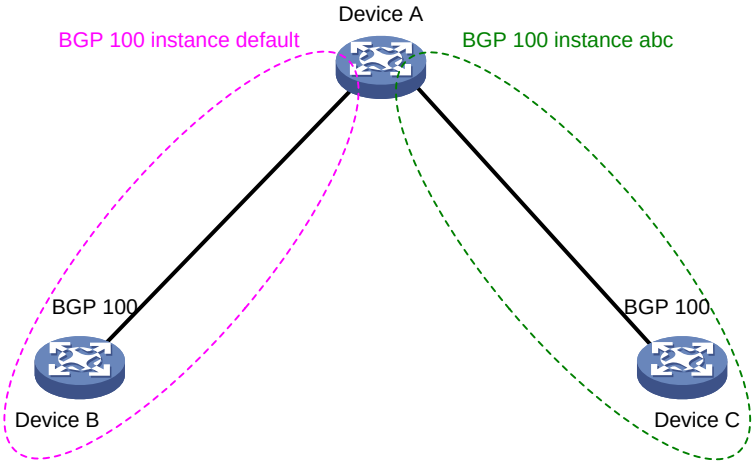
BGP multi-instance

About this feature

A BGP router can run multiple BGP processes. Each BGP process corresponds to a BGP instance. BGP maintains an independent routing table for each BGP instance.

When you create multiple BGP instances, follow these guidelines:

- You can create multiple public address families for a BGP instance. However, each public address family (except for IPv4 unicast address family, IPv6 unicast address family, VPNv4 address family, VPNv6 address family, and IPv4 RT-filter address family) can belong to only one BGP instance.
- You can create multiple VPN instances for a BGP instance, and each VPN instance can have multiple address families. A VPN instance can belong to only one BGP instance.
- On the public network, a peer address can establish a session to only one BGP instance. Multiple BGP instances cannot synchronously establish sessions to the same peer address.
- The IPv4 and IPv6 multicast address families must belong to the same BGP instance.
- Different BGP instances can have the same AS number but cannot have the same name.



Examples

As shown in Figure 21, Device A, Device B, and Device C all run in AS 100. To enable Device A to communicate with Device B and Device C and implement service isolation between Device B and Device C, perform the following task on Device A:

1. Create two BGP instances, for example, default and abc.
2. Use BGP instance **default** to establish a session to Device B.
3. Use BGP instance **abc** to establish a session to Device C.

After you complete this task, Device A can learn routes from Device B and Device C. However, Device B and Device C cannot learn routes from each other, because BGP instance **default** and **abc** are two independent instances.

Figure 21 Service isolation with BGP multi-instance

BGP configuration views

BGP uses different views to manage routing information for different BGP instances, VPN instances, and address families. Most BGP commands are available in all BGP views. BGP supports multiple VPN instances by establishing a separate routing table for each VPN instance.

If a command is supported only in BGP instance view, this command takes effect for both the public instance and all VPN instances in the BGP instance.

If a command is supported both in BGP instance view and BGP-VPN instance view, this command takes effect as follows:

- In BGP instance view, this command takes effect only for the public instance in the BGP instance.
- In BGP-VPN instance view, this command takes effect only for VPN instances associated with in the BGP-VPN instance.

Table 8 describes different BGP configuration views.

Table 8 BGP configuration views

View names	Ways to enter the views	Remarks

BGP instance view	`<Sysname> system-view`
	`[Sysname] bgp 100 instance abc`
	`[Sysname-bgp-abc]`
		You can create a BGP instance and enter its view by specifying the **`instance`** keyword in the **`bgp`** command.
		Configurations in this view apply to all public address families for the specified BGP instance. Some configurations (such as confederation, GR, and logging configurations) also apply to the address families of VPN instances.

View names	Ways to enter the views	Remarks
BGP IPv4 unicast address family view	<Sysname> system-view [Sysname] bgp 100 instance abc [Sysname-bgp-abc] address-family ipv4 unicast [Sysname-bgp-abc-ipv4]	Configurations in this view apply to public IPv4 unicast routes and peers of the specified BGP instance.
BGP IPv6 unicast address family view	<Sysname> system-view [Sysname] bgp 100 instance abc [Sysname-bgp-abc] address-family ipv6 unicast [Sysname-bgp-abc-ipv6]	Configurations in this view apply to public IPv6 unicast routes and peers of the specified BGP instance.
BGP IPv4 multicast address family view	<Sysname> system-view [Sysname] bgp 100 instance abc [Sysname-bgp-abc] address-family ipv4 multicast [Sysname-bgp-abc-mul-ipv4]	Configurations in this view apply to IPv4 multicast routes and peers of the specified BGP instance.
BGP IPv6 multicast address family view	<Sysname> system-view [Sysname] bgp 100 instance abc [Sysname-bgp-abc] address-family ipv6 multicast [Sysname-bgp-abc-mul-ipv6]	Configurations in this view apply to IPv6 multicast routes and peers of the specified BGP instance.
BGP-VPN instance view	<Sysname> system-view [Sysname] bgp 100 instance abc [Sysname-bgp-abc] ip vpn-instance vpn1 [Sysname-bgp-abc-vpn1]	Configurations in this view apply to all address families in the specified VPN instance of the specified BGP instance. For more information about VPN instances, see *MCE Configuration Guide.*
BGP-VPN IPv4 unicast address family view	<Sysname> system-view [Sysname] bgp 100 instance abc [Sysname-bgp-abc] ip vpn-instance vpn1 [Sysname-bgp-abc-vpn1] address-family ipv4 unicast [Sysname-bgp-abc-ipv4-vpn1]	Configurations in this view apply to IPv4 unicast routes and peers in the specified VPN instance of the specified BGP instance. For more information about VPN instances, see *MCE Configuration Guide.*
BGP-VPN IPv6 unicast address family view	<Sysname> system-view [Sysname] bgp 100 instance abc [Sysname-bgp-abc] ip vpn-instance vpn1 [Sysname-bgp-abc-vpn1] address-family ipv6 unicast [Sysname-bgp-abc-ipv6-vpn1]	Configurations in this view apply to IPv6 unicast routes and peers in the specified VPN instance of the specified BGP instance. For more information about VPN instances, see *MCE Configuration Guide.*
BGP LS address family view	<Sysname> system-view [Sysname] bgp 100 instance abc [Sysname-bgp-abc] address-family link-state [Sysname-bgp-abc-ls]	Configurations in this view apply to LS messages and peers of the specified BGP instance.

Hardware compatibility with BGP

S5200-EI-G does not supoort BGP.

Building basic BGP networks

Basic BGP network configuration tasks at a glance (IPv4 unicast/IPv4 multicast)

To build basic BGP networks for the IPv4 unicast or IPv4 multicast address family, perform the following tasks:

1. Configuring basic BGP
   a. Enabling BGP
   b. Configuring a BGP peer
   c. Configuring dynamic BGP peers
   d. Configuring an IBGP peer group

      Configure BGP peer groups on large-scale BGP networks for easy configuration and maintenance.
   e. Configuring an EBGP peer group

      Configure BGP peer groups on large-scale BGP networks for easy configuration and maintenance.
   f. (Optional.) Specifying the source address of TCP connections
2. Controlling BGP route generation

   Choose the following tasks as needed:
   - Injecting a local network
   - Redistributing IGP routes
   - (Optional.) Configuring BGP route summarization
   - (Optional.) Advertising a default route to a peer or peer group
3. (Optional.) Controlling BGP route advertisement
   - Advertising optimal routes in the IP routing table

     BGP cannot advertise optimal routes in the IP routing table for IPv4 multicast address family.
   - Enabling prioritized withdrawal of the default route
   - Enabling prioritized withdrawal of specific routes
   - Configuring BGP route distribution filtering policies
   - Enabling first-AS-number check for EBGP route advertisement
   - Setting the BGP route sending rate

     This task applies only to IPv4 unicast routes.
   - Configuring BGP to delay sending route updates on reboot
   - Configuring the interval for sending updates for the same route
   - Configuring BGP route advertisement delay
   - Setting the refresh route advertisement delay timer
   - Configuring a startup policy for BGP route updates
4. (Optional.) Controlling BGP route reception
   - Limiting routes received from a peer or peer group
   - Configuring BGP route reception filtering policies
   - Configuring the SoO attribute

5. (Optional.) Configuring BGP timers
   - Configuring the keepalive interval and hold time
   - Setting the session retry timer
6. (Optional.) Configuring BGP logging and notifications
   - Enabling logging for session state changes
   - Enabling logging for BGP route flapping
   - Configuring BGP network management

Basic BGP network configuration tasks at a glance (IPv6 unicast/IPv6 multicast)

To build basic BGP networks for the IPv6 unicast or IPv6 multicast address family, perform the following tasks:

1. Configuring basic BGP
   a. Enabling BGP
   b. Configuring a BGP peer
   c. Configuring dynamic BGP peers
   d. Configuring an IBGP peer group

      Configure BGP peer groups on large-scale BGP networks for easy configuration and maintenance.
   e. Configuring an EBGP peer group

      Configure BGP peer groups on large-scale BGP networks for easy configuration and maintenance.
   f. (Optional.) Specifying the source address of TCP connections
2. Controlling BGP route generation

   Choose the following tasks as needed:
   - Injecting a local network
   - Redistributing IGP routes
   - (Optional.) Configuring BGP route summarization
   - (Optional.) Advertising a default route to a peer or peer group
3. (Optional.) Controlling BGP route advertisement
   - Advertising optimal routes in the IP routing table

     BGP cannot advertise optimal routes in the IP routing table for IPv6 multicast address family.
   - Enabling prioritized withdrawal of the default route
   - Enabling prioritized withdrawal of specific routes
   - Configuring BGP route distribution filtering policies
   - Setting the BGP route sending rate

     This task applies only to IPv6 unicast routes.
   - Configuring BGP to delay sending route updates on reboot
   - Configuring the interval for sending updates for the same route
   - Configuring BGP route advertisement delay
   - Setting the refresh route advertisement delay timer
   - Configuring a startup policy for BGP route updates

4. (Optional.) Controlling BGP route reception
   - Limiting routes received from a peer or peer group
   - Configuring BGP route reception filtering policies
   - Configuring the SoO attribute
5. (Optional.) Configuring BGP timers
   - Configuring the keepalive interval and hold time
   - Setting the session retry timer
6. (Optional.) Configuring BGP logging and notifications
   - Enabling logging for session state changes
   - Enabling logging for BGP route flapping
   - Configuring BGP network management

Configuring basic BGP

Enabling BGP

Restrictions and guidelines

A router ID is the unique identifier of a BGP router in an AS.

- To ensure the uniqueness of a router ID and enhance availability, specify in BGP instance view the IP address of a local loopback interface as the router ID. Different BGP instances can have the same router ID.
- If no router ID is specified in BGP instance view, the global router ID is used.
- To modify a non-zero router ID of a BGP instance, use the **`router-id`** command in BGP instance view, rather than the **`router id`** command in system view.
- If you specify a router ID in BGP instance view and then remove the interface that owns the router ID, the router does not select a new router ID. To select a new router ID, use the **`undo router-id`** command in BGP instance view.

Procedure

1. Enter system view.

   `system-view`
2. Configure a global router ID.

   `router id` *`router-id`*

   By default, no global router ID is configured.

   If no global router ID is configured, the following rules apply:
   - If loopback interfaces configured with an IP address exist, BGP uses the highest loopback interface IP address as the router ID.
   - If no loopback interface IP address is available, BGP uses the highest physical interface IP address as the route ID regardless of the interface status.
3. Enable BGP and enter BGP instance view.

   `bgp` *`as-number`* [**`instance`** *`instance-name`*]

   By default, BGP is disabled and no BGP instances exist.
4. (Optional.) Configure a router ID for the BGP instance.

   `router-id` *`router-id`*

   By default, no router ID is configured for a BGP instance, and the BGP instance uses the global router ID configured by the **`router-id`** command in system view.

5. (Optional.) Enter BGP-VPN instance view.

   ip vpn-instance *vpn-instance-name*

   The specified VPN instance must have been created and have an RD.

6. (Optional.) Configure a router ID for the BGP VPN instance.

   router-id { *router-id* | **auto-select** }

   By default, no router ID is configured for a BGP VPN instance.

   The BGP VPN instance uses the router ID configured in BGP instance view. If no router ID is configured in BGP instance view, the BGP VPN instance uses the global router ID configured in system view.

Configuring a BGP peer

Restrictions and guidelines

You can configure BGP peers for the local device by using one of the following methods:

- Specify a BGP peer by its global unicast address.
- Specify a BGP peer by its link-local address. A BGP peer at an IPv6 link-local address must be directly connected to the local router. If you do not specify the interface connected to the peer, you must specify the interface directly connected to the BGP peer as the source interface of TCP connections on the local router.
- Specify a local interface and establish peer relationships with link-local addresses that the interface learned in ND entries.

To exchange IPv4 routes with an IPv6 peer or exchange IPv6 routes with an IPv4 peer, you must configure a routing policy to perform the following tasks:

- Change the next hop of IPv4 routes received from the IPv6 peer to the IPv4 address of the interface that connects the IPv6 peer to the local router.
- Change the next hop of IPv6 routes received from the IPv4 peer to the IPv6 address of the interface that connects the IPv4 peer to the local router.

Procedure (Exchanging IPv4 unicast routes with IPv4 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an IPv4 BGP peer and specify its AS number.

   peer *ipv4-address* **as-number** *as-number*

4. (Optional.) Configure a description for a peer.

   peer *ipv4-address* **description** *text*

   By default, no description is configured for a peer.

5. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]

6. Enable the router to exchange IPv4 unicast routing information with the specified peer.

   peer *ipv4-address* **enable**

By default, the router cannot exchange IPv4 unicast routing information with the peer.

Procedure (Exchanging IPv6 unicast routes with IPv4 peers)

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Create an IPv4 BGP peer and specify its AS number.
   peer *ipv4-address* **as-number** *as-number*
4. (Optional.) Configure a description for the IPv4 peer.
   peer *ipv4-address* **description** *text*

   By default, no description is configured for an IPv4 peer.
5. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.
   address-family ipv6 [**unicast**]
6. Enable BGP to exchange IPv6 unicast routing information with the IPv4 peer.
   peer *ipv4-address* **enable**

   By default, BGP cannot exchange IPv6 unicast routing information with an IPv4 peer.
7. Use a routing policy to modify the next hop of routes received from the IPv4 peer.
   peer *ipv4-address* **route-policy** *route-policy-name* **import**

Procedure (Exchanging IPv6 unicast routes with IPv6 peers)

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Create an IPv6 BGP peer and specify its AS number.
   peer { *ipv6-address* | *link-local-address* **interface** *interface-type interface-number* } **as-number** *as-number*
4. (Optional.) Configure a description for a peer.
   peer { *ipv6-address* | *link-local-address* **interface** *interface-type interface-number* } **description** *text*

   By default, no description is configured for a peer.
5. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.
   address-family ipv6 [**unicast**]
6. Enable the router to exchange IPv6 unicast routing information with the specified peer.

peer { *ipv6-address* | *link-local-address* **interface** *interface-type interface-number* } **enable**

By default, the router cannot exchange IPv6 unicast routing information with the peer.

Procedure (Exchanging IPv6 unicast routes with IPv6 peers created by specifying an interface)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Create peer relationships with link-local addresses that the specified interface learned in ND entries, and specify an AS number for the peers.

   interface-peer *interface-type interface-number* **as-number** *as-number*
4. (Optional.) Configure a description for the peers.

   interface-peer *interface-type interface-number* **description** *text*

   By default, no description is configured for a peer.
5. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.

   address-family ipv6 [**unicast**]
6. Enable the router to exchange IPv6 unicast routing information with the specified peers.

   interface-peer *interface-type interface-number* **enable**

   By default, the router cannot exchange IPv6 unicast routing information with a peer.

Procedure (Exchanging IPv4 unicast routes with IPv6 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Create an IPv6 BGP peer and specify its AS number.

   peer *ipv6-address* **as-number** *as-number*
4. (Optional.) Configure a description for the IPv6 peer.

   peer *ipv6-address* **description** *text*

   By default, no description is configured for an IPv6 peer.
5. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]
6. Enable BGP to exchange IPv4 unicast routing information with the IPv6 peer.

   peer *ipv6-address* **enable**

By default, BGP cannot exchange IPv4 unicast routing information with an IPv6 peer.

7. Use a routing policy to modify the next hop of routes received from the IPv6 peer.
   peer *ipv6-address* **route-policy** *route-policy-name* **import**

Procedure (Exchanging IPv4 unicast routes with IPv6 peers created by specifying an interface)

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Create peer relationships with link-local addresses that the specified interface learned in ND entries, and specify an AS number for the peers.
   interface-peer *interface-type interface-number* **as-number** *as-number*
4. (Optional.) Configure a description for the IPv6 peers.
   interface-peer *interface-type interface-number* **description** *text*
   By default, no description is configured for an IPv6 peer.
5. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.
   address-family ipv4 [**unicast**]
6. Enable BGP to exchange IPv4 unicast routing information with the specified peers.
   interface-peer *interface-type interface-number* **enable**
   By default, the router cannot exchange IPv4 unicast routing information with a peer.
7. Use a routing policy to modify the next hop of routes received from the IPv6 peer.
   interface-peer *interface-type interface-number* **route-policy** *route-policy-name* **import**

Procedure (Exchanging IPv4 multicast routes with IPv4 peers)

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Create an IPv4 BGP peer and specify its AS number.
   peer *ipv4-address* **as-number** *as-number*
4. (Optional.) Configure a description for the peer.
   peer *ipv4-address* **description** *text*
   By default, no description is configured for a peer.
5. Create the BGP IPv4 multicast address family and enter its view.
   address-family ipv4 multicast
6. Enable the router to exchange IPv4 unicast routing information used for RPF check with the specified peer.
   peer *ipv4-address* **enable**

By default, the router cannot exchange IPv4 unicast routing information used for RPF check with the peer.

Procedure (Exchanging IPv6 multicast routes with IPv6 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
3. Create an IPv6 BGP peer and specify its AS number.

   peer *ipv6-address* **as-number** *as-number*
4. (Optional.) Configure a description for the peer.

   peer *ipv6-address* **description** *text*

   By default, no description is configured for a peer.
5. Create the BGP IPv6 multicast address family and enter its view.

   address-family ipv6 multicast
6. Enable the router to exchange IPv6 unicast routing information used for RPF check with the specified peer.

   peer *ipv6-address* **enable**

   By default, the router cannot exchange IPv6 unicast routing information used for RPF check with the peer.

Configuring dynamic BGP peers

About this task

This feature enables BGP to establish dynamic BGP peer relationships with devices in a network. BGP accepts connection requests from the network but it does not initiate connection requests to the network.

After a device in the network initiates a connection request, BGP establishes a dynamic peer relationship with the device.

If multiple BGP peers reside in the same network, you can use this feature to simplify BGP peer configuration.

If BGP establishes a large number of dynamic peer sessions, these sessions might consume system resources excessively. To control the number of dynamic BGP peer sessions, use the **dynamic-peer-limit** command to set an upper limit on the number of dynamic peer sessions. BGP will not establish new dynamic peer sessions if the number of established dynamic peer sessions exceeds the specified limit.

Restrictions and guidelines

For a remote device to establish a peer relationship with the local device, you must specify the IP address of the local device on the remote device.

A BGP peer at an IPv6 link-local address must be directly connected to the local router. If you do not specify the interface connected to the peer, you must specify the interface directly connected to the BGP peer as the source interface of TCP connections on the local router.

To exchange IPv4 routes with an IPv6 peer or exchange IPv6 routes with an IPv4 peer, you must configure a routing policy to perform the following tasks:

- Change the next hop of IPv4 routes received from the IPv6 peer to the IPv4 address of the interface that connects the IPv6 peer to the local router.
- Change the next hop of IPv6 routes received from the IPv4 peer to the IPv6 address of the interface that connects the IPv4 peer to the local router.

When you configure the **dynamic-peer-limit** command, the number of established dynamic peer sessions might already exceed the specified limit. In this scenario, BGP does not terminate the existing dynamic peer sessions. However, if BGP resets and re-establishes peer sessions later, the number of established dynamic peer sessions cannot exceed the specified limit.

When you use the **dynamic-peer-limit** command in a scenario where BGP needs to re-establish peer sessions, make sure the specified limit is not smaller than the number of existing dynamic peer sessions. Otherwise, traffic interruption will occur because BGP cannot re-establish some of the dynamic peer sessions.

If the local device has established a dynamic peer relationship with an IP address through network segment matching, you cannot configure that IP address as a static peer. Before you configure an IP address as a static peer, make sure that IP address is not in the network segment to which any existing dynamic peer belongs. If the IP address belongs to a predefined dynamic-peer network segment, create that network segment as a dynamic peer only after you finish configuring the IP address as a static peer. For example, if you configure network segment 10.1.1.0/24 as a dynamic peer and the local device establishes a BGP connection with 10.1.1.1, you cannot configure 10.1.1.1 as a static peer. In contrast, if you first configure 10.1.1.1 as a static peer, you can continue to configure network segment 10.1.1.0/24 as a dynamic peer.

Exchanging IPv4 unicast routes with dynamic IPv4 peers

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Specify devices in a network as a dynamic BGP peer and specify one or multiple AS numbers for the peer. Choose one of the following options:
   - Specify a single AS number for the dynamic peer.

     peer *ipv4-address mask-length* **as-number** *as-number*
   - Specify multiple AS numbers for the dynamic peer.

     peer *ipv4-address mask-length* **listen-as** *as-number-list*
   - Specify an AS number range for the dynamic peer.

     peer *ipv4-address mask-length* **listen-as-segment begin-as** *as-number* **end-as** *as-number*

4. (Optional.) Configure a description for dynamic BGP peers.

   peer *ipv4-address mask-length* **description** *text*

   By default, no description is configured for dynamic BGP peers.

5. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]

6. Enable BGP to exchange IPv4 unicast routing information with dynamic BGP peers in the specified network.

   peer *ipv4-address mask-length* **enable**

   By default, BGP cannot exchange IPv4 unicast routing information with dynamic BGP peers.

Exchanging IPv6 unicast routes with dynamic IPv4 peers

1. Enter system view.

system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Specify devices in an IPv4 network as a dynamic IPv4 BGP peer and specify one or multiple AS numbers for the peer. Choose one of the following options:
   - Specify a single AS number for the dynamic peer.
     peer *ipv4-address mask-length* **as-number** *as-number*
   - Specify multiple AS numbers for the dynamic peer.
     peer *ipv4-address mask-length* **listen-as** *as-number-list*
   - Specify an AS number range for the dynamic peer.
     peer *ipv4-address mask-length* **listen-as-segment begin-as** *as-number* **end-as** *as-number*
4. (Optional.) Configure a description for the dynamic IPv4 peers.
   peer *ipv4-address mask-length* **description** *text*
   By default, no description is configured for dynamic IPv4 peers.
5. Create the BGP IPv6 unicast address family and enter its view.
   address-family ipv6 [**unicast**]
6. Enable BGP to exchange IPv6 unicast routing information with the dynamic IPv4 peers.
   peer *ipv4-address mask-length* **enable**
   By default, BGP cannot exchange IPv6 unicast routing information with dynamic IPv4 peers.
7. Use a routing policy to modify the next hop of routes received from the dynamic IPv4 peers.
   peer *ipv4-address mask-length* **route-policy** *route-policy-name* **import**

Exchanging IPv6 unicast routes with dynamic IPv6 peers

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Specify devices in a network as a dynamic BGP peer and specify one or multiple AS numbers for the peer. Choose one of the following options:
   - Specify a single AS number for the dynamic peer.
     peer { *ipv6-address prefix-length* | *link-local-address* **interface** *interface-type interface-number* } **as-number** *as-number*
   - Specify multiple AS numbers for the dynamic peer.
     peer *ipv6-address prefix-length* **listen-as** *as-number-list*
   - Specify an AS number range for the dynamic peer.

peer *ipv6-address prefix-length* **listen-as-segment begin-as** *as-number* **end-as** *as-number*

4. (Optional.) Configure a description for dynamic BGP peers.

   peer { *ipv6-address prefix-length* | *link-local-address* **interface** *interface-type interface-number* } **description** *text*

   By default, no description is configured for dynamic BGP peers.

5. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.

   address-family ipv6 [**unicast**]

6. Enable BGP to exchange IPv6 unicast routing information with dynamic BGP peers in the specified network.

   peer { *ipv6-address prefix-length* | *link-local-address* **interface** *interface-type interface-number* } **enable**

   By default, BGP cannot exchange IPv6 unicast routing information with dynamic BGP peers.

Exchanging IPv4 unicast routes with dynamic IPv6 peers

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Specify devices in an IPv6 network as a dynamic IPv6 BGP peer and specify one or multiple AS numbers for the peer. Choose one of the following options:
   - Specify a single AS number for the dynamic peer.

     peer *ipv6-address prefix-length* **as-number** *as-number*
   - Specify multiple AS numbers for the dynamic peer.

     peer *ipv6-address prefix-length* **listen-as** *as-number-list*
   - Specify an AS number range for the dynamic peer.

     peer *ipv6-address prefix-length* **listen-as-segment begin-as** *as-number* **end-as** *as-number*

4. (Optional.) Configure a description for the dynamic IPv6 peers.

   peer *ipv6-address prefix-length* **description** *text*

   By default, no description is configured for dynamic IPv6 peers.

5. Create the BGP IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]

6. Enable BGP to exchange IPv4 unicast routing information with the dynamic IPv6 peers.

   peer *ipv6-address prefix-length* **enable**

   By default, BGP cannot exchange IPv4 unicast routing information with dynamic IPv6 peers.

7. Use a routing policy to modify the next hop of routes received from the dynamic IPv6 peers.

   peer *ipv6-address mask-length* **route-policy** *route-policy-name* **import**

Exchanging IPv4 multicast routes with dynamic IPv4 peers

1. Enter system view.

system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Specify devices in a network as a dynamic BGP peer and specify one or multiple AS numbers for the peer. Choose one of the following options:
   - Specify a single AS number for the dynamic peer.

     peer *ipv4-address mask-length* **as-number** *as-number*
   - Specify multiple AS numbers for the dynamic peer.

     peer *ipv4-address mask-length* **listen-as** *as-number-list*
   - Specify an AS number range for the dynamic peer.

     peer *ipv4-address mask-length* **listen-as-segment begin-as** *as-number* **end-as** *as-number*

4. (Optional.) Configure a description for dynamic BGP peers.

   peer *ipv4-address mask-length* **description** *text*

   By default, no description is configured for dynamic BGP peers.

5. Create the BGP IPv4 multicast address family and enter its view.

   address-family ipv4 multicast

6. Enable BGP to exchange IPv4 unicast routing information used for RPF check with dynamic BGP peers in the specified network.

   peer *ipv4-address mask-length* **enable**

   By default, BGP cannot exchange IPv4 unicast routing information used for RPF check with dynamic BGP peers.

Exchanging IPv6 multicast routes with dynamic IPv6 peers

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Specify devices in a network as a dynamic BGP peer and specify one or multiple AS numbers for the peer. Choose one of the following options:
   - Specify a single AS number for the dynamic peer.

     peer *ipv6-address prefix-length* **as-number** *as-number*
   - Specify multiple AS numbers for the dynamic peer.

     peer *ipv6-address prefix-length* **listen-as** *as-number-list*
   - Specify an AS number range for the dynamic peer.

     peer *ipv6-address prefix-length* **listen-as-segment begin-as** *as-number* **end-as** *as-number*

4. (Optional.) Configure a description for dynamic BGP peers.

   peer *ipv6-address prefix-length* **description** *text*

   By default, no description is configured for dynamic BGP peers.

5. Create the BGP IPv6 multicast address family and enter its view.

   address-family ipv6 multicast

6. Enable BGP to exchange IPv6 unicast routing information used for RPF check with dynamic BGP peers in the specified network.

   peer *ipv6-address prefix-length* **enable**

By default, BGP cannot exchange IPv6 unicast routing information used for RPF check with dynamic BGP peers.

Setting the maximum number of dynamic BGP peer sessions that BGP can establish

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Configure the maximum number of dynamic BGP peer sessions that BGP can establish.
   dynamic-peer-limit *max-peer-number*

   By default, the number of dynamic BGP peer sessions is not limited.

   If you execute this command multiple times for a BGP instance, the most recent configuration takes effect.

Configuring an IBGP peer group

About this task

A peer group is an IBGP peer group if peers in it belong to the same AS as the local router.

After you create an IBGP peer group and then add a peer into it, the system creates the peer in BGP instance view and specifies the local AS number for the peer.

Restrictions and guidelines

A BGP peer at an IPv6 link-local address must be directly connected to the local router. If you do not specify the interface connected to the peer, you must specify the interface directly connected to the BGP peer as the source interface of TCP connections on the local router.

To exchange IPv4 routes with an IPv6 peer or exchange IPv6 routes with an IPv4 peer, you must configure a routing policy to perform the following tasks:

- Change the next hop of IPv4 routes received from the IPv6 peer to the IPv4 address of the interface that connects the IPv6 peer to the local router.
- Change the next hop of IPv6 routes received from the IPv4 peer to the IPv6 address of the interface that connects the IPv4 peer to the local router.

If you configure a BGP setting at both the peer group and the peer level, the most recent configuration takes effect on the peer.

Procedure (Exchanging IPv4 unicast routes with IPv4 peers)

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Create an IBGP peer group.
   group *group-name* [**internal**]
4. Add a peer into the IBGP peer group.
   peer *ipv4-address* [*mask-length*] **group** *group-name* [**as-number** *as-number*]

The **as-number** *as-number* option must specify the local AS number.

5. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

6. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]

7. Enable the router to exchange IPv4 unicast routing information with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv4 unicast routing information with the peers.

Procedure (Exchanging IPv6 unicast routes with IPv4 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an IBGP peer group.

   group *group-name* [**internal**]

4. Add an IPv4 peer into the IBGP peer group.

   peer *ipv4-address* [*mask-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the local AS number.

5. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for a peer group.

6. Create the BGP IPv6 unicast address family and enter its view.

   address-family ipv6 [**unicast**]

7. Enable BGP to exchange IPv6 unicast routing information with peers in the peer group.

   peer *group-name* **enable**

   By default, BGP cannot exchange IPv6 unicast routing information with peers in a peer group.

8. Use a routing policy to modify the next hop of routes received from peers in the peer group.

   peer *group-name* **route-policy** *route-policy-name* **import**

Procedure (Exchanging IPv4 multicast routes with IPv4 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Create an IBGP peer group.

   group *group-name* [**internal**]

4. Add an IPv4 peer into the IBGP peer group.

   peer *ipv4-address* [*mask-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the local AS number.

5. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

6. Create the BGP IPv4 multicast address family and enter its view.

   address-family ipv4 multicast

7. Enable the router to exchange IPv4 unicast routing information used for RPF check with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv4 unicast routing information used for RPF check with the peers in the peer group.

Procedure (Exchanging IPv6 unicast routes with IPv6 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an IBGP peer group.

   group *group-name* [**internal**]

4. Add a peer into the IBGP peer group. Choose the options to configure as needed:
   - Specify a peer by its address.

     peer { *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **group** *group-name* [**as-number** *as-number*]
   - Specify peers that are established through link-local addresses that the specified interface learned in ND entries.

     interface-peer *interface-type interface-number* **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the local AS number.

5. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

6. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.

   address-family ipv6 [**unicast**]

7. Enable the router to exchange IPv6 unicast routing information with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv6 unicast routing information with the peers.

Procedure (Exchanging IPv4 unicast routes with IPv6 peers)

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Create an IBGP peer group.
   group *group-name* [**internal**]
4. Add an IPv6 peer into the IBGP peer group. Choose the options to configure as needed:
   - Specify a peer by its address.
     peer *ipv6-address* [*prefix-length*] **group** *group-name* [**as-number** *as-number*]
   - Specify peers that are established through link-local addresses that the specified interface learned in ND entries.
     interface-peer *interface-type interface-number* **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the local AS number.
5. (Optional.) Configure a description for the peer group.
   peer *group-name* **description** *text*

   By default, no description is configured for a peer group.
6. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.
   address-family ipv4 [**unicast**]
7. Enable BGP to exchange IPv4 unicast routing information with peers in the peer group.
   peer *group-name* **enable**

   By default, BGP cannot exchange IPv4 unicast routing information with peers in a peer group.
8. Use a routing policy to modify the next hop of routes received from peers in the peer group.
   peer *group-name* **route-policy** *route-policy-name* **import**

Procedure (Exchanging IPv6 multicast routes with IPv6 peers)

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Create an IBGP peer group.
   group *group-name* [**internal**]
4. Add a peer into the IBGP peer group.
   peer *ipv6-address* [*prefix-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the local AS number.
5. (Optional.) Configure a description for the peer group.
   peer *group-name* **description** *text*

By default, no description is configured for the peer group.

6. Create the BGP IPv6 multicast address family and enter its view.

   address-family ipv6 multicast

7. Enable the router to exchange IPv6 unicast routing information used for RPF check with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv6 unicast routing information used for RPF check with the peers in the peer group.

Configuring an EBGP peer group

About this task

A peer group is an EBGP peer group if peers in it belong to different ASs.

If peers in an EBGP group belong to the same external AS, the EBGP peer group is a pure EBGP peer group. If not, it is a mixed EBGP peer group.

Restrictions and guidelines

Use one of the following methods to configure an EBGP peer group:

- **Method 1**—Create an EBGP peer group, specify its AS number, and add peers into it. All the added peers have the same AS number. All peers in the peer group have the same AS number as the peer group. You can specify an AS number for a peer before adding it into the peer group. The AS number must be the same as that of the peer group.
- **Method 2**—Create an EBGP peer group, specify an AS number for a peer, and add the peer into the peer group. Peers added in the group can have different AS numbers.
- **Method 3**—Create an EBGP peer group and add a peer with an AS number into it. Peers added in the group can have different AS numbers.

To exchange IPv4 routes with an IPv6 peer or exchange IPv6 routes with an IPv4 peer, you must configure a routing policy to perform the following tasks:

- Change the next hop of IPv4 routes received from the IPv6 peer to the IPv4 address of the interface that connects the IPv6 peer to the local router.
- Change the next hop of IPv6 routes received from the IPv4 peer to the IPv6 address of the interface that connects the IPv4 peer to the local router.

If you configure a BGP setting at both the peer group and the peer level, the most recent configuration takes effect on the peer.

Configuring an EBGP peer group by using Method 1 (Exchanging IPv4 unicast routes with IPv4 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an EBGP peer group.

   group *group-name* **external**

4. Specify the AS number of the group.

peer *group-name* **as-number** *as-number*

By default, no AS number is specified.

If a peer group contains peers, you cannot remove or change its AS number.

5. Add a peer into the EBGP peer group.

   peer *ipv4-address* [*mask-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the same AS number as the **peer** *group-name* **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

7. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]

8. Enable the router to exchange IPv4 unicast routing information with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv4 unicast routing information with the peers.

Configuring an EBGP peer group by using Method 2 (Exchanging IPv4 unicast routes with IPv4 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an EBGP peer group.

   group *group-name* **external**

4. Create an IPv4 BGP peer and specify its AS number.

   peer *ipv4-address* [*mask-length*] **as-number** *as-number*

5. Add the peer into the EBGP peer group.

   peer *ipv4-address* [*mask-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the same AS number as the **peer** *ipv4-address* [*mask-length*] **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

7. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]

8. Enable the router to exchange IPv4 unicast routing information with peers in the specified peer group.

peer *group-name* **enable**

By default, the router cannot exchange IPv4 unicast routing information with the peers.

Configuring an EBGP peer group by using Method 3 (Exchanging IPv4 unicast routes with IPv4 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Create an EBGP peer group.

   group *group-name* **external**
4. Add a peer into the EBGP peer group.

   peer *ipv4-address* [*mask-length*] **group** *group-name* **as-number** *as-number*
5. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.
6. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]
7. Enable the router to exchange IPv4 unicast routing information with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv4 unicast routing information with the peers.

Configuring an EBGP peer group by using Method 1 (Exchanging IPv6 unicast routes with IPv4 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Create an EBGP peer group.

   group *group-name* **external**
4. Specify an AS number for the peer group.

   peer *group-name* **as-number** *as-number*

   By default, no AS number is specified for a peer group.

   If a peer group contains peers, you cannot remove or change its AS number.
5. Add an IPv4 peer into the EBGP peer group.

peer *ipv4-address* [*mask-length*] **group** *group-name* [**as-number** *as-number*]

The **as-number** *as-number* option must specify the same AS number as the **peer** *group-name* **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for a peer group.

7. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.

   address-family ipv6 [**unicast**]

8. Enable BGP to exchange IPv6 unicast routing information with peers in the peer group.

   peer *group-name* **enable**

   By default, BGP cannot exchange IPv6 unicast routing information with peers in a peer group.

9. Use a routing policy to modify the next hop of routes received from peers in the peer group.

   peer *group-name* **route-policy** *route-policy-name* **import**

Configuring an EBGP peer group by using Method 2 (Exchanging IPv6 unicast routes with IPv4 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an EBGP peer group.

   group *group-name* **external**

4. Create an IPv4 BGP peer and specify its AS number.

   peer *ipv4-address* [*mask-length*] **as-number** *as-number*

5. Add the IPv4 peer into the EBGP peer group.

   peer *ipv4-address* [*mask-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the same AS number as the **peer** *ipv4-address* [*mask-length*] **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for a peer group.

7. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.

   address-family ipv6 [**unicast**]

8. Enable BGP to exchange IPv6 unicast routing information with peers in the peer group.

   peer *group-name* **enable**

   By default, BGP cannot exchange IPv6 unicast routing information with peers in a peer group.

9. Use a routing policy to modify the next hop of routes received from peers in the peer group.

   peer *group-name* **route-policy** *route-policy-name* **import**

Configuring an EBGP peer group by using Method 3 (Exchanging IPv6 unicast routes with IPv4 peers)

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Create an EBGP peer group.
   group *group-name* **external**
4. Add an IPv4 peer into the EBGP peer group.
   peer *ipv4-address* [*mask-length*] **group** *group-name* **as-number** *as-number*
5. (Optional.) Configure a description for the peer group.
   peer *group-name* **description** *text*

   By default, no description is configured for a peer group.
6. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.
   address-family ipv6 [**unicast**]
7. Enable BGP to exchange IPv6 unicast routing information with peers in the peer group.
   peer *group-name* **enable**

   By default, BGP cannot exchange IPv6 unicast routing information with peers in a peer group.
8. Use a routing policy to modify the next hop of routes received from peers in the peer group.
   peer *group-name* **route-policy** *route-policy-name* **import**

Configuring an EBGP peer group by using Method 1 (Exchanging IPv4 multicast routes with IPv4 peers)

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Create an EBGP peer group.
   group *group-name* **external**
4. Specify the AS number of the group.
   peer *group-name* **as-number** *as-number*

   By default, no AS number is specified.

   If a peer group contains peers, you cannot remove or change its AS number.
5. Add an IPv4 BGP peer into the EBGP peer group.
   peer *ipv4-address* [*mask-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the same AS number as the **peer** *group-name* **as-number** *as-number* command.
6. (Optional.) Configure a description for the peer group.
   peer *group-name* **description** *text*

By default, no description is configured for the peer group.

7. Create the BGP IPv4 multicast address family and enter its view.

   address-family ipv4 multicast

8. Enable the router to exchange IPv4 unicast routing information used for RPF check with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv4 unicast routing information used for RPF check with the peers in the group.

Configuring an EBGP peer group by using Method 2 (Exchanging IPv4 multicast routes with IPv4 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Create an EBGP peer group.

   group *group-name* **external**

4. Create an IPv4 BGP peer and specify its AS number.

   peer *ipv4-address* [*mask-length*] **as-number** *as-number*

5. Add the peer into the EBGP peer group.

   peer *ipv4-address* [*mask-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the same AS number as the **peer** *ipv4-address* [*mask-length*] **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

7. Create the BGP IPv4 multicast address family and enter its view.

   address-family ipv4 multicast

8. Enable the router to exchange IPv4 unicast routing information used for RPF check with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv4 unicast routing information used for RPF check with the peers in the group.

Configuring an EBGP peer group by using Method 3 (Exchanging IPv4 multicast routes with IPv4 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Create an EBGP peer group.

   group *group-name* **external**

4. Add an IPv4 BGP peer into the EBGP peer group.

   peer *ipv4-address* [*mask-length*] **group** *group-name* **as-number** *as-number*

5. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

By default, no description is configured for the peer group.

6. Create the BGP IPv4 multicast address family and enter its view.

   address-family ipv4 multicast

7. Enable the router to exchange IPv4 unicast routing information used for RPF check with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv4 unicast routing information used for RPF check with the peers.

Configuring an EBGP peer group by using Method 1 (Exchanging IPv6 unicast routes with IPv6 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an EBGP peer group.

   group *group-name* **external**

4. Specify the AS number of the group.

   peer *group-name* **as-number** *as-number*

   By default, no AS number is specified.

   If a peer group contains peers, you cannot remove or change its AS number.

5. Add a peer into the EBGP peer group. Choose the options to configure as needed:
   - Specify a peer by its address.

     peer { *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **group** *group-name* [**as-number** *as-number*]
   - Specify peers that are established through link-local addresses that the specified interface learned in ND entries.

     interface-peer *interface-type interface-number* **group** *group-name* [**as-number** *as-number*]

     The **as-number** *as-number* option must specify the same AS number as the **peer** *group-name* **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

7. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.

   address-family ipv6 [**unicast**]

8. Enable the router to exchange IPv6 unicast routing information with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv6 unicast routing information with the peers.

Configuring an EBGP peer group by using Method 2 (Exchanging IPv6 unicast routes with IPv6 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an EBGP peer group.

   group *group-name* **external**

4. Create an IPv6 BGP peer and specify its AS number. Choose the options to configure as needed:
   - Specify a peer by its address.

     peer { *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **as-number** *as-number*
   - Specify a peer by its directly connected interface. The address of the peer is the link-local address on an ND entry learned by the interface.

     interface-peer *interface-type interface-number* **as-number** *as-number*

5. Add the peer into the EBGP peer group. Choose the options to configure based on the configuration of the above step:
   - Specify a peer by its address.

     peer { *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **group** *group-name* [**as-number** *as-number*]

     The **as-number** *as-number* option must specify the same AS number as the **peer** *ipv6-address* [*prefix-length*] **as-number** *as-number* command.
   - Specify peers that are established through link-local addresses that the specified interface learned in ND entries.

     interface-peer *interface-type interface-number* **group** *group-name* [**as-number** *as-number*]

     The **as-number** *as-number* option must specify the same AS number as the **interface-peer** *interface-type interface-number* **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

7. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.

   address-family ipv6 [**unicast**]

8. Enable the router to exchange IPv6 unicast routing information with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv6 unicast routing information with the peers.

Configuring an EBGP peer group by using Method 3 (Exchanging IPv6 unicast routes with IPv6 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an EBGP peer group.

   group *group-name* **external**

4. Add the peer into the EBGP peer group. Choose the options to configure as needed:
   - Specify a peer by its address.

     peer { *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **group** *group-name* **as-number** *as-number*
   - Specify peers that are established through link-local addresses that the specified interface learned in ND entries.

     interface-peer *interface-type interface-number* **group** *group-name* [**as-number** *as-number*]

5. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

6. Create the BGP IPv6 unicast address family or BGP-VPN IPv6 unicast address family and enter its view.

   address-family ipv6 [**unicast**]

7. Enable the router to exchange IPv6 unicast routing information with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv6 unicast routing information with the peers.

Configuring an EBGP peer group by using Method 1 (Exchanging IPv4 unicast routes with IPv6 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Create an EBGP peer group.

   group *group-name* **external**

4. Specify an AS number for the peer group.

   peer *group-name* **as-number** *as-number*

By default, no AS number is specified for a peer group.

If a peer group contains peers, you cannot remove or change its AS number.

5. Add an IPv6 peer into the EBGP peer group. Choose the options to configure as needed:
   - Specify a peer by its address.

     peer *ipv6-address* [*prefix-length*] **group** *group-name* [**as-number** *as-number*]
   - Specify peers that are established through link-local addresses that the specified interface learned in ND entries.

     interface-peer *interface-type interface-number* **group** *group-name* [**as-number** *as-number*]

     The **as-number** *as-number* option must specify the same AS number as the **peer** *group-name* **as-number** *as-number* command.
6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for a peer group.
7. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]
8. Enable BGP to exchange IPv4 unicast routing information with peers in the peer group.

   peer *group-name* **enable**

   By default, BGP cannot exchange IPv4 unicast routing information with peers in a peer group.
9. Use a routing policy to modify the next hop of routes received from peers in the peer group.

   peer *group-name* **route-policy** *route-policy-name* **import**

Configuring an EBGP peer group by using Method 2 (Exchanging IPv4 unicast routes with IPv6 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Create an EBGP peer group.

   group *group-name* **external**
4. Create an IPv6 BGP peer and specify its AS number. Choose the options to configure as needed:
   - Specify a peer by its address.

     peer *ipv6-address* [*prefix-length*] **as-number** *as-number*
   - Specify peers that are established through link-local addresses that the specified interface learned in ND entries.

     interface-peer *interface-type interface-number* **as-number** *as-number*
5. Add the IPv6 peer into the EBGP peer group. Choose the options to configure based on the configuration of the above step:

- Specify a peer by its address.

  peer *ipv6-address* [*prefix-length*] **group** *group-name* [**as-number** *as-number*]

  The **as-number** *as-number* option must specify the same AS number as the **peer** *ipv6-address* [*prefix-length*] **as-number** *as-number* command.
- Specify peers that are established through link-local addresses that the specified interface learned in ND entries.

  interface-peer *interface-type interface-number* **group** *group-name* [**as-number** *as-number*]

  The **as-number** *as-number* option must specify the same AS number as the **interface-peer** *interface-type interface-number* **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for a peer group.
7. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]
8. Enable BGP to exchange IPv4 unicast routing information with peers in the peer group.

   peer *group-name* **enable**

   By default, BGP cannot exchange IPv4 unicast routing information with peers in a peer group.
9. Use a routing policy to modify the next hop of routes received from peers in the peer group.

   peer *group-name* **route-policy** *route-policy-name* **import**

Configuring an EBGP peer group by using Method 3 (Exchanging IPv4 unicast routes with IPv6 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Create an EBGP peer group.

   group *group-name* **external**
4. Add an IPv6 peer into the EBGP peer group. Choose the options to configure as needed:
   - Specify a peer by its address.

     peer *ipv6-address* [*prefix-length*] **group** *group-name* **as-number** *as-number*
   - Specify peers that are established through link-local addresses that the specified interface learned in ND entries.

     interface-peer *interface-type interface-number* **group** *group-name* **as-number** *as-number*
5. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for a peer group.

6. Create the BGP IPv4 unicast address family or BGP-VPN IPv4 unicast address family and enter its view.

   address-family ipv4 [**unicast**]

7. Enable BGP to exchange IPv4 unicast routing information with peers in the peer group.

   peer *group-name* **enable**

   By default, BGP cannot exchange IPv4 unicast routing information with peers in a peer group.

8. Use a routing policy to modify the next hop of routes received from peers in the peer group.

   peer *group-name* **route-policy** *route-policy-name* **import**

Configuring an EBGP peer group by using Method 1 (Exchanging IPv6 multicast routes with IPv6 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Create an EBGP peer group.

   group *group-name* **external**

4. Specify the AS number of the group.

   peer *group-name* **as-number** *as-number*

   By default, no AS number is specified.

   If a peer group contains peers, you cannot remove or change its AS number.

5. Add an IPv6 BGP peer into the EBGP peer group.

   peer *ipv6-address* [*prefix-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the same AS number as the **peer** *group-name* **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

7. Create the BGP IPv6 multicast address family and enter its view.

   address-family ipv6 multicast

8. Enable the router to exchange IPv6 unicast routing information used for RPF check with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv6 unicast routing information used for RPF check with the peers in the group.

Configuring an EBGP peer group by using Method 2 (Exchanging IPv6 multicast routes with IPv6 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Create an EBGP peer group.

   group *group-name* **external**

4. Create an IPv6 BGP peer and specify its AS number.

peer *ipv6-address* [*prefix-length*] **as-number** *as-number*

5. Add the peer into the EBGP peer group.

   peer *ipv6-address* [*prefix-length*] **group** *group-name* [**as-number** *as-number*]

   The **as-number** *as-number* option must specify the same AS number as the **peer** *ipv6-address* [*prefix-length*] **as-number** *as-number* command.

6. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

7. Create the BGP IPv6 multicast address family and enter its view.

   address-family ipv6 multicast

8. Enable the router to exchange IPv6 unicast routing information used for RPF check with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv6 unicast routing information used for RPF check with the peers in the group.

Configuring an EBGP peer group by using Method 3 (Exchanging IPv6 multicast routes with IPv6 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Create an EBGP peer group.

   group *group-name* **external**

4. Add an IPv6 BGP peer into the EBGP peer group.

   peer *ipv6-address* [*prefix-length*] **group** *group-name* **as-number** *as-number*

5. (Optional.) Configure a description for the peer group.

   peer *group-name* **description** *text*

   By default, no description is configured for the peer group.

6. Create the BGP IPv6 multicast address family and enter its view.

   address-family ipv6 multicast

7. Enable the router to exchange IPv6 unicast routing information used for RPF check with peers in the specified peer group.

   peer *group-name* **enable**

   By default, the router cannot exchange IPv6 unicast routing information used for RPF check with the peers in the group.

Specifying the source address of TCP connections

About this task

BGP uses TCP as the transport layer protocol. Perform this task in the following scenarios to specify the source address or source interface of TCP connections to a peer or peer group:

- The peer's IPv4/IPv6 address does not belong to the interface directly connected to the local router. To ensure successful TCP connection establishment, use one of the following methods:

- Specify the interface to which the IPv4/IPv6 address belongs as the source interface on the peer.
- Specify the IPv4/IPv6 address of the interface directly connected to the local router as the source address on the peer.

- A BGP peer at an IPv6 link-local address must be directly connected to the local router. If you do not specify the interface connected to the peer, you must specify the interface directly connected to the BGP peer as the source interface of TCP connections on the local router.
- On a BGP router that has multiple links to a peer, the source interface for TCP connection changes because the primary source interface fails. To avoid this problem, specify a loopback interface as the source interface or specify the IP address of a loopback interface as the source address.
- You want to establish multiple BGP sessions to a router. In this case, BGP might fail to determine the source address for each TCP connection based on the optimal route to the peer. To prevent this problem, use one of the following methods:
  - If the BGP sessions use IP addresses of different interfaces, specify a source interface or source address for each session.
  - If the BGP sessions use different IP addresses of the same interface, specify a source address for each session.

Restrictions and guidelines

BGP immediately tears down the session to an IBGP peer or peer group when the following conditions exist:

- The source interface of TCP connections to the IBGP peer or peer group is a physical interface.
- The source interface fails and the link to the IBGP peer or peer group goes down.

Procedure (IPv4 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Specify the source address or source interface of TCP connections to a peer or peer group.
   - Specify the source address of TCP connections to a peer or peer group.

     peer { *group-name* | *ipv4-address* [*mask-length*] } **source-address** *source-ipv4-address*
   - Specify the source interface of TCP connections to a peer or peer group.

     peer { *group-name* | *ipv4-address* [*mask-length*] } **connect-interface** *interface-type interface-number*

   By default, BGP uses the primary IPv4 address of the output interface in the optimal route to a peer or peer group as the source address of TCP connections to the peer or peer group.

Procedure (IPv6 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

bgp *as-number* [**instance** *instance-name*]

- Enter BGP-VPN instance view.

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

3. Specify the source IPv6 address or source interface of TCP connections to a peer or peer group.
   - Specify the source IPv6 address of TCP connections to a peer or peer group.

     peer { *group-name* | *ipv6-address* [*prefix-length*] } **source-address** *source-ipv6-address*
   - Specify the source interface of TCP connections to a peer or peer group.

     peer { *group-name* | *ipv6-address* [*prefix-length*] } **connect-interface** *interface-type interface-number*

   By default, BGP uses the IPv6 address of the output interface in the optimal route to the BGP peer or peer group as the source address of TCP connections to the peer or peer group.

Controlling BGP route generation

Injecting a local network

About this task

Perform this task to inject a network in the local routing table to the BGP routing table, so BGP can advertise the network to BGP peers. The ORIGIN attribute of BGP routes advertised in this way is IGP. You can also use a routing policy to control route advertisement.

The specified network must be available and active in the local IP routing table.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast
3. Configure BGP to advertise a local network.

   network *ipv4-address* [*mask-length* | *mask*] [**route-policy** *route-policy-name*]

   By default, BGP does not advertise local networks.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast

3. Configure BGP to advertise a local network.

   network *ipv6-address prefix-length* [**route-policy** *route-policy-name*]

   By default, BGP does not advertise local networks.

Redistributing IGP routes

About this task

Perform this task to configure route redistribution from an IGP to BGP.

By default, BGP does not redistribute default IGP routes. You can use the **default-route imported** command to redistribute default IGP routes into the BGP routing table.

The ORIGIN attribute of BGP routes redistributed from IGPs is INCOMPLETE.

Only active routes can be redistributed. To view route state information, use the **display ip routing-table protocol** or **display ipv6 routing-table protocol** command. For more information about the commands, see *Layer 3—IP Routing Command Reference*.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

address-family ipv4 [**unicast**]

- Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv4 multicast

3. Enable route redistribution from the specified IGP into BGP.
   - Redistribute **IS-IS, OSPF, or RIP routes.**

     import-route { **isis** | **ospf** | **rip** } [{ *process-id* | **all-processes** } [**allow-direct** | **med** *med-value* | **route-policy** *route-policy-name*] *]
   - Redistribute direct or static routes.

     import-route { **direct** | **static** } [**med** *med-value* | **route-policy** *route-policy-name*] *

   By default, BGP does not redistribute IGP routes.
4. (Optional.) Redistribute all routes with the same destination address.

   import-route multipath

   This command is not supported in BGP IPv4 multicast address family view.

   By default, BGP redistributes only the optimal routes to its routing table when multiple routes with the same destination address exist.

   This command takes effect only on the routes redistributed by the **import-route** command in the same address family.
5. (Optional.) Enable default route redistribution into BGP.

   default-route imported

   By default, BGP does not redistribute default routes.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
3. Enable route redistribution from the specified IGP into BGP.
   - Redistribute IPv6 **IS-IS, OSPFv3, or RIPng routes.**

     import-route { **isisv6** | **ospfv3** | **ripng** } [{ *process-id* | **all-processes** } [**allow-direct** | **med** *med-value* | **route-policy** *route-policy-name*] *]

- Redistribute direct or static routes.

  import-route { **direct** | **static** } [**med** *med-value* | **route-policy** *route-policy-name*] *

By default, BGP does not redistribute IGP routes.

4. (Optional.) Redistribute all routes with the same destination address.

   import-route multipath

   This command is not supported in BGP IPv6 multicast address family view.

   By default, BGP redistributes only the optimal routes to its routing table when multiple routes with the same destination address exist.

   This command takes effect only on the routes redistributed by the **import-route** command in the same address family.

5. (Optional.) Enable default route redistribution into BGP.

   default-route imported

   By default, BGP does not redistribute default routes.

Configuring BGP route summarization

About this task

Route summarization can reduce the number of redistributed routes and the routing table size. IPv4 BGP supports automatic route summarization and manual route summarization. Manual summarization takes precedence over automatic summarization. IPv6 BGP supports only manual route summarization.

Automatic route summarization enables BGP to summarize IGP subnet routes redistributed by the **import-route** command, so BGP advertises only natural network routes.

By configuring manual route summarization, you can do the following:

- Summarize both redistributed routes and routes injected using the **network** command.
- Determine the mask length for a summary route.

Restrictions and guidelines for configuring BGP route summarization

The output interface of a BGP summary route is Null 0 on the originating router. Therefore, a summary route must not be an optimal route on the originating router. Otherwise, BGP will fail to forward packets matching the route. If a summarized specific route has the same mask as the summary route, but has a lower priority, the summary route becomes the optimal route. To ensure correct packet forwarding, change the priority of the summary or specific route to make the specific route the optimal route.

Configuring automatic route summarization (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

ip vpn-instance *vpn-instance-name*

address-family ipv4 [**unicast**]

- Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv4 multicast

3. Configure automatic route summarization.

   summary automatic

   By default, automatic route summarization is not configured.

Configuring manual route summarization (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Create a summary route in the BGP routing table.

   aggregate *ipv4-address* { *mask-length* | *mask* } [**as-set** | **attribute-policy** *route-policy-name* | **detail-suppressed** | **origin-policy** *route-policy-name* | **suppress-policy** *route-policy-name*] *

   By default, no summary routes are configured.

Configuring BGP manual route summarization (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

ip vpn-instance *vpn-instance-name*

address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv6 multicast

3. Create a summary route in the IPv6 BGP routing table.

   aggregate *ipv6-address prefix-length* [**as-set** | **attribute-policy** *route-policy-name* | **detail-suppressed** | **origin-policy** *route-policy-name* | **suppress-policy** *route-policy-name*] *

   By default, no summary routes are configured.

Advertising a default route to a peer or peer group

About this task

Perform this task to advertise a default BGP route with the next hop being the advertising router to a peer or peer group.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Advertise a default route to a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **default-route-advertise** [**route-policy** *route-policy-name*]

   interface-peer *interface-type interface-number* **default-route-advertise** [**route-policy** *route-policy-name*]

   By default, no default route is advertised.

   The *ipv6-address* [*prefix-length*] argument and the **interface-peer** command are not supported in BGP IPv4 multicast address family view.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
3. Advertise a default route to a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **default-route-advertise** [**route-policy** *route-policy-name*]

   interface-peer *interface-type interface-number* **default-route-advertise** [**route-policy** *route-policy-name*]

   By default, no default route is advertised.

   The *ipv4-address* [*mask-length*] and *link-local-address* **interface** *interface-type interface-number* options and the **interface-peer** command are not supported in BGP IPv6 multicast address family view.

Controlling BGP route advertisement

Advertising optimal routes in the IP routing table

About this task

By default, BGP advertises optimal routes in the BGP routing table, which may not be optimal in the IP routing table. This task allows you to advertise BGP routes that are optimal in the IP routing table

Restrictions and guidelines

The **advertise-rib-active** command does not apply to the following routes:

- Routes redistributed by using the **import-route** command.
- Routes advertised by using the **network** command.
- Default routes redistributed by using the **default-route imported** command.
- VPNv4 routes.
- VPNv6 routes.
- IPv4 multicast routes.
- IPv6 multicast routes.

The **advertise-rib-active** command takes effect only on the routes generated after you execute this command. To apply this command to existing routes, use the **reset bgp** command to reset BGP sessions.

The configuration of the **advertise-rib-active** command in BGP unicast address family view applies when it is different from that in BGP instance view.

The **advertise-rib-active** command is mutually exclusive with the **routing-table bgp-rib-only** command.

Procedure (IPv4 unicast)

1. Enter system view.

   system-view
2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
3. Enable BGP to advertise optimal routes in the IP routing table.

   advertise-rib-active

   By default, BGP advertises optimal routes in the BGP routing table.
4. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.
   - Enter BGP IPv4 unicast address family view.

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
5. Enable BGP to advertise optimal routes in the IP routing table of the address family in the VPN instance.

   advertise-rib-active

   By default, the setting is the same as that in BGP instance view.

Procedure (IPv6 unicast)

1. Enter system view.

   system-view
2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
3. Enable BGP to advertise optimal routes in the IPv6 routing table.

   advertise-rib-active

   By default, BGP advertises optimal routes in the BGP routing table.
4. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.
   - Enter BGP IPv6 unicast address family view.

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
5. Enable BGP to advertise optimal routes in the IPv6 routing table of the address family in the VPN instance.

   advertise-rib-active

By default, the setting is the same as that in BGP instance view.

Enabling prioritized withdrawal of the default route

About this task

Typically a BGP router does not send withdrawal messages of the default route prior to other routes to its peers. If the peer relationship is down, the default route cannot be withdrawn first. Traffic interruption might occur. Perform this task to configure BGP to send the withdrawal messages of the default route prior to other routes. This can reduce the traffic interruption time when the peer relationship is down.

Procedure

1. Enter system view.

   system-view
2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
3. Enable BGP to send withdrawal messages of the default route prior to other routes.

   default-route update-first

   By default, BGP does not send withdrawal messages of the default route prior to other routes.

Enabling prioritized withdrawal of specific routes

About this task

Perform this task to configure BGP to send the withdrawal messages of specific routes prior to other routes. This can achieve fast route switchover and reduce the traffic interruption time.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast
3. Enable BGP to send withdrawal messages of routes matching the specified routing policy prior to other routes.

   update-first route-policy *route-policy-name*

   By default, BGP does not send withdrawal messages of specific routes prior to other routes.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
3. Enable BGP to send withdrawal messages of routes matching the specified routing policy prior to other routes.

   update-first route-policy *route-policy-name*

   By default, BGP does not send withdrawal messages of specific routes prior to other routes.

Configuring BGP route distribution filtering policies

About this task

To configure BGP route distribution filtering policies, use the following methods:

- Use an ACL or prefix list to filter routing information advertised to all peers.
- Use a routing policy, conditional advertisement policy (existent policy or nonexistent policy), ACL, AS path list, or prefix list to filter routing information advertised to a peer or peer group.

If you configure multiple filtering policies, apply them in the following sequence:

1. **peer prefix-list export**
2. **peer as-path-acl export**
3. **filter-policy export**
4. **peer filter-policy export**
5. **peer advertise-policy exist-policy**
6. **peer advertise-policy non-exist-policy**
7. **peer route-policy export**

Only routes passing all the configured policies can be advertised.

Prerequisites

Before you configure BGP routing filtering policies, configure the following filters used for route filtering as needed:

- ACL (see *ACL and QoS Configuration Guide*).
- Prefix list (see "Configuring routing policies").

- Routing policy (see "Configuring routing policies").
- AS path list (see "Configuring routing policies").

Restrictions and guidelines

When you specify an ACL, prefix list, or routing policy as a filtering policy to filter BGP routing information, follow these guidelines:

- If the specified ACL, prefix list, or routing policy does not exist, all BGP routes can pass the filtering policy.
- When you specify an ACL or prefix list as a BGP route filtering policy (for example, use **filter-policy export** to specify an ACL for route filtering), the following rules apply:
  - BGP routes can pass the filtering policy only when one of the following conditions exists:
    - They match a **permit** rule in the specified ACL.
    - They match a **permit** item in the specified prefix list.

    When the ACL has only **deny** rules or the prefix list has only **deny** items, no BGP routes can pass the filtering policy.
  - When the ACL match order is **config**, BGP routes match against rules in ascending order of rule ID. When BGP routes match against the items of the prefix list, an item with a smaller index number is matched first.
  - In either of the match modes above, a BGP route does not match against the next ACL rule or prefix list item when it already matches the current ACL rule or prefix list item. To avoid wasting filter resources, set a small match range for each ACL rule or prefix list item when you configure multiple ACL rules or prefix list items for an ACL or prefix list.
  - You can use the **rule** [*rule-id*] **permit ip source** *sour-addr sour-wildcard* **destination** *dest-addr dest-wildcard* command to create a rule for an advanced ACL to match specific routes. The **source** *sour-addr* option represents the destination network address and the **destination** *dest-addr* option represents the mask in dotted decimal notation. For example, to match route 3.3.3.0/24, the rule configuration should be **rule** [*rule-id*] **permit ip source** *3.3.3.0 0.0.0.255* **destination** *255.255.255.0 0.0.0.255*.
- When you specify a routing policy as a BGP route filtering policy, the following rules apply:
  - BGP routes can pass the filtering policy only when they match a **permit** node in the routing policy.
  - A BGP route matches against the nodes of the routing policy in ascending order of node number. It does not match against the next node when it already matches the current node (unless a continue clause exists).
  - When a BGP route matches against a node that has an ACL or prefix-list **if-match** clause, it can pass the filtering policy only when the following conditions exist:
    - The route matches a **permit** rule in the ACL or a **permit** item in the prefix list.
    - The route matches a **permit** node in the routing policy.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

- Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

  address-family ipv4 [**unicast**]

- Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv4 multicast

3. Configure BGP route distribution filtering policies. Choose the options to configure as needed:

- Reference an ACL or IP prefix list to filter advertised BGP routes.

  filter-policy { *ipv4-acl-number* | **name** *ipv4-acl-name* | **prefix-list** *ipv4-prefix-list-name* } **export** [**direct** | { **isis** | **ospf** | **rip** } *process-id* | **static**]

- Specify a routing policy as the existent policy to control route advertisement. Choose one command as needed:

  peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise-policy** *advertise-policy-name* **exist-policy** *exist-policy-name*

  interface-peer *interface-type interface-number* **advertise-policy** *advertise-policy-name* **exist-policy** *exist-policy-name*

  This command is supported only in BGP IPv4 unicast address family view.

- Specify a routing policy as the nonexistent policy to control route advertisement. Choose one command as needed:

  peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise-policy** *advertise-policy-name* **non-exist-policy** *non-exist-policy-name*

  interface-peer *interface-type interface-number* **advertise-policy** *advertise-policy-name* **non-exist-policy** *non-exist-policy-name*

  This command is supported only in BGP IPv4 unicast address family view.

- Reference a routing policy to filter BGP routes advertised to a peer or peer group. Choose one command as needed:

  peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **route-policy** *route-policy-name* **export**

  interface-peer *interface-type interface-number* **route-policy** *route-policy-name* **export**

- Reference an ACL to filter BGP routes advertised to a peer or peer group. Choose one command as needed:

  peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **filter-policy** { *ipv4-acl-number* | **name** *ipv4-acl-name* } **export**

  interface-peer *interface-type interface-number* **filter-policy** { *ipv4-acl-number* | **name** *ipv4-acl-name* } **export**

- Reference an AS path list to filter BGP routes advertised to a peer or peer group. Choose one command as needed:

  peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } { **as-path-acl** *as-path-acl-number* | *as-path-acl-name* } **export**

interface-peer *interface-type interface-number* **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* } **export**

- Reference an IPv4 prefix list to filter BGP routes advertised to a peer or peer group. Choose one command as needed:

  peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **prefix-list** *ipv4-prefix-list-name* **export**

  interface-peer *interface-type interface-number* **prefix-list** *ipv4-prefix-list-name* **export**

By default, no BGP distribution filtering policy is configured.

The *ipv6-address* [*prefix-length*] argument and the **interface-peer** command are not supported in BGP IPv4 multicast address family view.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast

3. Configure BGP route distribution filtering policies. Choose the options to configure as needed:

   - Reference an ACL or IPv6 prefix list to filter advertised BGP routes.

     filter-policy { *ipv6-acl-number* | **name** *ipv6-acl-name* | **prefix-list** *ipv6-prefix-list-name* } **export** [**direct** | { **isisv6** | **ospfv3** | **ripng** } *process-id* | **static**]

   - Specify a routing policy as the existent policy to control route advertisement. Choose one command as needed:

     peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **advertise-policy** *advertise-policy-name* **exist-policy** *exist-policy-name*

     interface-peer *interface-type interface-number* **advertise-policy** *advertise-policy-name* **exist-policy** *exist-policy-name*

     This command is supported only in BGP IPv6 unicast address family view.

   - Specify a routing policy as the nonexistent policy to control route advertisement. Choose one command as needed:

     peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type*

interface-number } **advertise-policy** *advertise-policy-name* **non-exist-policy** *non-exist-policy-name*

interface-peer *interface-type interface-number* **advertise-policy** *advertise-policy-name* **non-exist-policy** *non-exist-policy-name*

This command is supported only in BGP IPv6 unicast address family view.

- Reference a routing policy to filter BGP routes advertised to a peer or peer group. Choose one command as needed:

  peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **route-policy** *route-policy-name* **export**

  interface-peer *interface-type interface-number* **route-policy** *route-policy-name* **export**

- Reference an ACL to filter BGP routes advertised to a peer or peer group. Choose one command as needed:

  peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **filter-policy** { *ipv6-acl-number* | **name** *ipv6-acl-name* } **export**

  interface-peer *interface-type interface-number* **filter-policy** { *ipv6-acl-number* | **name** *ipv6-acl-name* } **export**

- Reference an AS path list to filter BGP routes advertised to a peer or peer group. Choose one command as needed:

  peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* } **export**

  interface-peer *interface-type interface-number* **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* } **export**

- Reference an IPv6 prefix list to filter BGP routes advertised to a peer or peer group. Choose one command as needed:

  peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **prefix-list** *ipv6-prefix-list-name* **export**

  interface-peer *interface-type interface-number* **prefix-list** *ipv6-prefix-list-name* **export**

By default, no BGP distribution filtering policy is configured.

The *ipv4-address* [*mask-length*] and *link-local-address* **interface** *interface-type interface-number* options and the **interface-peer** command are not supported in BGP IPv6 multicast address family view.

Enabling first-AS-number check for EBGP route advertisement

About this task

By default, BGP does not check the first AS number of a received EBGP route and directly advertises it to all peers except the source peer. The default setting for EBGP route advertisement brings about a large number of BGP routes and is not friendly to network maintenance.

To resolve this issue, perform this task. When the first AS number of an EBGP route to be advertised is the same as that of an EBGP peer, BGP does not advertise the route to that peer. This can reduce the number of routes received by EBGP peers.

Procedure (IPv4 unicast)

1. Enter system view.

   system-view
2. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
3. Enable BGP to perform first-AS-number check for EBGP routes before route advertisement.

   peer-as-check enable

   By default, BGP does not check the first AS number of a received EBGP route and directly advertises it to all peers except the source peer.

Procedure (IPv6 unicast)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
3. Enable BGP to perform first-AS-number check for EBGP routes before route advertisement.

   peer-as-check enable

   By default, BGP does not check the first AS number of a received EBGP route and directly advertises it to all peers except the source peer.

Setting the BGP route sending rate

About this task

If a device sends many new routes within a short time period, it might be unable to add the routes to the FIB before the peer device adds them. This might result in traffic forwarding failure. To avoid this problem, you can perform this task to set an appropriate route sending rate for the device.

Restrictions and guidelines

For a device with high performance, you can set a high BGP route sending rate as needed. For a device without high performance, set a relatively low BGP route sending rate as a best practice.

As a best practice to avoid route withdrawal failures, do not set the BGP route sending rate to 0 or a small value when network flapping occurs.

This task applies only to IPv4 unicast routes and IPv6 unicast routes.

Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Set the BGP route sending rate.
   route-rate-limit *rate*
   By default, the BGP route sending rate is not limited.

Configuring BGP to delay sending route updates on reboot

About this task

This task reduces traffic loss. With this task performed, BGP delays sending route updates when it restores after a device reboot. During the delay time, BGP learns all routes from other neighbors, and then selects the optimal route. After the delay time elapses, BGP will advertise the optimal route.

You can specify a prefix list and enable BGP to immediately send route updates for routes that match the prefix list.

Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Configure BGP to delay sending route updates when it restores after a device reboot.
   bgp update-delay on-startup *seconds*
   By default, BGP immediately sends route updates to BGP peers in established state when it restores after a device reboot.
4. (Optional.) Configure BGP to immediately send route updates for routes that match an IPv4 prefix list.
   bgp update-delay on-startup prefix-list *ipv4-prefix-list-name*
   By default, no IPv4 prefix list is specified to filter routes.
5. (Optional.) Configure BGP to immediately send route updates for routes that match an IPv6 prefix list.
   bgp update-delay on-startup ipv6-prefix-list *ipv6-prefix-list-name*
   By default, no IPv6 prefix list is specified to filter routes.

Configuring the interval for sending updates for the same route

About this task

A BGP router sends an UPDATE message to its peers when a route is changed. If the route changes frequently, the BGP router keeps sending update or withdrawal messages for the same route, resulting route flapping. To prevent this situation, perform this task to configure the interval for sending updates for the same route to a peer or peer group.

This feature takes effect on withdrawn routes only after you apply the route update interval setting to withdrawn routes.

Restrictions and guidelines

BGP compares the intervals specified for a BGP peer by using the **peer route-update-interval** and **route-update-delay** commands. Only the larger interval takes effect. If you did not execute the **peer route-update-interval** command, BGP uses the default value of this command to compare with the interval configured by the **route-update-delay** command.

Procedure (IPv4 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. (Optional.) Apply route update interval setting to withdrawn routes.

   route-update-interval withdrawn enable

   By default, route update interval setting does not apply to withdrawn routes. BGP sends withdrawal messages for withdrawn routes immediately.

4. (Optional.) Enter BGP-VPN instance view.

   ip vpn-instance *vpn-instance-name*

5. Configure the interval for sending updates for the same route to a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] }
   route-update-interval *interval*

   By default, the interval is 15 seconds for an IBGP peer and 30 seconds for an EBGP peer.

Procedure (IPv6 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. (Optional.) Apply route update interval setting to withdrawn routes.

   route-update-interval withdrawn enable

   By default, route update interval setting does not apply to withdrawn routes. BGP sends withdrawal messages for withdrawn routes immediately.

4. (Optional.) Enter BGP-VPN instance view.

   ip vpn-instance *vpn-instance-name*

5. Configure the interval for sending updates for the same route to a peer or peer group. Choose one command as needed:

peer { *group-name* | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **route-update-interval** *interval*

interface-peer *interface-type interface-number* **route-update-interval** *interval*

By default, the interval is 15 seconds for an IBGP peer and 30 seconds for an EBGP peer.

Configuring BGP route advertisement delay

About this task

BGP sends update messages to peers when route changes occur or peer relationship establishment is complete. If a large number of routes need to be updated within a short time period, BGP might send update messages to peers before issuing the updated routes to the FIB. As a result, some packets might be discarded because BGP cannot find the forwarding path for the packets.

To resolve this issue, perform this task to enable BGP route advertisement delay and set a delay timer. When route changes occur or peer relationship establishment is complete, BGP cannot send any update messages unless the delay timer expires.

Restrictions and guidelines

BGP compares the timer values specified for a BGP peer by using the **route-update-delay** command and the **peer route-update-interval** command. Only the larger timer value takes effect. If you did not execute the **peer route-update-interval** command, BGP compares the BGP route advertisement delay timer with the default value of the **peer route-update-interval** command.

This feature applies to the following routes:

- BGP IPv4 unicast routes.
- BGP IPv6 unicast routes.

Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Enable BGP route advertisement delay and set a delay timer.
   route-update-delay *delay-value*
   By default, BGP route advertisement delay is disabled.

Setting the refresh route advertisement delay timer

About this task

BGP advertises all routes to a peer in the following scenarios:

- BGP establishes a session to the peer for the first time.
- The update group of the peer changes.
- BGP receives route-refresh messages from the peer.

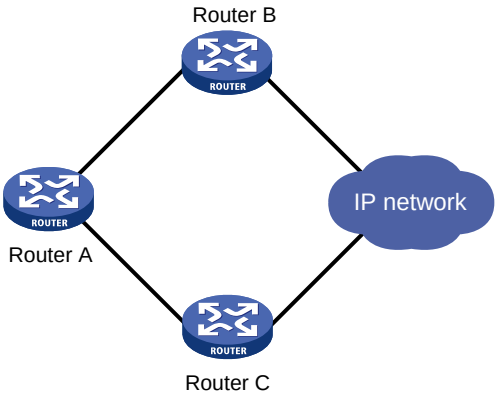
Routes advertised in the above scenarios are called refresh routes.

Perform this task to set the refresh route advertisement delay timer that starts when BGP advertises refresh routes for the first time. BGP delays refresh route advertisement to all peers until the timer

expires. After the timer expires, BGP advertises refresh routes to the corresponding peers by update group, which improves route advertisement efficiency and saves system resources.

Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Set the refresh route advertisement delay timer.
   refresh delay *delay-value*
   By default, the refresh route advertisement delay timer is five seconds.



Configuring a startup policy for BGP route updates

About this task

Perform this task to configure BGP to send route updates with the specified attributes within the specified period after reboot.

As shown in Figure 22, if Router B restarts and sends route updates before route convergence completes, traffic sent from Router A through Router B might be lost. This feature enables Router B to send route updates with the specified attribute values within the specified period after reboot, so that Router A can forward traffic through Router C.

Figure 22 Network diagram

Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Specify the period after reboot within which the startup policy is effective.
   bgp apply-policy on-startup duration *seconds*
   By default, the startup policy does not take effect.
4. Specify a MED attribute value in the startup policy.
   bgp policy on-startup med *med-value*
   By default, the MED attribute value in the startup policy is 4294967295.

Controlling BGP route reception

Limiting routes received from a peer or peer group

About this task

This feature can prevent attacks that send a large number of BGP routes to the router.

If the number of routes received from a peer or peer group exceeds the upper limit, the router takes one of the following actions based on your configuration:

- Tears down the BGP session to the peer or peer group and does not attempt to re-establish the session.
- Continues to receive routes from the peer or peer group and generates a log message.
- Retains the session to the peer or peer group, but it discards excess routes and generates a log message.
- Tears down the BGP session to the peer or peer group and, after a specific period of time, re-establishes a BGP session to the peer or peer group.

You can specify a percentage threshold for the router to generate a log message. When the ratio of the number of received routes to the maximum number reaches the percentage value, the router generates a log message.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Specify the maximum number of routes that a router can receive from a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **route-limit** *prefix-number* [{ **alert-only** | **discard** | **reconnect** *reconnect-time* } | *percentage-value*] *

   interface-peer *interface-type interface-number* **route-limit** *prefix-number* [{ **alert-only** | **discard** | **reconnect** *reconnect-time* } | *percentage-value*] *

   By default, the number of routes that a router can receive from a peer or peer group is not limited.

The *ipv6-address* [*prefix-length*] argument and the **interface-peer** command are not supported in BGP IPv4 multicast address family view.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
3. Specify the maximum number of routes that a router can receive from a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **route-limit** *prefix-number* [{ **alert-only** | **discard** | **reconnect** *reconnect-time* } | *percentage-value*] *

   interface-peer *interface-type interface-number* **route-limit** *prefix-number* [{ **alert-only** | **discard** | **reconnect** *reconnect-time* } | *percentage-value*] *

   By default, the number of routes that a router can receive from a peer or peer group is not limited.

   The *ipv4-address* [*mask-length*] and *link-local-address* **interface** *interface-type interface-number* options and the **interface-peer** command are not supported in BGP IPv6 multicast address family view.

