Make sure the server quiet timer is set correctly. A timer that is too short might result in frequent authentication or accounting failures. This is because the device will continue to attempt to communicate with an unreachable server that is in active state. A timer that is too long might temporarily block a reachable server that has recovered from a failure. This is because the server will remain in blocked state until the timer expires.

A short real-time accounting interval helps improve accounting precision but requires many system resources. When there are 1000 or more users, set the interval to 15 minutes or longer.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*
3. Set RADIUS timers. Choose the following tasks as needed:
   - Set the RADIUS server response timeout timer.
     timer response-timeout *seconds*
     The default setting is 3 seconds.
   - Set the quiet timer for the servers.
     timer quiet *minutes*
     The default setting is 5 minutes.
   - Set the real-time accounting timer.
     timer realtime-accounting *interval* [**second**]
     The default setting is 12 minutes.

Specifying the source IP address for outgoing RADIUS packets

About this task

The source IP address of RADIUS packets that a NAS sends must match the IP address of the NAS configured on the RADIUS server. A RADIUS server identifies a NAS by its IP address. Upon receiving a RADIUS packet, the RADIUS server checks the source IP address of the packet.

- If it is the IP address of a managed NAS, the server processes the packet.
- If it is not the IP address of a managed NAS, the server drops the packet.

Before sending a RADIUS packet, the NAS selects a source IP address in the following order:

1. The source IP address specified for the RADIUS scheme.
2. The source IP address specified in system view for the VPN or public network, depending on where the RADIUS server resides.
3. The IP address of the outbound interface specified by the route.

Restrictions and guidelines for source IP address configuration

You can specify a source IP address for outgoing RADIUS packets in RADIUS scheme view or in system view.

- The IP address specified in RADIUS scheme view applies only to one RADIUS scheme.
- The IP address specified in system view applies to all RADIUS schemes.

The source IP address of RADIUS packets that a NAS sends must match the IP address of the NAS that is configured on the RADIUS server.

As a best practice, specify a loopback interface address as the source IP address for outgoing RADIUS packets to avoid RADIUS packet loss caused by physical port errors.

The source address of outgoing RADIUS packets is typically the IP address of an egress interface on the NAS to communicate with the RADIUS server. However, in some situations, you must change the source IP address. For example, when VRRP is configured for stateful failover, configure the virtual IP of the uplink VRRP group as the source address.

You can directly specify a source IP address for outgoing RADIUS packets or specify a source interface to provide the source IP address for outgoing RADIUS packets. The source interface configuration and the source IP address configuration overwrite each other.

Specifying a source interface or source IP address for all RADIUS schemes

1. Enter system view.

   system-view

2. Specify a source interface or source IP address for outgoing RADIUS packets.

   radius nas-ip { **interface** *interface-type interface-number* | { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] }

   By default, the source IP address of an outgoing RADIUS packet is the primary IPv4 address or the IPv6 address of the outbound interface.

Specifying a source interface or source IP address for a RADIUS scheme

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Specify a source interface or source IP address for outgoing RADIUS packets.

   nas-ip { *ipv4-address* | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

   By default, the source IP address of an outgoing RADIUS packet is that specified by using the **radius nas-ip** command in system view. If the **radius nas-ip** command is not used, the source IP address is the primary IP address of the outbound interface.

Setting the username format and traffic statistics units

About this task

A username is in the *userid@isp-name* format, where the *isp-name* part represents the user's ISP domain name. By default, the ISP domain name is included in a username. However, older RADIUS servers might not recognize usernames that contain the ISP domain names. In this case, you can configure the device to remove the domain name of each username to be sent.

The device reports online user traffic statistics in accounting packets. The traffic measurement units are configurable.

Restrictions and guidelines

If two or more ISP domains use the same RADIUS scheme, configure the RADIUS scheme to keep the ISP domain name in usernames for domain identification.

For accounting accuracy, make sure the traffic statistics units configured on the device and on the RADIUS accounting servers are the same.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*
3. Set the format for usernames sent to the RADIUS servers.
   user-name-format { **keep-original** | **with-domain** | **without-domain** }
   By default, the ISP domain name is included in a username.
   If the device is specified as the RADIUS server in the scheme, the username format must be set to **without-domain**.
4. Set the data flow and packet measurement units for traffic statistics.
   data-flow-format { **data** { **byte** | **giga-byte** | **kilo-byte** | **mega-byte** } | **packet** { **giga-packet** | **kilo-packet** | **mega-packet** | **one-packet** } }*
   By default, traffic is counted in bytes and packets.

Setting the maximum number of RADIUS request transmission attempts

About this task

RADIUS uses UDP packets to transfer data. Because UDP communication is not reliable, RADIUS uses a retransmission mechanism to improve reliability. A RADIUS request is retransmitted if the NAS does not receive a server response for the request within the response timeout timer. For more information about the RADIUS server response timeout timer, see "Setting the status of RADIUS servers."

You can set the maximum number for the NAS to retransmit a RADIUS request to the same server. When the maximum number is reached, the NAS tries to communicate with other RADIUS servers in active state. If no other servers are in active state at the time, the NAS considers the authentication or accounting attempt a failure.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*
3. Set the maximum number of RADIUS request transmission attempts.
   retry *retries*
   By default, the maximum number is 3 for RADIUS request transmission attempts.

Setting the maximum number of real-time accounting attempts

About this task

If you set the maximum number of real-time accounting attempts, the device will disconnect users from whom no accounting responses are received within the permitted attempts.

Procedure

1. Enter system view.

system-view

2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*
3. Set the maximum number of real-time accounting attempts.
   retry realtime-accounting *retries*

   By default, the maximum number is 5 for real-time accounting attempts.

Setting the DSCP priority for RADIUS packets

About this task

The DSCP priority in the ToS field determines the transmission priority of RADIUS packets. A larger value represents a higher priority.

Procedure

1. Enter system view.
   system-view
2. Set the DSCP priority for RADIUS packets.
   radius [**ipv6**] **dscp** *dscp-value*

   By default, the DSCP priority is 0 for RADIUS packets.

Configuring the Login-Service attribute check method for SSH, FTP, and terminal users

About this task

The device supports the following check methods for the Login-Service attribute (RADIUS attribute 15) of SSH, FTP, and terminal users:

- **Strict**—Matches Login-Service attribute values 50, 51, and 52 for SSH, FTP, and terminal services, respectively.
- **Loose**—Matches the standard Login-Service attribute value 0 for SSH, FTP, and terminal services.

An Access-Accept packet received for a user must contain the matching attribute value. Otherwise, the user cannot log in to the device.

Restrictions and guidelines

Use the loose check method only when the server does not issue Login-Service attribute values 50, 51, and 52 for SSH, FTP, and terminal users.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*
3. Configure the Login-Service attribute check method for SSH, FTP, and terminal users.
   attribute 15 check-mode { **loose** | **strict** }

   The default check method is strict.

Interpreting the RADIUS class attribute as CAR parameters

About this task

A RADIUS server may deliver CAR parameters for user-based traffic monitoring and control by using the RADIUS class attribute (attribute 25) in RADIUS packets. You can configure the device to interpret the class attribute to CAR parameters.

Procedure

1. Enter system view.

   system-view
2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*
3. Interpret the RADIUS class attribute as CAR parameters.

   attribute 25 car

   By default, the RADIUS class attribute is not interpreted as CAR parameters.

Configuring the MAC address format for RADIUS attribute 31

Restrictions and guidelines

RADIUS servers of different types might have different requirements for the MAC address format in RADIUS attribute 31. Configure the MAC address format for RADIUS attribute 31 to meet the requirements of the RADIUS servers.

Procedure

1. Enter system view.

   system-view
2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*
3. Configure the MAC address format for RADIUS attribute 31.

   attribute 31 mac-format section { **one** | { **six** | **three** } **separator** *separator-character* } { **lowercase** | **uppercase** }

   By default, a MAC address is in the format of HH-HH-HH-HH-HH-HH. The MAC address is separated by hyphen (-) into six sections with letters in upper case.

Setting the data measurement unit for the Remanent_Volume attribute

About this task

The RADIUS server uses the Remanent_Volume attribute in authentication or real-time accounting responses to notify the device of the current amount of data available for online users.

Restrictions and guidelines

Make sure the configured measurement unit is the same as the user data measurement unit on the RADIUS server.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Set the data measurement unit for the Remanent_Volume attribute.

   attribute remanent-volume unit { **byte** | **giga-byte** | **kilo-byte** | **mega-byte** }

   By default, the data measurement unit is kilobyte.

Including subattribute 218 of vendor 25506 in outgoing RADIUS packets

About this task

The RADIUS Vendor-Specific attribute (attribute 26) allows vendors to define extended attributes to implement functions that the standard RADIUS protocol does not provide. Vendor 25506 defines subattribute 218 to carry user DHCP option information.

To send user DHCP option information to RADIUS servers, perform this task to include subattribute 218 of vendor 25506 in outgoing RADIUS start-accounting and update-accounting requests.

In the current software version, only DHCP Option 55 and DHCP Option 61 can be carried in the subattribute.

Restrictions and guidelines

You can repeat the **include-attribute 218 vendor-id 25506** command to configure the device to encapsulate both DHCP Option 55 and DHCP Option 61 in the subattribute. The length of each option is limited to 246 bytes.

If you repeat this command multiple times with the same DHCP option specified, the most recent configuration takes effect.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Include subattribute 218 of vendor 25506 in outgoing RADIUS packets.

   include-attribute 218 vendor-id 25506 dhcp-option { **55** | **61** } * { **format1** | **format2** }

   By default, the device uses format 1 to encapsulate DHCP Option 61 in subattribute 218 of vendor 25506 in RADIUS packets.

Configuring the RADIUS attribute translation feature

About this task

The RADIUS attribute translation feature enables the device to work correctly with the RADIUS servers of different vendors that support RADIUS attributes incompatible with the device.

RADIUS attribute translation has the following implementations:

- **Attribute conversion**—Converts source RADIUS attributes into destination RADIUS attributes based on RADIUS attribute conversion rules.
- **Attribute rejection**—Rejects RADIUS attributes based on RADIUS attribute rejection rules.

When the RADIUS attribute translation feature is enabled, the device processes RADIUS packets as follows:

- For the sent RADIUS packets:
  - Deletes the rejected attributes from the packets.
  - Uses the destination RADIUS attributes to replace the attributes that match RADIUS attribute conversion rules in the packets.
- For the received RADIUS packets:
  - Ignores the rejected attributes in the packets.
  - Interprets the attributes that match RADIUS attribute conversion rules as the destination RADIUS attributes.

To identify proprietary RADIUS attributes, you can define the attributes as extended RADIUS attributes, and then convert the extended RADIUS attributes to device-supported attributes.

Restrictions and guidelines for RADIUS attribute translation configuration

Configure either conversion rules or rejection rules for a RADIUS attribute.

Configure either direction-based rules or packet type-based rules for a RADIUS attribute.

For direction-based translation of a RADIUS attribute, you can configure a rule for each direction (inbound or outbound). For packet type-based translation of a RADIUS attribute, you can configure a rule for each RADIUS packet type (RADIUS Access-Accept, RADIUS Access-Request, or RADIUS accounting).

Configuring the RADIUS attribute translation feature for a RADIUS scheme

1. Enter system view.

   system-view

2. (Optional.) Define an extended RADIUS attribute.

   radius attribute extended *attribute-name* [**vendor** *vendor-id*] **code** *attribute-code* **type** { **binary** | **date** | **integer** | **interface-id** | **ip** | **ipv6** | **ipv6-prefix** | **octets** | **string** }

3. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

4. Enable the RADIUS attribute translation feature.

   attribute translate

   By default, this feature is disabled.

5. Configure a RADIUS attribute conversion rule or a RADIUS attribute reject rule. Choose the following tasks as needed:
   - Configure a RADIUS attribute conversion rule.

     attribute convert *src-attr-name* **to** *dest-attr-name* { { **access-accept** | **access-request** | **accounting** } * | { **received** | **sent** } * }

     By default, no RADIUS attribute conversion rules are configured.
   - Configure a RADIUS attribute rejection rule.

     attribute reject *attr-name* { { **access-accept** | **access-request** | **accounting** } * | { **received** | **sent** } * }

     By default, no RADIUS attribute rejection rules are configured.

Configuring the RADIUS attribute translation feature for a RADIUS DAS

1. Enter system view.

   system-view

2. (Optional.) Define an extended RADIUS attribute.

radius attribute extended *attribute-name* [**vendor** *vendor-id*] **code** *attribute-code* **type** { **binary** | **date** | **integer** | **interface-id** | **ip** | **ipv6** | **ipv6-prefix** | **octets** | **string** }

3. Enter RADIUS DAS view.

   radius dynamic-author server

4. Enable the RADIUS attribute translation feature.

   attribute translate

   By default, this feature is disabled.

5. Configure a RADIUS attribute conversion rule or a RADIUS attribute rejection rule. Choose the following tasks as needed:

   - Configure a RADIUS attribute conversion rule.

     attribute convert *src-attr-name* **to** *dest-attr-name* { { **coa-ack** | **coa-request** } * | { **received** | **sent** } * }

     By default, no RADIUS attribute conversion rules are configured.

   - Configure a RADIUS attribute rejection rule.

     attribute reject *attr-name* { { **coa-ack** | **coa-request** } * | { **received** | **sent** } * }

     By default, no RADIUS attribute rejection rules are configured.

Configuring RADIUS stop-accounting packet buffering

About this task

The device sends RADIUS stop-accounting requests when it receives connection teardown requests from hosts or connection teardown commands from an administrator. However, the device might fail to receive a response for a stop-accounting request in a single transmission. Enable the device to buffer RADIUS stop-accounting requests that have not received responses from the accounting server. The device will resend the requests until responses are received.

To limit the transmission times, set a maximum number of transmission attempts that can be made for individual RADIUS stop-accounting requests. When the maximum attempts are made for a request, the device discards the buffered request.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Enable buffering of RADIUS stop-accounting requests to which no responses have been received.

   stop-accounting-buffer enable

   By default, the buffering feature is enabled.