Configuring BGP route reception filtering policies

About this task

You can use the following methods to configure BGP route reception filtering policies:

- Use an ACL or prefix list to filter routing information received from all peers.
- Use a routing policy, ACL, AS path list, or prefix list to filter routing information received from a peer or peer group.

If you configure multiple filtering policies, apply them in the following sequence:

1. **filter-policy import**
2. **peer filter-policy import**
3. **peer as-path-acl import**

4. **peer prefix-list import**
5. **peer route-policy import**

Only routes passing all the configured policies can be received.

Prerequisites

Before you configure BGP route reception filtering policies, configure the following filters used for route filtering as needed:

- ACL (see *ACL and QoS Configuration Guide*).
- Prefix list (see "Configuring routing policies").
- Routing policy (see "Configuring routing policies").
- AS path list (see "Configuring routing policies").

Restrictions and guidelines

When you specify an ACL, prefix list, or routing policy as a filtering policy to filter BGP routing information, follow these guidelines:

- If the specified ACL, prefix list, or routing policy does not exist, all BGP routes can pass the filtering policy.
- When you specify an ACL or prefix list as a BGP route filtering policy (for example, use **filter-policy import** to specify an ACL for routing filtering), the following rules apply:
  - BGP routes can pass the filtering policy only when one of the following conditions exists:
    - They match a **permit** rule in the specified ACL.
    - They match a **permit** item in the specified prefix list.

    When the ACL has only **deny** rules or the prefix list has only **deny** items, no BGP routes can pass the filtering policy.
  - When the ACL match order is **config**, BGP routes match against rules in ascending order of rule ID. When BGP routes match against the items of the prefix list, an item with a smaller index number is matched first.

    In either of the match modes above, a BGP route does not match against the next ACL rule or prefix list item when it already matches the current ACL rule or prefix list item. To avoid wasting filter resources, set a small match range for each ACL rule or prefix list item when you configure multiple ACL rules or prefix list items for an ACL or prefix list.
  - You can use the **rule** [*rule-id*] **permit ip source** *sour-addr sour-wildcard* **destination** *dest-addr dest-wildcard* command to create a rule for an advanced ACL to match specific routes. The **source** *sour-addr* option represents the destination network address and the **destination** *dest-addr* option represents the mask in dotted decimal notation. For example, to match route 3.3.3.0/24, the rule configuration should be **rule** [*rule-id*] **permit ip source** *3.3.3.0 0.0.0.255* **destination** *255.255.255.0 0.0.0.255*.
- When you specify a routing policy as a BGP route filtering policy, the following rules apply:
  - BGP routes can pass the filtering policy only when they match a **permit** node in the routing policy.
  - A BGP route matches against the nodes of the routing policy in ascending order of node number. It does not match against the next node when it already matches the current node (unless a continue clause exists).
  - When a BGP route matches against a node that has an ACL or prefix-list **if-match** clause, it can pass the filtering policy only when the following conditions exist:
    - The route matches a **permit** rule in the ACL or a **permit** item in the prefix list.
    - The route matches a **permit** node in the routing policy.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Configure BGP route reception filtering policies. Choose the options to configure as needed:

   - Reference an ACL or IP prefix list to filter BGP routes received from all peers.

     filter-policy { *ipv4-acl-number* | **name** *ipv4-acl-name* | **prefix-list** *ipv4-prefix-list-name* } **import**

   - Reference a routing policy to filter BGP routes received from a peer or peer group. Choose one command as needed:

     peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **route-policy** *route-policy-name* **import**

     interface-peer *interface-type interface-number* **route-policy** *route-policy-name* **import**

   - Reference an ACL to filter BGP routes received from a peer or peer group. Choose one command as needed:

     peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **filter-policy** { *ipv4-acl-number* | **name** *ipv4-acl-name* } **import**

     interface-peer *interface-type interface-number* **filter-policy** { *ipv4-acl-number* | **name** *ipv4-acl-name* } **import**

   - Reference an AS path list to filter BGP routes received from a peer or peer group. Choose one command as needed:

     peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* } **import**

     interface-peer *interface-type interface-number* **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* } **import**

   - Reference an IPv4 prefix list to filter BGP routes received from a peer or peer group. Choose one command as needed:

     peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **prefix-list** *ipv4-prefix-list-name* **import**

     interface-peer *interface-type interface-number* **prefix-list** *ipv4-prefix-list-name* **import**

By default, no route reception filtering is configured.

The *ipv6-address* [*prefix-length*] argument and the **interface-peer** command are not supported in BGP IPv4 multicast address family view.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast

3. Configure BGP route reception filtering policies. Choose the options to configure as needed:
   - Reference ACL or IPv6 prefix list to filter BGP routes received from all peers.

     filter-policy { *ipv6-acl-number* | **name** *ipv6-acl-name* | **prefix-list** *ipv6-prefix-list-name* } **import**
   - Reference a routing policy to filter BGP routes received from a peer or peer group. Choose one command as needed:

     peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **route-policy** *route-policy-name* **import**

     interface-peer *interface-type interface-number* **route-policy** *route-policy-name* **import**
   - Reference an ACL to filter BGP routes received from a peer or peer group. Choose one command as needed:

     peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **filter-policy** { *ipv6-acl-number* | **name** *ipv6-acl-name* } **import**

     interface-peer *interface-type interface-number* **filter-policy** { *ipv6-acl-number* | **name** *ipv6-acl-name* } **import**
   - Reference an AS path list to filter BGP routes received from a peer or peer group. Choose one command as needed:

     peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* } **import**

     interface-peer *interface-type interface-number* **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* } **import**

- Reference an IPv6 prefix list to filter BGP routes received from a peer or peer group. Choose one command as needed:

  peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **prefix-list** *ipv6-prefix-list-name* **import**

  interface-peer *interface-type interface-number* **prefix-list** *ipv6-prefix-list-name* **import**

  By default, no route reception filtering is configured.

  The *ipv4-address* [*mask-length*] and *link-local-address* **interface** *interface-type interface-number* options and the **interface-peer** command are not supported in BGP IPv6 multicast address family view.

Configuring the SoO attribute

About this task

After you configure the SoO attribute for a BGP peer or peer group, BGP adds the SoO attribute into the route updates received from the BGP peer or peer group. In addition, before advertising route updates to the peer or peer group, BGP checks the SoO attribute of the route update against the configured SoO attribute. If they are the same, BGP does not advertise the route updates to the BGP peer or peer group.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast
3. Configure the SoO attribute for a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **soo** *site-of-origin*

   interface-peer *interface-type interface-number* **soo** *site-of-origin*

   By default, no SoO attribute is configured for a peer or peer group.

   The *ipv6-address* [*prefix-length*] argument and the **interface-peer** command are not supported in BGP IPv4 multicast address family view.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
3. Configure the SoO attribute for a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **soo** *site-of-origin*

   interface-peer *interface-type interface-number* **soo** *site-of-origin*

   By default, no SoO attribute is configured for a peer or peer group.

   The *ipv4-address* [*mask-length*] and *link-local-address* **interface** *interface-type interface-number* options and the **interface-peer** command are not supported in BGP IPv6 multicast address family view.

Configuring BGP timers

Configuring the keepalive interval and hold time

About this task

BGP sends KEEPALIVE messages regularly to keep the BGP session between two routers.

If a router receives no KEEPALIVE or UPDATE message from a peer within the hold time, it tears down the session.

You can configure the keepalive interval and hold time globally or for a peer or peer group. The individual settings take precedence over the global settings.

The actual keepalive interval and hold time are determined as follows:

- If the local device is configured with a different hold time from a peer, the smaller hold time takes effect after peer negotiation. To ensure an appropriate negotiated hold time, use the **min-holdtime** *min-holdtime* option to specify the minimum hold time. If the negotiated hold time is smaller than the minimum hold time configured on the local device, it terminates the related BGP session. If either the local device or the peer device has a hold time of 0, the local device will not be affected by the configured minimum hold time. They can establish a BGP session regardless of the minimum hold time.

  If the hold time is set to 0, the local device does not send keepalive messages to the peer after negotiation. In this case, the peer session will never time out, because the keepalive mechanism will not be triggered. As a best practice, set the hold time to 0 only in certain scenarios, for example, debugging or testing.

- If the keepalive interval is not 0, the actual keepalive interval is the smaller one between 1/3 of the hold time and the keepalive interval.

Restrictions and guidelines

The hold time must be a minimum of three times the keepalive interval. The minimum hold time must be smaller than or equal to the hold time.

You can perform this task for all BGP peers or for a specific BGP peer or peer group. For a BGP peer or peer group, the configuration of the **peer timer** command takes precedence over that of the **timer** command. If you do not configure the **peer timer** command for the peer or peer group, the configuration of the **timer** command takes effect on the peer or peer group.

Procedure (IPv4 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Configure the keepalive interval and hold time.
   - Configure the global keepalive interval and hold time.

     timer keepalive *keepalive* **hold** *holdtime* [**min-holdtime** *min-holdtime*]

     This command takes effect for new BGP sessions and does not affect existing sessions.
   - Configure the keepalive interval and hold time for a peer or peer group.

     peer { *group-name* | *ipv4-address* [*mask-length*] } **timer keepalive** *keepalive* **hold** *holdtime* [**min-holdtime** *min-holdtime*]

   By default, the keepalive interval is 60 seconds, and hold time is 180 seconds.

   The timers configured with the **timer** and **peer timer** commands do not take effect until a session is re-established (for example, a session is reset).

Procedure (IPv6 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Configure the keepalive interval and hold time.
   - Configure the global keepalive interval and hold time.

     timer keepalive *keepalive* **hold** *holdtime*

     This command takes effect for new BGP sessions and does not affect existing sessions.
   - Configure the keepalive interval and hold time for a peer or peer group. Choose one command as needed:

peer { *group-name* | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **timer keepalive** *keepalive* **hold** *holdtime* [**min-holdtime** *min-holdtime*]

interface-peer *interface-type interface-number* **timer keepalive** *keepalive* **hold** *holdtime* [**min-holdtime** *min-holdtime*]

By default, the keepalive interval is 60 seconds, and hold time is 180 seconds.

The timers configured with the **timer** and **peer timer** commands do not take effect until a session is re-established (for example, a session is reset).

Setting the session retry timer

About this task

To speed up session establishment to a peer or peer group and route convergence, set a small session retry timer. If the BGP session flaps, you can set a large session retry timer to reduce the impact.

Restrictions and guidelines

The timer set by the **peer timer connect-retry** command takes precedence over the timer set by the **timer connect-retry** command.

Procedure (IPv4 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Set the session retry timer.
   - Set the session retry timer for all peers or peer groups.

     timer connect-retry *retry-time*
   - Set the session retry timer for a peer or peer group.

     peer { *group-name* | *ipv4-address* [*mask-length*] } **timer connect-retry** *retry-time*

   By default, the session retry timer is 32 seconds for a peer or peer group.

Procedure (IPv6 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Set the session retry timer.

- Set the session retry timer for all peers or peer groups.

  timer connect-retry *retry-time*
- Set the session retry timer for a peer or peer group. Choose one command as needed:

  peer { *group-name* | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **timer connect-retry** *retry-time*

  interface-peer *interface-type interface-number* **timer connect-retry** *retry-time*

By default, the session retry timer is 32 seconds for a peer or peer group.

Configuring BGP logging and notifications

Enabling logging for session state changes

About this task

Perform this task to enable BGP to log BGP session establishment and disconnection events. To display the log information, use the **display bgp peer ipv4 unicast log-info** command or the **display bgp peer ipv6 unicast log-info** command. The logs are sent to the information center. The output rules of the logs (whether to output the logs and where to output) are determined by the information center configuration.

For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Procedure (IPv4 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
3. Enable logging for session state changes globally.

   log-peer-change

   By default, logging for session state changes is enabled globally.
4. (Optional.) Enter BGP-VPN instance view.

   ip vpn-instance *vpn-instance-name*
5. Enable logging for session state changes for a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **log-change**

   By default, logging for session state changes is enabled for all peers and peer groups.

Procedure (IPv6 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
3. Enable logging for session state changes globally.

   log-peer-change

   By default, logging for session state changes is enabled globally.
4. (Optional.) Enter BGP-VPN instance view.

ip vpn-instance *vpn-instance-name*

5. Enable logging for session state changes for a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **log-change**

   interface-peer *interface-type interface-number* **log-change**

   By default, logging for session state changes is enabled for all peers and peer groups.

Enabling logging for BGP route flapping

About this task

This feature enables BGP to generate logs for BGP route flapping events that trigger log generation. The generated logs are sent to the information center. For the logs to be output correctly, you must also configure information center on the device. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Procedure (IPv4 unicast/IPv4 multicast)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Enable logging for BGP route flapping.

   log-route-flap *monitor-time monitor-count* [*log-count-limit* | **route-policy** *route-policy-name*] *

   By default, logging for BGP route flapping is disabled.

Procedure (IPv6 unicast/IPv6 multicast)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

  address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv6 multicast

3. Enable logging for BGP route flapping.

   log-route-flap *monitor-time monitor-count* [*log-count-limit* | **route-policy** *route-policy-name*] *

   By default, logging for BGP route flapping is disabled.

Configuring BGP network management

About this task

After you enable SNMP notifications for BGP, the device generates a notification when a BGP session state change occurs. The notification includes the neighbor address, the error code and subcode of the most recent error, and the current neighbor state. For BGP notifications to be sent correctly, you must also configure SNMP on the device.

BGP does not know the BGP instance to which a managed MIB node belongs. To resolve this issue, configure different SNMP contexts for different BGP instances.

The device selects a MIB for an SNMP packet according to the context (for SNMPv3) or community name (for SNMPv1/v2c) in the following ways:

- For an SNMPv3 packet:
  - The device selects the MIB of the default BGP instance if the packet does not carry a context and no SNMP context is configured for the default BGP instance.
  - The device selects the MIB of a BGP instance if the packet meets the following conditions:
    - Carries a context that is configured with the **snmp-agent context** command in system view.
    - Matches the context of the BGP instance.
  - The device does not process any MIBs in other situations.
- For an SNMPv1/v2c packet:
  - The device selects the MIB of the default BGP instance if the following conditions are met:
    - No community name-to-SNMP context mapping is configured with the **snmp-agent community-map** command in system view.
    - No SNMP context is configured for the default BGP instance.
  - The device selects the MIB of a BGP instance if the community name is mapped to an SNMP context and the context matches the context of the BGP instance.
  - The device does not process any MIBs in other situations.

For more information about SNMP contexts and community names, see SNMP configuration in *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

After you configure the **snmp-agent trap enable bgp** command, the following rules apply:

- Whether notifications specified by the **peer-addrfamily-routeexceed**, **peer-addrfamily-routeexceed-clear**, **peer-addrfamily-routethreshold-exceed**, **peer-addrfamily-routethreshold-clear**, **peer-routeexceed**, **peer-routeexceed-clear**, **peer-routethreshold-clear**, or **peer-routethreshold-exceed** keyword can be generated depends on the configuration of the **peer route-limit** command. The **peer route-limit** command determines the number of routes that the router can receive and the log generation threshold. If the **peer route-limit** command is not executed, the maximum number of routes that triggers notifications is 4294967295 and the route quantity alarm threshold is 70%.
- Whether notifications specified by the **peer-rpkisession-roaexceed** or **peer-rpkisession-roaexceed-clear** keyword can be generated depends on the configuration of the **rpki-limit** command. If the **rpki-limit** command is not configured in RPKI server view, the device generates notifications when the number of ROAs received from the RPKI server reaches or exceeds 4294967295.

Procedure

1. Enter system view.

   system-view
2. Enable SNMP notifications for BGP.

   snmp-agent trap enable bgp [**instance** *instance-name*] [**dynamic-peer-limit-exceed** | **dynamic-peer-limit-exceed-clear** | **originator-id-conflict** | **peer-addrfamily-routeexceed** | **peer-addrfamily-routeexceed-clear** | **peer-addrfamily-routethreshold-clear** | **peer-addrfamily-routethreshold-exceed** | **peer-backward-transition** | **peer-established** | **peer-gr-status-change** | **peer-routeexceed** | **peer-routeexceed-clear** | **peer-route-flap** | **peer-routethreshold-clear** | **peer-routethreshold-exceed** | **peer-rpkisession-roaexceed** | **peer-rpkisession-roaexceed-clear** | **remote-routerid-conflict**] *

   By default, SNMP notifications for BGP are enabled.

   If you do not specify any notification types, this command enables all types of notifications for BGP. If you specify notification types, this command enables only the specified types of notifications for BGP.
3. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
4. Configure an SNMP context for the BGP instance.

   snmp context-name *context-name*

   By default, no SNMP context is configured for the BGP instance.

Display and maintenance commands for basic BGP network building

Displaying BGP

Execute **display** commands in any view.

Displaying BGP (IPv4 unicast address family)

Task	Command
Display BGP IPv4 unicast peer group information.	**display bgp** [**instance** *instance-name*] **group ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [**group-name** *group-name*]
Display information about routes advertised by the **network** command and shortcut routes configured by the **network short-cut** command.	**display bgp** [**instance** *instance-name*] **network ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*]
Display information about a peer or peer group in BGP IPv4 unicast address family.	**display bgp** [**instance** *instance-name*] **peer ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv4-address mask-length* | { *ipv4-address* | **group-name** *group-name* } **log-info** | [*ipv4-address*] **verbose**] **display bgp** [**instance** *instance-name*] **peer ipv4** [**unicast**] [*ipv6-address prefix-length* | **interface** *interface-type interface-number* | *ipv6-address* [**interface** *interface-type interface-number*] { **log-info** | **verbose** }] **display bgp** [**instance** *instance-name*] **peer ipv4** [**unicast**] **vpn-instance-all** [**verbose**]
Display BGP IPv4 unicast route flapping statistics.	**display bgp** [**instance** *instance-name*] **routing-table flap-info ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv4-address* [{ *mask-length* | *mask* } [**longest-match**]] | **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* }]
Display BGP IPv4 unicast routing information.	**display bgp** [**instance** *instance-name*] **routing-table ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv4-address* [{ *mask-length* | *mask* } [**longest-match**]] | *ipv4-address* [*mask-length* | *mask*] **advertise-info** | *ipv4-address* [*mask-length* | *mask*] { **as-path** | **cluster-list** | **community** | **ext-community** } | **peer** { *ipv4-address* | *ipv6-address* [**interface** *interface-type interface-number*] } { **advertised-routes** | **received-routes** } [*ipv4-address* [*mask-length* | *mask*] | **statistics**] | **statistics**] **display bgp** [**instance** *instance-name*] **routing-table ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* }

Task	Command
	display bgp [**instance** *instance-name*] **routing-table ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [**statistics**] **community** [*community-number*&<1-32> | *aa:nn*&<1-32>] [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] [**whole-match**] **display bgp** [**instance** *instance-name*] **routing-table ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [**statistics**] **community-list** { *basic-community-list-number* | *adv-community-list-number* | *comm-list-name* } [**whole-match**] **display bgp** [**instance** *instance-name*] **routing-table ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [**statistics**] **ext-community** [**bandwidth** *link-bandwidth-value* | **rt** *route-target* | **soo** *site-of-origin*]&<1-32> [**whole-match**]
Display information about BGP peer relationship down events.	**display bgp** [**instance** *instance-name*] **troubleshooting** [*event-count*] [**reverse**]
Display BGP IPv4 unicast address family update group information.	**display bgp** [**instance** *instance-name*] **update-group ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv4-address*] **display bgp** [**instance** *instance-name*] **update-group ipv4** [**unicast**] [*ipv6-address*]
Display information about all BGP instances.	**display bgp instance-info**

Displaying BGP (IPv6 unicast address family)

Task	Command
Display BGP IPv6 unicast peer group information.	**display bgp** [**instance** *instance-name*] **group ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [**group-name** *group-name*]
Display information about routes advertised by the **network** command and shortcut routes configured by the **network short-cut** command.	**display bgp** [**instance** *instance-name*] **network ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*]
Display information about a peer or peer group in BGP IPv6 unicast address family.	**display bgp** [**instance** *instance-name*] **peer ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv6-address prefix-length* | { *ipv6-address* |

Task	Command
	group-name *group-name* } **log-info** | [*ipv6-address*] **verbose**] **display bgp** [**instance** *instance-name*] **peer ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [[*link-local-address*] **interface** *interface-type interface-number* | *link-local-address* **interface** *interface-type interface-number* { **log-info** | **verbose** }] **display bgp** [**instance** *instance-name*] **peer ipv6** [**unicast**] [*ipv4-address mask-length* | *ipv4-address* **log-info** | [*ipv4-address*] **verbose**] **display bgp** [**instance** *instance-name*] **peer ipv6** [**unicast**] **vpn-instance-all** [**verbose**]
Display BGP IPv6 unicast route flapping statistics.	**display bgp** [**instance** *instance-name*] **routing-table flap-info ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv6-address prefix-length* | **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* }]
Display BGP IPv6 unicast routing information.	**display bgp** [**instance** *instance-name*] **routing-table ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv6-address prefix-length* [**advertise-info**] | *ipv6-address prefix-length* { **as-path** | **cluster-list** | **community** | **ext-community** } | **peer** *ipv6-address* { **advertised-routes** | **received-routes** } [*ipv6-address prefix-length* | **statistics**] | **statistics**] **display bgp** [**instance** *instance-name*] **routing-table ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] **peer** { *ipv4-address* | [*link-local-address*] **interface** *interface-type interface-number* } { **advertised-routes** | **received-routes** } [*ipv6-address prefix-length* | **statistics**] **display bgp** [**instance** *instance-name*] **routing-table ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* } **display bgp** [**instance** *instance-name*] **routing-table ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [**statistics**] **community** [*community-number*&<1-32> |

Task	Command
	aa:nn&<1-32>] [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] [**whole-match**] **display bgp** [**instance** *instance-name*] **routing-table ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [**statistics**] **community-list** { *basic-community-list-number* | *adv-community-list-number* | *comm-list-name* } [**whole-match**] **display bgp** [**instance** *instance-name*] **routing-table ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [**statistics**] **ext-community** [**bandwidth** *link-bandwidth-value* | **rt** *route-target* | **soo** *site-of-origin*]&<1-32> [**whole-match**]
Display information about BGP peer relationship down events.	**display bgp** [**instance** *instance-name*] **troubleshooting** [*event-count*] [**reverse**]
Display BGP IPv6 unicast address family update group information.	**display bgp** [**instance** *instance-name*] **update-group ipv6** [**unicast**] [*ipv4-address* | *ipv6-address*] **display bgp** [**instance** *instance-name*] **update-group ipv6** [**unicast**] **vpn-instance** *vpn-instance-name* [*ipv6-address*]
Display information about all BGP instances.	**display bgp instance-info**

Displaying BGP (IPv4 multicast address family)

Task	Command
Display BGP IPv4 multicast peer group information.	**display bgp** [**instance** *instance-name*] **group ipv4 multicast** [**group-name** *group-name*]
Display information about routes advertised by the **network** command and shortcut routes configured by the **network short-cut** command.	**display bgp** [**instance** *instance-name*] **network ipv4 multicast**
Display BGP path attribute information.	**display bgp** [**instance** *instance-name*] **paths** [*as-regular-expression*]
Display BGP IPv4 multicast peer or peer group information.	**display bgp** [**instance** *instance-name*] **peer ipv4 multicast** [*ipv4-address mask-length* | { *ipv4-address* | **group-name** *group-name* } **log-info** | [*ipv4-address*] **verbose**]
Display BGP IPv4 multicast route flapping statistics.	**display bgp** [**instance** *instance-name*] **routing-table flap-info ipv4 multicast**

Task	Command
	[*ipv4-address* [{ *mask-length* | *mask* } [**longest-match**]] | **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* }]
Display BGP IPv4 multicast routing information.	**display bgp** [**instance** *instance-name*] **routing-table ipv4 multicast** [*ipv4-address* [{ *mask-length* | *mask* } [**longest-match**]] | *ipv4-address* [*mask-length* | *mask*] **advertise-info** | *ipv4-address* [*mask-length* | *mask*] { **as-path** | **cluster-list** | **community** | **ext-community** } | **peer** *ipv4-address* { **advertised-routes** | **received-routes** } [*ipv4-address* [*mask-length* | *mask*] | **statistics**] | **statistics**] **display bgp** [**instance** *instance-name*] **routing-table ipv4 multicast as-path-acl** { *as-path-acl-number* | *as-path-acl-name* } **display bgp** [**instance** *instance-name*] **routing-table ipv4 multicast** [**statistics**] **community** [*community-number*&<1-32> | *aa:nn*&<1-32>] [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] [**whole-match**] **display bgp** [**instance** *instance-name*] **routing-table ipv4 multicast** [**statistics**] **community-list** { *basic-community-list-number* | *adv-community-list-number* | *comm-list-name* } [**whole-match**] **display bgp** [**instance** *instance-name*] **routing-table ipv4 multicast** [**statistics**] **ext-community** [**bandwidth** *link-bandwidth-value* | **rt** *route-target* | **soo** *site-of-origin*]&<1-32> [**whole-match**]
Display information about BGP peer relationship down events.	**display bgp** [**instance** *instance-name*] **troubleshooting** [*event-count*] [**reverse**]
Display BGP IPv4 multicast address family update group information.	**display bgp** [**instance** *instance-name*] **update-group ipv4 multicast** [*ipv4-address*]
Display information about all BGP instances.	**display bgp instance-info**

Displaying BGP (IPv6 multicast address family)

Task	Command
Display BGP IPv6 multicast peer group information.	**display bgp** [**instance** *instance-name*] **group ipv6 multicast** [**group-name**

Task	Command
	group-name]
Display information about routes advertised by the **network** command and shortcut routes configured by the **network short-cut** command.	**display bgp** [**instance** *instance-name*] **network ipv6 multicast**
Display BGP path attribute information.	**display bgp** [**instance** *instance-name*] **paths** [*as-regular-expression*]
Display BGP IPv6 multicast peer or peer group information.	**display bgp** [**instance** *instance-name*] **peer ipv6 multicast** [*ipv6-address prefix-length* | { *ipv6-address* | **group-name** *group-name* } **log-info** | [*ipv6-address*] **verbose**]
Display BGP IPv6 multicast route flapping statistics.	**display bgp** [**instance** *instance-name*] **routing-table flap-info ipv6 multicast** [*ipv6-address prefix-length* | **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* }]
Display BGP IPv6 multicast routing information.	**display bgp** [**instance** *instance-name*] **routing-table ipv6 multicast** [*ipv6-address prefix-length* [**advertise-info**] | *ipv6-address prefix-length* { **as-path** | **cluster-list** | **community** | **ext-community** } | **peer** *ipv6-address* { **advertised-routes** | **received-routes** } [*ipv6-address prefix-length* | **statistics**] | **statistics**] **display bgp** [**instance** *instance-name*] **routing-table ipv6 multicast as-path-acl** { *as-path-acl-number* | *as-path-acl-name* } **display bgp** [**instance** *instance-name*] **routing-table ipv6 multicast** [**statistics**] **community** [*community-number*&<1-32> | *aa:nn*&<1-32>] [**internet** | **no-advertise** | **no-export** | **no-export-subconfed**] [**whole-match**] **display bgp** [**instance** *instance-name*] **routing-table ipv6 multicast** [**statistics**] **community-list** { *basic-community-list-number* | *adv-community-list-number* | *comm-list-name* } [**whole-match**] **display bgp** [**instance** *instance-name*] **routing-table ipv6 multicast** [**statistics**] **ext-community** [**bandwidth** *link-bandwidth-value* | **rt** *route-target* | **soo** *site-of-origin*]&<1-32> [**whole-match**]
Display information about BGP peer	**display bgp** [**instance** *instance-name*]

Task	Command
relationship down events.	**troubleshooting** [*event-count*] [**reverse**]
Display BGP IPv6 multicast address family update group information.	**display bgp** [**instance** *instance-name*] **update-group ipv6 multicast** [*ipv6-address*]
Display information about all BGP instances.	**display bgp instance-info**

Resetting BGP sessions

CAUTION:

A reset operation tears down BGP sessions for a short period of time.

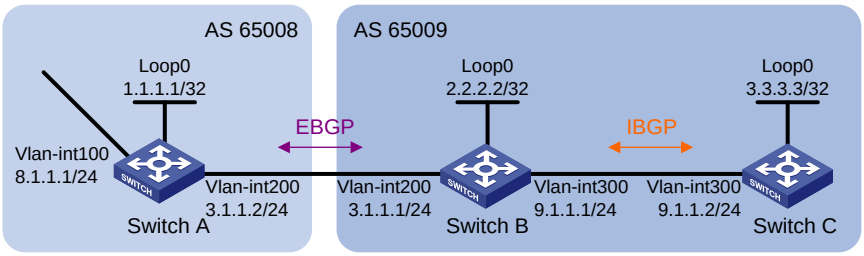
Execute **reset** commands in user view.

Task	Command
Reset BGP sessions for IPv4 unicast address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv4-address* [*mask-length*] | **all** | **external** | **group** *group-name* | **internal** } **ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] **reset bgp** { *ipv6-address* [*prefix-length*] | **interface** *interface-type interface-number* } **ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*]
Reset BGP sessions for IPv4 multicast address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv4-address* [*mask-length*] | **all** | **external** | **group** *group-name* | **internal** } **ipv4 multicast**
Reset BGP sessions for IPv6 unicast address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv6-address* [*prefix-length*] | [*link-local-address*] **interface** *interface-type interface-number* | **all** | **external** | **group** *group-name* | **internal** } **ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] **reset bgp** *ipv4-address* [*mask-length*] **ipv6** [**unicast**]
Reset BGP sessions for IPv6 multicast address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv6-address* [*prefix-length*] | **all** | **external** | **group** *group-name* | **internal** } **ipv6 multicast**
Reset all BGP sessions.	**reset bgp** [**instance** *instance-name*] **all**

Clearing BGP information

Execute **reset** commands in user view.

Task	Command
Clear flap information for BGP IPv4 unicast routes.	**reset bgp** [**instance** *instance-name*] **flap-info ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv4-address* [*mask-length* | *mask*] | **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* } | **peer** *ipv4-address* [*mask-length*]]
Clear flap information for BGP IPv4 multicast routes.	**reset bgp** [**instance** *instance-name*] **flap-info ipv4 multicast** [*ipv4-address* [*mask-length* | *mask*] | **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* } | **peer** *ipv4-address* [*mask-length*]]
Clear flap information for BGP IPv6 unicast routes.	**reset bgp** [**instance** *instance-name*] **flap-info ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv6-address prefix-length* | **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* } | **peer** *ipv6-address* [*prefix-length*]]
Clear flap information for BGP IPv6 multicast routes.	**reset bgp** [**instance** *instance-name*] **flap-info ipv6 multicast** [*ipv6-address prefix-length* | **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* } | **peer** *ipv6-address* [*prefix-length*]]



Basic IPv4 BGP network configuration examples

Example: Configuring basic BGP

Network configuration

As shown in Figure 23, all switches run BGP. Run EBGP between Switch A and Switch B, and run IBGP between Switch B and Switch C to allow Switch C to access network 8.1.1.0/24 connected to Switch A.

Figure 23 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)

2. Configure IBGP:

- To prevent route flapping caused by port state changes, this example uses loopback interfaces to establish IBGP connections.
- Loopback interfaces are virtual interfaces. Therefore, use the **peer connect-interface** command to specify the loopback interface as the source interface for establishing BGP connections.
- Enable OSPF in AS 65009 to ensure that Switch B can communicate with Switch C through loopback interfaces.

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 65009
[SwitchB-bgp-default] router-id 2.2.2.2
[SwitchB-bgp-default] peer 3.3.3.3 as-number 65009
[SwitchB-bgp-default] peer 3.3.3.3 connect-interface loopback 0
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 3.3.3.3 enable
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
[SwitchB] ospf 1
[SwitchB-ospf-1] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 2.2.2.2 0.0.0.0
[SwitchB-ospf-1-area-0.0.0.0] network 9.1.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 65009
[SwitchC-bgp-default] router-id 3.3.3.3
[SwitchC-bgp-default] peer 2.2.2.2 as-number 65009
[SwitchC-bgp-default] peer 2.2.2.2 connect-interface loopback 0
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 2.2.2.2 enable
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
[SwitchC] ospf 1
[SwitchC-ospf-1] area 0
[SwitchC-ospf-1-area-0.0.0.0] network 3.3.3.3 0.0.0.0
[SwitchC-ospf-1-area-0.0.0.0] network 9.1.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] quit
[SwitchC-ospf-1] quit
[SwitchC] display bgp peer ipv4

 BGP local router ID : 3.3.3.3
 Local AS number : 65009
 Total number of peers : 1                 Peers in established state : 1

  * - Dynamically created peer
  ^ - Peer created through link-local address
  Peer                    AS  MsgRcvd  MsgSent OutQ PrefRcv Up/Down  State
```

```
  2.2.2.2              65009        2        2    0       0 00:00:13 Established
```

The output shows that Switch C has established an IBGP peer relationship with Switch B.

3. Configure EBGP:

- The EBGP peers, Switch A and Switch B (usually belong to different carriers), are located in different ASs. Typically, their loopback interfaces are not reachable to each other, so directly connected interfaces are used for establishing EBGP sessions.
- To enable Switch C to access the network 8.1.1.0/24 connected directly to Switch A, inject network 8.1.1.0/24 to the BGP routing table of Switch A.

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 65008
[SwitchA-bgp-default] router-id 1.1.1.1
[SwitchA-bgp-default] peer 3.1.1.1 as-number 65009
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 3.1.1.1 enable
[SwitchA-bgp-default-ipv4] network 8.1.1.0 24
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

Configure Switch B.

```
[SwitchB] bgp 65009
[SwitchB-bgp-default] peer 3.1.1.2 as-number 65008
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 3.1.1.2 enable
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

Display BGP peer information on Switch B.

```
[SwitchB] display bgp peer ipv4

 BGP local router ID : 2.2.2.2
 Local AS number : 65009
 Total number of peers : 2                 Peers in established state : 2

  * - Dynamically created peer
  ^ - Peer created through link-local address
  Peer                    AS  MsgRcvd  MsgSent OutQ PrefRcv Up/Down  State

  3.3.3.3              65009        4        4    0       0 00:02:49 Established
  3.1.1.2              65008        2        2    0       0 00:00:05 Established
```

The output shows that Switch B has established an IBGP peer relationship with Switch C and an EBGP peer relationship with Switch A.

Display the BGP routing table on Switch A.

```
[SwitchA] display bgp routing-table ipv4

 Total number of routes: 1

 BGP local router ID is 1.1.1.1
 Status codes: * - valid, > - best, d - dampened, h - history,
```

```
              s - suppressed, S - stale, i - internal, e - external
              a – additional-path
      Origin: i - IGP, e - EGP, ? - incomplete

    Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >  8.1.1.0/24         8.1.1.1         0                     32768   i
```

Display the BGP routing table on Switch B.

```
[SwitchB] display bgp routing-table ipv4

 Total number of routes: 1

 BGP local router ID is 2.2.2.2
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >e 8.1.1.0/24         3.1.1.2         0                     0       65008i
```

Display the BGP routing table on Switch C.

```
[SwitchC] display bgp routing-table ipv4

 Total number of routes: 1

 BGP local router ID is 3.3.3.3
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

   i 8.1.1.0/24         3.1.1.2         0          100        0       65008i
```

The outputs show that Switch A has learned no route to AS 65009, and Switch C has learned network 8.1.1.0, but the next hop 3.1.1.2 is unreachable. As a result, the route is invalid.

4. Redistribute direct routes:

Configure BGP to redistribute direct routes on Switch B, so that Switch A can obtain the route to 9.1.1.0/24, and Switch C can obtain the route to 3.1.1.0/24.

Configure Switch B.

```
[SwitchB] bgp 65009
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] import-route direct
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

Display the BGP routing table on Switch A.

```
[SwitchA] display bgp routing-table ipv4
```

```
 Total number of routes: 4

 BGP local router ID is 1.1.1.1
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >e 2.2.2.2/32         3.1.1.1         0                     0       65009?
* >e 3.1.1.0/24         3.1.1.1         0                     0       65009?
* >  8.1.1.0/24         8.1.1.1         0                     32768   i
* >e 9.1.1.0/24         3.1.1.1         0                     0       65009?
```

Two routes, 2.2.2.2/32 and 9.1.1.0/24, have been added in Switch A's routing table.

Display the BGP routing table on Switch C.

```
[SwitchC] display bgp routing-table ipv4

 Total number of routes: 4

 BGP local router ID is 3.3.3.3
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

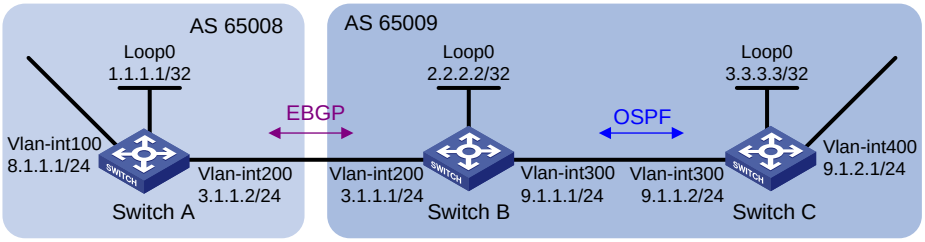
* >i 2.2.2.2/32         2.2.2.2         0          100        0       ?
* >i 3.1.1.0/24         2.2.2.2         0          100        0       ?
* >i 8.1.1.0/24         3.1.1.2         0          100        0       65008i
* >i 9.1.1.0/24         2.2.2.2         0          100        0       ?
```

The output shows that the route 8.1.1.0 becomes valid with the next hop as Switch A.

Verifying the configuration

Verify that Switch C can ping 8.1.1.1.

```
[SwitchC] ping 8.1.1.1
Ping 8.1.1.1 (8.1.1.1): 56 data bytes, press CTRL+C to break
56 bytes from 8.1.1.1: icmp_seq=0 ttl=254 time=10.000 ms
56 bytes from 8.1.1.1: icmp_seq=1 ttl=254 time=4.000 ms
56 bytes from 8.1.1.1: icmp_seq=2 ttl=254 time=4.000 ms
56 bytes from 8.1.1.1: icmp_seq=3 ttl=254 time=3.000 ms
56 bytes from 8.1.1.1: icmp_seq=4 ttl=254 time=3.000 ms
--- Ping statistics for 8.1.1.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 3.000/4.800/10.000/2.638 ms
```



Example: Configuring BGP and IGP route redistribution

Network configuration

As shown in Figure 24, all devices of company A belong to AS 65008, and all devices of company B belong to AS 65009.

Configure BGP and IGP route redistribution to allow Switch A to access network 9.1.2.0/24 in AS 65009, and Switch C to access network 8.1.1.0/24 in AS 65008.

Figure 24 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF:

   Enable OSPF in AS 65009, so Switch B can obtain the route to 9.1.2.0/24.

   # Configure Switch B.

   ```
   <SwitchB> system-view
   [SwitchB] ospf 1
   [SwitchB-ospf-1] area 0
   [SwitchB-ospf-1-area-0.0.0.0] network 2.2.2.2 0.0.0.0
   [SwitchB-ospf-1-area-0.0.0.0] network 9.1.1.0 0.0.0.255
   [SwitchB-ospf-1-area-0.0.0.0] quit
   [SwitchB-ospf-1] quit
   ```

   # Configure Switch C.

   ```
   <SwitchC> system-view
   [SwitchC] ospf 1
   [SwitchC-ospf-1] import-route direct
   [SwitchC-ospf-1] area 0
   [SwitchC-ospf-1-area-0.0.0.0] network 9.1.1.0 0.0.0.255
   [SwitchC-ospf-1-area-0.0.0.0] quit
   [SwitchC-ospf-1] quit
   ```

3. Configure the EBGP connection:

   Configure the EBGP connection and inject network 8.1.1.0/24 to the BGP routing table of Switch A, so that Switch B can obtain the route to 8.1.1.0/24.

   # Configure Switch A.

   ```
   <SwitchA> system-view
   [SwitchA] bgp 65008
   [SwitchA-bgp-default] router-id 1.1.1.1
   [SwitchA-bgp-default] peer 3.1.1.1 as-number 65009
   [SwitchA-bgp-default] address-family ipv4 unicast
   [SwitchA-bgp-default-ipv4] peer 3.1.1.1 enable
   [SwitchA-bgp-default-ipv4] network 8.1.1.0 24
   ```

```
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

Configure Switch B.

```
[SwitchB] bgp 65009
[SwitchB-bgp-default] router-id 2.2.2.2
[SwitchB-bgp-default] peer 3.1.1.2 as-number 65008
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 3.1.1.2 enable
```

4. Configure BGP and IGP route redistribution:

- Configure BGP to redistribute routes from OSPF on Switch B, so Switch A can obtain the route to 9.1.2.0/24.
- Configure OSPF to redistribute routes from BGP on Switch B, so Switch C can obtain the route to 8.1.1.0/24.

Configure route redistribution between BGP and OSPF on Switch B.

```
[SwitchB-bgp-default-ipv4] import-route ospf 1
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
[SwitchB] ospf 1
[SwitchB-ospf-1] import-route bgp
[SwitchB-ospf-1] quit
```

Display the BGP routing table on Switch A.

```
[SwitchA] display bgp routing-table ipv4

 Total number of routes: 3

 BGP local router ID is 1.1.1.1
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >e 3.3.3.3/32         3.1.1.1         1                     0       65009?
* >  8.1.1.0/24         8.1.1.1         0                     32768   i
* >e 9.1.2.0/24         3.1.1.1         1                     0       65009?
```

Display the OSPF routing table on Switch C.

```
[SwitchC] display ospf routing

          OSPF Process 1 with Router ID 3.3.3.3
                  Routing Table

 Routing for Network
 Destination        Cost     Type    NextHop         AdvRouter       Area
 9.1.1.0/24         1        Transit 9.1.1.2         3.3.3.3         0.0.0.0

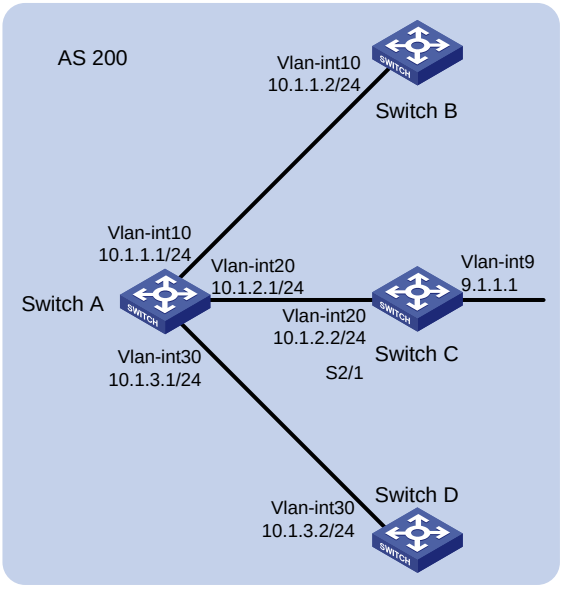
--- Ping statistics for 8.1.1.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 3.000/4.400/9.000/2.332 ms
```



Example: Configuring dynamic BGP peers

Network configuration

As shown in Figure 25, Switch A needs to establish IBGP peer relationships with Switch B, Switch C, and Switch D in network 10.1.0.0/16. Configure dynamic BGP peers to simplify the configuration.

Configure Switch A as the route reflector, and configure Switch B, Switch C, and Switch D as its clients.

Figure 25 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure IBGP peer relationship:

   # Configure Switch A to establish dynamic BGP peer relationships with switches in network 10.1.0.0/16.

```
<SwitchA> system-view
[SwitchA] bgp 200
[SwitchA-bgp-default] router-id 1.1.1.1
[SwitchA-bgp-default] peer 10.1.0.0 16 as-number 200
[SwitchA-bgp-default] address-family ipv4
[SwitchA-bgp-default-ipv4] peer 10.1.0.0 16 enable
```

   # Configure Switch B to establish an IBGP peer relationship with Switch A.

```
<SwitchB> system-view
[SwitchB] bgp 200
[SwitchB-bgp-default] router-id 2.2.2.2
[SwitchB-bgp-default] peer 10.1.1.1 as-number 200
[SwitchB-bgp-default] address-family ipv4
[SwitchB-bgp-default-ipv4] peer 10.1.1.1 enable
```

   # Configure Switch C to establish an IBGP peer relationship with Switch A.

```
<SwitchC> system-view
[SwitchC] bgp 200
[SwitchC-bgp-default] router-id 3.3.3.3
[SwitchC-bgp-default] peer 10.1.2.1 as-number 200
[SwitchC-bgp-default] address-family ipv4
[SwitchC-bgp-default-ipv4] peer 10.1.2.1 enable
```

   # Configure Switch D to establish an IBGP peer relationship with Switch A.

```
<SwitchD> system-view
[SwitchD] bgp 200
[SwitchD-bgp-default] router-id 4.4.4.4
```

```
[SwitchD-bgp-default] peer 10.1.3.1 as-number 200
[SwitchD-bgp-default] address-family ipv4
[SwitchD-bgp-default-ipv4] peer 10.1.3.1 enable
```

Display BGP peer information on Switch A. The output shows that Switch A has established IBGP peer relationships with Switch B, Switch C, and Switch D.

```
[SwitchA] display bgp peer ipv4

 BGP local router ID : 1.1.1.1
 Local AS number : 200

 Total number of peers : 3                 Peers in established state : 3

 * - Dynamically created peer
 ^ - Peer created through link-local address
 Peer                    AS  MsgRcvd  MsgSent OutQ PrefRcv Up/Down  State

*10.1.1.2               200        7       10    0       0 00:06:09 Established
*10.1.2.2               200        7       10    0       0 00:06:09 Established
*10.1.3.2               200        7       10    0       0 00:06:09 Established
```

3. Configure Switch A as the route reflector, and configure peers in network 10.1.0.0/16 as its clients.

```
[SwitchA-bgp-default-ipv4] peer 10.1.0.0 16 reflect-client
```

4. Configure Switch C to advertise network 9.1.1.0/24.

```
[SwitchC-bgp-default-ipv4] network 9.1.1.0 24
```

Verifying the configuration

Verify that route 9.1.1.0/24 exists in the BGP routing table on Switch A, Switch B, and Switch D. This example uses Switch A.

```
[SwitchA-bgp-default] display bgp routing-table ipv4

 Total Number of Routes: 1

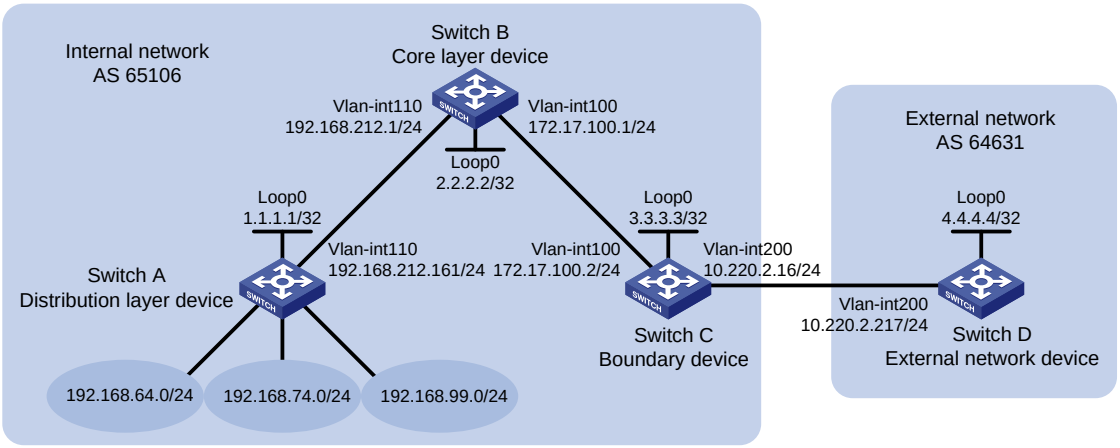
 BGP Local router ID is 1.1.1.1
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
      Origin: i - IGP, e - EGP, ? - incomplete

    Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

 * i 9.1.1.0/24        10.1.2.2        0          100        0       ?
```

Example: Configuring BGP route summarization

Network configuration



As shown in Figure 26, run EBGP between Switch C and Switch D, so the internal network and external network can communicate with each other.

- In AS 65106, perform the following configurations so the devices in the internal network can communicate:

- Configure static routing between Switch A and Switch B.
- Configure OSPF between Switch B and Switch C.
- Configure OSPF to redistribute static routes.

- Configure route summarization on Switch C so BGP advertises a summary route instead of advertising routes to the 192.168.64.0/24, 192.168.74.0/24, and 192.168.99.0/24 networks to Switch D.

Figure 26 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure static routing between Switch A and Switch B:

   # Configure a default route with the next hop 192.168.212.1 on Switch A.

   ```
   <SwitchA> system-view
   [SwitchA] ip route-static 0.0.0.0 0 192.168.212.1
   ```

   # Configure static routes to 192.168.64.0/24, 192.168.74.0/24, and 192.168.99.0/24 with the same next hop 192.168.212.161 on Switch B.

   ```
   <SwitchB> system-view
   [SwitchB] ip route-static 192.168.64.0 24 192.168.212.161
   [SwitchB] ip route-static 192.168.74.0 24 192.168.212.161
   [SwitchB] ip route-static 192.168.99.0 24 192.168.212.161
   ```

3. Configure OSPF between Switch B and Switch C and configure OSPF on Switch B to redistribute static routes:

   # Configure OSPF to advertise the local network and enable OSPF to redistribute static routes on Switch B.

   ```
   [SwitchB] ospf
   [SwitchB-ospf-1] area 0
   [SwitchB-ospf-1-area-0.0.0.0] network 172.17.100.0 0.0.0.255
   [SwitchB-ospf-1-area-0.0.0.0] quit
   [SwitchB-ospf-1] import-route static
   [SwitchB-ospf-1] quit
   ```

   # Configure OSPF to advertise the local networks on Switch C.

   ```
   [SwitchC] ospf
   [SwitchC-ospf-1] area 0
   [SwitchC-ospf-1-area-0.0.0.0] network 172.17.100.0 0.0.0.255
   [SwitchC-ospf-1-area-0.0.0.0] network 10.220.2.0 0.0.0.255
   ```

```
[SwitchC-ospf-1-area-0.0.0.0] quit
[SwitchC-ospf-1] quit
```

Display the IP routing table on Switch C.

```
[SwitchC] display ip routing-table protocol ospf

Summary count : 5

OSPF Routing table Status : <Active>
Summary count : 3

Destination/Mask    Proto   Pre  Cost         NextHop         Interface
192.168.64.0/24     O_ASE2  150  1            172.17.100.1    Vlan100
192.168.74.0/24     O_ASE2  150  1            172.17.100.1    Vlan100
192.168.99.0/24     O_ASE2  150  1            172.17.100.1    Vlan100

OSPF Routing table Status : <Inactive>
Summary count : 2

Destination/Mask    Proto    Pre  Cost         NextHop         Interface
10.220.2.0/24       O_INTRA  10   1            10.220.2.16     Vlan200
172.17.100.0/24     O_INTRA  10   1            172.17.100.2    Vlan100
```

The output shows that Switch C has learned routes to 192.168.64.0/24, 192.168.99.0/24, and 192.168.64.0/18 through OSPF.

4. Configure BGP between Switch C and Switch D and configure BGP on Switch C to redistribute OSPF routes:

On Switch C, enable BGP, specify Switch D as an EBGP peer, and configure BGP to redistribute OSPF routes.

```
[SwitchC] bgp 65106
[SwitchC-bgp-default] router-id 3.3.3.3
[SwitchC-bgp-default] peer 10.220.2.217 as-number 64631
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 10.220.2.217 enable
[SwitchC-bgp-default-ipv4] import-route ospf
```

Enable BGP, and configure Switch C as an EBGP peer on Switch D.

```
[SwitchD] bgp 64631
[SwitchD-bgp-default] router-id 4.4.4.4
[SwitchD-bgp-default] peer 10.220.2.16 as-number 65106
[SwitchD-bgp-default] address-family ipv4 unicast
[SwitchD-bgp-default-ipv4] peer 10.220.2.16 enable
[SwitchD-bgp-default-ipv4] quit
[SwitchD-bgp-default] quit
```

Display the IP routing table on Switch D.

```
[SwitchD] display ip routing-table protocol bgp

Summary count : 3

BGP Routing table Status : <Active>
Summary count : 3
```

```
Destination/Mask    Proto  Pre  Cost         NextHop         Interface
192.168.64.0/24     BGP    255  1            10.220.2.16     Vlan200
192.168.74.0/24     BGP    255  1            10.220.2.16     Vlan200
192.168.99.0/24     BGP    255  1            10.220.2.16     Vlan200

BGP Routing table Status : <Inactive>
Summary count : 0
```

The output shows that Switch D has learned routes to 192.168.64.0/24, 192.168.74.0/24, and 192.168.99.0/24 through BGP.

Verify that Switch D can ping hosts on networks 192.168.74.0/24, 192.168.99.0/24, and 192.168.64.0/18. (Details not shown.)

5. Configure route summarization on Switch C to summarize 192.168.64.0/24, 192.168.74.0/24, and 192.168.99.0/24 into a single route 192.168.64.0/18, and disable advertisement of specific routes.

```
[SwitchC-bgp-default-ipv4] aggregate 192.168.64.0 18 detail-suppressed
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

Verifying the configuration

Display IP routing table on Switch C.

```
[SwitchC] display ip routing-table | include 192.168
192.168.64.0/18    BGP     130  0            127.0.0.1       NULL0
192.168.64.0/24    O_ASE2  150  1            172.17.100.1    Vlan100
192.168.74.0/24    O_ASE2  150  1            172.17.100.1    Vlan100
192.168.99.0/24    O_ASE2  150  1            172.17.100.1    Vlan100
```

The output shows that Switch C has a summary route 192.168.64.0/18 with the output interface Null0.

Display IP routing table on Switch D.

```
[SwitchD] display ip routing-table protocol bgp

Summary count : 1

BGP Routing table Status : <Active>
Summary count : 1

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
192.168.64.0/18     BGP    255  0            10.220.2.16     Vlan200

BGP Routing table Status : <Inactive>
Summary count : 0
```

The output shows that Switch D has only one route 192.168.64.0/18 to AS 65106.

Verify that Switch D can ping the hosts on networks 192.168.64.0/24, 192.168.74.0/24, and 192.168.99.0/24. (Details not shown.)

Example: Configuring multicast BGP

Network configuration

As shown in Figure 27, OSPF runs within AS 100 and AS 200 to ensure intra-AS connectivity. MBGP runs between the two ASs to exchange IPv4 unicast routes used for RPF check.

- Configure the Loopback 0 interface of Switch A and Switch B as the C-BSR and C-RP.
- Configure Switch A and Switch B to establish a Multicast Source Discovery Protocol (MSDP) peer relationship through MBGP, so that the receiver can receive multicast traffic from the source.

Figure 27 Network diagram

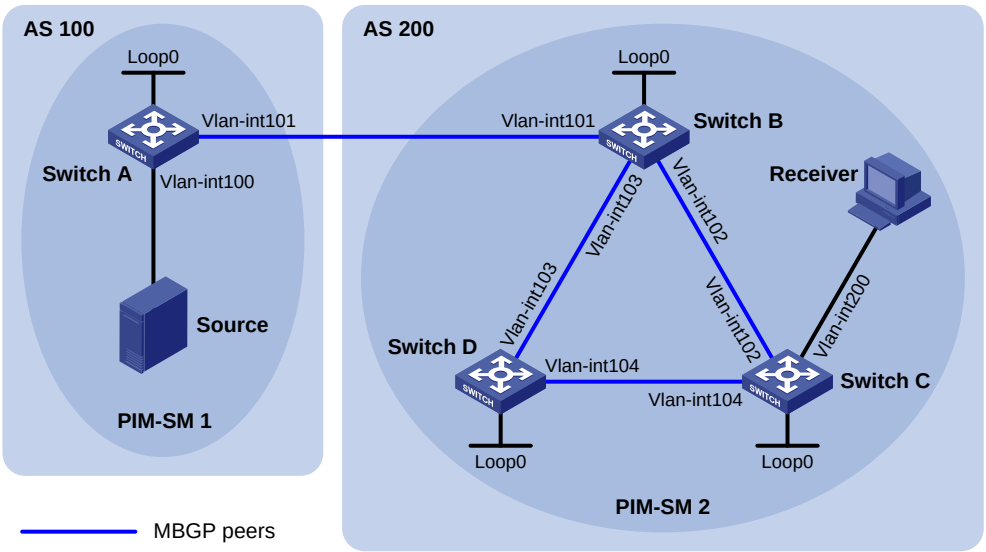


Table 9 Interface and IP address assignment

Device	Interface	IP address	Device	Interface	IP address
Source	N/A	10.110.1.100/24	Switch C	Vlan-int200	10.110.2.1/24
Switch A	Vlan-int100	10.110.1.1/24		Vlan-int102	192.168.2.2/24
	Vlan-int101	192.168.1.1/24		Vlan-int104	192.168.4.1/24
	Loop0	1.1.1.1/32		Loop0	3.3.3.3/32
Switch B	Vlan-int101	192.168.1.2/24	Switch D	Vlan-int103	192.168.3.2/24
	Vlan-int102	192.168.2.1/24		Vlan-int104	192.168.4.2/24
	Vlan-int103	192.168.3.1/24		Loop0	4.4.4.4/32
	Loop0	2.2.2.2/32			

Procedure

1. Configure IP addresses for interfaces and configure OSPF (this example uses OSPF process 1) in AS 200 to ensure intra-AS connectivity. (Details not shown.)
2. Enable IP multicast routing, PIM-SM, and IGMP, and configure BSR boundaries:

   # On Switch A, enable multicast routing globally, and enable PIM-SM on interfaces.

   ```
   <SwitchA> system-view
   [SwitchA] multicast routing
   ```

```
[SwitchA-mrib] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] pim sm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim sm
[SwitchA-Vlan-interface101] quit
```

Configure Switch B and Switch D in the same way that Switch A was configured.

On Switch C, enable multicast routing globally.

```
<SwitchC> system-view
[SwitchC] multicast routing
[SwitchA-mrib] quit
```

Enable PIM-SM on interfaces, and enable IGMP on VLAN-interface 200.

```
[SwitchC] interface vlan-interface 102
[SwitchC-Vlan-interface102] pim sm
[SwitchC-Vlan-interface102] quit
[SwitchC] interface vlan-interface 104
[SwitchC-Vlan-interface104] pim sm
[SwitchC-Vlan-interface104] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] pim sm
[SwitchC-Vlan-interface200] igmp enable
[SwitchC-Vlan-interface200] quit
```

Configure the BSR boundary on Switch A.

```
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] pim bsr-boundary
[SwitchA-Vlan-interface101] quit
```

Configure the BSR boundary on Switch B.

```
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] pim bsr-boundary
[SwitchB-Vlan-interface101] quit
```

3. Configure Loopback 0, C-BSR, and C-RP:

Configure the Loopback 0 interface and specify it as the C-BSR and C-RP on Switch A.

```
[SwitchA] interface loopback 0
[SwitchA-LoopBack0] ip address 1.1.1.1 32
[SwitchA-LoopBack0] pim sm
[SwitchA-LoopBack0] quit
[SwitchA] pim
[SwitchA-pim] c-bsr 1.1.1.1
[SwitchA-pim] c-rp 1.1.1.1
[SwitchA-pim] quit
```

Configure the Loopback 0 interface and specify it as the C-BSR and C-RP on Switch B.

```
[SwitchB] interface loopback 0
[SwitchB-LoopBack0] ip address 2.2.2.2 32
[SwitchB-LoopBack0] pim sm
[SwitchB-LoopBack0] quit
[SwitchB] pim
[SwitchB-pim] c-bsr 2.2.2.2
```

```
[SwitchB-pim] c-rp 2.2.2.2
[SwitchB-pim] quit
```

4. Configure BGP to establish BGP IPv4 multicast peers and redistribute routes:

On Switch A, establish an EBGP session to Switch B.

```
[SwitchA] bgp 100
[SwitchA-bgp-default] router-id 1.1.1.1
[SwitchA-bgp-default] peer 192.168.1.2 as-number 200
```

Enable exchange of IPv4 unicast routes used for RPF check with Switch B.

```
[SwitchA-bgp-default] address-family ipv4 multicast
[SwitchA-bgp-default-mul-ipv4] peer 192.168.1.2 enable
```

Redistribute direct routes into BGP.

```
[SwitchA-bgp-default-mul-ipv4] import-route direct
[SwitchA-bgp-default-mul-ipv4] quit
[SwitchA-bgp-default] quit
```

On Switch B, establish an EBGP session to Switch A.

```
[SwitchB] bgp 200
[SwitchB-bgp-default] router-id 2.2.2.2
[SwitchB-bgp-default] peer 192.168.1.1 as-number 100
```

Enable exchange of IPv4 unicast routes used for RPF check with Switch B.

```
[SwitchB-bgp-default] address-family ipv4 multicast
[SwitchB-bgp-default-mul-ipv4] peer 192.168.1.1 enable
```

Redistribute OSPF routes into BGP.

```
[SwitchB-bgp-default-mul-ipv4] import-route ospf 1
[SwitchB-bgp-default-mul-ipv4] quit
[SwitchB-bgp-default] quit
```

5. Configure MSDP peers:

Configure an MSDP peer on Switch A.

```
[SwitchA] msdp
[SwitchA-msdp] peer 192.168.1.2 connect-interface vlan-interface 101
[SwitchA-msdp] quit
```

Configure an MSDP peer on Switch B.

```
[SwitchB] msdp
[SwitchB-msdp] peer 192.168.1.1 connect-interface vlan-interface 101
[SwitchB-msdp] quit
```

Verifying the configuration

Verify the BGP IPv4 multicast peer information on Switch B.

```
[SwitchB] display bgp peer ipv4 multicast

 BGP local router ID : 2.2.2.2
 Local AS number : 200
 Total number of peers : 3                 Peers in established state : 3

  Peer            AS  MsgRcvd  MsgSent  OutQ PrefRcv Up/Down  State

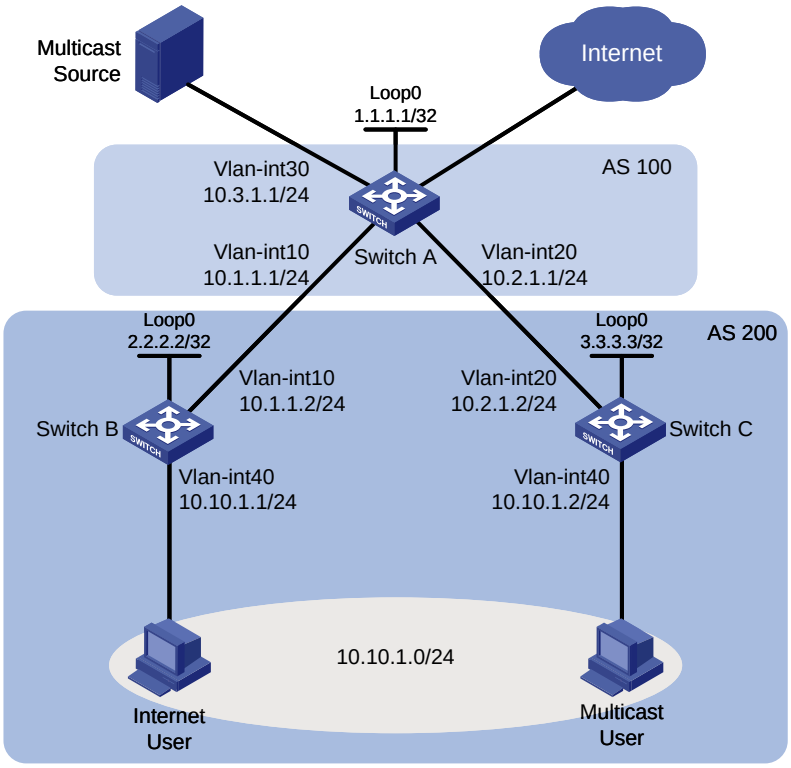
  192.168.1.1    100       56       56     0       0 00:40:54 Established
```

Verify the MSDP peer information on Switch B.

```
[SwitchB] display msdp brief
```

```
Configured    Established  Listen       Connect      Shutdown     Disabled
1             1            0            0            0            0

Peer address    State       Up/Down time    AS         SA count    Reset count
192.168.1.1     Established 00:07:17        100        1           0
```



Example: Separating unicast traffic and multicast traffic

Network configuration

Switch A is located in AS 100 and is connected to a multicast source and the Internet. Switch B and Switch C run in AS 200 and are connected to Internet users and multicast users, respectively. Unicast traffic and multicast traffic need to be separated, which ensures that traffic from AS 100 to AS 200 is forwarded along the following paths:

- **Internet traffic**: **Switch A** > **Switch B** > **Internet user**
- **Multicast traffic**: **Switch A** > **Switch C** > **Multicast user**

Figure 28 Network diagram

Procedure

1. Configure IP addresses for interfaces and configure OSPF (this example uses OSPF process 1) in AS 200 to ensure intra-AS connectivity. (Details not shown.)
2. Establish BGP sessions.

   # Configure Switch A.

   ```
   <SwitchA> system-view
   [SwitchA] bgp 100
   [SwitchA-bgp-default] router-id 1.1.1.1
   [SwitchA-bgp-default] peer 10.1.1.2 as-number 200
   [SwitchA-bgp-default] peer 10.2.1.2 as-number 200
   ```

```
[SwitchA-bgp-default] address-family ipv4 multicast
[SwitchA-bgp-default-mul-ipv4] peer 10.1.1.2 enable
[SwitchA-bgp-default-mul-ipv4] peer 10.2.1.2 enable
[SwitchA-bgp-default-mul-ipv4] quit
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 10.1.1.2 enable
[SwitchA-bgp-default-ipv4] peer 10.2.1.2 enable
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 200
[SwitchB-bgp-default] router-id 2.2.2.2
[SwitchB-bgp-default] peer 10.1.1.1 as-number 100
[SwitchB-bgp-default] peer 10.10.1.2 as-number 200
[SwitchB-bgp-default] address-family ipv4 multicast
[SwitchB-bgp-default-mul-ipv4] peer 10.1.1.1 enable
[SwitchB-bgp-default-mul-ipv4] peer 10.10.1.2 enable
[SwitchB-bgp-default-mul-ipv4] quit
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 10.1.1.1 enable
[SwitchB-bgp-default-ipv4] peer 10.10.1.2 enable
[SwitchB-bgp-default-ipv4] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 200
[SwitchC-bgp-default] router-id 3.3.3.3
[SwitchC-bgp-default] peer 10.2.1.1 as-number 100
[SwitchC-bgp-default] peer 10.10.1.1 as-number 200
[SwitchC-bgp-default] address-family ipv4 multicast
[SwitchC-bgp-default-mul-ipv4] peer 10.2.1.1 enable
[SwitchC-bgp-default-mul-ipv4] peer 10.10.1.1 enable
[SwitchC-bgp-default-mul-ipv4] quit
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 10.2.1.1 enable
[SwitchC-bgp-default-ipv4] peer 10.10.1.1 enable
[SwitchC-bgp-default-ipv4] quit
```

3. Configure BGP unicast routes used for unicast traffic forwarding, and BGP unicast routes used for multicast RPF check.

Configure Switch B.

```
[SwitchB-bgp-default] address-family ipv4 multicast
[SwitchB-bgp-default-mul-ipv4] network 2.2.2.2 32
[SwitchB-bgp-default-mul-ipv4] network 10.10.1.0 24
[SwitchB-bgp-default-mul-ipv4] quit
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] network 10.10.1.0 24
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

Configure Switch C.

```
[SwitchC-bgp-default] address-family ipv4 multicast
[SwitchC-bgp-default-mul-ipv4] network 2.2.2.2 32
[SwitchC-bgp-default-mul-ipv4] network 10.10.1.0 24
[SwitchC-bgp-default-mul-ipv4] quit
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] network 10.10.1.0 24
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

4. Configure a routing policy on Switch B and Switch C separately, so the two routers can modify the MED values of routes before route advertisement. This operation ensures that Switch A selects the BGP unicast route from Switch B for unicast traffic forwarding and selects the BGP unicast route from Switch C for multicast RPF check.

Configure Switch B.

```
[SwitchB] acl basic 2077
[SwitchB-acl-ipv4-basic-2077] rule permit source 10.10.1.0 0.0.0.255
[SwitchB-acl-ipv4-basic-2077] quit
[SwitchB] route-policy b2a permit node 10
[SwitchB-route-policy-b2a-10] if-match ip address acl 2077
[SwitchB-route-policy-b2a-10] apply cost 200
[SwitchB-route-policy-b2a-10] quit
[SwitchB] route-policy b2a permit node 20
[SwitchB-route-policy-b2a-20] quit
[SwitchB] bgp 200
[SwitchB-bgp-default] address-family ipv4 multicast
[SwitchB-bgp-default-mul-ipv4] peer 10.1.1.1 route-policy b2a export
[SwitchB-bgp-default-mul-ipv4] quit
[SwitchB-bgp-default] quit
```

Configure Switch C.

```
[SwitchC] acl basic 2077
[SwitchC-acl-ipv4-basic-2077] rule permit source 10.10.1.0 0.0.0.255
[SwitchC-acl-ipv4-basic-2077] quit
[SwitchC] route-policy b2a permit node 10
[SwitchC-route-policy-b2a-10] if-match ip address acl 2077
[SwitchC-route-policy-b2a-10] apply cost 200
[SwitchC-route-policy-b2a-10] quit
[SwitchC] route-policy b2a permit node 20
[SwitchC-route-policy-b2a-20] quit
[SwitchC] bgp 200
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 10.2.1.1 route-policy b2a export
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

5. Configure IP multicast.

Configure Switch A.

```
[SwitchA] multicast routing
[SwitchA-mrib] quit
[SwitchA] interface vlan-interface 10
```

```
[SwitchA-Vlan-interface10] pim sm
[SwitchA-Vlan-interface10] quit
[SwitchA] interface vlan-interface 20
[SwitchA-Vlan-interface20] pim sm
[SwitchA-Vlan-interface20] quit
[SwitchA] interface loopback 0
[SwitchA-LoopBack0] pim sm
[SwitchA-LoopBack0] quit
[SwitchA] pim
[SwitchA-pim] c-bsr 1.1.1.1
[SwitchA-pim] c-rp 1.1.1.1
[SwitchA-pim] quit
```

Configure Switch B.

```
[SwitchB] multicast routing
[SwitchB-mrib] quit
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] pim sm
[SwitchB-Vlan-interface10] quit
[SwitchB] interface vlan-interface 40
[SwitchB-Vlan-interface40] pim sm
[SwitchB-Vlan-interface40] igmp enable
[SwitchB-Vlan-interface40] quit
[SwitchB] interface loopback 0
[SwitchB-LoopBack0] pim sm
[SwitchB-LoopBack0] quit
```

Configure Switch C.

```
[SwitchC] multicast routing
[SwitchC-mrib] quit
[SwitchC] interface vlan-interface 20
[SwitchC-Vlan-interface20] pim sm
[SwitchC-Vlan-interface20] quit
[SwitchC] interface vlan-interface 40
[SwitchC-Vlan-interface40] pim sm
[SwitchC-Vlan-interface40] igmp enable
[SwitchC-Vlan-interface40] quit
[SwitchC] interface loopback 0
[SwitchC-LoopBack0] pim sm
[SwitchC-LoopBack0] quit
[SwitchC] pim
[SwitchC-pim] c-bsr 3.3.3.3
[SwitchC-pim] c-rp 3.3.3.3
[SwitchC-pim] quit
```

6. Configure BSR boundaries.

Configure Switch A.

```
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] pim bsr-boundary
[SwitchA-Vlan-interface10] quit
[SwitchA] interface vlan-interface 20
```

```
[SwitchA-Vlan-interface20] pim bsr-boundary
[SwitchA-Vlan-interface20] quit
```

Configure Switch B.

```
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] pim bsr-boundary
[SwitchB-Vlan-interface10] quit
```

Configure Switch C.

```
[SwitchC] interface vlan-interface 20
[SwitchC-Vlan-interface20] pim bsr-boundary
[SwitchC-Vlan-interface20] quit
```

7. Configure MSDP peers.

Configure Switch A.

```
[SwitchA] msdp
[SwitchA-msdp] peer 10.1.1.2 connect-interface vlan-interface 10
[SwitchA-msdp] peer 10.2.1.2 connect-interface vlan-interface 20
[SwitchA-msdp] quit
```

Configure Switch B.

```
[SwitchB] msdp
[SwitchB-msdp] peer 10.1.1.1 connect-interface vlan-interface 10
[SwitchB-msdp] quit
```

Configure Switch C.

```
[SwitchC] msdp
[SwitchC-msdp] peer 10.2.1.1 connect-interface vlan-interface 20
[SwitchC-msdp] quit
```

Verifying the configuration

View BGP IPv4 unicast routing information on Switch A.

```
[SwitchA] display bgp routing-table ipv4 unicast

 Total number of routes: 2

 BGP local router ID is 1.1.1.1
 Status codes: * - valid, > - best, d - dampened, h - history
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >e  10.10.1.0/24      10.1.1.2        0                     0       200i
*  e                    10.2.1.2        200                   0       200i
```

View BGP IPv4 multicast routing information on Switch A.

```
[SwitchA] display bgp routing-table ipv4 multicast

 Total number of routes: 6

 BGP local router ID is 1.1.1.1
 Status codes: * - valid, > - best, d - dampened, h - history
```

```
                s - suppressed, S - stale, i - internal, e - external
                a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >e  2.2.2.2/32        10.1.1.2        0                     0       200i
*  e                    10.2.1.2                              0       200i
* >e  3.3.3.3/32        10.2.1.2        0                     0       200i
*  e                    10.1.1.2                              0       200i
* >e  10.10.1.0/24      10.2.1.2        0                     0       200i
*  e                    10.1.1.2        200                   0       200i
```

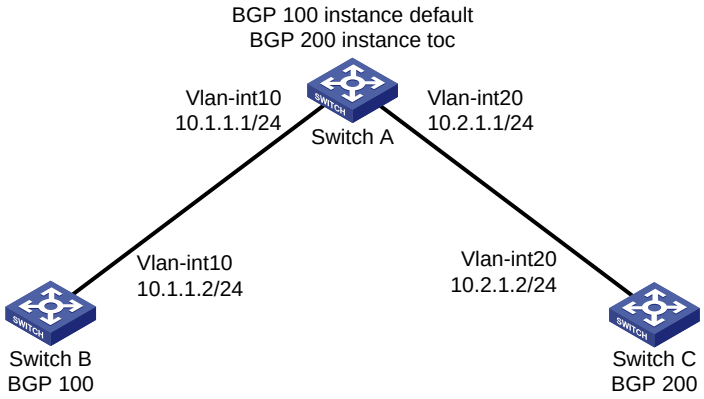
在 Switch A 上，查看 MSDP 对等体的建立情况。

According to the above command outputs, Switch A selects the BGP unicast route from Switch B for unicast traffic forwarding and selects the BGP unicast route from Switch C for multicast RPF check.

On Switch A, view MSDP peers.

```
[SwitchA] display msdp brief
Configured    Established  Listen       Connect      Shutdown     Disabled
2             2            0            0            0            0

Peer address     State       Up/Down time    AS         SA count    Reset count
10.1.1.2         Established 00:40:17        200        0           0
10.2.1.2         Established 00:41:17        200        0           0
```



According to the above command output, Switch A has established an MSDP peer relationship with Switch B and Switch C separately.

Example: Configuring multiple BGP instances on one switch

Network configuration

To achieve separate management and maintenance of different switches' routes, Switch A uses different BGP instances to establish a BGP session to Switch B and Switch C separately. After Switch A receive routes from Switch B and Switch C, it does not advertise the routes of Switch B to Switch C or the routes of Switch C to Switch B.

Figure 29 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure BGP connections.

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA-bgp-default] router-id 10.1.1.1
[SwitchA-bgp-default] peer 10.1.1.2 as-number 100
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 10.1.1.2 enable
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
[SwitchA] bgp 200 instance toc
[SwitchA-bgp-toc] router-id 10.2.1.1
[SwitchA-bgp-toc] peer 10.2.1.2 as-number 200
[SwitchA-bgp-toc] address-family ipv4 unicast
[SwitchA-bgp-toc-ipv4] peer 10.2.1.2 enable
[SwitchA-bgp-toc-ipv4] quit
[SwitchA-bgp-toc] quit
```

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 100
[SwitchB-bgp-default] peer 10.1.1.1 as-number 100
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 10.1.1.1 enable
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

   # Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 200
[SwitchC-bgp-default] peer 10.2.1.1 as-number 200
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 10.2.1.1 enable
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

3. Configure route advertisement.

   # Configure Switch B.

```
[SwitchB] ip route-static 192.168.10.10 32 null 0
[SwitchB] bgp 100
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] import-route static
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

   # Configure Switch C.

```
[SwitchC] ip route-static 192.168.20.20 32 null 0
[SwitchC] bgp 200
[SwitchC-bgp-default] address-family ipv4 unicast
```

```
[SwitchC-bgp-default-ipv4] import-route static
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

Verifying the configuration

View the IP routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 12       Routes : 12

Destination/Mask   Proto   Pre Cost        NextHop         Interface

View the IP routing table of Switch C.

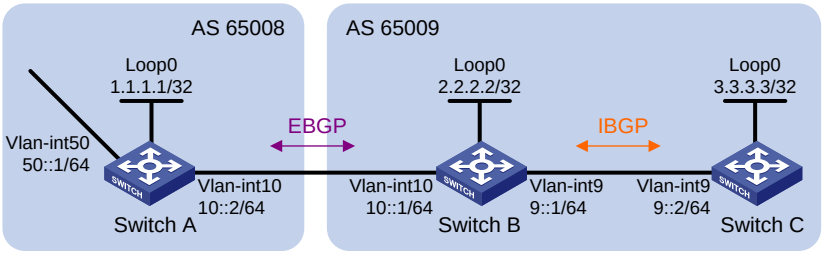
```
[SwitchC] display ip routing-table

Destinations : 8        Routes : 8

Destination/Mask   Proto   Pre Cost        NextHop         Interface
10.2.1.0/24        Direct  0   0           10.2.1.2        Vlan20
10.2.1.2/32        Direct  0   0           127.0.0.1       Vlan20
10.2.1.255/32      Direct  0   0           10.2.1.2        Vlan20
127.0.0.0/8        Direct  0   0           127.0.0.1       InLoop0
127.0.0.1/32       Direct  0   0           127.0.0.1       InLoop0
```

```
127.255.255.255/32 Direct  0   0           127.0.0.1       InLoop0
192.168.20.20/32   Static  60  0           0.0.0.0         NULL0
255.255.255.255/32 Direct  0   0           127.0.0.1       InLoop0
```

According to the above command outputs, Switch A can receive routes from Switch B and Switch C, but the routing table of Switch B or Switch C only has their own routes.



Basic IPv6 BGP network configuration examples

Example: Configuring IPv6 BGP basics

Network configuration

As shown in Figure 30, all switches run BGP. Run EBGP between Switch A and Switch B, and run IBGP between Switch B and Switch C to allow Switch C to access network 50::/64 connected to Switch A.

Figure 30 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure IBGP:

   # Configure Switch B.

   ```
   <SwitchB> system-view
   [SwitchB] bgp 65009
   [SwitchB-bgp-default] router-id 2.2.2.2
   [SwitchB-bgp-default] peer 9::2 as-number 65009
   [SwitchB-bgp-default] address-family ipv6
   [SwitchB-bgp-default-ipv6] peer 9::2 enable
   [SwitchB-bgp-default-ipv6] quit
   ```

   # Configure Switch C.

   ```
   <SwitchC> system-view
   [SwitchC] bgp 65009
   [SwitchC-bgp-default] router-id 3.3.3.3
   [SwitchC-bgp-default] peer 9::1 as-number 65009
   [SwitchC-bgp-default] address-family ipv6
   [SwitchC-bgp-default-ipv6] peer 9::1 enable
   ```

3. Configure EBGP:

   # Configure Switch A.

   ```
   <SwitchA> system-view
   [SwitchA] bgp 65008
   [SwitchA-bgp-default] router-id 1.1.1.1
   ```

```
[SwitchA-bgp-default] peer 10::1 as-number 65009
[SwitchA-bgp-default] address-family ipv6
[SwitchA-bgp-default-ipv6] peer 10::1 enable
```

Configure Switch B.

```
[SwitchB-bgp-default] peer 10::2 as-number 65008
[SwitchB-bgp-default] address-family ipv6
[SwitchB-bgp-default-ipv6] peer 10::2 enable
```

4. Inject network routes to the BGP routing table:

Configure Switch A.

```
[SwitchA-bgp-default-ipv6] network 10:: 64
[SwitchA-bgp-default-ipv6] network 50:: 64
[SwitchA-bgp-default-ipv6] quit
[SwitchA-bgp-default] quit
```

Configure Switch B.

```
[SwitchB-bgp-default-ipv6] network 10:: 64
[SwitchB-bgp-default-ipv6] network 9:: 64
[SwitchB-bgp-default-ipv6] quit
[SwitchB-bgp-default] quit
```

Configure Switch C.

```
[SwitchC-bgp-default-ipv6] network 9:: 64
[SwitchC-bgp-default-ipv6] quit
[SwitchC-bgp-default] quit
```

Verifying the configuration

Display IPv6 BGP peer information on Switch B.

```
[SwitchB] display bgp peer ipv6

 BGP local router ID: 2.2.2.2
 Local AS number: 65009
 Total number of peers: 2                 Peers in established state: 2

  * - Dynamically created peer
  ^ - Peer created through link-local address
  Peer                    AS  MsgRcvd  MsgSent OutQ PrefRcv Up/Down  State

  9::2                 65009       41       43    0       1 00:29:00 Established
  10::2                65008       38       38    0       2 00:27:20 Established
```

The output shows that Switch A and Switch B have established an EBGP connection, and Switch B and Switch C have established an IBGP connection.

Display IPv6 BGP routing table information on Switch A.

```
[SwitchA] display bgp routing-table ipv6

 Total number of routes: 4

 BGP local router ID is 1.1.1.1
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
```

```
       Origin: i - IGP, e - EGP, ? - incomplete

* >e Network : 9::                                        PrefixLen : 64
     NextHop : 10::1                                     LocPrf    :
     PrefVal : 0                                         OutLabel  : NULL
     MED     : 0
     Path/Ogn: 65009i

* >  Network : 10::                                       PrefixLen : 64
     NextHop : ::                                        LocPrf    :
     PrefVal : 32768                                     OutLabel  : NULL
     MED     : 0
     Path/Ogn: i

*  e Network : 10::                                       PrefixLen : 64
     NextHop : 10::1                                     LocPrf    :
     PrefVal : 0                                         OutLabel  : NULL
     MED     : 0
     Path/Ogn: 65009i

* >  Network : 50::                                       PrefixLen : 64
     NextHop : ::                                        LocPrf    :
     PrefVal : 32768                                     OutLabel  : NULL
     MED     : 0
     Path/Ogn: i
```

The output shows that Switch A has learned routing information of AS 65009.

Display IPv6 BGP routing table information on Switch C.

```
[SwitchC] display bgp routing-table ipv6

 Total number of routes: 4

 BGP local router ID is 3.3.3.3
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

* >  Network : 9::                                        PrefixLen : 64
     NextHop : ::                                        LocPrf    :
     PrefVal : 32768                                     OutLabel  : NULL
     MED     : 0
     Path/Ogn: i

*  i Network : 9::                                        PrefixLen : 64
     NextHop : 9::1                                      LocPrf    : 100
     PrefVal : 0                                         OutLabel  : NULL
     MED     : 0
     Path/Ogn: i
```

```
* >i Network : 10::                                    PrefixLen : 64
     NextHop : 9::1                                   LocPrf    : 100
     PrefVal : 0                                      OutLabel  : NULL
     MED     : 0
     Path/Ogn: i

* >i Network : 50::                                    PrefixLen : 64
     NextHop : 10::2                                  LocPrf    : 100
     PrefVal : 0                                      OutLabel  : NULL
     MED     : 0
     Path/Ogn: 65008i
```

The output shows that Switch C has learned the route 50::/64.

Verify that Switch C can ping hosts on network 50::/64. (Details not shown.)

Example: Configuring IPv6 multicast BGP

Network configuration

As shown in Figure 31, OSPFv3 runs within AS 100 and AS 200 to ensure intra-AS connectivity. IPv6 MBGP runs between the two ASs to exchange IPv6 unicast routes used for RPF check.

Enable Anycast RP on Switch A and Switch B.

Figure 31 Network diagram

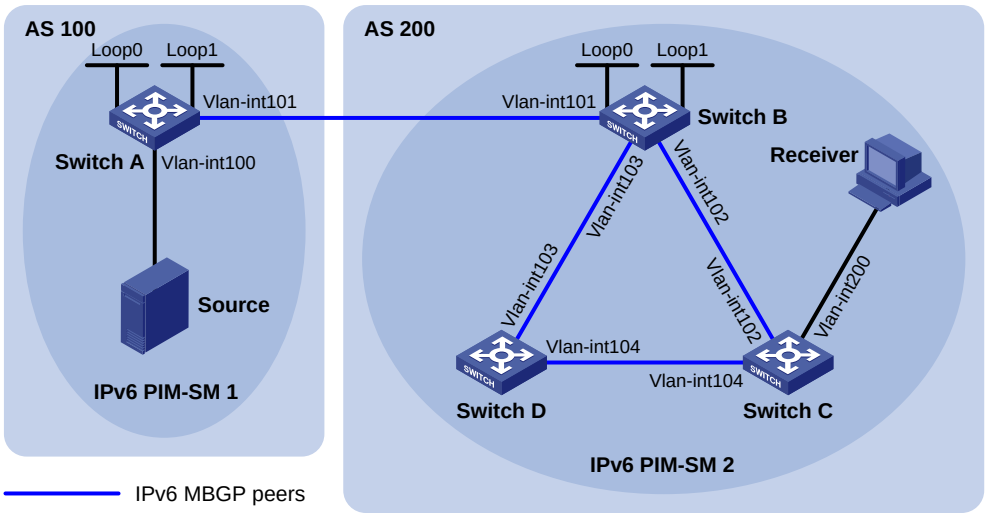


Table 10 Interface and IP address assignment

Device	Interface	IP address	Device	Interface	IP address
Source	-	1002::100/64	Switch B	Vlan-int101	1001::2/64
Switch A	Vlan-int100	1002::1/64		Vlan-int102	2001::1/64
	Vlan-int101	1001::1/64		Vlan-int103	2002::1/64
	Loop0	1:1::1/128		Loop0	1:1::1/128
	Loop1	1:1::2/128		Loop1	2:2::2/128

Device	Interface	IP address	Device	Interface	IP address
Switch C	Vlan-int200	3002::1/64	Switch D	Vlan-int103	2002::2/64
	Vlan-int102	2001::2/64		Vlan-int104	3001::2/64
	Vlan-int104	3001::1/64			

Procedure

1. Configure IPv6 addresses for interfaces and configure OSPFv3 (this example uses OSPFv3 process 1) in AS 200 to ensure intra-AS connectivity. (Details not shown.)
2. Enable IPv6 multicast routing, IPv6 PIM-SM, and MLD, and configure BSR boundaries:

   # On Switch A, enable IPv6 multicast routing globally, and enable IPv6 PIM-SM on interfaces.

```
<SwitchA> system-view
[SwitchA] ipv6 multicast routing
[SwitchA-mrib6] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ipv6 pim sm
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] ipv6 pim sm
[SwitchA-Vlan-interface101] quit
[SwitchA] interface loopback 0
[SwitchA-LoopBack0] ipv6 pim sm
[SwitchA-LoopBack0] quit
```

   # Configure Switch B and Switch D in the same way that Switch A was configured.

   # On Switch C, enable IPv6 multicast routing globally.

```
<SwitchC> system-view
[SwitchC] ipv6 multicast routing
[SwitchC-mrib6] quit
```

   # Enable IPv6 PIM-SM on interfaces, and enable MLD on VLAN-interface 200.

```
[SwitchC] interface vlan-interface 102
[SwitchC-Vlan-interface102] ipv6 pim sm
[SwitchC-Vlan-interface102] quit
[SwitchC] interface vlan-interface 104
[SwitchC-Vlan-interface104] ipv6 pim sm
[SwitchC-Vlan-interface104] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] ipv6 pim sm
[SwitchC-Vlan-interface200] mld enable
[SwitchC-Vlan-interface200] quit
```

   # Configure the BSR boundary on Switch A.

```
[SwitchA] interface vlan-interface 101
[SwitchA-Vlan-interface101] ipv6 pim bsr-boundary
[SwitchA-Vlan-interface101] quit
```

   # Configure the BSR boundary on Switch B.

```
[SwitchB] interface vlan-interface 101
[SwitchB-Vlan-interface101] ipv6 pim bsr-boundary
[SwitchB-Vlan-interface101] quit
```

3. Enable Anycast RP, and specify C-BSR and C-RP:

   # Configure Switch A.

```
[SwitchA] ipv6 pim
[SwitchA-pim6] anycast-rp 1:1::1 1:1::2
[SwitchA-pim6] anycast-rp 1:1::1 2:2::2
[SwitchA-pim6] c-bsr 1:1::1
[SwitchA-pim6] c-rp 1:1::1
[SwitchA-pim6] quit
```

   # Configure Switch B.

```
[SwitchB] ipv6 pim
[SwitchB-pim6] anycast-rp 1:1::1 1:1::2
[SwitchB-pim6] anycast-rp 1:1::1 2:2::2
[SwitchB-pim6] c-bsr 1:1::1
[SwitchB-pim6] c-rp 1:1::1
[SwitchB-pim6] quit
```

4. Configure BGP to establish BGP IPv6 multicast peers and redistribute routes:

   # On Switch A, establish an EBGP session to Switch B.

```
[SwitchA] bgp 100
[SwitchA-bgp-default] router-id 1.1.1.1
[SwitchA-bgp-default] peer 1001::2 as-number 200
```

   # Enable exchange of IPv6 unicast routes used for RPF check with Switch B.

```
[SwitchA-bgp-default] address-family ipv6 multicast
[SwitchA-bgp-default-mul-ipv6] peer 1001::2 enable
```

   # Redistribute direct routes into BGP.

```
[SwitchA-bgp-default-mul-ipv6] import-route direct
[SwitchA-bgp-default-mul-ipv6] quit
```

   # On Switch B, establish an EBGP session to Switch A.

```
[SwitchB] bgp 200
[SwitchB-bgp-default] router-id 2.2.2.2
[SwitchB-bgp-default] peer 1001::1 as-number 100
```

   # Enable exchange of IPv6 unicast routes used for RPF check with Switch B.

```
[SwitchB-bgp-default] address-family ipv6 multicast
[SwitchB-bgp-default-mul-ipv6] peer 1001::1 enable
```

   # Redistribute OSPFv3 routes into BGP.

```
[SwitchB-bgp-default-mul-ipv6] import-route ospfv3 1
[SwitchB-bgp-default-mul-ipv6] quit
```

5. Establish BGP IPv6 unicast peer relationships between Switch A and Switch B and redistribute routes:

   # On Switch A, enable BGP to exchange IPv6 unicast routes with Switch B, and redistribute direct routes into BGP.

```
[SwitchA-bgp-default] address-family ipv6 unicast
[SwitchA-bgp-default-ipv6] peer 1001::2 enable
[SwitchA-bgp-default-ipv6] import-route direct
[SwitchA-bgp-default-ipv6] quit
[SwitchA-bgp-default] quit
```

   # On Switch B, enable BGP to exchange IPv6 unicast routes with Switch A, and redistribute direct routes into BGP.

```
[SwitchB-bgp-default] address-family ipv6 unicast
```

```
[SwitchB-bgp-default-ipv6] peer 1001::1 enable
[SwitchB-bgp-default-ipv6] import-route direct
[SwitchB-bgp-default-ipv6] quit
[SwitchB-bgp-default] quit
```

Verifying the configuration

Verify the BGP IPv6 multicast peer information on Switch B.

```
[SwitchB] display bgp peer ipv6 multicast

 BGP local router ID : 2.2.2.2
 Local AS number : 200
 Total number of peers : 3                 Peers in established state : 3

  Peer        AS  MsgRcvd  MsgSent  OutQ PrefRcv Up/Down  State

  1001::1     100       56       56      0        0 00:40:54 Established
```

Verify the RPF information for the multicast source on Switch B.

```
[SwitchB] display ipv6 multicast rpf-info 1002::1
 RPF information about source 1002::1:
     RPF interface: Vlan-interface101, RPF neighbor: 1001::1
     Referenced prefix/prefix length: 1002::/64
     Referenced route type: mbgp
     Route selection rule: preference-preferred
     Load splitting rule: disable
```

Troubleshooting BGP

State of the connection to a peer cannot become established

Symptom

The **`display bgp peer ipv4 unicast`** or **`display bgp peer ipv6 unicast`** command output shows that the state of the connection to a peer cannot become established.

Analysis

To become BGP peers, any two routers must establish a TCP connection using port 179 and exchange OPEN messages successfully.

Solution

1. To resolve the problem:
   a. Use the **`display current-configuration`** command to verify the current configuration, and verify that the peer's AS number is correct.
   b. Use the **`display bgp peer ipv4 unicast`** or **`display bgp peer ipv6 unicast`** command to verify that the peer's IP/IPv6 address is correct.
   c. If a loopback interface is used, verify that the loopback interface is specified with the **`peer connect-interface`** command.
   d. If the peer is a non-direct EBGP peer, verify that the **`peer ebgp-max-hop`** command is configured.

e. If the **peer ttl-security hops** command is configured, verify that the command is configured on the peer. Verify that the *hop-count* values configured on them are greater than the number of hops between them.

f. Verify that a valid route to the peer is available.

g. Use the **ping** command to verify the connectivity to the peer.

h. Use the **display tcp verbose** or **display ipv6 tcp verbose** command to verify the TCP connection.

i. Verify that no ACL rule is applied to disable TCP port 179.

2. If the problem persists, contact H3C Support.

Configuring large-scale BGP networks

Large-scale BGP network configuration tasks at a glance

To configure large-scale BGP networks, perform the following tasks:

- Configuring BGP route dampening
- Configuring BGP communities
- Configuring BGP route reflection
- Configuring a route server
- Configuring BGP confederation settings
  - Configuring a BGP confederation
  - (Optional.) Configuring confederation compatibility

Configuring BGP route dampening

About this task

Route dampening enables BGP to not select unstable routes as optimal routes.

Restrictions and guidelines

This feature applies to EBGP routes but not to IBGP routes.

If an EBGP peer goes down after you configure this feature, routes coming from the peer are dampened but not deleted.

After an active/standby switchover, BGP route dampening processes and information will be reset. The device needs to recalculate the dampening mechanism of BGP routes.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Configure BGP route dampening.

   dampening [*half-life-reachable half-life-unreachable reuse suppress ceiling* | **route-policy** *route-policy-name*] *

   By default, BGP route dampening is not configured.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast

3. Configure IPv6 BGP route dampening.

   dampening [*half-life-reachable half-life-unreachable reuse suppress ceiling* | **route-policy** *route-policy-name*] *

   By default, IPv6 BGP route dampening is not configured.

Configuring BGP communities

About this task

By default, a router does not advertise the COMMUNITY or extended community attribute to its peers or peer groups. When the router receives a route carrying the COMMUNITY or extended community attribute, it removes the attribute before advertising the route to other peers or peer groups.

Perform this task to enable a router to advertise the COMMUNITY or extended community attribute to its peers for route filtering and control. You can also use a routing policy to add or modify the COMMUNITY or extended community attribute for specific routes. For more information about routing policy, see "Configuring routing policies."

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Create a routing policy and a node, and enter routing policy node view.

   route-policy *route-policy-name* { **deny** | **permit** } **node** *node-number*

   For more information about this command, see routing policy commands in *Layer 3—IP Routing Command Reference*.

3. (Optional.) Configure **if-match** clauses as BGP route match criteria.
4. The routing policy can configure the COMMUNITY attribute of BGP routes only when these routes match a **permit** node.

   For more information about **if-match** clauses, see routing policy configuration in *Layer 3—IP Routing Configuration Guide.*
5. Configure the COMMUNITY attribute and the extended community attributes of BGP routes.
   - Set the COMMUNITY attribute for BGP routes.

     apply community { **none** | **additive** | { *community-number*&<1-32> | *aa:nn*&<1-32> | **internet** | **no-advertise** | **no-export** | **no-export-subconfed** } * [**additive**] }
   - Delete COMMUNITY attribute values from BGP routes.

     apply comm-list { *comm-list-number* | *comm-list-name* } **delete**

     By default, no COMMUNITY attribute value is deleted from BGP routes.
   - Set the link bandwidth extended community attribute for BGP routes.

     apply extcommunity bandwidth *link-bandwidth-value* [**additive**]
   - Set the RT extended community attribute for BGP routes.

     apply extcommunity { **rt** *route-target* }&<1-32> [**additive**]
   - Set the SoO extended community attribute for BGP routes.

     apply extcommunity soo *site-of-origin*&<1-32> [**additive**]

   For more information about these commands, see routing policy commands in *Layer 3—IP Routing Command Reference*.
6. Return to system view.

   quit
7. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast
8. Advertise the COMMUNITY attribute to a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise-community**

   interface-peer *interface-type interface-number* **advertise-community**

   By default, the COMMUNITY attribute is not advertised.

   The *ipv6-address* [*prefix-length*] argument and the **interface-peer** command are not supported in BGP IPv4 multicast address family view.

9. Advertise the extended community attributes to a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise-ext-community**

   interface-peer *interface-type interface-number* **advertise-ext-community**

   By default, the extended community attributes is not advertised.

   The *ipv6-address* [*prefix-length*] argument and the **interface-peer** command are not supported in BGP IPv4 multicast address family view.

10. Apply a routing policy to routes advertised to a peer or peer group. Choose one command as needed:

    peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **route-policy** *route-policy-name* **export**

    interface-peer *interface-type interface-number* **route-policy** *route-policy-name* **export**

    The *ipv6-address* [*prefix-length*] argument and the **interface-peer** command are not supported in BGP IPv4 multicast address family view.

    By default, no routing policy is applied.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Create a routing policy and a node, and enter routing policy node view.

   route-policy *route-policy-name* { **deny** | **permit** } **node** *node-number*

   For more information about this command, see routing policy commands in *Layer 3—IP Routing Command Reference*.

3. (Optional.) Configure **if-match** clauses as BGP route match criteria. The routing policy can configure the COMMUNITY attribute of BGP routes only when these routes match a **permit** node.

   For more information about **if-match** clauses, see routing policy configuration in *Layer 3—IP Routing Configuration Guide.*

4. Configure the COMMUNITY attribute and the extended community attributes of BGP routes.
   - Set the COMMUNITY attribute for BGP routes.

     apply community { **none** | **additive** | { *community-number*&<1-32> | *aa:nn*&<1-32> | **internet** | **no-advertise** | **no-export** | **no-export-subconfed** } * [**additive**] }
   - Delete COMMUNITY attribute values from BGP routes.

     apply comm-list { *comm-list-number* | *comm-list-name* } **delete**

     By default, no COMMUNITY attribute value is deleted from BGP routes.
   - Set the link bandwidth extended community attribute for BGP routes.

     apply extcommunity bandwidth *link-bandwidth-value* [**additive**]
   - Set the RT extended community attribute for BGP routes.

     apply extcommunity { **rt** *route-target* }&<1-32> [**additive**]
   - Set the SoO extended community attribute for BGP routes.

     apply extcommunity soo *site-of-origin*&<1-32> [**additive**]

   For more information about these commands, see routing policy commands in *Layer 3—IP Routing Command Reference*.

5. Return to system view.

quit

6. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
7. Advertise the COMMUNITY attribute to a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **advertise-community**

   interface-peer *interface-type interface-number* **advertise-community**

   By default, the COMMUNITY attribute is not advertised.

   The *ipv4-address* [*mask-length*] and *link-local-address* **interface** *interface-type interface-number* options and the **interface-peer** command are not supported in BGP IPv6 multicast address family view.
8. Advertise the extended community attributes to a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **advertise-ext-community**

   interface-peer *interface-type interface-number* **advertise-ext-community**

   By default, the extended community attributes is not advertised.

   The *ipv4-address* [*mask-length*] and *link-local-address* **interface** *interface-type interface-number* options and the **interface-peer** command are not supported in BGP IPv6 multicast address family view.
9. Apply a routing policy to routes advertised to a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **route-policy** *route-policy-name* **export**

   interface-peer *interface-type interface-number* **route-policy** *route-policy-name* **export**

   By default, no routing policy is applied.

   The *ipv4-address* [*mask-length*] and *link-local-address* **interface** *interface-type interface-number* options and the **interface-peer** command are not supported in BGP IPv6 multicast address family view.

Configuring BGP route reflection

Configuring a BGP route reflector

About this task

Perform this task to configure a BGP route reflector and its clients. The route reflector and its clients automatically form a cluster identified by the router ID of the route reflector. The route reflector forwards route updates among its clients.

To improve availability, you can specify multiple route reflectors for a cluster. The route reflectors in the cluster must have the same cluster ID to avoid routing loops.

When a route reflector is connected to multiple clusters in the network, you can specify different cluster IDs for different peers and peer groups to control route reflection.

You only need to configure BGP route reflection on the device that acts as a route reflector. Other devices do not need to know the role of the local device in route reflection.

After you configure a device as a route reflector, it advertises routes as follows:

- Advertises routes received from a non-client IBGP peer to all clients.
- Advertises routes received from an IBGP peer that acts as a client to all peers.
- Advertises routes received from an EBGP peer to all peers.

Restrictions and guidelines

By default, the route reflector does not change the attributes of routes before route reflection to avoid routing loops. When you replan network traffic, you can perform this task to allow the route reflector to change the attributes of the routes to be reflected.

After using the **reflect change-path-attribute** command, you can use the **peer route-policy export** command to apply a routing policy that can change the attributes of the routes to be reflected. The following **apply** commands can define how the routing policy modifies route attributes:

- Use **apply origin** to change the ORIGIN attribute of routes.
- Use **apply ip-address next-hop** or **apply ipv6 next-hop** to change the NEXT_HOP attribute of routes.
- Use **apply cost** to change the MED attribute of routes.
- Use **apply local-preference** to change the local preference for routes.
- Use **apply community** to configure the COMMUNITY attribute of routes. For BGP to advertise the COMMUNITY attribute to a peer or peer group, use the **peer advertise-community** command.
- Use **apply comm-list delete** to delete COMMUNITY attribute values from routes.
- Use **apply extcommunity** to configure the link bandwidth extended community attribute or the RT extended community attribute of routes. For BGP to advertise the extended community attribute to a peer or peer group, use the **peer advertise-ext-community** command.
- Use **apply extcommunity soo** to configure the SoO extended community attribute of routes.

For more information about the **apply** commands, see routing policy commands in *Layer 3—IP Routing Command Reference*.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Configure the router as a route reflector and specify a peer or peer group as its client. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **reflect-client**

   interface-peer *interface-type interface-number* **reflect-client**

   By default, no route reflector or client is configured.

   The *ipv6-address* [*prefix-length*] argument and the **interface-peer** command are not supported in BGP IPv4 multicast address family view.

4. (Optional.) Enable route reflection between clients.

   reflect between-clients

   By default, route reflection between clients is enabled.

5. (Optional.) Configure the cluster ID of the route reflector.

   reflector cluster-id { *cluster-id* | *ipv4-address* }

   By default, a route reflector uses its own router ID as the cluster ID.

6. (Optional.) Enable the route reflector to change the attributes of routes to be reflected.

   reflect change-path-attribute

   By default, the route reflector cannot change the attributes of routes to be reflected.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view or BGP IPv6 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

bgp *as-number* [**instance** *instance-name*]

address-family ipv6 multicast

3. Configure the router as a route reflector and specify a peer or peer group as its client. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **reflect-client**

   interface-peer *interface-type interface-number* **reflect-client**

   By default, no route reflector or client is configured.

   The *ipv4-address* [*mask-length*] and *link-local-address* **interface** *interface-type interface-number* options and the **interface-peer** command are not supported in BGP IPv6 multicast address family view.

4. (Optional.) Enable route reflection between clients.

   reflect between-clients

   By default, route reflection between clients is enabled.

5. (Optional.) Configure the cluster ID of the route reflector.

   reflector cluster-id { *cluster-id* | *ipv4-address* }

   By default, a route reflector uses its own router ID as the cluster ID.

6. (Optional.) Enable the route reflector to change the attributes of routes to be reflected.

   reflect change-path-attribute

   By default, the route reflector cannot change the attributes of routes to be reflected.

Ignoring the ORIGINATOR_ID attribute

About this task

By default, BGP drops incoming route updates whose ORIGINATOR_ID attribute is the same as the local router ID. Some special networks such as firewall networks require BGP to accept such route updates. To meet the requirement, you must configure BGP to ignore the ORIGINATOR_ID attribute.

Restrictions and guidelines

Make sure this command does not result in a routing loop.

After you execute this command, BGP also ignores the CLUSTER_LIST attribute.

Procedure (IPv4 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Ignore the ORIGINATOR_ID attribute.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **ignore-originatorid**

   By default, BGP does not ignore the ORIGINATOR_ID attribute.

Procedure (IPv6 peers)

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Ignore the ORIGINATOR_ID attribute. Choose one command as needed:
   peer { *group-name* | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **ignore-originatorid**
   interface-peer *interface-type interface-number* **ignore-originatorid**
   By default, BGP does not ignore the ORIGINATOR_ID attribute.

Configuring a route server

About this task

Some networks require the border devices in multiple ASs to establish full mesh connections, which consumes many network resources and reduces device performance. To resolve this issue, configure a device as a route server and the border devices in different ASs as its clients as needed.

Once a device is configured as a route server, it advertises routes to the clients without changing their AS path, next hop, and MED attributes. The clients can exchange routes without establishing EBGP connections and forward traffic to each other without the participation of the route server.

Restrictions and guidelines

The route server does not add its AS number in the EBGP routes advertised to a peer. To avoid peer establishment failures, execute the **peer ignore-first-as** command on the clients.

If you do not specify the **external** keyword, the route server advertises IBGP routes to its clients without changing the routes' AS path, next hop, and MED attributes. As a result, these routes might be unusable for EBGP peers. To resolve this issue, specify the **external** keyword when you use the **peer route-server-client** command. The route server can change the AS path, next hop, and MED attributes of IBGP routes before advertising them to the clients.

Procedure (IPv4 unicast)

1. Enter system view.
   system-view
2. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:
     bgp *as-number* [**instance** *instance-name*]
     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
     address-family ipv4 [**unicast**]

3. Configure the device as a route server and specify a peer or peer group as a client.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **route-server-client** [**external**]

   By default, neither the route server nor the client is configured.

Procedure (IPv6 unicast)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]

3. Configure the device as a route server and specify a peer or peer group as a client.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **route-server-client** [**external**]

   By default, neither the route server nor the client is configured.

Configuring BGP confederation settings

About BGP confederation

BGP confederation provides another way to reduce IBGP connections in an AS.

A confederation contains sub-ASs. In each sub-AS, IBGP peers are fully meshed. Sub-ASs establish EBGP connections in between.

Configuring a BGP confederation

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Configure a confederation ID.

   confederation id *as-number*

   By default, no confederation ID is configured.

   From an outsider's perspective, the sub-ASs of the confederation is a single AS, which is identified by the confederation ID.

4. Specify confederation peer sub-ASs in the confederation.

   confederation peer-as *as-number-list*

   By default, no confederation peer sub-ASs are specified.

A confederation can contain a maximum of 32 sub-ASs. The AS number of a sub-AS is effective only in the confederation.

If the router needs to establish EBGP connections to other sub-ASs, you must specify the peering sub-ASs in the confederation.

Configuring confederation compatibility

About this task

If any routers in the confederation do not comply with RFC 3065, enable confederation compatibility to allow the router to work with those routers.

Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Enable confederation compatibility.
   confederation nonstandard
   By default, confederation compatibility is disabled.

Display and maintenance commands for large-scale BGP network configuration

Execute **display** commands in any view.

Displaying BGP (IPv4 unicast address family)

Task	Command
Display BGP IPv4 unicast route dampening parameter information.	**display bgp** [**instance** *instance-name*] **dampening parameter ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*]
Display BGP IPv4 unicast peer group information.	**display bgp** [**instance** *instance-name*] **group ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [**group-name** *group-name*]
Display information about a peer or peer group in BGP IPv4 unicast address family.	**display bgp** [**instance** *instance-name*] **peer ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv4-address mask-length* | { *ipv4-address* | **group-name** *group-name* } **log-info** | [*ipv4-address*] **verbose**] **display bgp** [**instance** *instance-name*] **peer ipv4** [**unicast**] [[*ipv6-address prefix-length* | **interface** *interface-type interface-number*] | [*ipv6-address* [**interface** *interface-type interface-number*] **log-info** | [*ipv6-address* [**interface** *interface-type interface-number*] **verbose**]

Task	Command
Display dampened BGP IPv4 unicast route information.	**display bgp** [**instance** *instance-name*] **routing-table dampened ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*]
Display BGP IPv4 unicast route flapping statistics.	**display bgp** [**instance** *instance-name*] **routing-table flap-info ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv4-address* [{ *mask-length* | *mask* } [**longest-match**]] | **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* }]

Displaying BGP (IPv6 unicast address family)

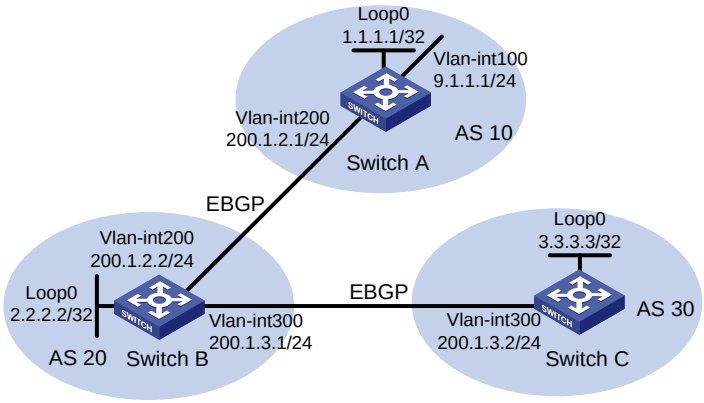
Task	Command
Display BGP IPv6 unicast route dampening parameter information.	**display bgp** [**instance** *instance-name*] **dampening parameter ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*]
Display BGP IPv6 unicast peer group information.	**display bgp** [**instance** *instance-name*] **group ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [**group-name** *group-name*]
Display information about a peer or peer group in BGP IPv6 unicast address family.	**display bgp** [**instance** *instance-name*] **peer ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv6-address prefix-length* | { *ipv6-address* | **group-name** *group-name* } **log-info** | [*ipv6-address*] **verbose**] **display bgp** [**instance** *instance-name*] **peer ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [[*link-local-address*] **interface** *interface-type interface-number* | *link-local-address* **interface** *interface-type interface-number* { **log-info** | **verbose** }] **display bgp** [**instance** *instance-name*] **peer ipv6** [**unicast**] [*ipv4-address mask-length* | *ipv4-address* **log-info** | [*ipv4-address*] **verbose**]
Display dampened BGP IPv6 unicast route information.	**display bgp** [**instance** *instance-name*] **routing-table dampened ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*]
Display BGP IPv6 unicast route flapping statistics.	**display bgp** [**instance** *instance-name*] **routing-table flap-info ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] [*ipv6-address prefix-length* | **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* }]

Displaying BGP (IPv4 multicast address family)

Task	Command
Display BGP IPv4 multicast route dampening parameter information.	**display bgp** [**instance** *instance-name*] **dampening parameter ipv4 multicast**
Display BGP IPv4 multicast peer group information.	**display bgp** [**instance** *instance-name*] **group ipv4 multicast** [**group-name** *group-name*]
Display BGP IPv4 multicast peer or peer group information.	**display bgp** [**instance** *instance-name*] **peer ipv4 multicast** [*ipv4-address mask-length* | { *ipv4-address* | **group-name** *group-name* } **log-info** | [*ipv4-address*] **verbose**]
Display dampened BGP IPv4 multicast route information.	**display bgp** [**instance** *instance-name*] **routing-table dampened ipv4 multicast**
Display BGP IPv4 multicast route flapping statistics.	**display bgp** [**instance** *instance-name*] **routing-table flap-info ipv4 multicast** [*ipv4-address* [{ *mask-length* | *mask* } [**longest-match**]] | **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* }]

Displaying BGP (IPv6 multicast address family)

Task	Command
Display BGP IPv6 multicast route dampening parameter information.	**display bgp** [**instance** *instance-name*] **dampening parameter ipv6 multicast**
Display BGP IPv6 multicast peer group information.	**display bgp** [**instance** *instance-name*] **group ipv6 multicast** [**group-name** *group-name*]
Display BGP IPv6 multicast peer or peer group information.	**display bgp** [**instance** *instance-name*] **peer ipv6 multicast** [*ipv6-address prefix-length* | { *ipv6-address* | **group-name** *group-name* } **log-info** | [*ipv6-address*] **verbose**]
Display dampened BGP IPv6 multicast route information.	**display bgp** [**instance** *instance-name*] **routing-table dampened ipv6 multicast**
Display BGP IPv6 multicast route flapping statistics.	**display bgp** [**instance** *instance-name*] **routing-table flap-info ipv6 multicast** [*ipv6-address prefix-length* | **as-path-acl** { *as-path-acl-number* | *as-path-acl-name* }]



Large-scale BGP network configuration examples

Example: Configuring BGP communities

Network configuration

As shown in Figure 32, Switch B establishes EBGP connections with Switch A and Switch C. Configure NO_EXPORT community attribute on Switch A to make routes from AS 10 not advertised by AS 20 to any other AS.

Figure 32 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure EBGP connections:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 10
[SwitchA-bgp-default] router-id 1.1.1.1
[SwitchA-bgp-default] peer 200.1.2.2 as-number 20
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 200.1.2.2 enable
[SwitchA-bgp-default-ipv4] network 9.1.1.0 255.255.255.0
[SwitchA-bgp-default] quit
```

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 20
[SwitchB-bgp-default] router-id 2.2.2.2
[SwitchB-bgp-default] peer 200.1.2.1 as-number 10
[SwitchB-bgp-default] peer 200.1.3.2 as-number 30
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 200.1.2.1 enable
[SwitchB-bgp-default-ipv4] peer 200.1.3.2 enable
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 30
[SwitchC-bgp-default] router-id 3.3.3.3
[SwitchC-bgp-default] peer 200.1.3.1 as-number 20
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 200.1.3.1 enable
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

Display the BGP routing table on Switch B.

```
[SwitchB] display bgp routing-table ipv4 9.1.1.0

 BGP local router ID: 2.2.2.2
 Local AS number: 20

 Paths:   1 available, 1 best

 BGP routing table information of 9.1.1.0/24:
 From            : 200.1.2.1 (1.1.1.1)
 Rely nexthop    : 200.1.2.1
 Original nexthop: 200.1.2.1
 Route age       : 03h30m59s
 OutLabel        : NULL
 RxPathID        : 0x0
 TxPathID        : 0x0
 AS-path         : 10
 Origin          : igp
 Attribute value : pref-val 0
 State           : valid, external, best
 IP precedence   : N/A
 QoS local ID    : N/A
 Traffic index   : N/A
```

Display advertisement information of network 9.1.1.0 on Switch B.

```
[SwitchB] display bgp routing-table ipv4 9.1.1.0 advertise-info

 BGP local router ID: 2.2.2.2
 Local AS number: 20

 Paths:   1 best

 BGP routing table information of 9.1.1.0/24:
 Advertised to peers (1 in total):
    200.1.3.2
```

The output shows that Switch B can advertise the route with the destination 9.1.1.0/24 to other ASs through BGP.

Display the BGP routing table on Switch C.

```
[SwitchC] display bgp routing-table ipv4
```

```
Total number of routes: 1

BGP local router ID is 3.3.3.3
Status codes: * - valid, > - best, d - dampened, h - history,
              s - suppressed, S - stale, i - internal, e - external
              a – additional-path
      Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >e 9.1.1.0/24         200.1.3.1                              0       20 10i
```

The output shows that Switch C has learned route 9.1.1.0/24 from Switch B.

3. Configure a BGP community:

Configure a routing policy.

```
[SwitchA] route-policy comm_policy permit node 0
[SwitchA-route-policy-comm_policy-0] apply community no-export
[SwitchA-route-policy-comm_policy-0] quit
```

Apply the routing policy.

```
[SwitchA] bgp 10
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 200.1.2.2 route-policy comm_policy export
[SwitchA-bgp-default-ipv4] peer 200.1.2.2 advertise-community
```

Verifying the configuration

Display the routing table on Switch B.

```
[SwitchB] display bgp routing-table ipv4 9.1.1.0

 BGP local router ID: 2.2.2.2
 Local AS number: 20

 Paths:   1 available, 1 best

 BGP routing table information of 9.1.1.0/24:
 From            : 200.1.2.1 (1.1.1.1)
 Rely nexthop    : 200.1.2.1
 Original nexthop: 200.1.2.1
 Route age       : 03h30m59s
 OutLabel        : NULL
 RxPathID        : 0x0
 TxPathID        : 0x0
 Community       : No-Export
 AS-path         : 10
 Origin          : igp
 Attribute value : pref-val 0
 State           : valid, external, best
 IP precedence   : N/A
 QoS local ID    : N/A
 Traffic index   : N/A
```

Display advertisement information for the route 9.1.1.0 on Switch B.

```
[SwitchB] display bgp routing-table ipv4 9.1.1.0 advertise-info

 BGP local router ID: 2.2.2.2
 Local AS number: 20

 Paths:   1 best

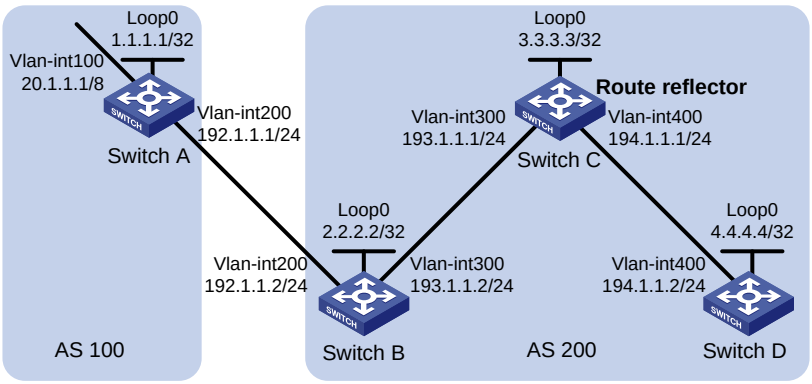
 BGP routing table information of 9.1.1.0/24:
 Not advertised to any peers yet
```

Display the BGP routing table on Switch C.

```
[SwitchC] display bgp routing-table ipv4

 Total number of routes: 0
```

The output shows that BGP has not learned any route.



Example: Configuring BGP route reflector

Network configuration

As shown in Figure 33, all switches run BGP. Run EBGP between Switch A and Switch B, and run IBGP between Switch C and Switch B, and between Switch C and Switch D.

Configure Switch C as a route reflector with clients Switch B and Switch D to allow Switch D to learn route 20.0.0.0/8 from Switch C.

Figure 33 Network diagram

Procedure

1. Configure IP addresses for interfaces and configure OSPF in AS 200. (Details not shown.)
2. Configure BGP connections:

   # Configure Switch A.

   ```
   <SwitchA> system-view
   [SwitchA] bgp 100
   [SwitchA-bgp-default] router-id 1.1.1.1
   [SwitchA-bgp-default] peer 192.1.1.2 as-number 200
   [SwitchA-bgp-default] address-family ipv4 unicast
   [SwitchA-bgp-default-ipv4] peer 192.1.1.2 enable
   ```

   # Inject network 20.0.0.0/8 to the BGP routing table.

```
[SwitchA-bgp-default-ipv4] network 20.0.0.0
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 200
[SwitchB-bgp-default] router-id 2.2.2.2
[SwitchB-bgp-default] peer 192.1.1.1 as-number 100
[SwitchB-bgp-default] peer 193.1.1.1 as-number 200
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 192.1.1.1 enable
[SwitchB-bgp-default-ipv4] peer 193.1.1.1 enable
[SwitchB-bgp-default-ipv4] peer 193.1.1.1 next-hop-local
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 200
[SwitchC-bgp-default] router-id 3.3.3.3
[SwitchC-bgp-default] peer 193.1.1.2 as-number 200
[SwitchC-bgp-default] peer 194.1.1.2 as-number 200
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 193.1.1.2 enable
[SwitchC-bgp-default-ipv4] peer 194.1.1.2 enable
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] bgp 200
[SwitchD-bgp-default] router-id 4.4.4.4
[SwitchD-bgp-default] peer 194.1.1.1 as-number 200
[SwitchD-bgp-default] address-family ipv4 unicast
[SwitchD-bgp-default-ipv4] peer 194.1.1.1 enable
[SwitchD-bgp-default-ipv4] quit
[SwitchD-bgp-default] quit
```

3. Configure Switch C as the route reflector.

```
[SwitchC] bgp 200
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 193.1.1.2 reflect-client
[SwitchC-bgp-default-ipv4] peer 194.1.1.2 reflect-client
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

Verifying the configuration

Display the BGP routing table on Switch B.

```
[SwitchB] display bgp routing-table ipv4

 Total number of routes: 1
```

```
 BGP local router ID is 2.2.2.2
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >e 20.0.0.0/8         192.1.1.1       0                     0       100i
```

Display the BGP routing table on Switch D.

```
[SwitchD] display bgp routing-table ipv4

 Total number of routes: 1

 BGP local router ID is 4.4.4.4
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >i 20.0.0.0/8         193.1.1.2       0          100        0       100i
```

The output shows that Switch D has learned route 20.0.0.0/8 from Switch C.

Example: Configuring BGP confederation

Network configuration

As shown in Figure 34, split AS 200 into three sub-ASs (AS 65001, AS 65002, and AS 65003) to reduce IBGP connections. Switches in AS 65001 are fully meshed.

Figure 34 Network diagram

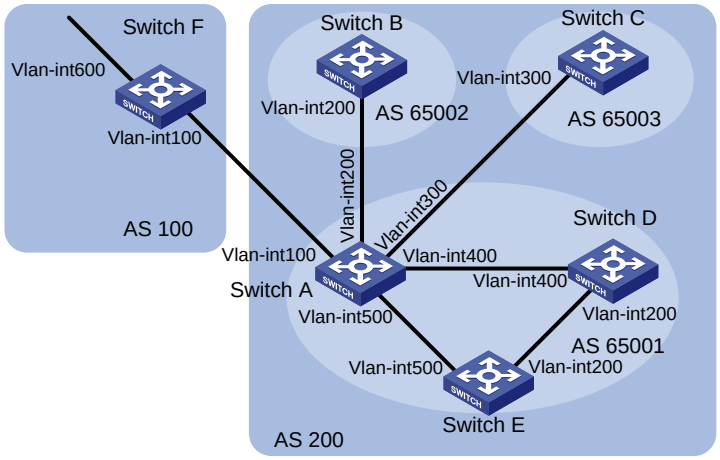


Table 11 Interface and IP address assignment

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int100	200.1.1.1/24	Switch D	Vlan-int200	10.1.5.1/24
	Vlan-int200	10.1.1.1/24		Vlan-int400	10.1.3.2/24
	Vlan-int300	10.1.2.1/24	Switch E	Vlan-int200	10.1.5.2/24
	Vlan-int400	10.1.3.1/24		Vlan-int500	10.1.4.2/24
	Vlan-int500	10.1.4.1/24	Switch F	Vlan-int100	200.1.1.2/24
Switch B	Vlan-int200	10.1.1.2/24		Vlan-int600	9.1.1.1/24
Switch C	Vlan-int300	10.1.2.2/24			

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure BGP confederation:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 65001
[SwitchA-bgp-default] router-id 1.1.1.1
[SwitchA-bgp-default] confederation id 200
[SwitchA-bgp-default] confederation peer-as 65002 65003
[SwitchA-bgp-default] peer 10.1.1.2 as-number 65002
[SwitchA-bgp-default] peer 10.1.2.2 as-number 65003
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 10.1.1.2 enable
[SwitchA-bgp-default-ipv4] peer 10.1.2.2 enable
[SwitchA-bgp-default-ipv4] peer 10.1.1.2 next-hop-local
[SwitchA-bgp-default-ipv4] peer 10.1.2.2 next-hop-local
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 65002
[SwitchB-bgp-default] router-id 2.2.2.2
[SwitchB-bgp-default] confederation id 200
[SwitchB-bgp-default] confederation peer-as 65001 65003
[SwitchB-bgp-default] peer 10.1.1.1 as-number 65001
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 10.1.1.1 enable
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

   # Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 65003
[SwitchC-bgp-default] router-id 3.3.3.3
[SwitchC-bgp-default] confederation id 200
[SwitchC-bgp-default] confederation peer-as 65001 65002
```

```
[SwitchC-bgp-default] peer 10.1.2.1 as-number 65001
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 10.1.2.1 enable
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

3. Configure IBGP connections in AS 65001:

Configure Switch A.

```
[SwitchA] bgp 65001
[SwitchA-bgp-default] peer 10.1.3.2 as-number 65001
[SwitchA-bgp-default] peer 10.1.4.2 as-number 65001
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 10.1.3.2 enable
[SwitchA-bgp-default-ipv4] peer 10.1.4.2 enable
[SwitchA-bgp-default-ipv4] peer 10.1.3.2 next-hop-local
[SwitchA-bgp-default-ipv4] peer 10.1.4.2 next-hop-local
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] bgp 65001
[SwitchD-bgp-default] router-id 4.4.4.4
[SwitchD-bgp-default] confederation id 200
[SwitchD-bgp-default] peer 10.1.3.1 as-number 65001
[SwitchD-bgp-default] peer 10.1.5.2 as-number 65001
[SwitchD-bgp-default] address-family ipv4 unicast
[SwitchD-bgp-default-ipv4] peer 10.1.3.1 enable
[SwitchD-bgp-default-ipv4] peer 10.1.5.2 enable
[SwitchD-bgp-default-ipv4] quit
[SwitchD-bgp-default] quit
```

Configure Switch E.

```
<SwitchE> system-view
[SwitchE] bgp 65001
[SwitchE-bgp-default] router-id 5.5.5.5
[SwitchE-bgp-default] confederation id 200
[SwitchE-bgp-default] peer 10.1.4.1 as-number 65001
[SwitchE-bgp-default] peer 10.1.5.1 as-number 65001
[SwitchE-bgp-default] address-family ipv4 unicast
[SwitchE-bgp-default-ipv4] peer 10.1.4.1 enable
[SwitchE-bgp-default-ipv4] peer 10.1.5.1 enable
[SwitchE-bgp-default-ipv4] quit
[SwitchE-bgp-default] quit
```

4. Configure the EBGP connection between AS 100 and AS 200:

Configure Switch A.

```
[SwitchA] bgp 65001
[SwitchA-bgp-default] peer 200.1.1.2 as-number 100
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 200.1.1.2 enable
[SwitchA-bgp-default-ipv4] quit
```

```
[SwitchA-bgp-default] quit
```

Configure Switch F.

```
<SwitchF> system-view
[SwitchF] bgp 100
[SwitchF-bgp-default] router-id 6.6.6.6
[SwitchF-bgp-default] peer 200.1.1.1 as-number 200
[SwitchF-bgp-default] address-family ipv4 unicast
[SwitchF-bgp-default-ipv4] peer 200.1.1.1 enable
[SwitchF-bgp-default-ipv4] network 9.1.1.0 255.255.255.0
[SwitchF-bgp-default-ipv4] quit
[SwitchF-bgp-default] quit
```

Verifying the configuration

Display the routing table on Switch B.

```
[SwitchB] display bgp routing-table ipv4

 Total number of routes: 1

 BGP local router ID is 2.2.2.2
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

```

```
 Traffic index   : N/A
```

Display the BGP routing table on Switch D.

```
[SwitchD] display bgp routing-table ipv4

 Total number of routes: 1

 BGP local router ID is 4.4.4.4
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >i 9.1.1.0/24         10.1.3.1        0          100        0       100i
[SwitchD] display bgp routing-table ipv4 9.1.1.0

 BGP local router ID: 4.4.4.4
 Local AS number: 65001

 Paths:   1 available, 1 best

 BGP routing table information of 9.1.1.0/24:
 From            : 10.1.3.1 (1.1.1.1)
 Rely nexthop    : 10.1.3.1
 Original nexthop: 10.1.3.1
 Route age       : 03h30m59s
 OutLabel        : NULL
 RxPathID        : 0x0
 TxPathID        : 0x0
 AS-path         : 100
 Origin          : igp
 Attribute value : MED 0, localpref 100, pref-val 0, pre 255
 State           : valid, internal-confed, best
 IP precedence   : N/A
 QoS local ID    : N/A
 Traffic index   : N/A
```

The output shows the following:

- Switch F can send route information to Switch B and Switch C through the confederation by establishing only an EBGP connection with Switch A.
- Switch B and Switch D are in the same confederation, but belong to different sub-ASs. They obtain external route information from Switch A, and generate identical BGP route entries although they have no direct connection in between.

Controlling BGP path selection

BGP path selection control tasks at a glance

By configuring BGP path attributes, you can control BGP path selection.

To control BGP path selection, perform the following tasks:

1. Configuring preferences for BGP routes
2. Configuring the NEXT_HOP attribute
   - Setting the local device IP as the next hop
   - Advertising only the global unicast address in the NEXT_HOP attribute
3. Setting a preferred value for received routes
4. Configuring the default local preference
5. Configuring the AS_PATH attribute
   - Permitting local AS number to appear in routes from a peer or peer group
   - Ignoring the AS_PATH attribute during optimal route selection
   - Advertising a fake AS number to a peer or peer group
   - Configuring AS number substitution
   - Removing private AS numbers from sent updates
   - Ignoring the first AS number of EBGP route updates
6. Configuring the MED attribute
   - Configuring the default MED value
   - Enabling MED comparison for routes from different ASs
   - Enabling MED comparison for routes on a per-AS basis
   -
   - Enabling MED comparison for routes from confederation peers
7. Configuring the link bandwidth attribute
8. Minimizing the priority of BGP routes advertised to peers
   - Minimizing the priority of BGP routes advertised to peers with a DOWN-to-UP state change
   - Minimizing the priority of BGP routes advertised to peers after a device reboot
   - (Optional.) Restoring the priority of advertised BGP routes
9. Configuring BGP route selection specifications

   To view the impact of this configuration step on BGP route selection rules, see "BGP route selection."
   - Preferring BGP routes of a specific next hop IP type
   - Ignoring IGP metrics during optimal route selection
   - Ignoring router IDs during optimal route selection
   - Configuring the next hop type selection rule for optimal route selection
10. Associating a track entry with a BGP peer or peer group

Configuring preferences for BGP routes

About this task

Routing protocols each have a default preference. If they find multiple routes destined for the same network, the route found by the routing protocol with the highest preference is selected as the optimal route. A smaller preference value indicates a higher preference.

You can use the **preference** command to modify preferences for EBGP, IBGP, and local BGP routes, or use a routing policy to set a preference for matching routes. For routes not matching the routing policy, the default preference applies.

If a device has an EBGP route and a local BGP route to reach the same destination, it does not select the EBGP route because the EBGP route has a lower preference than the local BGP route by default. You can use the **network short-cut** command to configure the EBGP route as a shortcut route that has the same preference as the local BGP route. The EBGP route will more likely become the optimal route.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Configure preferences for EBGP, IBGP, and local BGP routes.

   preference { *external-preference internal-preference local-preference* | **route-policy** *route-policy-name* }

   By default, the preferences for EBGP, IBGP, and local BGP routes are 255, 255, and 130, respectively.

   You can use the **preference** command to configure preferences for BGP routes generated by the local device. In the current software version, this command takes effect only on BGP summary routes generated by using the **aggregate** command.

4. (Optional.) Configure an EBGP route as a shortcut route.

   network *ipv4-address* [*mask-length* | *mask*] **short-cut**

   By default, an EBGP route has a preference of 255.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
3. Configure preferences for EBGP, IBGP, and local BGP routes.

   preference { *external-preference internal-preference local-preference* | **route-policy** *route-policy-name* }

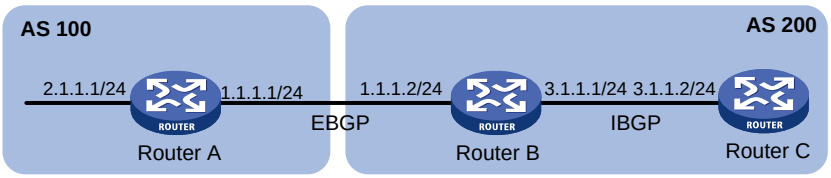
   By default, the preferences for EBGP, IBGP, and local BGP routes are 255, 255, and 130, respectively.

   You can use the **preference** command to configure preferences for BGP routes generated by the local device. In the current software version, this command takes effect only on BGP summary routes generated by using the **aggregate** command.
4. (Optional.) Configure an EBGP route as a shortcut route.

   network *ipv6-address prefix-length* **short-cut**

   By default, an EBGP route has a preference of 255.

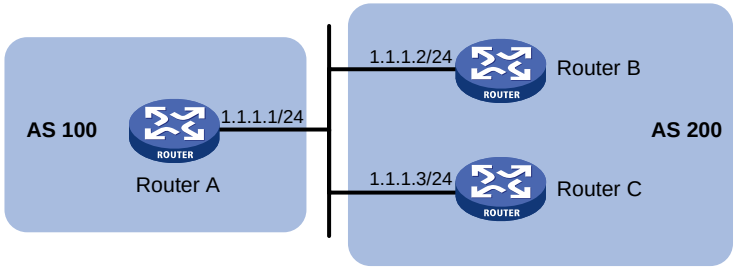
Configuring the NEXT_HOP attribute



Setting the local device IP as the next hop

About this task

By default, a BGP router does not set itself as the next hop for routes advertised to an IBGP peer or peer group. In some cases, however, you must configure the advertising router as the next hop to ensure that the BGP peer can find the correct next hop.



For example, as shown in Figure 35, Router A and Router B establish an EBGP neighbor relationship, and Router B and Router C establish an IBGP neighbor relationship. If Router C has no route destined for IP address 1.1.1.1/24, you must configure Router B to set itself 3.1.1.1/24 as the next hop for the network 2.1.1.1/24 advertised to Router C.

Figure 35 NEXT_HOP attribute configuration

If a BGP router has two peers on a broadcast network, it does not set itself as the next hop for routes sent to an EBGP peer by default. As shown in Figure 36, Router A and Router B establish an EBGP neighbor relationship, and Router B and Router C establish an IBGP neighbor relationship. They are on the same broadcast network 1.1.1.0/24. When Router B sends EBGP routes to Router A, it does not set itself as the next hop by default. However, you can configure Router B to set it (1.1.1.2/24) as the next hop for routes sent to Router A by using the **peer next-hop-local** command as needed.

Figure 36 NEXT_HOP attribute configuration

Restrictions and guidelines

If you have configured BGP load balancing, the router sets itself as the next hop for routes sent to an IBGP peer or peer group regardless of whether the **peer next-hop-local** command is configured.

A route reflector can change the NEXT_HOP attribute of reflected routes only if it is configured with both of the **peer next-hop-local** and **reflect change-path-attribute** commands.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Specify the local device IP as the next hop for routes sent to a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **next-hop-local**

   interface-peer *interface-type interface-number* **next-hop-local**

   The default settings are as follows:

- When the device advertises a route to an EBGP peer, it processes the next hop of that route as follows:
  - If the EBGP peer is a directly connected peer and the next hop of the route is in the same network as the peer-facing interface of the local device, the device does not change the next hop of the route.
  - In other scenarios, the device sets the local device IP as the next hop of the route.
- The device does not change the next hops of routes sent to an IBGP peer or peer group. When the device sends ECMP BGP routes to IBGP peers, it sets the local device IP as the next hop of the optimal route among these routes.

The *ipv6-address* [*prefix-length*] argument and the **interface-peer** command are not supported in BGP IPv4 multicast address family view.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast

3. Specify the local device IP as the next hop for routes sent to a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **next-hop-local**

   interface-peer *interface-type interface-number* **next-hop-local**

   The default settings are as follows:
   - When the device advertises a route to an EBGP peer, it processes the next hop of that route as follows:
     - If the EBGP peer is a directly connected peer and the next hop of the route is in the same network as the peer-facing interface of the local device, the device does not change the next hop of the route.
     - In other scenarios, the device sets the local device IP as the next hop of the route.
   - The device does not change the next hops of routes sent to an IBGP peer or peer group. When the device sends ECMP BGP routes to IBGP peers, it sets the local device IP as the next hop of the optimal route among these routes.

   The *ipv4-address* [*mask-length*] and *link-local-address* **interface** *interface-type interface-number* options and the **interface-peer** command are not supported in BGP IPv6 multicast address family view.

Advertising only the global unicast address in the NEXT_HOP attribute

About this task

A directly-connected IPv6 EBGP peer might fail to learn routes if it cannot parse a route update that contains both the link-local address and the global unicast address. To resolve this issue, perform this task to enable the local device to advertise only the global unicast address in the NEXT_HOP attribute to its IPv6 peers.

Restrictions and guidelines

This feature might not apply to EBGP peers established through directly connected broadcast interfaces. If the next hop of the advertised route and the directly connected broadcast interfaces belong to the same subnet, this feature does not take effect.

Procedure (IPv4 unicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]

3. Enable the device to advertise only the global unicast address in the NEXT_HOP attribute to its IPv6 peers.

   nexthop global-address-only

   By default, if the local device has a link-local address, it advertises both the link-local address and the global unicast address in the NEXT_HOP attribute to the directly-connected IPv6 EBGP peers established with its global unicast address.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv6 multicast

3. Enable the device to advertise only the global unicast address in the NEXT_HOP attribute to its IPv6 peers.

   nexthop global-address-only

   By default, if the local device has a link-local address, it advertises both the link-local address and the global unicast address in the NEXT_HOP attribute to the directly-connected IPv6 EBGP peers established with its global unicast address.

Setting a preferred value for received routes

About this task

Perform this task to set a preferred value for specific routes to control BGP path selection.

Among multiple routes that have the same destination/mask and are learned from different peers, the one with the greatest preferred value is selected as the optimal route.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Set a preferred value for routes received from a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **preferred-value** *value*

   interface-peer *interface-type interface-number* **preferred-value** *value*

   By default, the preferred value is 0 for routes received from a peer or peer group.

   The *ipv6-address* [*prefix-length*] argument and the **interface-peer** command are not supported in BGP IPv4 multicast address family view.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
3. Set a preferred value for routes received from a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **preferred-value** *value*

   interface-peer *interface-type interface-number* **preferred-value** *value*

   By default, the preferred value is 0 for routes received from a peer or peer group.

   The *ipv4-address* [*mask-length*] and *link-local-address* **interface** *interface-type interface-number* options and the **interface-peer** command are not supported in BGP IPv6 multicast address family view.

Configuring the default local preference

About this task

The local preference is used to determine the optimal route for traffic leaving the local AS. When a BGP router obtains from several IBGP peers multiple routes to the same destination, but with different next hops, it selects the route with the highest local preference as the optimal route.

This task allows you to specify the default local preference for routes sent to IBGP peers.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

ip vpn-instance *vpn-instance-name*

address-family ipv4 [**unicast**]

- Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv4 multicast

3. Configure the default local preference.

   default local-preference *value*

   The default local preference is 100.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
3. Configure the default local preference.

   default local-preference *value*

   The default local preference is 100.

Configuring the AS_PATH attribute

Permitting local AS number to appear in routes from a peer or peer group

About this task

In general, BGP checks whether the AS_PATH attribute of a route from a peer contains the local AS number. If yes, it discards the route to avoid routing loops.

In certain network environments, however, the AS_PATH attribute of a route from a peer must be allowed to contain the local AS number. Otherwise, the route cannot be advertised correctly.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast
3. Permit the local AS number to appear in routes from a peer or peer group and set the appearance times. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **allow-as-loop** [*number*]

   interface-peer *interface-type interface-number* **allow-as-loop** [*number*]

   By default, the local AS number is not allowed in routes from a peer or peer group.

   The *ipv6-address* [*prefix-length*] argument and the **interface-peer** command are not supported in BGP IPv4 multicast address family view.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
3. Permit the local AS number to appear in routes from a peer or peer group and set the appearance times. Choose one command as needed:

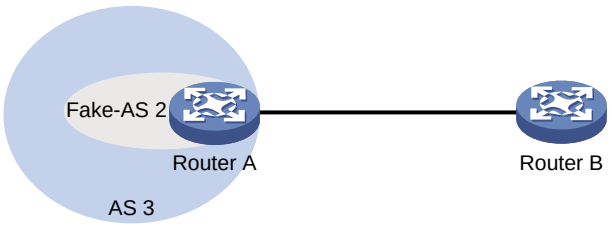
peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **allow-as-loop** [*number*]

interface-peer *interface-type interface-number* **allow-as-loop** [*number*]

By default, the local AS number is not allowed in routes from a peer or peer group.

The *ipv4-address* [*mask-length*] and *link-local-address* **interface** *interface-type interface-number* options and the **interface-peer** command are not supported in BGP IPv6 multicast address family view.

Ignoring the AS_PATH attribute during optimal route selection



1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Configure BGP to ignore the AS_PATH attribute during optimal route selection.
   bestroute as-path-neglect
   By default, BGP includes the AS_PATH attribute in optimal route selection.

Advertising a fake AS number to a peer or peer group

About this task

After you move a BGP router from an AS to another AS (from AS 2 to AS 3 for example), you have to modify the AS number of the router on all its EBGP peers. To avoid such modifications, you can configure the router to advertise a fake AS number 2 to its EBGP peers so that the EBGP peers still think that Router A is in AS 2.

Figure 37 Network diagram

Restrictions and guidelines

The **peer fake-as** command is applicable only to EBGP peers and peer groups. When you set the AS number of the specified peer as the fake AS number in the **peer fake-as** command, follow these restrictions and guidelines:

- If the device successfully establishes a session to the specified peer by using the fake AS number, the device considers the peer as an IBGP peer.

- If the device successfully establishes a session to the specified peer by using the actual AS number, the device considers the peer as an EBGP peer.
- Both the features supported only by IBGP peers and the features supported only by EBGP peers are configurable for the peer. However, only features supported by the established peer session can take effect on the peer.
- BGP clears the configuration that takes effect on only IBGP peers for the peer if one of the following conditions exists:
  - The value for the *as-number* argument in the **peer fake-as** command is different from that in the **peer as-number** command.
  - The **undo peer fake-as** command is executed.

Procedure (IPv4 peers)

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Advertise a fake AS number to a peer or peer group.
   peer { *group-name* | *ipv4-address* [*mask-length*] } **fake-as** *as-number*
   By default, no fake AS number is advertised to a peer or peer group.

Procedure (IPv6 peers)

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Advertise a fake AS number to a peer or peer group. Choose one command as needed:
   peer { *group-name* | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **fake-as** *as-number*
   interface-peer *interface-type interface-number* **fake-as** *as-number*
   By default, no fake AS number is advertised to a peer or peer group.

Configuring AS number substitution

About this task

To use EBGP between PE and CE in some networks, VPN sites in different geographical areas should have different AS numbers. Otherwise, BGP discards route updates containing the local AS number. If two CEs connected to different PEs use the same AS number, you must configure AS number substitution on each PE. This substitution can replace the AS number in route updates originated by the remote CE as its own AS number before advertising them to the connected CE.

Restrictions and guidelines

Do not configure AS number substitution in normal circumstances. Otherwise, routing loops might occur.

Procedure (IPv4 peers)

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Configure AS number substitution for a peer or peer group.
   peer { *group-name* | *ipv4-address* [*mask-length*] } **substitute-as**
   By default, AS number substitution is not configured.

Procedure (IPv6 peers)

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Configure AS number substitution for a peer or peer group. Choose one command as needed:
   peer { *group-name* | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **substitute-as**
   interface-peer *interface-type interface-number* **substitute-as**
   By default, AS number substitution is not configured.

Removing private AS numbers from sent updates

About this task

Private AS numbers are typically used in test networks, and should not be transmitted in public networks. The range of private AS numbers is from 64512 to 65535.

Perform this task to enable BGP to remove or replace private AS numbers from the AS_PATH attribute of updates sent to a peer or peer group.

Restrictions and guidelines

This feature is applicable only to EBGP peers or peer groups.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.
   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast
3. Configure BGP to remove private AS numbers from the AS_PATH attribute of updates sent to an EBGP peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **public-as-only** [{ **force** | **limited** } [**replace**] [**include-peer-as**]]

   interface-peer *interface-type interface-number* **public-as-only** [{ **force** | **limited** } [**replace**] [**include-peer-as**]]

   By default, BGP updates sent to an EBGP peer or peer group can carry both public and private AS numbers.

   The *ipv6-address* [*prefix-length*] argument and the **interface-peer** command are not supported in BGP IPv4 multicast address family view.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
3. Configure BGP to remove private AS numbers from the AS_PATH attribute of updates sent to an EBGP peer or peer group. Choose one command as needed:

peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **public-as-only** [{ **force** | **limited** } [**replace**] [**include-peer-as**]]

interface-peer *interface-type interface-number* **public-as-only** [{ **force** | **limited** } [**replace**] [**include-peer-as**]]

By default, BGP updates sent to an EBGP peer or peer group can carry both public and private AS numbers.

The *ipv4-address* [*mask-length*] and *link-local-address* **interface** *interface-type interface-number* options and the **interface-peer** command are not supported in BGP IPv6 multicast address family view.

This command applies only to EBGP peers and peer groups.

Ignoring the first AS number of EBGP route updates

About this task

By default, BGP checks the first AS number of an EBGP-learned route update. If the first AS number is neither the AS number of the BGP peer nor a private AS number, the BGP router disconnects the BGP session to the peer.

Ignoring the first AS number of EBGP route updates

1. Enter system view.

   system-view
2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
3. Configure BGP to ignore the first AS number of EBGP route updates.

   ignore-first-as

   By default, BGP checks the first AS number of EBGP-learned route updates.

Ignoring the first AS number of EBGP route updates received from a peer or peer group (IPv4 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Enable BGP to ignore the first AS number of EBGP route updates received from the specified peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **ignore-first-as**

   By default, BGP checks the first AS number of route updates learned from EBGP peers or peer groups.

Ignoring the first AS number of EBGP route updates received from a peer or peer group (IPv6 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Enable BGP to ignore the first AS number of EBGP route updates received from a peer or peer group. Choose one command as needed:
   peer { *group-name* | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **ignore-first-as**
   interface-peer *interface-type interface-number* **ignore-first-as**
   By default, BGP checks the first AS number of route updates learned from EBGP peers or peer groups.

Configuring the MED attribute

About the MED attribute

BGP uses MED to determine the optimal route for traffic going into an AS. When a BGP router obtains multiple routes with the same destination but with different next hops, it selects the route with the smallest MED value as the optimal route if other conditions are the same.

Configuring the default MED value

Configuring the default MED value (IPv4 unicast/multicast address family)

1. Enter system view.
   system-view
2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:
     bgp *as-number* [**instance** *instance-name*]
     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:
     bgp *as-number* [**instance** *instance-name*]
     address-family ipv4 multicast
3. Configure the default MED value.
   default med *med-value*
   The default MED value is 0.

Configuring the default MED value (IPv6 unicast/multicast address family)

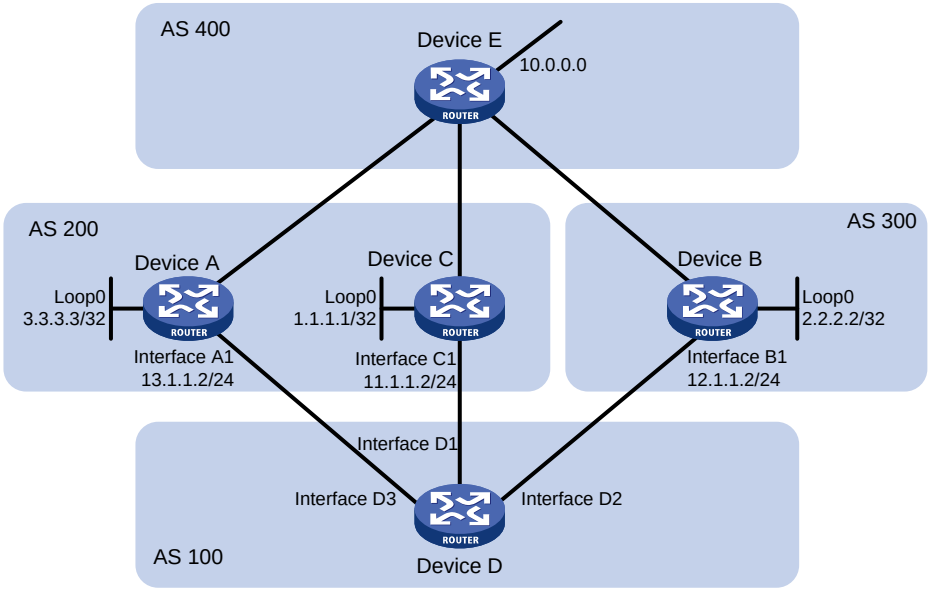
1. Enter system view.
   system-view
2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:
     bgp *as-number* [**instance** *instance-name*]
     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:
     bgp *as-number* [**instance** *instance-name*]
     address-family ipv6 multicast
3. Configure the default MED value.
   default med *med-value*
   The default MED value is 0.

Enabling MED comparison for routes from different ASs

About this task

By default, BGP only compares the MEDs of routes from the same AS. This task enables BGP to compare the MEDs of routes from different ASs.

Procedure



1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Enable MED comparison for routes from different ASs.
   compare-different-as-med
   By default, MED comparison for routes from different ASs is disabled.

Enabling MED comparison for routes on a per-AS basis

About this task

This task enables BGP to compare the MEDs of routes from an AS.

Figure 38 Route selection based on MED (in an IPv4 network)

As shown in Figure 38, Device D establishes indirect EBGP peer relationships with Device A, Device B, and Device C, and learns addresses 1.1.1.1/32, 2.2.2.2/32, and 3.3.3.3/32 through OSPF. The following output shows the routing information on Device D.

```
Destination/Mask    Proto   Pre Cost        NextHop         Interface
1.1.1.1/32          O_INTRA 10  10          11.1.1.2        Interface D1
2.2.2.2/32          O_INTRA 10  20          12.1.1.2        Interface D2
3.3.3.3/32          O_INTRA 10  30          13.1.1.2        Interface D3
```

Device D learns network 10.0.0.0 from both Device A and Device B. Because the route learned from Device B has a smaller IGP metric, the route is optimal. The following output shows the BGP routing table on Device D.

```
     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn
 *>e 10.0.0.0/8         2.2.2.2         50                    0       300 400e
 * e                    3.3.3.3         50                    0       200 400e
```

When Device D learns network 10.0.0.0 from Device C, it compares the route with the optimal route in its routing table. Because Device C and Device B reside in different ASs, BGP does not compare the MEDs of the two routes. The route from Device C has a smaller IGP metric than the route from Device B, so the route from Device C becomes optimal. The following output shows the BGP routing table on Device D.

```
     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn
 *>e 10.0.0.0/8         1.1.1.1         60                    0       200 400e
 *  e 10.0.0.0/8        2.2.2.2         50                    0       300 400e
 * e                    3.3.3.3         50                    0       200 400e
```

However, Device C and Device A reside in the same AS, and Device C has a greater MED, so network 10.0.0.0 learned from Device C should not be optimal.

To avoid this problem, you can configure the **bestroute compare-med** command to enable MED comparison for routes from the same AS on Device D. After that, Device D puts the routes received from each AS into a group, selects the route with the lowest MED from each group, and compares routes from different groups. Network 10.0.0.0 learned from Device B is the optimal route. The following output shows the BGP routing table on Device D.