4. (Optional.) Set the maximum number of transmission attempts for individual RADIUS stop-accounting requests.

   retry stop-accounting *retries*

   The default setting is 500.

Enabling forcibly sending stop-accounting packets

About this task

Typically, if the device does not send a start-accounting packet to the RADIUS server for an authenticated user, it does not send a stop-accounting packet when the user goes offline. If the server has generated a user entry for the user without start-accounting packets, it does not release the user entry when the user goes offline. This feature forces the device to send stop-accounting packets to the RADIUS server when the user goes offline for timely releasing the user entry on the server.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Enable the device to send stop-accounting packets when users for which no start-accounting packets are sent go offline.

   stop-accounting-packet send-force

   By default, forcibly sending stop-accounting packets is disabled. The device does not send stop-accounting packets when users for which no start-accounting packets are sent go offline.

Enabling the RADIUS server load sharing feature

About this task

By default, the device communicates with RADIUS servers based on the server roles. It first attempts to communicate with the primary server, and, if the primary server is unreachable, it then searches for the secondary servers in the order they are configured. The first secondary server in active state is used for communication. In this process, the workload is always placed on the active server.

Use the RADIUS server load sharing feature to dynamically distribute the workload over multiple servers regardless of their server roles. The device forwards an AAA request to the most appropriate server of all active servers in the scheme after it compares the weight values and numbers of currently served users. Specify a weight value for each RADIUS server based on the AAA capacity of the server. A larger weight value indicates a higher AAA capacity.

In RADIUS server load sharing, once the device sends a start-accounting request to a server for a user, it forwards all subsequent accounting requests of the user to the same server. If the accounting server is unreachable, the device returns an accounting failure message rather than searching for another active accounting server.

Procedure

1. Enter system view.

   system-view

2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*

3. Enable the RADIUS server load sharing feature.

   server-load-sharing enable

   By default, this feature is disabled.

Specifying a RADIUS server selection mode for reauthentication

About this task

Use this feature to configure the RADIUS server selection mechanism in reauthentication. The following RADIUS server selection modes are available:

- **Inherit**—The device uses the RADIUS server that performed authentication for a user to reauthenticate that user. This mode reduces the amount of time used in reauthentication. However, if the RADIUS server is unreachable, the reauthentication will fail.
- **Reselect**—The device searches for a reachable RADIUS server to reauthenticate a user. This mode requires more time than the inherit mode. However, this mode ensures that the device uses the optimal reachable RADIUS server for reauthentication. The following factors affect the RADIUS server selection:
  - Server configuration in the RADIUS scheme, including the configuration order.
  - Enabling status of the RADIUS server load sharing feature.
  - Status of the RADIUS servers in the RADIUS scheme.

Procedure

1. Enter system view.

   system-view
2. Enter RADIUS scheme view.

   radius scheme *radius-scheme-name*
3. Specify a RADIUS server selection mode for reauthentication.

   reauthentication server-select { **inherit** | **reselect** }

   By default, the inherit mode is used.

Configuring the RADIUS accounting-on feature

About this task

When the accounting-on feature is enabled, the device automatically sends an accounting-on packet to the RADIUS server after the entire device reboots. Upon receiving the accounting-on packet, the RADIUS server logs out all online users so they can log in again through the device. Without this feature, users cannot log in again after the reboot, because the RADIUS server considers them to come online.

You can configure the interval for which the device waits to resend the accounting-on packet and the maximum number of retries.

The extended accounting-on feature enhances the accounting-on feature in a distributed architecture.

The extended accounting-on feature is applicable to LAN users. The user data is saved to the IRF member devices through which the users access the system. When the extended accounting-on feature is enabled, the system automatically sends an accounting-on packet to the RADIUS server after a member device reboots. The packet contains the member device identifier. Upon receiving the accounting-on packet, the RADIUS server logs out all online users that access the system through the member device. If no users have come online through the member device, the IRF fabric does not send an accounting-on packet after the member device reboots.

Restrictions and guidelines

For the extended accounting-on feature to take effect, the RADIUS server must run on IMC and the accounting-on feature must be enabled.

Procedure

1. Enter system view.
   system-view
2. Enter RADIUS scheme view.
   radius scheme *radius-scheme-name*
3. Enable accounting-on.
   accounting-on enable [**interval** *interval* | **send** *send-times*] *
   By default, the accounting-on feature is disabled.
4. (Optional.) Enable extended accounting-on.
   accounting-on extended
   By default, extended accounting-on is disabled.

Configuring the RADIUS session-control feature

About this task

Enable this feature for the RADIUS server to dynamically change the user authorization information (for example, authorization ACL, VLAN, user group, or blackhole MAC) or forcibly disconnect users by using session-control packets. This task enables the device to receive RADIUS session-control packets on UDP port 1812.

To verify the session-control packets sent from a RADIUS server, specify the RADIUS server as a session-control client to the device.

Restrictions and guidelines

The RADIUS session-control feature can only work with RADIUS servers running on IMC. The session-control client configuration takes effect only when the session-control feature is enabled.

Procedure

1. Enter system view.
   system-view
2. Enable the session-control feature.
   radius session-control enable
   By default, the session-control feature is disabled.
3. Specify a session-control client.
   radius session-control client { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**key** { **cipher** | **simple** } *string* | **vpn-instance** *vpn-instance-name*] *
   By default, no session-control clients are specified.

Configuring the RADIUS DAS feature

About this task

Dynamic Authorization Extensions (DAE) to RADIUS, defined in RFC 5176, can log off online users and change online user authorization information.

In a RADIUS network, the RADIUS server typically acts as the DAE client (DAC) and the NAS acts as the DAE server (DAS).

When the RADIUS DAS feature is enabled, the NAS performs the following operations:

1. Listens to the default or specified UDP port to receive DAE requests.

2. Logs off online users that match the criteria in the requests, changes their authorization information, shuts down or reboots their access ports, or reauthenticates the users.
3. Sends DAE responses to the DAC.

DAE defines the following types of packets:

- **Disconnect Messages (DMs)**—The DAC sends DM requests to the DAS to log off specific online users.
- **Change of Authorization Messages (CoA Messages)**—The DAC sends CoA requests to the DAS to change the authorization information of specific online users.

Procedure

1. Enter system view.

   system-view
2. Enable the RADIUS DAS feature and enter RADIUS DAS view.

   radius dynamic-author server

   By default, the RADIUS DAS feature is disabled.
3. Specify a RADIUS DAC.

   client { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**key** { **cipher** | **simple** } *string* | **vpn-instance** *vpn-instance-name*] *

   By default, no RADIUS DACs are specified.
4. (Optional.) Specify the RADIUS DAS port.

   port *port-number*

   By default, the RADIUS DAS port is 3799.

Enabling SNMP notifications for RADIUS

About this task

When SNMP notifications are enabled for RADIUS, the SNMP agent supports the following notifications generated by RADIUS:

- **RADIUS server unreachable notification**—The RADIUS server cannot be reached. RADIUS generates this notification if it does not receive a response to an accounting or authentication request within the specified number of RADIUS request transmission attempts.
- **RADIUS server reachable notification**—The RADIUS server can be reached. RADIUS generates this notification for a previously blocked RADIUS server after the quiet timer expires.
- **Excessive authentication failures notification**—The number of authentication failures compared to the total number of authentication attempts exceeds the specified threshold.

For RADIUS SNMP notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

Make sure the RADIUS server status change notifications sent by the device can be recognized by the NMS. Choose a MIB node version depending on the NMS requirements. For more information about the MIB node versions, see AAA in *Security Command Reference*.

Procedure

1. Enter system view.

   system-view
2. Enable SNMP notifications for RADIUS.

snmp-agent trap enable radius [**accounting-server-down** | **accounting-server-up** | **authentication-error-threshold** | **authentication-server-down** | **authentication-server-up**] *

By default, all SNMP notifications are disabled for RADIUS.

3. Set the version of RADIUS server status change MIB nodes.

radius trap-version { **v1** | **v2** } [**accounting-server-down** | **accounting-server-up** | **authentication-server-down** | **authentication-server-up**] *

By default, the device sends notifications about RADIUS server status change MIB nodes over SNMPv1.

Disabling the RADIUS service

About this task

By default, the RADIUS service is enabled. The device can send and receive RADIUS packets. Attackers might use RADIUS session-control and DAE ports to attack the device. To protect the device when such an attack occurs, disable the RADIUS service temporarily on the device. After the network is secure, re-enable the RADIUS service.

If settings on the RADIUS servers require modification or the RADIUS servers cannot provide services temporarily, you can temporarily disable the RADIUS service on the device.

When the RADIUS service is disabled, the device stops sending and receiving RADIUS packets. If a new user comes online, the device uses the backup authentication, authorization, or accounting method to process that user. If the device has not finished requesting authentication or accounting for a user before the RADIUS service is disabled, it uses the following rules to process that user:

- If the device has sent RADIUS authentication requests for that user to a RADIUS server, the device processes that user depending on whether it receives a response from the RADIUS server.
  - If the device receives a response from the RADIUS server, it uses the response to determine whether that user has passed authentication. If that user has passed authentication, the device assigns authorization information to that user according to the response.
  - If the device does not receive any response from the RADIUS server, it attempts to use the backup authentication method to authenticate that user.
- If the device has sent RADIUS start-accounting requests for that user to a RADIUS server, the device processes that user depending on whether it receives a response from the RADIUS server.
  - If the device receives a response from the RADIUS server, it allows that user to come online. However, the device cannot send out accounting-update or stop-accounting requests to the RADIUS server. It cannot buffer the accounting requests, either. When that user goes offline, the RADIUS server cannot log off that user in time. The accounting result might be inaccurate.
  - If the device does not receive any response from the RADIUS server, it attempts to use the backup accounting method.

Restrictions and guidelines

Disabling the RADIUS service does not affect the RADIUS server feature of the device.

The authentication, authorization, and accounting processes undertaken by other methods are not switched to RADIUS when you re-enable the RADIUS service.

Procedure

1. Enter system view.

system-view

2. Disable the RADIUS service.

   undo radius enable

   By default, the RADIUS service is enabled.

   To re-enable the RADIUS service, use the **radius enable** command.

Display and maintenance commands for RADIUS

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the RADIUS scheme configuration.	**display radius scheme** [*radius-scheme-name*]
Display authentication and accounting load statistics for all RADIUS servers.	**display radius server-load statistics**
Display RADIUS packet statistics.	**display radius statistics**
Display information about buffered RADIUS stop-accounting requests to which no responses have been received.	**display stop-accounting-buffer** { **radius-scheme** *radius-scheme-name* | **session-id** *session-id* | **time-range** *start-time end-time* | **user-name** *user-name* }
Clear history authentication and accounting load statistics for all RADIUS servers.	**reset radius server-load statistics**
Clear RADIUS statistics.	**reset radius statistics**
Clear the buffered RADIUS stop-accounting requests to which no responses have been received.	**reset stop-accounting-buffer** { **radius-scheme** *radius-scheme-name* | **session-id** *session-id* | **time-range** *start-time end-time* | **user-name** *user-name* }

Configuring HWTACACS

HWTACACS tasks at a glance

To configure HWTACACS, perform the following tasks:

1. Creating an HWTACACS scheme
2. Specifying the HWTACACS authentication servers
3. Specifying the HWTACACS authorization servers
4. Specifying the HWTACACS accounting servers
5. Specifying the shared keys for secure HWTACACS communication

   Perform this task if no shared keys are specified when configuring HWTACACS servers.
6. Specifying an MPLS L3VPN instance for the scheme

   Perform this task if no MPLS L3VPN instances are specified when configuring HWTACACS servers.
7. (Optional.) Setting HWTACACS timers
8. (Optional.) Configuring parameters for HWTACACS packets

Specifying the source IP address for outgoing HWTACACS packets

Setting the username format and traffic statistics units

9. (Optional.) Configuring HWTACACS stop-accounting packet buffering

Creating an HWTACACS scheme

Restrictions and guidelines

You can configure a maximum of 16 HWTACACS schemes. An HWTACACS scheme can be used by multiple ISP domains.

Procedure

1. Enter system view.

   system-view

2. Create an HWTACACS scheme and enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

Specifying the HWTACACS authentication servers

About this task

You can specify one primary authentication server and a maximum of 16 secondary authentication servers for an HWTACACS scheme. When the primary server is unreachable, the device searches for the secondary servers in the order they are configured. The first secondary server in active state is used for communication.

Restrictions and guidelines

If redundancy is not required, specify only the primary server.

An HWTACACS server can function as the primary authentication server in one scheme and as the secondary authentication server in another scheme at the same time.

Two HWTACACS authentication servers in a scheme, primary or secondary, cannot have the same combination of VPN instance, host name, IP address, and port number.

Procedure

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Specify the primary HWTACACS authentication server.

   primary authentication { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

   By default, no primary HWTACACS authentication server is specified.

4. (Optional.) Specify a secondary HWTACACS authentication server.

   secondary authentication { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

   By default, no secondary HWTACACS authentication servers are specified.

Specifying the HWTACACS authorization servers

About this task

You can specify one primary authorization server and a maximum of 16 secondary authorization servers for an HWTACACS scheme. When the primary server is not available, the device searches for the secondary servers in the order they are configured. The first secondary server in active state is used for communication.

Restrictions and guidelines

If redundancy is not required, specify only the primary server.

An HWTACACS server can function as the primary authorization server of one scheme and as the secondary authorization server of another scheme at the same time.

Two HWTACACS authorization servers in a scheme, primary or secondary, cannot have the same combination of VPN instance, host name, IP address, and port number.

Procedure

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Specify the primary HWTACACS authorization server.

   primary authorization { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

   By default, no primary HWTACACS authorization server is specified.

4. (Optional.) Specify a secondary HWTACACS authorization server.

   secondary authorization { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

   By default, no secondary HWTACACS authorization servers are specified.

Specifying the HWTACACS accounting servers

About this task

You can specify one primary accounting server and a maximum of 16 secondary accounting servers for an HWTACACS scheme. When the primary server is not available, the device searches for the secondary servers in the order they are configured. The first secondary server in active state is used for communication.

Restrictions and guidelines

If redundancy is not required, specify only the primary server.