```
     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn
 *>e 10.0.0.0/8         2.2.2.2         50                    0       300 400e
```

```
 * e                3.3.3.3         50                  0       200 400e
 * e                1.1.1.1         60                  0       200 400e
```

Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Enable MED comparison for routes on a per-AS basis.
   bestroute compare-med
   By default, MED comparison for routes on a per-AS basis is disabled.

Enabling MED comparison for routes from confederation peers

About this task

This task enables BGP to compare the MEDs of routes received from confederation peers. However, if a route received from a confederation peer has an AS number that does not belong to the confederation, BGP does not compare the route with other routes. For example, a confederation has three AS numbers 65006, 65007, and 65009. BGP receives three routes from different confederation peers. The AS_PATH attributes of these routes are 65006 65009, 65007 65009, and 65008 65009, and the MED values of them are 2, 3, and 1. Because the third route's AS_PATH attribute contains AS number 65008 that does not belong to the confederation, BGP does not compare it with other routes. As a result, the first route becomes the optimal route.

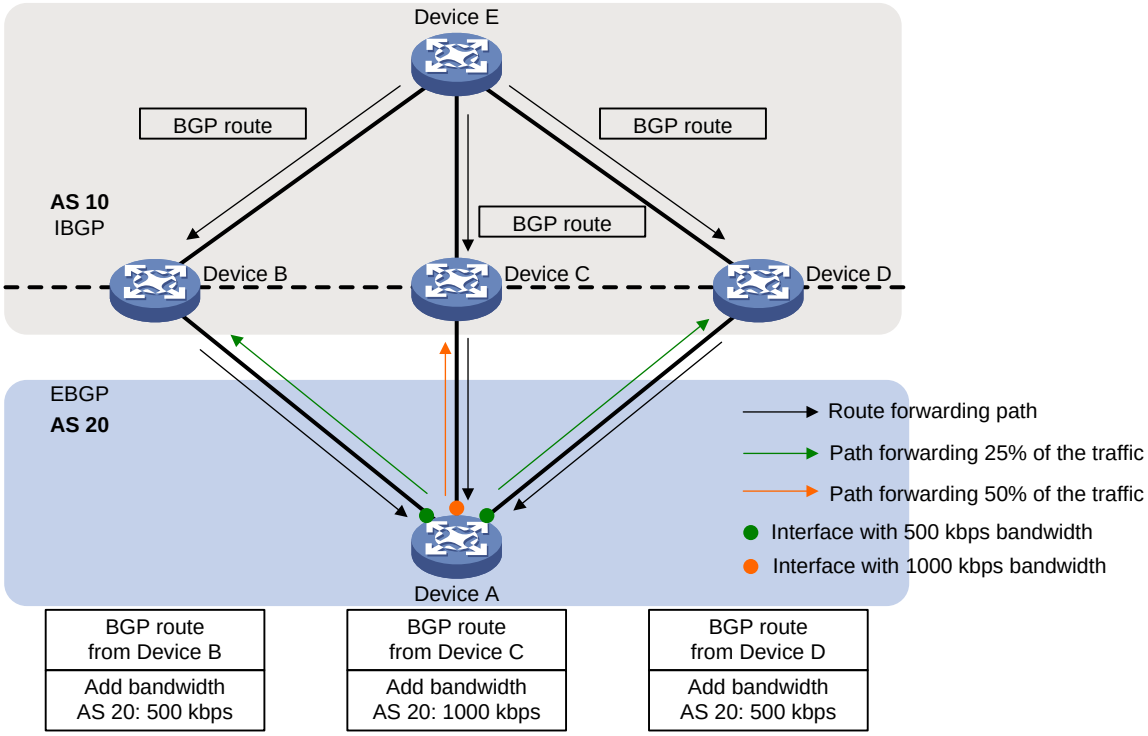
Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Enable MED comparison for routes from confederation peers.
   bestroute med-confederation
   By default, MED comparison for routes from confederation peers is disabled.

Configuring the link bandwidth attribute

About this task

ECMP load balancing equally distributes traffic to the equal-cost links without considering link bandwidth differences. This might cause insufficient usage of high-speed links and traffic congestion



on low-speed links. To resolve this issue, you can configure Unequal Cost Multiple Path (UCMP) load balancing based on the link bandwidth attributes of BGP routes.

The link bandwidth attribute of a route indicates the link bandwidth of the outgoing interface of the route. After UCMP load balancing is enabled for an EBGP peer on the device, the device adds the link bandwidth attribute into the route received from the EBGP peer. This attribute carries the AS number of the current BGP process and the interface bandwidth for direct EBGP session establishment. UCMP BGP routes are formed in the following situation:

- BGP route load balancing is configured by the **balance** command.
- All BGP routes used for load balancing carry a link bandwidth attribute.

During traffic forwarding, the proportion of the traffic carried on each BGP route is that of the route's link bandwidth to the total link bandwidth of all UCMP routes. As shown in Figure 39, Device A receives routes for the same destination address from three EBGP peers. Assume Device A adds link bandwidth attribute values 500 kbps, 1000 kbps, and 500 kbps for the three BGP routes. The traffic load proportions carried on the three BGP routes are 25%, 50%, and 25%, respectively.

Figure 39 UCMP load balancing based on BGP routes with link bandwidth attributes

By default, the BGP routes with link bandwidth attributes are advertised only to IBGP peers and the added link bandwidth attributes are optional non-transitive attributes. You can change the advertisement rule for BGP routes with link bandwidth attributes as needed:

- To advertise link bandwidth attributes to EBGP peers, execute the **peer advertise ebgp bandwidth** command.
- To make BGP peers that cannot identify link bandwidth attributes to carry link bandwidth attributes when they forward BGP routes, execute the **peer advertise bandwidth transitive** command. This command can convert the link bandwidth attributes carried in BGP routes into optional transitive attributes.

Restrictions and guidelines

When you configure this feature to add link bandwidth attributes to BGP routes, follow these restrictions and guidelines:

- This feature applies only to direct EBGP peers or peer groups. If the specified peer or peer group becomes an indirectly connected one, BGP stops adding the link bandwidth attribute to routes received from the EBGP peer or peer group.
- Only if all BGP routes for the same destination address carry the link bandwidth attributes, can these routes provide UCMP load balancing. Otherwise, the routes can only provide ECMP load balancing.
- A BGP route can carry a maximum of one link bandwidth attribute. If a received route already has a link bandwidth attribute, the device cannot add a link bandwidth attribute to the route any more.

In advertisement of BGP routes with link bandwidth attributes, the following restrictions apply:

- For a BGP peer or peer group, the configuration of the **peer route-policy export** command takes precedence over that of the **peer bandwidth** command when the following requirements are met:
  - You use the **peer route-policy export** command to apply a routing policy to the BGP peer or peer group. The routing policy uses the **apply extcommunity** command to configure a link bandwidth attribute for BGP routes.
  - You configure the **peer bandwidth** command for the BGP peer or peer group.
- Before advertisement, the device deletes the link bandwidth attribute of a received route if the device needs to change the next hop of that route. This is because the forwarding link instructed by this route has changed and thus the original link bandwidth no longer indicates the bandwidth of the real forwarding link. This restriction does not exist if the device receives a route without any link bandwidth attribute and adds a link bandwidth attribute to the route.
- For UCMP routes, if the Add-Path feature is configured to advertise only one optimal route, the link bandwidth attribute value for the optimal route equals the total link bandwidth of all UCMP routes. If the Add-Path feature is configured to advertise more than one optimal route, the advertised routes carry their respective link bandwidth attributes.

Prerequisites

Configure the **peer advertise-ext-community** command. BGP can advertise the link bandwidth attribute to a BGP peer or peer group only after you execute this command for the BGP peer or peer group.

Procedure (IPv4 unicast/IPv4 multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Configure a link bandwidth attribute for a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **bandwidth** [*bandwidth-value*]

   By default, no link bandwidth attribute is configured for a peer or peer group.

4. (Optional.) Enable advertising the link bandwidth attribute to EBGP peers.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **advertise ebgp bandwidth**

   By default, the device does not advertise the link bandwidth attribute to EBGP peers.

5. (Optional.) Convert the type of the link bandwidth attribute to optional transitive for BGP routes advertised to a peer.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **advertise bandwidth transitive**

   By default, the link bandwidth attribute of BGP routes is optional non-transitive.

Procedure (IPv6 unicast/IPv6 multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast

3. Configure a link bandwidth attribute for a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **bandwidth** [*bandwidth-value*]

   By default, no link bandwidth attribute is configured for a peer or peer group.

   The *ipv4-address* [*mask-length*] option is supported only in BGP IPv6 unicast address family view.

4. (Optional.) Enable advertising the link bandwidth attribute to EBGP peers.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise ebgp bandwidth**

   By default, the device does not advertise the link bandwidth attribute to EBGP peers.

   The *ipv4-address* [*mask-length*] option is supported only in BGP IPv6 unicast address family view.

5. (Optional.) Convert the type of the link bandwidth attribute to optional transitive for BGP routes advertised to a peer.

peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise bandwidth transitive**

By default, the link bandwidth attribute of BGP routes is optional non-transitive.

The *ipv4-address* [*mask-length*] option is supported only in BGP IPv6 unicast address family view.

Minimizing the priority of BGP routes advertised to peers

Minimizing the priority of BGP routes advertised to peers with a DOWN-to-UP state change

About this task

By default, the device sends BGP routes immediately to a peer when the peer state changes to UP. If the device advertises routes before completing ARP or ND table convergence, the traffic matching these advertised routes might not be forwarded correctly, which causes traffic loss.

To resolve this issue, use this feature to minimize the priority of the routes to be advertised after the state of a peer changes from DOWN to UP. The peer will not select the routes received from the device as the optimal routes. After the device completes ARP or ND table convergence and the specified wait time elapses, the device restores the priority of the routes advertised to the peer.

After you use this feature, the device performs the following tasks when the state of a peer changes from DOWN to UP:

1. Set the local preference value to the minimum (zero) and the MED value to the maximum (4294967295) for the routes to be advertised.
2. After the specified wait time elapses, restore the local preference value and the MED value for the advertised routes, and then advertise these routes immediately.

   For the device to restore the priority of the advertised routes before the specified wait time elapses, use one of the following commands:

   - **reset bgp advertise lowest-priority on-peer-up**

     After you use this command, the device immediately sends BGP routes with the original local preference value and MED value to the peer. If the state of a peer changes from DOWN to UP later, the device still minimizes the priority of the routes advertised to that peer.
   - **undo advertise lowest-priority on-peer-up duration**

     After you use this command, the device immediately sends BGP routes with the original local preference value and MED value to the peer. The device does not change the original local preference value and MED value for the subsequent routes advertised to peers.

Restrictions and guidelines

You can use the **advertise lowest-priority on-peer-up duration** command in BGP instance view or BGP address family view:

- If you use this command in the view of a BGP instance, this command takes effect on all address families in the instance.
- If you use this command in the view of a BGP address family, this command takes effect only on the address family.
- For a BGP address family, the configuration of this command in BGP address family view takes precedence over that in BGP instance view.

You can use this command multiple times to change the wait time. After you change the wait time, the following rules apply:

- If the original wait time setting is taking effect, the new wait time setting will immediately take over and the device will update the time to wait for route priority restoration.

  For example, you can set the wait time to 10 seconds by using the **advertise lowest-priority on-peer-up duration** 10 command. Then, you use the **advertise lowest-priority on-peer-up duration** 6 command to set a new wait time six seconds after the state of a peer changes from DOWN to UP. The device will still minimize the priority of the routes advertised to the peer during the following six seconds.
- If the original wait time is not taking effect, the new wait time will take effect after the state of a peer changes from DOWN to UP.

The following commands can influence each other:

- **advertise lowest-priority on-peer-up duration**
- **advertise lowest-priority on-startup duration**
- **bgp update-delay on-startup**
- **route-update-delay**

When you use two of the commands above together, the configuration result varies by command as follows:

Table 12 Configuration results

Command A	Command B	Configuration result
bgp update-delay on-startup	**advertise lowest-priority on-startup duration** in BGP instance view	Command A and command B overwrite each other. The command executed at last takes effect.
	advertise lowest-priority on-peer-up duration in BGP instance view	Provided that the delay time specified in command A is TA and the wait time specified in command B is TB, the two commands take effect as follows after the device restarts and the BGP process recovers: • If TA ≥ TB, only command A takes effect. • If TA < TB, the device performs the following tasks: **a.** The device does not send any BGP routes to peers within TA. **b.** After TA elapses, the device sends BGP routes to peers and minimizes the priority of these routes during the remaining time (TB minus TA). **c.** After TB elapses, the device restores the priority of the advertised routes, and then immediately sends them to peers. The device does not minimize the priority of the subsequent routes advertised to peers.
	route-update-delay	Both command A and command B

		take effect after the device restarts and the BGP process recovers. Provided that the delay time specified in command A is TA, the device can advertise BGP routes to a peer only after TA plus TS elapses. TS represents the larger interval between the intervals specified in the **peer route-update-interval** command and command B. If you did not execute the **peer route-update-interval** command for the peer, the device uses the default value of this command to compare with the interval configured in command B.
	advertise lowest-priority on-startup duration in the view of a BGP address family	• In the address family configured with command B, only command B takes effect. • In the address families not configured with command B, command A takes effect.
	advertise lowest-priority on-peer-up duration in the view of a BGP address family	Provided that the delay time specified in command A is TA and the wait time specified in command B is TB, the following rules apply: • In the address families not configured with command B, only command A takes effect. • In the address family configured with command B, the two commands take effect as follows after the device restarts and the BGP process recovers: o If TA ≥ TB, only command A takes effect. o If TA < TB, the device performs the following tasks: o i. The device does not send any BGP routes to peers within TA. o ii. The device sends BGP routes to peers and minimizes the priority of these routes during the remaining time (TB minus TA). o iii. After TB elapses, the device restores the priority of the advertised routes, and then immediately sends them to peers. The device does not minimize the priority of the subsequent routes advertised to peers.
route-update-delay	**advertise lowest-priority on-startup duration** in BGP instance view	The following description applies to BGP IPv4 unicast address family, BGP-VPN IPv4 unicast address family, BGP IPv6 unicast address family, and BGP-VPN IPv6 unicast

		address family. Provided that the wait time specified in command B is TB, the two commands take effect as follows after the device restarts and the BGP process recovers: • If TS ≥ TB, only command A takes effect. • If TS < TB, the device performs the following tasks: **d.** The device does not send any BGP routes to peers within TS. **e.** After TS elapses, the device sends BGP routes to peers and minimizes the priority of these routes during the remaining time (TB minus TS). **f.** After TB elapses, the device restores the priority of the advertised routes, and then immediately sends them to peers. The device does not minimize the priority of the subsequent routes advertised to peers. TS represents the larger interval between the intervals specified in the **peer route-update-interval** command and command A. If you did not execute the **peer route-update-interval** command for the peers, the device uses the default value of this command to compare with the interval configured in command A.
	advertise lowest-priority on-peer-up duration in BGP instance view	The following description applies to BGP IPv4 unicast address family, BGP-VPN IPv4 unicast address family, BGP IPv6 unicast address family, and BGP-VPN IPv6 unicast address family. Provided that the wait time specified in command B is TB, the two commands take effect as follows when the state of a peer changes from DOWN to UP: • If TS ≥ TB, only command A takes effect. • If TS < TB, the device performs the following tasks: **g.** The device does not send any BGP routes to the peer within TS. **h.** After TS elapses, the device sends BGP routes to the peer and minimizes the priority of these routes during the remaining time (TB minus

		TS). **i.** After TB elapses, the device restores the priority of the advertised routes, and then immediately sends them to the peer. The device does not minimize the priority of the subsequent routes advertised to the peer. TS represents the larger interval between the intervals specified in the **peer route-update-interval** command and command A. If you did not execute the **peer route-update-interval** command for the peer, the device uses the default value of this command to compare with the interval configured in command A.
	advertise lowest-priority on-startup duration in BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, BGP IPv6 unicast address family view, or BGP-VPN IPv6 unicast address family view	Provided that the wait time specified in command B is TB, the following rules apply: • In the address families not configured with command B, only command A takes effect. • In the address family configured with command B, the two commands take effect as follows after the device restarts and the BGP process recovers: o If TS ≥ TB, only command A takes effect. o If TS < TB, the device performs the following tasks: o i. The device does not send any BGP routes to peers within TS. o ii. After TS elapses, the device sends BGP routes to peers and minimizes the priority of these routes during the remaining time (TB minus TS). o iii. After TB elapses, the device restores the priority of the advertised routes, and then immediately sends them to peers. The device does not minimize the priority of the subsequent routes advertised to peers. • TS represents the larger interval between the intervals specified in the **peer route-update-interval** command and command A. If you did not execute the **peer route-update-interval** command for the peers, the device uses the default value of

		this command to compare with the interval configured in command A.
	advertise lowest-priority on-peer-up duration in BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, BGP IPv6 unicast address family view, or BGP-VPN IPv6 unicast address family view	Provided that the wait time specified in command B is TB, the following rules apply: • In the address families not configured with command B, only command A takes effect. • In the address family configured with command B, the two commands take effect as follows when the state of a peer changes from DOWN to UP: o If TS ≥ TB, only command A takes effect. o If TS < TB, the device performs the following tasks: o i. The device does not send any BGP routes to the peer within TS. o ii. After TS elapses, the device sends BGP routes to the peer and minimizes the priority of these routes during the remaining time (TB minus TS). o iii. After TB elapses, the device restores the priority of the advertised routes, and then immediately sends them to the peer. The device does not minimize the priority of the subsequent routes advertised to the peer. • TS represents the larger interval between the intervals specified in the **peer route-update-interval** command and command A. If you did not execute the **peer route-update-interval** command for the peer, the device uses the default value of this command to compare with the interval configured in command A.
advertise lowest-priority on-startup duration in BGP instance view	**advertise lowest-priority on-peer-up duration** in BGP instance view	Command A is mutually exclusive with command B.
	advertise lowest-priority on-peer-up duration in the view of a BGP address family	• In the address family configured with command B, only command B takes effect. • In the address families not configured with command B, only command A takes effect.
advertise lowest-priority	**advertise lowest-priority**	• In the address family configured with command B, only command

on-peer-up duration in BGP instance view	**on-startup duration** in the view of a BGP address family	B takes effect. • In the address families not configured with command B, only command A takes effect.
advertise lowest-priority on-peer-up duration in the view of a BGP address family	**advertise lowest-priority on-startup duration** in the view of a BGP address family	Command A is mutually exclusive with command B in the same address family.

Procedure (BGP instance view)

1. Enter system view.

   system-view
2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
3. Minimize the priority of the routes advertised to a peer after the peer state changes from DOWN to UP.

   advertise lowest-priority on-peer-up duration *seconds*

   By default, BGP does not change the priority of the routes advertised to its peers.

Procedure (BGP IPv4 unicast)

1. Enter system view.

   system-view
2. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
3. Minimize the priority of the routes advertised to a peer after the peer state changes from DOWN to UP.

   advertise lowest-priority on-peer-up duration *seconds*

   By default, BGP does not change the priority of the routes advertised to its peers.
4. (Optional.) Restore the route priority adjusted by the **advertise lowest-priority on-peer-up duration** command.

   reset bgp [**instance** *instance-name*] **advertise lowest-priority on-peer-up**

   This command is supported only in user view.

Procedure (BGP IPv6 unicast)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.

- Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

  address-family ipv6 [**unicast**]

3. Minimize the priority of the routes advertised to a peer after the peer state changes from DOWN to UP.

   advertise lowest-priority on-peer-up duration *seconds*

   By default, BGP does not change the priority of the routes advertised to its peers.

Minimizing the priority of BGP routes advertised to peers after a device reboot

About this task

By default, the device sends BGP routes immediately to peers after the device restarts and the BGP process recovers. If the device advertises routes before completing ARP or ND table convergence, the traffic matching these advertised routes might not be forwarded correctly, which causes traffic loss.

To resolve this issue, use this feature to minimize the priority of the routes to be advertised after the device restarts and the BGP process recovers. Peers will not select the routes received from the device as the optimal routes. After the device completes ARP or ND table convergence and the specified wait time elapses, the device restores the priority of the routes advertised to the peers.

After you use this feature, the device performs the following tasks after the device restarts and the BGP process recovers:

1. Set the local preference value to the minimum (zero) and the MED value to the maximum (4294967295) for the routes to be advertised.
2. After the specified wait time elapses, restore the local preference value and the MED value for the advertised routes, and then advertise these routes immediately.

   For the device to restore the priority of the advertised routes before the specified wait time elapses, use one of the following commands:

   - **reset bgp advertise lowest-priority on-startup**

     After you use this command, the device immediately sends BGP routes with the original local preference value and MED value to peers. The device does not minimize the priority of the subsequent routes advertised to the peers unless the device restarts again.

   - **undo advertise lowest-priority on-startup duration**

     After you use this command, the device immediately sends BGP routes with the original local preference value and MED value to peers. The device does not change the original local preference value and MED value for the subsequent routes advertised to the peers.

Restrictions and guidelines

When you use the **advertise lowest-priority on-startup duration** command, follows these guidelines:

- You can use this command in BGP instance view or BGP address family view:
  - If you use this command in the view of a BGP instance, this command takes effect on all address families in the instance.

    - If you use this command in the view of a BGP address family, this command takes effect only on the address family.
    - For a BGP address family, the configuration of this command in BGP address family view takes precedence over that in BGP instance view.
- The configuration of this command does not take effect immediately. It takes effect only after the device restarts.

The following commands can influence the configuration of each other:

- **advertise lowest-priority on-peer-up duration**
- **advertise lowest-priority on-startup duration**
- **bgp update-delay on-startup**
- **route-update-delay**

When you use two of the commands above together, the configuration result varies by command. For more information, see the related table in "Minimizing the priority of BGP routes advertised to peers with a DOWN-to-UP state change."

Procedure (BGP instance view)

1. Enter system view.

   system-view
2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
3. Minimize the priority of the routes advertised to peers after the device restarts and the BGP process recovers.

   advertise lowest-priority on-startup duration *seconds*

   By default, BGP does not change the priority of the routes advertised to its peers.

Procedure (BGP IPv4 unicast)

1. Enter system view.

   system-view
2. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
3. Minimize the priority of the routes advertised to peers after the device restarts and the BGP process recovers.

   advertise lowest-priority on-startup duration *seconds*

   By default, BGP does not change the priority of the routes advertised to its peers.

Procedure (BGP IPv6 unicast)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.

- Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

  address-family ipv6 [**unicast**]

3. Minimize the priority of the routes advertised to peers after the device restarts and the BGP process recovers.

   advertise lowest-priority on-startup duration *seconds*

   By default, BGP does not change the priority of the routes advertised to its peers.

Restoring the priority of advertised BGP routes

About this task

Before performing this task, make sure the following conditions exist:

- The device has completed ARP or ND table convergence and is ready to advertise routes with original priority.
- The **advertise lowest-priority on-peer-up duration** or **advertise lowest-priority on-startup duration** command still takes effect after a peer comes up or the device restarts.

After you perform this task, the device immediately sends BGP routes with the original local preference value and MED value to peers.

- If the state of a peer changes from DOWN to UP later, the device still minimizes the priority of the routes advertised to that peer.
- If the device restarts again later, the device still minimizes the priority of the routes advertised to peers.

Procedure

To restore the priority of the advertised BGP routes, use the **reset bgp** [**instance** *instance-name*] **advertise lowest-priority** { **on-peer-up** | **on-startup** } command in user view.

Preferring BGP routes of a specific next hop IP type

About this task

In scenarios where multiple networks coexist, the device might simultaneously learn BGP routes with the same destination network address but different types of next hops. Supported next hop types include IPv4 and IPv6.

In scenarios where multiple networks coexist, the device might simultaneously learn BGP routes with the same destination network address but different types of next hops. Supported next hop types include IPv4 and IPv6. For example, the device might be able to reach the same destination address through either an MPLS network or the public IPv4 network. In this case, it might learn a route with an IPv6 next hop from the MPLS network and a route with an IPv4 next hop from the public IPv4 network. By default, the device selects the route learned from the public IPv4 network as the optimal

route. To have the device select the route learned from the MPLS network as the optimal route, you need to configure other route attributes to affect the route selection result. This task enables you to specify the next hop IP type that BGP prefers during optimal route selection, thus providing more flexibility and convenience in BGP route planning.

To view the priority of the nexthop IP type-based route selection rule among the BGP route selection rules, see "BGP route selection."

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

3. Prefer BGP routes of a specific next hop IP type during optimal route selection.

   bestroute nexthop-priority { **ipv4** | **ipv6** } [**preferred**]

   By default, BGP prefers routes with IPv4 next hops during optimal route selection.

   If you execute this command multiple times in the same address family, the most recent configuration takes effect.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

address-family ipv6 multicast

3. Prefer BGP routes of a specific next hop IP type during optimal route selection.

   bestroute nexthop-priority { **ipv4** | **ipv6** } [**preferred**]

   By default, BGP prefers routes with IPv4 next hops during optimal route selection.

   If you execute this command multiple times in the same address family, the most recent configuration takes effect.

Ignoring IGP metrics during optimal route selection

About this task

By default, BGP takes IGP metrics into account during optimal route selection. If multiple routes to the same destination are available, BGP selects the route with the smallest IGP metric as the optimal route.

Perform this task to enable BGP to ignore IGP metrics during optimal route selection.

Procedure

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Configure BGP to ignore IGP metrics during optimal route selection.

   bestroute igp-metric-ignore

   By default, BGP takes IGP metrics into account during optimal route selection.

Ignoring router IDs during optimal route selection

About this task

By default, BGP compares router IDs during optimal route selection. If multiple routes to the same destination are available, BGP selects the route with the smallest router ID as the optimal route.

Perform this task to enable BGP to ignore router IDs during optimal route selection.

Procedure

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Configure BGP to ignore router IDs during optimal route selection.
   bestroute router-id-ignore
   By default, BGP compares router IDs during optimal route selection.

Configuring the next hop type selection rule for optimal route selection

About tunnel-type recursive next hops

NOTE:

In this section, a recursive next hop refers to a next hop obtained through route recursion. Recursive next hops include the following:

- **IP-type recursive next hops**: This type of recursive next hops are IP addresses.
- **Tunnel-type recursive next hops**: This type of recursive next hops are tunnels.

When the next hop of a BGP route is recursed to a tunnel, the tunnel can be one of the following:

- Label switched path (LSP).
- GRE or VXLAN tunnel.

Each tunnel-type recursive next hop has a unique tunnel ID. To view the tunnel-type recursive next hops of BGP routes, see the **Rely tunnel IDs** field in the output of the **display bgp routing-table** command.

Configuring the condition for BGP routes to participate in optimal route selection

About this task

The next hop of a BGP route can be recursed to an IP addresses and a tunnel synchronously. By default, a BGP route can participate in optimal route selection only when its next hop is recursed to an IP address. This command is applicable to the following scenarios:

- When the device acts as a route reflector, it only reflects routes to clients and does not provide traffic forwarding guidance. To ensure that the device can reflect all received routes to its clients, execute the **bestroute nexthop-resolved none** command. This command disables BGP from examining the reachability of next hops during optimal route selection.
- In some special networks, the next hop of a route might be a tunnel only after route recursion if its AS_PATH attribute is modified by an intermediate device. In this situation, the route cannot participate in optimal route selection though its next hop is reachable, which leads to traffic forwarding failure. To resolve this issue, use the **bestroute nexthop-resolved tunnel** command. This command allows BGP routes that have only tunnel-type recursive next hops to participate in optimal route selection.

Restrictions and guidelines

Although the **bestroute nexthop-resolved none** command enables BGP routes with unreachable next hops to participate in optimal route selection, those routes cannot be added into the IP routing table or FIB. As a result, they are not used to direct traffic forwarding.

Procedure

1. Enter system view.

system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Configure the condition for BGP routes to participate in optimal route selection
   bestroute nexthop-resolved { **none** | **tunnel** }
   By default, BGP routes can participate in optimal route selection only when their next hops are recursed to IP addresses.
   If you execute this command multiple times in the same address family, the most recent configuration takes effect.

Preferring BGP routes of a specific recursive next hop type during optimal route selection

About this task

By default, the recursive next hops of BGP routes does not affect their priorities during optimal route selection. If the next hop of a BGP route is recursed to an IP address and that of another BGP route is recursed to a tunnel, the two routes still have the same priority during optimal route selection.

This feature enables BGP to prefer routes with IP-type or tunnel-type recursive next hops during optimal route selection.

To view the priority of the route selection rule configured by this feature during optimal route selection, see "BGP route selection."

Restrictions and guidelines

A BGP route that does not have an IP-type recursive next hop cannot participate in optimal route selection. For BGP routes with only tunnel-type recursive next hops, they cannot participate in optimal route selection even if you have executed the **bestroute nexthop-type tunnel** command. To resolve this issue, execute the **bestroute nexthop-resolved tunnel** command.

Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Prefer routes with IP-type or tunnel-type recursive next hops during optimal route selection.
   bestroute nexthop-type { **ip** | **tunnel** } [**preferred**]
   By default, the recursive next hops of BGP routes does not affect their priorities during optimal route selection. If the next hop of a BGP route is recursed to an IP address and that of another BGP route is recursed to a tunnel, the two routes still have the same priority during optimal route selection.

If you execute this command multiple times, the most recent configuration takes effect..

Associating a track entry with a BGP peer or peer group

About this task

This feature enables BGP to monitor the session to each peer, such as the link state of a peer interface. BGP can adjust the priority of routes received from a peer or peer group based on the track entry state. If a network state change occurs, BGP can response quickly to avoid traffic loss due to network issues, such as link failures.

After BGP associates a track entry with a peer, BGP adjusts the priority of routes received from the peer as follows:

- When the state of the associated track entry becomes negative, BGP increases the MED value of the routes to the maximum and set the route priority to the lowest.
- When the state of the associated track entry restores to positive, BGP restores the MED value and the priority of the routes to the original values.

Restrictions and guidelines

When you specify a track entry to be associated with a peer, the track entry must have been created. As a best practice, use a track entry associated with the link state of the peer interface. The track feature can obtain the link state of the peer interface easily and notify BGP to adjust the route priority when the link state changes to down.

For more information about track entries, see track configuration in *High Availability Configuration Guide*.

Procedure (IPv4 unicast)

1. Enter system view.

   system-view
2. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
3. Associate a track entry with a BGP peer or peer group for route priority adjustment.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **route-priority-track** *track-entry-number*

   By default, BGP does not use track entries for route priority adjustment.

Procedure (IPv6 unicast)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.

- Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

  address-family ipv6 [**unicast**]

3. Associate a track entry with a BGP peer or peer group for route priority adjustment.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **route-priority-track** *track-entry-number*

   By default, BGP does not use track entries for route priority adjustment.

Display and maintenance commands for BGP path selection control

Execute **display** commands in any view.

Displaying BGP (IPv4 unicast address family)

Task	Command
Display BGP path attribute information.	**display bgp** [**instance** *instance-name*] **paths** [*as-regular-expression*]
Restore the priority of the routes to be advertised during the time to wait for route priority restoration.	**reset bgp** [**instance** *instance-name*] **advertise lowest-priority** { **on-peer-up** | **on-startup** }

Displaying BGP (IPv6 unicast address family)

Task	Command
Display BGP path attribute information.	**display bgp** [**instance** *instance-name*] **paths** [*as-regular-expression*]
Restore the priority of the routes to be advertised during the time to wait for route priority restoration.	**reset bgp** [**instance** *instance-name*] **advertise lowest-priority** { **on-peer-up** | **on-startup** }

Displaying BGP (IPv4 multicast address family)

Task	Command
Display BGP path attribute information.	**display bgp** [**instance** *instance-name*] **paths** [*as-regular-expression*]

Displaying BGP (IPv6 multicast address family)

Task	Command
Display BGP path attribute information.	**display bgp** [**instance** *instance-name*] **paths** [*as-regular-expression*]

BGP path selection control configuration examples

Example: Configuring route selection based on the LOCAL_PREF attribute

Network configuration

As shown in Figure 40, all switches run BGP.

- EBGP runs between Switch A and Switch B, and between Switch A and Switch C.
- IBGP runs between Switch B and Switch D, and between Switch D and Switch C. OSPF is the IGP protocol in AS 200.

Configure routing policies for LOCAL_PREF attribute adding, which makes Switch D select route 1.0.0.0/8 from Switch C as the optimal.

Figure 40 Network diagram

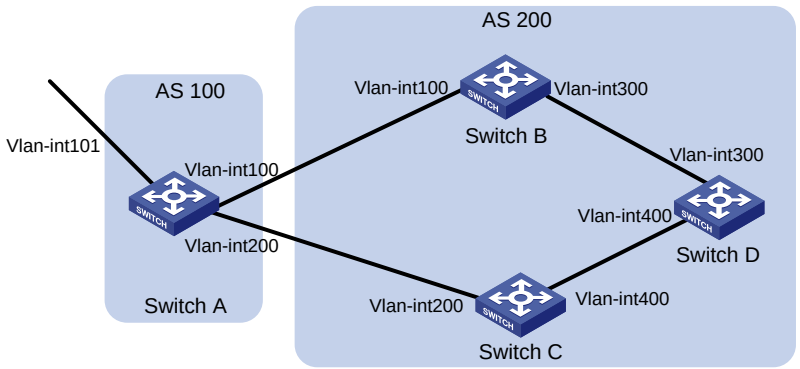


Table 13 Interface and IP address assignment

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int101	1.0.0.1/8	Switch D	Vlan-int400	195.1.1.1/24
	Vlan-int100	192.1.1.1/24		Vlan-int300	194.1.1.1/24
	Vlan-int200	193.1.1.1/24	Switch C	Vlan-int400	195.1.1.2/24
Switch B	Vlan-int100	192.1.1.2/24		Vlan-int200	193.1.1.2/24
	Vlan-int300	194.1.1.2/24			

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF on Switch B, Switch C, and Switch D:

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ospf
[SwitchB-ospf] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 192.1.1.0 0.0.0.255
```

```
[SwitchB-ospf-1-area-0.0.0.0] network 194.1.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ospf
[SwitchC-ospf] area 0
[SwitchC-ospf-1-area-0.0.0.0] network 193.1.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] network 195.1.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] quit
[SwitchC-ospf-1] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] ospf
[SwitchD-ospf] area 0
[SwitchD-ospf-1-area-0.0.0.0] network 194.1.1.0 0.0.0.255
[SwitchD-ospf-1-area-0.0.0.0] network 195.1.1.0 0.0.0.255
[SwitchD-ospf-1-area-0.0.0.0] quit
[SwitchD-ospf-1] quit
```

3. Configure BGP connections:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA-bgp-default] peer 192.1.1.2 as-number 200
[SwitchA-bgp-default] peer 193.1.1.2 as-number 200
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 192.1.1.2 enable
[SwitchA-bgp-default-ipv4] peer 193.1.1.2 enable
```

Inject network 1.0.0.0/8 to the BGP routing table on Switch A.

```
[SwitchA-bgp-default-ipv4] network 1.0.0.0 8
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

Configure Switch B.

```
[SwitchB] bgp 200
[SwitchB-bgp-default] peer 192.1.1.1 as-number 100
[SwitchB-bgp-default] peer 194.1.1.1 as-number 200
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 192.1.1.1 enable
[SwitchB-bgp-default-ipv4] peer 194.1.1.1 enable
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

Configure Switch C.

```
[SwitchC] bgp 200
[SwitchC-bgp-default] peer 193.1.1.1 as-number 100
[SwitchC-bgp-default] peer 195.1.1.1 as-number 200
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 193.1.1.1 enable
[SwitchC-bgp-default-ipv4] peer 195.1.1.1 enable
```

```
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

Configure Switch D.

```
[SwitchD] bgp 200
[SwitchD-bgp-default] peer 194.1.1.2 as-number 200
[SwitchD-bgp-default] peer 195.1.1.2 as-number 200
[SwitchD-bgp-default] address-family ipv4 unicast
[SwitchD-bgp-default-ipv4] peer 194.1.1.2 enable
[SwitchD-bgp-default-ipv4] peer 195.1.1.2 enable
[SwitchD-bgp-default-ipv4] quit
[SwitchD-bgp-default] quit
```

4. Configure local preference for route 1.0.0.0/8, making Switch D give priority to the route learned from Switch C:

Define IPv4 basic ACL 2000 on Switch C to permit route 1.0.0.0/8.

```
[SwitchC] acl basic 2000
[SwitchC-acl-ipv4-basic-2000] rule permit source 1.0.0.0 0.255.255.255
[SwitchC-acl-ipv4-basic-2000] quit
```

Configure a routing policy named **localpref** on Switch C, setting the local preference of route 1.0.0.0/8 to 200 (the default is 100).

```
[SwitchC] route-policy localpref permit node 10
[SwitchC-route-policy-localpref-10] if-match ip address acl 2000
[SwitchC-route-policy-localpref-10] apply local-preference 200
[SwitchC-route-policy-localpref-10] quit
```

Apply routing policy **localpref** to routes from peer 193.1.1.1.

```
[SwitchC] bgp 200
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 193.1.1.1 route-policy localpref import
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

Display the BGP routing table on Switch D.

```
[SwitchD] display bgp routing-table ipv4

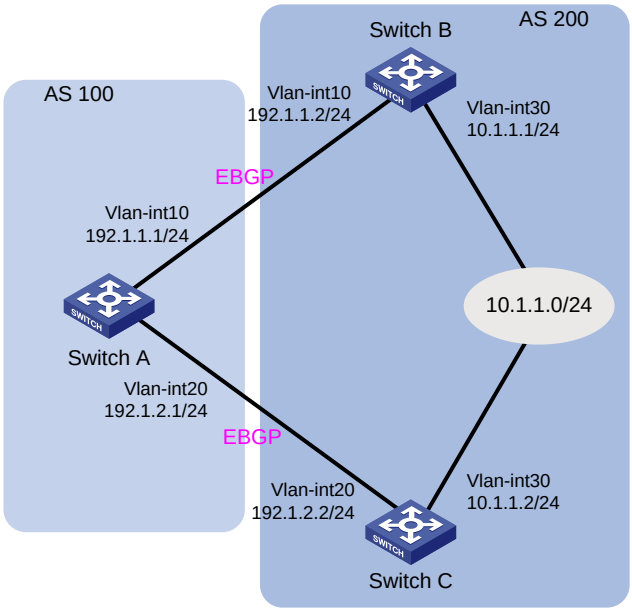
 Total number of routes: 2

BGP local router ID is 195.1.1.1
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >i 1.0.0.0/8          193.1.1.1                  200        0       100i
*  i                    192.1.1.1                  100        0       100i
```

Route 1.0.0.0/8 learned from Switch C is the optimal.



Example: Configuring route selection based on the MED attribute

Network configuration

As shown in Figure 41, all devices run BGP. EBGP runs between Switch A and Switch B, and between Switch A and Switch C. IBGP runs between Switch B and Switch C.

For Switch A, traffic destined for network segment 10.1.1.0/24 can reach AS 200 via Switch B or Switch. To achieve this goal, configure a routing policy that adds the MED attribute to BGP routes, so Switch A can select Switch C as the ingress of AS 200.

Figure 41 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure BGP connections.

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA-bgp-default] peer 192.1.1.2 as-number 200
[SwitchA-bgp-default] peer 192.1.2.2 as-number 200
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 192.1.1.2 enable
[SwitchA-bgp-default-ipv4] peer 193.1.2.2 enable
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 200
[SwitchB-bgp-default] peer 192.1.1.1 as-number 100
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 192.1.1.1 enable
```

```
[SwitchB-bgp-default-ipv4] network 10.1.1.0 24
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 200
[SwitchC-bgp-default] peer 192.1.2.1 as-number 100
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 192.1.2.1 enable
[SwitchC-bgp-default-ipv4] network 10.1.1.0 24
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

3. Configure the MED attribute, ensuring that Switch A selects the route from Switch C as the optimal route.

Configure IPv4 basic ACL 2000 on Switch A. This ACL only permits route 10.1.1.0/24.

```
[SwitchA] acl basic 2000
[SwitchA-acl-ipv4-basic-2000] rule permit source 10.1.1.0 0.0.0.255
[SwitchA-acl-ipv4-basic-2000] quit
```

Configure routing policy **med** on Switch A. This routing policy sets the local preference of route 10.1.1.0/24 to 100. The default MED value is 0.

```
[SwitchA] route-policy med permit node 10
[SwitchA-route-policy-med-10] if-match ip address acl 2000
[SwitchA-route-policy-med-10] apply cost 100
[SwitchA-route-policy-med-10] quit
```

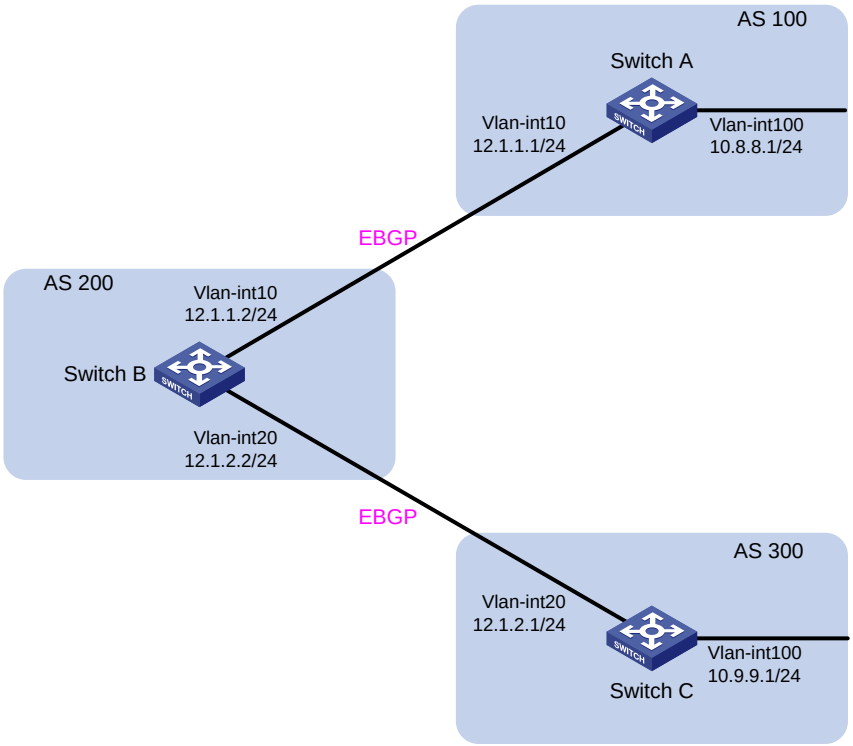
On Switch A, apply routing policy **med** to BGP routes received from Switch B.

```
[SwitchA] bgp 100
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 192.1.1.2 route-policy med import
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

Verifying the configuration

View the BGP routing table of Switch A.

```
<SwitchA> display bgp routing-table ipv4 unicast
 Total number of routes: 2
 BGP local router ID is 192.1.2.1
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a - additional-path
       Origin: i - IGP, e - EGP, ? - incomplete
     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn
* >e 10.1.1.0/24        192.1.2.2       0                     0       200i
*  e                    192.1.1.2       100                   0       200i
```



The command output shows that Switch A has selected route 10.1.1.0/24 learned from Switch C as the optimal route.

Example: Configuring route selection based on the AS_PATH attribute

Network configuration

As shown in Figure 42, Switch A, Switch B, and Switch C are located in different ASs. Switch B communicates with the other routers through EBGP. For security purposes, Switch A and Switch C should not learn the routes that the other advertises to Switch B. To meet this requirement, configure a BGP route filtering policy based on the AS_PATH attribute on Switch B. This policy prevents Switch B from advertising routes learned from Switch C to Switch A, and from advertising routes learned from Switch A to Switch C. With this route filtering policy, AS 100 and AS 300 are isolated from each other.

Figure 42 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure BGP connections.

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA-bgp-default] peer 12.1.1.2 as-number 200
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 12.1.1.2 enable
[SwitchA-bgp-default-ipv4] network 10.8.8.0 24
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

   # Configure Switch B.

```
<SwitchB> system-view
```

```
[SwitchB] bgp 100
[SwitchB-bgp-default] peer 12.1.1.1 as-number 100
[SwitchB-bgp-default] peer 12.1.2.1 as-number 300
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 12.1.1.1 enable
[SwitchB-bgp-default-ipv4] peer 12.1.2.1 enable
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 100
[SwitchC-bgp-default] peer 12.1.2.2 as-number 200
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 12.1.2.2 enable
[SwitchC-bgp-default-ipv4] network 10.9.9.0 24
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

3. Configure a BGP route distribution policy based on the AS_PATH attribute on Switch B.

Create AS path list **deny100** to deny BGP routes whose AS_PATH attribute contains AS 100.

```
[SwitchB] ip as-path deny100 deny _100_
[SwitchB] ip as-path deny100 permit .*
```

Create AS path list **deny300** to deny BGP routes whose AS_PATH attribute contains AS 300.

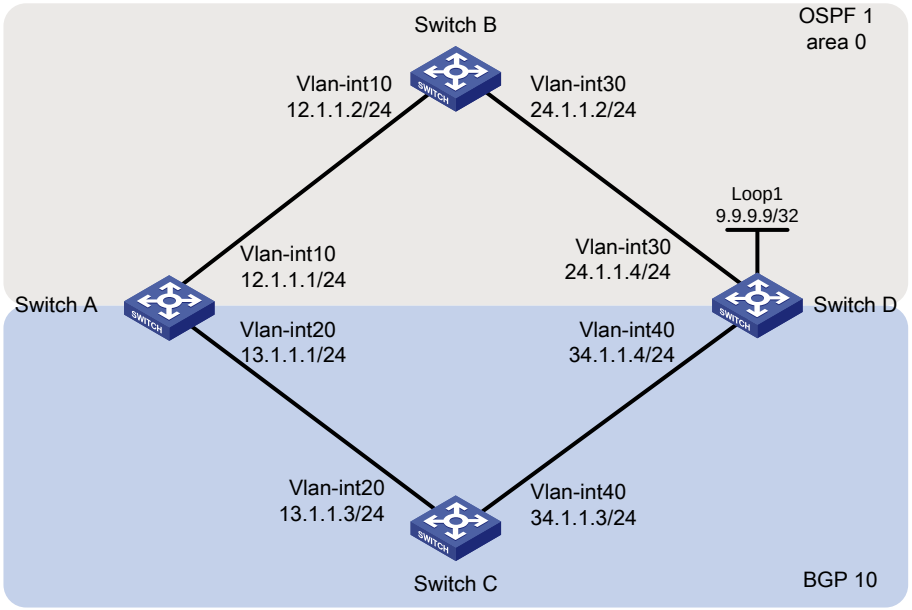
```
[SwitchB] ip as-path deny300 deny _300_
[SwitchB] ip as-path deny300 permit .*
```

Apply AS path lists **deny100** and **deny300** to routes advertised to Switch A and Switch C, respectively.

```
[SwitchB] bgp 100
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 12.1.1.1 as-path-acl deny 300 export
[SwitchB-bgp-default-ipv4] peer 12.1.2.1 as-path-acl deny 100 export
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

Verifying the configuration

Execute the **display bgp routing-table ipv4 unicast** command on Switch A, Switch B, and Switch C separately. The command outputs show that:



- Switch B has learned route 10.8.8.0/24 from Switch A and route 10.9.9.0/24 from Switch C.
- Switch A has not learned route 10.9.9.0/24 from Switch C, and Switch C has not learned route10.8.8.0/24 from Switch A. This indicates that Switch B does not forward Switch A's routes to Switch C or forward Switch C's routes to Switch A.

Example: Changing the preference value for a BGP route

Network configuration

As shown in Figure 43, Switches A, C, and D establish IBGP peer relationships, with Switch C acting as the route reflector. Switches A, B, and D establish OSPF neighbor relationships. Switch D advertises IPv4 unicast route 9.9.9.9/32 through OSPF and BGP. Upon receiving OSPF route 9.9.9.9/32 and BGP route 9.9.9.9/32, Switch A changes the preference value for BGP route 9.9.9.9/32, so the route can be selected as optimal route in Switch A's IP routing table.

Figure 43 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure Switch A.

   # Configure basic OSPF settings.

   ```
   [SwitchA] ospf 1
   [SwitchA-ospf-1] area 0.0.0.0
   [SwitchA-ospf-1] quit
   ```

   # Enable OSPF on VLAN-interface 10.

   ```
   [SwitchA] interface vlan-interface 10
   [SwitchA-Vlan-interface10] ospf 1 area 0.0.0.0
   [SwitchA-Vlan-interface10] quit
   ```

   # Configure BGP settings.

   ```
   [SwitchA] bgp 10
   [SwitchA-bgp-default] peer 13.1.1.3 as-number 10
   [SwitchA-bgp-default] address-family ipv4 unicast
   [SwitchA-bgp-default-ipv4] peer 13.1.1.3 enable
   [SwitchA-bgp-default-ipv4] quit
   [SwitchA-bgp-default] quit
   ```

3. Configure Switch B.

   # Configure basic OSPF settings.

   ```
   [SwitchB] ospf 1
   [SwitchB-ospf-1] area 0.0.0.0
   [SwitchB-ospf-1] quit
   ```

   # Enable OSPF on VLAN-interface 10 and VLAN-interface 30.

   ```
   [SwitchB] interface interface vlan-interface 10
   [SwitchB-Vlan-interface10] ospf 1 area 0.0.0.0
   [SwitchB-Vlan-interface10] quit
   [SwitchB] interface interface vlan-interface 30
   ```

```
[SwitchB-Vlan-interface30] ospf 1 area 0.0.0.0
[SwitchB-Vlan-interface30] quit
```

4. Configure Switch C:

Configure BGP settings.

```
[SwitchC] bgp 10
[SwitchC-bgp-default] peer 13.1.1.1 as-number 10
[SwitchC-bgp-default] peer 34.1.1.4 as-number 10
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 13.1.1.1 enable
[SwitchC-bgp-default-ipv4] peer 13.1.1.1 reflect-client
[SwitchC-bgp-default-ipv4] peer 13.1.1.1 next-hop-local
[SwitchC-bgp-default-ipv4] peer 34.1.1.4 enable
[SwitchC-bgp-default-ipv4] peer 34.1.1.4 reflect-client
[SwitchC-bgp-default-ipv4] peer 34.1.1.4 next-hop-local
[SwitchC-bgp-default-ipv4] reflect change-path-attribute
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

5. Configure Switch D:

Configure basic OSPF settings.

```
[SwitchD] ospf 1
[SwitchD-ospf-1] area 0.0.0.0
[SwitchD-ospf-1] quit
```

Enable OSPF on Loopback 1 and VLAN-interface 30.

```
[SwitchD] interface LoopBack1
[SwitchD-LoopBack1] ip address 9.9.9.9 255.255.255.255
[SwitchD-LoopBack1] ospf 1 area 0.0.0.0
[SwitchD-LoopBack1] quit
[SwitchD] interface interface vlan-interface 30
[SwitchD-Vlan-interface30] ospf 1 area 0.0.0.0
[SwitchD-Vlan-interface30] quit
```

Configure BGP settings.

```
[SwitchD] bgp 10
[SwitchD-bgp-default] peer 34.1.1.3 as-number 10
[SwitchD-bgp-default] address-family ipv4 unicast
[SwitchD-bgp-default-ipv4] network 9.9.9.9 255.255.255.255
[SwitchD-bgp-default-ipv4] peer 34.1.1.3 enable
[SwitchD-bgp-default-ipv4] quit
[SwitchD-bgp-default] quit
```

6. Enable Switch A to change the preference value for BGP route 9.9.9.9/32.

On Switch A, view detailed information about BGP route 9.9.9.9/32 in the IP routing table.

```
[SwitchA] displey ip routing-table 9.9.9.9 verbose

Summary count : 2

 Destination: 9.9.9.9/32
    Protocol: O_INTRA

         SID: N/A
       BkSID: N/A
CommBlockLen: 0                     Priority: Low
  MemberPort: N/A                   ExtFlags: 0x0
    UCMIndex: 0x0                   UserVLAN: 65535
      UCMMTU: 0                     BrasHash: 0
   SessionID: 0                 UserGroupID: 0
  IsoGroupID: 256               BkIsoGroupID: 256
```

The IP routing table has two routes destined for 9.9.9.9/32. The preference value is 10 for OSPF route 9.9.9.9/32 and is 255 for BGP route 9.9.9.9/32. Consequently, only OSPF route 9.9.9.9/32 is active.

On Switch A, configure an ACL that match routes with prefix 9.9.9.9/32, and then apply the ACL to a routing policy. Then, configure the routing policy to change the preference value to 5 for matching routes in the IP routing table.

```
[SwitchA] acl basic 2077
[SwitchA-acl-ipv4-basic-2077] rule 5 permit source 9.9.9.9 0
[SwitchA-acl-ipv4-basic-2077] quit
[SwitchA] route-policy change-preference permit node 10
[SwitchA-route-policy-change-preference-10] if-match ip address acl 2077
[SwitchA-route-policy-change-preference-10] apply preference 5
[SwitchA-route-policy-change-preference-10] quit
```

On Switch A, apply the previous routing policy to BGP. Switch A can then set the preference value to 5 for BGP route 9.9.9.9/32.

```
[SwitchA] bgp 10
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] preference route-policy change-preference
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

Verifying the configuration

On Switch A, view detailed information about BGP route 9.9.9.9/32 in the IP routing table.

```
[SwitchA] displey ip routing-table 9.9.9.9 verbose

Summary count : 2
```

```
 Destination: 9.9.9.9/32

```

According to the command output, the preference value for BGP route 9.9.9.9/32 has been changed to 5. The BGP route is in active state, because its preference is higher than that of OSPF route 9.9.9.9/32.

Tuning and optimizing BGP networks

BGP network tuning and optimization tasks at a glance

To tune and optimize BGP networks, perform the following tasks:

- Setting the TCP MSS for TCP connections
- Establishing and resetting EBGP sessions
  - Enabling BGP to establish an EBGP session over multiple hops
  - Enabling immediate re-establishment of direct EBGP connections upon link failure
- Enabling BGP to negotiate special capabilities
  - Enabling prefix-based BGP ORF capabilities negotiation
  - Enabling 4-byte AS number suppression
  - Enabling BGP to exchange withdrawal ROUTE-REFRESH messages with peers
- Enabling Track-based priority adjustment for BGP routes advertised to a peer or peer group
- Establishing, terminating, and resetting BGP sessions
  - Disabling BGP session establishment
  - Configuring BGP soft-reset
- Configuring BGP load balancing
- Configuring the BGP Additional Paths feature
- Protecting an EBGP peer when memory usage reaches level 2 threshold
- Setting a DSCP value for outgoing BGP packets
- Disabling route recursion policy control for routes received from a peer or peer group
- Flushing the suboptimal BGP route to the RIB
- Configuring a peer monitoring group
- Disabling BGP from flushing specific routes to the routing table
- Configuring BGP optimal route selection delay
- Configuring the BGP session state to collaborate with the monitor link downlink interfaces
- Specifying the longest match principle for next hop recursion
- Enabling conversational remote host route learning
- Enabling peer unreachability detection
- Displaying 4-byte AS numbers in asdot or asdot+ notation
- Converting AS numbers in effective device configurations
- Configuring the tag community attribute

Setting the TCP MSS for TCP connections

About this task

BGP typically establishes a multihop TCP connection with a peer. Multiple intermediate devices might fragment BGP packets due to their MTU settings, resulting in frequent packet encapsulations and decapsulations that reduce forwarding efficiency.

To resolve this issue, you can perform this task to set the TCP maximum segment size (MSS) for a peer or peer group. TCP segments sent by the source will not be re-fragmented along the path to the destination.

During TCP connection establishment with the peer or peer group specified in the **peer tcp-mss** command, the minimum of the following MSSs takes effect:

- The MSS calculated according to the IPv4 MTU set by the **ip mtu** command on the peer-facing interface.
- The MSS set by the **tcp mss** command for the peer-facing interface.
- The MSS calculated according to the path MTU detected by TCP path MTU discovery (enabled with the **tcp path-mtu-discovery** command).
- The MSS set by the **peer tcp-mss** command.

The MSS is calculated by using the following formula:

MSS = path MTU (or interface MTU) – IP header length – TCP header length

For more information about MTU and MSS, see IP performance optimization configuration in *Layer 3—IP Services Configuration Guide*.

Restrictions and guidelines

This task might cause BGP session re-establishment. Make sure you understand the potential impact before performing this task.

Procedure

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Set the TCP MSS for a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **tcp-mss** *mss-value*

   By default, the TCP MSS is not set.

Enabling BGP to establish an EBGP session over multiple hops

About this task

To establish an EBGP session, two routers must have a direct physical link and use directly connected interfaces. If no direct link is available, you must use the **peer ebgp-max-hop** command to enable BGP to establish an EBGP session over multiple hops and specify the maximum hops.

Restrictions and guidelines

When the BGP GTSM feature is enabled, two peers can establish an EBGP session after passing GTSM check, regardless of whether the maximum number of hops is reached.

To ensure correct BGP route recursion, do not specify any direct EBGP peer or peer group when you configure the **peer ebgp-max-hop** command.

Procedure (IPv4 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Enable BGP to establish an EBGP session to an indirectly connected peer or peer group and specify the maximum hop count.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **ebgp-max-hop** [*hop-count*]

   By default, BGP cannot establish an EBGP session to an indirectly connected peer or peer group.

Procedure (IPv6 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Enable BGP to establish an EBGP session to an indirectly connected peer or peer group and specify the maximum hop count.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **ebgp-max-hop** [*hop-count*]

   By default, BGP cannot establish an EBGP session to an indirectly connected peer or peer group.

Enabling immediate re-establishment of direct EBGP connections upon link failure

About this task

With this feature disabled, when the link to a directly connected EBGP peer goes down, the router does not re-establish a session to the peer until the hold time timer expires. This feature enables BGP to immediately discover the link failure and recreate the session in that situation. When this feature is disabled, route flapping does not affect EBGP session state.

Procedure

1. Enter system view.

system-view

2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Enable immediate re-establishment of direct EBGP connections upon link failure.
   ebgp-interface-sensitive
   By default, immediate re-establishment of direct EBGP connections is enabled.

Enabling prefix-based BGP ORF capabilities negotiation

About BGP ORF

Configure this feature in scenarios where the route sender is supposed to send only the desired BGP routes to the route receiver. Without BGP ORF configured, you must configure a route distribution policy on the route sender on a per receiver basis, which is complex and larborious. This feature helps you get rid of this situaiton.

BGP Outbound Route Filtering (ORF) reduces the bandwidth usage by reducing the route updates that are sent between BGP peers.

The BGP peers negotiate the ORF capabilities through OPEN messages. After completing the negotiation process, the BGP peers can exchange ORF information (local route reception filtering policy) through ROUTE-REFRESH messages. Then, only routes that pass both the local route distribution filtering policy and the received route reception filtering policy can be advertised.

ORF information includes the local address prefix list used for selective BGP route reception. After a peer receives the local device's ORF information, it will only send BGP routes that match the address prefix list to the local device. This approach reduces the number of UPDATE messages transmitted between BGP peers, saving network resources.

Restrictions and guidelines

You can enable the ORF information sending, receiving, or both sending and receiving capabilities on a BGP router. For two BGP peers to successfully negotiate the ORF capabilities, make sure one end has the sending capability and the other end has the receiving capability.

After you enable BGP ORF capabilities negotiation for a peer, the local device negotiates standard ORF capabilities as defined in RFC with the peer. If the peer uses nonstandard ORF, you must also enable nonstandard ORF capabilities negotiation for the peer.

Prerequisites

Before enabling BGP ORF capabilities negotiation for a peer, use the **peer prefix-list import** command to set a BGP route reception policy referencing an address prefix list. If you fail to do so, BGP does not send address prefix list information to that peer.

Enabling BGP ORF capabilities negotiation for a peer or peer group

Procedure (IPv4 unicast/IPv4 multicast)

1. Enter system view.

system-view

2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast
3. Reference an address prefix list to filter BGP routes received from a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **prefix-list** *ipv4-prefix-list-name* **import**

   By default, no address prefix list is referenced to filter BGP routes received from a peer or peer group.
4. Enable prefix-based BGP ORF capabilities negotiation for a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **capability-advertise orf prefix-list** { **both** | **receive** | **send** }

   interface-peer *interface-type interface-number* **capability-advertise orf prefix-list** { **both** | **receive** | **send** }

   By default, BGP ORF capabilities negotiation is disabled for a peer or peer group.

   The *ipv6-address* [*prefix-length*] argument and the **interface-peer** command are not supported in BGP IPv4 multicast address family view.

Procedure (IPv6 unicast/IPv6 multicast)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

bgp *as-number* [**instance** *instance-name*]

address-family ipv6 multicast

3. Reference an address prefix list to filter BGP routes received from a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **prefix-list** *ipv6-prefix-list-name* **import**

   By default, no address prefix list is referenced to filter BGP routes received from a peer or peer group.

4. Enable prefix-based BGP ORF capabilities negotiation for a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **capability-advertise orf prefix-list** { **both** | **receive** | **send** }

   interface-peer *interface-type interface-number* **capability-advertise orf prefix-list** { **both** | **receive** | **send** }

   By default, BGP ORF capabilities negotiation is disabled for a peer or peer group.

   The *ipv4-address* [*mask-length*] and *link-local-address* **interface** *interface-type interface-number* options and the **interface-peer** command are not supported in BGP IPv6 multicast address family view.

Enabling nonstandard BGP ORF capabilities negotiation for a peer or peer group

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enable nonstandard BGP ORF capabilities negotiation for a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **capability-advertise orf non-standard**

   By default, nonstandard BGP ORF capabilities negotiation is disabled for a peer or peer group.

Enabling 4-byte AS number suppression

About this task

BGP supports 4-byte AS numbers. The 4-byte AS number occupies four bytes, in the range of 1 to 4294967295. By default, a device sends an OPEN message to the peer device for session establishment. The OPEN message indicates that the device supports 4-byte AS numbers. If the peer device supports 2-byte AS numbers instead of 4-byte AS numbers, the session cannot be established. To resolve this issue, enable the 4-byte AS number suppression feature. The device then sends an OPEN message to inform the peer that it does not support 4-byte AS numbers, so the BGP session can be established.

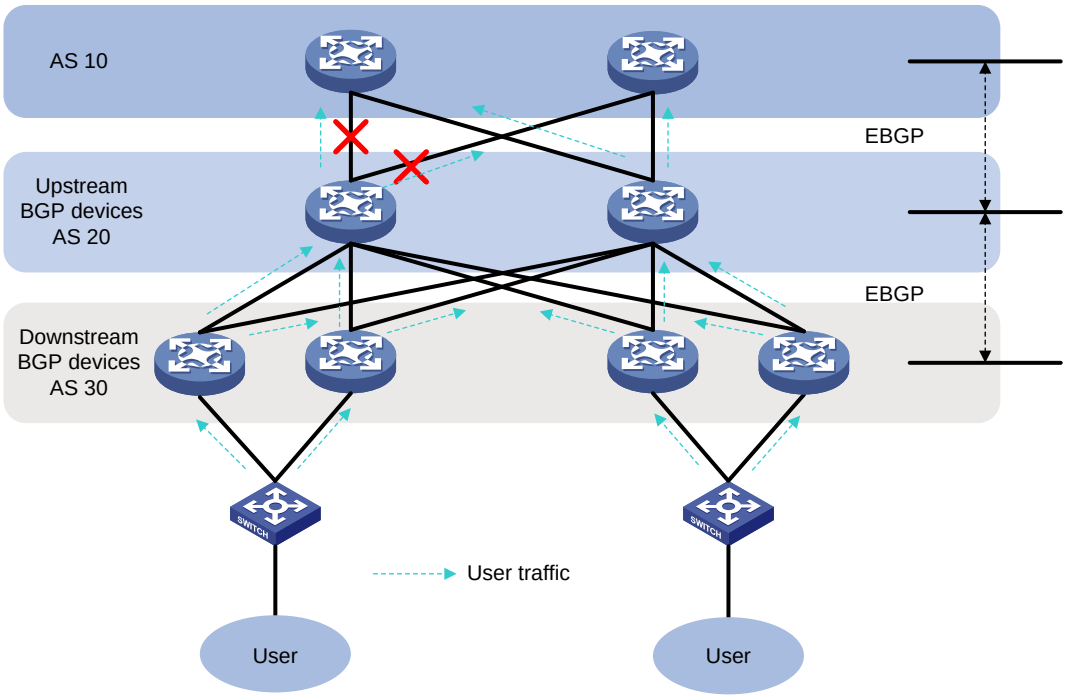
Restrictions and guidelines

If the peer device supports 4-byte AS numbers and the peer AS number is greater than 65535, do not enable the 4-byte AS number suppression feature. Otherwise, the BGP session cannot be established.

Procedure (IPv4 peers)

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Enable 4-byte AS number suppression.
   peer { *group-name* | *ipv4-address* [*mask-length*] } **capability-advertise suppress-4-byte-as**
   By default, 4-byte AS number suppression is disabled.

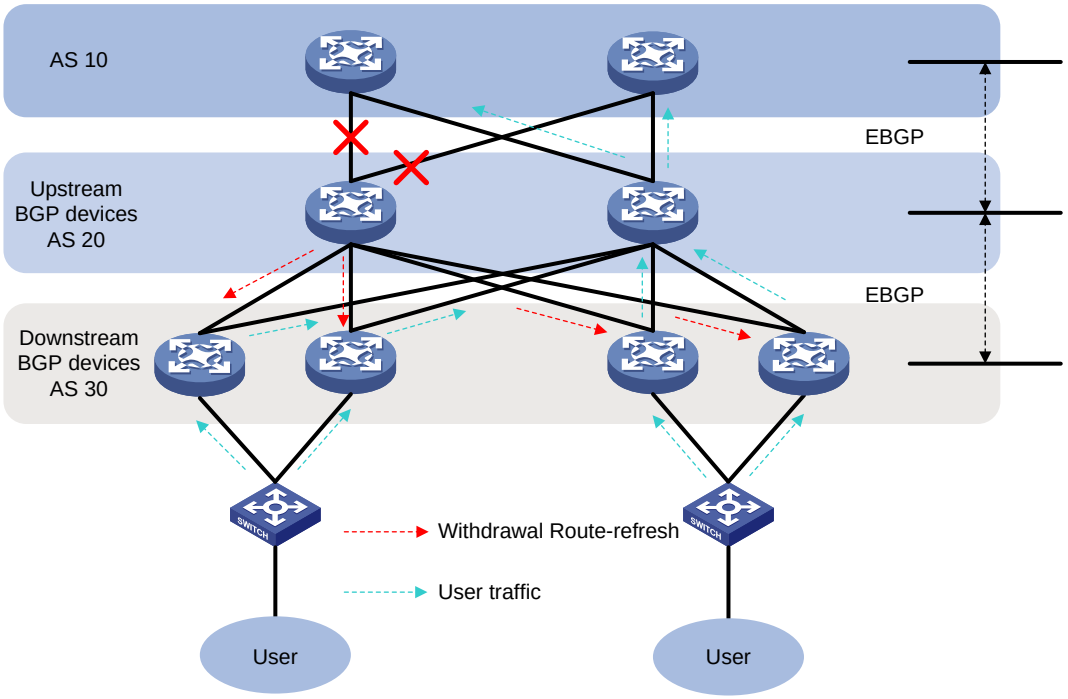
Procedure (IPv6 peers)



1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Enable 4-byte AS number suppression.
   peer { *group-name* | *ipv6-address* [*prefix-length*] } **capability-advertise suppress-4-byte-as**
   By default, 4-byte AS number suppression is disabled.

Enabling BGP to exchange withdrawal ROUTE-REFRESH messages with peers

About this task



As shown in Figure 44, two upstream BGP devices are deployed in a multi-level BGP network. When all uplinks of an upstream device fail and the device cannot complete route convergence in time, the device might also fail to send route withdrawal messages to downstream devices in time. At this time, those downstream devices still forward some user traffic to the upstream device, resulting in traffic forwarding failure.

Figure 44 Multi-level BGP network

To avoid this issue, enable the upstream device to exchange withdrawal ROUTE-REFRESH messages with downstream devices. As shown in Figure 45, when all uplinks of the upstream device fail, it sends withdrawal ROUTE-REFRESH messages to the downstream devices. On receipt of the withdrawal ROUTE-REFRESH messages, the downstream devices immediately perform route switchover and forward traffic to another upstream device with normal uplinks.

Figure 45 Exchanging withdrawal ROUTE-REFRESH messages in the multi-level BGP network

After this feature is configured, the upstream device performs the following operations:

1. Terminates and re-establishes the BGP session to the specified downstream device.
2. Exchanges OPEN messages with the downstream device to negotiate the capability of exchanging withdrawal ROUTE-REFRESH messages.

   To ensure successful negotiation, you must configure this command at both ends of the BGP session, specifying the other end.

With the withdrawal ROUTE-REFRESH capability negotiated successfully, if the upstream device is disconnected from all peers in the same AS, it sends a withdrawal ROUTE-REFRESH message to the downstream device. The sent message carries the AS number from which the upstream device is disconnected. In this example, the disconnected AS is AS 10.

After receiving the withdrawal ROUTE-REFRESH message, the downstream device performs the following operations:

3. Searches in all BGP routes received from the upstream BGP device for routes with AS 10 as the first AS number in the NEXT_HOP attribute.

   To view AS number information in the NEXT_HOP attribute of a BGP route, see the **AS-path** field in the output of the **display rib nib** or **display ipv6 rib nib** command. For more information about the two commands, see IP routing basics commands in *Layer 3—IP Routing Command Reference*.
4. After finding routes with AS 10 as the first AS number in the NEXT_HOP attribute, marks the IP routes corresponding to those routes as backup routes.

   The downstream device no longer uses these routes for traffic forwarding, achieving fast route switchover.

After receiving a withdrawal ROUTE-REFRESH message, the device forwards the message to its peers as follows:

- If the message is received from an IBGP peer, the device forwards the message only to EBGP peers.
- If the message is received from an EBGP peer, the device forwards the message to IBGP peers without changing the original AS number of the message.

You can use the **peer capability-advertise withdraw-refresh** command in conjunction with the **peer tracking** command on an upstream device. The **peer tracking** command enables the upstream device to fast detect status of the specified BGP peer session. When the related peer is unreachable, the local device immediately terminates the BGP peer session in time and sends withdrawal ROUTE-REFRESH messages to downstream devices. Collaboration of the two commands expedites forwarding path convergence upon uplink failures.

Restrictions and guidelines

Execute the **peer capability-advertise withdraw-refresh** command with caution, because this operation will terminate and re-establish the BGP session between the local device and the specified peer.

This feature is only applicable to the scenario described in "About this task." It is not applicable to scenarios where upstream devices that advertise withdrawal ROUTE-REFRESH messages are connected to IBGP peers in the uplink direction.

Procedure

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

ip vpn-instance *vpn-instance-name*

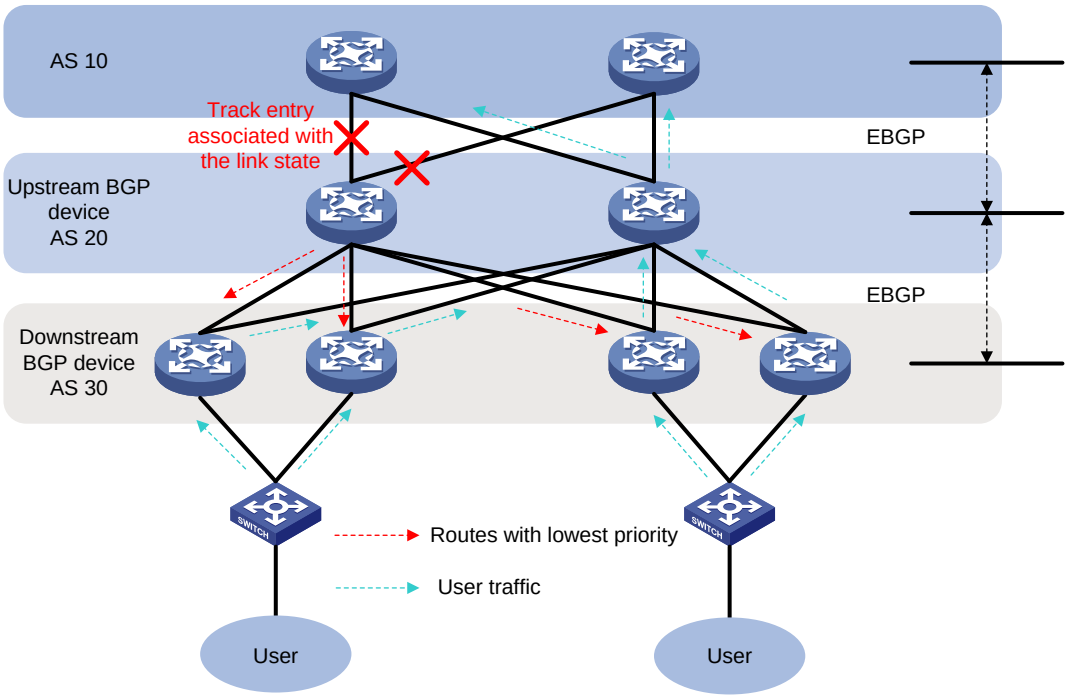
3. Enable BGP to exchange withdrawal ROUTE-REFRESH messages with a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **capability-advertise withdraw-refresh**

   By default, BGP cannot exchange withdrawal ROUTE-REFRESH messages with any peer or peer group.

Enabling Track-based priority adjustment for BGP routes advertised to a peer or peer group

About this task



This feature collaborates BGP with Track to achieve fast switchover of traffic forwarding paths in multi-level BGP networks. As shown in Figure 46, two upstream BGP devices are deployed on the network, for example, Device 1 and Device 2. When all uplinks of Device 1 fail and the device cannot complete route convergence in time, the device might also fail to send route withdrawal messages to downstream devices in time. At this time, those downstream devices still forward some user traffic to Device 1, resulting in traffic forwarding failure.

Figure 46 Multi-level BGP network diagram

To avoid this issue, enable BGP to collaborate with Track on upstream BGP devices. When uplink failures occur on an upstream BGP device, route switchover is triggered immediately and user traffic can be forwarded to another upstream BGP device with normal uplinks.

Figure 47 Track-based priority adjustment for BGP routes advertised to a peer or peer group

To enable Track-based priority adjustment for BGP routes advertised to a downstream BGP device, perform the following operations on each upstream BGP device:

1. Associate the link state of its upstream interface with a track entry. For more information about Track, see track configuration in *High Availability Configuration Guide*.
2. Execute the **`apply track`** command to configure an apply clause that references the associated track entry.
3. Execute the **`peer advertise lowest-priority track-route-policy`** command to enable BGP to collaborate with Track. The { *`group-name`* | *`ipv4-address`* [*`mask-length`*] | *`ipv6-address`* [*`prefix-length`*] } parameter specifies the desired downstream BGP device and the *`route-policy-name`* parameter specifies the routing policy configured in the previous step.

When certain uplinks of the upstream BGP device go down, the associated track entry transitions to Negative state. After perceiving the track entry state change, BGP immediately performs the following operations on the upstream BGP device:

4. Minimizes the priority of all routes advertised to the specified downstream BGP device by setting the local preference value to 0 and MED value to the maximum.
5. Advertises those routes again to the downstream BGP device.

The downstream BGP device will no longer select routes from the upstream BGP device as optimal routes and will forward user traffic to another upstream BGP device. This mechanism accelerates forwarding path switchover upon uplink failures on an upstream BGP device by skipping the process of hold timer timeout > route invalidation > route withdrawal.

For more information about routing policies and the **`apply track`** command, see routing policy configuration in *Layer 3—IP Routing Configuration Guide*.

Restrictions and guidelines

If a routing policy is specified in the **`peer advertise lowest-priority track-route-policy`** command, only the **`apply track`** clause of that routing policy can take effect.

Although the **peer advertise lowest-priority track-route-policy** command and the **peer capability-advertise withdraw-refresh** command function similarly, they are different in the following aspects:

- To use the feature associated with the **peer advertise lowest-priority track-route-policy** command, you only need to configure this command on the desired device. The device and devices from different vendors can co-locate in the same network. However, this command cannot provide selective traffic forwarding path control, because it minimizes the priority of all routes advertised to the specified peer or peer group.
- The **peer capability-advertise withdraw-refresh** command can take effect only if the specified downstream BGP device supports withdraw ROUTE-REFRESH messages. This command can provide selective traffic forwarding path control, because it can perform traffic forwarding path switchover in scenarios where only uplink failures occur.

Procedure (IPv4 unicast)

1. Enter system view.

   system-view
2. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view.

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
3. Enable Track-based priority adjustment for BGP routes advertised to a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise lowest-priority track-route-policy** *route-policy-name*

   By default, Track-based priority adjustment is disabled for BGP routes advertised to a peer or peer group.

Procedure (IPv6 unicast)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view.

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
3. Enable Track-based priority adjustment for BGP routes advertised to a peer or peer group.

peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise lowest-priority track-route-policy** *route-policy-name*

By default, Track-based priority adjustment is disabled for BGP routes advertised to a peer or peer group.

Disabling BGP session establishment

About disabling BGP session establishment

This task enables you to temporarily tear down BGP sessions to a peer/peer group or all peers/peer groups. You can perform network upgrade and maintenance without needing to delete and reconfigure the peers and peer groups. To recover the sessions, execute the **undo peer ignore** or **undo ignore all-peers** command.

To lower the priority of the routes advertised by BGP, you can specify the **graceful** keyword in the **peer ignore** command or the **ignore all-peers** command, and configure route attribures. BGP peers can then select other peers' routes as optimal routes, which avoids traffic interruption upon wait timer expiration or peer disconnection. To enable BGP to advertise low-priority routes without tearing down BGP sessions, you can set the value for the **graceful** *graceful-time* option to 0.

If you specify the **graceful** keyword in the **peer ignore** command, BGP performs the following tasks:

1. Starts the wait timer specified with the **graceful** keyword.
2. Advertises all routes to the specified peer or peer group and changes the attribute of the advertised routes to the specified value.

   Advertises the routes from the specified peer or peer group to other IBGP peers and peer groups and changes the attribute of the advertised routes to the specified value.
3. Shuts down the session to the specified peer or peer group after the wait timer expires.

If you specify the **graceful** keyword in the **ignore all-peers** command, BGP performs the following tasks:

4. Starts the wait timer specified with the **graceful** keyword.
5. Advertises all routes to all peers and peer groups and changes the attribute of the advertised routes to the specified value.
6. Shuts down all sessions to peers and peer groups after the wait timer expires.

Restrictions and guidelines

For a BGP peer or peer group, the configuration made by the **peer ignore** command takes precedence over the configuration made by the **ignore all-peers** command.

Disabling BGP session establishment with a peer or peer group (IPv4 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

bgp *as-number* [**instance** *instance-name*]

- Enter BGP-VPN instance view.

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

3. Disable BGP session establishment with a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **ignore** [**graceful** *graceful-time* { **community** { *community-number* | *aa:nn* } | **local-preference** *preference* | **med** *med* } *]

   By default, BGP can establish a session to a peer or peer group.

CAUTION:

- If a session has been established to a peer, executing this command for the peer tears down the session and clears all related routing information.
- If sessions have been established to a peer group, executing this command for the peer group tears down the sessions to all peers in the group and clears all related routing information.

Disabling BGP session establishment with a peer or peer group (IPv6 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.

   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Disable BGP session establishment with a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **ignore** [**graceful** *graceful-time* { **community** { *community-number* | *aa:nn* } | **local-preference** *preference* | **med** *med* } *]

   interface-peer *interface-type interface-number* **ignore** [**graceful** *graceful-time* { **community** { *community-number* | *aa:nn* } | **local-preference** *preference* | **med** *med* } *]

   By default, BGP can establish a session to a peer or peer group.

CAUTION:

- If a session has been established to a peer, executing the **peer ignore** command for the peer tears down the session and clears all related routing information.
- If sessions have been established to a peer group, executing the **peer ignore** command for the peer group tears down the sessions to all peers in the group and clears all related routing information.

Disabling BGP session establishment with all peers or peer groups

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Disable BGP session establishment with all peers or peer groups.

   ignore all-peers [**graceful** *graceful-time* { **community** { *community-number* | *aa:nn* } | **local-preference** *preference* | **med** *med* } *]

   By default, BGP can establish sessions to all peers and peer groups.

CAUTION:

Executing this command tears down all existing sessions to peers and peer groups and clears all related routing information.

Configuring BGP soft-reset

About BGP soft-reset

After you modify the route selection policy, for example, modify the preferred value, you must reset BGP sessions to apply the new policy. The reset operation tears down and re-establishes BGP sessions.

To avoid tearing down BGP sessions, you can use one of the following soft-reset methods to apply the new policy:

- **Enabling route refresh**—The BGP router advertises a ROUTE-REFRESH message to the specified peer, and the peer resends its routing information to the router. After receiving the routing information, the router filters the routing information by using the new policy.

  This method requires that both the local router and the peer support route refresh.

- **Saving updates**—Use the **peer keep-all-routes** command to save all route updates from the specified peer. After modifying the route selection policy, filter routing information by using the new policy.

  This method does not require that the local router and the peer support route refresh but it uses more memory resources to save routes.

- **Manual soft-reset**—Use the **refresh bgp** command to enable BGP to send local routing information or advertise a ROUTE-REFRESH message to the specified peer. The peer then resends its routing information. After receiving the routing information, the router filters the routing information by using the new policy.

  This method requires that both the local router and the peer support route refresh.

Enabling route refresh (IPv4 peers)

1. Enter system view.

system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Enable BGP route refresh for a peer or peer group.
   - Enable BGP route refresh for the specified peer or peer group.

     peer { *group-name* | *ipv4-address* [*mask-length*] }
     capability-advertise route-refresh
   - Enable the BGP route refresh, multi-protocol extension, and 4-byte AS number features for the specified peer or peer group.

     undo peer { *group-name* | *ipv4-address* [*mask-length*] }
     capability-advertise conventional

   By default, the BGP route refresh, multi-protocol extension, and 4-byte AS number features are enabled.

Enabling route refresh (IPv6 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Enable BGP route refresh for a peer or peer group.
   - Enable BGP route refresh for the specified peer or peer group.

     peer { *group-name* | *ipv6-address* [*prefix-length*] }
     capability-advertise route-refresh
   - Enable the BGP route refresh, multi-protocol extension, and 4-byte AS number features for the specified peer or peer group.

     undo peer { *group-name* | *ipv6-address* [*prefix-length*] }
     capability-advertise conventional

   By default, the BGP route refresh, multi-protocol extension, and 4-byte AS number features are enabled.

Saving updates (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

bgp *as-number* [**instance** *instance-name*]

address-family ipv4 [**unicast**]

- Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

  address-family ipv4 [**unicast**]

- Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv4 multicast

3. Save all route updates from the peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **keep-all-routes**

   interface-peer *interface-type interface-number* **keep-all-routes**

   By default, route updates from peers and peer groups are not saved.

   The *ipv6-address* [*prefix-length*] argument and the **interface-peer** command are not supported in BGP IPv4 multicast address family view.

   This command takes effect only for the routes received after this command is executed.

Saving updates (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.

   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast

3. Save all route updates from the peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **keep-all-routes**

   interface-peer *interface-type interface-number* **keep-all-routes**

   By default, route updates from peers and peer groups are not saved.

   This command takes effect only for the routes received after this command is executed.

The *ipv4-address* [*mask-length*] option, the *link-local-address* **interface** *interface-type interface-number* option, and the **interface-peer** command are not supported in BGP IPv6 multicast address family view.

Configuring manual soft-reset (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Enable BGP route refresh for a peer or peer group.
   - Enable BGP route refresh for the specified peer or peer group.

     peer { *group-name* | *ipv4-address* [*mask-length*] } **capability-advertise route-refresh**
   - Enable the BGP route refresh, multi-protocol extension, and 4-byte AS number features for the specified peer or peer group.

     undo peer { *group-name* | *ipv4-address* [*mask-length*] } **capability-advertise conventional**

   By default, the BGP route refresh, multi-protocol extension, and 4-byte AS number features are enabled.
4. Return to user view.

   return
5. Perform manual soft-reset. Choose one option as needed:
   - Perform manual soft-reset on IPv4 sessions in BGP IPv4 address family.

     refresh bgp [**instance** *instance-name*] { *ipv4-address* [*mask-length*] | **all** | **external** | **group** *group-name* | **internal** } { **export** | **import** } **ipv4** [**multicast** | [**unicast**] [**vpn-instance** *vpn-instance-name*]]
   - Perform manual soft-reset on IPv6 sessions in BGP IPv4 address family.

     refresh bgp [**instance** *instance-name*] { *ipv6-address* [*prefix-length*] | [*link-local-address*] **interface** *interface-type interface-number* } { **export**|**import** } **ipv4** [**unicast**]

Configuring manual soft-reset (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

bgp *as-number* [**instance** *instance-name*]

ip vpn-instance *vpn-instance-name*

3. Enable BGP route refresh for a peer or peer group.
   - Enable BGP route refresh for the specified peer or peer group.

     peer { *group-name* | *ipv6-address* [*prefix-length*] }
     capability-advertise route-refresh
   - Enable the BGP route refresh, multi-protocol extension, and 4-byte AS number features for the specified peer or peer group.

     undo peer { *group-name* | *ipv6-address* [*prefix-length*] }
     capability-advertise conventional

   By default, the BGP route refresh, multi-protocol extension, and 4-byte AS number features are enabled.
4. Return to user view.

   return
5. Perform manual soft-reset. Choose one option as needed:
   - Perform manual soft-reset on IPv6 sessions in BGP IPv6 address family.

     refresh bgp [**instance** *instance-name*] { *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* | **all** | **external** | **group** *group-name* | **internal** } { **export** | **import** } **ipv6** [**multicast** | [**unicast**] [**vpn-instance** *vpn-instance-name*]]
   - Perform manual soft-reset on IPv4 sessions in BGP IPv6 address family.

     refresh bgp [**instance** *instance-name*] *ipv4-address* [*mask-length*] { **export** | **import** } **ipv6** [**unicast**]

Configuring BGP load balancing

About this task

Perform this task to specify the maximum number of BGP ECMP routes for load balancing.

Restrictions and guidelines

When you use the **balance** command, follow these guidelines:

- If you specify the **ecmp-nexthop-local** keyword, BGP sets the local device IP as the next hop of each load balancing route.
- If you specify the **ecmp-nexthop-unchanged** keyword, BGP does not change the next hop of each load balancing route.
- If you specify neither the **ecmp-nexthop-local** keyword nor the **ecmp-nexthop-unchanged** keyword, BGP advertises the routes used for load balancing to IBGP peers as follows:
  - Without the Add-Path feature configured, BGP advertises only the optimal route among the routes used for load balancing and sets the local device IP as the next hop of that optimal route.
  - With the Add-Path feature configured, BGP performs the following tasks:
    - Advertises the routes used for load balancing. The number of routes that BGP can advertise equals the maximum number of Add-Path optimal routes that can be advertised.
    - Sets the local device IP as the next hop of the optimal route among the advertised routes.

Both the **balance igp-metric-ignore** and **bestroute igp-metric-ignore** commands can enable BGP to use routes with different IGP metrics for load balancing. The two commands are different as follows:

- The **balance igp-metric-ignore** command can be used only for load balancing. It does not change the rules of optimal route selection. BGP still compares the IGP metric value of each route during optimal route selection.
- The **bestroute igp-metric-ignore** command takes effect on optimal route selection and route selection for load balancing. With this command executed, BGP will ignore the IGP metric values of routes in both cases.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. (Optional.) Enable BGP to ignore IGP metrics during optimal route selection.

   bestroute igp-metric-ignore

   By default, BGP compares IGP metrics during optimal route selection, and selects the route with the smallest IGP metric as the optimal route.

   BGP cannot use routes with different IGP metrics to implement load balancing. To resolve this issue, you can use this command.

4. Return to system view.
   - In BGP instance view:

     quit
   - In BGP-VPN instance view:

     quit

     quit

5. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast

6. Specify the maximum number of BGP ECMP routes for load balancing.

balance [**ebgp** | **eibgp** | **ibgp**] *number* [**ecmp-nexthop-local** | **ecmp-nexthop-unchanged**]

By default, load balancing is disabled.

7. (Optional.) Enable BGP to ignore the AS_PATH attribute when it implements load balancing.

   balance as-path-neglect

   By default, BGP does not ignore the AS_PATH attribute when it implements load balancing.

8. (Optional.) Enable BGP to perform load balancing for routes that have different AS_PATH attributes of the same length.

   balance as-path-relax [**ebgp** | **ibgp**]

   By default, BGP cannot perform load balancing for routes that have different AS_PATH attributes of the same length.

9. (Optional.) Enable BGP to use routes with different IGP metrics for load balancing.

   balance igp-metric-ignore

   By default, BGP cannot use routes with different IGP metrics for load balancing.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. (Optional.) Enable BGP to ignore IGP metrics during optimal route selection.

   bestroute igp-metric-ignore

   By default, BGP compares IGP metrics during optimal route selection, and selects the route with the smallest IGP metric as the optimal route.

   BGP cannot use routes with different IGP metrics to implement load balancing. To resolve this issue, you can use this command.

4. Return to system view.
   - In BGP instance view:

     quit
   - In BGP-VPN instance view:

     quit

     quit

5. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv6 multicast

6. Specify the maximum number of BGP ECMP routes for load balancing.

   balance [**ebgp** | **eibgp** | **ibgp**] *number* [**ecmp-nexthop-local** | **ecmp-nexthop-unchanged**]

   By default, load balancing is disabled.

7. (Optional.) Enable BGP to ignore the AS_PATH attribute when it implements load balancing.

   balance as-path-neglect

   By default, BGP does not ignore the AS_PATH attribute when it implements load balancing.

8. (Optional.) Enable BGP to perform load balancing for routes that have different AS_PATH attributes of the same length.

   balance as-path-relax [**ebgp** | **ibgp**]

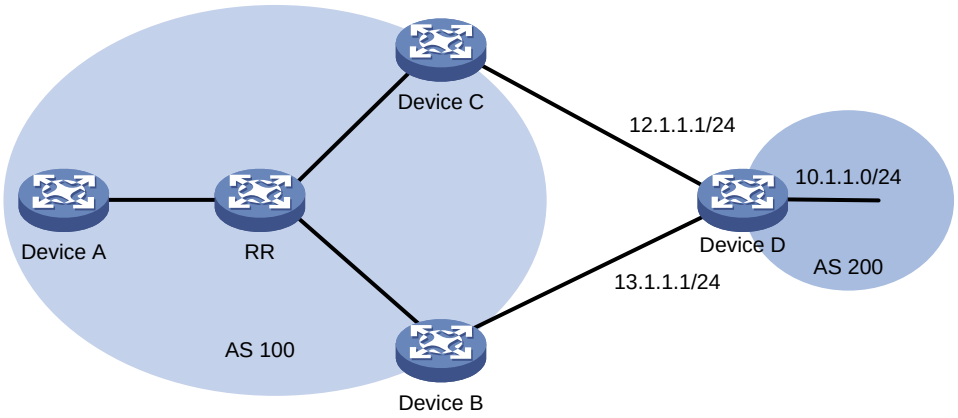
   By default, BGP cannot perform load balancing for routes that have different AS_PATH attributes of the same length.

9. (Optional.) Enable BGP to use routes with different IGP metrics for load balancing.

   balance igp-metric-ignore

   By default, BGP cannot use routes with different IGP metrics for load balancing.

Configuring the BGP Additional Paths feature



About this task

On a large-scale network, a route reflector can receive multiple BGP routes with the same prefix. By default, BGP advertises only one optimal route. When the optimal route fails, traffic forwarding will be interrupted until route convergence completes.

To resolve this issue, configure the BGP Additional Paths (Add-Path) feature on the route reflector. This feature enables the device to advertise multiple routes with the same prefix to a peer or peer group. On receipt of these routes, the peer generates multiple links to the same destination network. You can use these links to implement load balancing with the **balance** command or use them as backup routes. When the optimal link fails, another link can take over to forward traffic, which enhances the reliability of data transmission.

As shown in Figure 48, Device A, Device B, and Device C are located in AS 100, exchanging routing information within the domain through the RR. Both Device B and Device C establish an EBGP session to Device D and learn a route with prefix 10.1.1.0/24 from Device D.

Figure 48 Network diagram

In this situation, the RR can learn two routes destined for 10.1.1.0/24 from Device B and Device C. To have the RR advertise multiple routes with the same prefix to Device A, configure the BGP Additional Paths feature. Table 14 shows the effect of the BGP Additional Paths feature on route advertisement and route convergence upon link failure:

Table 14 Route advertisement and route convergence upon link failure

Whether the BGP Additional Paths feature is configured	Route advertisement	Route convergence upon failure of a single link
Not configured	The RR selects the optimal route from the two routes destined for 10.1.1.0/24, and only advertises the optimal route to Device A.	Device A needs to perform route convergence again.
Configured	RR advertises the two routes destined for 10.1.1.0/24 to Device A. The next hops of the two routes are 12.1.1.1 and 13.1.1.1, respectively.	• If Device A establishes an FRR relationship between the two routes and the primary path to 10.1.1.0/24 fails, Device A can quickly use the backup path for traffic forwarding. • If Device A establishes an ECMP relationship between the two routes and one of them fails, Device A switches all traffic to the other path.

Restrictions and guidelines

BGP Additional Paths capabilities include the sending capability and the receiving capability. You can enable either of the sending and receiving capabilities or both on a peer. For two BGP peers to successfully negotiate the Additional Paths capabilities, make sure one end has the sending capability and the other end has the receiving capability.

Procedure (IPv4 unicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

address-family ipv4 [**unicast**]

- Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

  address-family ipv4 [**unicast**]

3. Configure the BGP Additional Paths capabilities. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **additional-paths** { **receive** | **send** } *

   interface-peer *interface-type interface-number* **additional-paths** { **receive** | **send** } *

   By default, no BGP Additional Paths capabilities are configured.

4. Set the maximum number of Add-Path optimal routes that can be advertised to a peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise additional-paths best** *number*

   interface-peer *interface-type interface-number* **advertise additional-paths best** *number*

   By default, a maximum of one Add-Path optimal route can be advertised to a peer or peer group.

5. Set the maximum number of Add-Path optimal routes that can be advertised to all peers.

   additional-paths select-best *best-number*

   By default, a maximum of one Add-Path optimal route can be advertised to all peers.

Procedure (IPv6 unicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.

   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]

3. Configure the BGP Additional Paths capabilities. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **additional-paths** { **receive** | **send** } *

   interface-peer *interface-type interface-number* **additional-paths** { **receive** | **send** } *

   By default, no BGP Additional Paths capabilities are configured.

4. Set the maximum number of Add-Path optimal routes that can be advertised to a peer or peer group. Choose one command as needed:

peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **advertise additional-paths best** *number*

interface-peer *interface-type interface-number* **advertise additional-paths best** *number*

By default, a maximum of one Add-Path optimal route can be advertised to a peer or peer group.

5. Set the maximum number of Add-Path optimal routes that can be advertised to all peers.

   additional-paths select-best *best-number*

   By default, a maximum of one Add-Path optimal route can be advertised to all peers.

Protecting an EBGP peer when memory usage reaches level 2 threshold

About this task

Memory usage includes the following threshold levels: normal, level 1, level 2, and level 3. When the level 2 threshold is reached, BGP periodically tears down an EBGP session to release memory resources until the memory usage falls below the level 2 threshold. You can configure this feature to avoid tearing down the EBGP session to an EBGP peer when the memory usage reaches the level 2 threshold.

For more information about memory usage thresholds, see device management configuration in *Fundamentals Configuration Guide*.

Procedure (IPv4 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Configure BGP to protect an EBGP peer or peer group when the memory usage reaches level 2 threshold.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **low-memory-exempt**

   By default, BGP periodically tears down an EBGP session to release memory resources when level 2 threshold is reached.

Procedure (IPv6 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

ip vpn-instance *vpn-instance-name*

3. Configure BGP to protect an EBGP peer or peer group when the memory usage reaches level 2 threshold. Choose one command as needed:

   peer { *group-name* | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **low-memory-exempt**

   interface-peer *interface-type interface-number* **low-memory-exempt**

   By default, BGP tears down an EBGP session to release memory resources periodically when level 2 threshold is reached.

Setting a DSCP value for outgoing BGP packets

About this task

The DSCP value of an IP packet specifies the priority level of the packet and affects the transmission priority of the packet.

Procedure

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Set a DSCP value for outgoing BGP packets. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **dscp** *dscp-value*

   interface-peer *interface-type interface-number* **dscp** *dscp-value*

   By default, the DSCP value for outgoing BGP packets is 48.

Disabling route recursion policy control for routes received from a peer or peer group

About this task

If you configure routing policy-based recursive lookup for BGP routes, this route recursion policy applies to BGP routes learned from all peers. This task allows you to disable route recursion policy control for routes learned from certain peers, for example, direct EBGP peers.

Procedure

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

- Enter BGP-VPN instance view.

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

3. Disable route recursion policy control for routes received from the specified peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number*} **nexthop-recursive-policy disable**

   interface-peer *interface-type interface-number* **nexthop-recursive-policy disable**

   By default, the route recursion policy applies to routes received from the peer or peer group.

Flushing the suboptimal BGP route to the RIB

About this task

This feature flushes the suboptimal BGP route to the RIB when the following conditions are met:

- The optimal route is generated by the **network** command or is redistributed by the **import-route** command.
- The suboptimal route is received from a BGP peer.

After the suboptimal route is flushed to the RIB on a network, BGP immediately switches traffic to the suboptimal route when the optimal route fails.

For example, the device has a static route to the subnet 1.1.1.0/24 that has a higher priority than a BGP route. BGP redistributes the static route and receives a route to 1.1.1.0/24 from a peer. After the **flush suboptimal-route** command is executed, BGP flushes the received BGP route to the RIB as the suboptimal route. When the static route fails, BGP immediately switches traffic to the suboptimal route if inter-protocol FRR is enabled. For more information about inter-protocol FRR, see "Configuring basic IP routing."

Procedure

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Flush the suboptimal BGP route to the RIB.

   flush suboptimal-route

   By default, BGP is disabled from flushing the suboptimal BGP route to the RIB, and only the optimal route is flushed to the RIB.

Configuring a peer monitoring group

About this task

A peer monitoring group is mainly used in traffic switchover scenarios. For example, when the local device receives multiple BGP routes to the same destination from multiple BGP peers in AS 10 and AS 20, the traffic to that destination can be load shared between AS 10 and AS 20. If multiple BGP peers within AS 10 are disconnected from the local device, the network administrator might perceive a risk in the network status within AS 10 even if there are still running BGP sessions within the AS. The administrator might need to switch all traffic passing through AS 10 to other ASs. You can configure this feature to implement automatic traffic switchover in such scenarios.

Execute the **monitor-group** command to create a peer monitoring group, and then execute the **peer monitor-group** command to add shared-risk BGP peers to the group. The state of a BGP peer in a peer monitoring group depends on the state of the BGP session between the local device and that peer:

- If the BGP session is in Established state when you add the peer to the peer monitoring group, the peer is in UP state. If the BGP session is not in Established state, the peer is in INIT state.
- If the BGP session state transitions from INIT to Established after you add the peer to the peer monitoring group, the peer state will change to UP.
- If the BGP session state transitions from Established to another state, the peer state will change from UP to DOWN. This rule does not apply to the following scenarios where BGP configurations bring about BGP session state changes:
  - The BGP session is terminated during a normal GR process. In this situation, the state of the BGP peer does not change in the peer monitoring group.
  - The BGP session is terminated due to other BGP configurations (for example, the **peer ignore** command). In this situation, if the number of DOWN-state BGP peers in the peer monitoring group does not reach the specified threshold, the state of the disconnected peer will change to INIT. If the specified threshold is reached, the state of the disconnected peer remains DOWN.

When the number of DOWN-state BGP peers in the peer monitoring group reaches the specified threshold, the local device will disconnect from all BGP peers in the group to avoid potential traffic loss.

With the peer monitoring group feature configured, when the number of DOWN-state BGP peers reaches the specified threshold, the local device disconnects from all peers in the peer monitoring group. The local device will not proactively establish sessions to the devices in the group. To re-establish BGP sessions to the devices in the peer monitoring group, execute the **reset bgp monitor-group** command. This command places the entire peer monitoring group in INIT state. The state of each normal BGP session will be restored to Established in the group, and the state of BGP peers corresponding to those BGP sessions will be restored to UP in the group.

Restrictions and guidelines

The number of BGP sessions in a peer monitoring group depends on the number of BGP peers in the group. Each BGP peer is counted as one BGP session, regardless of whether the peer has established sessions in multiple address families. The BGP sessions created by using the same IP address in different BGP-VPN instances and the public instance are considered as different sessions.

A BGP peer or peer group can be added to only one peer monitoring group.

Procedure

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Create a peer monitoring group.

   monitor-group *monitor-group-name* **threshold** *number*

   By default, no peer monitoring groups exist.

4. (Optional.) Enter BGP-VPN instance view.

   ip vpn-instance *vpn-instance-name*

5. Add the specified peer or peer group to the peer monitoring group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **monitor-group** *monitor-group-name*

   By default, a peer or peer group does not belong to any peer monitoring group.

6. (Optional.) Restore the normal sessions in the peer monitoring group.

   reset bgp [**instance** *instance-name*] **monitor-group** *monitor-group-name*

   This command is supported in user view. Before you use this command, execute the **quit** *command once or more times as needed to return to user view.*

Disabling BGP from flushing specific routes to the routing table

About this task

Perform this task to enable BGP to not flush routes matching the specified routing policy to the routing table. In a route reflection network, configure this feature to not flush specific BGP routes to the routing table of the RR. Then, the RR only advertises and receives routes but does not forward service traffic, which saves the system resources of the RR.

Procedure (IPv4 unicast)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]

3. Disable BGP from flushing routes matching the specified routing policy to the routing table.

   routing-table bgp-rib-only [[**all**] [**route-policy** *route-policy-name*] | **cross-pod-host**]

   By default, BGP flushes the optimal routes to the routing table.

   The **cross-pod-host** keyword is supported only in BGP IPv4 unicast address family view.

Procedure (IPv6 unicast)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

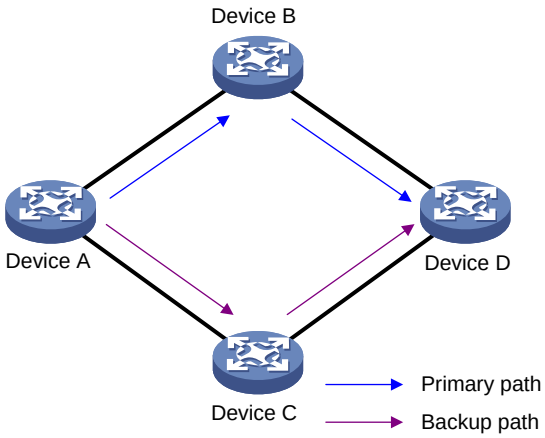
address-family ipv6 [**unicast**]

3. Disable BGP from flushing routes matching the specified routing policy to the routing table.

   routing-table bgp-rib-only [[**all**] [**route-policy** *route-policy-name*] | **cross-pod-host**]

   By default, BGP flushes the optimal routes to the routing table.

   The **cross-pod-host** keyword is supported only in BGP IPv6 unicast address family view.



Configuring BGP optimal route selection delay

About this task

Typically BGP optimal route selection is triggered in real time by the events such as attribute change, configuration change, and route recursion. To avoid packet loss upon switchover between redundant links, you can perform this task to delay optimal route selection.

As shown in Figure 49, BGP runs on all devices in the network. Device A and Device D uses the primary path for communication. When the primary path fails, Device A and Device D switch to the backup path for communication and then back to the primary path after the primary path recovers. In such case, traffic loss might occur if Device A forwards packets through Device B before Device B completes route convergence. You can configure optimal route selection delay on Device A to resolve the problem.

Figure 49 Network diagram

To configure BGP optimal route selection delay, you can use either of the following commands:

- **route-select delay**

  If you execute this command for an address family, the device delays optimal route selection as long as the address family has a route change.

- **route-select suppress on-peer-up**

  When the state of a peer changes from DOWN to UP, the device delays optimal route selection only for BGP routes received from that peer.

If you configure the two commands synchronously, only the longer delay timer takes effect.

Restrictions and guidelines

Follow these restrictions and guidelines when you configure this feature:

- The optimal route selection delay setting applies only when multiple effective routes with the same prefix exist after a route change occurs.
- For routes being delayed for optimal route selection, modifying the optimal route selection delay timer has the following effects:

- If you modify the delay timer to a non-zero value, the routes are not affected, and they still use the original delay timer.
- If you execute the **undo** form of the **route-select delay** command or modify the delay timer to 0, the device performs optimal route selection immediately.

- If you configure this feature multiple times for an address family, the most recent configuration takes effect.
- The optimal route selection delay configuration does not apply to the following conditions:
  - A route change is caused by execution of a command or by route withdrawal.
  - After a route change occurs, only one route exists for a specific destination network.
  - An active/standby process switchover occurs.
  - A route change occurs among equal-cost routes.
  - Only the optimal and suboptimal routes exist when FRR is configured.
  - Optimal route selection is triggered by a redistributed route.
- To have the device immediately perform optimal route selection for routes being delayed, execute either of the following commands:
  - **undo route-select suppress on-peer-up**

    This command takes effect only on routes that are delayed by the **route-select suppress on-peer-up** command.
  - **undo route-select delay**

    This command takes effect only on routes that are delayed by the **route-select suppress on-peer-up** command or the **route-select delay** command.

Procedure (IPv4 unicast/multicast address family)

1. Enter system view.

   system-view
2. Enter BGP IPv4 unicast address family view, BGP-VPN IPv4 unicast address family view, or BGP IPv4 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv4 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 multicast
3. Set the optimal route selection delay timer. Choose one of the following option:
   - Enable optimal route selection delay for all routes in the address family.

     route-select delay *delay-value*

     With this command configured, the device delays optimal route selection as long as the address family has a route change.
   - Enable optimal route selection delay based on DOWN-to-UP peer state changes.

     route-select suppress on-peer-up *milliseconds*

With this command configured, when the state of a peer changes from DOWN to UP, the device performs optimal route selection for BGP routes received from that peer only after the delay timer expires.

By default, the device does not delay optimal route selection.

Procedure (IPv6 unicast/multicast address family)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view, BGP-VPN IPv6 unicast address family view, or BGP IPv6 multicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP IPv6 multicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 multicast
3. Set the optimal route selection delay timer. Choose one of the following option:
   - Enable optimal route selection delay for all routes in the address family.

     route-select delay *delay-value*

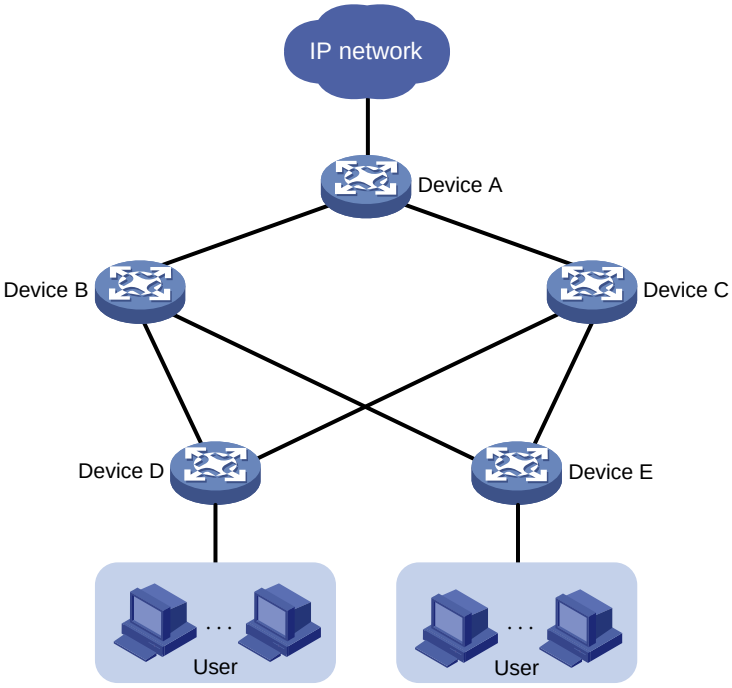
     With this command configured, the device delays optimal route selection as long as the address family has a route change.
   - Enable optimal route selection delay based on DOWN-to-UP peer state changes.

     route-select suppress on-peer-up *milliseconds*

     With this command configured, when the state of a peer changes from DOWN to UP, the device performs optimal route selection for BGP routes received from that peer only after the delay timer expires.

   By default, the device does not delay optimal route selection.

Configuring the BGP session state to collaborate with the monitor link downlink interfaces



About this task

On the network as shown in Figure 50, Device A establishes BGP sessions to Device B and Device C, and both Device B and Device C establish BGP sessions to Device D and Device E. Users accessing Device D and Device E communicate with the external network through the BGP routes deployed by Device A. In normal conditions, traffic from users to the external network is load-shared between Device B and Device C.

In this scenario, if the link between Device A and Device B fails, the BGP session between Device A and Device B will be terminated. Then, the BGP routes advertised by Device A cannot be forwarded

to Device D and Device E through Device B. As a result, the traffic from users to the external network will not be forwarded through Device B. In this case, BGP sessions from Device B to Device D and Device E do not need to be established. You can disconnect these BGP sessions to save system resources.

Figure 50 Network diagram for the BGP session state to collaborate with the monitor link downlink interfaces

With this feature configured, when the BGP session between Device A and Device B is disconnected, the BGP sessions from Device B to Device D and Device E are also automatically disconnected. When the BGP session between Device A and Device B recovers, the BGP sessions from Device B to Device D and Device E also automatically recover.

After this feature is configured, the BGP session between the local device and the peer or peer group specified by this feature will be used as a type of uplink interface in the specified monitor link group. The uplink interfaces and downlink interfaces in a monitor link group collaborate as follows:

- Uplink interfaces are defined as follows:
  - In a monitor link group, an interface specified by using the **`port uplink`** or **`port monitor-link group uplink`** command is considered as an uplink interface.
  - In a monitor link group, each BGP process specified by using the **`monitor bgp`** command is considered as an uplink interface.
  - In a monitor link group, a BGP session specified by using the **`peer monitor-link group`** command is considered as an uplink interface.

  If the BGP sessions specified by using the **`peer monitor-link group`** command are established in the BGP process specified by using the **`monitor bgp`** command, and at least one of these BGP session is in **Established** state, the BGP process is not an uplink interface.

  The BGP sessions specified by using the **`peer monitor-link group`** command are not considered as uplink interfaces if the following conditions exist:
  - These BGP sessions are established in the BGP process specified by using the **`monitor bgp`** command.
  - None of these BGP sessions is in **Established** state.

  In this situation, only the BGP process is considered as an uplink interface.

For example, use the **monitor bgp** command to specify BGP instances **aaa** and **bbb** as two uplink interfaces in a monitor link group, use the **peer monitor-link group** command in BGP instance **aaa** to specify two BGP sessions as the uplink interfaces, and do not use the **peer monitor-link group** command in BGP instance **bbb** to specify uplink interfaces. In this case, when at least one of the two specified BGP sessions are in **Established** state, the monitor link group has three uplink interfaces in total, including two BGP sessions and one BGP process without BGP sessions specified. When neither of the two specified BGP sessions is in **Established** state, the monitor link group has two uplink interfaces in total. One uplink interface is the BGP process with BGP sessions specified but neither of the BGP sessions is in **Established** state. The other is the BGP process without BGP sessions specified.

- Downlink interfaces are defined as follows: In a monitor link group, an interface specified by using the **port downlink** or **port monitor-link group downlink** command is considered as a downlink interface.
- Uplink interfaces and downlink interfaces collaborate as follows:
  - When the number of uplink interfaces in up state in a monitor link group is lower than the threshold configured by using the **uplink up-port-threshold** command, the physical state is set to down for all downlink interfaces in the monitor link group. An uplink interface is determined as up or down following these rules:
    - For an interface specified by using the **port uplink** or **port monitor-link group uplink** command, the uplink interface is considered as up if the interface is physically up, and the uplink interface is considered as down if the interface is physically down.
    - For a BGP process specified by using the **monitor bgp** command, the uplink interface is considered as up when the BGP instance exists and runs normally, and the uplink interface is considered as down when the BGP instance is deleted and corresponding process exits.
    - For a BGP session specified by using the **peer monitor-link group** command, the uplink interface is considered as up when the BGP session is in **Established** state, and the uplink interface is considered as down when the BGP session is in any other state.
  - When the number of uplink interfaces in up state in a monitor link group is greater than or equal to the threshold configured by using the **uplink up-port-threshold** command, the physical state is set to up for all downlink interfaces in the monitor link group.

As shown in Figure 51, use Device B as an example. Configure the monitor link group as follows: Configure the BGP session between Device A and Device B as the only uplink interface of the monitor link group. Configure the interfaces connecting Device B to Device D and Device E as the downlink interfaces of the monitor link group. When the BGP session between Device A and Device B is disconnected, the physical interfaces connecting Device B to Device D and Device E go down physically. As a result, the BGP sessions from Device B to Device D and Device E are automatically disconnected, and you do not need to modify the BGP-related settings. When the BGP session between Device A and Device B restores to the **Established** state, the physical interfaces connecting Device B to Device D and Device E come up physically. As a result, the BGP sessions from Device B to Device D and Device E automatically recover, and you still do not need to modify the BGP-related settings.

Figure 51 Schematic diagram for the BGP session state to collaborate with the monitor link downlink interfaces

For more information about monitor link, see monitor link configuration in *High Availability Configuration Guide*. For more information about the **monitor bgp**, **monitor-link group**, **port**, and **port monitor-link group** commands, see monitor link commands in *High Availability Command Reference*.

Restrictions and guidelines

To prevent BGP sessions flappings from causing frequent downlink switchovers in a monitor link group, execute the **downlink up-delay** command in the monitor link group to set the switchover delay for the downlink interfaces in the monitor link group.

For more information about the **downlink up-delay** command, see monitor link commands in *High Availability Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Create a monitor link group and enter its view.

   monitor-link group *group-id*

   For more information about this command, see monitor link commands in *High Availability Command Reference*.

3. Configure downlink interfaces for the monitor link group. Choose one of the following tasks:
   - Configure downlink interfaces for the monitor link group in monitor link group view.

     port *interface-type* { *interface-number* | *interface-number.subnumber* } **downlink**
   - Execute the following commands in sequence to configure downlink interfaces for the monitor link group in interface view.

     quit

interface *interface-type* { *interface-number* | *interface-number.subnumber* }

port monitor-link group *group-id* **downlink**

By default, a monitor link group does not have member ports.

For more information about this command, see monitor link commands in *High Availability Command Reference*.

4. (Optional.) Configure the uplink interface threshold for triggering state switchover in the monitor link group.

   uplink up-port-threshold *number-of-port*

   By default, the uplink interface threshold for triggering state switchover in the monitor link group is 1.

   This command is supported only in monitor link group view.

   For more information about this command, see monitor link commands in *High Availability Command Reference*.

5. Return to system view.

   quit

6. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

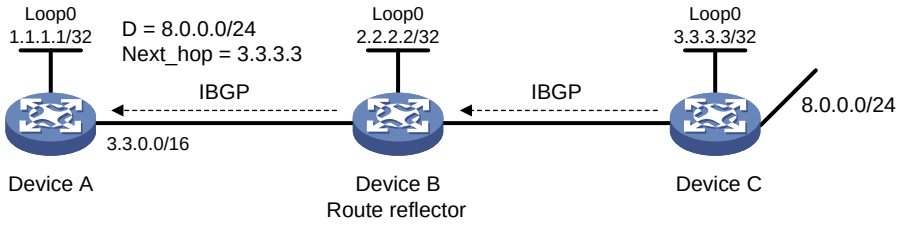
     ip vpn-instance *vpn-instance-name*

7. Configure the BGP session state to collaborate with the monitor link downlink interfaces.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **monitor-link group** *group-id*

   By default, the BGP session state does not collaborate with the monitor link downlink interfaces.

Specifying the longest match principle for next hop recursion



About this task

By default, BGP first looks up in its directly connected routes for a recursive route during a route recursion. If no matching routes exist, BGP will look up in routes generated by all routing protocols based on the longest match principle. The device considers the next hop of a received BGP route as directly connected when the next hop belongs to the same subnet as a direct route. As a result, packet forwarding failure will occur when the device uses this BGP route to forward matching packets.

As shown in Figure 52, Device B has established an IBGP session to Device A and Device C respectively. All devices use a loopback interface as the source port for TCP connection. On receipt of BGP route 8.0.0.0/24 from Device C, Device B reflects the route to Device A. The addresses of the interfaces that connect Device A and Device B belong to subnet 3.3.0.0/16.

If the next hop information exchanged between IBGP peers remains unchanged, the next hop of BGP route 8.0.0.0/24 is 3.3.3.3. Device A considers 3.3.3.3 as a directly connected next hop because 3.3.3.3 belongs to subnet 3.3.0.0/16 and a direct route to 3.3.0.0/16 exists. Packet forwarding failure will occur if Device A forwards packets destined for subnet 8.0.0.0/24 over 3.3.3.3.

Figure 52 Next hop recursion error

To resolve this issue, you can specify the longest match principle for next hop recursion to ensure the recursive route is reachable. BGP will directly look up in routes generated by all routing protocols and select a matching route based on the longest match principle.

Procedure (IPv4 unicast)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]

3. Specify the longest match principle for BGP next hop recursion.

   nexthop recursive-lookup longest-match [**route-policy** *route-policy-name*]

   By default, BGP first looks up in its directly connected routes for a recursive route during route recursion.

   This command applies to all BGP routes received from peers in one of the following scenarios:
   - The **route-policy** *route-policy-name* option is not specified.
   - The specified routing policy does not exist.

Procedure (IPv6 unicast)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]

3. Specify the longest match principle for BGP next hop recursion.

   nexthop recursive-lookup longest-match [**route-policy** *route-policy-name*]

   By default, BGP first looks up in its directly connected routes for a recursive route during route recursion.

   This command applies to all BGP routes received from peers in one of the following scenarios:

   - The **route-policy** *route-policy-name* option is not specified.
   - The specified routing policy does not exist.

Enabling conversational remote host route learning

About this task

By default, BGP generates FIB entries for all host routes received from peers (remote host routes) and issues the routes to the FIB. To conserve device resources, you can enable conversational remote host route learning. This feature enables BGP to issue a remote host route to the FIB only if it is required for forwarding a packet.

Restrictions and guidelines

This feature takes effect only on remote host routes generated based on ARP or ND entries and does not take effect on local host routes and other BGP routes. Host routes generated based on ARP or ND entries carry a special mark advertised through the extended community attribute. Enabling this feature also enables BGP to advertise the extended community attribute to all peers and peer groups.

This feature takes effect only if you execute the **ip forwarding-conversational-learning** command.

The device can perform conversational learning for a remote host route only if a local interface belongs to a network segment that contains the destination address of the host route.

Procedure (IPv4 unicast)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Enter BGP IPv4 unicast address family view.

   address-family ipv4 [**unicast**]

4. Enable conversational remote host route learning.

   forwarding-conversational-learning [**route-policy** *route-policy-name*]

   By default, conversational remote host route learning is disabled.

Procedure (IPv6 unicast)

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Enter BGP IPv6 unicast address family view.

   address-family ipv6 [**unicast**]

4. Enable conversational remote host route learning.

   forwarding-conversational-learning [**route-policy** *route-policy-name*]

   By default, conversational remote host route learning is disabled.

Enabling peer unreachability detection

About this task

Peer unreachability detection achieves fast route convergence by enabling BGP to discover link failures in a timely manner. With this feature enabled, BGP will disconnect from the specified peer or peer group if that peer or peer group is detected unreachable.

BGP considers a peer unreachable if one of the following conditions exists:

- BGP cannot find a route to that peer in the routing table of the public network instance or VPN instance to which the peer belongs.
- BGP finds the route to that peer is a blackhole route in the routing table of the public network instance or VPN instance to which the peer belongs.

As shown in Figure 53, Device A, Device B, and DeviceC are IGP neighbors. Device A and Device C are BGP peers. When a link failure occurs between Devices A and B after peer unreachability detection is enabled on Device A, the IGP immediately performs route convergence. As a result, Device A cannot find the IP route destined for Device C and thus terminates its BGP session with Device C without waiting for the hold timer to expire.

Figure 53 Network diagram

Restrictions and guidelines

If you do not set the delay time of peer disconnection, BGP disconnects from the specified peer or peer group immediately if that peer or peer group is detected unreachable.

When you set the delay time of peer disconnection, follow these guidelines to improve network stability:

- To avoid IBGP session flappings caused by unstable traffic, make sure the delay time of peer disconnection specified for an IBGP peer or peer group is longer than the convergence time of IGP routes.
- With peer unreachability detection enabled, the GR helper can detect whether the GR restarter is reachable. To ensure successful GR, make sure the delay time of peer disconnection is longer than the GR timer plus the extra timer to wait.

For more information about the GR timer and the extra timer to wait, see "Configuring BGP GR."

Procedure

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

ip vpn-instance *vpn-instance-name*

3. Enable peer unreachability detection for a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **tracking** [**delay** *delay-time*]

   By default, peer unreachability detection is disabled.

   This command does not take effect if you enter a link-local address for the *ipv6-address* argument.

Displaying 4-byte AS numbers in asdot or asdot+ notation

About this task

NOTE:

In the current software version, the following AS number notations are supported:

- **asplain**—Represents AS numbers with decimal integers, for example, 65535. AS numbers in this notation are called integer AS numbers.
- **asdot+**—Represents each AS number with two decimal integers separated by a period character: *<higher 16-bit value in decimal>.<lower 16-bit value in decimal>*, for example, 65535.65535. AS numbers in this notation are called dotted AS numbers.
- **asdot**—Represents AS numbers less than 65536 with the asplain notation and represents AS numbers equal to or greater than 65536 with the asdot+ notation.

By default, a BGP display command uses the asplain notation to represent 4-byte AS numbers. A 4-byte AS number in asplain notation tends to be long and reader-unfriendly. To resolve this issue, use this feature to display AS numbers in asdot or asdot+ notation.

The asdot+ notation refers to a method of representing AS numbers in **X.Y** format. The value range for argument *Y* is 0 to 65535, and the value range for a dotted AS number is 0.1 to 65535.65535. To convert a dotted AS number into an integer one, use the following formula: *integer* = *X x 65536* + *Y*. For example, if a 4-byte dotted AS number is 2.1, the corresponding integer AS number is 131073, which equals 2 x 65536 + 1.

Restrictions and guidelines

After you configure this feature, the AS path list can match only 4-byte dotted AS numbers. To avoid route filtering failure, make sure the AS path list used in the route filtering policy referenced by BGP, OSPF, IS-IS, RIP, OSPFv3, or RIPng is configured to match 4-byte dotted AS numbers.

This feature does not take effect on the 4-byte AS numbers in the system configuration file.

Before using this feature, configure an AS path list that matches 4-byte dotted AS numbers, avoiding route filtering failure.

Procedure

1. Enter system view.

   system-view

2. Display 4-byte AS numbers in asdot or asdot+ notation.

   as-notation dotted [**4-octet-only**]

   By default, 4-byte AS numbers are displayed in asplain notation.

Converting AS numbers in effective device configurations

About this task

Before upgrading a device to a version that supports 4-byte AS numbers, use the **as-notation convert asdot** command to convert all AS numbers (greater than 65535) in effective device configurations into dotted AS numbers. This operation improves configuration readability.

Before downgrading a device, use the **as-notation convert asplain** command to convert all AS numbers in effective device configurations into integer AS numbers. This operation ensures successful device downgrade.

Restrictions and guidelines

The **as-notation convert** command is an operational command and takes effect only on existing configurations. This command does not convert the AS numbers configured after it is executed. You can repeat this command to convert the AS numbers in effective device configurations multiple times as needed.

As a best practice, save the configurations after you convert the AS numbers in effective device configurations.

Procedure

1. Enter system view.

   system-view

2. Convert the AS numbers in effective device configurations between asplain notation and asdot notation.

   as-notation convert { **asdot** | **asplain** }

   By default, the format of an AS number in effective device configurations is the same as the format in which the AS number is configured.

Configuring the tag community attribute

About this task

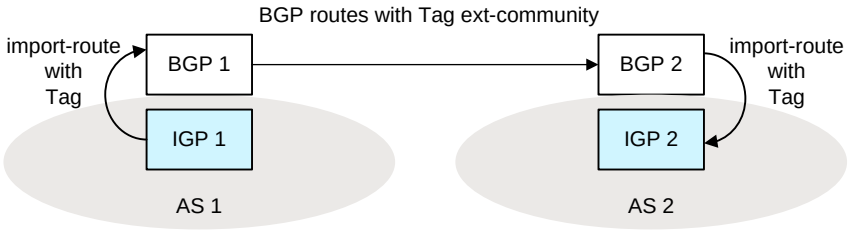
When routes are redistributed from a routing protocol into an IGP, the IGP can add a tag for them. This tag can be used for route filtering methods such as routing policies. Routing information is distributed across ASs after it is redistributed between IGPs and BGP. As a result, different route filtering methods might be applied to an IGP route when it exists in different ASs. To remove the impact of route location on the selection of route filtering methods, you can enable BGP to transmit the tag of IGP routes. After IGP routes are distributed to other ASs, IGP routes with the same tag will match the same route filtering method, regardless of their locations.

The tag community attribute is an H3C-proprietary extended community attribute, which is designed for transmitting IGP route tags.

NOTE:

For brief introduction, a BGP route carrying the tag community attribute is called tagged route. When BGP tags a route, it adds the tag community attribute to that route. When BGP untags a route, it removes the tag community attribute from that route.

The **peer advertise tag** command functions as follows:



- Before advertising a BGP route generated from a redistributed IGP route to the specified peer or peer group, BGP tags that route. The value of the tag community attribute depends on the configuration of the **import-route** command.
- After receiving a tagged BGP route, BGP forwards that route to the specified peer or peer group without untagging.

If the **peer advertise tag** commands is not configured or the **undo peer advertise tag** command is configured, BGP untags BGP routes (if tagged) before advertising them to peers. In this situation, BGP does not support the following operations:

- Tags BGP routes before route advertisement.
- Advertises BGP routes without untagging.

Route tag information is distributed across ASs as shown in Figure 54.

Figure 54 Distributing route tag information

1. In the source AS, the network administrator redistributes IGP routes to BGP and enables BGP to inherit IGP route tags. To have BGP inherit IGP route tags, use one of the following methods:
   - Execute the **import-route** command with the **inherit-tag** keyword specified. BGP will directly inherit the original tags of redistributed IGP routes.
   - Execute the **import-route** command with the **inherit-tag** keyword and the **route-policy** *route-policy-name* option specified, and configure an **apply tag** clause for the specified routing policy. BGP will tag the BGP routes generated from redistributed IGP routes according to the configuration of that **apply tag** clause.
2. The inherited tag information forms a tag community attribute, which is inserted into BGP routes and transmitted to another AS.
3. The network administrator of the receiver AS redistributes the tagged BGP routes into the desired IGP. The generated IGP routes can inherit those BGP routes' tags. You can use multiple methods to set the tag of IGP routes derived from redistributed BGP routes. For an IGP route, the priorities of tags configured by using those methods are as follows:
   a. Tag configured in the **apply tag** clause of the specified routing policy.
   b. Tag specified by using the **tag** keyword in the **import-route** command configured for the IGP.
   c. Tag inherited from the tag community attribute of the redistributed BGP route.
   d. Tag specified by using the tag keyword in the **route-tag** command.

Procedure (IPv4 unicast)

1. Enter System view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. (Optional.) Configure the type value for the tag community attribute.
   extcommunity-type tag *tag-type-value*

By default, the type value is 83cf in hexadecimal notation.

4. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.
   - Enter BGP IPv4 unicast address family view.

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
5. Redistribute IGP routes into the BGP routing table.

   import-route { **isis** | **ospf** | **rip** } [{ *process-id* | **all-processes** } [**allow-direct** | **med** *med-value* | **route-policy** *route-policy-name*] *] [**inherit-tag**]

   By default, IGP routes are not redistributed into BGP.
6. Enable BGP to advertise the tag community attribute to a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise tag**

   By default, BGP does not advertise the tag community attribute to a peer or peer group.

Procedure (IPv6 unicast)

1. Enter system view.

   system-view
2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
3. (Optional.) Configure the type value for the tag community attribute.

   extcommunity-type tag *tag-type-value*

   By default, the type value is 83cf in hexadecimal notation.
4. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.
   - Enter BGP IPv6 unicast address family view.

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     ip vpn-instance *vpn-instance-name*

     address-family ipv6 [**unicast**]
5. Redistribute IGP routes into the BGP routing table.

   import-route { **isisv6** | **ospfv3** | **ripng** } [{ *process-id* | **all-processes** } [**allow-direct** | **med** *med-value* | **route-policy** *route-policy-name*] *] [**inherit-tag**]

   By default, IGP routes are not redistributed into BGP.
6. Enable BGP to advertise the tag community attribute to a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise tag**

   By default, BGP does not advertise the tag community attribute to a peer or peer group.

Display and maintenance commands for BGP network tuning and optimization

Displaying BGP

Execute **display** commands in any view.

Displaying BGP (IPv4 unicast address family)

Task	Command
Display ORF prefix information received by a peer.	**display bgp** [**instance** *instance-name*] **peer ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] *ipv4-address* **received prefix-list** **display bgp** [**instance** *instance-name*] **peer ipv4** [**unicast**] *ipv6-address* [**interface** *interface-type interface-number*] **received prefix-list**
Display peer monitoring group information.	**display bgp** [**instance** *instance-name*] **monitor-group** { **all** | **group-name** *monitor-group-name* }

Displaying BGP (IPv6 unicast address family)

Task	Command
Display ORF prefix information received by a peer.	**display bgp** [**instance** *instance-name*] **peer ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] *ipv6-address* **received prefix-list** **display bgp** [**instance** *instance-name*] **peer ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] { *ipv4-address* | [*link-local-address*] **interface** *interface-type interface-number* } **received prefix-list**

Displaying BGP (IPv4 multicast address family)

Task	Command
Display ORF prefix information received by a peer.	**display bgp** [**instance** *instance-name*] **peer ipv4 multicast** *ipv4-address* **received prefix-list**

Displaying BGP (IPv6 multicast address family)

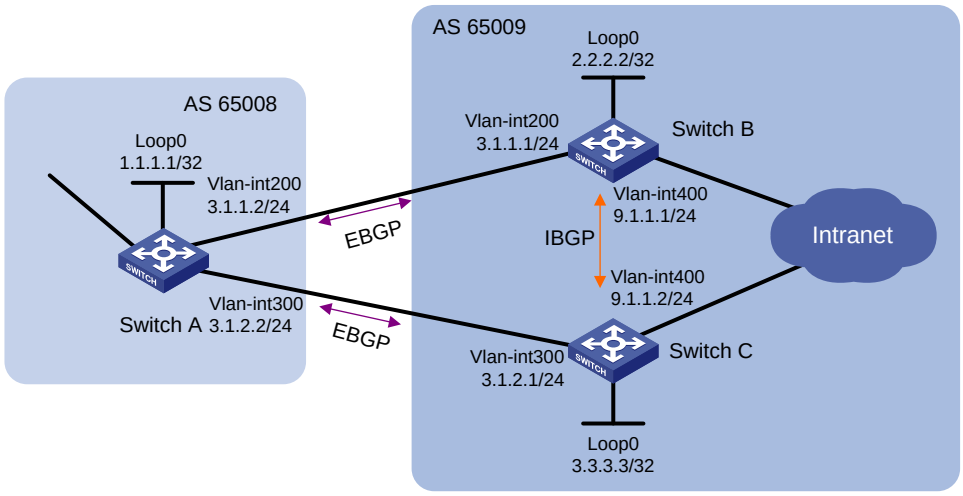
Task	Command
Display ORF prefix information received by a peer.	**display bgp** [**instance** *instance-name*] **peer ipv6 multicast** *ipv6-address* **received prefix-list**

Resetting BGP sessions

CAUTION:
A reset operation tears down BGP sessions for a short period of time.

Execute **reset** commands in user view.

Task	Command
Reset BGP sessions for IPv4 unicast address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv4-address* [*mask-length*] | **all** | **external** | **group** *group-name* | **internal** } **ipv4** [**unicast**] [**vpn-instance** *vpn-instance-name*] **reset bgp** [**instance** *instance-name*] { *ipv6-address* [*prefix-length*] | **interface** *interface-type interface-number* } **ipv4** [*unicast*]
Reset BGP sessions for IPv4 multicast address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv4-address* [*mask-length*] | **all** | **external** | **group** *group-name* | **internal** } **ipv4 multicast**
Reset BGP sessions for IPv6 unicast address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv6-address* [*prefix-length*] | [*link-local-address*] **interface** *interface-type interface-number* | **all** | **external** | **group** *group-name* | **internal** } **ipv6** [**unicast**] [**vpn-instance** *vpn-instance-name*] **reset bgp** *ipv4-address* [*mask-length*] **ipv6** [**unicast**]
Reset BGP sessions for IPv6 multicast address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv6-address* [*prefix-length*] | **all** | **external** | **group** *group-name* | **internal** } **ipv6 multicast**
Reset all BGP sessions.	**reset bgp** [**instance** *instance-name*] **all**



BGP network tuning and optimization configuration examples

Example: Configuring BGP load balancing

Network configuration

As shown in Figure 55, run EBGP between Switch A and Switch B, and between Switch A and Switch C. Run IBGP between Switch B and Switch C.

Figure 55 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure BGP connections:
   - On Switch A, establish EBGP connections with Switch B and Switch C. Configure BGP to advertise network 8.1.1.0/24 to Switch B and Switch C, so that Switch B and Switch C can access the internal network connected to Switch A. Configure load balancing over the two EBGP links on Switch A.
   - On Switch B, establish an EBGP connection with Switch A and an IBGP connection with Switch C. Configure BGP to advertise network 9.1.1.0/24 to Switch A, so that Switch A can access the intranet through Switch B. Configure a static route to interface loopback 0 on Switch C (or use a routing protocol like OSPF) to establish the IBGP connection.
   - On Switch C, establish an EBGP connection with Switch A and an IBGP connection with Switch B. Configure BGP to advertise network 9.1.1.0/24 to Switch A, so that Switch A can access the intranet through Switch C. Configure a static route to interface loopback 0 on Switch B (or use another protocol like OSPF) to establish the IBGP connection.

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 65008
[SwitchA-bgp-default] router-id 1.1.1.1
[SwitchA-bgp-default] peer 3.1.1.1 as-number 65009
[SwitchA-bgp-default] peer 3.1.2.1 as-number 65009
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 3.1.1.1 enable
[SwitchA-bgp-default-ipv4] peer 3.1.2.1 enable
[SwitchA-bgp-default-ipv4] network 8.1.1.0 24
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 65009
[SwitchB-bgp-default] router-id 2.2.2.2
[SwitchB-bgp-default] peer 3.1.1.2 as-number 65008
[SwitchB-bgp-default] peer 3.3.3.3 as-number 65009
```

```
[SwitchB-bgp-default] peer 3.3.3.3 connect-interface loopback 0
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 3.1.1.2 enable
[SwitchB-bgp-default-ipv4] peer 3.3.3.3 enable
[SwitchB-bgp-default-ipv4] network 9.1.1.0 24
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
[SwitchB] ip route-static 3.3.3.3 32 9.1.1.2
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 65009
[SwitchC-bgp-default] router-id 3.3.3.3
[SwitchC-bgp-default] peer 3.1.2.2 as-number 65008
[SwitchC-bgp-default] peer 2.2.2.2 as-number 65009
[SwitchC-bgp-default] peer 2.2.2.2 connect-interface loopback 0
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 3.1.2.2 enable
[SwitchC-bgp-default-ipv4] peer 2.2.2.2 enable
[SwitchC-bgp-default-ipv4] network 9.1.1.0 24
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
[SwitchC] ip route-static 2.2.2.2 32 9.1.1.1
```

Display the BGP routing table on Switch A.

```
[SwitchA] display bgp routing-table ipv4

 Total number of routes: 3

 BGP local router ID is 1.1.1.1
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >  8.1.1.0/24         8.1.1.1         0                     32768   i
* >e 9.1.1.0/24         3.1.1.1         0                     0       65009i
*  e                    3.1.2.1         0                     0       65009i
```

- The output shows two valid routes to destination 9.1.1.0/24. The route with next hop 3.1.1.1 is marked with a greater-than sign (>), indicating that it is the optimal route (because the ID of Switch B is smaller). The route with next hop 3.1.2.1 is marked with an asterisk (*), indicating that it is a valid route, but not the optimal route.
- By using the **`display ip routing-table`** command, you can find only one route to 9.1.1.0/24 with next hop 3.1.1.1 and output interface VLAN-interface 200.

3. Configure loading balancing:

Because Switch A has two routes to reach AS 65009, configuring load balancing over the two BGP routes on Switch A can improve link usage.

Configure Switch A.

```
[SwitchA] bgp 65008
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] balance 2
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

Verifying the configuration

Display the BGP routing table on Switch A.

```
[SwitchA] display bgp routing-table ipv4

 Total number of routes: 3

 BGP local router ID is 1.1.1.1
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >  8.1.1.0/24         8.1.1.1         0                     32768   i
* >e 9.1.1.0/24         3.1.1.1         0                     0       65009i
* >e                    3.1.2.1         0                     0       65009i
```

- The route 9.1.1.0/24 has two next hops, 3.1.1.1 and 3.1.2.1, both of which are marked with a greater-than sign (>), indicating that they are the optimal routes.
- By using the **`display ip routing-table`** command, you can find two routes to 9.1.1.0/24. One has next hop 3.1.1.1 and output interface VLAN-interface 200, and the other has next hop 3.1.2.1 and output interface VLAN-interface 300.

Example: Configuring the BGP Additional Paths feature

Network configuration

As shown in Figure 56, all switches run BGP. EBGP runs between Switch A and Switch B, and between Switch A and Switch C. IBGP runs between Switch B and Switch D, between Switch C and Switch D, and between Switch D and Switch E. Switch D is a route reflector and Switch E is its client.

Configure the BGP Additional Paths feature to enable Switch E to learn routes with the same prefix and different next hops from Switch B and Switch C.

Figure 56 Network diagram

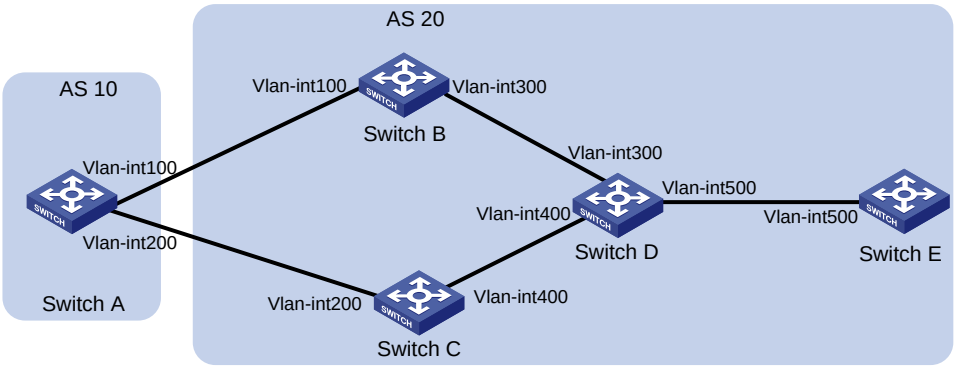


Table 15 Interface and IP address assignment

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int100	10.1.1.1/24	Switch D	Vlan-int300	30.1.1.1/24
	Vlan-int200	20.1.1.1/24		Vlan-int400	40.1.1.1/24
Switch B	Vlan-int100	10.1.1.2/24		Vlan-int500	50.1.1.1/24
	Vlan-int300	30.1.1.2/24	Switch E	Vlan-int500	50.1.1.2/24
Switch C	Vlan-int200	20.1.1.2/24			
	Vlan-int400	40.1.1.2/24			

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure BGP connections:

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 10
[SwitchA-bgp-default] peer 10.1.1.2 as-number 20
[SwitchA-bgp-default] peer 20.1.1.2 as-number 20
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 10.1.1.2 enable
[SwitchA-bgp-default-ipv4] peer 20.1.1.2 enable
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 20
[SwitchB-bgp-default] peer 10.1.1.1 as-number 10
[SwitchB-bgp-default] peer 30.1.1.1 as-number 20
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 10.1.1.1 enable
[SwitchB-bgp-default-ipv4] peer 30.1.1.1 enable
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 20
[SwitchC-bgp-default] peer 20.1.1.1 as-number 10
[SwitchC-bgp-default] peer 40.1.1.1 as-number 20
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 20.1.1.1 enable
[SwitchC-bgp-default-ipv4] peer 40.1.1.1 enable
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] bgp 20
[SwitchD-bgp-default] peer 30.1.1.2 as-number 20
[SwitchD-bgp-default] peer 40.1.1.2 as-number 20
[SwitchD-bgp-default] peer 50.1.1.2 as-number 20
[SwitchD-bgp-default] address-family ipv4 unicast
[SwitchD-bgp-default-ipv4] peer 30.1.1.2 enable
[SwitchD-bgp-default-ipv4] peer 40.1.1.2 enable
[SwitchD-bgp-default-ipv4] peer 50.1.1.2 enable
```

Configure Switch E.

```
<SwitchE> system-view
[SwitchE] bgp 20
[SwitchE-bgp-default] peer 50.1.1.1 as-number 20
[SwitchE-bgp-default] address-family ipv4 unicast
[SwitchE-bgp-default-ipv4] peer 50.1.1.1 enable
```

3. Configure Switch A to advertise network 10.1.1.0/24.

```
[SwitchA-bgp-default-ipv4] network 10.1.1.0 24
```

4. Set the local switch as the next hop for routes sent to a peer:

Configure Switch B.

```
[SwitchB-bgp-default-ipv4] peer 30.1.1.1 next-hop-local
```

Configure Switch C.

```
[SwitchC-bgp-default-ipv4] peer 40.1.1.1 next-hop-local
```

5. Configure Switch D as a route reflector.

```
[SwitchD-bgp-default-ipv4] peer 50.1.1.2 reflect-client
```

6. Configure the Additional Paths feature:

Enable the additional path sending capability on Switch D.

```
[SwitchD-bgp-default-ipv4] peer 50.1.1.2 additional-paths send
```

Set the maximum number to 2 for Add-Path optimal routes that can be advertised.

```
[SwitchD-bgp-default-ipv4] additional-paths select-best 2
```

Set the maximum number to 2 for Add-Path optimal routes that can be advertised to peer 50.1.1.2.

```
[SwitchD-bgp-default-ipv4] peer 50.1.1.2 advertise additional-paths best 2
```

Enable the additional path receiving capability on Switch E.

```
[SwitchE-bgp-default-ipv4] peer 50.1.1.1 additional-paths receive
```

Verifying the configuration

Display BGP routing information on Switch E.

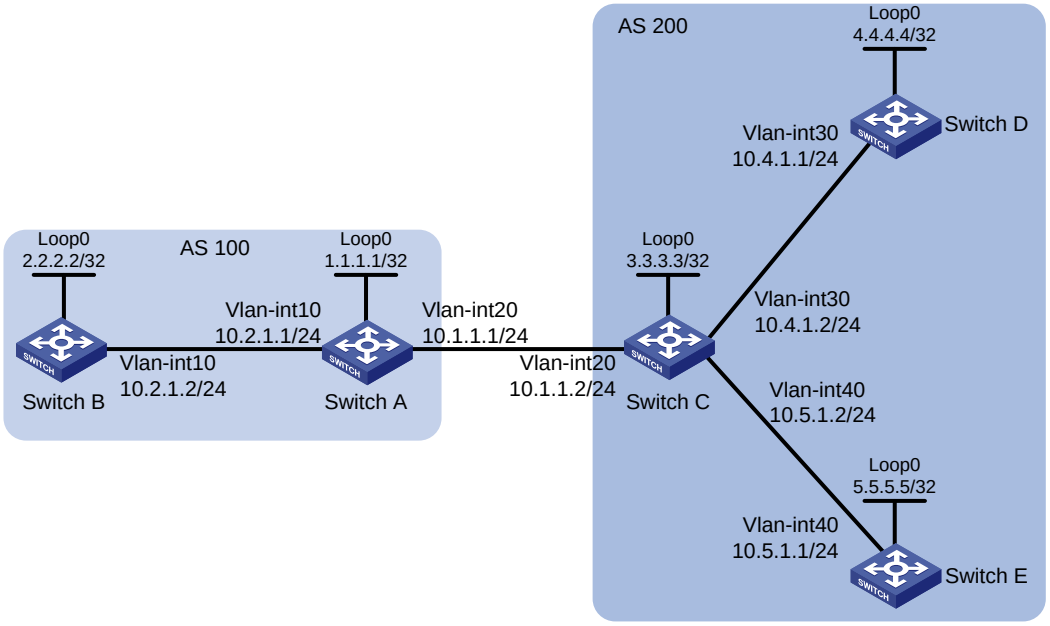
```
[Switch E] display bgp routing-table ipv4

 Total number of routes: 2

 BGP local Switch ID is 50.1.1.2
 Status codes: * - valid, > - best, d - dampened, h - history
               s - suppressed, S - stale, i - internal, e - external
               a - additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

   i 10.1.1.0/24        30.1.1.2        0          100        0       10i
   i                    40.1.1.2        0          100        0       10i
```



The output shows that Switch D has learned two routes with the same prefix and different next hops.

Example: Configuring prefix-based BGP ORF

Network configuration

As shown in Figure 57, AS 100 and AS 200 can exchange BGP routes. To ensure network security and optimize network performance, devices in AS 100 and AS 200 need to filter routes before route advertisement. The routes required by Switch A frequently change. Configure prefix-based BGP ORF on both Switch A and Switch C, so Switch C sends only routes matching Switch A's route reception policy to Switch A.

Figure 57 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure BGP connections:
   - On Switch A, establish an IBGP connection with Switch B and an EBGP connection with Switch C.
   - On Switch C, establish an IBGP connection with Switch D and Switch E separately.

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA-bgp-default] router-id 1.1.1.1
[SwitchA-bgp-default] peer 10.1.1.2 as-number 200
[SwitchA-bgp-default] peer 10.2.1.2 as-number 100
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 10.1.1.2 enable
[SwitchA-bgp-default-ipv4] peer 10.2.1.2 enable
[SwitchA-bgp-default-ipv4] import-route direct
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

Configure Switch B.

```
<SwitchB> system-view
```

```
[SwitchB] bgp 100
[SwitchB-bgp-default] router-id 2.2.2.2
[SwitchB-bgp-default] peer 10.2.1.1 as-number 100
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 10.2.1.1 enable
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 200
[SwitchC-bgp-default] router-id 3.3.3.3
[SwitchC-bgp-default] peer 10.1.1.1 as-number 100
[SwitchC-bgp-default] peer 10.4.1.1 as-number 200
[SwitchC-bgp-default] peer 10.5.1.1 as-number 200
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 10.1.1.1 enable
[SwitchC-bgp-default-ipv4] peer 10.4.1.1 enable
[SwitchC-bgp-default-ipv4] peer 10.5.1.1 enable
[SwitchC-bgp-default-ipv4] import-route direct
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] bgp 200
[SwitchD-bgp-default] router-id 4.4.4.4
[SwitchD-bgp-default] peer 10.4.1.2 as-number 200
[SwitchD-bgp-default] address-family ipv4 unicast
[SwitchD-bgp-default-ipv4] peer 10.4.1.2 enable
[SwitchD-bgp-default-ipv4] quit
[SwitchD-bgp-default] quit
```

Configure Switch E.

```
<SwitchE> system-view
[SwitchE] bgp 200
[SwitchE-bgp-default] router-id 5.5.5.5
[SwitchE-bgp-default] peer 10.5.1.2 as-number 200
[SwitchE-bgp-default] address-family ipv4 unicast
[SwitchE-bgp-default-ipv4] peer 10.5.1.2 enable
[SwitchE-bgp-default-ipv4] quit
[SwitchE-bgp-default] quit
```

3. On Switch A, reference an address prefix list to filter BGP routes received from Switch C.

Configure Switch A.

```
[SwitchA] ip refix-list policy1 permit 10.4.1.0 24 less-equal 32
[SwitchA] bgp 100
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 10.1.1.2 prefix-list policy1 import
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

On Switch C, view the routes advertised to Switch A.

```
[SwitchC] display bgp routing-table ipv4 unicast peer 10.1.1.1 advertised-routes

 Total number of routes: 4

 BGP local router ID is 3.3.3.3
 Status codes: * - valid, > - best, d - dampened, h - history
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf             Path/Ogn

* >  3.3.3.3/32         127.0.0.1       0                             200?
* >  10.1.1.0/24        10.1.1.2        0                             200?
* >  10.4.1.0/24        10.4.1.2        0                             200?
* >  10.5.1.0/24        10.5.1.2        0                             200?
```

On Switch A, view the routes received from Switch C.

```
[SwitchA] display bgp routing-table ipv4 unicast peer 10.1.1.2 received-routes

 Total number of routes: 1

 BGP local router ID is 1.1.1.1
 Status codes: * - valid, > - best, d - dampened, h - history
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf     PrefVal Path/Ogn

* >e 10.4.1.0/24        10.1.1.2        0                     0       ?
```

According to the above command outputs, Switch C has advertised four routes to Switch A, but Switch A only received one of them under the restriction of its BGP route reception policy.

4. Configure prefix-based BGP ORF.

On Switch A, enable prefix-based BGP ORF capabilities negotiation for Switch C.

```
[SwitchA] bgp 100
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 10.1.1.2 capability-advertise orf prefix-list both
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

On Switch C, enable prefix-based BGP ORF capabilities negotiation for Switch A.

```
[SwitchC] bgp 200
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 10.1.1.1 capability-advertise orf prefix-list both
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

Verifying the configuration

On Switch C, view address prefix list information in the ORF information received from Switch A.

```
[SwitchC] display bgp peer ipv4 10.1.1.1 received prefix-list

ORF prefix list entries: 2
ge: greater-equal   le: less-equal
  Index     Rule    Prefix                                  Ge    Le
  10        permit  10.4.1.0/24                             0     32
```

On Switch C, view the routes advertised to Switch A.

```
[SwitchC] display bgp routing-table ipv4 unicast peer 10.1.1.1 advertised-routes

 Total number of routes: 1

 BGP local router ID is 3.3.3.3
 Status codes: * - valid, > - best, d - dampened, h - history
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete

     Network            NextHop         MED        LocPrf             Path/Ogn

* >  10.4.1.0/24        10.4.1.2        0                             200?
```

According to the above command outputs, Switch C only advertised the route matching Switch A's route reception policy to Switch A.

Configuring BGP security features

BGP security feature configuration tasks at a glance

To configure BGP security features, perform the following tasks:

- Enabling MD5 authentication for BGP peers
- Configuring GTSM for BGP
- Enabling keychain authentication for BGP peers
- Configuring IPsec for IPv6 BGP
- Configuring BGP RPKI

Enabling MD5 authentication for BGP peers

About this task

MD5 authentication provides the following benefits:

- Peer authentication ensures that only BGP peers that have the same password can establish TCP connections.
- Integrity check ensures that BGP packets exchanged between peers are intact.

Procedure (IPv4 peers)

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Enable MD5 authentication for a BGP peer group or peer.
   peer { *group-name* | *ipv4-address* [*mask-length*] } **password** { **cipher** | **simple** } *password*
   By default, MD5 authentication is disabled.

Procedure (IPv6 peers)

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*

3. Enable MD5 authentication for a BGP peer group or peer. Choose one command as needed:

   peer { *group-name* | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **password** { **cipher** | **simple** } *password*

   interface-peer *interface-type interface-number* **password** { **cipher** | **simple** } *password*

   By default, MD5 authentication is disabled.

Configuring GTSM for BGP

About this task

The Generalized TTL Security Mechanism (GTSM) protects a BGP session by comparing the TTL value in the IP header of incoming BGP packets against a valid TTL range. If the TTL value is within the valid TTL range, the packet is accepted. If not, the packet is discarded.

The valid TTL range is from 255 – the configured hop count + 1 to 255.

When GTSM is configured, the BGP packets sent by the device have a TTL of 255.

GTSM provides best protection for directly connected EBGP sessions, but not for multihop EBGP or IBGP sessions because the TTL of packets might be modified by intermediate devices.

Restrictions and guidelines

When GTSM is configured, the local device can establish an EBGP session to the peer after both devices pass GTSM check, regardless of whether the maximum number of hops is reached.

To use GTSM, you must configure GTSM on both the local and peer devices. You can specify different *hop-count* values for them.

Procedure (IPv4 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Configure GTSM for the specified BGP peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **ttl-security hops** *hop-count*

   By default, GTSM is disabled.

Procedure (IPv6 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

bgp *as-number* [**instance** *instance-name*]

ip vpn-instance *vpn-instance-name*

3. Configure GTSM for the specified BGP peer or peer group.

   peer { *group-name* | *ipv6-address* [*prefix-length*] } **ttl-security hops** *hop-count*

   By default, GTSM is disabled.

Enabling keychain authentication for BGP peers

About this task

Keychain authentication enhances the security of TCP connection establishment between BGP peers. It allows BGP peers to establish TCP connections only when the following conditions are met:

- Keychain authentication is enabled on both BGP peers.
- The keys used by the BGP peers at the same time must have the same ID.
- The keys with the same ID must use the same authentication algorithm and key string.

Before configuring keychain authentication, make sure the specified keychain has been created.

For more information about keychains, see *Security Configuration Guide*.

Restrictions and guidelines

Follow these restrictions and guidelines when you configure the algorithm and key ID in keychain authentication:

- BGP supports the HMAC-MD5, MD5, HMAC-SM3, SM3, and HMAC-SHA-256 algorithms. To configure an algorithm, execute the **authentication-algorithm** command.
- BGP supports key IDs in the range of 0 to 63. To configure a key ID, execute the **key** command.

Procedure (IPv4 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enable keychain authentication for a BGP peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **keychain** *keychain-name*

   By default, keychain authentication is disabled.

Procedure (IPv6 peers)

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

bgp *as-number* [**instance** *instance-name*]

- Enter BGP-VPN instance view.

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

3. Enable keychain authentication for a BGP peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **keychain** *keychain-name*

   interface-peer *interface-type interface-number* **keychain** *keychain-name*

   By default, keychain authentication is disabled.

Configuring IPsec for IPv6 BGP

About this task

Perform this task to configure IPsec for IPv6 BGP. IPsec can provide privacy, integrity, and authentication for IPv6 BGP packets exchanged between BGP peers.

When two IPv6 BGP peers are configured with IPsec (for example, Device A and Device B), Device A encapsulates an IPv6 BGP packet with IPsec before sending it to Device B. If Device B successfully receives and de-encapsulates the packet, it establishes an IPv6 BGP peer relationship with Device A and learns IPv6 BGP routes from Device A. If Device B receives but fails to de-encapsulate the packet, or receives a packet not protected by IPsec, it discards the packet.

Procedure

1. Enter system view.

   system-view

2. Configure an IPsec transform set and a manual IPsec profile.

   See *Security Configuration Guide*.

3. Enter BGP instance view or BGP-VPN instance view.

   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

4. Apply the IPsec profile to an IPv6 BGP peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **ipsec-profile** *profile-name*

   interface-peer *interface-type interface-number* **ipsec-profile** *profile-name*

   By default, no IPsec profile is configured for any IPv6 BGP peer or peer group.

   This command supports only IPsec profiles in manual mode.

Configuring BGP RPKI

About BGP RPKI

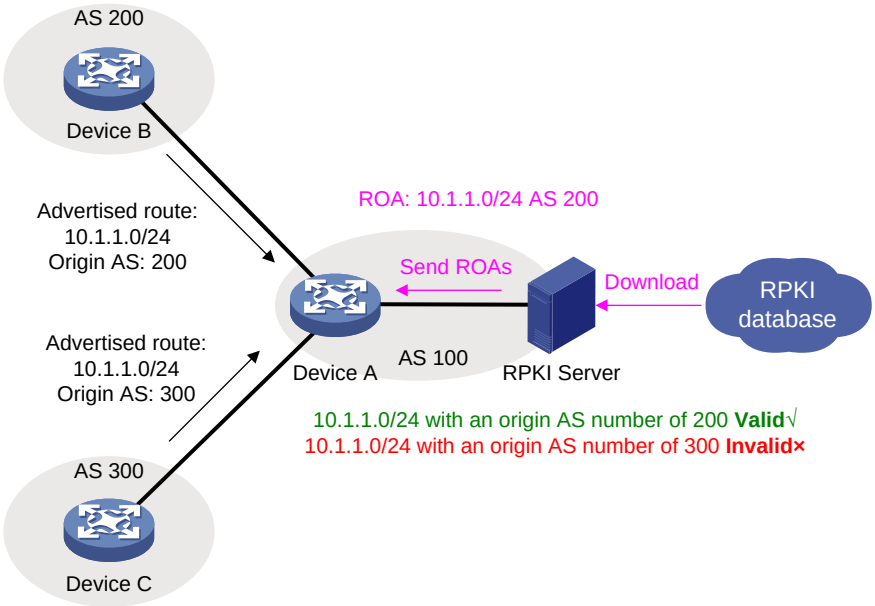
About RPKI

The AS_PATH attribute identifies the ASs through which a route has passed, and the AS that originated the route is the origin AS of the route. If the origin AS number of a route is incorrect, traffic transmission failure or even network collapse might occur.

To avoid this problem, you can configure the BGP Resource Public Key Infrastructure (RPKI) feature. It enables BGP to validate the origin AS of a route and determine whether to use and advertise the route based on the validation state.

BGP RPKI can address the issue of traffic hijacking. For example, an ISP advertises a legitimate route with a prefix of 192.168.0.0/16 to its users, and an attacker advertises a route with a prefix of 192.168.10.0/24. After receiving the two routes, a user prefers route 192.168.10.0/24 during route selection, because this route is more specific. As a result, the user might send traffic to the attacker mistakenly. To avoid this issue, configure BGP RPKI.

About ROAs



Route Origin Authorization (ROA) is a digital certificate that binds a route prefix to an origin AS number. With ROAs, the device can verify the validity of a route based on its origin AS number.

As shown in Figure 58, Device A and the RPKI server are connected. The RPKI server downloads ROA information from the RPKI database and sends the downloaded ROAs to Device A. Device A then stores the received ROAs in its local ROA database. Upon receiving a route, Device A searches the local ROA database for an ROA that matches the route prefix. If such an ROA exists, Device A compares the origin AS number of the route with that of the matching ROA.

- If the two AS numbers are the same, the route is valid.
- If the two AS numbers are different, the route is invalid.

In this example, Device A determines that route 10.1.1.0/24 from Device B is valid and route 10.1.1.0/24 from Device C is invalid.

Figure 58 Route validation with ROAs

Configuring RPKI connection parameters

About this task

A router establishes a TCP connection with an RPKI server to obtain the Route Origin Authorization (ROA) information used for RPKI validation. The router checks the connection to the RPKI server at the specified interval. If the router does not receive a response from the RPKI server within the specified time period, it tears down the connection to the RPKI server.

When the connection between a router and an RPKI server goes down (except when the **shutdown** command is executed), the router takes the following actions:

- Attempts to reconnect to the server.
- Places the ROA information obtained from the server in aging state, and starts the aging timer for the ROA information.

If the router reconnects to the server before the aging timer expires, it releases the ROA information from the aging state. If the router fails to reconnect to the server when the aging timer expires, it deletes the ROA information obtained from the server.

Restrictions and guidelines

Follow these restrictions and guidelines when you configure RPKI connection parameters:

- As a best practice, set an ROA information aging time longer than the time to wait for the response from the RPKI server.
- To tear down the connection to an RPKI server, execute the **undo port** command in RPKI server view.
- If you execute the **undo rpki** command, all configurations in RPKI view are removed.

Procedure

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Enter BGP RPKI view.

   rpki

4. Specify an RPKI server by its IP address and enter RPKI server view.

   server [**vpn-instance** *vpn-instance-name*] **tcp** { *ipv4-address* | *ipv6-address* }

   By default, no RPKI server is specified.

5. Specify the port number of the RPKI server.

   port *port-number*

   By default, the port number of the RPKI server is not specified.

   To enable a router to establish a TCP connection with the RPKI server, you must configure the port number of the RPKI server on the router.

6. (Optional.) Specify the MD5 authentication password.

   passwords { **cipher** | **simple** } *string*

   By default, the RPKI server does not perform MD5 authentication.

   The MD5 authentication password must be the same as the authentication password configured on the RPKI server.

   MD5 authentication ensures the validity of the RPKI server and the security of BGP RPKI packets.