An HWTACACS server can function as the primary accounting server of one scheme and as the secondary accounting server of another scheme at the same time.

Two HWTACACS accounting servers in a scheme, primary or secondary, cannot have the same combination of VPN instance, host name, IP address, and port number.

HWTACACS does not support accounting for FTP, SFTP, and SCP users.

Procedure

1. Enter system view.

system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Specify the primary HWTACACS accounting server.

   primary accounting { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

   By default, no primary HWTACACS accounting server is specified.

4. (Optional.) Specify a secondary HWTACACS accounting server.

   secondary accounting { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection** | **vpn-instance** *vpn-instance-name*] *

   By default, no secondary HWTACACS accounting servers are specified.

Specifying the shared keys for secure HWTACACS communication

About this task

The HWTACACS client and server use the MD5 algorithm and shared keys to generate the Authenticator value for packet authentication and user password encryption. The client and server must use the same key for each type of communication.

Perform this task to configure shared keys for servers in an HWTACACS scheme. The keys take effect on all servers for which a shared key is not individually configured.

Restrictions and guidelines

Make sure the shared key configured on the device is the same as the shared key configured on the HWTACACS server.

Procedure

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Specify a shared key for secure HWTACACS authentication, authorization, or accounting communication.

   key { **accounting** | **authentication** | **authorization** } { **cipher** | **simple** } *string*

   By default, no shared key is specified for secure HWTACACS communication.

Specifying an MPLS L3VPN instance for the scheme

About this task

The VPN instance specified for an HWTACACS scheme applies to all servers in that scheme. If a VPN instance is also configured for an individual HWTACACS server, the VPN instance specified for the HWTACACS scheme does not take effect on that server.

Procedure

1. Enter system view.

system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Specify a VPN instance for the HWTACACS scheme.

   vpn-instance *vpn-instance-name*

   By default, an HWTACACS scheme belongs to the public network.

Setting HWTACACS timers

About this task

The device uses the following timers to control communication with an HWTACACS server:

- **Server response timeout timer (response-timeout)**—Defines the HWTACACS server response timeout timer. The device starts this timer immediately after an HWTACACS authentication, authorization, or accounting request is sent. If the device does not receive a response from the server within the timer, it sets the server to blocked. Then, the device sends the request to another HWTACACS server.
- **Real-time accounting timer (realtime-accounting)**—Defines the interval at which the device sends real-time accounting packets to the HWTACACS accounting server for online users.
- **Server quiet timer (quiet)**—Defines the duration to keep an unreachable server in blocked state. If a server is not reachable, the device changes the server status to blocked, starts this timer for the server, and tries to communicate with another server in active state. After the server quiet timer expires, the device changes the status of the server back to active.

The server quiet timer setting affects the status of HWTACACS servers. If the scheme includes one primary HWTACACS server and multiple secondary HWTACACS servers, the device communicates with the HWTACACS servers based on the following rules:

- When the primary server is in active state, the device communicates with the primary server. When the primary server is unreachable, the device researches a secondary server in active status in the order they are configured.
- When one or more servers are in active state, the device tries to communicate with these servers only, even if they are unreachable.
- When all servers are in blocked state, the device only tries to communicate with the primary server.
- If the primary server is unreachable, the device changes the server status to blocked and starts a quiet timer for the server. When the quiet timer of the server expires, the status of the server changes back to active. The device does not check the server again during the authentication, authorization, or accounting process.
- The search process continues until the device finds an available secondary server or has checked all secondary servers in active state. If no server is available, the device considers the authentication, authorization, or accounting attempt a failure.
- When you remove a server in use, communication with the server times out. The device looks for a server in active state by first checking the primary server, and then checking secondary servers in the order they are configured.
- When an HWTACACS server's status changes automatically, the device changes this server's status accordingly in all HWTACACS schemes in which this server is specified.

Restrictions and guidelines

A short real-time accounting interval helps improve accounting precision but requires many system resources. When there are 1000 or more users, set a real-time accounting interval longer than 15 minutes.

Procedure

1. Enter system view.
   system-view
2. Enter HWTACACS scheme view.
   hwtacacs scheme *hwtacacs-scheme-name*
3. Set the HWTACACS timers. Choose the following tasks as needed:
   - Set the HWTACACS server response timeout timer.
     timer response-timeout *seconds*
     By default, the HWTACACS server response timeout timer is 5 seconds.
   - Set the real-time accounting interval.
     timer realtime-accounting *minutes*
     By default, the real-time accounting interval is 12 minutes.
   - Set the server quiet timer.
     timer quiet *minutes*
     By default, the server quiet timer is 5 minutes.

Specifying the source IP address for outgoing HWTACACS packets

About this task

The source IP address of HWTACACS packets that a NAS sends must match the IP address of the NAS configured on the HWTACACS server. An HWTACACS server identifies a NAS by IP address. When the HWTACACS server receives a packet, it checks the source IP address of the packet.

- If it is the IP address of a managed NAS, the server processes the packet.
- If it is not the IP address of a managed NAS, the server drops the packet.

Before sending an HWTACACS packet, the NAS selects a source IP address in the following order:

1. The source IP address specified for the HWTACACS scheme.
2. The source IP address specified in system view for the VPN or public network, depending on where the HWTACACS server resides.
3. The IP address of the outbound interface specified by the route.

Restrictions and guidelines for source IP address configuration

You can specify the source IP address for outgoing HWTACACS packets in HWTACACS scheme view or in system view.

- The IP address specified in HWTACACS scheme view applies to one HWTACACS scheme.
- The IP address specified in system view applies to all HWTACACS schemes.

The source IP address of HWTACACS packets that a NAS sends must match the IP address of the NAS that is configured on the HWTACACS server.

As a best practice, specify a loopback interface address as the source IP address for outgoing HWTACACS packets to avoid HWTACACS packet loss caused by physical port errors.

To communicate with the HWTACACS server, the source address of outgoing HWTACACS packets is typically the IP address of an egress interface on the NAS. However, in some situations, you must change the source IP address. For example, when VRRP is configured for stateful failover, configure the virtual IP of the uplink VRRP group as the source address.

You can directly specify a source IP address for outgoing HWTACACS packets or specify a source interface to provide the source IP address for outgoing HWTACACS packets. The source interface configuration and the source IP address configuration overwrite each other.

Specifying a source interface or source IP address for all HWTACACS schemes

1. Enter system view.

   system-view

2. Specify a source interface or source IP address for outgoing HWTACACS packets.

   hwtacacs nas-ip { **interface** *interface-type interface-number* | { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] }

   By default, the source IP address of an HWTACACS packet sent to the server is the primary IPv4 address or the IPv6 address of the outbound interface.

Specifying a source interface or source IP address for an HWTACACS scheme

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Specify a source interface or source IP address for outgoing HWTACACS packets.

   nas-ip { *ipv4-address* | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

   By default, the source IP address of an outgoing HWTACACS packet is that configured by using the **hwtacacs nas-ip** command in system view. If the **hwtacacs nas-ip** command is not used, the source IP address is the primary IP address of the outbound interface.

Setting the username format and traffic statistics units

About this task

A username is typically in the *userid@isp-name* format, where the *isp-name* part represents the user's ISP domain name. By default, the ISP domain name is included in a username. If HWTACACS servers do not recognize usernames that contain ISP domain names, you can configure the device to send usernames without domain names to the servers.

The device reports online user traffic statistics in accounting packets.

Restrictions and guidelines

If two or more ISP domains use the same HWTACACS scheme, configure the HWTACACS scheme to keep the ISP domain name in usernames for domain identification.

For accounting accuracy, make sure the traffic measurement units configured on the device are the same as the traffic measurement units configured on the HWTACACS accounting servers.

Procedure

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Set the format of usernames sent to the HWTACACS servers.

   user-name-format { **keep-original** | **with-domain** | **without-domain** }

   By default, the ISP domain name is included in a username.

4. Set the data flow and packet measurement units for traffic statistics.

   data-flow-format { **data** { **byte** | **giga-byte** | **kilo-byte** | **mega-byte** } | **packet** { **giga-packet** | **kilo-packet** | **mega-packet** | **one-packet** } }*

   By default, traffic is counted in bytes and packets.

Configuring HWTACACS stop-accounting packet buffering

About this task

The device sends HWTACACS stop-accounting requests when it receives connection teardown requests from hosts or connection teardown commands from an administrator. However, the device might fail to receive a response for a stop-accounting request in a single transmission. Enable the device to buffer HWTACACS stop-accounting requests that have not received responses from the accounting server. The device will resend the requests until responses are received.

To limit the transmission times, set a maximum number of attempts that can be made for transmitting individual HWTACACS stop-accounting requests. When the maximum attempts are made for a request, the device discards the buffered request.

Procedure

1. Enter system view.

   system-view

2. Enter HWTACACS scheme view.

   hwtacacs scheme *hwtacacs-scheme-name*

3. Enable buffering of HWTACACS stop-accounting requests to which no responses have been received.

   stop-accounting-buffer enable

   By default, the buffering feature is enabled.

4. (Optional.) Set the maximum number of transmission attempts for individual HWTACACS stop-accounting requests.

   retry stop-accounting *retries*

   The default setting is 100.

Display and maintenance commands for HWTACACS

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the configuration or server statistics of HWTACACS schemes.	**display hwtacacs scheme** [*hwtacacs-scheme-name* [**statistics**]]
Display information about buffered HWTACACS stop-accounting requests to which no responses have been received.	**display stop-accounting-buffer hwtacacs-scheme** *hwtacacs-scheme-name*
Clear HWTACACS statistics.	**reset hwtacacs statistics** { **accounting** | **all** | **authentication** | **authorization** }
Clear the buffered HWTACACS stop-accounting requests to which no responses have been received.	**reset stop-accounting-buffer hwtacacs-scheme** *hwtacacs-scheme-name*

Configuring LDAP

LDAP tasks at a glance

To configure LDAP, perform the following tasks:

1. Configuring an LDAP server
   a. Creating an LDAP server
   b. Configuring the IP address of the LDAP server
   c. (Optional.) Specifying the LDAP version
   d. (Optional.) Setting the LDAP server timeout period
   e. Configuring administrator attributes
   f. Configuring LDAP user attributes
2. (Optional.) Configuring an LDAP attribute map
3. Creating an LDAP scheme
4. Specifying the LDAP authentication server
5. (Optional.) Specifying the LDAP authorization server
6. (Optional.) Specifying an LDAP attribute map for LDAP authorization

Creating an LDAP server

1. Enter system view.
   system-view
2. Create an LDAP server and enter LDAP server view.
   ldap server *server-name*

Configuring the IP address of the LDAP server

Restrictions and guidelines

You can configure either an IPv4 address or an IPv6 address for an LDAP server. If you configure the IP address for an LDAP server multiple times, the most recent configuration takes effect.

Procedure

1. Enter system view.
   system-view
2. Enter LDAP server view.
   ldap server *server-name*
3. Configure the IP address of the LDAP server.
   { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port-number*] [**vpn-instance** *vpn-instance-name*]
   By default, an LDAP server does not have an IP address.

Specifying the LDAP version

Restrictions and guidelines

The device supports LDAPv2 and LDAPv3.

A Microsoft LDAP server supports only LDAPv3.

The LDAP version specified on the device must be consistent with the version specified on the LDAP server.

Procedure

1. Enter system view.
   system-view
2. Enter LDAP server view.
   ldap server *server-name*
3. Specify the LDAP version.
   protocol-version { **v2** | **v3** }
   By default, LDAPv3 is used.

Setting the LDAP server timeout period

About this task

If the device sends a bind or search request to an LDAP server without receiving the server's response within the server timeout period, the authentication or authorization request times out. Then, the device tries the backup authentication or authorization method. If no backup method is configured in the ISP domain, the device considers the authentication or authorization attempt a failure.

Procedure

1. Enter system view.
   system-view
2. Enter LDAP server view.
   ldap server *server-name*
3. Set the LDAP server timeout period.
   server-timeout *time-interval*
   By default, the LDAP server timeout period is 10 seconds.

Configuring administrator attributes

About this task

To configure the administrator DN and password for binding with the LDAP server during LDAP authentication:

Procedure

1. Enter system view.
   system-view
2. Enter LDAP server view.
   ldap server *server-name*
3. Specify the administrator DN.
   login-dn *dn-string*
   By default, no administrator DN is specified.
   The administrator DN specified on the device must be the same as the administrator DN configured on the LDAP server.
4. Configure the administrator password.

login-password { **cipher** | **simple** } *string*

By default, no administrator password is specified.

Configuring LDAP user attributes

About this task

To authenticate a user, an LDAP client must complete the following operations:

1. Establish a connection to the LDAP server.
2. Obtain the user DN from the LDAP server.
3. Use the user DN and the user's password to bind with the LDAP server.

LDAP provides a DN search mechanism for obtaining the user DN. According to the mechanism, an LDAP client sends search requests to the server based on the search policy determined by the LDAP user attributes of the LDAP client.

The LDAP user attributes include:

- Search base DN.
- Search scope.
- Username attribute.
- Username format.
- User object class.

Restrictions and guidelines

If the LDAP server contains many directory levels, a user DN search starting from the root directory can take a long time. To improve efficiency, you can change the start point by specifying the search base DN.

Procedure

1. Enter system view.
   system-view
2. Enter LDAP server view.
   ldap server *server-name*
3. Specify the user search base DN.
   search-base-dn *base-dn*
   By default, no user search base DN is specified.
4. (Optional.) Specify the user search scope.
   search-scope { **all-level** | **single-level** }
   By default, the user search scope is **all-level**.
5. (Optional.) Specify the username attribute.
   user-parameters user-name-attribute { *name-attribute* | **cn** | **uid** }
   By default, the username attribute is **cn**.
6. (Optional.) Specify the username format.
   user-parameters user-name-format { **with-domain** | **without-domain** }
   By default, the username format is **without-domain**.
7. (Optional.) Specify the user object class.
   user-parameters user-object-class *object-class-name*
   By default, no user object class is specified, and the default user object class on the LDAP server is used. The default user object class for this command varies by server model.