7. (Optional.) Set the RPKI connection check interval.
   refresh-time *refresh-time*
   By default, the RPKI connection check interval is 600 seconds.
8. (Optional.) Set the time to wait for the response from the RPKI server.
   response-time *response-time*
   By default, the time to wait for the response from the RPKI server is 30 seconds.
9. (Optional.) Set the aging time for the ROA information.
   purge-time *purge-time*
   By default, the aging time for the ROA information is 60 seconds.
10. (Optional.) Set the maximum number of ROAs that can be received from the RPKI server.
    rpki-limit *limit* [**alert-only** | **discard** | **reconnect** *reconnect-time*]
    By default, the number of ROAs that can be received from an RPKI server is not limited.

Enabling BGP RPKI validation

About this task

After you configure this feature, BGP validates the prefix and origin AS number of a received route. BGP determines the validation state of the route based on the following requirements:

1. A minimum of one ROA in the ROA database contains the prefix.
2. The mask length of the route does not exceed the longest mask length among all ROAs in the ROA database.
3. The AS number of an ROA in the ROA database is the same as the origin AS number of the route.

If the route meets all requirements, the route is in **Valid** state. If the route cannot meet requirement 1, the route is in **Not-found** state. If the route meets requirement 1, but cannot meet requirement 2 or 3, the route is in **Invalid** state.

Restrictions and guidelines

If you configure this feature, BGP uses the local RPKI validation states. If you do not configure this feature, BGP uses the validation states in the received BGP routes.

Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Enter BGP RPKI view.
   rpki
4. Enable BGP RPKI validation.
   check-origin-validation
   By default, BGP RPKI validation is disabled.

Applying the BGP RPKI validation state to optimal route selection

About this task

If multiple routes to the same destination are available, BGP first discards routes with unreachable next hops, and then selects the optimal route according to the following rules:

- Routes with a BGP RPKI validation state of **Valid** takes precedence over routes with a validation state of **Not-found** or **Invalid**.
- Routes with a BGP RPKI validation state of **Not-found** takes precedence over routes with a validation state of **Invalid**.
- Routes without a BGP RPKI validation state have the same priority as routes with a BGP RPKI validation state of **Not-found**.
- For routes that have the same BGP RPKI validation state, BGP selects the optimal route according to the rules in "BGP route selection."

You can configure a routing policy to filter routes based on the BGP RPKI validation state. For more information about routing policies, see "Configuring routing policies."

Procedure (IPv4 unicast)

1. Enter system view.

   system-view
2. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]
3. Apply the BGP RPKI validation state to optimal route selection.

   bestroute origin-as-validation [**allow-invalid**]

   By default, BGP ignores the BGP RPKI validation state during optimal route selection.

   To allow routes with a validation state of **Invalid** to participate in optimal route selection, you must specify the **allow-invalid** keyword.

Procedure (IPv6 unicast)

1. Enter system view.

   system-view
2. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.
   - Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv6 [**unicast**]
   - Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

ip vpn-instance *vpn-instance-name*

address-family ipv6 [**unicast**]

3. Apply the BGP RPKI validation state to optimal route selection.

   bestroute origin-as-validation [**allow-invalid**]

   By default, BGP ignores the BGP RPKI validation state during optimal route selection.

   To allow routes with a validation state of **Invalid** to participate in optimal route selection, you must specify the **allow-invalid** keyword.

Advertising BGP RPKI validation state to a peer or peer group

Restrictions and guidelines

BGP advertises the BGP RPKI validation state to a peer or peer group through the extended community attribute. To enable this feature, you must first enable BGP to advertise the extended community attribute to the peer or peer group and make sure RPKI settings are correct.

In the current software version, BGP can advertise the BGP RPKI validation state only to IBGP peers and peer groups.

Procedure (IPv4 unicast)

1. Enter system view.

   system-view

2. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.

   - Execute the following commands in sequence to enter BGP IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     address-family ipv4 [**unicast**]

   - Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

     address-family ipv4 [**unicast**]

3. Advertise the extended community attribute to a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise-ext-community**

   By default, BGP does not advertise the extended community attribute.

4. Advertise the BGP RPKI validation state to the specified peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **advertise origin-as-validation**

   interface-peer *interface-type interface-number* **advertise origin-as-validation**

   By default, BGP does not advertise the BGP RPKI validation state.

Procedure (IPv6 unicast)

1. Enter system view.

   system-view

2. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.

- Execute the following commands in sequence to enter BGP IPv6 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  address-family ipv6 [**unicast**]

- Execute the following commands in sequence to enter BGP-VPN IPv6 unicast address family view:

  bgp *as-number* [**instance** *instance-name*]

  ip vpn-instance *vpn-instance-name*

  address-family ipv6 [**unicast**]

3. Advertise the extended community attribute to a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **advertise-ext-community**

   By default, BGP does not advertise the extended community attribute.

4. Advertise the BGP RPKI validation state to the specified peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **advertise origin-as-validation**

   interface-peer *interface-type interface-number* **advertise origin-as-validation**

   By default, BGP does not advertise the BGP RPKI validation state.

Resetting BGP RPKI sessions

Execute the following command in user view.

reset bgp [**instance** *instance-name*] **rpki server** [**vpn-instance** *vpn-instance-name*] **tcp** { *ipv4 address* | *ipv6 address* }

CAUTION:

After you execute this command, the device will delete and re-establish the specified BGP RPKI session and cause temporary session interruption.

Display and maintenance commands for BGP security features

Execute **display** commands in any view.

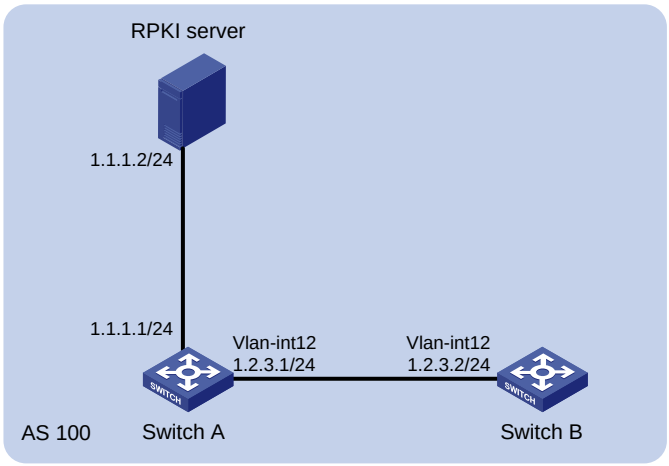
Displaying BGP (IPv4 unicast address family)

Step	Command
Display information about connections to RPKI servers.	**display bgp** [**instance** *instance-name*] **rpki server** [[**vpn-instance** *vpn-instance-name*] *ipv4-address*]
Display the ROA information obtained from RPKI servers.	**display bgp** [**instance** *instance-name*] **rpki table ipv4** [*ipv4-address* **min** *min-length* **max** *max-length*]

Displaying BGP (IPv6 unicast address family)

Step	Command
Display information about connections to RPKI servers.	**display bgp** [**instance** *instance-name*] **rpki server** [[**vpn-instance** *vpn-instance-name*] *ipv6-address*]
Display the ROA information obtained from RPKI servers.	**display bgp** [**instance** *instance-name*] **rpki table ipv6** [*ipv6-address* **min** *min-length* **max** *max-length*

IPv4 BGP security feature configuration examples



Example: Configuring BGP RPKI

Network configuration

As shown in Figure 59, all switches run BGP. Establish a TCP connection between Switch A and the RPKI server, and establish an IBGP connection between Switch A and Switch B.

Configure Switch A to advertise the BGP RPKI validation state to Switch B, and configure a routing policy to filter routes based on the validation state for Switch B.

Figure 59 Network diagram

Procedure

1. Configure IP addresses for interfaces and establish an IBGP connection between Switch A and Switch B. (Details not shown.)
2. Configure Switch A to establish a TCP connection to the RPKI server.

```
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA-bgp-default] rpki
[SwitchA-bgp-default-rpki] server tcp 1.1.1.2
[SwitchA-bgp-default-rpki-server] port 1234
[SwitchA-bgp-default-rpki-server] quit
```

3. Enable BGP RPKI validation on Switch A.

```
[SwitchA-bgp-default-rpki] check-origin-validation
[SwitchA-bgp-default-rpki] quit
```

4. Apply the BGP RPKI validation state to optimal route selection.

```
[SwitchA-bgp-default] address-family ipv4
[SwitchA-bgp-default-ipv4] bestroute origin-as-validation
```

5. Configure Switch A to advertise the BGP RPKI validation state to peer 1.2.3.2.

```
[SwitchA-bgp-default-ipv4] peer 1.2.3.2 advertise-ext-community
[SwitchA-bgp-default-ipv4] peer 1.2.3.2 advertise origin-as-validation
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

6. Configure Switch B to permit routes with a BGP RPKI validation state of **Valid**:

Configure a routing policy.

```
<SwitchB> system-view
[SwitchB] route-policy rpki_policy permit node 0
[SwitchB-route-policy-rpki_policy-0] if-match rpki valid
[SwitchB-route-policy-rpki_policy-0] quit
```

Apply the routing policy.

```
[SwitchB] bgp 100
[SwitchB-bgp-default] address-family ipv4
[SwitchB-bgp-default-ipv4] peer 1.2.3.1 route-policy rpki_policy import
```

Verifying the configuration

Display information about the connection between Switch A and the RPKI server.

```
[SwitchA] display bgp rpki server

  Server          VPN-index  Port        State      Time       ROAs(IPv4/IPv6)
  1.1.1.2         0          1234        Establish  00:04:43   5/4
```

The output shows that Switch A has established a TCP connection to the RPKI server.

Display the ROA information on Switch A.

```
[SwitchA] display bgp rpki table ipv4

 Total number of entries: 5

 Status codes: S - stale, U - used

  Network         Mask-range    Origin-AS    Server       Status
  1.2.3.4         8-24          100          1.1.1.2      U
  2.2.3.6         8-32          100          1.1.1.2      U
  2.2.3.6         10-24         4294967295   1.1.1.2      U
  2.2.3.9         20-24         4294967295   1.1.1.2      U
  3.2.3.5         8-26          200          1.1.1.2      U
```

The output shows that Switch A has obtained the ROA information from the RPKI server.

Display the BGP RPKI validation state on Switch A.

```
[SwitchA] display bgp routing-table ipv4 1.2.3.0

 BGP local router ID: 2.2.2.2
 Local AS number: 100
```

```
 Paths:   1 available, 1 best

 BGP routing table information of 1.2.3.0/24:
 Imported route.
 Original nexthop: 0.0.0.0
 Route age       : 03h30m59s
 OutLabel        : NULL
 RxPathID        : 0x0
 TxPathID        : 0x0
 Org-validation  : Valid
 AS-path         : (null)
 Origin          : incomplete
 Attribute value : MED 0, pref-val 32768
 State           : valid, local, best
 IP precedence   : N/A
 QoS local ID    : N/A
 Traffic index   : N/A
```

The route to 1.2.3.0 matches the ROA with a prefix of 1.2.3.4, a mask length range of 8 to 24, and an origin AS number of 100. Therefore, the BGP RPKI validation state of the route to 1.2.3.0 is **Valid**.

On Switch B, display detailed information about the BGP IPv4 unicast route to 1.2.3.0.

```
[SwitchB] display bgp routing-table ipv4 1.2.3.0
RR-client route.
 From            : 1.2.3.1 (192.168.56.22)
 Rely nexthop    : 1.2.3.1
 Original nexthop: 1.2.3.1
 Route age       : 03h30m59s
 OutLabel        : NULL
 Ext-Community   : <Origin Valid State: Valid >
 RxPathID        : 0x0
 TxPathID        : 0x0
 Org-validation  : Valid
 AS-path         : (null)
 Origin          : incomplete
 Attribute value : MED 0, localpref 100, pref-val 0
 State           : valid, internal, best
 IP precedence   : N/A
 QoS local ID    : N/A
 Traffic index   : N/A
```

The output displays information about the BGP IPv4 unicast route to 1.2.3.0 because Switch B permits routes with a BGP RPKI validation state of **Valid**.

Example: Configuring BGP keychain authentication

Network configuration

Configure keychain authentication to better protect the BGP connection between Switch A and Switch B.

Figure 60 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure EBGP connections.

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA-bgp-default] peer 10.1.1.2 as-number 200
[SwitchA-bgp-default] address-family ipv4
[SwitchA-bgp-default-ipv4] peer 10.1.1.2 enable
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 200
[SwitchB-bgp-default] peer 10.1.1.1 as-number 100
[SwitchB-bgp-default] address-family ipv4
[SwitchB-bgp-default-ipv4] peer 10.1.1.1 enable
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

3. Configure basic keychain authentication settings.

   # Configure Switch A.

```
[SwitchA] keychain abc mode absolute
[SwitchA-keychain-abc] key 1
[SwitchA-keychain-abc-key-1] authentication-algorithm hmac-md5
[SwitchA-keychain-abc-key-1] key-string plain pwd123
[SwitchA-keychain-abc-key-1] send-lifetime utc 11:00:00 2023/01/01 to 12:00:00
2023/12/30
[SwitchA-keychain-abc-key-1] accept-lifetime utc 11:00:00 2023/01/01 to 12:00:00
2023/12/30
[SwitchA-keychain-abc-key-1] quit
[SwitchA-keychain-abc] quit
```

   # Configure Switch B.

```
[SwitchB] keychain abc mode absolute
[SwitchB-keychain-abc] key 1
[SwitchB-keychain-abc-key-1] authentication-algorithm hmac-md5
[SwitchB-keychain-abc-key-1] key-string plain pwd123
[SwitchB-keychain-abc-key-1] send-lifetime utc 11:00:00 2023/01/01 to 12:00:00
2023/12/30
[SwitchB-keychain-abc-key-1] accept-lifetime utc 11:00:00 2023/01/01 to 12:00:00
2023/12/30
[SwitchB-keychain-abc-key-1] quit
[SwitchB-keychain-abc] quit
```

4. Configure BGP keychain authentication settings.

   # Configure Switch A.

```
[SwitchA] bgp 100
[SwitchA-bgp-default] peer 10.1.1.2 keychain abc
[SwitchA-bgp-default] quit
```

   # Configure Switch B.

```
[SwitchB] bgp 200
[SwitchB-bgp-default] peer 10.1.1.1 keychain abc
[SwitchB-bgp-default] quit
```

Verifying the configuration

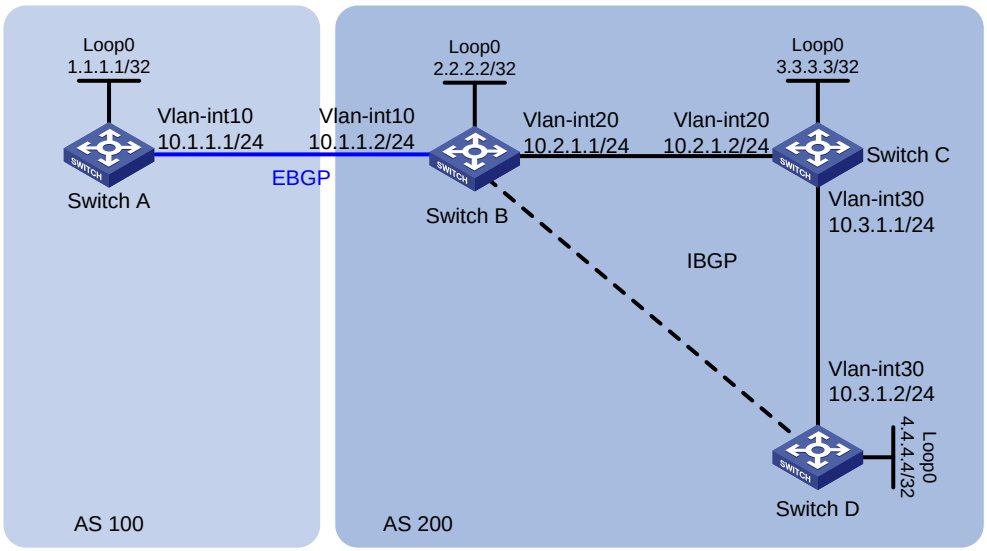
View IPv4 unicast peer information on Switch A.

```
[SwitchA] display bgp peer ipv4 unicast

 BGP local router ID: 10.1.1.1
 Local AS number: 100
 Total number of peers: 1                 Peers in established state: 1

 * - Dynamically created peer
 Peer                    AS  MsgRcvd  MsgSent OutQ  PrefRcv Up/Down  State

 10.1.1.2                200      13       16    0        0 00:10:34 Established
```



The output shows that Switch A and Switch B have passed keychain authentication and established a BGP session.

Example: Configuring BGP GTSM

Network configuration

As shown in Figure 61, Switch A is located in AS 100, and Switches B, C, and D are in AS 200. They all run BGP. Switch A and Switch B are EBGP peers, and Switches B, C, and D are IBGP peers. Configure BGP GTSM to protect all devices from CPU utilization-type packet attacks.

Figure 61 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF to ensure the loopback interfaces of Switch B, Switch C, and Switch D are reachable.

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ospf 1
[SwitchB-ospf-1] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 2.2.2.2 0.0.0.0
[SwitchB-ospf-1-area-0.0.0.0] network 10.2.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] quit
```

   # Configure Switch C.

```
<SwitchC> system-view
[SwitchC] ospf 1
[SwitchC-ospf-1] area 0
[SwitchC-ospf-1-area-0.0.0.0] network 3.3.3.3 0.0.0.0
[SwitchC-ospf-1-area-0.0.0.0] network 10.2.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] network 10.3.1.0 0.0.0.255
[SwitchC-ospf-1-area-0.0.0.0] quit
[SwitchC-ospf-1] quit
```

   # Configure Switch D.

```
<SwitchD> system-view
[SwitchD] ospf 1
[SwitchD-ospf-1] area 0
[SwitchD-ospf-1-area-0.0.0.0] network 4.4.4.4 0.0.0.0
[SwitchD-ospf-1-area-0.0.0.0] network 10.3.1.0 0.0.0.255
[SwitchD-ospf-1-area-0.0.0.0] quit
[SwitchD-ospf-1] quit
```

3. Configure IBGP connections in a full-mesh manner.

   To avoid route flaps caused by unstable port states, this example uses loopback interfaces for IBGP peer session establishment.

   # Configure Switch B.

```
[SwitchB] bgp 200
[SwitchB-bgp-default] router-id 2.2.2.2
[SwitchB-bgp-default] peer 3.3.3.3 as-number 65009
[SwitchB-bgp-default] peer 3.3.3.3 connect-interface loopback 0
[SwitchB-bgp-default] peer 4.4.4.4 as-number 65009
[SwitchB-bgp-default] peer 4.4.4.4 connect-interface loopback 0
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 3.3.3.3 enable
[SwitchB-bgp-default-ipv4] peer 4.4.4.4 enable
[SwitchB-bgp-default-ipv4] peer 3.3.3.3 next-hop-local
[SwitchB-bgp-default-ipv4] peer 4.4.4.4 next-hop-local
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

   # Configure Switch C.

```
[SwitchC] bgp 200
```

```
[SwitchC-bgp-default] router-id 3.3.3.3
[SwitchC-bgp-default] peer 2.2.2.2 as-number 65009
[SwitchC-bgp-default] peer 2.2.2.2 connect-interface loopback 0
[SwitchC-bgp-default] peer 4.4.4.4 as-number 65009
[SwitchC-bgp-default] peer 4.4.4.4 connect-interface loopback 0
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 2.2.2.2 enable
[SwitchC-bgp-default-ipv4] peer 4.4.4.4 enable
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

Configure Switch D.

```
[SwitchD] bgp 200
[SwitchD-bgp-default] router-id 4.4.4.4
[SwitchD-bgp-default] peer 3.3.3.3 as-number 65009
[SwitchD-bgp-default] peer 3.3.3.3 connect-interface loopback 0
[SwitchD-bgp-default] peer 2.2.2.2 as-number 65009
[SwitchD-bgp-default] peer 2.2.2.2 connect-interface loopback 0
[SwitchD-bgp-default] address-family ipv4 unicast
[SwitchD-bgp-default-ipv4] peer 3.3.3.3 enable
[SwitchD-bgp-default-ipv4] peer 2.2.2.2 enable
[SwitchD-bgp-default-ipv4] quit
[SwitchD-bgp-default] quit
```

4. Configure EBGP connections.

Configure Switch A.

```
<SwitchA>
[SwitchA] bgp 100
[SwitchA-bgp-default] router-id 1.1.1.1
[SwitchA-bgp-default] peer 10.1.1.2 as-number 200
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 10.1.1.2 enable
```

Configure Switch B.

```
[SwitchB] bgp 200
[SwitchB-bgp-default] peer 10.1.1.1 as-number 100
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 10.1.1.1 enable
```

5. Configure BGP GTSM.

Configure BGP GTSM between Switch A and Switch B. The maximum number of hops to each other is 1 and the valid TTL range is [255,255], because the two devices are directly connected.

```
[SwitchA] bgp 100
[SwitchA-bgp-default] peer 10.1.1.2 ttl-security hops 1
[SwitchA-bgp-default] quit
[SwitchB] bgp 200
[SwitchB-bgp-default] peer 10.1.1.1 ttl-security hops 1
```

Configure BGP GTSM between Switch B and Switch C. The maximum number of hops to each other is 1 and the valid TTL range is [255,255], because the two devices are directly connected.

```
[SwitchC] bgp 200
```

```
[SwitchC-bgp-default] peer 2.2.2.2 ttl-security hops 1
[SwitchB-bgp-default] peer 3.3.3.3 ttl-security hops 1
```

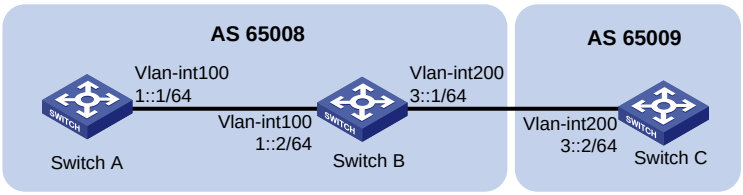
Configure BGP GTSM between Switch C and Switch D. The maximum number of hops to each other is 1 and the valid TTL range is [255,255], because the two devices are directly connected.

```
[SwitchD] bgp 200
[SwitchD-bgp-default] peer 3.3.3.3 ttl-security hops 1
[SwitchC-bgp-default] peer 4.4.4.4 ttl-security hops 1
[SwitchC-bgp-default] quit
```

Configure BGP GTSM between Switch B and Switch D. The maximum number of hops to each other is 2 and the valid TTL range is [254,255], because the two devices are indirectly connected via an intermediate device.

```
[SwitchB-bgp-default] peer 4.4.4.4 ttl-security hops 2
[SwitchB-bgp-default] quit
[SwitchD-bgp-default] peer 2.2.2.2 ttl-security hops 2
[SwitchD-bgp-default] quit
```

IPv6 BGP security feature configuration examples



Example: Configuring IPsec for IPv6 BGP packets

Network configuration

As shown in Figure 62, all switches run IPv6 BGP. Establish an IBGP connection between Switch A and Switch B, and establish an EBGP connection between Switch B and Switch C.

To enhance security, configure IPsec to protect IPv6 BGP packets.

Figure 62 Network diagram

Procedure

1. Configure IPv6 addresses for interfaces. (Details not shown.)
2. Establish an IBGP connection between Switch A and Switch B:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 65008
[SwitchA-bgp-default] router-id 1.1.1.1
[SwitchA-bgp-default] group ibgp internal
[SwitchA-bgp-default] peer 1::2 group ibgp
[SwitchA-bgp-default] address-family ipv6 unicast
[SwitchA-bgp-default-ipv6] peer ibgp enable
[SwitchA-bgp-default-ipv6] quit
```

```
[SwitchA-bgp-default] quit
```

Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 65008
[SwitchB-bgp-default] router-id 2.2.2.2
[SwitchB-bgp-default] group ibgp internal
[SwitchB-bgp-default] peer 1::1 group ibgp
[SwitchB-bgp-default] address-family ipv6 unicast
[SwitchB-bgp-default-ipv6] peer ibgp enable
[SwitchB-bgp-default-ipv6] quit
```

3. Establish an EBGP connection between Switch B and Switch C:

Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 65009
[SwitchC-bgp-default] router-id 3.3.3.3
[SwitchC-bgp-default] group ebgp external
[SwitchC-bgp-default] peer 3::1 as-number 65008
[SwitchC-bgp-default] peer 3::1 group ebgp
[SwitchC-bgp-default] address-family ipv6 unicast
[SwitchC-bgp-default-ipv6] peer ebgp enable
[SwitchC-bgp-default-ipv6] quit
[SwitchC-bgp-default] quit
```

Configure Switch B.

```
[SwitchB-bgp-default] group ebgp external
[SwitchB-bgp-default] peer 3::2 as-number 65009
[SwitchB-bgp-default] peer 3::2 group ebgp
[SwitchB-bgp-default] address-family ipv6 unicast
[SwitchB-bgp-default-ipv6] peer ebgp enable
[SwitchB-bgp-default-ipv6] quit
[SwitchB-bgp-default] quit
```

4. Configure IPsec transform sets and IPsec profiles:

On Switch A, create an IPsec transform set named **tran1**.

```
[SwitchA] ipsec transform-set tran1
```

Set the encapsulation mode to transport mode.

```
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode transport
```

Set the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1.

```
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm des
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create an IPsec profile named **policy001**, and specify the manual mode for it.

```
[SwitchA] ipsec profile policy001 manual
```

Use IPsec transform set **tran1**.

```
[SwitchA-ipsec-profile-policy001-manual] transform-set tran1
```

Set the SPIs of the inbound and outbound SAs to **12345**.

```
[SwitchA-ipsec-profile-policy001-manual] sa spi outbound esp 12345
[SwitchA-ipsec-profile-policy001-manual] sa spi inbound esp 12345
```

Set the keys for the inbound and outbound SAs using ESP to **abcdefg**.

```
[SwitchA-ipsec-profile-policy001-manual] sa string-key outbound esp simple abcdefg
[SwitchA-ipsec-profile-policy001-manual] sa string-key inbound esp simple abcdefg
[SwitchA-ipsec-profile-policy001-manual] quit
```

On Switch B, create an IPsec transform set named **tran1**.

```
[SwitchB] ipsec transform-set tran1
```

Set the encapsulation mode to transport mode.

```
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode transport
```

Set the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1.

```
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm des
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Create IPsec profile named **policy001**, and specify the manual mode for it.

```
[SwitchB] ipsec profile policy001 manual
```

Use IPsec transform set **tran1**.

```
[SwitchB-ipsec-profile-policy001-manual] transform-set tran1
```

Set the SPIs of the inbound and outbound SAs to **12345**.

```
[SwitchB-ipsec-profile-policy001-manual] sa spi outbound esp 12345
[SwitchB-ipsec-profile-policy001-manual] sa spi inbound esp 12345
```

Set the keys for the inbound and outbound SAs using ESP to **abcdefg**.

```
[SwitchB-ipsec-profile-policy001-manual] sa string-key outbound esp simple abcdefg
[SwitchB-ipsec-profile-policy001-manual] sa string-key inbound esp simple abcdefg
[SwitchB-ipsec-profile-policy001-manual] quit
```

Create an IPsec transform set named **tran2**.

```
[SwitchB] ipsec transform-set tran2
```

Set the encapsulation mode to transport mode.

```
[SwitchB-ipsec-transform-set-tran2] encapsulation-mode transport
```

Set the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1.

```
[SwitchB-ipsec-transform-set-tran2] esp encryption-algorithm des
[SwitchB-ipsec-transform-set-tran2] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran2] quit
```

Create IPsec profile named **policy002**, and specify the manual mode for it.

```
[SwitchB] ipsec profile policy002 manual
```

Use IPsec transform set **tran2**.

```
[SwitchB-ipsec-profile-policy002-manual] transform-set tran2
```

Set the SPIs of the inbound and outbound SAs to **54321**.

```
[SwitchB-ipsec-profile-policy002-manual] sa spi outbound esp 54321
[SwitchB-ipsec-profile-policy002-manual] sa spi inbound esp 54321
```

Set the keys for the inbound and outbound SAs using ESP to **gfedcba**.

```
[SwitchB-ipsec-profile-policy002-manual] sa string-key outbound esp simple gfedcba
[SwitchB-ipsec-profile-policy002-manual] sa string-key inbound esp simple gfedcba
[SwitchB-ipsec-profile-policy002-manual] quit
```

On Switch C, create an IPsec transform set named **tran2**.

```
[SwitchC] ipsec transform-set tran2
```

Set the encapsulation mode to transport mode.

```
[SwitchC-ipsec-transform-set-tran2] encapsulation-mode transport
```

Set the security protocol to ESP, the encryption algorithm to DES, and authentication algorithm to SHA1.

```
[SwitchC-ipsec-transform-set-tran2] esp encryption-algorithm des
[SwitchC-ipsec-transform-set-tran2] esp authentication-algorithm sha1
[SwitchC-ipsec-transform-set-tran2] quit
```

Create IPsec profile named **policy002**, and specify the manual mode for it.

```
[SwitchC] ipsec profile policy002 manual
```

Use IPsec transform set **tran2**.

```
[SwitchC-ipsec-profile-policy002-manual] transform-set tran2
```

Set the SPIs of the inbound and outbound SAs to **54321**.

```
[SwitchC-ipsec-profile-policy002-manual] sa spi outbound esp 54321
[SwitchC-ipsec-profile-policy002-manual] sa spi inbound esp 54321
```

Set the keys for the inbound and outbound SAs using ESP to **gfedcba**.

```
[SwitchC-ipsec-profile-policy002-manual] sa string-key outbound esp simple gfedcba
[SwitchC-ipsec-profile-policy002-manual] sa string-key inbound esp simple gfedcba
[SwitchC-ipsec-profile-policy002-manual] quit
```

5. Configure IPsec to protect IPv6 BGP packets between Switch A and Switch B:

Configure Switch A.

```
[SwitchA] bgp 65008
[SwitchA-bgp-default] peer 1::2 ipsec-profile policy001
[SwitchA-bgp-default] quit
```

Configure Switch B.

```
[SwitchB] bgp 65008
[SwitchB-bgp-default] peer 1::1 ipsec-profile policy001
[SwitchB-bgp-default] quit
```

6. Configure IPsec to protect IPv6 BGP packets between Router B and Switch C:

Configure Switch C.

```
[SwitchC] bgp 65009
[SwitchC-bgp-default] peer ebgp ipsec-profile policy002
[SwitchC-bgp-default] quit
```

Configure Switch B.

```
[SwitchB] bgp 65008
[SwitchB-bgp-default] peer ebgp ipsec-profile policy002
[SwitchB-bgp-default] quit
```

Verifying the configuration

Display detailed information about IPv6 BGP peers on Switch B.

```
[SwitchB] display bgp peer ipv6 verbose

  Peer: 1::1      Local: 2.2.2.2
  Type: IBGP link

```

Example: Configuring BGP RPKI

Network configuration

As shown in Figure 63, all switches run IPv6 BGP. Establish a TCP connection between Switch A and the RPKI server, and establish an IBGP connection between Switch A and Switch B.

Configure Switch A to advertise the BGP RPKI validation state to Switch B, and configure a routing policy to filter routes based on the validation state for Switch B.

Figure 63 Network diagram

Procedure

1. Configure IPv6 addresses for interfaces and establish an IBGP connection between Switch A and Switch B. (Details not shown.)
2. Configure Switch A to establish a TCP connection to the RPKI server.

```
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA-bgp-default] rpki
[SwitchA-bgp-default-rpki] server tcp 1::2
[RouterA-bgp-default-rpki-server] port 1234
[RouterA-bgp-default-rpki-server] quit
```

3. Enable BGP RPKI validation on Switch A.

```
[SwitchA-bgp-default-rpki] check-origin-validation
[SwitchA-bgp-default-rpki] quit
```

4. Apply the BGP RPKI validation state to optimal route selection.

```
[SwitchA-bgp-default] address-family ipv6
[SwitchA-bgp-default-ipv6] bestroute origin-as-validation
```

5. Configure Switch A to advertise the BGP RPKI validation state to peer 2001::2.

```
[SwitchA-bgp-default-ipv6] peer 2001::2 advertise-ext-community
[SwitchA-bgp-default-ipv6] peer 2001::2 advertise origin-as-validation
[SwitchA-bgp-default-ipv6] quit
[SwitchA-bgp-default] quit
```

6. Configure Switch B to permit routes with a BGP RPKI validation state of **Valid**:

   # Configure a routing policy.

```
<SwitchB> system-view
[SwitchB] route-policy rpki_policy permit node 0
[SwitchB-route-policy-rpki_policy-0] if-match rpki valid
```

   # Apply the routing policy.

```
<SwitchB> system-view
[SwitchB] bgp 100
[SwitchB-bgp-default] address-family ipv6
[SwitchB-bgp-default-ipv6] peer 2001::1 route-policy rpki_policy import
```

Verifying the configuration

Display information about the connection between Switch A and the RPKI server.

```
[SwitchA] display bgp rpki server

  Server          VPN-index  Port        State      Time       ROAs(IPv4/IPv6)
  1::2            0          1234        Establish  00:04:43   5/5
```

The output shows that Switch A has established a TCP connection to the RPKI server.

Display the ROA information on Switch A.

```
[SwitchA] display bgp rpki table ipv6

 Total number of entries: 5

 Status codes: S - stale, U - used

  Network         Mask-range    Origin-AS    Server       Status
  2001:4860::     32-32         100          1::2         U
```

```
  2404:6800::     32-32         100          1::2         U
  2607:F8B0::     28-28         4294967295   1::2         U
  2A03:ACE0::     40-40         4294967295   1::2         U
  2001::1         64-64         200          1::2         U
```

The output shows that Switch A has obtained ROAs from the RPKI server.

Display the BGP RPKI validation state on Switch A.

```
[SwitchA] display bgp routing-table ipv6 2001::1 64

 BGP local router ID: 2.2.2.2
 Local AS number: 100

 Paths:   1 available, 1 best

 BGP routing table information of 2001::1/64:
 Imported route.
 Original nexthop: 0.0.0.0
 Route age       : 03h30m59s
 OutLabel        : NULL
 RxPathID        : 0x0
 TxPathID        : 0x0
 Org-validation  : Valid
 AS-path         : (null)
 Origin          : incomplete
 Attribute value : MED 0, pref-val 32768
 State           : valid, local, best
 IP precedence   : N/A
 QoS local ID    : N/A
```

The route to 2001::1 matches the ROA with a prefix of 2001::1, a prefix length range of 64 to 64, and an origin AS number of 200. Therefore, the BGP RPKI validation state of the route to 2001::1 is **Valid**.

On Switch B, display detailed information about the BGP IPv6 unicast route to network 2001::1.

```
[SwitchB] display bgp routing-table ipv6 2001::1 64

RR-client route.
 From            : 2001::1 64 (192.168.56.22)
 Rely nexthop    : 2001::1
 Original nexthop: 2001::1
 Route age       : 03h30m59s
 OutLabel        : NULL
 Ext-Community   : <Origin Valid State: Valid >
 RxPathID        : 0x0
 TxPathID        : 0x0
 Org-validation  : Invalid
 AS-path         : (null)
 Origin          : incomplete
 Attribute value : MED 0, localpref 100, pref-val 0
 State           : valid, internal, best
 IP precedence   : N/A
```

```
QoS local ID     : N/A
Traffic index    : N/A
```

The output displays information about the BGP IPv6 unicast route to 2001::1 because Switch B permits routes with a BGP RPKI validation state of **Valid**.

Improving BGP network reliability

BGP network reliability improvement tasks at a glance

To improve the BGP network reliability, perform the following tasks:

- Configuring BGP GR
- Configuring BGP NSR
- Configuring BFD for BGP
- Configuring BGP FRR
- Configuring BGP maintenance features
  - Configuring BGP isolation
  - Configuring BGP shutdown

Configuring BGP GR

BGP GR operating mechanism

Graceful Restart (GR) ensures forwarding continuous when a routing protocol restarts or an active/standby switchover occurs. Two routers are required to complete a GR process. The following are router roles in a GR process:

- **GR restarter**—Performs GR upon a BGP restart or active/standby switchover.
- **GR helper**—Helps the GR restarter to complete the GR process.

A device can act as a GR restarter and GR helper at the same time.

BGP GR works as follows:

1. The BGP GR restarter and helper exchange OPEN messages for GR capability negotiation. If both parties have the GR capability, they establish a GR-capable session. The GR restarter sends the GR timer set by the **`graceful-restart timer restart`** command to the GR helper in an OPEN message.
2. When an active/standby switchover occurs or BGP restarts, the GR restarter does not remove existing BGP routes from Routing Information Base (RIB) and Forwarding Information Base (FIB). It still uses these routes for packet forwarding, and it starts the RIB purge timer (set by the **`graceful-restart timer purge-time`** command). The GR helper marks all routes learned from the GR restarter as stale instead of deleting them. It continues to use these routes for packet forwarding. During the GR process, packet forwarding is not interrupted.
3. After the active/standby switchover or BGP restart completes, the GR restarter re-establishes a BGP session to the GR helper. If the BGP session fails to be established after both the GR timer and the extra timer to wait expire, the GR helper removes the stale routes. To set the extra timer to wait after the restart timer expires, execute the **`peer graceful-restart timer restart extra`** command.
4. If the BGP session is established, routing information is exchanged for the GR restarter to retrieve route entries and for the GR helper to recover stale routes.
5. Both the GR restarter and the GR helper start the End-Of-RIB marker waiting timer.

   The End-Of-RIB marker waiting timer is set by the **`graceful-restart timer wait-for-rib`** command.

- If routing information exchange is completed within the waiting timer, the GR restarter and the GR helper act as follows:
  - The GR restarter updates its routing table with learned BGP routes, removes the aged routes from the RIB, and quits the GR process.
  - The GR helper removes the stale routes and quits the GR process.
- If routing information exchange is not completed within the waiting timer, the GR restarter and the GR helper act as follows:
  - The GR restarter updates the RIB with the BGP routes already learned, removes the aged routes from the RIB, and quits the GR process.
  - The GR helper removes the stale routes and quits the GR process.

The End-Of-RIB marker is an update message that does not contain any NLRI or withdrawn NLRI. After the GR restarter and the GR helper complete route exchange, they additionally send an End-Of-RIB marker to each other. The marker indicates the completion of route update.

6. The GR restarter quits the GR process if routing information exchange is not completed within the RIB purge timer. It updates the RIB with the BGP routes already learned, and removes the aged routes.

After BGP completes GR, it advertises updated routes as follows:

- If the routes rely on other protocols, for example, redistributed OSPF routes , BGP starts a wait timer for these protocols to complete GR. This ensures that incorrect and unreachable routes are not advertised.
  - If the protocols complete GR and notify BGP before the wait timer expires, BGP cancels the wait timer and advertises the routes.
  - If the protocols does not complete GR or notify BGP before the wait timer expires, BGP immediately advertises the routes after the wait timer expires.
- If the routes do not rely on other protocols, BGP immediately advertises the routes.

Enabling the GR capability globally or on a per peer basis

The **graceful-restart** command globally enables the BGP GR capability for a BGP instance. The BGP instance can establishes GR-capable sessions to all peers. However, enabling the BGP GR capability globally will terminate and re-establish all BGP sessions and thus cause unnecessary traffic interruption. To avoid this issue, use the **peer capability-advertise graceful-restart** command to enable the capability of BGP GR negotiation with only desired peers.

After you configure the **peer capability-advertise graceful-restart** command, the local device re-establishes the session to the specified peer and performs GR capability negotiation with the peer through Open messages. If both the local device and the peer have GR capability, they can establish a GR-capable session.

Enabling BGP to gracefully reset peer sessions gracefully

When the TCP connection goes down, the hold timer expires, or the support for a new address family is added, BGP terminates and re-establishes the peer sessions, which will cause traffic interruption. To avoid traffic interruption in these cases, enable BGP to reset peer sessions gracefully.

Setting the F-bit to 0 in OPEN messages used for GR negotiation

When BGP has a GR negotiation with a peer, it sends OPEN messages with the F-bit to that peer. Supported F-bit values include:

- **1**—When BGP acts as the GR helper, it retains forwarding entries and thus can forward traffic to the GR restarter.
- **0**—When BGP acts as the GR helper, it updates forwarding entries and thus cannot forward traffic to the GR restarter.

By default, the GR restarter sets the F-bit to 1 in OPEN messages used for GR negotiation. During the GR process, the GR restarter does not have forwarding capabilities, but it still receives traffic from the GR helper, which causes data loss. To avoid data loss, use this command on the GR helper to set the F-bit to 0 in OPEN messages used for GR negotiation.

Restrictions and guidelines

Follow these guidelines when you configure BGP GR:

- The maximum time to wait for the End-of-RIB marker configured on the local end is not advertised to the peer. It controls the time for the local end to receive updates from the peer. Set a large value for the maximum time to wait for the End-of-RIB marker when a large number of routes need to be exchanged. When you use the **peer graceful-restart timer restart extra** command, you can specify the **no-limit** keyword. In this situation, the GR helper does not start the End-of-RIB marker waiting timer after BGP session re-establishment and keeps waiting for the End-of-RIB marker from the GR restarter.
- As a best practice, perform the BGP GR configuration on both the GR restarter and GR helper.
- When the following conditions exist, BGP might advertise incomplete routes after completing GR:
  - The routes rely on other protocols, for example, redistributed OSPF routes.
  - BGP maintains a large amount of routing information. In this case, BGP and the protocols take a long time to complete GR.

  For BGP to correctly advertise the routes after BGP and the protocols complete GR, set a longer wait timer for BGP.
- The local device can negotiate GR capability with a peer successfully when the GR negotiation capability is enabled globally or only for the peer on the local device.
- If the local device starts BGP GR through the configuration of the **peer capability-advertise graceful-restart** command, enable or disable the global GR capability with caution. This operation will terminate the current BGP GR process and re-establish BGP sessions.
- If the local device starts BGP GR through the configuration of the **graceful-restart** command, use the **peer capability-advertise graceful-restart** command with caution. This command will terminate the BGP GR process associated with the local device and the specified peer and re-establish the session between the two peers.
- If you enable the capability of GR negotiation with a single peer, the time settings used by the GR process that involves the local device and the peer depend on the following commands:
  - **peer graceful-restart timer restart**
  - **peer graceful-restart timer wait-for-rib**
  - **graceful-restart timer purge-time**
  - **peer graceful-restart timer restart extra**

  You can enable the GR negotiation capability globally and for a single peer on the local device at the same time. In this case, the GR time settings configured for the peer take precedence over the global GR time settings.

Enabling the GR capability globally

1. Enter system view.

   system-view
2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
3. Enable the GR capability for BGP globally.

   graceful-restart

   By default, the GR capability is disabled for BGP.

4. Configure the GR timer.

   graceful-restart timer restart *timer*

   The default setting is 150 seconds.

   The time that a peer waits to re-establish a session must be less than the hold time.

5. (Optional.) Set the extra time to wait after the restart timer expires. Choose one command as needed:

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **graceful-restart timer restart extra** { *time* | **no-limit** }

   interface-peer *interface-type interface-number* **graceful-restart timer restart extra** { *time* | **no-limit** }

   By default, the extra time to wait after the restart timer expires is 0 seconds.

6. Configure the maximum time to wait for the End-of-RIB marker.

   graceful-restart timer wait-for-rib *timer*

   The default setting is 600 seconds.

7. Configure the RIB purge timer.

   graceful-restart timer purge-time *timer*

   The default setting is 480 seconds.

8. (Optional.) Configure the time that BGP must wait for other protocols to complete GR after BGP completes GR.

   bgp update-delay wait-other-protocol *seconds*

   By default, after BGP completes GR, it must wait a maximum of 300 seconds for other protocols to complete GR.

9. (Optional.) Enable BGP to reset peer sessions gracefully.

   graceful-restart peer-reset [**all**]

   By default, BGP does not reset peer sessions gracefully.

Enabling the GR capability on a per peer basis

1. Enter system view.

   system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

3. Enable the capability of GR negotiation with a peer.

   peer { *group-name* | *ipv4-address* | *ipv6-address* } **capability-advertise graceful-restart**

   By default, the capability of GR negotiation with peers is disabled.

4. Configure the GR timer for a peer.

   peer { *group-name* | *ipv4-address* | *ipv6-address* } **graceful-restart timer restart** *time-value*

   By default, the GR timer is 150 seconds for peers.

   The time that a peer waits to re-establish a session must be less than the hold time.

5. (Optional.) Set the extra time to wait after the GR timer expires.

   peer { *group-name* | *ipv4-address* | *ipv6-address* } **graceful-restart timer restart extra** { *time* | **no-limit** }

   By default, the extra time to wait after the GR timer expires is 0 seconds.

6. Configure the maximum time to wait for the End-of-RIB marker from a peer.

   peer { *group-name* | *ipv4-address* | *ipv6-address* } **graceful-restart timer wait-for-rib** *time-value*

   The default setting is 600 seconds.

7. Configure the RIB purge timer.

   graceful-restart timer purge-time *timer*

   The default setting is 480 seconds.

Configuring BGP NSR

About this task

BGP nonstop routing (NSR) backs up BGP state and data information from the active BGP process to the standby BGP process. The standby BGP process takes over when any of the following events occurs:

- The active BGP process restarts.
- The member device that runs the active BGP process fails.
- An ISSU starts on the member device that runs the active BGP process.

Choose BGP NSR or BGP GR according to the actual situation and make sure data forwarding is not interrupted. The differences between BGP NSR and BGP GR as follows:

- **Device requirements**—The active and standby processes of BGP must run on different IRF member devices. To run BGP NSR, you must set up an IRF fabric that contains a minimum of two member devices. To run BGP GR, IRF fabric setup is not required. If an IRF fabric already exists, you can run BGP GR when the IRF fabric contains only one member device.
- **BGP peer requirements**—When you use BGP NSR, BGP peers cannot detect process restart or active/standby switchover on the local device. BGP NSR can recover BGP route information without requiring the cooperation of BGP peers. BGP GR requires BGP peers to have the GR helper capability to help the GR restarter complete the GR process.

After BGP completes NSR, it advertises updated routes as follows:

- If the routes rely on other protocols, for example, redistributed OSPF routes, BGP starts a wait timer for these protocols to complete NSR. This ensures that incorrect and unreachable routes are not advertised.
  - If the protocols complete NSR and notify BGP before the wait timer expires, BGP cancels the wait timer and advertises the routes.
  - After the wait timer expires, BGP immediately advertises the routes.
- If the routes do not rely on other protocols, BGP immediately advertises the routes.

Restrictions and guidelines

When both BGP GR and BGP NSR are configured on the device, the following rules apply:

- BGP NSR has a higher priority than BGP GR. When the active process goes down, the device does not act as the GR restarter and performs NSR to ensure nonstop forwarding.
- When the following conditions exist, the GR process might fail even if BGP NSR is enabled on the GR helper:
  - BGP is restarted through GR.
  - An active/standby switchover is triggered on the GR helper before the GR process finishes.

When the following conditions exist, BGP might advertise incomplete routes after completing NSR:

- The routes rely on other protocols, for example, redistributed OSPF routes.
- BGP maintains a large amount of routing information. In this case, BGP and the protocols take a long time to complete NSR.

To ensure BGP advertises the routes after BGP and the protocols complete NSR, set a longer wait timer for BGP.

Procedure

1. Enter system view.

   system-view
2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
3. Enable BGP NSR.

   non-stop-routing

   By default, BGP NSR is enabled.
4. (Optional.) Configure the time that BGP must wait for other protocols to complete NSR after BGP completes NSR.

   bgp update-delay wait-other-protocol *seconds*

   By default, after BGP completes NSR, it must wait a maximum of 300 seconds for other protocols to complete NSR.

Configuring BFD for BGP

About this task

BGP maintains neighbor relationships based on the keepalive timer and hold timer in seconds. It requires that the hold time must be at least three times the keepalive interval. This mechanism slows down link failure detection. Once a failure occurs on a high-speed link, a large quantity of packets will be dropped before routing convergence completes. BFD for BGP can solve this problem by fast detecting link failures to reduce convergence time.

Before you enable BFD for a BGP peer or peer group, you must establish a BGP session between the local router and the peer or peer group.

For more information about BFD, see *High Availability Configuration Guide*.

Restrictions and guidelines

Follow these restrictions and guidelines when you configure echo packet mode BFD:

- Echo packet mode BFD is applicable only to directly connected BGP peers.
- Echo packet mode BFD is not applicable to BGP peers established through loopback interfaces.

To detect the link to a BGP peer established through link-local addresses, you must configure single-hop BFD in control packet mode.

To establish a control packet mode BFD session to a BGP peer, you must configure the same BFD detection mode (multi-hop or single-hop) on the local device and the BGP peer.

If you have enabled GR, use BFD with caution because BFD might detect a failure before the system performs GR, which will result in GR failure. If you have enabled both BFD and GR for BGP, do not disable BFD during a GR process to avoid GR failure.

Procedure (IPv4 peers)

1. Enter system view.

system-view

2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Enable BFD to detect the link to the specified BGP peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] } **bfd** [**echo** | **multi-hop** | **single-hop**]

   By default, BFD is disabled.

Procedure (IPv6 peers)

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

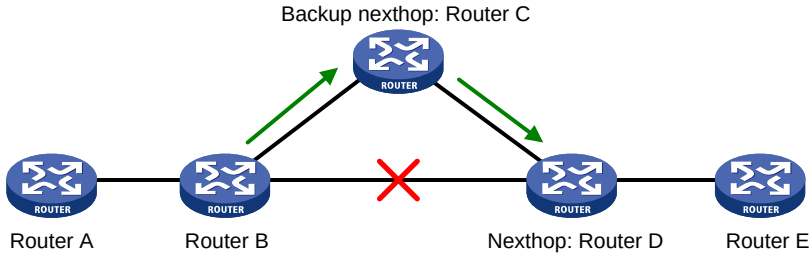
     ip vpn-instance *vpn-instance-name*
3. Enable BFD to detect the link to the specified IPv6 BGP peer or peer group. Choose one command as needed:

   peer { *group-name* | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **bfd** [**echo** | **multi-hop** | **single-hop**]

   interface-peer *interface-type interface-number* **bfd** [**multi-hop** | **single-hop**]

   By default, BFD is disabled.

   The *link-local-address* **interface** *interface-type interface-number* option and the **echo** keyword are mutually exclusive.



Configuring BGP FRR

About BGP FRR

When a link fails, the packets on the link are discarded, and a routing loop might occur until BGP completes routing convergence based on the new network topology.

You can enable BGP fast reroute (FRR) to resolve this issue.

Figure 64 Network diagram for BGP FRR

After you configure FRR on Router B as shown in Figure 64, BGP generates a backup next hop Router C for the primary route. BGP uses ARP or BFD echo packet mode in an IPv4 network or ND in an IPv6 network to detect the connectivity to Router D. When the link to Router D fails, BGP directs packets to the backup next hop. At the same time, BGP calculates a new optimal route, and forwards packets over the optimal route.

You can use the following methods to configure BGP FRR:

- **Method 1**—Execute the **pic** command in BGP address family view. BGP calculates a backup next hop for each BGP route in the address family if there are two or more unequal-cost routes that reach the destination.
- **Method 2**—Execute the **fast-reroute route-policy** command to use a routing policy in which a backup next hop is specified by using the command **apply** [**ipv6**] **fast-reroute backup-nexthop**. The backup next hop calculated by BGP must be the same as the specified backup next hop. Otherwise, BGP does not generate a backup next hop for the primary route. You can also configure **if-match** clauses in the routing policy to identify the routes protected by FRR.

If both methods are configured, Method 2 takes precedence over Method 1.

BGP supports FRR for IPv4 and IPv6 unicast routes, but not for IPv4 and IPv6 multicast routes.

Configuring BGP FRR by using a routing policy (IPv4 unicast address family)

1. Enter system view.

   system-view
2. Create a routing policy and enter routing policy view.

   route-policy *route-policy-name* **permit node** *node-number*

   For more information about this command, see routing policy commands in *Layer 3—IP Routing Command Reference*.
3. Set the backup next hop for FRR.

   apply fast-reroute backup-nexthop *ipv4-address*

   By default, no backup next hop is set.

   For more information about this command, see routing policy commands in *Layer 3—IP Routing Command Reference*.
4. Return to system view.

   quit
5. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
6. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.
   - Enter BGP IPv4 unicast address family view.

address-family ipv4 [**unicast**]

- Execute the following commands in sequence to enter BGP-VPN IPv4 unicast address family view:

  ip vpn-instance *vpn-instance-name*

  address-family ipv4 [**unicast**]

7. Apply a routing policy to FRR for the address family.

   fast-reroute route-policy *route-policy-name*

   By default, no routing policy is applied.

   The **apply fast-reroute backup-nexthop** command and **apply ipv6 fast-reroute backup-nexthop** command can take effect in the applied routing policy. Other **apply** commands do not take effect.

Configuring BGP FRR by using a routing policy (IPv6 unicast address family)

1. Enter system view.

   system-view

2. Create a routing policy and enter routing policy view.

   route-policy *route-policy-name* **permit node** *node-number*

   For more information about this command, see routing policy commands in *Layer 3—IP Routing Command Reference*.

3. Set the backup next hop for FRR.

   apply ipv6 fast-reroute backup-nexthop *ipv6-address*

   By default, no backup next hop is set.

   For more information about this command, see routing policy commands in *Layer 3—IP Routing Command Reference*.

4. Return to system view.

   quit

5. Enter BGP instance view or BGP-VPN instance view.

   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]

   - Enter BGP-VPN instance view.

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*

6. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.

   address-family ipv6 [**unicast**]

7. Apply a routing policy to FRR for the address family.

   fast-reroute route-policy *route-policy-name*

   By default, no routing policy is applied.

   The **apply fast-reroute backup-nexthop** and **apply ipv6 fast-reroute backup-nexthop** commands can take effect in the applied routing policy. Other **apply** commands do not take effect.

Configuring BGP FRR through PIC (IPv4 unicast address family)

Restrictions and guidelines

This feature might result in routing loops. Use it with caution.

Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Enter BGP IPv4 unicast address family view or BGP-VPN IPv4 unicast address family view.
   address-family ipv4 [**unicast**]
4. Enable BGP FRR through PIC.
   pic
   By default, BGP FRR is disabled.

Configuring BGP FRR through PIC (IPv6 unicast address family)

Restrictions and guidelines

This feature might result in routing loops. Use it with caution.

Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.
     bgp *as-number* [**instance** *instance-name*]
   - Enter BGP-VPN instance view.
     bgp *as-number* [**instance** *instance-name*]
     ip vpn-instance *vpn-instance-name*
3. Enter BGP IPv6 unicast address family view or BGP-VPN IPv6 unicast address family view.
   address-family ipv6 [**unicast**]
4. Enable BGP FRR through PIC.
   pic
   By default, BGP FRR is disabled.

Configuring BFD-powered nexthop connectivity detection for BGP FRR

About this task

By default, BGP FRR uses ARP to detect next hop connectivity for the primary route. This method is not efficient at detecting the failure of the primary route. As a result, data loss might occur when the primary route fails, because the backup path might not take over to forward traffic in time. To resolve this issue, enable BFD-powered nexthop connectivity detection for BGP FRR. This feature enables BGP to create an IP FRR BFD session that detects next hop connectivity for the primary route. This can speed up primary and backup route switchover when the next hop of the primary route fails.

Restrictions and guidelines

This feature takes effect and creates an IP FRR BFD session only when the primary route has a backup next hop.

BGP does not support backup next hop calculation for the routes used for load balancing. This command cannot take effect when the primary route is an equal-cost route.

BGP can establish a control-mode BFD session with a peer only after negotiation. To use control-mode BFD to detect the next hop of the primary link, perform one of the following tasks:

- Configure the **primary-path-detect bfd** command on the peer device in the primary link.

  This task is applicable when both ends of the primary link are configured with FRR.
- Manually configure a static BFD session that uses the following settings on the peer device in the primary link:
  - Source IP address: Destination IP address of the BFD session automatically created on the local device in the primary link.
  - Destination IP address: Source IP address of the BFD session automatically created on the local device in the primary link.
  - Remote ID: Local ID of the BFD session automatically created on the local device in the primary link.

When you configure echo-mode BFD for nexthop connectivity detection, you only need to configure this feature on the local router.

When another routing protocol (such as OSPF or IS-IS) uses BFD to detect next hop connectivity for the primary route, it also creates a BFD session. If the detected link is the same as the link attached to the next hop of the BGP primary route, BGP reuses the BFD session created by the protocol. In this situation, BGP will not create an additional BFD session.

Procedure

1. Enter system view.

   system-view
2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
3. (Optional.) Enable BFD-powered nexthop connectivity detection for BGP FRR.

   primary-path-detect bfd { **ctrl** | **echo** }

   By default, BGP FRR uses ARP to detect nexthop connectivity for the primary route.

Configuring BGP maintenance features

About this task

For maintenance purposes, you can use either BGP isolation or BGP shutdown to remove the device from the network. The device will not be used for forwarding traffic from its peers after they reselect an optimal route. Both BGP isolation and BGP shutdown retain the device configuration to facilitate maintenance workload.

After maintenance, you can disable BGP isolation or BGP shutdown to add the device back to the network.

Configuring BGP isolation

About this task

To reduce impact on traffic forwarding, you can isolate the device from the network before upgrading it. BGP isolation works as follows:

1. BGP withdraws all routes advertised by the device except for the directly-connected routes.
2. BGP keeps all routes learned from its peers.

   With BGP isolation enabled, BGP minimizes the preferences of direct routes advertised to peers by maximizing their MED values and minimizing their local preferences.
3. Each peer of the device reselects an optimal route and updates the FIB table. During optimal route selection, the peers can still use the routes advertised by the device to forward traffic.
4. After an optimal route is selected and the FIB table is updated, the peers stop forwarding packets except for those destined for the device to the device. The device is fully isolated from the network and you can upgrade it.
5. After the maintenance, disable BGP isolation on the device to gracefully add it back to the network. After returning to the network, the device advertises and learns routes as follows:
   - Advertises routes to its peers.
   - Learns routes if BGP was restarted during the isolation.

Restrictions and guidelines

To avoid isolation failure, do not use this feature when GR or NSR is enabled for the device.

Procedure

1. Enter system view.

   system-view
2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
3. Enable BGP isolation to gracefully remove the device from the network.

   isolate enable

   By default, BGP isolation is disabled.
4. Disable BGP isolation to gracefully add the device back to the network.

   undo isolate enable

Configuring BGP shutdown

About this task

For maintenance purposes, you can use this feature to temporarily disconnect BGP sessions from all peers and peer groups. After maintenance, you can disable this feature to restore these sessions.

Restrictions and guidelines

With this feature enabled, the device tears down all sessions and clears all routing information.

The device cannot establish BGP sessions in one of the following conditions:

- BGP shutdown is configured.
- BGP session establishment is disabled. For more information about disabling BGP session establishment, see "Disabling BGP session establishment."

Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Shut down BGP sessions to all peers and peer groups.
   shutdown process
   By default, BGP does not shut down sessions to any peers or peer groups.
4. Restore the BGP sessions to add the device back to the network.
   undo shutdown process

Display and maintenance commands for BGP network reliability improvement

Execute **display** commands in any view.

Displaying BGP (IPv4 unicast address family)

Task	Command
Display BGP NSR status information.	**display bgp** [**instance** *instance-name*] **non-stop-routing status**

Displaying BGP (IPv6 unicast address family)

Task	Command
Display BGP NSR status information.	**display bgp** [**instance** *instance-name*] **non-stop-routing status**

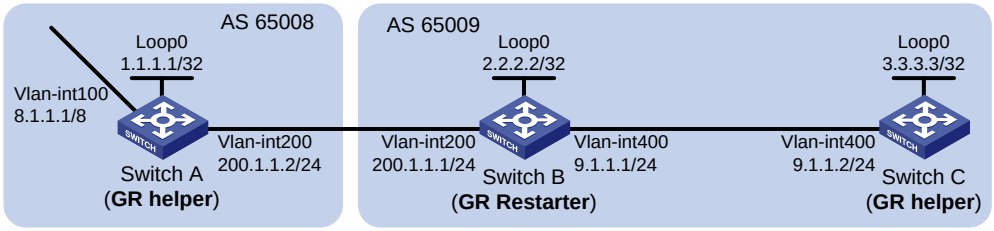
Displaying BGP (IPv4 multicast address family)

Task	Command
Display BGP NSR status information.	**display bgp** [**instance** *instance-name*] **non-stop-routing status**

Displaying BGP (IPv6 multicast address family)

Task	Command
Display BGP NSR status information.	**display bgp** [**instance** *instance-name*] **non-stop-routing status**

IPv4 BGP network reliability improvement configuration examples



Example: Configuring BGP GR

Network configuration

As shown in Figure 65, all switches run BGP. EBGP runs between Switch A and Switch B. IBGP runs between Switch B and Switch C.

Enable GR capability for BGP so that the communication between Switch A and Switch C is not affected when an active/standby switchover occurs on Switch B.

Figure 65 Network diagram

Procedure

1. Configure Switch A:

   # Configure IP addresses for interfaces. (Details not shown.)

   # Configure the EBGP connection.

   ```
   <SwitchA> system-view
   [SwitchA] bgp 65008
   [SwitchA-bgp-default] router-id 1.1.1.1
   [SwitchA-bgp-default] peer 200.1.1.1 as-number 65009
   ```

   # Enable GR capability for BGP.

   ```
   [SwitchA-bgp-default] graceful-restart
   ```

   # Inject network 8.0.0.0/8 to the BGP routing table.

   ```
   [SwitchA-bgp-default] address-family ipv4
   [SwitchA-bgp-default-ipv4] network 8.0.0.0
   ```

   # Enable Switch A to exchange IPv4 unicast routing information with Switch B.

   ```
   [SwitchA-bgp-default-ipv4] peer 200.1.1.1 enable
   ```

2. Configure Switch B:

   # Configure IP addresses for interfaces. (Details not shown.)

   # Configure the EBGP connection.

   ```
   <SwitchB> system-view
   [SwitchB] bgp 65009
   ```

```
[SwitchB-bgp-default] router-id 2.2.2.2
[SwitchB-bgp-default] peer 200.1.1.2 as-number 65008
```

Configure the IBGP connection.

```
[SwitchB-bgp-default] peer 9.1.1.2 as-number 65009
```

Enable GR capability for BGP.

```
[SwitchB-bgp-default] graceful-restart
```

Inject networks 200.1.1.0/24 and 9.1.1.0/24 to the BGP routing table.

```
[SwitchB-bgp-default] address-family ipv4
[SwitchB-bgp-default-ipv4] network 200.1.1.0 24
[SwitchB-bgp-default-ipv4] network 9.1.1.0 24
```

Enable Switch B to exchange IPv4 unicast routing information with Switch A and Switch C.

```
[SwitchB-bgp-default-ipv4] peer 200.1.1.2 enable
[SwitchB-bgp-default-ipv4] peer 9.1.1.2 enable
```

3. Configure Switch C:

Configure IP addresses for interfaces. (Details not shown.)

Configure the IBGP connection.

```
<SwitchC> system-view
[SwitchC] bgp 65009
[SwitchC-bgp-default] router-id 3.3.3.3
[SwitchC-bgp-default] peer 9.1.1.1 as-number 65009
```

Enable GR capability for BGP.

```
[SwitchC-bgp-default] graceful-restart
```

Enable Switch C to exchange IPv4 unicast routing information with Switch B.

```
[SwitchC-bgp-default-ipv4] peer 9.1.1.1 enable
```

Verifying the configuration

Ping Switch C on Switch A. Meanwhile, perform an active/standby switchover on Switch B. The ping operation is successful during the whole switchover process. (Details not shown.)

Example: Configuring BFD for BGP

Network configuration

As shown in Figure 66, configure OSPF as the IGP in AS 200.

- Establish two IBGP connections between Switch A and Switch C. When both paths operate correctly, Switch C uses the path Switch A<—>Switch B<—>Switch C to exchange packets with network 1.1.1.0/24.
- Configure BFD over the path. When the path fails, BFD can quickly detect the failure and notify it to BGP. Then, the path Switch A<—>Switch D<—>Switch C takes effect immediately.

Figure 66 Network diagram

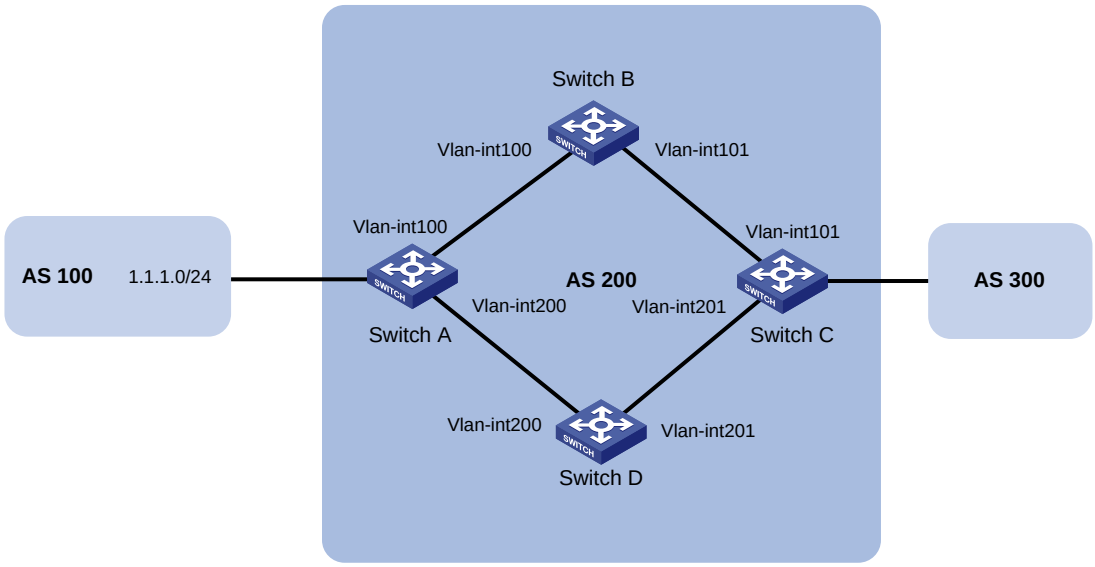


Table 16 Interface and IP address assignment

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int100	3.0.1.1/24	Switch C	Vlan-int101	3.0.2.2/24
	Vlan-int200	2.0.1.1/24		Vlan-int201	2.0.2.2/24
Switch B	Vlan-int100	3.0.1.2/24	Switch D	Vlan-int200	2.0.1.2/24
	Vlan-int101	3.0.2.1/24		Vlan-int201	2.0.2.1/24

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF to ensure that Switch A and Switch C are reachable to each other. (Details not shown.)
3. Configure BGP on Switch A:

   # Establish two IBGP connections to Switch C.

```
<SwitchA> system-view
[SwitchA] bgp 200
[SwitchA-bgp-default] peer 3.0.2.2 as-number 200
[SwitchA-bgp-default] peer 2.0.2.2 as-number 200
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 3.0.2.2 enable
[SwitchA-bgp-default-ipv4] peer 2.0.2.2 enable
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

   # Create IPv4 basic ACL 2000 to permit 1.1.1.0/24 to pass.

```
[SwitchA] acl basic 2000
[SwitchA-acl-ipv4-basic-2000] rule permit source 1.1.1.0 0.0.0.255
[SwitchA-acl-ipv4-basic-2000] quit
```

   # Create two routing policies to set the MED for route 1.1.1.0/24. The policy **apply_med_50** sets the MED to 50, and the policy **apply_med_100** sets the MED to 100.

```
[SwitchA] route-policy apply_med_50 permit node 10
```

```
[SwitchA-route-policy-apply_med_50-10] if-match ip address acl 2000
[SwitchA-route-policy-apply_med_50-10] apply cost 50
[SwitchA-route-policy-apply_med_50-10] quit
[SwitchA] route-policy apply_med_100 permit node 10
[SwitchA-route-policy-apply_med_100-10] if-match ip address acl 2000
[SwitchA-route-policy-apply_med_100-10] apply cost 100
[SwitchA-route-policy-apply_med_100-10] quit
```

Apply routing policy **apply_med_50** to routes outgoing to peer 3.0.2.2, and apply routing policy **apply_med_100** to routes outgoing to peer 2.0.2.2.

```
[SwitchA] bgp 200
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 3.0.2.2 route-policy apply_med_50 export
[SwitchA-bgp-default-ipv4] peer 2.0.2.2 route-policy apply_med_100 export
[SwitchA-bgp-default-ipv4] quit
```

Enable BFD for peer 3.0.2.2.

```
[SwitchA-bgp-default] peer 3.0.2.2 bfd
[SwitchA-bgp-default] quit
```

4. Configure BGP on Switch C:

Establish two IBGP connections to Switch A.

```
<SwitchC> system-view
[SwitchC] bgp 200
[SwitchC-bgp-default] peer 3.0.1.1 as-number 200
[SwitchC-bgp-default] peer 2.0.1.1 as-number 200
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 3.0.1.1 enable
[SwitchC-bgp-default-ipv4] peer 2.0.1.1 enable
[SwitchC-bgp-default-ipv4] quit
```

Enable BFD for peer 3.0.1.1.

```
[SwitchC-bgp-default] peer 3.0.1.1 bfd
[SwitchC-bgp-default] quit
[SwitchC] quit
```

Verifying the configuration

Display detailed BFD session information on Switch C.

```
<SwitchC> display bfd session verbose
 Total Session Num: 1     Up Session Num: 1     Init Mode: Active

     Min Rx Inter: 500ms                Detect Inter: 2500ms
         Rx Count: 135                      Tx Count: 135
     Connect Type: Indirect           Running Up for: 00:00:58
        Hold Time: 2457ms                 Auth mode: None
      Detect Mode: Async                       Slot: 01
         Protocol: BGP
          Version: 1
```

```
         Diag Info: No Diagnostic
     Hardware mode: Disable
```

The output shows that a BFD session has been established between Switch A and Switch C.

Display BGP peer information on Switch C.

```
<SwitchC> display bgp peer ipv4

 BGP local router ID: 3.3.3.3
 Local AS number: 200
 Total number of peers: 2                 Peers in established state: 2

  * - Dynamically created peer
  ^ - Peer created through link-local address
  Peer                    AS  MsgRcvd  MsgSent OutQ PrefRcv Up/Down  State

  2.0.1.1                200        4        5    0       0 00:01:55 Established

   LinkCost: 0               MicroSegID: 0
RealFIRType: Normal           RealThres: 0
```

The output shows that Switch C communicates with network 1.1.1.0/24 through the path Switch C<—>Switch D<—>Switch A.

Example: Configuring BGP FRR

Network configuration

As shown in Figure 67, configure BGP FRR so that when Link B fails, BGP uses Link A to forward traffic.

Figure 67 Network diagram

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure OSPF in AS 200 to ensure connectivity among Switch B, Switch C, and Switch D. (Details not shown.)
3. Configure BGP connections:

   # Configure Switch A to establish EBGP sessions to Switch B and Switch C, and advertise network 1.1.1.1/32.

```
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA-bgp-default] router-id 1.1.1.1
[SwitchA-bgp-default] peer 10.1.1.2 as-number 200
[SwitchA-bgp-default] peer 30.1.1.3 as-number 200
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] peer 10.1.1.2 enable
[SwitchA-bgp-default-ipv4] peer 30.1.1.3 enable
[SwitchA-bgp-default-ipv4] network 1.1.1.1 32
```

   # Configure Switch B to establish an EBGP session to Switch A, and an IBGP session to Switch D.

```
<SwitchB> system-view
[SwitchB] bgp 200
[SwitchB-bgp-default] router-id 2.2.2.2
[SwitchB-bgp-default] peer 10.1.1.1 as-number 100
[SwitchB-bgp-default] peer 4.4.4.4 as-number 200
[SwitchB-bgp-default] peer 4.4.4.4 connect-interface loopback 0
[SwitchB-bgp-default] address-family ipv4 unicast
[SwitchB-bgp-default-ipv4] peer 10.1.1.1 enable
[SwitchB-bgp-default-ipv4] peer 4.4.4.4 enable
[SwitchB-bgp-default-ipv4] peer 4.4.4.4 next-hop-local
[SwitchB-bgp-default-ipv4] quit
[SwitchB-bgp-default] quit
```

Configure Switch C to establish an EBGP session to Switch A, and an IBGP session to Switch D.

```
<SwitchC> system-view
[SwitchC] bgp 200
[SwitchC-bgp-default] router-id 3.3.3.3
[SwitchC-bgp-default] peer 30.1.1.1 as-number 100
[SwitchC-bgp-default] peer 4.4.4.4 as-number 200
[SwitchC-bgp-default] peer 4.4.4.4 connect-interface loopback 0
[SwitchC-bgp-default] address-family ipv4 unicast
[SwitchC-bgp-default-ipv4] peer 30.1.1.1 enable
[SwitchC-bgp-default-ipv4] peer 4.4.4.4 enable
[SwitchC-bgp-default-ipv4] peer 4.4.4.4 next-hop-local
[SwitchC-bgp-default-ipv4] quit
[SwitchC-bgp-default] quit
```

Configure Switch D to establish IBGP sessions to Switch B and Switch C, and advertise network 4.4.4.4/32.

```
<SwitchD> system-view
[SwitchD] bgp 200
[SwitchD-bgp-default] router-id 4.4.4.4
[SwitchD-bgp-default] peer 2.2.2.2 as-number 200
[SwitchD-bgp-default] peer 2.2.2.2 connect-interface loopback 0
[SwitchD-bgp-default] peer 3.3.3.3 as-number 200
[SwitchD-bgp-default] peer 3.3.3.3 connect-interface loopback 0
[SwitchD-bgp-default] address-family ipv4 unicast
[SwitchD-bgp-default-ipv4] peer 2.2.2.2 enable
[SwitchD-bgp-default-ipv4] peer 3.3.3.3 enable
[SwitchD-bgp-default-ipv4] network 4.4.4.4 32
```

4. Configure preferred values so Link B is used to forward traffic between Switch A and Switch D:

Configure Switch A to set the preferred value to 100 for routes received from Switch B.

```
[SwitchA-bgp-default-ipv4] peer 10.1.1.2 preferred-value 100
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

Configure Switch D to set the preferred value to 100 for routes received from Switch B.

```
[SwitchD-bgp-default-ipv4] peer 2.2.2.2 preferred-value 100
[SwitchD-bgp-default-ipv4] quit
[SwitchD-bgp-default] quit
```

5. Configure BGP FRR:

On Switch A, create routing policy **frr** to set a backup next hop 30.1.1.3 (Switch C) for the route destined for 4.4.4.4/32.

```
[SwitchA] ip prefix-list abc index 10 permit 4.4.4.4 32
[SwitchA] route-policy frr permit node 10
[SwitchA-route-policy] if-match ip address prefix-list abc
[SwitchA-route-policy] apply fast-reroute backup-nexthop 30.1.1.3
[SwitchA-route-policy] quit
```

Use BFD echo packet mode to detect the connectivity to Switch D.

```
[SwitchA] bgp 100
[SwitchA-bgp-default] primary-path-detect bfdecho
```

Apply the routing policy to BGP FRR for BGP IPv4 unicast address family.

```
[SwitchA-bgp-default] address-family ipv4 unicast
[SwitchA-bgp-default-ipv4] fast-reroute route-policy frr
[SwitchA-bgp-default-ipv4] quit
[SwitchA-bgp-default] quit
```

On Switch D, create routing policy **frr** to set a backup next hop 3.3.3.3 (Switch C) for the route destined for 1.1.1.1/32.

```
[SwitchD] ip prefix-list abc index 10 permit 1.1.1.1 32
[SwitchD] route-policy frr permit node 10
[SwitchD-route-policy] if-match ip address prefix-list abc
[SwitchD-route-policy] apply fast-reroute backup-nexthop 3.3.3.3
[SwitchD-route-policy] quit
```

Use BFD echo packet mode to detect the connectivity to Switch A.

```
[SwitchD] bgp 200
[SwitchD-bgp-default] primary-path-detect bfdecho
```

Apply the routing policy to BGP FRR for BGP IPv4 unicast address family.

```
[SwitchD-bgp-default] address-family ipv4 unicast
[SwitchD-bgp-default-ipv4] fast-reroute route-policy frr
[SwitchD-bgp-default-ipv4] quit
[SwitchD-bgp-default] quit
```

Verifying the configuration

Display detailed information about the route to 4.4.4.4/32 on Switch A. The output shows the backup next hop for the route.

```
[SwitchA] display ip routing-table 4.4.4.4 32 verbose

Summary count : 1

Destination: 4.4.4.4/32
   Protocol: BGP             Process ID: 0

```

IPv6 BGP network reliability improvement configuration examples

Example: Configuring BFD for IPv6 BGP

Network configuration

As shown in Figure 68, configure OSPFv3 as the IGP in AS 200.

- Establish two IBGP connections between Switch A and Switch C. When both paths operate correctly, Switch C uses the path Switch A<—>Switch B<—>Switch C to exchange packets with network 1200::0/64.
- Configure BFD over the path. When the path fails, BFD can quickly detect the failure and notify it to IPv6 BGP. Then, the path Switch A<—>Switch D<—>Switch C takes effect immediately.

Figure 68 Network diagram

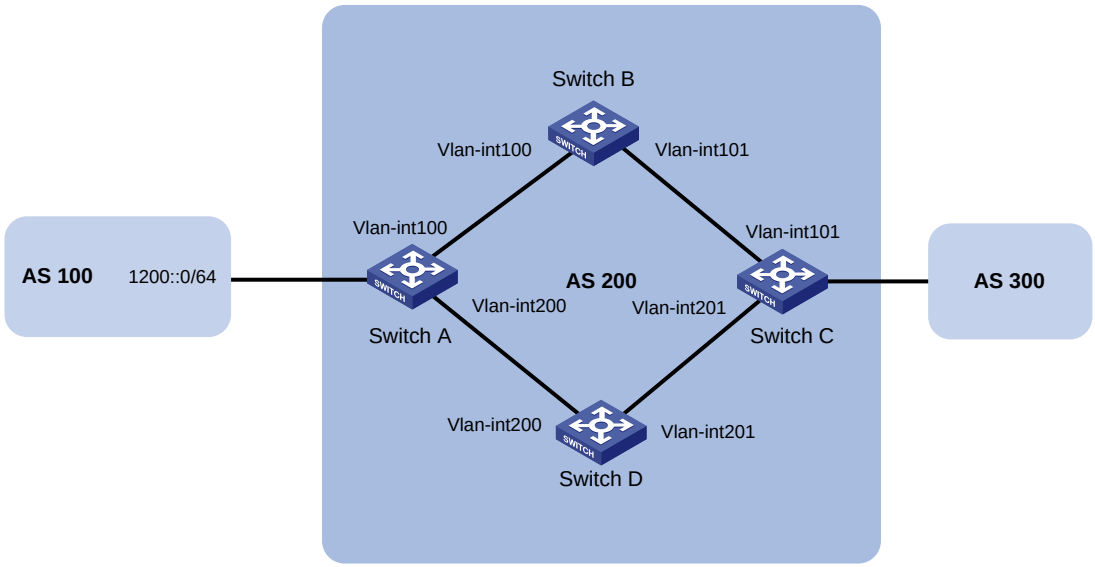

Table 17 Interface and IP address assignment

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int100	3000::1/64	Switch C	Vlan-int101	3001::3/64
	Vlan-int200	2000::1/64		Vlan-int201	2001::3/64
Switch B	Vlan-int100	3000::2/64	Switch D	Vlan-int200	2000::2/64
	Vlan-int101	3001::2/64		Vlan-int201	2001::2/64

Procedure

1. Configure IPv6 addresses for interfaces. (Details not shown.)
2. Configure OSPFv3 so that Switch A and Switch C can reach each other. (Details not shown.)
3. Configure IPv6 BGP on Switch A:

   # Establish two IBGP connections to Switch C.

```
<SwitchA> system-view
[SwitchA] bgp 200
[SwitchA-bgp-default] router-id 1.1.1.1
[SwitchA-bgp-default] peer 3001::3 as-number 200
[SwitchA-bgp-default] peer 2001::3 as-number 200
[SwitchA-bgp-default] address-family ipv6
[SwitchA-bgp-default-ipv6] peer 3001::3 enable
[SwitchA-bgp-default-ipv6] peer 2001::3 enable
[SwitchA-bgp-default-ipv6] quit
```

   # Create IPv6 basic ACL 2000 to permit 1200::0/64 to pass.

```
[SwitchA] acl ipv6 basic 2000
[SwitchA-acl-ipv6-basic-2000] rule permit source 1200:: 64
[SwitchA-acl-ipv6-basic-2000] quit
```

   # Create two routing policies to set the MED for route 1200::0/64. The policy **apply_med_50** sets the MED to 50, and the policy **apply_med_100** sets the MED to 100.

```
[SwitchA] route-policy apply_med_50 permit node 10
```

```
[SwitchA-route-policy-apply_med_50-10] if-match ipv6 address acl 2000
[SwitchA-route-policy-apply_med_50-10] apply cost 50
[SwitchA-route-policy-apply_med_50-10] quit
[SwitchA] route-policy apply_med_100 permit node 10
[SwitchA-route-policy-apply_med_100-10] if-match ipv6 address acl 2000
[SwitchA-route-policy-apply_med_100-10] apply cost 100
[SwitchA-route-policy-apply_med_100-10] quit
```

Apply routing policy **apply_med_50** to routes outgoing to peer 3001::3, and apply routing policy **apply_med_100** to routes outgoing to peer 2001::3.

```
[SwitchA] bgp 200
[SwitchA-bgp-default] address-family ipv6 unicast
[SwitchA-bgp-default-ipv6] peer 3001::3 route-policy apply_med_50 export
[SwitchA-bgp-default-ipv6] peer 2001::3  route-policy apply_med_100 export
[SwitchA-bgp-default-ipv6] quit
```

Enable BFD for peer 3001::3.

```
[SwitchA-bgp-default] peer 3001::3 bfd
[SwitchA-bgp-default] quit
```

4. Configure IPv6 BGP on Switch C:

Establish two IBGP connections to Switch A.

```
<SwitchC> system-view
[SwitchC] bgp 200
[SwitchC-bgp-default] router-id 3.3.3.3
[SwitchC-bgp-default] peer 3000::1 as-number 200
[SwitchC-bgp-default] peer 2000::1 as-number 200
[SwitchC-bgp-default] address-family ipv6
[SwitchC-bgp-default-ipv6] peer 3000::1 enable
[SwitchC-bgp-default-ipv6] peer 2000::1 enable
[SwitchC-bgp-default-ipv6] quit
```

Enable BFD for peer 3001::1.

```
[SwitchC-bgp-default] peer 3000::1 bfd
[SwitchC-bgp-default] quit
[SwitchC] quit
```

Verifying the configuration

Display detailed BFD session information on Switch C.

```
<SwitchC> display bfd session verbose
Total Session Num: 1     Up Session Num: 1     Init Mode: Active

 IPv6 Session Working in control packet mode:
       Local Discr: 513                 Remote Discr: 513
         Source IP: 3001::3
    Destination IP: 3000::1
     Session State: Up                     Interface: N/A
      Min Tx Inter: 500ms                Act Tx Inter: 500ms
      Min Rx Inter: 500ms                Detect Inter: 2500ms
          Rx Count: 13                       Tx Count: 14
      Connect Type: Indirect           Running Up for: 00:00:05
         Hold Time: 2243ms                  Auth mode: None
       Detect Mode: Async                        Slot: 01
```

```
          Protocol: BGP4+
           Version:1
         Diag Info: No Diagnostic
     Hardware mode: Disable
```

The output shows that a BFD session has been established between Switch A and Switch C.

Display BGP peer information on Switch C.

```
<SwitchC> display bgp peer ipv6

 BGP local router ID: 3.3.3.3
 Local AS number: 200
 Total number of peers: 2                 Peers in established state: 2

  * - Dynamically created peer
  ^ - Peer created through link-local address
  Peer                    AS  MsgRcvd  MsgSent OutQ PrefRcv Up/Down  State

  2000::1                200        8        8    0       0 00:04:45 Established
  3000::1                200        5        4    0       0 00:01:53 Established
```

The output shows that Switch C has established two BGP connections with Switch A, and both connections are in Established state.

Display route 1200::0/64 on Switch C.

```
<SwitchC> display ipv6 routing-table 1200::0 64 verbose

Summary count : 1

Destination: 1200::/64
   Protocol: BGP4+           Process ID: 0

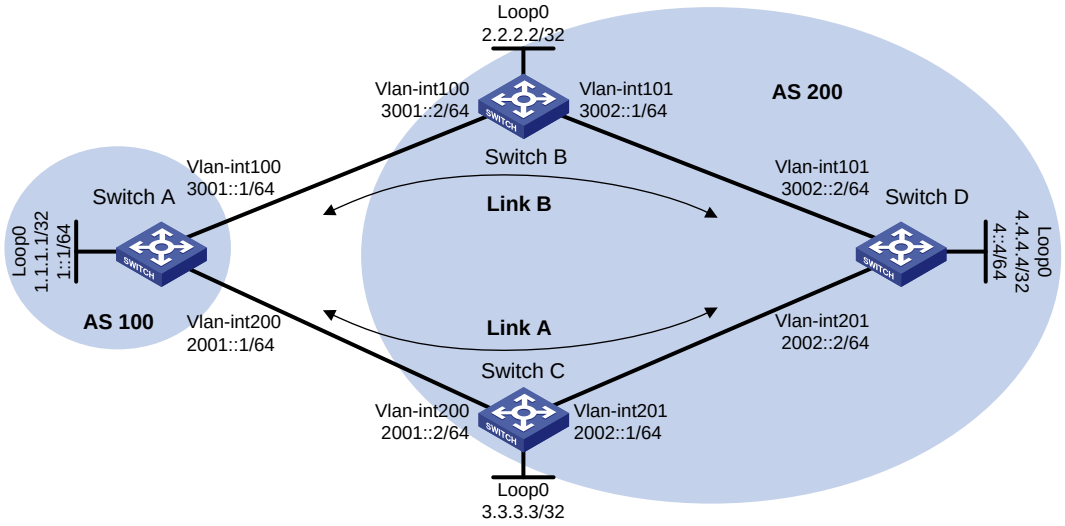
RealFIRType: Normal            RealThres: 0
```



The output shows that Switch C communicates with network 1200::0/64 through the path Switch C<—>Switch D<—>Switch A.

Example: Configuring IPv6 BGP FRR

Network configuration

As shown in Figure 69, configure BGP FRR so that when Link B fails, BGP uses Link A to forward traffic.

Figure 69 Network diagram

Procedure

1. Configure IPv6 addresses for interfaces. (Details not shown.)
2. Configure OSPFv3 in AS 200 to ensure connectivity among Switch B, Switch C, and Switch D. (Details not shown.)
3. Configure BGP connections:

   # Configure Switch A to establish EBGP sessions to Switch B and Switch C, and advertise network 1::/64.

```
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA] router-id 1.1.1.1
[SwitchA-bgp-default] peer 3001::2 as-number 200
[SwitchA-bgp-default] peer 2001::2 as-number 200
[SwitchA-bgp-default] address-family ipv6 unicast
[SwitchA-bgp-default-ipv6] peer 3001::2 enable
[SwitchA-bgp-default-ipv6] peer 2001::2 enable
[SwitchA-bgp-default-ipv6] network 1:: 64
[SwitchA-bgp-default-ipv6] quit
[SwitchA-bgp-default] quit
```

   # Configure Switch B to establish an EBGP session to Switch A, and an IBGP session to Switch D.

```
<SwitchB> system-view
[SwitchB] bgp 200
[SwitchB] router-id 2.2.2.2
[SwitchB-bgp-default] peer 3001::1 as-number 100
[SwitchB-bgp-default] peer 3002::2 as-number 200
[SwitchB-bgp-default] address-family ipv6 unicast
[SwitchB-bgp-default-ipv6] peer 3001::1 enable
[SwitchB-bgp-default-ipv6] peer 3002::2 enable
[SwitchB-bgp-default-ipv6] peer 3002::2 next-hop-local
[SwitchB-bgp-default-ipv6] quit
[SwitchB-bgp-default] quit
```

Configure Switch C to establish an EBGP session to Switch A, and an IBGP session to Switch D.

```
<SwitchC> system-view
[SwitchC] bgp 200
[SwitchC] router-id 3.3.3.3
[SwitchC-bgp-default] peer 2001::1 as-number 100
[SwitchC-bgp-default] peer 2002::2 as-number 200
[SwitchC-bgp-default] address-family ipv6 unicast
[SwitchC-bgp-default-ipv6] peer 2001::1 enable
[SwitchC-bgp-default-ipv6] peer 2002::2 enable
[SwitchC-bgp-default-ipv6] peer 2002::2 next-hop-local
[SwitchC-bgp-default-ipv6] quit
[SwitchC-bgp-default] quit
```

Configure Switch D to establish IBGP sessions to Switch B and Switch C, and advertise network 4::/64.

```
<SwitchD> system-view
[SwitchD] bgp 200
[SwitchD-bgp-default] peer 3002::1 as-number 200
[SwitchD-bgp-default] peer 2002::1 as-number 200
[SwitchD-bgp-default] address-family ipv6 unicast
[SwitchD-bgp-default-ipv6] peer 3002::1 enable
[SwitchD-bgp-default-ipv6] peer 2002::1 enable
[SwitchD-bgp-default-ipv6] network 4:: 64
[SwitchD-bgp-default-ipv6] quit
[SwitchD-bgp-default] quit
```

4. Configure preferred values so Link B is used to forward traffic between Switch A and Switch D:

Configure Switch A to set the preferred value to 100 for routes received from Switch B.

```
[SwitchA-bgp-default-ipv6] peer 3001::2 preferred-value 100
[SwitchA-bgp-default-ipv6] quit
[SwitchA-bgp-default] quit
```

Configure Switch D to set the preferred value to 100 for routes received from Switch B.

```
[SwitchD-bgp-default-ipv6] peer 3002::1 preferred-value 100
[SwitchD-bgp-default-ipv6] quit
[SwitchD-bgp-default] quit
```

5. Configure BGP FRR:

On Switch A, create routing policy **frr** to set a backup next hop 2001::2 (Switch C) for the route destined for 4::/64.

```
<SwitchA> system-view
[SwitchA] ipv6 prefix-list abc index 10 permit 4:: 64
[SwitchA] route-policy frr permit node 10
[SwitchA-route-policy] if-match ipv6 address prefix-list abc
[SwitchA-route-policy] apply ipv6 fast-reroute backup-nexthop 2001::2
[SwitchA-route-policy] quit
```

Apply the routing policy to BGP FRR for BGP IPv6 unicast address family.

```
[SwitchA] bgp 100
[SwitchA-bgp-default] address-family ipv6 unicast
[SwitchA-bgp-default-ipv6] fast-reroute route-policy frr
[SwitchA-bgp-default-ipv6] quit
```

```
[SwitchA-bgp-default] quit
```

On Switch D, create routing policy **frr** to set a backup next hop 2002::1 (Switch C) for the route destined for 1::/64.

```
<SwitchD> system-view
[SwitchD] ipv6 prefix-list abc index 10 permit 1:: 64
[SwitchD] route-policy frr permit node 10
[SwitchD-route-policy] if-match ipv6 address prefix-list abc
[SwitchD-route-policy] apply ipv6 fast-reroute backup-nexthop 2002::1
[SwitchD-route-policy] quit
```

Apply the routing policy to BGP FRR for BGP IPv6 unicast address family.

```
[SwitchD] bgp 200
[SwitchD-bgp-default] address-family ipv6 unicast
[SwitchD-bgp-default-ipv6] fast-reroute route-policy frr
[SwitchD-bgp-default-ipv6] quit
[SwitchD-bgp-default] quit
```

Verifying the configuration

Display detailed information about the route to 4::/64 on Switch A. The output shows the backup next hop for the route.

```
[SwitchA] display ipv6 routing-table 4:: 64 verbose

Summary count : 1

Destination: 4::/64
   Protocol: BGP4+           Process ID: 0
  SubProtID: 0x2                    Age: 00h00m58s
       Cost: 0              Preference: 255
      IpPre: N/A            QosLocalID: N/A
        Tag: 0                   State: Active Adv
  OrigTblID: 0x0               OrigVrf: default-vrf
    TableID: 0xa                OrigAs: 200
      NibID: 0x25000003         LastAs: 200
     AttrID: 0x3              Neighbor: 3001::2
      Flags: 0x10060        OrigNextHop: 3001::2
      Label: NULL           RealNextHop: 3001::2
    BkLabel: NULL             BkNextHop: 2001::2

```

Configuring extended BGP features

Extended BGP feature configuration tasks at a glance

To configure extended BGP features, perform the following tasks:

- Configuring BMP
- Configuring BGP LS
  - Configuring basic BGP LS
  - (Optional.) Configuring BGP LS route reflection
  - (Optional.) Specifying an AS number and a router ID for BGP LS messages
  - (Optional.) Performing manual soft-reset for BGP sessions of LS address family
- Configuring BGP dedicated routes
  - Configuring basic BGP dedicated route settings
  - (Optional.) Configuring BGP dedicated route reflection
  - (Optional.) Resetting BGP sessions in dedicated address family

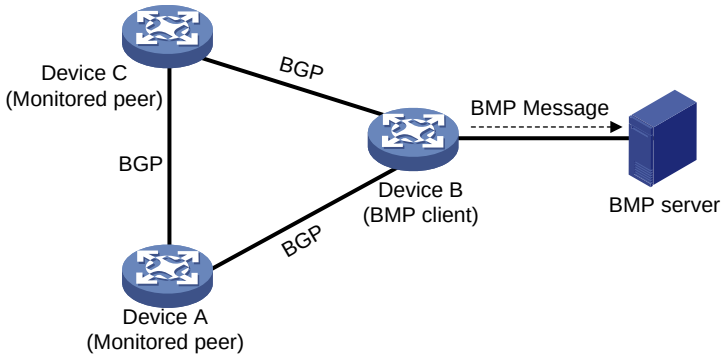
Configuring BMP

About this task

BGP monitors only the real-time states of BGP sessions and BGP routes. It cannot directly monitor session state change and route update processes. To resolve this issue, configure the BGP monitoring protocol (BMP) feature. BMP enables a BGP router (BMP client) to send session state information of the specified peers to BMP servers for monitoring. The session status information includes peer relationship establishment and termination as well as routing information.

BMP benefits

- BMP uses TCP as its transmission layer protocol, which ensures the transmission reliability.
- As an extended feature of BGP, BMP collects the required information through a simple work mechanism.
- All BMP settings are configured on the BMP client, which simplifies the configuration and management.
- To implement BMP, the BMP client only needs to send BMP packets to the BMP server. It does not require any BMP packets from the BMP server, which barely affects the current network.



BMP components

BMP contains the following components:

- **Client**—Device configured with the BMP feature. You must specify the IP address and port number of the BMP server on the BMP client to enable them to establish a TCP connection. A BMP client can connect to multiple BMP servers.
- **Server**— Monitoring server.
- **Monitored peer**—Device being monitored. It must be a peer of the BMP client.

As shown in Figure 70, Device A, Device B, and Device C have established a BGP session with one another. You can configure BMP on Device B (BMP client) to enable the BMP server to monitor the running state changes and route updates of Device A and Device C (monitored peers).

Figure 70 BMP components

BMP messages

BMP defines the following messages:

- **Initiation**—After establishing a TCP connection to the BMP server, the BMP client sends an initiation message to the BMP server to report its software version and vendor.
- **Termination**—Reports TCP connection down causes to the BMP server. After sending a termination message to the BMP server, the BMP client terminates the TCP connection and stops sending messages to the BMP server through the TCP connection.
- **Peer Up Notification**—Reports information about BGP sessions between the BMP client and monitored peers to the BMP server. A peer up notification contains information in the open messages exchanged with a monitored peer and TCP connection information. The BMP client will send a peer up notification for each BGP session in established state.
- **Peer Down Notification**—Reports BGP session down events and causes to the BMP server. The BMP client sends a peer down notification when the state of a monitored peer changes from Established to another value.
- **Stats Reports**—Reports BGP running statistics information to the BMP server. The statistics information includes number of routes discarded because of duplicated AS path attributes, number of routes received from peers, and number of duplicated up messages.
- **Route Monitoring**—Reports BGP routes (including initial, updated, and withdrawal routes) exchanged between the BMP client and monitored peers to the BMP server.

BMP mechanism

BMP works as follows:

1. The BMP client establishes a TCP connection with the BMP server.
2. The BMP client sends an initiation message to the BMP server to advertise its information.
3. The BMP client sends a peer up notification and a route monitoring message to the BMP server to advertise the initial state and routing information of the monitored peer.
4. The BMP client sends peer up notifications, peer down notifications, route monitoring messages, and stats reports to the BMP server to report state changes and route updates of the monitored peers.
5. The BMP client sends a termination message to the BMP server and tears down the TCP connection to terminate the monitoring.

BMP configuration tasks at a glance

To configure BMP, perform the following tasks on the BMP client:

- Establishing a TCP connection between the BMP client and BMP server
- Enabling a BMP server to monitor a peer or peer group

- Sending routes to the BMP server
- Configuring the BMP client to send notifications with mode flags to the BMP server
- Sending statistics information to the BMP server

Establishing a TCP connection between the BMP client and BMP server

1. Enter system view.
   system-view
2. Create a BMP server and enter BMP server view.
   bmp server *server-number*
3. Configure an IP address and port number for the BMP server.
   server address { *ipv4-address* | *ipv6-address* } **port** *port-number*
   By default, no IP address and port number are configured for the BMP server.
4. (Optional.) Specify a VPN instance for the BMP server.
   server vpn-instance *vpn-instance-name*
   By default, no VPN instance is specified for a BMP server. A BMP server belongs to the public network.
5. (Optional.) Specify the source interface of TCP connections to the BMP server.
   server connect-interface *interface-type interface-number*
   By default, BGP uses the primary IPv4 or IPv6 address of the output interface in the optimal route to the BMP server as the source address of TCP connections to the BMP server.
   For a BMP server, this command does not take effect if the VPN instance of the specified interface is different from that specified by the **server vpn-instance** command.
6. (Optional.) Specify the source address of TCP connections to the BMP server.
   server source-address { *ipv4-address* | *ipv6-address* }
   By default, BGP uses the primary IPv4 or IPv6 address of the output interface in the optimal route to the BMP server as the source address of TCP connections to the BMP server.
   If you execute both this command and the **server connect-interface** command for a BMP server, the configuration of this command takes effect.
7. (Optional.) Specify the authentication mode and key for the local device to establish TCP connections to the BMP server.
   server password { **keychain** *keychain-name* | **md5** { **cipher** | **simple** } *string* }
   By default, the local device establishes TCP connections to the BMP server without authentication.

Enabling a BMP server to monitor a peer or peer group

About this task

You can execute one of the following commands to enable a BMP server to monitor BGP peers:

- Execute the **peer bmp server** command to enable the specified BMP server to monitor the specified peer or peer group.
- Execute the **bmp server monitor current-instance** command to enable the specified BMP server to monitor all peers in the current instance.

- Execute the **bmp server monitor all-vpn-instance** command to enable the specified BMP server to monitor all peers in all BGP-VPN instances.

For a BGP peer, the following rules apply:

- The BMP server specified by the **peer bmp server** command takes precedence over that specified by the **bmp server monitor current-instance** command.
- The BMP server specified by the **bmp server monitor current-instance** command takes precedence over that specified by the **bmp server monitor all-vpn-instance** command.

Procedure

1. Enter system view.

   system-view
2. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
3. Enable a BMP server to monitor a peer or peer group. Choose the options to configure as needed:
   - Enable the specified BMP server to monitor the specified peer or peer group.

     peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | *link-local-address* **interface** *interface-type interface-number* } **bmp server** *server-number-list*

     interface-peer *interface-type interface-number* **bmp server** *server-number-list*

     By default, a BMP server cannot monitor a peer or peer group.
   - Enable the specified BMP server to monitor all peers in the current instance.

     bmp server *server-number* **monitor current-instance** [**route-mode** { **adj-rib-in** { **pre-policy** | **post-policy** | **both** } | **adj-rib-out** { **pre-policy** | **post-policy** | **both** } } *]

     By default, a BMP server cannot monitor the peers in the current instance.
   - Enable the specified BMP server to monitor all peers in all BGP-VPN instances.

     bmp server *server-number* **monitor all-vpn-instance** [**route-mode** { **adj-rib-in** { **pre-policy** | **post-policy** | **both** } | **adj-rib-out** { **pre-policy** | **post-policy** | **both** } } *]

     By default, a BMP server cannot monitor the peers in a BGP-VPN instance.

     This command is not supported in BGP-VPN instance view.

Sending routes to the BMP server

About this task

For a peer or peer group, the following rules apply when BGP determines the type of routes to send to the BMP server:

- The route type specified by the **peer route-mode** command takes precedence over that specified by the **bmp server monitor current-instance route-mode** command.

- The route type specified by the **bmp server monitor current-instance route-mode** command takes precedence over that specified by the **bmp server monitor all-vpn-instance route-mode** command.
- The route type specified by the **bmp server monitor all-vpn-instance route-mode** command takes precedence over that specified by the **route-mode adj-rib-in** or **route-mode adj-rib-out** command.

You can execute the **route-mode loc-rib** command to configure BGP to send the optimal routes in the routing table to the BMP server.

Procedure

1. Enter system view.

   system-view
2. Enter BMP server view.

   bmp server *server-number*
3. (Optional.) Enable BGP to send routes to the BMP server globally. Choose the following options to configure as needed:
   - Enable BGP to send routes advertised to all the monitored peers and peer groups to the BMP server.

     route-mode adj-rib-out [**pre-policy** | **post-policy** | **both**]

     By default, BGP does not send routes advertised to a monitored peer or peer group to the BMP server.
   - Enable BGP to send routes received from all the monitored peers and peer groups to the BMP server.

     route-mode adj-rib-in [**pre-policy** | **post-policy** | **both**]

     By default, BGP does not send routes received from a monitored peer or peer group to the BMP server.
   - Configure BGP to send the optimal routes in the routing table to the BMP server.

     route-mode loc-rib

     By default, BGP does not send the optimal routes in the routing table to the BMP server.

     With this feature configured, BGP sends all routes to the BMP server first. If routes update later, BGP sends only the optimal routes to the server.
4. Return to system view.

   quit
5. Enter BGP instance view or BGP-VPN instance view.
   - Enter BGP instance view.

     bgp *as-number* [**instance** *instance-name*]
   - Execute the following commands in sequence to enter BGP-VPN instance view:

     bgp *as-number* [**instance** *instance-name*]

     ip vpn-instance *vpn-instance-name*
6. Enable BGP to send routes exchanged with a monitored peer or peer group to the BMP server. Choose the following options to configure as needed:
   - Enable BGP to send routes exchanged with the specified monitored peer or peer group to the BMP server.

     peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **route-mode** { **adj-rib-in** { **pre-policy** | **post-policy** | **both** } | **adj-rib-out** { **pre-policy** | **post-policy** | **both** } } *

- Enable BGP to send routes exchanged with all the monitored peers and peer groups in the current instance to the BMP server.

  bmp server *server-number* **monitor current-instance route-mode** { **adj-rib-in** { **pre-policy** | **post-policy** | **both** } | **adj-rib-out** { **pre-policy** | **post-policy** | **both** } } *

- Enable BGP to send routes exchanged with all the monitored peers and peer groups in all BGP-VPN instances to the BMP server.

  bmp server *server-number* **monitor all-vpn-instance route-mode** { **adj-rib-in** { **pre-policy** | **post-policy** | **both** } | **adj-rib-out** { **pre-policy** | **post-policy** | **both** } } *

  This command is not supported in BGP-VPN instance view.

By default, BGP determines whether to send routes exchanged with a peer or peer group to the BMP server based on the following configurations:

- Configuration of the **route-mode adj-rib-in** command in BMP server view.
- Configuration of the **route-mode adj-rib-out** command in BMP server view.

Configuring the BMP client to send notifications with mode flags to the BMP server

About this task

Perform this task to configure the BMP client to send peer up/down notifications with the following flags:

- **Adj-RIB-In**—The BMP client sends routes received from monitored peers to the BMP server.
- **Adj-RIB-Out**—The BMP client sends routes advertised to monitored peers to the BMP server.
- **pre-policy**—The BMP client sends routes to the BMP server without filtering.
- **post-policy**—The BMP client sends routes to the BMP server after filtering.

By default, the BMP client sends peer up/down notifications with the Adj-RIB-In and pre-policy flags to the BMP server after you configure this feature.

- After you add a route sending mode by executing the **route-mode adj-rib-in**, **route-mode adj-rib-out**, or **peer route-mode** command, the BMP client will send peer up notifications with the new mode flag to the BMP server.
- After you delete the route sending mode by executing the **route-mode adj-rib-in**, **route-mode adj-rib-out**, or **peer route-mode** command, the BMP client will send peer down notifications with the new mode flag to the BMP server.

For example, if you execute the **route-mode adj-rib-out post-policy** command after executing the **route-mode adj-rib-out pre-policy** command, the BMP client sends routes to the BMP server after filtering. The BMP client will send both peer up and peer down notifications with the new mode flags to the BMP server.

Procedure

1. Enter system view.

   system-view

2. Enter BMP server view.

   bmp server *server-number*

3. Configure the BMP client to send notifications with mode flags to the BMP server. Choose a minimum of one task.

- Configure the BMP client to send peer up notifications with mode flags to the BMP server.
  pu-monitor-mode enable
- Configure the BMP client to send peer down notifications with mode flags to the BMP server.
  pd-monitor-mode enable

By default, the BMP client sends peer up/down notifications without mode flags to the BMP server.

Sending statistics information to the BMP server

About this task

The BMP client uses stats reports to report statistics information to the BMP server. Perform this task to set the interval at which the BMP client sends stats reports to the BMP server.

Procedure

1. Enter system view.
   system-view
2. Create a BMP server and enter BMP server view.
   bmp server *server-number*
3. Set the interval at which the BMP client sends statistics information to the BMP server.
   statistics-interval *value*
   By default, the BMP client does not send statistics information to the BMP server.

Configuring BGP LS

About BGP LS

Traditional BGP focuses on the propagation of routing information and lacks detailed understanding of network topology and link conditions. BGP Link State (LS) is a feature that collects and reports network topology information and link state information to the controller. This feature helps network administrators better understand and manage network links. Although IGPs can report network topology information and link state information to the controller, they have the following disadvantages:

- The controllers need to support those IGPs and their algorithms, which requires higher compute performance.
- IGPs cannot collect information across different domains.
- Different IGPs report information to the controller separately. It is complex for the controller to process the reported information.

With BGP LS configured, BGP can report the link state and topology information collected by IGPs to the controller, regardless of the IGP capabilities of the controller. In addition, BGP supports cross-domain deployment. All BGP LS-enabled devices can maintain a complete link state database with the route advertisement mechanism of BGP. The topology information reported to the controller will also be complete.

The link state and topology information collected through BGP LS helps achieve the following purposes:

- **Topology maintenance and calculation**: This information can be used for calculating the shortest paths and building network maps.

- **Path selection optimization**: Network administrators can optimize path selection results based on this information.
- **Link failure detection**: Network administrators can quickly detect link failures by using this information.
- **Support for advanced applications**: This information provides support for multiple tasks, such as traffic engineering, network planning, and resource allocation.

BGP LS extensions

BGP places network topology and link state information in a series of NLRIs, and adds those NLRIs into the MP_REACH_NLRI and MP_UNREACH_NLRI attributes of BGP UPDATE messages. This approach allows BGP LS peers to exchange topology and link state information.

Configuring basic BGP LS

1. Enter system view.

   system-view
2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]
3. Specify an AS number for an LS peer or peer group.

   peer { *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **as-number** *as-number*

   By default, no AS number is specified.
4. Create the BGP LS address family and enter its view.

   address-family link-state
5. Enable the device to exchange LS information with the peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **enable**

   By default, the device cannot exchange LS information with the peer or peer group.
6. (Optional.) Set the optimal route selection delay timer for BGP LS routes. Choose one of the following option:
   - Enable optimal route selection delay for all routes in the address family.

     route-select delay *delay-value*

     With this command configured, the device delays optimal route selection as long as the address family has a route change.
   - Enable optimal route selection delay based on DOWN-to-UP peer state changes.

     route-select suppress on-peer-up *milliseconds*

     With this command configured, when the state of a peer changes from DOWN to UP, the device performs optimal route selection for BGP routes received from that peer only after the delay timer expires.

   By default, the device does not delay optimal route selection.

Configuring BGP LS route reflection

About this task

Perform this task to configure a BGP route reflector and its clients. The route reflector and its clients automatically form a cluster identified by the router ID of the route reflector. The route reflector forwards route updates among its clients.

Procedure

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Enter BGP LS address family view.
   address-family link-state
4. Configure BGP LS route reflection.
   - Configure the device as a route reflector and specify a peer or peer group as its client.
     peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **reflect-client**
     By default, no route reflector or client is configured.
   - (Optional.) Enable route reflection between clients.
     reflect between-clients
     By default, route reflection between clients is enabled.
     This command can reduce the number of IBGP connections in an AS.
   - (Optional.) Configure the cluster ID of the route reflector.
     reflector cluster-id { *cluster-id* | *ipv4-address* }
     By default, a route reflector uses its own router ID as the cluster ID.

Specifying an AS number and a router ID for BGP LS messages

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Enter BGP LS address family view.
   address-family link-state
4. Specify an AS number and a router ID for BGP LS messages.
   domain-distinguisher *as-number:router-id*
   By default, the AS number and router ID of the current BGP process are used.
   Configure this command to ensure that LS messages sent by devices in the same AS have the same AS number and router ID.

Performing manual soft-reset for BGP sessions of LS address family

1. Enter system view.
   system-view
2. Enter BGP instance view.
   bgp *as-number* [**instance** *instance-name*]
3. Enable BGP route refresh.
   - Enable BGP route refresh for a peer or peer group.

peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **capability-advertise route-refresh**

- Enable the BGP route refresh, multi-protocol extension, and 4-byte AS number features for a peer or peer group.

  undo peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **capability-advertise conventional**

By default, the BGP route refresh, multi-protocol extension, and 4-byte AS number features are enabled.

4. Perform manual soft-reset for BGP sessions of LS address family:
   a. Return to system view.

      quit

   b. Return to user view.

      quit

   c. Perform manual soft-reset for BGP sessions of LS address family.

      refresh bgp [**instance** *instance-name*] { *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | **all** | **external** | **group** *group-name* | **internal** } { **export** | **import** } **link-state**

Configuring BGP dedicated routes

About BGP dedicated routes

As shown in Figure 71, Device B and Device C are EBGP peers of both Device A and Device D, and the EBGP peers can exchange dedicated routes. Both Device A and Device D are enabled with IPSG. When a client accesses Device A through AP 1, Device A generates an IPSG binding for the client based on the DHCP, DHCPv6, or ND snooping entry. Then, Device B and Device C synchronize the IPSG binding of the client through BGP dedicated routes, and they synchronize the IPSG binding to Device D. When the client migrates from Device A to Device D, the client can quickly come online based on the synchronized IPSG binding. For more information about IPSG and IPSG bindings, see IP source guard configuration in *Security Configuration Guide*.

Figure 71 Network diagram

Configuring basic BGP dedicated route settings

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Specify an AS number for a peer or peer group.

   peer { *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **as-number** *as-number*

   By default, no AS number is specified for a peer or peer group.

4. Create the BGP dedicated address family and enter its view.

   address-family dedicated

5. Enable BGP to exchange dedicated routes with a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **enable**

   By default, BGP cannot exchange dedicated routes with a peer or peer group.

6. (Optional.) Specify the device as the next hop for routes sent to a peer or peer group.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **next-hop-local**

   By default, the device sets itself as the next hop for routes sent to an EBGP peer or peer group. It does not set itself as the next hop for routes sent to an IBGP peer or peer group.

7. (Optional.) Permit the local AS number to appear in routes from a peer or peer group and set the appearance times.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **allow-as-loop** [*number*]

   By default, the local AS number is not allowed in routes from a peer or peer group.

Configuring BGP dedicated route reflection

About this task

Perform this task to configure a BGP route reflector and its clients. The route reflector and its clients automatically form a cluster identified by the router ID of the route reflector. The route reflector forwards route updates among its clients.

Procedure

1. Enter system view.

   system-view

2. Enter BGP instance view.

   bgp *as-number* [**instance** *instance-name*]

3. Enter BGP dedicated address family view.

   address-family dedicated

4. Configure the device as a route reflector and specify a peer or peer group as its client.

   peer { *group-name* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] } **reflect-client**

   By default, no route reflector or client is configured.

5. (Optional.) Enable route reflection between clients.

   reflect between-clients

   By default, route reflection between clients is enabled.

   This command can reduce the number of IBGP connections in an AS.

6. (Optional.) Configure the cluster ID of the route reflector.

   reflector cluster-id { *cluster-id* | *ipv4-address* }

By default, a route reflector uses its own router ID as the cluster ID.

Resetting BGP sessions in dedicated address family

Execute one command in user view.

- Perform manual soft-reset on BGP sessions of the dedicated address family.

  refresh bgp [**instance** *instance-name*] { *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | **all** | **external** | **group** *group-name* | **internal** } { **export** | **import** } **dedicated**

- Reset BGP sessions of the dedicated address family.

  reset bgp [**instance** *instance-name*] { *as-number* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | **all** | **external** | **group** *group-name* | **internal** } **dedicated**

Display and maintenance commands for extended BGP features

Displaying BGP

Execute **display** commands in any view.

Displaying BGP (IPv4 unicast address family)

Task	Command
Display BMP server information.	**display bgp** [**instance** *instance-name*] **bmp server** *server-number*
Display information about BGP peers monitored by the specified BMP server for the specified BGP instance.	**display bgp** [**instance** *instance-name*] **bmp server** *server-number* **monitor-peer all** **display bgp** [**instance** *instance-name*] **bmp server** *server-number* **monitor-peer** [**vpn-instance** *vpn-instance-name*] **ipv4** { *ipv4-address* | *ipv6-address* }

Displaying BGP (IPv6 unicast address family)

Task	Command
Display information about BGP peers monitored by the specified BMP server for the specified BGP instance.	**display bgp** [**instance** *instance-name*] **bmp server** *server-number* **monitor-peer all** **display bgp** [**instance** *instance-name*] **bmp server** *server-number* **monitor-peer** [**vpn-instance** *vpn-instance-name*] **ipv6** { *ipv4-address* | *ipv6-address* }

Displaying BGP (IPv4 multicast address family)

Task	Command
Display BMP server information.	**display bgp** [**instance** *instance-name*] **bmp server** *server-number*

Displaying BGP (LS address family)

Task	Command
Display BGP LS peer group information.	**display bgp** [**instance** *instance-name*] **group link-state** [**group-name** *group-name*]
Display BGP LS information.	**display bgp** [**instance** *instance-name*] **link-state** [*ls-prefix* [**advertise-info** | **as-path** | **cluster-list**] | **peer** { *ipv4-address* | *ipv6-address* } { **advertised** | **received** } [**statistics**] | **statistics**]
Display BGP LS peer or peer group information.	**display bgp** [**instance** *instance-name*] **peer link-state** [*ipv4-address mask-length* | *ipv6-address prefix-length* | { *ipv4-address* | *ipv6-address* | **group-name** *group-name* } **log-info** | [*ipv4-address* | *ipv6-address*] **verbose**]
Display BGP LS address family update group information.	**display bgp** [**instance** *instance-name*] **update-group link-state** [*ipv4-address* | *ipv6-address*]

Displaying BGP (dedicated address family)

Task	Command
Display BGP dedicated peer group information.	**display bgp** [**instance** *instance-name*] **group dedicated** [**group-name** *group-name*]
Display BGP dedicated peer or peer group information.	**display bgp** [**instance** *instance-name*] **peer dedicated** [{ *ipv4-address mask-length* | *ipv6-address prefix-length* } | { *ipv4-address* | *ipv6-address* | **group-name** *group-name* } **log-info** | [*ipv4-address* | *ipv6-address*] **verbose**]
Display BGP dedicated address family update group information.	**display bgp** [**instance** *instance-name*] **update-group dedicated** [*ipv4-address* | *ipv6-address*]

Displaying BGP (VPNv4 address family)

Task	Command
Display information about BGP peers monitored by the specified BMP server for the specified BGP instance.	**display bgp** [**instance** *instance-name*] **bmp server** *server-number* **monitor-peer all** **display bgp** [**instance** *instance-name*] **server** *server-number* **monitor-peer vpnv4** { *ipv4-address* | *ipv6-address* } **display bgp** [**instance** *instance-name*] **bmp server** *server-number* **monitor-peer vpn-instance** *vpn-instance-name* **vpnv4** *ipv4-address*

Displaying BGP (VPNv6 address family)

Task	Command
Display information about BGP peers monitored by the specified BMP server for the specified BGP instance.	**display bgp** [**instance** *instance-name*] **bmp server** *server-number* **monitor-peer all** **display bgp** [**instance** *instance-name*] **bmp server** *server-number* **monitor-peer vpnv6** { *ipv4-address* | *ipv6-address* }

Resetting BGP sessions

CAUTION:
A reset operation tears down BGP sessions for a short period of time.

Execute **reset** commands in user view.

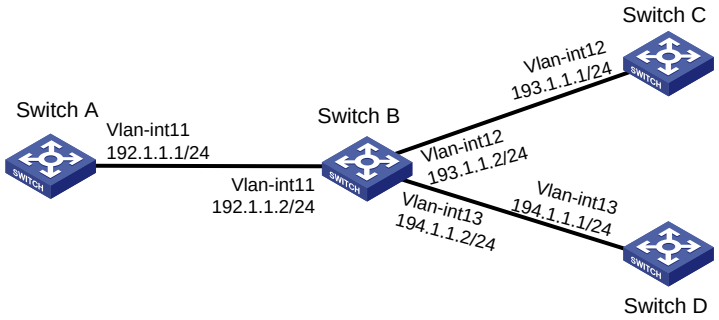
Task	Command
Reset BGP sessions for LS address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | **all** | **external** | **group** *group-name* | **internal** } **link-state**
Reset BGP sessions for dedicated address family.	**reset bgp** [**instance** *instance-name*] { *as-number* | *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | **all** | **external** | **group** *group-name* | **internal** } **dedicated**
Perform manual soft-reset on BGP sessions of the dedicated address family.	**refresh bgp** [**instance** *instance-name*] { *ipv4-address* [*mask-length*] | *ipv6-address* [*prefix-length*] | **all** | **external** | **group** *group-name* | **internal** } { **export** | **import** } **dedicated**

Clearing BGP information

Execute **reset** commands in user view.

Task	Command
Reset the connection to a BMP server and clear statistics information.	**reset bgp** [**instance** *instance-name*] **bmp server** { *server-number* | **all** }
Clear BMP server statistics.	**reset bgp** [**instance** *instance-name*] **bmp server** *server-number* **statistics**

Extended BGP feature configuration examples



Example: Configuring BGP LS

Network configuration

As shown in Figure 72, all switches run BGP. Run IBGP between Switch A and Switch B, between Switch B and Switch C, and between Switch B and Switch D.

Configure Switch B as a route reflector with client Switch A to allow Switch A to learn LS information advertised by Switch C and Switch D.

Figure 72 Network diagram

Procedure

1. Configure IP addresses for interfaces and configure OSPF on Switch C and Switch D. (Details not shown.)
2. Configure BGP connections:

   # Configure Switch A.

   ```
   <SwitchA> system-view
   [SwitchA] bgp 100
   [SwitchA-bgp-default] peer 192.1.1.2 as-number 100
   [SwitchA-bgp-default] address-family link-state
   [SwitchA-bgp-default-ls] peer 192.1.1.2 enable
   [SwitchA-bgp-default-ls] quit
   [SwitchA-bgp-default] quit
   ```

   # Configure Switch B.

   ```
   <SwitchB> system-view
   [SwitchB] bgp 100
   [SwitchB-bgp-default] peer 192.1.1.1 as-number 100
   [SwitchB-bgp-default] peer 193.1.1.1 as-number 100
   [SwitchB-bgp-default] peer 194.1.1.1 as-number 100
   [SwitchB-bgp-default] address-family link-state
   [SwitchB-bgp-default-ls] peer 192.1.1.1 enable
   [SwitchB-bgp-default-ls] peer 193.1.1.1 enable
   [SwitchB-bgp-default-ls] peer 194.1.1.1 enable
   [SwitchB-bgp-default-ls] quit
   [SwitchB-bgp-default] quit
   ```

   # Configure Switch C.

   ```
   <SwitchC> system-view
   ```

```
[SwitchC] bgp 100
[SwitchC-bgp-default] peer 193.1.1.2 as-number 100
[SwitchC-bgp-default] address-family link-state
[SwitchC-bgp-default-ls] peer 193.1.1.2 enable
[SwitchC-bgp-default-ls] quit
[SwitchC-bgp-default] quit
[SwitchC] ospf
[SwitchC-ospf-1] distribute bgp-ls
[SwitchC-ospf-1] area 0
[SwitchC-ospf-1-area-0.0.0.0] network 0.0.0.0 0.0.0.0
[SwitchC-ospf-1-area-0.0.0.0] quit
[SwitchC-ospf-1] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] bgp 100
[SwitchD-bgp-default] peer 194.1.1.2 as-number 100
[SwitchD-bgp-default] address-family link-state
[SwitchD-bgp-default-ls] peer 194.1.1.2 enable
[SwitchD-bgp-default-ls] quit
[SwitchD-bgp-default] quit
[SwitchD] ospf
[SwitchD-ospf-1] distribute bgp-ls
[SwitchD-ospf-1] area 0
[SwitchD-ospf-1-area-0.0.0.0] network 0.0.0.0 0.0.0.0
[SwitchD-ospf-1-area-0.0.0.0] quit
[SwitchD-ospf-1] quit
```

3. Configure Switch B as the route reflector.

```
[SwitchB] bgp 100
[SwitchB-bgp-default] address-family link-state
[SwitchB-bgp-default-ls] peer 192.1.1.1 reflect-client
[SwitchB-bgp-default-ls] quit
[SwitchB-bgp-default] quit
```

Verifying the configuration

Verify that Switch A has learned LS information advertised by Switch C and Switch D.

```
[SwitchA] display bgp link-state

 Total number of routes: 4

 BGP local Switch ID is 192.1.1.1
 Status codes: * - valid, > - best, d - dampened, h - history,
               s - suppressed, S - stale, i - internal, e - external
               a – additional-path
       Origin: i - IGP, e - EGP, ? - incomplete
 Prefix codes: E link, V node, T IP reachable route, u/U unknown,
               I Identifier, N local node, R remote node, L link, P prefix,
               L1/L2 ISIS level-1/level-2, O OSPF, D direct, S static, B BGP
               a area-ID, , l link-ID, t topology-ID, s ISO-ID,
               c confed-ID/ASN, b bgp-identifier, r Switch-ID,
```

```

Example: Configuring BGP dedicated routes

Network configuration

As shown in Figure 73, all switches run BGP. Configure Switch B and Switch C as EBGP peers of both Switch A and Switch D. Switch A and Switch D provide access services to clients through AP 1 and AP 2. To ensure that a client can quickly come online on the access devices after migration, perform the following tasks:

- Configure IPSG on Switch A and Switch D to enable Switch A and Switch D to generate an IPSG binding for the client after the client comes online.
- Enable BGP to exchange dedicated routes with its peers and peer groups. Then, Switch B and Switch C can synchronize IPSG bindings from Switch A and Switch D, and Switch A and Switch D can withdraw expired IPSG bindings.

Figure 73 Network diagram

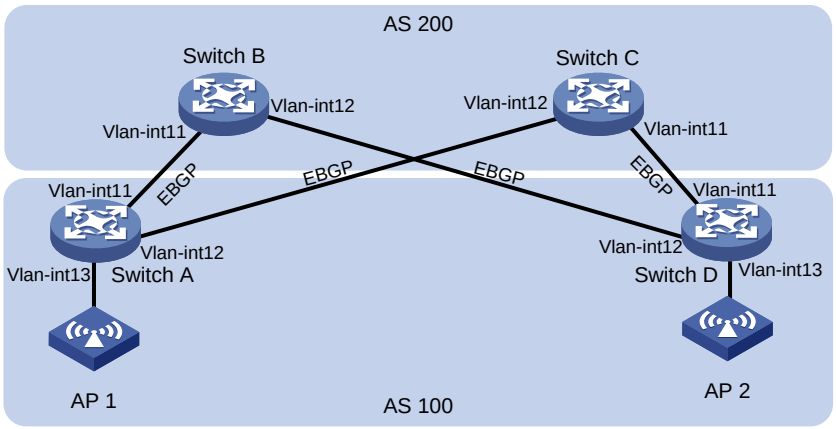

Table 18 Interface and IP address assignment

Device	Interface	IP address	Device	Interface	IP address
Switch A	Vlan-int11	11.11.11.11/24	Switch C	Vlan-int12	22.22.22.22/24
	Vlan-int12	22.22.22.11/24		Vlan-int11	44.44.44.11/24
Switch B	Vlan-int11	11.11.11.22/24	Switch D	Vlan-int11	44.44.44.22/24
	Vlan-int12	33.33.33.11/24		Vlan-int12	33.33.33.22/24

Procedure

1. Configure IP addresses for interfaces. (Details not shown.)
2. Configure BGP connections:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA-bgp-default] peer 11.11.11.22 as-number 200
[SwitchA-bgp-default] peer 22.22.22.22 as-number 200
[SwitchA-bgp-default] address-family dedicated
[SwitchA-bgp-default-dedicated] peer 11.11.11.22 enable
[SwitchA-bgp-default-dedicated] peer 22.22.22.22 enable
[SwitchA-bgp-default-dedicated] quit
[SwitchA-bgp-default] quit
```

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] bgp 200
[SwitchB-bgp-default] peer 11.11.11.11 as-number 100
[SwitchB-bgp-default] peer 33.33.33.22 as-number 100
[SwitchB-bgp-default] address-family dedicated
[SwitchB-bgp-default-dedicated] peer 11.11.11.11 enable
[SwitchB-bgp-default-dedicated] peer 33.33.33.22 enable
[SwitchB-bgp-default-dedicated] quit
[SwitchB-bgp-default] quit
```

   # Configure Switch C.

```
<SwitchC> system-view
[SwitchC] bgp 200
```

```
[SwitchC-bgp-default] peer 22.22.22.11 as-number 100
[SwitchC-bgp-default] peer 44.44.44.22 as-number 100
[SwitchC-bgp-default] address-family dedicated
[SwitchC-bgp-default-dedicated] peer 22.22.22.11 enable
[SwitchC-bgp-default-dedicated] peer 44.44.44.22 enable
[SwitchC-bgp-default-dedicated] quit
[SwitchC-bgp-default] quit
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] bgp 100
[SwitchD-bgp-default] peer 33.33.33.11 as-number 200
[SwitchD-bgp-default] peer 44.44.44.11 as-number 200
[SwitchD-bgp-default] address-family dedicated
[SwitchD-bgp-default-dedicated] peer 33.33.33.11 enable
[SwitchD-bgp-default-dedicated] peer 44.44.44.11 enable
```

On Switch D, enable BGP to permit the local AS number to appear in routes from Switch A.

```
[SwitchD-bgp-default-dedicated] peer 33.33.33.11 allow-as-loop 1
[SwitchD-bgp-default-dedicated] peer 44.44.44.11 allow-as-loop 1
[SwitchD-bgp-default-dedicated] quit
[SwitchD-bgp-default] quit
```

3. Configure IPv4SG on Switch A and Switch D.

Configure Switch A.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 13
[SwitchA-Vlan-interface13] ip verify source ip-address mac-address
```

Configure Switch D.

```
<SwitchD> system-view
[SwitchD] interface vlan-interface 13
[SwitchD-Vlan-interface13] ip verify source ip-address mac-address
```

Verifying the configuration

View IPv4SG bindings on Switch A.

```
[SwitchA] display ip source binding
Total entries found: 3
IP Address      MAC Address    Interface               VLAN Type

Configuring PBR

About PBR

Policy-based routing (PBR) uses user-defined policies to route packets. A policy can specify parameters for packets that match specific criteria such as ACLs. The parameters include the next hop and default next hop .

Packet forwarding process

When the device receives a packet, the device searches the PBR policy for a matching node to forward that packet.

- If a matching node is found and its match mode is **permit**, the device performs the following operations:
  a. Uses the next hops specified on the node to forward the packet.
  b. Searches the routing table for a route to forward the packet if one of the following conditions exists:
    - No next hops are specified on the node.
    - Forwarding failed based on the next hops.

  c. Uses the default next hops specified on the node to forward the packet if one of the following conditions exists:
    - No matching route was found in the routing table.
    - The routing table-based forwarding failed.

  d. Uses the default route to forward the packet if one of the following conditions exists:
    - No default next hops are specified on the node.
    - The forwarding failed based on the default next hops.
- The device perfoms routing table lookup to forward the packet in either of the following conditions:
  - No matching node is found.
  - A matching node is found, but its match mode is **deny**.

PBR types

PBR includes the following types:

- **Local PBR**—Guides the forwarding of locally generated packets, such as ICMP packets generated by using the **`ping`** command.
- **Interface PBR**—Guides the forwarding of packets received on an interface.

Policy

A policy includes match criteria and actions to be taken on the matching packets. A policy can have one or multiple nodes as follows:

- Each node is identified by a node number. A smaller node number has a higher priority.
- A node contains **`if-match`** and **`apply`** clauses. An **`if-match`** clause specifies a match criterion, and an **`apply`** clause specifies an action.

- A node has a match mode of **permit** or **deny**.

A policy compares packets with nodes in priority order. If a packet matches the criteria on a node, it is processed by the action on the node. If the packet does not match any criteria on the node, it goes to the next node for a match. If the packet does not match the criteria on any node, the device performs a routing table lookup.

Relationship between if-match clauses

On a node, you can specify multiple types of **`if-match`** clauses but only one **`if-match`** clause for each type.

Relationship between apply clauses

You can specify multiple **`apply`** clauses for a node, but some of them might not be executed. For more information about relationship between **`apply`** clauses, see "Configuring actions for a node."

Relationship between the match mode and clauses on the node

Does a packet match all the if-match **clauses on the node?**	**Match mode**	
	Permit	**Deny**
Yes.	• If the node contains **`apply`** clauses, PBR executes the **`apply`** clauses on the node. ○ If PBR-based forwarding succeeds, PBR does not compare the packet with the next node. ○ If PBR-based forwarding fails, PBR does not compare the packet with the next node. • If the node does not contain **`apply`** clauses, the device performs a routing table lookup for the packet.	The device does not execute any **`apply`** clauses except the **`apply mirror-to-destination`** clause, and performs a routing table lookup for the packet.
No.	PBR compares the packet with the next node.	PBR compares the packet with the next node.

NOTE:

A node that has no **`if-match`** clauses matches any packet.

PBR and Track

PBR can work with the Track feature to dynamically adapt the availability status of an **`apply`** clause to the link status of a tracked object. The tracked object can be a next hop or default next hop.

- When the track entry associated with an object changes to **Negative**, the **`apply`** clause is invalid.
- When the track entry changes to **Positive** or **NotReady**, the **`apply`** clause is valid.

For more information about Track and PBR collaboration, see *High Availability Configuration Guide*.

Restrictions and guidelines: PBR configuration

If a packet destined for the local device matches a PBR policy, PBR will execute the apply clauses in the policy, including the clause for forwarding. When you configure a PBR policy, be careful to avoid this situation.

PBR tasks at a glance

To configure PBR, perform the following tasks:

1. Configuring a policy
   a. Creating a node
   b. Setting match criteria for a node
   c. Configuring actions for a node
2. Specifying a policy for PBR

   Choose the following tasks as needed:
   - Specifying a policy for local PBR
   - Specifying a policy for interface PBR
   - Specifying a policy for global PBR

Configuring a policy

Creating a node

1. Enter system view.

   system-view
2. Create a node for a policy, and enter its view.

   policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*
3. (Optional.) Configure a description for the policy node.

   description *text*

   By default, no description is configured for a policy node.

Setting match criteria for a node

Procedure

1. Enter system view.

   system-view
2. Enter policy node view.

   policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*
3. Set match criteria.
   - Set an ACL match criterion.

     if-match acl [**user-defined**] { *acl-number* | **name** *acl-name* }

     By default, no ACL match criterion is set.

     The ACL match criterion cannot match Layer 2 information.

When using the ACL to match packets, PBR ignores the action (**permit** or **deny**) and time range settings in the ACL. If the specified ACL does not exist, no packets will match this criterion.

- Set a local QoS ID match criterion.
  if-match qos-local-id *local-id-value*
  By default, no local QoS ID match criterion is set.

Configuring actions for a node

About this task

The **apply** clauses allow you to specify the actions to be taken on matching packets on a node.

The following **apply** clauses determine the packet forwarding paths in a descending order:

- **apply next-hop**
- **apply output-interface**
- **apply default-next-hop**

PBR supports the **apply** clauses in Table 1.

Table 1 Apply clauses supported in PBR

Clause	Meaning	Remarks
apply precedence	Sets an IP precedence.	This clause is always executed.
apply loadshare next-hop	Enables load sharing among multiple next hops.	Multiple next hop options operate in either primary/backup or load sharing mode. • **Primary/backup mode**—One option is selected from all options in configuration order for packet forwarding, with all remaining options as backups. For example, if multiple next hops are configured, the first configured next hop is selected. When the selected next hop fails, the next available next hop takes over. • **Load sharing mode**—Matching traffic is distributed across the available options in round robin manner, starting from the first configured option. They perform per-packet load sharing for traffic that does not match any fast forwarding entry, and perform per-flow load sharing for traffic that matches a fast forwarding entry. After you configure the **apply loadshare-mode** command, the load sharing mode specified in the command applies. By default, the primary/backup mode applies. For the load sharing mode to take effect, make sure multiple next hops are set in the policy.
apply loadshare-mode next-hop robin	Specifies the load sharing mode for multiple next	Specify one of the following load sharing modes for multiple next hops:

	hops.	• **robin**: Selects load-shared links randomly based on packets.
apply next-hop and **apply output-interface**	Sets next hops and sets output interfaces.	If both clauses are configured, only the **apply next-hop** clause is executed.
apply default-next-hop	Sets default next hops.	The configuration takes effect only in the following cases: • No next hops are set or the next hops and output interfaces are invalid. • The packet does not match any route in the routing table.
apply statistics	Counts successful matches and matching bytes on the policy node.	To include the number of successful matches and matching bytes on a policy node in the statistics displayed by a **display** command, execute this command. This clause is always executed for matching packets.

Restrictions and guidelines

If you specify a next hop, PBR periodically performs FIB table lookup to determine its availability. Temporary service interruption might occur if PBR does not update the route immediately after its availability status changes.

If you configure the **apply loadshare-mode** command, you cannot specify next hop addresses as VXLAN tunnel addresses.

In a policy node, if you configure per-packet forwarding with the **apply loadshare-mode** command, and apply the policy locally with the **ip local policy-based-route** command, per-packet forwarding does not take effect. Instead, per-flow forwarding still takes effect. As a best practice to have PBR take effect correctly, configure other PBR types with the policy.

Configuring actions to modify packet fields

1. Enter system view.
   system-view
2. Enter policy node view.
   policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*
3. Set an IP precedence.
   apply precedence { *type* | *value* }
   By default, no IP precedence is specified.

Configuring actions to direct packet forwarding

1. Enter system view.
   system-view
2. Enter policy node view.
   policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*
3. Configure actions.
   - Set next hops.
     apply next-hop [**vpn-instance** *vpn-instance-name*] { *ip-address* [**direct**] [**track** *track-entry-number*] }&<1-8>
     By default, no next hops are specified.

On a node, you can specify a maximum of eight next hops for backup or load sharing in one command line or by executing this command multiple times.

If multiple next hops on the same subnet are specified for backup, the device first uses the subnet route for the next hops to forward packets when the primary next hop fails. If the subnet route is not available, the device selects a backup next hop.

For the S5200-EI-G switch series, you can specify a maximum of four next hops in one command, and a maximum of four next hops for each node.

- Enable load sharing among multiple next hops.

  apply loadshare next-hop

  By default, the next hops operate in primary/backup mode.

  Only the S5200-HI-G switch series supports load sharing among multiple next hops.

- Specify the load sharing mode for multiple next hops.

  apply loadshare-mode next-hop robin

  By default, multiple next hops load share traffic in round robin manner, starting from the first configured next hop. They perform per-packet load sharing for traffic that does not match any fast forwarding entry, and perform per-flow load sharing for traffic that matches a fast forwarding entry.

  .

- Set output interfaces.

  apply output-interface NULL 0

  By default, no output interfaces are specified.

- Set default next hops.

  apply default-next-hop [**vpn-instance** *vpn-instance-name*] { *ip-address* [**direct**] [**track** *track-entry-number*] }&<1-4>

  By default, no default next hops are specified.

  On a node, you can specify a maximum of eight default next hops for backup in one command line or by executing this command multiple times.

  Only the S5200-HI-G switch series supports this command.

Collecting policy node statistics

1. Enter system view.

   system-view

2. Enter policy node view.

   policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

3. Count successful matches and matching bytes on the policy node.

   apply statistics

   By default, match counting is disabled on policy nodes.

Specifying a policy for PBR

Specifying a policy for local PBR

About this task

Perform this task to specify a policy for local PBR to guide the forwarding of locally generated packets.

Restrictions and guidelines

You can specify only one policy for local PBR and must make sure the specified policy already exists. Before you apply a new policy, you must first remove the current policy.

Local PBR might affect local services such as ping and Telnet. When you use local PBR, make sure you fully understand its impact on local services of the device.

Procedure

1. Enter system view.
   system-view
2. Specify a policy for local PBR.
   ip local policy-based-route *policy-name*
   By default, local PBR is not enabled.

Specifying a policy for interface PBR

About this task

Perform this task to apply a policy to an interface to guide the forwarding of packets received on the interface.

Restrictions and guidelines

You can apply only one policy to an interface and must make sure the specified policy already exists. Before you can apply a new interface PBR policy to an interface, you must first remove the current policy from the interface.

You can apply a policy to multiple interfaces.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify a policy for interface PBR.
   ip policy-based-route *policy-name*
   By default, no interface policy is applied to an interface.

Specifying a policy for global PBR

About this task

Perform this task to apply a policy to all interfaces on the device to guide the forwarding of packets received on the interfaces.

Restrictions and guidelines

You can apply only one policy for global PBR and the specified policy must already exist. Before you can apply a new policy, you must first remove the current policy.

Interface PBR takes precedence over global PBR on an interface. When they are both configured and packets fail to match the interface PBR policy, global PBR applies.

Procedure

1. Enter system view.
   system-view

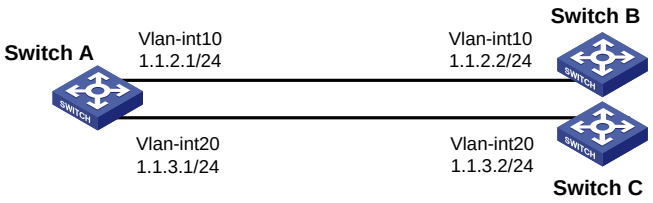
2. Specify a policy for global PBR.
   ip global policy-based-route *policy-name*
   By default, no policy is specified for global PBR.

Display and maintenance commands for PBR

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display PBR policy information.	**display ip policy-based-route** [**policy** *policy-name*]
Display global PBR configuration and statistics.	**display ip policy-based-route global** [**slot** *slot-number*]
Display interface PBR configuration and statistics.	**display ip policy-based-route interface** *interface-type interface-number* [**slot** *slot-number*]
Display local PBR configuration and statistics.	**display ip policy-based-route local** [**slot** *slot-number*]
Display PBR configuration.	**display ip policy-based-route setup**
Clear PBR statistics.	**reset ip policy-based-route statistics** [**policy** *policy-name*]

PBR configuration examples



Example: Configuring packet type-based local PBR

Network configuration

As shown in Figure 1, Switch B and Switch C do not have a route to reach each other.

Configure PBR on Switch A to forward all TCP packets to the next hop 1.1.2.2 (Switch B).

Figure 1 Network diagram

Procedure

1. Configure Switch A:

Create VLAN 10 and VLAN 20.

```
<SwitchA> system-view
[SwitchA] vlan 10
[SwitchA-vlan10] quit
[SwitchA] vlan 20
[SwitchA-vlan20] quit
```

Configure the IP addresses of VLAN-interface 10 and VLAN-interface 20.

```
[SwitchA] interface vlan-interface 10
[SwitchA-Vlan-interface10] ip address 1.1.2.1 24
[SwitchA-Vlan-interface10] quit
[SwitchA] interface vlan-interface 20
[SwitchA-Vlan-interface20] ip address 1.1.3.1 24
[SwitchA-Vlan-interface20] quit
```

Configure ACL 3101 to match TCP packets.

```
[SwitchA] acl advanced 3101
[SwitchA-acl-ipv4-adv-3101] rule permit tcp
[SwitchA-acl-ipv4-adv-3101] quit
```

Configure Node 5 for the policy **aaa** to forward TCP packets to next hop 1.1.2.2.

```
[SwitchA] policy-based-route aaa permit node 5
[SwitchA-pbr-aaa-5] if-match acl 3101
[SwitchA-pbr-aaa-5] apply next-hop 1.1.2.2
[SwitchA-pbr-aaa-5] quit
```

Configure local PBR by applying the policy **aaa** to Switch A.

```
[SwitchA] ip local policy-based-route aaa
```

2. Configure Switch B:

Create VLAN 10.

```
<SwitchB> system-view
[SwitchB] vlan 10
```

```
[SwitchB-vlan10] quit
```

Configure the IP address of VLAN-interface 10.

```
[SwitchB] interface vlan-interface 10
[SwitchB-Vlan-interface10] ip address 1.1.2.2 24
[SwitchB-Vlan-interface10] quit
```

3. Configure Switch C:

Create VLAN 20.

```
<SwitchC> system-view
[SwitchC] vlan 20
[SwitchC-vlan20] quit
```

Configure the IP address of VLAN-interface 20.

```
[SwitchC] interface vlan-interface 20
[SwitchC-Vlan-interface20] ip address 1.1.3.2 24
[SwitchC-Vlan-interface20] quit
```

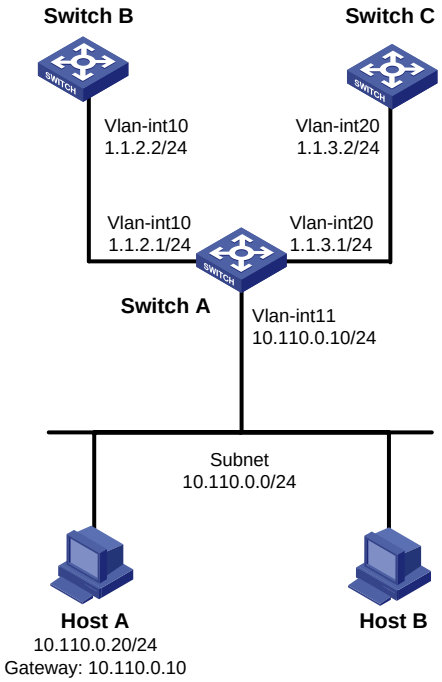
Verifying the configuration

1. Perform telnet operations to verify that local PBR on Switch A operates as configured to forward the matching TCP packets to the next hop 1.1.2.2 (Switch B), as follows:

   # Verify that you can telnet to Switch B from Switch A successfully. (Details not shown.)

   # Verify that you cannot telnet to Switch C from Switch A. (Details not shown.)

2. Verify that Switch A forwards packets other than TCP packets through VLAN-interface 20. For example, verify that you can ping Switch C from Switch A. (Details not shown.)



Example: Configuring packet type-based interface PBR

Network configuration

As shown in Figure 2, Switch B and Switch C do not have a route to reach each other.

Configure PBR on Switch A to forward all TCP packets received on VLAN-interface 11 to the next hop 1.1.2.2 (Switch B).

Figure 2 Network diagram

Procedure

1. Configure IP addresses and unicast routing protocol settings to make sure Switch B and Switch C can reach Host A. (Details not shown.)
2. Configure Switch A:

   # Configure ACL 3101 to match TCP packets.

   ```
   <SwitchA> system-view
   [SwitchA] acl advanced 3101
   [SwitchA-acl-ipv4-adv-3101] rule permit tcp
   [SwitchA-acl-ipv4-adv-3101] quit
   ```

   # Configure Node 5 for the policy **aaa** to forward TCP packets to next hop 1.1.2.2.

   ```
   [SwitchA] policy-based-route aaa permit node 5
   [SwitchA-pbr-aaa-5] if-match acl 3101
   [SwitchA-pbr-aaa-5] apply next-hop 1.1.2.2
   [SwitchA-pbr-aaa-5] quit
   ```

   # Configure interface PBR by applying the policy **aaa** to VLAN-interface 11.

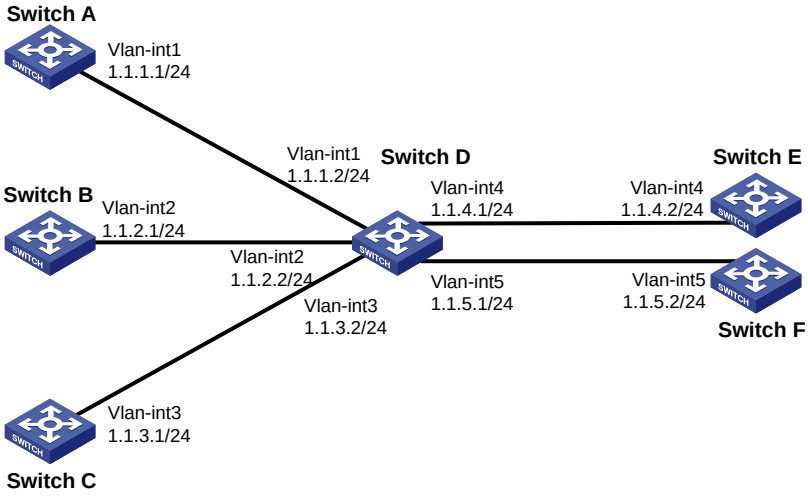
   ```
   [SwitchA] interface vlan-interface 11
   [SwitchA-Vlan-interface11] ip policy-based-route aaa
   [SwitchA-Vlan-interface11] quit
   ```

Verifying the configuration

1. Perform telnet operations to verify that interface PBR on Switch A operates as configured to forward the matching TCP packets to the next hop 1.1.2.2 (Switch B), as follows:

   # Verify that you can telnet to Switch B from Host A successfully. (Details not shown.)

   # Verify that you cannot telnet to Switch C from Host A. (Details not shown.)
2. Verify that Switch A forwards packets other than TCP packets through VLAN-interface 20. For example, verify that you can ping Switch C from Host A. (Details not shown.)



Example: Configuring packet type-based global PBR

Network configuration

As shown in Figure 3, Switch E and Switch F do not have a route to reach each other.

Configure global PBR on Switch D to forward TCP packets to the next hop 1.1.4.2 (Switch E).

Figure 3 Network diagram

Procedure

1. Assign IP addresses to the interfaces, as shown in Figure 3. (Details not shown.)
2. Configure unicast routing protocol settings to make sure Switch A, B and C can communicate with Switch E and Switch F, respectively. (Details not shown.)
3. Configure Switch D:

   # Configure ACL 3101 to match TCP packets sourced from networks 1.1.1.0/24, 1.1.2.0/24, and 1.1.3.0/24.

   ```
   <SwitchD> system-view
   [SwitchD] acl advanced 3101
   [SwitchD-acl-ipv4-adv-3101] rule permit tcp source 1.1.1.0 0.0.0.255
   [SwitchD-acl-ipv4-adv-3101] rule permit tcp source 1.1.2.0 0.0.0.255
   [SwitchD-acl-ipv4-adv-3101] rule permit tcp source 1.1.3.0 0.0.0.255
   [SwitchD-acl-ipv4-adv-3101] quit
   ```

   # Configure node 5 in PBR policy **aaa** to forward TCP packets that match ACL 3101 to next hop 1.1.4.2.

   ```
   [SwitchD] policy-based-route aaa permit node 5
   [SwitchD-pbr-aaa-5] if-match acl 3101
   [SwitchD-pbr-aaa-5] apply next-hop 1.1.4.2
   [SwitchD-pbr-aaa-5] quit
   ```

   # Specify PBR policy **aaa** as the global PBR policy.

   ```
   [SwitchD] ip global policy-based-route aaa
   ```

Verifying the configuration

1. Perform telnet operations to verify that global PBR on Switch D operates as configured to forward the matching TCP packets to the next hop 1.1.4.2 (Switch E), as follows:

   # Verify that you can telnet to Switch E from Switch A, Switch B, and Switch C successfully. (Details not shown.)

Verify that you cannot telnet to Switch F from Switch A, Switch B, or Switch C. (Details not shown.)

2. Verify that Switch D forwards packets other than TCP packets as long as a route is available. For example, verify that you can ping Switch F from Switch A, Switch B, and Switch C. (Details not shown.)

Configuring IPv6 static routing

About IPv6 static routing

Static routes are manually configured and cannot adapt to network topology changes. If a fault or a topological change occurs in the network, the network administrator must modify the static routes manually. IPv6 static routing works well in a simple IPv6 network.

Configuring an IPv6 static route

1. Enter system view.

   system-view

2. Configure an IPv6 static route.

   Public network:

   ipv6 route-static *ipv6-address prefix-length interface-type interface-number* [*next-hop-address*] [**permanent** | **track** *track-entry-number*] [**preference** *preference*] [**tag** *tag-value*] [**recursive-lookup**] [**description** *text*]

   ipv6 route-static *ipv6-address prefix-length* [**vpn-instance** *d-vpn-instance-name*] *next-hop-address* [**recursive-lookup** { **host-route** | **longest-match** }] [**permanent** | **track** *track-entry-number*] [**preference** *preference*] [**tag** *tag-value*] [**recursive-lookup**] [**description** *text*]

   ipv6 route-static *ipv6-address prefix-length interface-type interface-number next-hop-address* **track-nd** [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, no IPv6 static route is configured.

   The **recursive-lookup host-route**, **recursive-lookup longest-match**, and **recursive-lookup** keywords are mutually exclusive. You cannot specify them at the same time.

   VPN:

   ipv6 route-static vpn-instance *s-vpn-instance-name ipv6-address prefix-length interface-type interface-number* [*next-hop-address*] [**permanent** | **track** *track-entry-number*] [**preference** *preference*] [**tag** *tag-value*] [**recursive-lookup**] [**description** *text*]

   ipv6 route-static vpn-instance *s-vpn-instance-name ipv6-address prefix-length* { *nexthop-address* [**recursive-lookup** { **host-route** | **longest-match** }] [**public**] | **vpn-instance** *d-vpn-instance-name nexthop-address* [**recursive-lookup** { **host-route** | **longest-match** }] } [**permanent** | **track** *track-entry-number*] [**preference** *preference*] [**tag** *tag-value*] [**recursive-lookup**] [**description** *text*]

   ipv6 route-static vpn-instance *s-vpn-instance-name ipv6-address prefix-length interface-type interface-number next-hop-address* **track-nd** [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, no IPv6 static route is configured.

   The **recursive-lookup host-route**, **recursive-lookup longest-match**, and **recursive-lookup** keywords are mutually exclusive. You cannot specify them at the same time.

3. (Optional.) Set the default preference for IPv6 static routes.
   ipv6 route-static default-preference *default-preference*
   The default setting is 60.

Configuring IPv6 floating static routes

Perform this task to configure route backup to improve network reliability.

When an IPv6 static or dynamic route to a destination address already exists on the device, you configure another IPv6 static route with a lower priority as the backup route to improve the network reliability. This backup IPv6 static route is called an IPv6 floating static route and is activated only when the primary route fails. After the primary route recovers from failure, the IPv6 floating static route becomes inactive and data forwarding switches back to the primary route.

An IPv6 floating static route can be configured in either of the following ways

- Configure different priorities for multiple IPv6 static routes to the same destination address. The route with the lower priority automatically becomes the IPv6 floating static route.
- When an IPv6 route to a destination address already exists on the device, configure an IPv6 static route with a lower priority to the same destination address.

When you configure an IPv6 floating static route, the priority value of the route must be larger than then priority value of the primary route. For more information, see "Configuring an IPv6 static route."

Deleting IPv6 static routes

About this task

To delete an IPv6 static route, use the **undo ipv6 route-static** command. To delete all IPv6 static routes including the default route, use the **delete ipv6 static-routes all** command.

Procedure

1. Enter system view.
   system-view
2. Delete all IPv6 static routes, including the default route.
   delete ipv6 [**vpn-instance** *vpn-instance-name*] **static-routes all**

> **CAUTION:**
> Deleting all IPv6 static routes with caution. This operation might cause network connectivity failure and packet forwarding failure.

Configuring BFD for IPv6 static routes

About BFD for IPv6 static routes

BFD provides a general purpose, standard, and medium- and protocol-independent fast failure detection mechanism. It can uniformly and quickly detect the failures of the bidirectional forwarding paths between two routers for protocols, such as routing protocols. BFD for IPv6 static routes tests the reachability of the next hop for each IPv6 static route. If a next hop is unreachable, BFD deletes the associated IPv6 static route.

For more information about BFD, see *High Availability Configuration Guide*.

Restrictions and guidelines for BFD

When you configure BFD for IPv6 static routes, follow these restrictions and guidelines:

- If you specify a source IPv6 address for BFD packets on the local device, you must specify that IPv6 address as the next hop IPv6 address on the peer device.
- If you specify a non-P2P output interface and a direct next hop, specify the **bfd-source** *ipv6-address* option as a best practice. Make sure the source IPv6 address of BFD packets meets the following requirements:
  - The address is the same as the IPv6 address of the output interface.
  - The address is on the same network segment as the next hop IPv6 address of the same type.

    For example, if the next hop IPv6 address is a link-local address, the source IPv6 address of BFD packets must also be a link-local address.
- Enabling BFD for a flapping route could worsen the situation.

Configuring BFD control packet mode

About this task

This mode uses BFD control packets to detect the status of a link bidirectionally at a millisecond level.

BFD control packet mode can be applied to IPv6 static routes with a direct next hop or with an indirect next hop.

Restrictions and guidelines for BFD control packet mode

If you configure BFD control packet mode at the local end, you must also configure this mode at the peer end.

Configuring BFD control packet mode for an IPv6 static route (direct next hop)

1. Enter system view.

   system-view
2. Configure BFD control packet mode for an IPv6 static route.

   ipv6 route-static [**vpn-instance** *s-vpn-instance-name*] *ipv6-address prefix-length interface-type interface-number next-hop-address* **bfd control-packet** [**bfd-source** *ipv6-address*] [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, BFD control packet mode for an IPv6 static route is not configured.

Configuring BFD control packet mode for an IPv6 static route (indirect next hop)

1. Enter system view.

   system-view
2. Configure BFD control packet mode for an IPv6 static route.

   ipv6 route-static [**vpn-instance** *s-vpn-instance-name*] *ipv6-address prefix-length* [**vpn-instance** *d-vpn-instance-name*] { *next-hop-address* [**recursive-lookup** { **host-route** | **longest-match** }] **bfd control-packet bfd-source** *ipv6-address* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, BFD control packet mode for an IPv6 static route is not configured.

Configuring BFD echo packet mode

About this task

With BFD echo packet mode enabled for a static route, the output interface sends BFD echo packets to the destination device, which loops the packets back to test the link reachability.

Restrictions and guidelines

You do not need to configure BFD echo packet mode at the peer end.

Do not use BFD for a static route with the output interface in spoofing state.

Procedure

1. Enter system view.

   system-view

2. Configure the source address of echo packets.

   bfd echo-source-ipv6 *ipv6-address*

   By default, the source address of echo packets is not configured.

   As a best practice to avoid network congestion caused by excessive ICMPv6 redirect packets from the peer, use this command. Make sure the source IPv6 address is not on the subnet of any interfaces on the device.

   The source IPv6 address of echo packets can only be the global unicast address.

   For more information about this command, see *High Availability Command Reference*.

3. Configure BFD echo packet mode for an IPv6 static route.

   ipv6 route-static [**vpn-instance** *s-vpn-instance-name*] *ipv6-address prefix-length interface-type interface-number next-hop-address* **bfd echo-packet** [**bfd-source** *ipv6-address*] [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, BFD echo packet mode for an IPv6 static route is not configured.

   The next hop IPv6 address must be a global unicast address.