Configuring an LDAP attribute map

About this task

Configure an LDAP attribute map to define a list of LDAP-AAA attribute mapping entries. To apply the LDAP attribute map, specify the name of the LDAP attribute map in the LDAP scheme used for authorization.

The LDAP attribute map feature enables the device to convert LDAP attributes obtained from an LDAP authorization server to device-recognizable AAA attributes based on the mapping entries. Because the device ignores unrecognized LDAP attributes, configure the mapping entries to include important LDAP attributes that should not be ignored.

An LDAP attribute can be mapped only to one AAA attribute. Different LDAP attributes can be mapped to the same AAA attribute.

Procedure

1. Enter system view.
   system-view
2. Create an LDAP attribute map and enter LDAP attribute map view.
   ldap attribute-map *map-name*
3. Configure a mapping entry.
   map ldap-attribute *ldap-attribute-name* [**prefix** *prefix-value* **delimiter** *delimiter-value*] **aaa-attribute** { **user-group** | **user-profile** }

Creating an LDAP scheme

Restrictions and guidelines

You can configure a maximum of 16 LDAP schemes. An LDAP scheme can be used by multiple ISP domains.

Procedure

1. Enter system view.
   system-view
2. Create an LDAP scheme and enter LDAP scheme view.
   ldap scheme *ldap-scheme-name*

Specifying the LDAP authentication server

1. Enter system view.
   system-view
2. Enter LDAP scheme view.
   ldap scheme *ldap-scheme-name*
3. Specify the LDAP authentication server.
   authentication-server *server-name*
   By default, no LDAP authentication server is specified.

Specifying the LDAP authorization server

1. Enter system view.

system-view

2. Enter LDAP scheme view.
   ldap scheme *ldap-scheme-name*
3. Specify the LDAP authorization server.
   authorization-server *server-name*
   By default, no LDAP authorization server is specified.

Specifying an LDAP attribute map for LDAP authorization

About this task

Specify an LDAP attribute map for LDAP authorization to convert LDAP attributes obtained from the LDAP authorization server to device-recognizable AAA attributes.

Restrictions and guidelines

You can specify only one LDAP attribute map in an LDAP scheme.

Procedure

1. Enter system view.
   system-view
2. Enter LDAP scheme view.
   ldap scheme *ldap-scheme-name*
3. Specify an LDAP attribute map.
   attribute-map *map-name*
   By default, no LDAP attribute map is specified.

Display and maintenance commands for LDAP

Execute **display** commands in any view.

Task	Command
Display the configuration of LDAP schemes.	**display ldap scheme** [*ldap-scheme-name*]

Creating an ISP domain

About ISP domains

In a networking scenario with multiple ISPs, the device can connect to users of different ISPs. These users can have different user attributes, such as different username and password structures, different service types, and different rights. To manage users of different ISPs, configure authentication, authorization, and accounting methods and domain attributes for each ISP domain as needed.

The device supports a maximum of 16 ISP domains, including the system-defined ISP domain **system**. You can specify one of the ISP domains as the default domain.

On the device, each user belongs to an ISP domain. If a user does not provide an ISP domain name at login, the device considers the user belongs to the default ISP domain.

Each ISP domain has a set of system-defined AAA methods, which are local authentication, local authorization, and local accounting. If you do not configure any AAA methods for an ISP domain, the device uses the system-defined AAA methods for users in the domain.

The device chooses an authentication domain for each user in the following order:

1. The authentication domain specified for the access module.
2. The ISP domain in the username.
3. The default ISP domain of the device.

If the chosen domain does not exist on the device, the device searches for the ISP domain that accommodates users assigned to nonexistent domains. (Support for the authentication domain configuration depends on the access module.) If no such ISP domain is configured, user authentication fails.

Restrictions and guidelines for ISP domain configuration

An ISP domain cannot be deleted when it is the default ISP domain. Before you use the **undo domain** command, change the domain to a non-default ISP domain by using the **undo domain default enable** command.

You can modify the settings of the system-defined ISP domain **system**, but you cannot delete the domain.

To avoid RADIUS authentication, authorization, or accounting failures, use short domain names to ensure that usernames containing a domain name do not exceed 253 characters.

To avoid RADIUS accounting failures, make sure the domain name contained in usernames sent to the RADIUS server does not exceed 247 characters.

Creating an ISP domain

1. Enter system view.
   system-view
2. Create an ISP domain and enter ISP domain view.
   domain *isp-name*
   By default, a system-defined ISP domain exists. The domain name is **system**.

Specifying the default ISP domain

1. Enter system view.
   system-view
2. Specify the default ISP domain.
   domain default enable *isp-name*
   By default, the default ISP domain is the system-defined ISP domain **system**.

Specifying an ISP domain for users that are assigned to nonexistent domains

1. Enter system view.
   system-view
2. Specify the ISP domain to accommodate users that are assigned to nonexistent domains.
   domain if-unknown *isp-name*

By default, no ISP domain is specified to accommodate users that are assigned to nonexistent domains.

Configuring ISP domain attributes

Setting ISP domain status

About this task

By placing the ISP domain in active or blocked state, you allow or deny network service requests from users in the domain.

Procedure

1. Enter system view.
   system-view
2. Enter ISP domain view.
   domain *isp-name*
3. Set the status of the ISP domain.
   state { **active** | **block** }
   By default, an ISP domain is in active state, and users in the domain can request network services.

Configuring authorization attributes for an ISP domain

About this task

The device supports the following authorization attributes:

- **ACL**—The device restricts authenticated users to access only the network resources permitted by the ACL.
- **CAR action**—The attribute controls the traffic flow of authenticated users. The CAR attribute is not supported for authenticated users that come online from an aggregate interface.
- **Maximum number of multicast groups**—The attribute restricts the maximum number of multicast groups that an authenticated user can join concurrently.
- **IPv4 address pool**—The device assigns IPv4 addresses from the pool to authenticated users in the domain.
- **IPv6 address pool**—The device assigns IPv6 addresses from the pool to authenticated users in the domain.
- **Redirect URL**—The device redirects users in the domain to the URL after they pass authentication.
- **User group**—Authenticated users in the domain obtain all attributes of the user group.
- **User profile**—The device restricts the user's behavior based on the user profile.

The device assigns the authorization attributes in the ISP domain to the authenticated users that do not receive these attributes from the server.

Procedure

1. Enter system view.
   system-view
2. Enter ISP domain view.
   domain *isp-name*

3. Configure authorization attributes for authenticated users in the ISP domain.

   authorization-attribute { **acl** *acl-number* | **car inbound cir** *committed-information-rate* [**pir** *peak-information-rate*] **outbound cir** *committed-information-rate* [**pir** *peak-information-rate*] | **igmp max-access-number** *max-access-number* | **ip-pool** *ipv4-pool-name* | **ipv6-pool** *ipv6-pool-name* | **mld max-access-number** *max-access-number* | **url** *url-string* | **user-group** *user-group-name* | **user-profile** *profile-name* }

   The default settings are as follows:

   - An IPv4 user can concurrently join a maximum of four IGMP multicast groups.
   - An IPv6 user can concurrently join a maximum of four MLD multicast groups.
   - No other authorization attributes exist.

Including the idle timeout period in the user online duration to be sent to the server

About this task

If a user goes offline due to connection failure or malfunction, the user's online duration sent to the server includes the idle timeout period assigned by the authorization server. The online duration generated on the server is longer than the actual online duration of the user.

For portal users, the device includes the idle timeout period set for the online portal user detection feature in the user online duration. For more information about online detection for portal users, see "Configuring portal authentication."

Procedure

1. Enter system view.

   system-view

2. Enter ISP domain view.

   domain *isp-name*

3. Configure the device to include the idle timeout period in the user online duration to be sent to the server.

   session-time include-idle-time

   By default, the user online duration sent to the server does not include the idle timeout period.

Configuring AAA methods for an ISP domain

Configuring authentication methods for an ISP domain

Restrictions and guidelines

When you configure authentication, follow these restrictions and guidelines:

- For high availability, you can specify one primary authentication method and multiple backup authentication methods. When the primary method is invalid, the device attempts to use the backup methods in sequence.

  For example, the **radius-scheme** *radius-scheme-name* **local none** parameters specify a primary RADIUS authentication method and two backup methods (local authentication and no authentication). The device performs RADIUS authentication by default and performs local authentication when the RADIUS server is invalid. The device does not perform authentication when both of the previous methods are invalid.

The remote authentication method is invalid in the following situations:

- The specified authentication scheme does not exist.
- Authentication packet sending fails.
- The device does not receive any authentication response packets from an authentication server.

The local authentication method is invalid if the device fails to find the matching local user configuration.

- If the authentication method uses a RADIUS scheme and the authorization method does not use a RADIUS scheme, AAA accepts only the authentication result from the RADIUS server. The Access-Accept message from the RADIUS server also includes the authorization information, but the device ignores the information.
- If an HWTACACS scheme is specified, the device uses the entered username for role authentication. If a RADIUS scheme is specified, the device uses username **$enab***n***$** on the RADIUS server for role authentication. The variable *n* represents a user role level. For more information about user role authentication, see *Fundamentals Configuration Guide*.

The **none** keyword is not supported in FIPS mode.

Prerequisites

Before configuring authentication methods, complete the following tasks:

1. Determine the access type or service type to be configured. With AAA, you can configure an authentication method for each access type and service type.
2. Determine whether to configure the default authentication method for all access types or service types. The default authentication method applies to all access users. However, the method has a lower priority than the authentication method that is specified for an access type or service type.

Procedure

1. Enter system view.

   system-view

2. Enter ISP domain view.

   domain *isp-name*

3. (Optional.) Specify default authentication methods for all types of users.

   authentication default { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **ldap-scheme** *ldap-scheme-name* [**local**] [**none**] | **local** [**hwtacacs-scheme** *hwtacacs-scheme-name* | **radius-scheme** *radius-scheme-name*] * [**none**] | **local** [**ldap-scheme** *ldap-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

   By default, the default authentication method is **local**.

4. Specify authentication methods for a user type or a service.
   - Specify authentication methods for LAN users.

     authentication lan-access { **ldap-scheme** *ldap-scheme-name* [**local**] [**none**] | **local** [**ldap-scheme** *ldap-scheme-name* | **radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

     By default, the default authentication methods are used for LAN users.

   - Specify authentication methods for login users.

     authentication login { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **ldap-scheme**

ldap-scheme-name [**local**] [**none**] | **local** [**hwtacacs-scheme** *hwtacacs-scheme-name* | **radius-scheme** *radius-scheme-name*] * [**none**] | **local** [**ldap-scheme** *ldap-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

By default, the default authentication methods are used for login users.

- Specify authentication methods for portal users.

  authentication portal { **ldap-scheme** *ldap-scheme-name* [**local**] [**none**] | **local** [**ldap-scheme** *ldap-scheme-name* | **radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

  By default, the default authentication methods are used for portal users.

- Specify authentication methods for obtaining a temporary user role.

  authentication super { **hwtacacs-scheme** *hwtacacs-scheme-name* | **radius-scheme** *radius-scheme-name* } *

  By default, the default authentication methods are used for obtaining a temporary user role.

Configuring authorization methods for an ISP domain

Restrictions and guidelines

For high availability, you can specify one primary authorization method and multiple backup authorization methods. When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **radius-scheme** *radius-scheme-name* **local none** parameters specify a primary RADIUS authorization method and two backup methods (local authorization and no authorization). The device performs RADIUS authorization by default and performs local authorization when the RADIUS server is invalid. The device does not perform authorization when both of the previous methods are invalid.

The remote authorization method is invalid in the following situations:

- The specified authorization scheme does not exist.
- Authorization packet sending fails.
- The device does not receive any authorization response packets from an authorization server.

The local authorization method is invalid if the device fails to find the matching local user configuration.

Only SSL VPN users support LDAP authorization in the current software version.

To use a RADIUS scheme as the authorization method, specify the name of the RADIUS scheme that is configured as the authentication method for the ISP domain. If an invalid RADIUS scheme is specified as the authorization method, RADIUS authentication and authorization fail.

The **none** keyword is not supported in FIPS mode.

Prerequisites

Before configuring authorization methods, complete the following tasks:

1. Determine the access type or service type to be configured. With AAA, you can configure an authorization scheme for each access type and service type.
2. Determine whether to configure the default authorization method for all access types or service types. The default authorization method applies to all access users. However, the method has a lower priority than the authorization method that is specified for an access type or service type.

Procedure

1. Enter system view.

system-view

2. Enter ISP domain view.

   domain *isp-name*

3. (Optional.) Specify default authorization methods for all types of users.

   authorization default { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **local** [**hwtacacs-scheme** *hwtacacs-scheme-name* | **radius-scheme** *radius-scheme-name*] * [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

   By default, the authorization method is **local**.

4. Specify authorization methods for a user type or a service.

   - Specify command authorization methods.

     authorization command { **hwtacacs-scheme** *hwtacacs-scheme-name* [**local**] [**none**] | **local** [**none**] | **none** }

     By default, the default authorization methods are used for command authorization.

   - Specify authorization methods for LAN users.

     authorization lan-access { **local** [**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

     By default, the default authorization methods are used for LAN users.

   - Specify authorization methods for login users.

     authorization login { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **local** [**hwtacacs-scheme** *hwtacacs-scheme-name* | **radius-scheme** *radius-scheme-name*] * [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

     By default, the default authorization methods are used for login users.

   - Specify authorization methods for portal users.

     authorization portal { **local** [**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

     By default, the default authorization methods are used for portal users.

Configuring accounting methods for an ISP domain

Restrictions and guidelines

For high availability, you can specify one primary accounting method and multiple backup accounting methods. When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **radius-scheme** *radius-scheme-name* **local none** parameters specify a primary RADIUS accounting method and two backup methods (local accounting and no accounting). The device performs RADIUS accounting by default and performs local accounting when the RADIUS server is invalid. The device does not perform accounting when both of the previous methods are invalid.

The remote accounting method is invalid in the following situations:

- The specified accounting scheme does not exist.
- Accounting packet sending fails.
- The device does not receive any accounting response packets from an accounting server.

The local accounting method is invalid if the device fails to find the matching local user configuration.

FTP, SFTP, and SCP users do not support accounting.

Local accounting does not provide statistics for charging. It only counts and controls the number of concurrent users that use the same local user account. The threshold is configured by using the **access-limit** command.

The **none** keyword is not supported in FIPS mode.

Prerequisites

Before configuring accounting methods, complete the following tasks:

1. Determine the access type or service type to be configured. With AAA, you can configure an accounting method for each access type and service type.
2. Determine whether to configure the default accounting method for all access types or service types. The default accounting method applies to all access users. However, the method has a lower priority than the accounting method that is specified for an access type or service type.

Procedure

1. Enter system view.

   system-view

2. Enter ISP domain view.

   domain *isp-name*

3. (Optional.) Specify default accounting methods for all types of users.

   accounting default { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **local** [**hwtacacs-scheme** *hwtacacs-scheme-name* | **radius-scheme** *radius-scheme-name*] * [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

   By default, the accounting method is **local**.

4. Specify accounting methods for a user type.
   - Specify the command accounting method.

     accounting command hwtacacs-scheme *hwtacacs-scheme-name*

     By default, the default accounting methods are used for command accounting.
   - Specify accounting methods for LAN users.

     accounting lan-access { **broadcast radius-scheme** *radius-scheme-name1* **radius-scheme** *radius-scheme-name2* [**local**] [**none**] | **local** [**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

     By default, the default accounting methods are used for LAN users.
   - Specify accounting methods for login users.

     accounting login { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **local** [**hwtacacs-scheme** *hwtacacs-scheme-name* | **radius-scheme** *radius-scheme-name*] * [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

     By default, the default accounting methods are used for login users.
   - Specify accounting methods for portal users.

     accounting portal { **broadcast radius-scheme** *radius-scheme-name1* **radius-scheme** *radius-scheme-name2* [**local**] [**none**] | **local**

[**radius-scheme** *radius-scheme-name*] [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

By default, the default accounting methods are used for portal users.

Display and maintenance commands for ISP domains

Execute **display** commands in any view.

Task	Command
Display configuration information about an ISP domain or all ISP domains.	**display domain** [*isp-name*]

Configuring AAA fail-permit and recovery

About this task

This feature is used to resolve the issue that users that use a RADIUS scheme cannot come online when all RADIUS servers in the RADIUS scheme are unavailable. The feature contains the following settings in a user authentication domain:

- For the users to perform authentication, authorization, and accounting again, log off the users.
- For the users to stay in the original authentication domain without being re-authenticated, allow the users to stay online.
- For the users to perform reauthentication in the original authentication domain without user awareness, configure reauthentication.

For the device to obtain the status of RADIUS authentication servers in time, the system detects the status of the RADIUS authentication servers in each RADIUS scheme at intervals. In addition, it notifies access modules to cancel user fail-permit when the corresponding RADIUS scheme has reachable RADIUS servers.

Restrictions and guidelines

Only Release 1122 and later versions support this feature.

This feature takes effect only on 802.1X, Web, and MAC address authentication users.

As a best practice to accurately identify whether a RADIUS authentication server is available and the recovery configuration can take effect in time, configure RADIUS server status detection.

When you set the interval at which the device detects the status of RADIUS authentication servers, follow these restrictions and guidelines:

- A too short interval consumes too many system resources for access services. A too long interval cannot detect server status changes in time.
- As a best practice, consider the processing efficiency for access services and the accuracy for fail-permit and recovery when a large number of users come online in a short time.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Set the interval at which the device detects the status of RADIUS authentication servers.

   radius-server authen-state-check interval *interval*

   By default, the device detects the status of RADIUS authentication servers at intervals of 10 minutes.

3. Enter ISP domain view.

   domain *isp-name*

4. Specify an action to take on users in the critical domain when a RADIUS server becomes available.

   authen-radius-recover { **offline** | **online** | **re-authen** }

   By default, clients in the critical domain stay online in the original authentication domain when a RADIUS server becomes available.

Setting the maximum number of concurrent login users

About this task

Perform this task to set the maximum number of concurrent users that can log on to the device through a specific protocol, regardless of their authentication methods. The authentication methods include no authentication, local authentication, and remote authentication.

Procedure

1. Enter system view.

   system-view

2. Set the maximum number of concurrent login users.

   In non-FIPS mode:

   aaa session-limit { **ftp** | **http** | **https** | **ssh** | **telnet** } *max-sessions*

   In FIPS mode:

   aaa session-limit { **https** | **ssh** } *max-sessions*

   By default, the maximum number of concurrent login users is 32 for each user type.

Configuring local BYOD authorization

About BYOD endpoint identification rules

Bring Your Own Device (BYOD) solution provides authentication and authorization services for companies, organization, and users based on their identity information, endpoint information, and access scenarios.

A BYOD endpoint identification rule defines the mapping between an endpoint type and a fingerprint string or between a group of endpoint attributes and a fingerprint string. When a user comes online, the device obtains the fingerprint information of the user's endpoint and matches the fingerprint information with the local BYOD endpoint identification rules. If a match is found, the device recognizes the endpoint type or endpoint attributes of the user's endpoint as the endpoint type or endpoint attributes associated with the matching rule.

The device supports the following endpoint fingerprints:

- **DHCP Option 55 fingerprint**—Parameter request list option. The option is used by an endpoint to request specified configuration parameters.
- **HTTP user agent fingerprint**—Located in the header of HTTP requests to carry information about the endpoint operating system, Web browser, and versions.
- **MAC address fingerprint**—OUI of the endpoint or MAC address range to which the endpoint belongs.

The device can use BYOD endpoint identification rules to identify the following information:

- Endpoint attributes, including the endpoint vendor, category, and operating system.
- Endpoint type, for example, Generic Android.

The system has predefined BYOD endpoint identification rules. You can also configure BYOD endpoint identification rules depending on the network requirements. The following categories of BYOD endpoint identification rules are supported:

- **BYOD endpoint attribute identification rule**—Defines a mapping between a group of endpoint attributes with a fingerprint string. This category of BYOD endpoint identification rules are used by other service modules to identify endpoints. For example, when EPA is monitoring online and offline events of endpoints accessing the IP network through the device, it uses BYOD endpoint attribute identification rules to recognize endpoint attributes.
- **BYOD endpoint type identification rule**—Defines a mapping between an endpoint type and a fingerprint string. This category of BYOD endpoint identification rules are used for local BYOD authorization.

Restrictions: Software version compatibility with local BYOD authorization

Only Release 1112 and later versions support this feature.

BYOD endpoint identification tasks at a glance

To configure BYOD endpoint identification, perform the following tasks:

1. Configure BYOD endpoint identification rules
   - Configuring BYOD endpoint attribute identification rules

     Perform this task according to service module requirements.
   - Configuring BYOD endpoint type identification rules

     This task is applicable only to local BYOD authorization.
2. Specifying the supported BYOD endpoint identification rule types and their priority order
3. Configuring authorization attributes for local BYOD authorization

   This task is applicable only to local BYOD authorization.

Configuring BYOD endpoint attribute identification rules

Restrictions and guidelines

A fingerprint string can match only one set of endpoint attributes. However, the same endpoint attribute can be associated with multiple fingerprint strings.

Procedure

1. Enter system view.

   system-view
2. Create a BYOD endpoint attribute identification rule and enter its view, or enter the view of an existing BYOD endpoint attribute identification rule.

   byod rule { **dhcp-option** *option-string* | **http-user-agent** *agent-string* | **mac-address** *mac-address* **mask** *mac-mask* } **device-attributes**

   By default, only predefined BYOD endpoint attribute identification rules exist.
3. Specify an endpoint category to match the BYOD endpoint attribute identification rule.

   device-category *category-name*

By default, no endpoint category is specified for a user-defined BYOD endpoint attribute identification rule. To view whether an endpoint category is specified for a predefined BYOD endpoint attribute identification rule, use the **display byod rule** command.

4. Specify an endpoint operating system to match the BYOD BYOD endpoint attribute identification rule.

   device-os *os-name*

   By default, no endpoint operating system is specified for a user-defined BYOD endpoint attribute identification rule. To view whether an endpoint operating system is specified for a predefined BYOD endpoint attribute identification rule, use the **display byod rule** command.

5. Specify an endpoint vendor to match the BYOD endpoint attribute identification rule.

   device-vendor *vendor-name*

   By default, no endpoint vendor is specified for a user-defined BYOD endpoint attribute identification rule. To view whether an endpoint vendor is specified for a predefined BYOD endpoint attribute identification rule, use the **display byod rule** command.

Configuring BYOD endpoint type identification rules

Restrictions and guidelines

A fingerprint string can match only one endpoint type. However, an endpoint type can be associated with multiple fingerprint strings.

Procedure

1. Enter system view.

   system-view

2. Configure a BYOD endpoint type identification rule.

   byod rule { **dhcp-option** *option-string* | **http-user-agent** *agent-string* | **mac-address** *mac-address* **mask** *mac-mask* } **device-type** *type-name*

   By default, only predefined BYOD endpoint type identification rules exist.

Specifying the supported BYOD endpoint identification rule types and their priority order

About this task

By default, the device uses DHCP Option 55-based rules, HTTP user agent-based rules, and MAC address-based rules in sequence to identify endpoints.

To meet requirements in different networks, you can specify the supported BYOD endpoint identification rule types and their priority order.

Procedure

1. Enter system view.

   system-view

2. Specify the supported BYOD endpoint identification rule types and their priority order.

   byod rule-order { **dhcp-option** | **http-user-agent** | **mac-address** } *

   By default, the device uses the following types of BYOD endpoint identification rules to identify endpoints and the priority order is as follows:

   a. DHCP Option 55-based rules.

   b. HTTP user agent-based rules.

c. MAC address-based rule.

The order of the keywords in this command determines the priority order of the BYOD endpoint identification rule types. To preferentially use a type of BYOD endpoint identification rules, specify that rule type first in the command.

Configuring authorization attributes for local BYOD authorization

About this task

After a user passes local authentication, the device uses the local BYOD endpoint type identification rules to identify the endpoint type of the user. Then, the device assigns the BYOD authorization attributes specified in the user's user group to the user based on the endpoint type.

Restrictions and guidelines

For a user, an endpoint type-specific authorization attribute takes precedence over the same common authorization attribute specified for the user. A common authorization attribute specified for the user takes precedence over the same common authorization attribute specified for the user group to which the user belongs.

Procedure

1. Enter system view.

   system-view

2. Create a user group and enter user group view.

   user-group *group-name*

   By default, a user group named **system** exists on the device.

3. Configure authorization attributes for a type of BYOD endpoints in the user group.

   byod authorization device-type *type-name* { **acl** *acl-number* | **idle-cut** *minutes* | **ip-pool** *ipv4-pool-name* | **ipv6-pool** *ipv6-pool-name* | **session-timeout** *minutes* | **user-profile** *profile-name* | **vlan** *vlan-id* } *

   By default, no authorization attributes are configured for any type of BYOD endpoints.

Display and maintenance commands for local BYOD authorization

Execute **display** commands in any view.

Task	Command
Display BYOD endpoint identification rules.	**display byod rule** { **dhcp-option** [*option-string*] | **http-user-agent** [*agent-string*] | **mac-address** [*mac-address*] }
Display the supported types of BYOD endpoint identification rules and their priority order.	**display byod rule-order**
Display BYOD authorization information for a user group.	**display user-group name** *group-name* **byod-authorization**

Configuring a NAS-ID

About this task

During RADIUS authentication, the device uses a NAS-ID to set the NAS-Identifier attribute of RADIUS packets so that the RADIUS server can identify the access location of users.

The device selects the NAS-ID for the NAS-Identifier attribute in the following order:

1. NAS-ID in a VSRP instance. For more information, see VSRP configuration in *High Availability Configuration Guide*.
2. NAS-ID bound with VLANs in a NAS-ID profile.

If no NAS-ID is configured, the device uses the device name (set by using the **sysname** command) as the NAS-ID.

Configure a NAS-ID profile to maintain NAS-ID and VLAN bindings on the device so that the device can send different NAS-Identifier attribute strings in RADIUS requests from different VLANs.

Restrictions and guidelines

You can apply a NAS-ID profile to portal- or port security-enabled interfaces. For more information, see "Configuring portal authentication" and "Configuring port security."

You can configure multiple NAS-ID and VLAN bindings in a NAS-ID profile.

A NAS-ID can be bound with more than one VLAN, but a VLAN can be bound with only one NAS-ID. If you configure multiple bindings for the same VLAN, the most recent configuration takes effect.

Procedure

1. Enter system view.
   system-view
2. Create a NAS-ID profile and enter NAS-ID profile view.
   aaa nas-id profile *profile-name*
3. Configure a NAS-ID and VLAN binding in the profile.
   nas-id *nas-identifier* **bind vlan** *vlan-id*

Configuring the device ID

About this task

RADIUS uses the value of the Acct-Session-ID attribute as the accounting ID for a user. The device generates an Acct-Session-ID value for each online user based on the system time, random digits, and device ID.

Restrictions and guidelines

On a VSRP network where multiple devices use the same accounting server, accounting ID conflicts might occur. To avoid duplicate accounting IDs, perform this task to assign a unique device ID to each device.

Procedure

1. Enter system view.
   system-view
2. Configure the device ID.
   aaa device-id *device-id*

   By default, the device ID is 0.

Enabling password change prompt logging

About this task

Use this feature to enhance the protection of passwords for Telnet, SSH, HTTP, HTTPS, NETCONF over SSH, and NETCONF over SOAP users and improve the system security.

This feature enables the device to generate logs to prompt users to change their weak passwords at an interval of 24 hours and at the users' login.

A password is a weak password if it does not meet the following requirements:

- Password composition restriction configured by using the **`password-control composition`** command.
- Minimum password length restriction set by using the **`password-control length`** command.
- Password complexity checking policy configured by using the **`password-control complexity`** command.

For a NETCONF over SSH or NETCONF over SOAP user, the device also generates a password change prompt log if any of the following conditions exists:

- The current password of the user is the default password or has expired.
- The user logs in to the device for the first time or uses a new password to log in after global password control is enabled.