Enabling periodic sending of ND requests to the next hops of IPv6 static routes

About this task

As a best practice, use this feature when the following types of IPv6 static routes exist on the device:

- IPv6 static routes that recurse to host routes, which include the following IPv6 static routes:
  - IPv6 static routes with the **recursive-lookup host-route** keywords specified to recurse only to host routes.
  - IPv6 static routes that recurse to host routes according to routing policies (configured by using the **protocol nexthop recursive-lookup** command).

  The device might delete the ND entry for the next hop host address of an IPv6 static route after that entry ages out because the device cannot update that entry in time. As a result, the device does not have the host route of the directly connected device in the IPv6 routing table for that IPv6 static route. In this case, route recursion fails and that IPv6 static route cannot be activated.
- IPv6 static routes with the **track-nd** keyword specified to associate their next hops with the ND entries for these next hops.

The device might delete the ND entry for the next hop address of an IPv6 static route after that entry ages out because the device cannot update that entry in time. As a result, that IPv6 static route cannot be activated.

For IPv6 static routes that recurse to host routes, the **ipv6 route-static nd-request** command enables the device to periodically send ND requests to the next hops of the IPv6 static routes that meet the following requirements:

- The IPv6 static routes have no output interfaces specified.
- The IPv6 static routes fail the next-hop recursion.

When the device receives an ND response from the next hop host of an IPv6 static route, it automatically performs the following operations:

1. Adds the host route to the routing table.
2. Activates the IPv6 static route that recurses to the host route.
3. Stops sending ND requests to the host.

For IPv6 static routes with the **track-nd** keyword specified, the **ipv6 route-static nd-request** command enables the device to periodically send ND requests to the next hops of the IPv6 static routes associated with next hop ND entries. When the device receives an ND response from the next hop of an IPv6 static route, it automatically activates that IPv6 static route and stops sending ND requests to the next hop of that IPv6 static route.

Procedure

1. Enter system view.

   system-view
2. Enable periodic sending of ND requests to the next hops of IPv6 static routes.

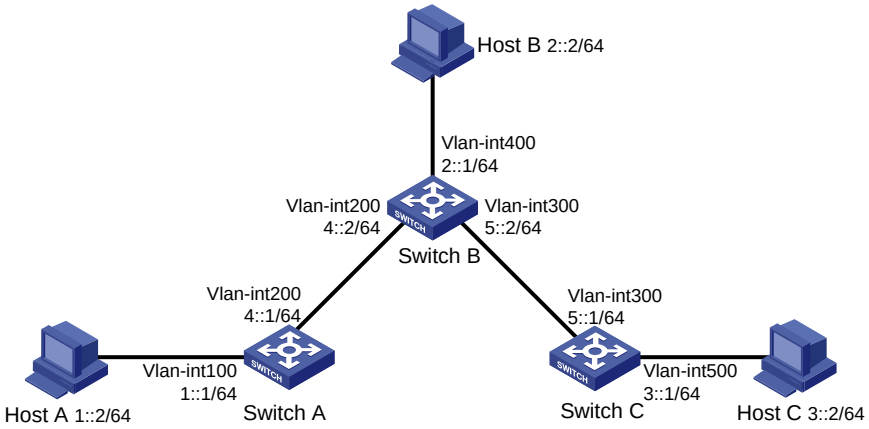
   ipv6 route-static nd-request [**interval** *interval*]

   By default, periodic sending of ND requests to the next hops of IPv6 static routes is disabled.

Display and maintenance commands for IPv6 static routing

Execute **display** commands in any view.

Task	Command
Display IPv6 static route next hop information.	**display ipv6 route-static nib** [*nib-id*] [**verbose**]
Display IPv6 static routing table information.	**display ipv6 route-static routing-table** [**vpn-instance** *vpn-instance-name*] [*ipv6-address prefix-length*]
Display IPv6 static route information.	**display ipv6 routing-table protocol static** [**inactive** | **verbose**]



IPv6 static routing configuration examples

Example: Configuring basic IPv6 static route

Network configuration

As shown in Figure 1, configure IPv6 static routes so that hosts can reach one another.

Figure 1 Network diagram

Procedure

1. Configure the IPv6 addresses for all VLAN interfaces. (Details not shown.)
2. Configure IPv6 static routes:

   # Configure a default IPv6 static route on Switch A.

   ```
   <SwitchA> system-view
   [SwitchA] ipv6 route-static :: 0 4::2
   ```

   # Configure two IPv6 static routes on Switch B.

   ```
   <SwitchB> system-view
   [SwitchB] ipv6 route-static 1:: 64 4::1
   [SwitchB] ipv6 route-static 3:: 64 5::1
   ```

   # Configure a default IPv6 static route on Switch C.

   ```
   <SwitchC> system-view
   [SwitchC] ipv6 route-static :: 0 5::2
   ```
3. Configure the IPv6 addresses for all the hosts and configure the default gateway of Host A, Host B, and Host C as 1::1, 2::1, and 3::1.

Verifying the configuration

Display the IPv6 static route information on Switch A.

```
[SwitchA] display ipv6 routing-table protocol static

Summary count : 1

Static Routing table status : <Active>
Summary count : 1

Destination: ::/0                                   Protocol  : Static
NextHop    : 4::2                                   Preference: 60
```

```
Interface  : Vlan200                                Cost      : 0

Static Routing table status : <Inactive>
Summary count : 0
```

Display the IPv6 static route information on Switch B.

```
[SwitchB] display ipv6 routing-table protocol static

Summary count : 2

Static Routing table status : <Active>
Summary count : 2

Destination: 1::/64                                 Protocol  : Static
NextHop    : 4::1                                   Preference: 60
Interface  : Vlan200                                Cost      : 0

Destination: 3::/64                                 Protocol  : Static
NextHop    : 5::1                                   Preference: 60
Interface  : Vlan300                                Cost      : 0

Static Routing table status : <Inactive>
Summary count : 0
```

Use the **ping** command to test the reachability.

```
[SwitchA] ping ipv6 3::1
Ping6(56 data bytes) 4::1 --> 3::1, press CTRL+C to break
56 bytes from 3::1, icmp_seq=0 hlim=62 time=0.700 ms
56 bytes from 3::1, icmp_seq=1 hlim=62 time=0.351 ms
56 bytes from 3::1, icmp_seq=2 hlim=62 time=0.338 ms
56 bytes from 3::1, icmp_seq=3 hlim=62 time=0.373 ms
56 bytes from 3::1, icmp_seq=4 hlim=62 time=0.316 ms

--- Ping6 statistics for 3::1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 0.316/0.416/0.700/0.143 ms
```

Example: Configuring BFD for IPv6 static routes (direct next hop)

Network configuration

As shown in Figure 2:

- Configure an IPv6 static route to subnet 120::/64 on Switch A.
- Configure an IPv6 static route to subnet 121::/64 on Switch B.
- Enable BFD for both routes.
- Configure an IPv6 static route to subnet 120::/64 and an IPv6 static route to subnet 121::/64 on Switch C.

When the link between Switch A and Switch B through the Layer 2 switch fails, BFD can detect the failure immediately, and Switch A and Switch B can communicate through Switch C.

Figure 2 Network diagram

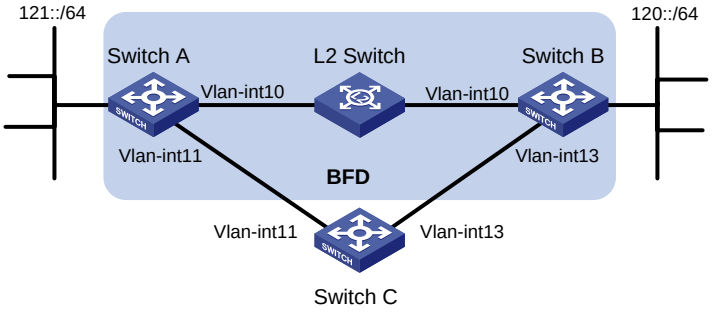


Table 1 Interface and IP address assignment

Device	Interface	IPv6 address
Switch A	Vlan-int10	12::1/64
Switch A	Vlan-int11	10::102/64
Switch B	Vlan-int10	12::2/64
Switch B	Vlan-int13	13::1/64
Switch C	Vlan-int11	10::100/64
Switch C	Vlan-int13	13::2/64

Procedure

1. Configure IPv6 addresses for interfaces. (Details not shown.)
2. Configure IPv6 static routes and BFD:

   # Configure IPv6 static routes on Switch A and enable BFD control packet mode for the static route that traverses the Layer 2 switch.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 10
[SwitchA-vlan-interface10] bfd min-control-interval 500
[SwitchA-vlan-interface10] bfd detect-multiplier 9
[SwitchA-vlan-interface10] quit
[SwitchA] ipv6 route-static 120:: 64 vlan-interface 10 12::2 bfd control-packet
[SwitchA] ipv6 route-static 120:: 64 10::100 preference 65
[SwitchA] quit
```

   # Configure IPv6 static routes on Switch B and enable BFD control packet mode for the static route that traverses the Layer 2 switch.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 10
[SwitchB-vlan-interface10] bfd min-control-interval 500
[SwitchB-vlan-interface10] bfd detect-multiplier 9
[SwitchB-vlan-interface10] quit
[SwitchB] ipv6 route-static 121:: 64 vlan-interface 10 12::1 bfd control-packet
[SwitchB] ipv6 route-static 121:: 64 vlan-interface 13 13::2 preference 65
[SwitchB] quit
```

   # Configure IPv6 static routes on Switch C.

```
<SwitchC> system-view
[SwitchC] ipv6 route-static 120:: 64 13::1
```

```
[SwitchC] ipv6 route-static 121:: 64 10::102
```

Verifying the configuration

Display the BFD sessions on Switch A.

```
<SwitchA> display bfd session
 Total sessions: 1        Up sessions: 1        Init mode: Active

 IPv6 session working in control packet mode:

       Local Discr: 513                Remote Discr: 33
         Source IP: 12::1
    Destination IP: 12::2
     Session State: Up                     Interface: Vlan10
         Hold Time: 2012ms
```

The output shows that the BFD session has been created.

Display IPv6 static routes on Switch A.

```
<SwitchA> display ipv6 routing-table protocol static

Summary count : 1

Static Routing table status : <Active>
Summary count : 1

Destination: 120::/64                                 Protocol  : Static
NextHop    : 12::2                                    Preference: 60
Interface  : Vlan10                                   Cost      : 0

Direct Routing table status : <Inactive>
Summary count : 0
```

The output shows that Switch A communicates with Switch B through VLAN-interface 10. The link over VLAN-interface 10 fails.

Display IPv6 static routes on Switch A again.

```
<SwitchA> display ipv6 routing-table protocol static

Summary count : 1

Static Routing table status : <Active>
Summary count : 1

Destination: 120::/64                                 Protocol  : Static
NextHop    : 10::100                                  Preference: 65
Interface  : Vlan11                                   Cost      : 0

Static Routing table status : < Inactive>
Summary count : 0
```

The output shows that Switch A communicates with Switch B through VLAN-interface 11.

Example: Configuring BFD for IPv6 static routes (indirect next hop)

Network configuration

As shown in Figure 3:

- Switch A has a route to interface Loopback 1 (2::9/128) on Switch B, and the output interface is VLAN-interface 10.
- Switch B has a route to interface Loopback 1 (1::9/128) on Switch A, and the output interface is VLAN-interface 12.
- Switch D has a route to 1::9/128, and the output interface is VLAN-interface 10. It also has a route to 2::9/128, and the output interface is VLAN-interface 12.

Configure the following:

- Configure an IPv6 static route to subnet 120::/64 on Switch A.
- Configure an IPv6 static route to subnet 121::/64 on Switch B.
- Enable BFD for both routes.
- Configure an IPv6 static route to subnet 120::/64 and an IPv6 static route to subnet 121::/64 on both Switch C and Switch D.

When the link between Switch A and Switch B through Switch D fails, BFD can detect the failure immediately and Switch A and Switch B can communicate through Switch C.

Figure 3 Network diagram

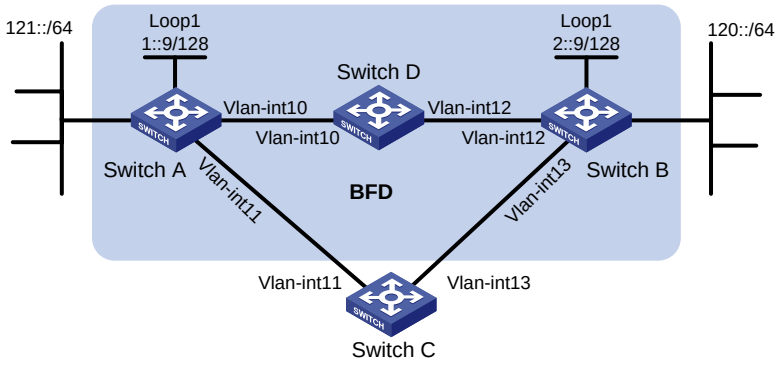

Table 2 Interface and IP address assignment

Device	Interface	IPv6 address
Switch A	Vlan-int10	12::1/64
Switch A	Vlan-int11	10::102/64
Switch A	Loop1	1::9/128
Switch B	Vlan-int12	11::2/64
Switch B	Vlan-int13	13::1/64
Switch B	Loop1	2::9/128
Switch C	Vlan-int11	10::100/64
Switch C	Vlan-int13	13::2/64
Switch D	Vlan-int10	12::2/64

Device	Interface	IPv6 address
Switch D	Vlan-int12	11::1/64

Procedure

1. Configure IPv6 addresses for interfaces. (Details not shown.)
2. Configure IPv6 static routes and BFD:

   # Configure IPv6 static routes on Switch A and enable BFD control packet mode for the IPv6 static route that traverses Switch D.

```
<SwitchA> system-view
[SwitchA] bfd multi-hop min-control-interval 500
[SwitchA] bfd multi-hop detect-multiplier 9
[SwitchA] ipv6 route-static 120:: 64 2::9 bfd control-packet bfd-source 1::9
[SwitchA] ipv6 route-static 120:: 64 10::100 preference 65
[SwitchA] ipv6 route-static 2::9 128 12::2
[SwitchA] quit
```

   # Configure IPv6 static routes on Switch B and enable BFD control packet mode for the static route that traverses Switch D.

```
<SwitchB> system-view
[SwitchB] bfd multi-hop min-control-interval 500
[SwitchB] bfd multi-hop detect-multiplier 9
[SwitchB] ipv6 route-static 121:: 64 1::9 bfd control-packet bfd-source 2::9
[SwitchB] ipv6 route-static 121:: 64 13::2 preference 65
[SwitchB] ipv6 route-static 1::9 128 11::1
[SwitchB] quit
```

   # Configure IPv6 static routes on Switch C.

```
<SwitchC> system-view
[SwitchC] ipv6 route-static 120:: 64 13::1
[SwitchC] ipv6 route-static 121:: 64 10::102
```

   # Configure IPv6 static routes on Switch D.

```
<SwitchD> system-view
[SwitchD] ipv6 route-static 120:: 64 11::2
[SwitchD] ipv6 route-static 121:: 64 12::1
[SwitchD] ipv6 route-static 2::9 128 11::2
[SwitchD] ipv6 route-static 1::9 128 12::1
```

Verifying the configuration

Display the BFD sessions on Switch A.

```
<SwitchA> display bfd session
 Total sessions: 1        Up sessions: 1        Init mode: Active

 IPv6 session working in control packet mode:

      Local Discr: 513                Remote Discr: 33
        Source IP: 1::9
   Destination IP: 2::9
    Session State: Up                     Interface: N/A
        Hold Time: 2012ms
```

The output shows that the BFD session has been created.

Display the IPv6 static routes on Switch A.

```
<SwitchA> display ipv6 routing-table protocol static

Summary count : 1

Static Routing table status : <Active>
Summary count : 1

Destination: 120::/64                                Protocol  : Static
NextHop    : 2::9                                    Preference: 60
Interface  : Vlan10                                  Cost      : 0

Static Routing table status : <Inactive>
Summary count : 0
```

The output shows that Switch A communicates Switch B through VLAN-interface 10. The link over VLAN-interface 10 fails.

Display IPv6 static routes on Switch A again.

```
<SwitchA> display ipv6 routing-table protocol static

Summary count : 1

Static Routing table status : <Active>
Summary count : 1

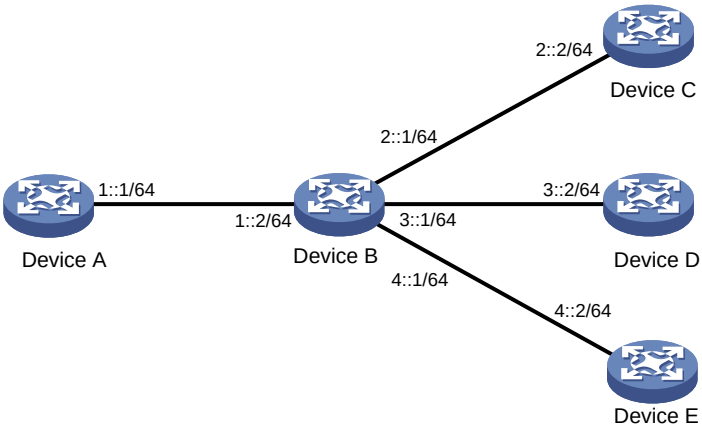
Destination: 120::/64                                Protocol  : Static
NextHop    : 10::100                                 Preference: 65
Interface  : Vlan11                                  Cost      : 0

Static Routing table status : <Inactive>
Summary count : 0
```

The output shows that Switch A communicates with Switch B through VLAN-interface 11.

Configuring an IPv6 default route

A default IPv6 route is used to forward packets that match no entry in the routing table.



A default IPv6 route can be configured in either of the following ways:

- The network administrator can configure a default route with a destination prefix of **::/0**. For more information, see "Configuring IPv6 static routing."
- Some dynamic routing protocols (such as OSPFv3, IPv6 IS-IS, and RIPng) can generate a default IPv6 route. For example, an upstream router running OSPFv3 can generate a default IPv6 route and advertise it to other routers. These routers install the default IPv6 route with the next hop being the upstream router. For more information, see the respective chapters on those routing protocols in this configuration guide.

As shown in Figure 4, Device B is the next hop for packets from Device A to Device C, Device D, and Device E. You can configure a default route on Device A to replace the three IPv6 static routes from Device A to Device C, Device D, and Device E, respectively.

The next hop address, destination address, and subnet mask of the IPv6 default route configured on Device A are 1::2, ::, and 0, respectively.

Configuring RIPng

About RIPng

RIP next generation (RIPng), as an extension of RIP-2 for support of IPv6, is a distance vector routing protocol. It employs UDP to exchange route information through port 521. Most RIP concepts are applicable to RIPng.

RIPng routing metrics

RIPng uses a hop count to measure the distance to a destination. The hop count is the metric or cost. The hop count from a router to a directly connected network is 0. The hop count between two directly connected routers is 1. When the hop count is greater than or equal to 16, the destination network or host is unreachable.

RIPng route entries

RIPng stores route entries in a database. Each route entry contains the following elements:

- **Destination address**—IPv6 address of a destination host or a network.
- **Next hop address**—IPv6 address of the next hop.
- **Egress interface**—Egress interface of the route.
- **Metric**—Cost from the local router to the destination.
- **Route time**—Time elapsed since the most recent update. The time is reset to 0 every time the route entry is updated.
- **Route tag**—Used for route control. For more information, see "Configuring routing policies."

RIPng packets and advertisement

RIPng multicasts request and response packets to exchange routing information. It uses FF02::9 as the destination address and link-local address FE80::/10 as the source address. RIPng exchanges routing information as follows:

1. When RIPng starts or needs to update some route entries, it sends a multicast request packet to neighbors.
2. When a RIPng neighbor receives the request packet, it sends back a response packet that contains the local routing table. RIPng can also advertise route updates in response packets periodically or advertise a triggered update caused by a route change.
3. After RIPng receives the response, it checks the validity of the response before adding routes to its routing table, including the following details:
   - Whether the source IPv6 address is the link-local address.
   - Whether the port number is correct.
4. A response packet that fails the check is discarded.

Protocols and standards

- RFC 2080, *RIPng for IPv6*
- RFC 2081, *RIPng Protocol Applicability Statement*

RIPng tasks at a glance

To configure RIPng, perform the following tasks:

1. Configuring basic RIPng
   a. Enabling RIPng
   b. (Optional.) Suppressing an interface
2. (Optional.) Configuring RIPng route control
   - Configuring an additional routing metric
   - Configuring RIPng route summarization
   - Advertising a default route
   - Configuring received/redistributed route filtering
   - Setting a preference for RIPng
   - Configuring RIPng route redistribution
3. (Optional.) Tuning and optimizing the RIPng network
   - Setting RIPng timers
   - Configuring split horizon and poison reverse
   - Setting the maximum number of ECMP routes
   - Configuring the RIPng packet sending rate
   - Setting the interval for sending triggered updates
4. (Optional.) Enhancing RIPng availability
   - Configuring RIPng GRConfiguring RIPng NSR
   - Enabling BFD for RIPng FRR
   - Configuring RIPng FRR
5. (Optional.) Enhancing RIPng security
   - Configuring zero field check for RIPng packetsApplying an IPsec profile

Configuring basic RIPng

Enabling RIPng

1. Enter system view.
   system-view
2. Enable RIPng and enter its view.
   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]
   By default, RIPng is disabled.
3. Return to system view.
   quit
4. Enter interface view.
   interface *interface-type interface-number*
5. Enable RIPng on the interface.
   ripng *process-id* **enable**
   By default, RIPng is disabled on the interface.
   If RIPng is not enabled on an interface, the interface does not send or receive any RIPng route.

Suppressing an interface

About this task

Perform this task to disable interfaces from sending RIPng messages. The interfaces can still receive RIPng messages.

Procedure

1. Enter system view.

   system-view
2. Enter RIPng view.

   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Suppress an interface.

   silent-interface { *interface-type interface-number* | **all** }

   By default, all RIPng-enabled interfaces can send RIP messages.

   The suppressed interface can still receive RIP messages and respond to unicast requests containing unknown ports.

Configuring RIPng route control

Configuring an additional routing metric

About this task

An additional routing metric (hop count) can be added to the metric of an inbound or outbound RIPng route.

- An outbound additional metric is added to the metric of a sent route, and it does not change the route's metric in the routing table.
- An inbound additional metric is added to the metric of a received route before the route is added into the routing table, and the route's metric is changed.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Specify an inbound additional routing metric.

   ripng metricin *value*

   The default additional metric of an inbound route is 0.
4. Specify an outbound additional routing metric.

   ripng metricout *value*

   The default additional metric of an outbound route is 1.

Configuring RIPng route summarization

About this task

RIPng route summarization is interface-based. RIPng advertises a summary route based on the longest match.

RIPng route summarization improves network scalability, reduces routing table size, and increases routing table lookup efficiency.

RIPng advertises a summary route with the smallest metric of all the specific routes.

For example, RIPng has two specific routes to be advertised through an interface: 1:11:11::24 with a metric of a 2 and 1:11:12::34 with a metric of 3. Configure route summarization on the interface, so RIPng advertises a single route 11::0/16 with a metric of 2.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Advertise a summary IPv6 prefix.

   ripng summary-address *ipv6-address prefix-length*

   By default, no summary IPv6 prefix is configured on the interface.

Advertising a default route

About this task

You can configure RIPng to advertise a default route with the specified cost to its neighbors.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Configure RIPng to advertise a default route.

   ripng default-route { **only** | **originate** } [**cost** *cost-value* | **route-policy** *route-policy-name*] *

   By default, RIPng does not advertise a default route.

   This command advertises a default route on the current interface regardless of whether the default route exists in the local IPv6 routing table.

Configuring received/redistributed route filtering

About this task

Perform this task to filter received or redistributed routes by using an IPv6 ACL, IPv6 prefix list, or routing policy. You can also configure RIPng to filter routes redistributed from other routing protocols and routes from a specified neighbor.

Procedure

1. Enter system view.

   system-view
2. Enter RIPng view.

   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Configure a filter policy to filter received routes.

   filter-policy { *ipv6-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } **import**

By default, RIPng does not filter received routes.

4. Configure a filter policy to filter redistributed routes.

   filter-policy { *ipv6-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } **export** [*protocol* [*process-id*]]

   By default, RIPng does not filter redistributed routes.

Setting a preference for RIPng

About this task

Routing protocols each have a preference. When they find routes to the same destination, the route found by the routing protocol with the highest preference is selected as the optimal route. You can manually set a preference for RIPng. The smaller the value, the higher the preference.

Procedure

1. Enter system view.

   system-view

2. Enter RIPng view.

   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Set a preference for RIPng.

   preference { *preference* | **route-policy** *route-policy-name* } *

   By default, the preference of RIPng is 100.

Configuring RIPng route redistribution

Restrictions and guidelines

Only the S5200-HI-G switch series supports the IPv6 BGP and IPv6 IS-IS related commands and parameters.

Procedure

1. Enter system view.

   system-view

2. Enter RIPng view.

   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Configure route redistribution.

   - Redistribute routes from BGP4+.

     import-route bgp4+ [*as-number*] [**allow-ibgp**] [**cost** *cost-value* | **route-policy** *route-policy-name*] *

   - Redistribute direct or static routes.

     import-route { **direct** | **static** } [**cost** *cost-value* | **route-policy** *route-policy-name*] *

   - Redistribute routes from OSPFv3, IPv6 IS-IS, or other RIPng processes.

     import-route { **isisv6** | **ospfv3** | **ripng** } [*process-id*] [**allow-direct** | **cost** *cost-value* | **route-policy** *route-policy-name*] *

   By default, RIPng does not redistribute routes.

4. (Optional.) Set a default routing metric for redistributed routes.

   default cost *cost-value*

   The default metric of redistributed routes is 0.

Tuning and optimizing the RIPng network

Setting RIPng timers

About this task

You can adjust RIPng timers to optimize the performance of the RIPng network.

Restrictions and guidelines

When you adjust RIPng timers, consider the network performance, and perform unified configurations on routers running RIPng to avoid unnecessary network traffic or route oscillation.

Procedure

1. Enter system view.

   system-view

2. Enter RIPng view.

   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Set RIPng timers.

   timers { **garbage-collect** *garbage-collect-value* | **suppress** *suppress-value* | **timeout** *timeout-value* | **update** *update-value* } *

   The default settings are as follows:

   - The update timer is 30 seconds.
   - The timeout timer is 180 seconds.
   - The suppress timer is 120 seconds.
   - The garbage-collect timer is 120 seconds.

Configuring split horizon and poison reverse

Restrictions and guidelines for split horizon and poison reverse

When you configure split horizon and poison reverse, following these restrictions and guidelines:

- If both split horizon and poison reverse are configured, only the poison reverse feature takes effect.
- Split horizon disables RIPng from sending routes through the interface where the routes were learned to prevent routing loops between neighbors. As a best practice, enable split horizon to prevent routing loops in normal cases.
- Poison reverse enables a route learned from an interface to be advertised through the interface. However, the metric of the route is set to 16, which means the route is unreachable.

Configuring split horizon

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable split horizon.

   ripng split-horizon

   By default, split horizon is enabled.

Configuring poison reverse

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable poison reverse.
   ripng poison-reverse
   By default, poison reverse is disabled.

Setting the maximum number of ECMP routes

1. Enter system view.
   system-view
2. Enter RIPng view.
   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Set the maximum number of RIPng ECMP routes.
   maximum load-balancing *number*
   By default, the maximum number of RIPng ECMP routes equals the maximum number of ECMP routes, which is configurable by using the **max-ecmp-num** command.

Configuring the RIPng packet sending rate

About this task

Perform this task to specify the interval for sending RIPng packets and the maximum number of RIPng packets that can be sent at each interval. This feature can avoid excessive RIPng packets from affecting system performance and consuming too much bandwidth.

Procedure

1. Enter system view.
   system-view
2. Enter RIPng view.
   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]
3. Configuring the RIPng packet sending rate.
   - Execute the following commands in sequence to configure the RIPng packet sending rate in RIPng view:
     ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]
     output-delay *time* **count** *count*
     By default, an interface that runs the RIPng process sends a maximum of three RIPng packets every 20 milliseconds.
   - Execute the following commands in sequence to configure the RIPng packet sending rate in interface view:
     interface *interface-type interface-number*
     ripng output-delay *time* **count** *count*
     By default, an interface uses the RIPng packet sending rate of the RIPng process that it runs.

Setting the interval for sending triggered updates

About this task

Perform this task to avoid network overhead and reduce system resource consumption caused by frequent RIPng triggered updates.

You can use the **timer triggered** command to set the maximum interval, minimum interval, and incremental interval for sending RIPng triggered updates.

For a stable network, the minimum interval is used. If network changes become frequent, the triggered update sending interval is incremented by the incremental interval × 2^{n-2} for each triggered update until the maximum interval is reached. The value *n* is the number of triggered update times.

Procedure

1. Enter system view.

   system-view

2. Enter RIPng view.

   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Set the interval for sending triggered updates.

   timer triggered *maximum-interval* [*minimum-interval* [*incremental-interval*]]

   The default maximum interval is 5 seconds, the default minimum interval is 50 milliseconds, and the default incremental interval is 200 milliseconds.

Configuring RIPng GR

About this task

GR ensures forwarding continuity when a routing protocol restarts or an active/standby switchover occurs.

Two routers are required to complete a GR process. The following are router roles in a GR process:

- **GR restarter**—Graceful restarting router. It must have GR capability.
- **GR helper**—A neighbor of the GR restarter. It helps the GR restarter to complete the GR process.

After RIPng restarts on a router, the router must learn RIPng routes again and updates its FIB table, which causes network disconnections and route reconvergence.

With the GR feature, the restarting router (known as the GR restarter) can notify the event to its GR capable neighbors. GR capable neighbors (known as GR helpers) maintain their adjacencies with the router within a configurable GR interval. During this process, the FIB table of the router does not change. After the restart, the router contacts its neighbors to retrieve its FIB.

By default, a RIPng-enabled device acts as the GR helper. Perform this task on the GR restarter.

Procedure

1. Enter system view.

   system-view

2. Enable RIPng and enter RIPng view.

   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enable the GR capability for RIPng.

   graceful-restart

   By default, RIPng GR is disabled.

4. (Optional.) Set the GR interval.

   graceful-restart interval *interval*

   The default GR interval is 60 seconds.

Configuring RIPng NSR

About this task

Nonstop routing (NSR) backs up RIPng routing information from the active process to the standby process. After an active/standby switchover, NSR can complete route regeneration without tearing down adjacencies or impacting forwarding services.

To use RIPng NSR, the system must have a minimum of two IRF member devices. NSR ensures nonstop services when RIPng has redundant processes on multiple IRF member devices.

In contrast to GR, NSR does not require a neighbor device to recover routing information.

Restrictions and guidelines

When both GR and NSR are configured for RIPng, the following rules apply:

- NSR has a higher priority than GR. When the active RIPng process goes down, the device does not act as the GR restarter and performs RIPng NSR to ensure nonstop forwarding.
- The device can participate in a GR process only when it acts as the GR helper. If it performs an active/standby RIPng process switchover before the GR process finishes, the GR process might fail even if RIPng NSR is enabled on the device.

RIPng NSR enabled for a RIPng process takes effect only on that process. As a best practice, enable RIPng NSR for each process if multiple RIPng processes exist.

Procedure

1. Enter system view.

   system-view

2. Enter RIPng view.

   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enable RIPng NSR.

   non-stop-routing

   By default, RIPng NSR is disabled.

Configuring BFD for RIPng

About this task

Configuring BFD for RIPng

About this task

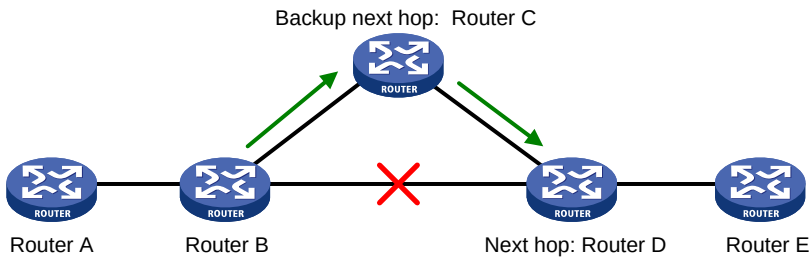
RIPng detects route failures by periodically sending requests. If it receives no response for a route within a certain time, RIPng considers the route unreachable. To speed up convergence, perform this task to enable BFD for RIPng. For more information about BFD, see *High Availability Configuration Guide*.

RIPng supports BFD in control packet mode. In this mode, a BFD session is established only when both ends have routes to send and BFD is enabled on the receiving interface.

Restrictions and guidelines

You need to perform this task to configure control-mode BFD detection on both the local and peer ends.

Procedure



1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable BFD for RIPng.
   ripng bfd enable
   By default, BFD for RIPng is disabled.

Configuring RIPng FRR

About RIPng FRR

A link or router failure on a path can cause packet loss and even routing loop until RIPng completes routing convergence based on the new network topology. FRR enables fast rerouting to minimize the impact of link or node failures.

Figure 1 Network diagram for RIPng FRR

As shown in Figure 1, configure FRR on Router B by using a routing policy to specify a backup next hop. When the primary link fails, RIPng directs packets to the backup next hop. At the same time, RIPng calculates the shortest path based on the new network topology. Then, the device forwards packets over that path after network convergence.

Restrictions and guidelines for RIPng FRR

RIPng FRR is available only when the state of the primary link (with Layer 3 interfaces staying up) changes from bidirectional to unidirectional or down.

RIPng FRR is only effective for RIPng routes that are learned from directly connected neighbors.

Equal-cost routes do not support RIPng FRR.

Enabling RIPng FRR

1. Enter system view.
   system-view
2. Configure a routing policy.

You must specify a next hop by using the **apply ipv6 fast-reroute backup-interface** command in a routing policy and specify the routing policy for FRR.

For more information about routing policy configuration, see "Configuring routing policies."

3. Enter RIPng view.
   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]
4. Enable RIPng FRR.
   fast-reroute route-policy *route-policy-name*

   By default, RIPng FRR is disabled.

Enabling BFD for RIPng FRR

About this task

By default, RIPng FRR does not use BFD to detect primary link failures. For quicker RIPng FRR, use BFD on the primary link of redundant links to detect link failure.

Procedure

1. Enter system view.
   system-view
2. Configure the source IP address of BFD echo packets.
   bfd echo-source-ipv6 *ipv6-address*

   By default, the source IP address of BFD echo packets is not configured.

   As a best practice, do not configure the source IP address on the same network segment as any local interfaces.

   Execute this command only when configuring echo-packet-mode BFD sessions.

   For more information about this command, see *High Availability Command Reference*.
3. Enter interface view.
   interface *interface-type interface-number*
4. Enable BFD for RIPng FRR.
   ripng primary-path-detect bfd { **ctrl** | **echo** }

   By default, BFD is disabled for RIPng FRR.

Enhancing RIPng security

Configuring zero field check for RIPng packets

About this task

Some fields in the RIPng packet header must be zero. These fields are called zero fields. You can enable zero field check for incoming RIPng packets. If a zero field of a packet contains a non-zero value, RIPng does not process the packets. If you are certain that all packets are trustworthy, disable the zero field check to save CPU resources.

Procedure

1. Enter system view.
   system-view
2. Enter RIPng view.
   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Enable the zero field check for incoming RIPng packets.

   checkzero

   By default, zero field check for incoming RIPng packets is enabled.

Applying an IPsec profile

About this task

To protect routing information and prevent attacks, you can configure RIPng to authenticate protocol packets by using an IPsec profile.

An IPsec profile contains inbound and outbound security parameter indexes (SPIs). RIPng compares the inbound SPI defined in the IPsec profile with the outbound SPI in the received packets. Two RIPng devices accept the packets from each other and establish a neighbor relationship only if the SPIs are the same and the relevant IPsec profiles match.

For more information about IPsec profiles, see *Security Configuration Guide*.

Restrictions and guidelines

You can apply an IPsec profile to a RIPng process or to an interface. If an interface and its process each have an IPsec profile, the IPsec profile applied to the interface takes effect.

Applying an IPsec profile to a process

1. Enter system view.

   system-view

2. Enter RIPng view.

   ripng [*process-id*] [**vpn-instance** *vpn-instance-name*]

3. Apply an IPsec profile to the process.

   enable ipsec-profile *profile-name*

   By default, no IPsec profile is applied.

Applying an IPsec profile to an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Apply an IPsec profile to the interface.

   ripng ipsec-profile *profile-name*

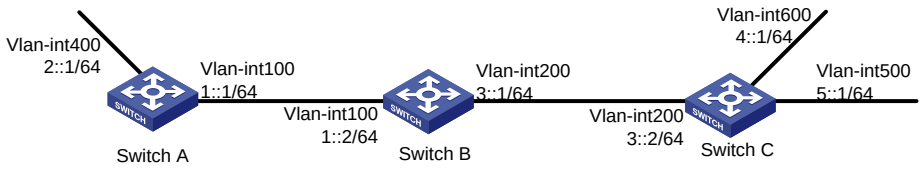
   By default, no IPsec profile is applied.

Display and maintenance commands for RIPng

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display configuration information for a RIPng process.	**display ripng** [*process-id*]
Display RIPng GR information.	**display ripng** [*process-id*] **graceful-restart**
Display RIPng NSR information.	**display ripng** [*process-id*]

Task	Command
	non-stop-routing
Display routes in the RIPng database.	**display ripng** *process-id* **database** [*ipv6-address prefix-length*]
Display interface information for a RIPng process.	**display ripng** *process-id* **interface** [*interface-type interface-number*]
Display neighbor information for a RIPng process.	**display ripng** *process-id* **neighbor** [*interface-type interface-number*]
Display the routing information for a RIPng process.	**display ripng** *process-id* **route** [*ipv6-address prefix-length* [**verbose**] | **peer** *ipv6-address* | **statistics**]
Restart a RIPng process.	**reset ripng** *process-id* **process**
Clear statistics for a RIPng process.	**reset ripng** *process-id* **statistics**



RIPng configuration examples

Example: Configuring basic RIPng

Network configuration

As shown in Figure 2, Switch A, Switch B, and Switch C run RIPng. Configure route filtering on Switch B to accept all received routes except the route 2::/64 and to advertise only the route 4::/64.

Figure 2 Network diagram

Procedure

1. Configure IPv6 addresses for the interfaces. (Details not shown.)
2. Configure basic RIPng settings:

   # Configure Switch A.

   ```
   <SwitchA> system-view
   [SwitchA] ripng 1
   [SwitchA-ripng-1] quit
   [SwitchA] interface vlan-interface 100
   [SwitchA-Vlan-interface100] ripng 1 enable
   [SwitchA-Vlan-interface100] quit
   [SwitchA] interface vlan-interface 400
   [SwitchA-Vlan-interface400] ripng 1 enable
   [SwitchA-Vlan-interface400] quit
   ```

   # Configure Switch B.

   ```
   <SwitchB> system-view
   [SwitchB] ripng 1
   ```

```
[SwitchB-ripng-1] quit
[SwitchB] interface vlan-interface 200

     via ::, cost 0, tag 0, DOF
 Destination 2::/64,
```

```
via ::, cost 0, tag 0, DOF
```

Example: Configuring RIPng route redistribution

Network configuration

As shown in Figure 3, Switch B communicates with Switch A through RIPng 100 and with Switch C through RIPng 200.

Configure route redistribution on Switch B, so the two RIPng processes can redistribute routes from each other.

Figure 3 Network diagram

Procedure

1. Configure IPv6 addresses for the interfaces. (Details not shown.)
2. Configure basic RIPng settings:

   # Enable RIPng 100 on Switch A.

```
<SwitchA> system-view
[SwitchA] ripng 100
[SwitchA-ripng-100] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ripng 100 enable
[SwitchA-Vlan-interface100] quit
[SwitchA] interface vlan-interface 200
[SwitchA-Vlan-interface200] ripng 100 enable
[SwitchA-Vlan-interface200] quit
```

   # Enable RIPng 100 and RIPng 200 on Switch B.

```
<SwitchB> system-view
[SwitchB] ripng 100
[SwitchB-ripng-100] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ripng 100 enable
[SwitchB-Vlan-interface100] quit
[SwitchB] ripng 200
[SwitchB-ripng-200] quit
[SwitchB] interface vlan-interface 300
[SwitchB-Vlan-interface300] ripng 200 enable
[SwitchB-Vlan-interface300] quit
```

   # Enable RIPng 200 on Switch C.

```
<SwitchC> system-view
[SwitchC] ripng 200
[SwitchC] interface vlan-interface 300
[SwitchC-Vlan-interface300] ripng 200 enable
```

```
[SwitchC-Vlan-interface300] quit
[SwitchC] interface vlan-interface 400
[SwitchC-Vlan-interface400] ripng 200 enable
[SwitchC-Vlan-interface400] quit
```

Display the routing table on Switch A.

```
[SwitchA] display ipv6 routing-table

Destinations : 7 Routes : 7

Destination: ::1/128                                Protocol  : Direct

```

Example: Configuring RIPng GR

Network configuration

As shown in Figure 4, Switch A, Switch B, and Switch C learn IPv6 routing information through RIPng.

Configure Switch A as the GR restarter. Configure Switch B and Switch C as the GR helpers to synchronize their routing tables with Switch A by using GR.

Figure 4 Network diagram

Procedure

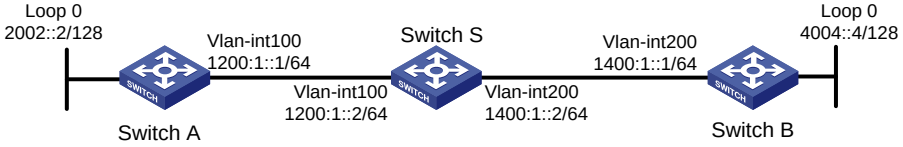
1. Configure IPv6 addresses for the interfaces. (Details not shown.)
2. Configure RIPng on the switches to ensure the following: (Details not shown.)
   - Switch A, Switch B, and Switch C can communicate with each other at Layer 3.
   - Dynamic route update can be implemented among them with RIPng.
3. Enable RIPng GR on Switch A.

```
<SwitchA> system-view
[SwitchA] ripng 1
[SwitchA-ripng-1] graceful-restart
```

Verifying the configuration

Restart RIPng or trigger an active/standby switchover, and then display GR status on Switch A.

```
<SwitchA> display ripng 1 graceful-restart
RIPng process: 1
 Graceful Restart capability     : Enabled
 Current GR state                : Normal
 Graceful Restart period         : 60  seconds
 Graceful Restart remaining time: 0   seconds
```



Example: Configuring RIPng NSR

Network configuration

As shown in Figure 5, Switch S, Switch A, and Switch B learn IPv6 routing information through RIPng.

Enable RIPng NSR on Switch S to ensure correct routing when an active/standby switchover occurs on Switch S.

Figure 5 Network diagram

Procedure

1. Configure IPv6 addresses for the interfaces. (Details not shown.)

2. Configure RIPng on the switches to ensure the following: (Details not shown.)
   - Switch S, Switch A, and Switch B can communicate with each other at Layer 3.
   - Dynamic route update can be implemented among them with RIPng.
3. Enable RIPng NSR.

   # Enable RIPng NSR on Switch S.

```
<SwitchS> system-view
[SwitchS] ripng 1
[SwitchS-ripng-1] non-stop-routing
[SwitchS-ripng-1] quit
```

Verifying the configuration

Perform an active/standby switchover on Switch S.

```

    via ::, cost 0, tag 0, DOF
 Destination 1200:1::/64,
    via ::, cost 0, tag 0, DOF
```

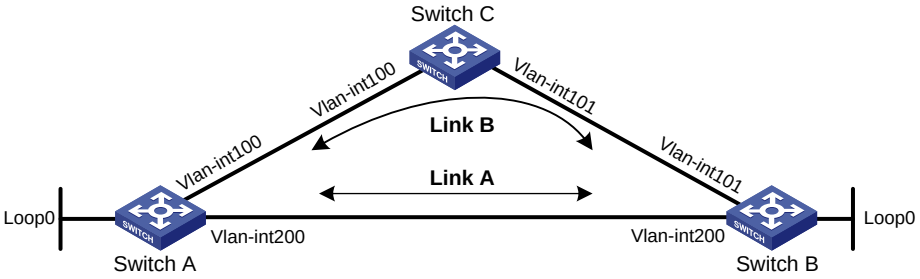
Display RIPng neighbors on Switch B to verify the neighbor relationship between Switch B and Switch S.

```
[SwitchB] display ripng 1 neighbor
 Neighbor Address: FE80::20C:29FF:FECE:6277
    Interface  : Vlan-interface200
    Version    : RIPng version 1     Last update: 00h00m18s
    BFD session: None
    Bad packets: 0                   Bad routes : 0
```

Display RIPng routes on Switch B to verify if Switch B has a route to the loopback interface on Switch A.

```
[SwitchB] display ripng 1 route
   Route Flags: A - Aging, S - Suppressed, G - Garbage-collect, D - Direct
                O - Optimal, F - Flush to RIB
 ----------------------------------------------------------------
 Peer FE80::20C:29FF:FECE:6277 on Vlan-interface200
 Destination 2002::2/128,
    via FE80::20C:29FF:FECE:6277, cost 2, tag 0, AOF, 24 secs
 Destination 1200:1::/64,
    via FE80::20C:29FF:FECE:6277, cost 1, tag 0, AOF, 24 secs
 Local route
 Destination 4004::4/128,
    via ::, cost 0, tag 0, DOF
 Destination 1400:1::/64,
    via ::, cost 0, tag 0, DOF
```

The output shows the following when an active/standby switchover occurs on Switch S:



- The neighbor relationships and routing information on Switch A and Switch B have not changed.
- The traffic from Switch A to Switch B has not been impacted.

Example: Configuring RIPng FRR

Network configuration

As shown in Figure 6, Switch A, Switch B, and Switch C run RIPng. Configure RIPng FRR so that when Link A becomes unidirectional, traffic can be switched to Link B immediately.

Figure 6 Network diagram

Device	Interface	IP address
Switch A	VLAN-interface 100	1::1/64
Switch A	VLAN-interface 200	2::1/64
Switch A	Loopback 0	10::1/128
Switch B	VLAN-interface 101	3::1/64
Switch B	VLAN-interface 200	2::2/64
Switch B	Loopback 0	20::1/128
Switch C	VLAN-interface 100	1::2/64
Switch C	VLAN-interface 101	3::2/64

Procedure

1. Configure IPv6 addresses for the interfaces on the switches. (Details not shown.)
2. Configure RIPng on the switches to make sure Switch A, Switch B, and Switch C can communicate with each other at Layer 3. (Details not shown.)
3. Configure RIPng FRR:

   # Configure Switch A.

```
<SwitchA> system-view
[SwitchA] ipv6 prefix-list abc index 10 permit 20::1 128
[SwitchA] route-policy frr permit node 10
[SwitchA-route-policy-frr-10] if-match ipv6 address prefix-list abc
[SwitchA-route-policy-frr-10] apply ipv6 fast-reroute backup-interface
vlan-interface 100 backup-nexthop fe80::6eab:8bff:fed4:205
[SwitchA-route-policy-frr-10] quit
[SwitchA] ripng 1
[SwitchA-ripng-1] fast-reroute route-policy frr
[SwitchA-ripng-1] quit
```

   # Configure Switch B.

```
<SwitchB> system-view
[SwitchB] ipv6 prefix-list abc index 10 permit 10::1 128
[SwitchB] route-policy frr permit node 10
[SwitchB-route-policy-frr-10] if-match ipv6 address prefix-list abc
[SwitchB-route-policy-frr-10] apply ipv6 fast-reroute backup-interface
vlan-interface 101 backup-nexthop fe80::6eab:8bff:fed4:206
[SwitchB-route-policy-frr-10] quit
[SwitchB] ripng 1
[SwitchB-ripng-1] fast-reroute route-policy frr
```

```
[SwitchB-ripng-1] quit
```

Verifying the configuration

Display the route 20::1/128 on Switch A to view the backup next hop information.

```
[SwitchA] display ipv6 routing-table 20::1 128 verbose

Example: Configuring RIPng IPsec profile

Network configuration

As shown in Figure 7, configure RIPng on the switches, and configure IPsec profiles on the switches to authenticate and encrypt protocol packets.

Figure 7 Network diagram

Procedure

1. Configure IPv6 addresses for the interfaces. (Details not shown.)
2. Configure basic RIPng settings:

   # Configure Switch A.

   ```
   <SwitchA> system-view
   [SwitchA] ripng 1
   [SwitchA-ripng-1] quit
   [SwitchA] interface vlan-interface 100
   [SwitchA-Vlan-interface100] ripng 1 enable
   [SwitchA-Vlan-interface100] quit
   ```

   # Configure Switch B.

   ```
   <SwitchB> system-view
   [SwitchB] ripng 1
   [SwitchB-ripng-1] quit
   [SwitchB] interface vlan-interface 200
   [SwitchB-Vlan-interface200] ripng 1 enable
   [SwitchB-Vlan-interface200] quit
   [SwitchB] interface vlan-interface 100
   [SwitchB-Vlan-interface100] ripng 1 enable
   [SwitchB-Vlan-interface100] quit
   ```

   # Configure Switch C.

   ```
   <SwitchC> system-view
   [SwitchC] ripng 1
   [SwitchC-ripng-1] quit
   [SwitchC] interface vlan-interface 200
   [SwitchC-Vlan-interface200] ripng 1 enable
   [SwitchC-Vlan-interface200] quit
   ```

3. Configure RIPng IPsec profiles:

- On Switch A:

  # Create an IPsec transform set named **protrf1**.

  ```
  [SwitchA] ipsec transform-set protrf1
  ```

  # Specify the ESP encryption and authentication algorithms.

  ```
  [SwitchA-ipsec-transform-set-protrf1] esp encryption-algorithm 3des-cbc
  [SwitchA-ipsec-transform-set-protrf1] esp authentication-algorithm md5
  ```

  # Specify transport mode for encapsulation.

  ```
   [SwitchA-ipsec-transform-set-protrf1] encapsulation-mode transport
  [SwitchA-ipsec-transform-set-protrf1] quit
  ```

  # Create a manual IPsec profile named **profile001**.

  ```
  [SwitchA] ipsec profile profile001 manual
  ```

  # Reference IPsec transform set **protrf1**.

  ```
  [SwitchA-ipsec-profile-profile001-manual] transform-set protrf1
  ```

  # Configure the inbound and outbound SPIs for ESP.

  ```
  [SwitchA-ipsec-profile-profile001-manual] sa spi inbound esp 256
  [SwitchA-ipsec-profile-profile001-manual] sa spi outbound esp 256
  ```

  # Configure the inbound and outbound SA keys for ESP.

  ```
  [SwitchA-ipsec-profile-profile001-manual] sa string-key inbound esp simple abc
  [SwitchA-ipsec-profile-profile001-manual] sa string-key outbound esp simple abc
  [SwitchA-ipsec-profile-profile001-manual] quit
  ```

- On Switch B:

  # Create an IPsec transform set named **protrf1**.

  ```
  [SwitchB] ipsec transform-set protrf1
  ```

  # Specify the ESP encryption and authentication algorithms.

  ```
  [SwitchB-ipsec-transform-set-protrf1] esp encryption-algorithm 3des-cbc
  [SwitchB-ipsec-transform-set-protrf1] esp authentication-algorithm md5
  ```

  # Specify transport mode for encapsulation.

  ```
   [SwitchB-ipsec-transform-set-protrf1] encapsulation-mode transport
  [SwitchB-ipsec-transform-set-protrf1] quit
  ```

  # Create a manual IPsec profile named **profile001**.

  ```
  [SwitchB] ipsec profile profile001 manual
  ```

  # Reference IPsec transform set **protrf1**.

  ```
  [SwitchB-ipsec-profile-profile001-manual] transform-set protrf1
  ```

  # Configure the inbound and outbound SPIs for ESP.

  ```
  [SwitchB-ipsec-profile-profile001-manual] sa spi inbound esp 256
  [SwitchB-ipsec-profile-profile001-manual] sa spi outbound esp 256
  ```

  # Configure the inbound and outbound SA keys for ESP.

  ```
  [SwitchB-ipsec-profile-profile001-manual] sa string-key inbound esp simple abc
  [SwitchB-ipsec-profile-profile001-manual] sa string-key outbound esp simple abc
  [SwitchB-ipsec-profile-profile001-manual] quit
  ```

- On Switch C:

  # Create an IPsec transform set named **protrf1**.

  ```
  [SwitchC] ipsec transform-set protrf1
  ```

  # Specify the ESP encryption and authentication algorithms.

  ```
  [SwitchC-ipsec-transform-set-protrf1] esp encryption-algorithm 3des-cbc
  ```

```
[SwitchC-ipsec-transform-set-protrf1] esp authentication-algorithm md5
```

Specify transport mode for encapsulation.

```
 [SwitchC-ipsec-transform-set-protrf1] encapsulation-mode transport
[SwitchC-ipsec-transform-set-protrf1] quit
```

Create a manual IPsec profile named **profile001**.

```
[SwitchC] ipsec profile profile001 manual
```

Reference IPsec transform set **protrf1**.

```
[SwitchC-ipsec-profile-profile001-manual] transform-set protrf1
```

Configure the inbound and outbound SPIs for ESP.

```
[SwitchC-ipsec-profile-profile001-manual] sa spi inbound esp 256
[SwitchC-ipsec-profile-profile001-manual] sa spi outbound esp 256
```

Configure the inbound and outbound SA keys for ESP.

```
[SwitchC-ipsec-profile-profile001-manual] sa string-key inbound esp simple abc
[SwitchC-ipsec-profile-profile001-manual] sa string-key outbound esp simple abc
[SwitchC-ipsec-profile-profile001-manual] quit
```

4. Apply the IPsec profiles to the RIPng process on each device:
   - On Switch A:

     ```
     [SwitchA] ripng 1
     [SwitchA-ripng-1] enable ipsec-profile profile001
     [SwitchA-ripng-1] quit
     ```

   - On Switch B:

     ```
     [SwitchB] ripng 1
     [SwitchB-ripng-1] enable ipsec-profile profile001
     [SwitchB-ripng-1] quit
     ```

   - On Switch C:

     ```
     [SwitchC] ripng 1
     [SwitchC-ripng-1] enable ipsec-profile profile001
     [SwitchC-ripng-1] quit
     ```

Verifying the configuration

Verify that the RIPng packets between Switches A, B and C are protected by IPsec. (Details not shown.)

Configuring OSPFv3

About OSPFv3

This chapter describes how to configure Open Shortest Path First version 3 (OSPFv3) for an IPv6 network.

Comparison of OSPFv3 with OSPFv2

OSPFv3 and OSPFv2 have the following in common:

- 32-bit router ID and area ID.
- Hello, Database Description (DD), Link State Request (LSR), Link State Update (LSU), Link State Acknowledgment (LSAck).
- Mechanisms for finding neighbors and establishing adjacencies.
- Mechanisms for advertising and aging LSAs.

OSPFv3 and OSPFv2 have the following differences:

- OSPFv3 runs on a per-link basis and uses link-local addresses for neighbor relationship establishment and LSA database synchronization. All OSPFv3 interfaces use their link-local addresses to forward packets except for virtual links.
- OSPFv3 supports running multiple processes on an interface, but OSPFv2 does not support.
- OSPFv3 identifies neighbors by router ID. OSPFv2 identifies neighbors by IP address.

For more information about OSPFv2, see "Configuring OSPF."

OSPFv3 packets

OSPFv3 uses the following packet types:

- **Hello**—Periodically sent to find and maintain neighbors, containing timer values, information about the DR, BDR, and known neighbors.
- **DD**—Describes the digest of each LSA in the LSDB, exchanged between two routers for data synchronization.
- **LSR**—Requests needed LSAs from the neighbor. After exchanging the DD packets, the two routers know which LSAs of the neighbor are missing from their LSDBs. They then send an LSR packet to each other, requesting the missing LSAs. The LSA packet contains the digest of the missing LSAs.
- **LSU**—Transmits the requested LSAs to the neighbor.
- **LSAck**—Acknowledges received LSU packets.

OSPFv3 LSA types

OSPFv3 sends routing information in LSAs. The following LSAs are commonly used:

- **Router LSA**—Type-1 LSA, originated by all routers. This LSA describes the collected states of the router's interfaces to an area, and is flooded throughout a single area only.
- **Network LSA**—Type-2 LSA, originated for broadcast and NBMA networks by the DR. This LSA contains the list of routers connected to the network, and is flooded throughout a single area only.

- **Inter-Area-Prefix LSA**—Type-3 LSA, originated by ABRs and flooded throughout the LSA's associated area. Each Inter-Area-Prefix LSA describes a route with IPv6 address prefix to a destination outside the area, yet still inside the AS.
- **Inter-Area-Router LSA**—Type-4 LSA, originated by ABRs and flooded throughout the LSA's associated area. Each Inter-Area-Router LSA describes a route to ASBR.
- **AS External LSA**—Type-5 LSA, originated by ASBRs, and flooded throughout the AS, except stub areas and Not-So-Stubby Areas (NSSAs). Each AS External LSA describes a route to another AS. A default route can be described by an AS External LSA.
- **NSSA LSA**—Type-7 LSA, originated by ASBRs in NSSAs and flooded throughout a single NSSA. NSSA LSAs describe routes to other ASs.
- **Link LSA**—Type-8 LSA. A router originates a separate Link LSA for each attached link. Link LSAs have link-local flooding scope. Each Link LSA describes the IPv6 address prefix of the link and Link-local address of the router.
- **Intra-Area-Prefix LSA**—Type-9 LSA. Each Intra-Area-Prefix LSA contains IPv6 prefix information on a router, stub area, or transit area information, and has area flooding scope. It was introduced because Router LSAs and Network LSAs contain no address information.
- **Grace LSA**—Type-11 LSA, generated by a GR restarter at reboot and transmitted on the local link. The GR restarter describes the cause and interval of the reboot in the Grace LSA to notify its neighbors that it performs a GR operation.

Protocols and standards

- RFC 7166, *Supporting Authentication Trailer for OSPFv3*

OSPFv3 tasks at a glance

To configure OSPFv3, perform the following tasks:

1. Enabling OSPFv3
2. (Optional.) Establishing OSPFv3 neighbor relationships on an M-LAG network
3. (Optional.) Configuring OSPFv3 area parameters
   - Configuring a stub area
   - Configuring an NSSA area
   - Configuring an OSPFv3 virtual link

     Perform this task on an ABR to create a virtual link when connectivity cannot be maintained between a non-backbone area and the backbone, or within the backbone.

4. (Optional.) Configuring OSPFv3 network types
   - Setting the broadcast network type for an OSPFv3 interface
   - Setting the NBMA network type for an OSPFv3 interface
   - Setting the P2MP network type for an OSPFv3 interface
   - Setting the P2P network type for an OSPFv3 interface
5. (Optional.) Configuring OSPFv3 route control
   - Configuring OSPFv3 inter-area route summarization
   - Configuring redistributed route summarization
   - Configuring OSPFv3 received route filtering
   - Configuring Inter-Area-Prefix LSA filtering
   - Setting an OSPFv3 cost for an interface
   - Advertising the maximum link cost to neighbors within the specified period
   - Associating OSPFv3 with Track
   - Setting the maximum number of OSPFv3 ECMP routes
   - Setting a preference for OSPFv3
   - Configuring OSPFv3 route redistribution
6. (Optional.) Setting OSPFv3 timers
   - Setting OSPFv3 packet timers
   - Setting the LSA transmission delay
   - Setting the OSPFv3 route calculation interval
   - Setting the LSA generation interval
   - Setting the LSU transmit rate
7. (Optional.) Setting a DR priority for an interface
8. (Optional.) Configuring OSPFv3 packet parameters
   - Ignoring MTU check for DD packets
   - Disabling interfaces from receiving and sending OSPFv3 packets
9. (Optional.) Configuring prefix suppression
10. (Optional.) Configuring OSPFv3 advanced features
    - Configuring a stub router
    - Configuring OSPFv3 isolation
    - Configuring OSPFv3 shutdown
11. (Optional.) Enhancing OSPFv3 availability
    - Configuring OSPFv3 GR
    - Configuring OSPFv3 NSR
    - Configuring BFD for OSPFv3
    - Configuring OSPFv3 FRR
12. (Optional.) Enhancing OSPFv3 security
    - Configuring OSPFv3 authentication
    - Applying an IPsec profile for authenticating OSPFv3 packets
13. (Optional.) Configuring OSPFv3 logging and SNMP notifications
    - Enabling logging for neighbor state changes
    - Setting the maximum number of OSPFv3 logs
    - Configuring OSPFv3 network management

Enabling OSPFv3

About this task

To enable an OSPFv3 process on a router:

1. Enable the OSPFv3 process globally.
2. Assign the OSPFv3 process a router ID.
3. Enable the OSPFv3 process on related interfaces.

An OSPFv3 process ID has only local significance. Process 1 on a router can exchange packets with process 2 on another router.

OSPFv3 requires you to manually specify a router ID for each router in an AS. Make sure all assigned router IDs in the AS are unique.

Restrictions and guidelines

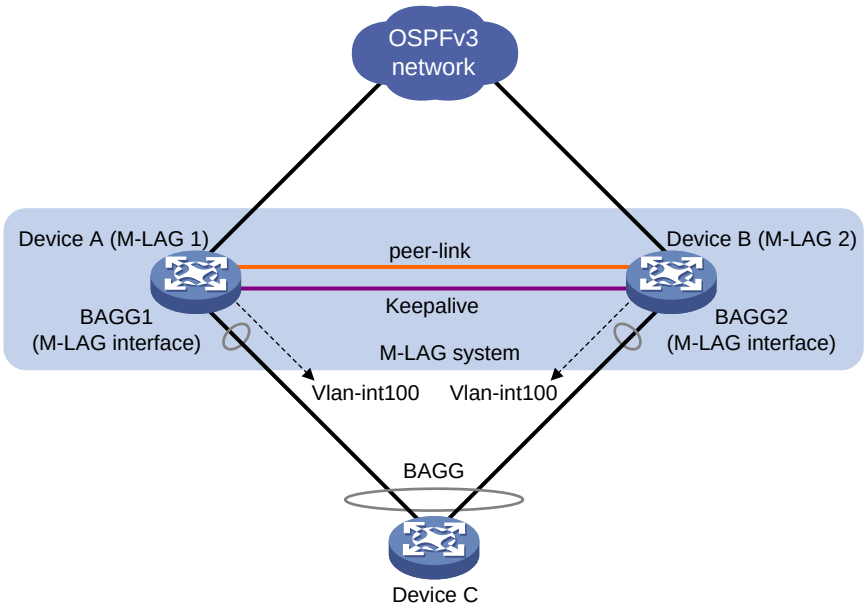
If a router runs multiple OSPFv3 processes, you must specify a unique router ID for each process.

Procedure

1. Enter system view.
   system-view
2. Enable an OSPFv3 process and enter its view.
   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *
   By default, no OSPFv3 processes are enabled.
3. Specify a router ID.
   router-id *router-id*
   By default, no router ID is configured.
4. (Optional.) Configure a description for the OSPFv3 process.
   description *text*
   By default, no description is configured for an OSPFv3 process.
   To identify and manage different OSPFv3 processes, configure a unique description for each process.
5. Return to system view.
   quit
6. Enter interface view.
   interface *interface-type interface-number*
7. Enable an OSPFv3 process on the interface.
   ospfv3 *process-id* **area** *area-id* [**instance** *instance-id*]
   By default, no OSPFv3 processes are enabled on an interface.

Establishing OSPFv3 neighbor relationships on an M-LAG network

About this task



When a customer-side device accesses the OSPFv3 network through both M-LAG member devices in an M-LAG system, the M-LAG member devices provide Layer 3 gateway services. The gateway interfaces (such as VLAN interfaces) on different M-LAG member devices might generate the same link-local address because they have the same IP address and MAC address. In this case, the

M-LAG member devices cannot establish OSPFv3 neighbor relationships with the customer-side device.

To resolve this issue, configure the gateway interfaces to use M-LAG virtual IPv6 addresses for OSPFv3 neighbor relationship establishment. The M-LAG virtual IPv6 address configured for a gateway interface must be a link-local address because OSPFv3 uses link-local addresses for OSPFv3 neighbor relationship establishment. For more information about M-LAG, see M-LAG configuration in *Layer 2—LAN Switching Configuration Guide*.

As shown in Figure 1, Device C accesses the OSPFv3 network through the M-LAG system that consists of Device A and Device B. Device A and Device B provide Layer 3 gateway services. The gateway interface VLAN-interface 100 on Device A and the gateway interface VLAN-interface 100 on Device B have the same IP address and the same MAC address. To ensure that both Device A and Device B can establish an OSPFv3 neighbor relationship with Device C, configure different M-LAG virtual IPv6 addresses for the VLAN interfaces on Device A and Device B.

Figure 1 OSPFv3 neighbor relationship establishment on an M-LAG network

Restrictions and guidelines

The S5200-EI-G switch series does not support M-LAG.

Procedure

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
3. Specify a link-local address as the M-LAG virtual IPv6 address to be assigned to the interface.
   `port m-lag ipv6 virtual-ip` *`ipv6-address`* **`link-local`**

   By default, no M-LAG virtual IPv6 address is assigned to an interface.

   For more information about this command, see M-LAG commands in *Layer 2—LAN Switching Ethernet Command Reference*.

Configuring OSPFv3 area parameters

About OSPFv3 areas

OSPFv3 has the same stub area, NSSA area, and virtual link features as OSPFv2.

After you split an OSPFv3 AS into multiple areas, the LSA number is reduced and OSPFv3 applications are extended. To further reduce the size of routing tables and the number of LSAs, configure the non-backbone areas at an AS edge as stub areas.

A stub area cannot import external routes, but an NSSA area can import external routes into the OSPFv3 routing domain while retaining other stub area characteristics.

Non-backbone areas exchange routing information through the backbone area, so the backbone and non-backbone areas (including the backbone itself) must be fully meshed. If no connectivity can be achieved, configure virtual links.

Configuring a stub area

Restrictions and guidelines

To configure a stub area, you must perform this task on all routers attached to the area.

Procedure

1. Enter system view.
   system-view
2. Enter OSPFv3 view.
   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *
3. Enter OSPFv3 area view.
   area *area-id*
4. Configure the area as a stub area.
   stub [**default-route-advertise-always** | **no-summary**] *

   By default, no area is configured as a stub area.

   The **no-summary** keyword is only available on the ABR of a stub area. If you specify the **no-summary** keyword, the ABR only advertises a default route in an Inter-Area-Prefix LSA into the stub area.
5. (Optional.) Set a cost for the default route advertised to the stub area.
   default-cost *cost-value*

   By default, the cost for the default route advertised to the stub area is 1.

Configuring an NSSA area

Restrictions and guidelines

To configure an NSSA area, you must perform this task on all routers attached to the area.

Procedure

1. Enter system view.
   system-view
2. Enter OSPFv3 view.
   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Enter OSPFv3 area view.

   area *area-id*

4. Configure the area as an NSSA area.

   nssa [**default-route-advertise** [**cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] * | **no-import-route** | **no-summary** | [**translate-always** | **translate-never**] | **suppress-fa** | **translator-stability-interval** *value*] *

   By default, no area is configured as an NSSA area.

   To configure a totally NSSA area, execute the **nssa no-summary** command on the ABR. The ABR of a totally NSSA area does not advertise inter-area routes into the area.

5. (Optional.) Set a cost for the default route advertised to the NSSA area.

   default-cost *cost-value*

   By default, the cost for the default route advertised to the NSSA area is 1.

   This command takes effect only on the ABR/ASBR of an NSSA or totally NSSA area.

Configuring an OSPFv3 virtual link

About this task

You can configure a virtual link to maintain connectivity between a non-backbone area and the backbone, or in the backbone itself.

Restrictions and guidelines

Both ends of a virtual link are ABRs that must be configured with the **vlink-peer** command.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Enter OSPFv3 area view.

   area *area-id*

4. Configure a virtual link.

   vlink-peer *router-id* [**dead** *seconds* | **hello** *seconds* | **instance** *instance-id* | **ipsec-profile** *profile-name* | **keychain** *keychain-name* | **retransmit** *seconds* | **trans-delay** *seconds*] *

Configuring OSPFv3 network types

Restrictions and guidelines for OSPFv3 network type configuration

Based on the link layer protocol, OSPFv3 classifies networks into different types, including broadcast, NBMA, P2MP, and P2P.

- If any routers in a broadcast network do not support multicasting, you can change the network type to NBMA.
- If only two routers running OSPFv3 exist on a network segment, you can change the network type to P2P to save costs.

Setting the broadcast network type for an OSPFv3 interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the network type to broadcast for the OSPFv3 interface.

   ospfv3 network-type broadcast [**instance** *instance-id*]

   By default, the network type of an OSPFv3 interface depends on the encapsulated link layer protocol.

Setting the NBMA network type for an OSPFv3 interface

Restrictions and guidelines

For NBMA interfaces, you must specify the link-local IP addresses and DR priorities for their neighbors because these interfaces cannot find neighbors by broadcasting hello packets.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the network type to NBMA for the OSPFv3 interface.

   ospfv3 network-type nbma [**instance** *instance-id*]

   By default, the network type of an OSPFv3 interface depends on the encapsulated link layer protocol.

4. (Optional.) Set the router priority for the interface

   ospfv3 dr-priority *priority*

   By default, an interface has a router priority of 1.

   An interface's router priority determines its privilege in DR/BDR selection.

5. Specify an NBMA neighbor.

   ospfv3 peer *ipv6-address* [**cost** *cost-value* | **dr-priority** *priority*] [**instance** *instance-id*]

   By default, no link-local address is specified for the neighbor interface.

Setting the P2MP network type for an OSPFv3 interface

Restrictions and guidelines

For P2MP interfaces (only when in unicast mode), you must specify the link-local IP addresses of their neighbors because these interfaces cannot find neighbors by broadcasting hello packets.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the network type to P2MP for the OSPFv3 interface.

   ospfv3 network-type p2mp [**unicast**] [**instance** *instance-id*]

   By default, the network type of an OSPFv3 interface depends on the encapsulated link layer protocol.

4. Specify a P2MP unicast neighbor.

   ospfv3 peer *ipv6-address* [**cost** *cost-value* | **dr-priority** *priority*] [**instance** *instance-id*]

   By default, no link-local address is specified for the neighbor interface.

Setting the P2P network type for an OSPFv3 interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the network type to P2P for the OSPFv3 interface.

   ospfv3 network-type p2p [**instance** *instance-id*]

   By default, the network type of an OSPFv3 interface depends on the encapsulated link layer protocol.

Configuring OSPFv3 route control

Configuring OSPFv3 inter-area route summarization

About this task

If contiguous network segments exist in an area, you can summarize them into one network segment on the ABR. The ABR will advertise only the summary route. Any LSA on the specified network segment will not be advertised, reducing the LSDB size in other areas.

Procedure

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

3. Enter OSPFv3 area view.

   area *area-id*

4. Configure route summarization on the ABR.

   abr-summary *ipv6-address prefix-length* [**not-advertise**] [**cost** *cost-value*]

   By default, route summarization is not configured on an ABR.

Configuring redistributed route summarization

About this task

Perform this task to enable an ASBR to summarize external routes within the specified address range into a single route.

An ASBR can summarize routes in the following LSAs:

- Type-5 LSAs.
- Type-7 LSAs in an NSSA area.
- Type-5 LSAs translated from Type-7 LSAs in an NSSA area if the ASBR (also an ABR) is a translator. If the ASBR is not a translator, it cannot summarize routes in Type-5 LSAs translated from Type-7 LSAs.

Procedure

1. Enter system view.
   system-view
2. Enter OSPFv3 view.
   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *
3. Configure route summarization on an ASBR.
   asbr-summary *ipv6-address prefix-length* [**cost** *cost-value* | **not-advertise** | **nssa-only** | **tag** *tag*] *
   By default, route summarization is not configured on an ASBR.

Configuring OSPFv3 received route filtering

About this task

This task allows you to filter routes calculated by using received LSAs.

Procedure

1. Enter system view.
   system-view
2. Enter OSPFv3 view.
   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *
3. Configure OSPFv3 to filter routes calculated by using received LSAs.
   filter-policy { *ipv6-acl-number* [**gateway** *prefix-list-name*] | **prefix-list** *prefix-list-name* [**gateway** *prefix-list-name*] | **gateway** *prefix-list-name* | **route-policy** *route-policy-name* } **import**
   By default, OSPFv3 accepts all routes calculated by using received LSAs.
   This command can only filter routes computed by OSPFv3. Only routes not filtered out can be added into the local routing table.

Configuring Inter-Area-Prefix LSA filtering

Restrictions and guidelines

The **filter** command takes effect only on ABRs.

Procedure

1. Enter system view.
   system-view
2. Enter OSPFv3 view.
   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *
3. Enter OSPFv3 area view.
   area *area-id*

4. Configure OSPFv3 to filter Inter-Area-Prefix LSAs.

   filter { *ipv6-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } { **export** | **import** }

   By default, OSPFv3 accepts all Inter-Area-Prefix LSAs.

Advertising the maximum link cost to neighbors within the specified period

About this task

On an OSPFv3 network, when a link recovers from failures or the state of an interface changes, OSPFv3 will re-establish neighbor relationships and perform route convergence. During the route convergence process, routing loops and traffic loss might occur because the convergence speeds of the nodes are different. To address this issue, enable OSPFv3 to advertise the maximum link cost (65535) to neighbors within the specified period, so the traffic forwarding path remains unchanged. After the specified period, OSPFv3 advertises the original link cost to neighbors and performs optimal route selection again.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the duration of the maximum link cost advertisement.

   ospfv3 peer hold-max-cost duration *timer* [**instance** *instance-id*]

   By default, OSPFv3 advertises the original link cost to neighbors during a route convergence.

Setting an OSPFv3 cost for an interface

About this task

You can set an OSPFv3 cost for an interface with one of the following methods:

- Set the cost value in interface view.
- Set a bandwidth reference value for the interface, and OSPFv3 computes the cost automatically based on the bandwidth reference value by using the following formula:

  Interface OSPFv3 cost = Bandwidth reference value (100 Mbps) / Interface bandwidth (Mbps)

  - If the calculated cost is greater than 65535, the value of 65535 is used.
  - If the calculated cost is smaller than 1, the value of 1 is used.
- If no cost is set for an interface, OSPFv3 automatically computes the cost for the interface.

Setting a cost in interface view

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set an OSPFv3 cost for the interface.

   ospfv3 cost *cost-value* [**instance** *instance-id*]

By default, the OSPFv3 cost is 1 for a VLAN interface, is 0 for a loopback interface. The OSPFv3 cost is automatically computed according to the interface bandwidth for other interfaces.

Setting a bandwidth reference value

1. Enter system view.

   system-view

2. Enter OSPFv3 view.

   ospfv3 [*process-id* | **vpn-instance** *vpn-instance-name*] *

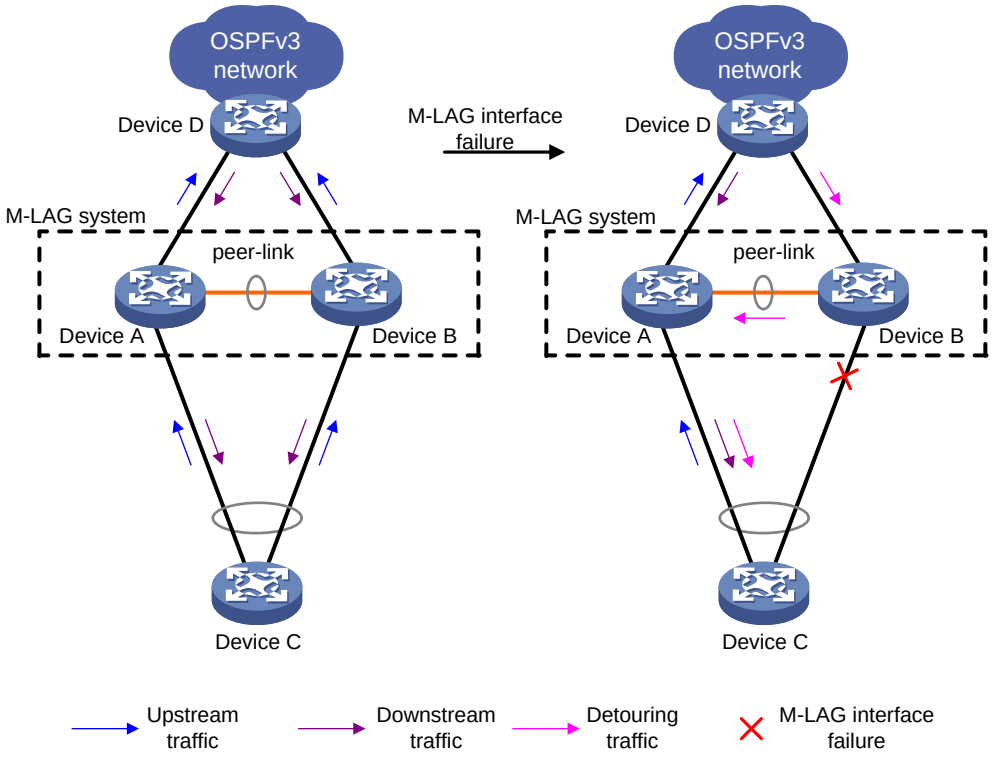
3. Set a bandwidth reference value.

   bandwidth-reference *value*

   The default bandwidth reference value is 100 Mbps.

Associating OSPFv3 with Track

About this task



Perform this task to associate an OSPFv3 interface with a track entry to adjust the cost of the interface as follows:

- When the track entry state becomes negative, OSPFv3 increases the cost of the interface.
- When the track entry state becomes positive, OSPFv3 restores the cost of the interface to the original value.

When a customer side device is dual-homed to an OSPFv3 network through M-LAG, you can configure this feature to prevent the traffic from detouring through the M-LAG peer link. As shown in Figure 2, customer-side device Device C is dual-homed to the OSPFv3 network through an M-LAG system formed by Device A and Device B. Device A and Device B share the traffic load between Device D and Device C. When the M-LAG interface that connects Device B to Device C fails, the upstream traffic and downstream traffic are forwarded as follows:

- Device C detects the M-LAG interface failure, and traffic from Device C to Device D is switched from path Device C->Device B->Device D to path Device C->Device A->Device D.