The device will no longer generate password change prompt logs for a user when one of the following conditions exists:

- The password change prompt logging feature is disabled.
- The user has changed the password and the new password meets the password control requirements.
- The enabling status of a related password control feature has changed so the current password of the user meets the password control requirements.
- The password composition policy or the minimum password length has changed.

Restrictions and guidelines

You can use the **`display password-control`** command to display password control configuration. For more information about password control commands, see password control commands in *Security Command Reference*.

Procedure

1. Enter system view.

   `system-view`
2. Enable password change prompt logging.

   `local-server log change-password-prompt`

   By default, password change prompt logging is enabled.

Configuring the connection recording policy

About the connection recording policy

Use this feature on scenarios where the device acts as an FTP, SSH, SFTP, or Telnet login client to establish a connection with a login server. This feature enables the device to provide an accounting server with the connection start and termination information. When the login client establishes a

connection with the login server, the system sends a start-accounting request to the accounting server. When the connection is terminated, the system sends a stop-accounting request to the accounting server.

Restrictions and guidelines

The device includes the username entered by a user in the accounting packets to be sent to the AAA server for connection recording. The username format configured by using the **user-name-format** command in the accounting scheme does not take effect.

Procedure

1. Enter system view.
   system-view
2. Create a connection recording policy and enter its view.
   aaa connection-recording policy
3. Specify the accounting method for the connection recording policy.
   accounting hwtacacs-scheme *hwtacacs-scheme-name*

Display and maintenance commands for the connection recording policy

Execute **display** commands in any view.

Task	Command
Display the connection recording policy configuration.	**display aaa connection-recording policy**

Configuring the AAA test feature

About this task

This feature enables the device to send authentication or accounting requests to the specified AAA servers to simulate an authentication or accounting process of a user. Use this feature to identify the reasons for the failure of the interaction between the device and the AAA servers. This feature is applicable only to RADIUS.

When performing an AAA test, the device ignores the status of the specified AAA servers and the RADIUS server load sharing feature. The process of an AAA test is as follows:

1. The device sends authentication requests that carry the specified username and password to the specified authentication server or to the authentication servers in the specified RADIUS scheme. The device tries to communicate with the authentication servers in the specified scheme in sequence.

   The process goes to the next step in the following situations:

   - The device receives an authentication response (no matter the authentication succeeds or fails).
   - The device does not receive any authentication response after making all authentication request attempts.

This step is skipped if no correct authentication server is specified for the AAA test or no authentication servers are configured in the specified RADIUS scheme.

2. The device sends start-accounting requests to the specified accounting server or to the accounting servers in the specified RADIUS scheme. The device tries to communicate with the accounting servers in the specified scheme in sequence.

   The process goes to the next step in the following situations:

   - The device receives a start-accounting response (no matter the accounting succeeds or fails).
   - The device does not receive any start-accounting response after making all start-accounting request attempts.

   This step and the next step are skipped if no correct accounting server is specified for the AAA test or no accounting servers are configured in the specified RADIUS scheme.

3. The device sends stop-accounting requests to the accounting servers to which it has sent a start-accounting request.

   The process finishes in the following situations:

   - The device receives a stop-accounting response.
   - The device does not receive any stop-accounting response after making all stop-accounting request attempts.

To identify attributes that cause authentication or accounting failures, you can configure the device to carry specific attributes in RADIUS requests or define values for specific attributes in the requests. Table 3 shows the attributes that RADIUS requests carry by default.

Table 3 Attributes that RADIUS requests carry by default

Packet type	Attributes that the type of packets carry by default
RADIUS authentication request	User-Name CHAP-Password (or User-Password) CHAP-Challenge NAS-IP-Address (or NAS-IPv6-Address) Service-Type Framed-Protocol NAS-Identifier NAS-Port-Type Acct-Session-Id
RADIUS accounting request	User-Name Acct-Status-Type NAS-IP-Address (or NAS-IPv6-Address) NAS-Identifier Acct-Session-Id Acct-Delay-Time Acct-Terminate-Cause

Restrictions and guidelines

When you perform an AAA test, follow these restrictions and guidelines:

- The device might communicate with the AAA servers incorrectly during an AAA test. Make sure no users come online or go offline during an AAA text.
- If the configuration of the specified RADIUS scheme changes, the new configuration does not affect the current AAA test. The modification will take effect in the next test.

- The system can have only one AAA test at a time. Another AAA test can be performed only after the current test finishes.

When you configure attributes to be included in or excluded from RADIUS requests, follow these restrictions and guidelines:

- Before you include an attribute that is already configured to be excluded from RADIUS requests, you must cancel the exclusion configuration by using the **undo exclude** command.
- Before you exclude an attribute that is already configured to be included in RADIUS requests, you must cancel the inclusion configuration by using the **undo include** command.

Prerequisites

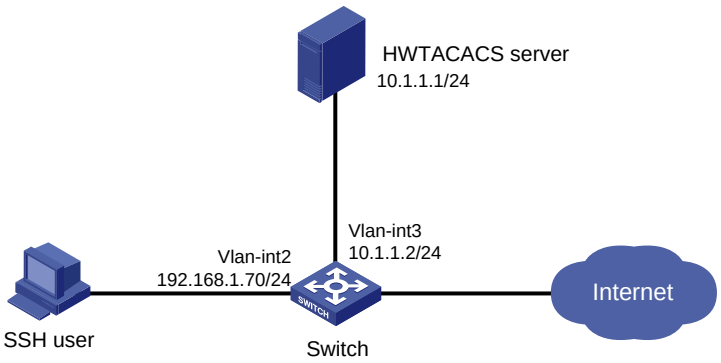
Before you perform an AAA test, you must configure a RADIUS scheme that contains the RADIUS servers to be tested.

Plan the RADIUS attributes to be included in RADIUS requests. Besides the attributes carried by default, the device adds the specified attributes to RADIUS packets in the order that they are specified by using the **include** command. Additional attributes cannot be added to a RADIUS request if the length of the RADIUS request reaches 4096 bytes.

Procedure

1. (Optional.) Configure a RADIUS attribute test group:
   a. Enter system view.
      system-view
   b. Create a RADIUS attribute test group and enter its view.
      radius attribute-test-group *attr-test-group-name*
      You can create multiple RADIUS attribute test groups.
   c. Include an attribute in RADIUS requests.
      include { **accounting** | **authentication** } { **name** *attribute-name* | [**vendor** *vendor-id*] **code** *attribute-code* } **type** { **binary** | **date** | **integer** | **interface-id** | **ip** | **ipv6** | **ipv6-prefix** | **octets** | **string** } value *attribute-value*
      Use this command to add attributes that RADIUS requests do not carry by default to the RADIUS requests.
      For an attribute that RADIUS requests carry by default, you can use this command to change its attribute value.
   d. Exclude an attribute from RADIUS requests.
      exclude { **accounting** | **authentication** } **name** *attribute-name*
      Use this command to exclude an attribute that RADIUS requests carry by default from the RADIUS requests sent during an AAA test to help troubleshoot authentication or accounting failures.
   e. Return to system view.
      quit
   f. Return to user view.
      quit
2. Perform an AAA test in user view.
   test-aaa user *user-name* **password** *password* **radius-scheme** *radius-scheme-name* [**radius-server** { *ipv4-address* | **ipv6** *ipv6-address* } *port-number* [**vpn-instance** *vpn-instance-name*]] [**chap** | **pap**] [**attribute-test-group** attr-*test-group-name*] [**trace**]

AAA configuration examples



Example: Configuring AAA for SSH users by an HWTACACS server

Network configuration

As shown in Figure 12, configure the switch to meet the following requirements:

- Use the HWTACACS server for SSH user authentication, authorization, and accounting.
- Assign the default user role **network-operator** to SSH users after they pass authentication.
- Exclude domain names from the usernames sent to the HWTACACS server.
- Use **expert** as the shared keys for secure HWTACACS communication.

Figure 12 Network diagram

Configuring the HWTACACS server

Set the shared keys to **expert** for secure communication with the switch, add an account for the SSH user, and specify the password. (Details not shown.)

Configuring the switch

Configure IP addresses for the interfaces. (Details not shown.)

Create an HWTACACS scheme.

```
<Switch> system-view
[Switch] hwtacacs scheme hwtac
```

Specify the primary authentication server.

```
[Switch-hwtacacs-hwtac] primary authentication 10.1.1.1 49
```

Specify the primary authorization server.

```
[Switch-hwtacacs-hwtac] primary authorization 10.1.1.1 49
```

Specify the primary accounting server.

```
[Switch-hwtacacs-hwtac] primary accounting 10.1.1.1 49
```

Set the shared keys to **expert** in plaintext form for secure HWTACACS communication.

```
[Switch-hwtacacs-hwtac] key authentication simple expert
[Switch-hwtacacs-hwtac] key authorization simple expert
[Switch-hwtacacs-hwtac] key accounting simple expert
```

Exclude domain names from the usernames sent to the HWTACACS server.

```
[Switch-hwtacacs-hwtac] user-name-format without-domain
```

```
[Switch-hwtacacs-hwtac] quit
```

Create an ISP domain named **bbb** and configure the domain to use the HWTACACS scheme for authentication, authorization, and accounting of login users.

```
[Switch-isp-bbb] authentication login hwtacacs-scheme hwtac
[Switch-isp-bbb] authorization login hwtacacs-scheme hwtac
[Switch-isp-bbb] accounting login hwtacacs-scheme hwtac
[Switch-isp-bbb] quit
```

Create local RSA and DSA key pairs.

```
[Switch] public-key local create rsa
[Switch] public-key local create dsa
```

Enable the Stelnet service.

```
[Switch] ssh server enable
```

Enable scheme authentication for user lines VTY 0 through VTY 63.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Enable the default user role feature to assign authenticated SSH users the default user role **network-operator**.

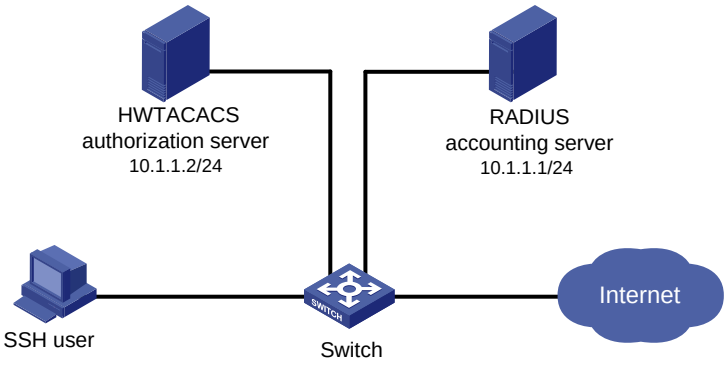
```
[Switch] role default-role enable
```

Verifying the configuration

Initiate an SSH connection to the switch, and enter the correct username and password. The user logs in to the switch. (Details not shown.)

Verify that the user can use the commands permitted by the network-operator user role. (Details not shown.)

Example: Configuring local authentication, HWTACACS authorization, and RADIUS accounting for SSH users



Network configuration

As shown in Figure 13, configure the switch to meet the following requirements:

- Perform local authentication for SSH users.
- Use the HWTACACS server and RADIUS server for SSH user authorization and accounting, respectively.
- Exclude domain names from the usernames sent to the servers.
- Assign the default user role **network-operator** to SSH users after they pass authentication.

Configure an account named **hello** for the SSH user. Configure the shared keys to **expert** for secure communication with the HWTACACS server and RADIUS server.

Figure 13 Network diagram

Configuring the HWTACACS server

Set the shared keys to **expert** for secure communication with the switch, add an account for the SSH user, and specify the password. (Details not shown.)

Configuring the RADIUS server

Set the shared keys to **expert** for secure communication with the switch, add an account for the SSH user, and specify the password. (Details not shown.)

Configuring the switch

Configure IP addresses for interfaces. (Details not shown.)

Create local RSA and DSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
[Switch] public-key local create dsa
```

Enable the Stelnet service.

```
[Switch] ssh server enable
```

Enable scheme authentication for user lines VTY 0 through VTY 63.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Configure an HWTACACS scheme.

```
[Switch] hwtacacs scheme hwtac
[Switch-hwtacacs-hwtac] primary authorization 10.1.1.2 49
[Switch-hwtacacs-hwtac] key authorization simple expert
[Switch-hwtacacs-hwtac] user-name-format without-domain
[Switch-hwtacacs-hwtac] quit
```

Configure a RADIUS scheme.

```
[Switch] radius scheme rd
[Switch-radius-rd] primary accounting 10.1.1.1 1813
[Switch-radius-rd] key accounting simple expert
[Switch-radius-rd] user-name-format without-domain
[Switch-radius-rd] quit
```

Create a device management user.

```
[Switch] local-user hello class manage
```

Assign the SSH service to the local user.

```
[Switch-luser-manage-hello] service-type ssh
```

Set the password to **123456TESTplat&!** in plaintext form for the local user. In FIPS mode, you must set the password in interactive mode.

```
[Switch-luser-manage-hello] password simple 123456TESTplat&!
[Switch-luser-manage-hello] quit
```

Create an ISP domain named **bbb** and configure the login users to use local authentication, HWTACACS authorization, and RADIUS accounting.

```
[Switch] domain bbb
[Switch-isp-bbb] authentication login local
[Switch-isp-bbb] authorization login hwtacacs-scheme hwtac
[Switch-isp-bbb] accounting login radius-scheme rd
[Switch-isp-bbb] quit
```

Enable the default user role feature to assign authenticated SSH users the default user role **network-operator**.

```
[Switch] role default-role enable
```

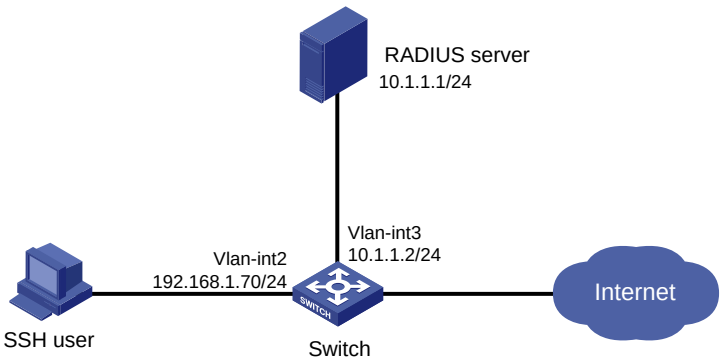
Verifying the configuration

Initiate an SSH connection to the switch, and enter username **hello@bbb** and the correct password. The user logs in to the switch. (Details not shown.)

Verify that the user can use the commands permitted by the network-operator user role. (Details not shown.)

Example: Configuring authentication and authorization for SSH users by a RADIUS server

Network configuration



As shown in Figure 14, configure the switch to meet the following requirements:

- Use the RADIUS server for SSH user authentication and authorization.
- Include domain names in the usernames sent to the RADIUS server.
- Assign the **network-admin** user role to SSH users after they pass authentication.

The RADIUS server runs IMC PLAT 7.3 (E0605) and IMC UAM 7.3 (E0512). Add an account with username **hello@bbb** on the RADIUS server.

The RADIUS server and the switch use **expert** as the shared key for secure RADIUS communication. The ports for authentication and accounting are **1812** and **1813**, respectively.

Figure 14 Network diagram

Configuring the RADIUS server

1. Add the switch to the IMC Platform as an access device:

   Log in to IMC, click the **User** tab, and select **User Access Policy** > **Access Device Management** > **Access Device** from the navigation tree. Then, click **Add** to configure an access device as follows:

   a. Set the ports for authentication and accounting to 1812 and 1813, respectively.

   b. Select **Device Management Service** from the **Service Type** list.

   c. Select **H3C (General)** from the **Access Device Type** list.

   d. Set the shared key to **expert** for secure RADIUS communication.

   e. Select an access device from the device list or manually add an access device. In this example, the device IP address is 10.1.1.2.

   f. Use the default values for other parameters and click **OK**.

   The IP address of the access device specified here must be the same as the source IP address of the RADIUS packets sent from the switch. The source IP address is chosen in the following order on the switch:

   - IP address specified by using the **`nas-ip`** command.
   - IP address specified by using the **`radius nas-ip`** command.
   - IP address of the outbound interface (the default).

   Figure 15 Adding the switch as an access device

2. Add an account for device management:

   Click the **User** tab, and select **Device User** > **Device User** from the navigation tree. Then, click **Add** to configure a device management account as follows:

   a. Enter account name **hello@bbb** and specify the password.

   b. Select **SSH** from the **Login Type** list.

   c. Enter user role **network-admin**.

   d. Specify 10.1.1.0 to 10.1.1.255 as the IP address range of the hosts to be managed.

   e. Click **OK**.

NOTE:

The IP address range must contain the IP address of the switch.

Figure 16 Adding an account for device management

Configuring the switch

Configure IP addresses for interfaces. (Details not shown.)

Create local RSA and DSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
[Switch] public-key local create dsa
```

Enable the Stelnet service.

```
[Switch] ssh server enable
```

Enable scheme authentication for user lines VTY 0 through VTY 63.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Create a RADIUS scheme.

```
[Switch] radius scheme rad
```

Specify the primary authentication server.

```
[Switch-radius-rad] primary authentication 10.1.1.1 1812
```

Set the shared key to **expert** in plaintext form for secure communication with the server.

```
[Switch-radius-rad] key authentication simple expert
```

Include domain names in the usernames sent to the RADIUS server.

```
[Switch-radius-rad] user-name-format with-domain
[Switch-radius-rad] quit
```

Create an ISP domain named **bbb** and configure authentication, authorization, and accounting methods for login users.

```
[Switch] domain bbb
[Switch-isp-bbb] authentication login radius-scheme rad
[Switch-isp-bbb] authorization login radius-scheme rad
[Switch-isp-bbb] accounting login none
[Switch-isp-bbb] quit
```

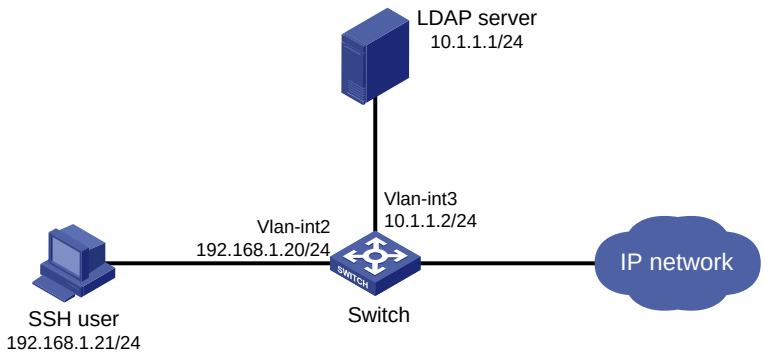
Verifying the configuration

Initiate an SSH connection to the switch, and enter username **hello@bbb** and the correct password. The user logs in to the switch. (Details not shown.)

Verify that the user can use the commands permitted by the network-admin user role. (Details not shown.)

Example: Configuring authentication for SSH users by an LDAP server

Network configuration



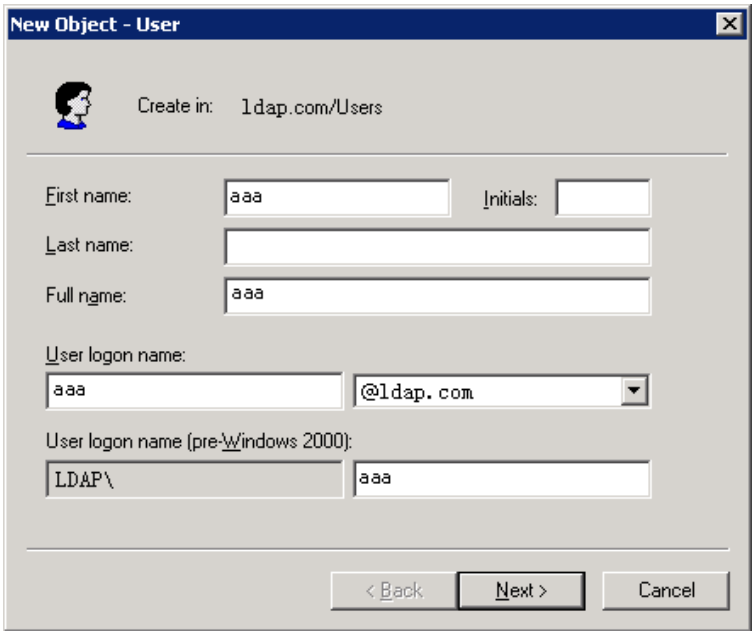
As shown in Figure 17, the LDAP server uses domain **ldap.com** and runs Microsoft Windows 2003 Server Active Directory.

Configure the switch to meet the following requirements:

- Use the LDAP server to authenticate SSH users.
- Assign the level-0 user role to SSH users after they pass authentication.

On the LDAP server, set the administrator password to **admin!123456**, add a user named **aaa**, and set the user's password to **ldap!123456**.

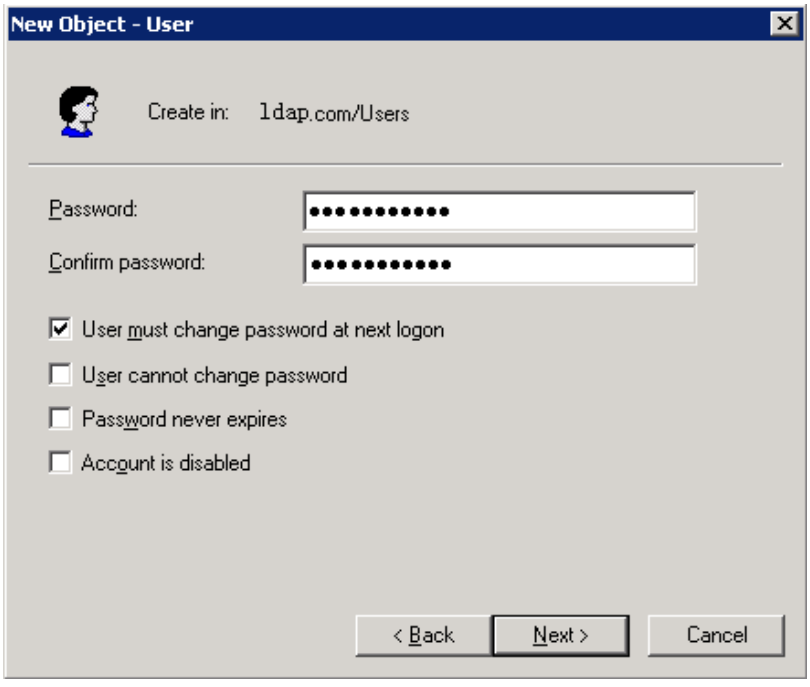
Figure 17 Network diagram



Configuring the LDAP server

1. Add a user named **aaa** and set the password to **ldap!123456**:
   a. On the LDAP server, select **Start** > **Control Panel** > **Administrative Tools**.
   b. Double-click **Active Directory Users and Computers**.
      The **Active Directory Users and Computers** window is displayed.
   c. From the navigation tree, click **Users** under the **ldap.com** node.

d. Select **Action** > **New** > **User** from the menu to display the dialog box for adding a user.



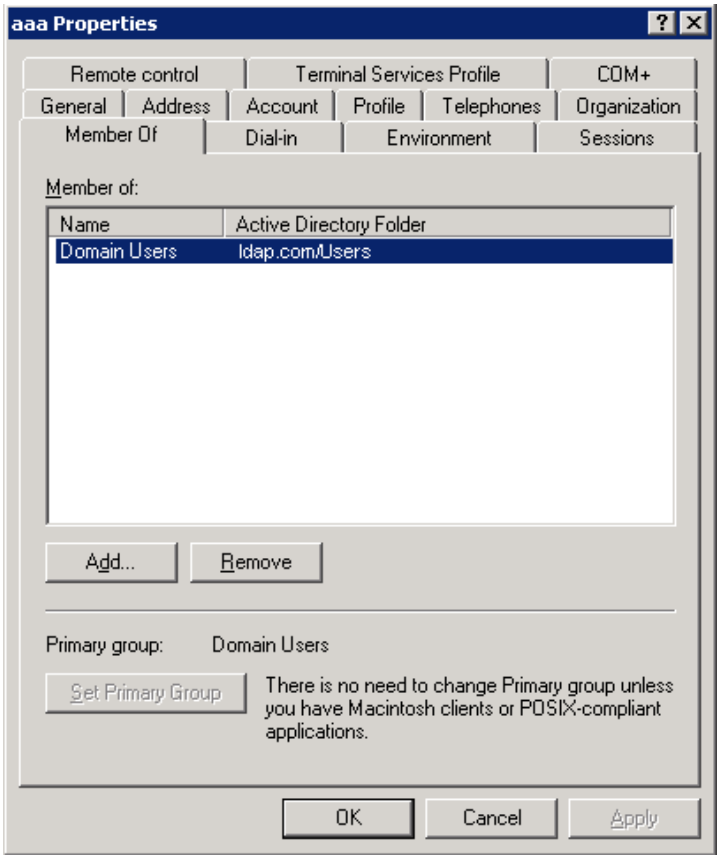
e. Enter logon name **aaa** and click **Next**.

Figure 18 Adding user aaa

f. In the dialog box, enter password **ldap!123456**, select options as needed, and click **Next**.

Figure 19 Setting the user's password

g. Click **OK**.



2. Add user **aaa** to group **Users**:

a. From the navigation tree, click **Users** under the **ldap.com** node.

b. In the right pane, right-click user **aaa** and select **Properties**.

c. In the dialog box, click the **Member Of** tab and click **Add**.

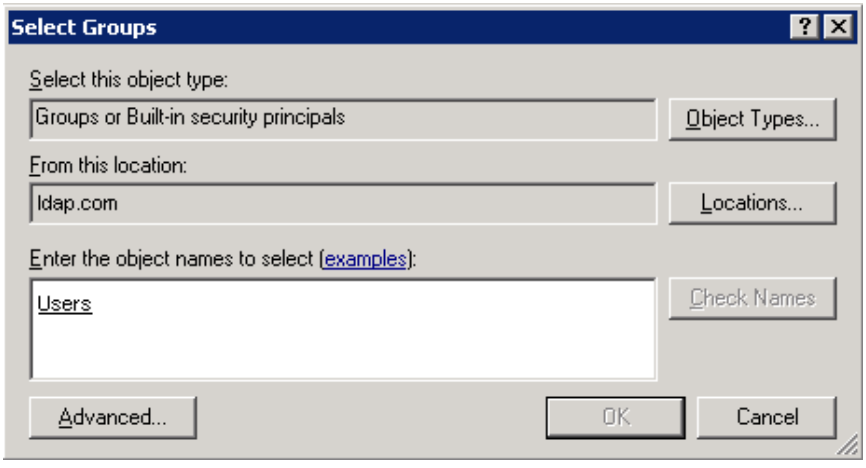


Figure 20 Modifying user properties

d. In the **Select Groups** dialog box, enter **Users** in the **Enter the object names to select** field, and click **OK**.

User **aaa** is added to group **Users**.

Figure 21 Adding user aaa to group Users

3. Set the administrator password to **admin!123456**:

a. In the right pane, right-click user **Administrator** and select **Set Password**.

b. In the dialog box, enter the administrator password. (Details not shown.)

Configuring the switch

Configure IP addresses for interfaces. (Details not shown.)

Create local RSA and DSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
[Switch] public-key local create dsa
```

Enable the Stelnet service.

```
[Switch] ssh server enable
```

Enable scheme authentication for user lines VTY 0 through VTY 63.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Configure an LDAP server.

```
[Switch] ldap server ldap1
```

Specify the IP address of the LDAP authentication server.

```
[Switch-ldap-server-ldap1] ip 10.1.1.1
```

Specify the administrator DN.

```
[Switch-ldap-server-ldap1] login-dn cn=administrator,cn=users,dc=ldap,dc=com
```

Specify the administrator password.

```
[Switch-ldap-server-ldap1] login-password simple admin!123456
```

Configure the base DN for user search.

```
[Switch-ldap-server-ldap1] search-base-dn dc=ldap,dc=com
[Switch-ldap-server-ldap1] quit
```

Create an LDAP scheme.

```
[Switch] ldap scheme ldap-shm1
```

Specify the LDAP authentication server.

```
[Switch-ldap-ldap-shm1] authentication-server ldap1
[Switch-ldap-ldap-shm1] quit
```

Create an ISP domain named **bbb** and configure authentication, authorization, and accounting methods for login users.

```
[Switch] domain bbb
[Switch-isp-bbb] authentication login ldap-scheme ldap-shm1
[Switch-isp-bbb] authorization login none
[Switch-isp-bbb] accounting login none
[Switch-isp-bbb] quit
```

Verifying the configuration

Initiate an SSH connection to the switch, and enter username **aaa@bbb** and password **ldap!123456**. The user logs in to the switch. (Details not shown.)

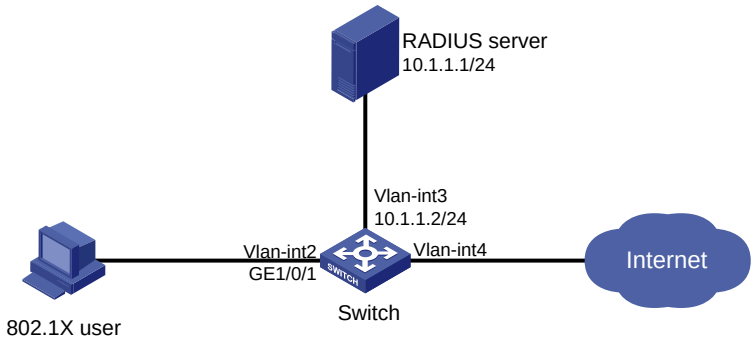
Verify that the user can use the commands permitted by the level-0 user role. (Details not shown.)

Example: Configuring AAA for 802.1X users by a RADIUS server

Network configuration

As shown in Figure 22, configure the switch to meet the following requirements:

- Use the RADIUS server for authentication, authorization, and accounting of 802.1X users.



- Use MAC-based access control on GigabitEthernet 1/0/1 to authenticate all 802.1X users on the port separately.
- Include domain names in the usernames sent to the RADIUS server.

In this example, the RADIUS server runs IMC PLAT 7.1 (E0303), IMC UAM 7.1 (E0304), and IMC CAMS 7.1 (E0301). On the RADIUS server, perform the following tasks:

- Add a service that charges 120 dollars for up to 120 hours per month and assigns authenticated users to VLAN 4.
- Configure a user with name **dot1x@bbb** and assign the service to the user.

Set the shared keys to **expert** for secure RADIUS communication. Set the ports for authentication and accounting to 1812 and 1813, respectively.

Figure 22 Network diagram

Configuring the RADIUS server

1. Add the switch to the IMC Platform as an access device:

   Log in to IMC, click the **User** tab, and select **User Access Policy** > **Access Device Management** > **Access Device** from the navigation tree. Then, click **Add** to configure an access device as follows:

   a. Set the ports for authentication and accounting to 1812 and 1813, respectively.

   b. Select **LAN Access Service** from the **Service Type** list.

   c. Select **H3C(General)** from the **Access Device Type** list.

   d. Set the shared key to **expert** for secure authentication and accounting communication.

   e. Select an access device from the device list or manually add an access device. In this example, the device IP address is 10.1.1.2.

   f. Use the default values for other parameters and click **OK**.

   The IP address of the access device specified here must be the same as the source IP address of the RADIUS packets sent from the switch. The source IP address is chosen in the following order on the switch:

   - IP address specified by using the **`nas-ip`** command.
   - IP address specified by using the **`radius nas-ip`** command.
   - IP address of the outbound interface (the default).

Figure 23 Adding the switch as an access device

2. Add a charging plan:

   Click the **User** tab, and select **Accounting Manager** > **Charging Plans** from the navigation tree to enter the charging plan configuration page. Then, click **Add** to configure a charging plan as follows:

   a. Add a plan named **UserAcct**.

   b. Select **Flat rate** from the **Charging Template** list.

   c. Select **time** for **Charge Based on**, select **Monthly** for **Billing Term**, and enter **120** in the **Fixed Fee** field.

   d. Enter **120** in the **Usage Threshold** field and select **hr** (hours) for the **in** field. The configuration allows the user to access the Internet for up to 120 hours per month.

   e. Click **OK**.

Figure 24 Adding a charging plan

3. Add an access policy:

   Click the **User** tab, and select **User Access Policy** > **Access Policy** from the navigation tree. Then, click **Add** to configure an access policy as follows:

   a. Enter access policy name **Dot1x auth**.

   b. Set the ID of the VLAN to be deployed to **4**.

   c. Configure other parameters as needed.

   d. Click **OK**.

Figure 25 Adding an access policy

4. Add an access service:

   Click the **User** tab, and select **User Access Policy** > **Access Service** from the navigation tree. Then, click **Add** to configure a service as follows:

   a. Add a service named **Dot1x Service,** and set the service suffix to **bbb**, the authentication domain for the 802.1X user. With the service suffix configured, you must configure the access device to send usernames that include domain names to the RADIUS server.

   b. Select **UserAcct** from the **Charging Plan** list.

   c. Select **Dot1x auth** from the **Default Access Policy** list.

   d. Configure other parameters as needed.

   e. Click **OK**.

Figure 26 Adding an access service

5. Add a user:

   Click the **User** tab, and select **All Access Users** from the navigation tree to enter the **All Access Users** page. Then, click **Add** to configure a user as follows:

   a. Select the user or add a user named **test**.

   b. Specify the account name as **dot1x** and configure the password.

   c. Select **Dot1x Service** in the **Access Service** area.

   d. Configure other parameters as needed and click **OK**.

Figure 27 Adding an access user account

Configuring the switch

1. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rad** and enter RADIUS scheme view.

   ```
   <Switch> system-view
   ```

```
[Switch] radius scheme rad
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Switch-radius-rad] primary authentication 10.1.1.1
[Switch-radius-rad] primary accounting 10.1.1.1
[Switch-radius-rad] key authentication simple expert
[Switch-radius-rad] key accounting simple expert
```

Include domain names in the usernames sent to the RADIUS server.

```
[Switch-radius-rad] user-name-format with-domain
[Switch-radius-rad] quit
```

2. Configure an ISP domain:

   # Create an ISP domain named **bbb** and enter ISP domain view.

   ```
   [Switch] domain bbb
   ```

   # Configure the ISP domain to use RADIUS scheme **rad** for authentication, authorization, and accounting of LAN users.

   ```
   [Switch-isp-bbb] authentication lan-access radius-scheme rad
   [Switch-isp-bbb] authorization lan-access radius-scheme rad
   [Switch-isp-bbb] accounting lan-access radius-scheme rad
   [Switch-isp-bbb] quit
   ```

3. Configure 802.1X authentication:

   # Enable 802.1X globally.

   ```
   [Switch] dot1x
   ```

   # Enable 802.1X for GigabitEthernet 1/0/1.

   ```
   [Switch] interface gigabitethernet 1/0/1
   [Switch-GigabitEthernet1/0/1] dot1x
   ```

   # Configure the access control method. By default, an 802.1X-enabled port uses the MAC-based access control.

   ```
   [Switch-GigabitEthernet1/0/1] dot1x port-method macbased
   ```

Verifying the configuration

1. On the host, use account **dot1x@bbb** to pass 802.1X authentication:

   # If the host runs the Windows XP 802.1X client, configure the network connection properties as follows:

   a. Click the **Authentication** tab of the properties window.
   b. Select the **Enable IEEE 802.1X authentication for this network** option.
   c. Select MD5 challenge as the EAP type.
   d. Click **OK**.

   The user passes authentication after entering the correct username and password on the authentication page.

   # If the host runs the iNode client, no advanced authentication options are required. The user can pass authentication after entering username **dot1x@bbb** and the correct password on the client property page.

   IMPORTANT:

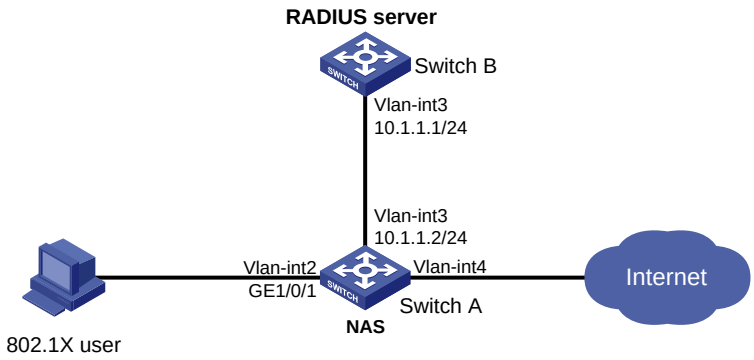
   Make sure the client can update its IP address to access the resources in the authorized VLAN after passing authentication.

2. On the switch, verify that the server assigns the port connecting the client to VLAN 4 after the user passes authentication. (Details not shown.)

3. Display 802.1X connection information on the switch.

```
[Switch] display dot1x connection
```

Example: Configuring authentication and authorization for 802.1X users by the device as a RADIUS server



Network configuration

As shown in Figure 28, Switch B acts as the RADIUS server for authentication and authorization of 802.1X users connected to the NAS (Switch A).

Configure the switches to meet the following requirements:

- Perform 802.1X user authentication on GigabitEthernet 1/0/1 of the NAS.
- The shared key is **expert** and the authentication port is 1812.
- Exclude domain names from the usernames sent to the RADIUS server.
- The user name for 802.1X authentication is **dot1x**.
- After the user passes authentication, the RADIUS server authorizes VLAN 4 to the NAS port that the user is connecting to.

Figure 28 Network diagram

Procedure

1. Configure the NAS:
   a. Configure a RADIUS scheme:

      # Configure a RADIUS scheme named **rad** and enter RADIUS scheme view.

      ```
      <SwitchA> system-view
      [SwitchA] radius scheme rad
      ```

      # Specify the primary authentication server with IP address 10.1.1.1 and set the shared key to **expert** in plaintext form.

      ```
      [SwitchA-radius-rad] primary authentication 10.1.1.1 key simple expert
      ```

      # Exclude domain names from the usernames sent to the RADIUS server.

      ```
      [SwitchA-radius-rad] user-name-format without-domain
      [SwitchA-radius-rad] quit
      ```

   b. Configure an ISP domain:

      # Create an ISP domain named **bbb** and enter ISP domain view.

      ```
      [SwitchA] domain bbb
      ```

      # Configure the ISP domain to use RADIUS scheme **rad** for authentication and authorization of LAN users and not to perform accounting for LAN users.

      ```
      [SwitchA-isp-bbb] authentication lan-access radius-scheme rad
      ```

```
[SwitchA-isp-bbb] authorization lan-access radius-scheme rad
[SwitchA-isp-bbb] accounting lan-access none
[SwitchA-isp-bbb] quit
```

c. Configure 802.1X authentication:

Enable 802.1X for GigabitEthernet 1/0/1.

```
[SwitchA] interface gigabitethernet 1/0/1
[SwitchA-GigabitEthernet1/0/1] dot1x
```

Specify **bbb** as the mandatory authentication domain for 802.1X users on the interface.

```
[SwitchA-GigabitEthernet1/0/1] dot1x mandatory-domain bbb
[SwitchA-GigabitEthernet1/0/1] quit
```

Enable 802.1X globally.

```
[SwitchA] dot1x
```

2. Configure the RADIUS server:

Create a network access user named **dot1x**.

```
<SwitchB> system-view
[SwitchB] local-user dot1x class network
```

Configure the password as **123456** in plaintext form.

```
[SwitchB-luser-network-dot1x] password simple 123456
```

Configure VLAN 4 as the authorization VLAN.

```
[SwitchB-luser-network-dot1x] authorization-attribute vlan 4
[SwitchB-luser-network-dot1x] quit
```

Configure the IP address of the RADIUS client as 10.1.1.2 and the shared key as **expert** in plaintext form.

```
[SwitchB] radius-server client ip 10.1.1.2 key simple expert
```

Activate the RADIUS server configuration.

```
[SwitchB] radius-server activate
```

Verifying the configuration

1. On the RADIUS server, display the activated RADIUS clients and users.

```
[SwitchB] display radius-server active-client
Total 1 RADIUS clients.
Client IP: 10.1.1.2
[SwitchB] display radius-server active-user dot1x
Total 1 RADIUS users matched.
Username: dot1x
  Description: Not configured
  Authorization attributes:
    VLAN ID: 4
    ACL number: Not configured
  Validity period:
    Expiration time: Not configured
```

2. On the host, use account **dot1x** for 802.1X authentication.

If the host runs the Windows built-in 802.1X client, configure the network connection properties as follows:

a. Click the **Authentication** tab of the properties window.

b. Select the **Enable IEEE 802.1X authentication for this network** option.

c. Select MD5 challenge as the EAP type.

d. Click **OK**.

If the host runs the iNode client, no advanced authentication options are required. The user passes authentication after entering the correct user name and password on the authentication page or the iNode client.

IMPORTANT:

Make sure the client can update its IP address to access the resources in the authorized VLAN after passing authentication.

3. On the NAS, verify that the RADIUS server assigns the port to VLAN 4 after the user passes authentication. (Details not shown.)
4. On the NAS, display online 802.1X user information.

```
[SwitchA] display dot1x connection
```

Troubleshooting AAA

RADIUS authentication failure

Symptom

User authentication always fails.

Analysis

Possible reasons include:

- A communication failure exists between the NAS and the RADIUS server.
- The username is not in the *userid@isp-name* format, or the ISP domain is not correctly configured on the NAS.
- The user is not configured on the RADIUS server.
- The password entered by the user is incorrect.
- The RADIUS server and the NAS are configured with different shared keys.

Solution

To resolve the problem:

1. Verify the following items:
   - The NAS and the RADIUS server can ping each other.
   - The username is in the *userid@isp-name* format and the ISP domain is correctly configured on the NAS.
   - The user is configured on the RADIUS server.
   - The correct password is entered.
   - The same shared key is configured on both the RADIUS server and the NAS.
2. If the problem persists, contact H3C Support.

RADIUS packet delivery failure

Symptom

RADIUS packets cannot reach the RADIUS server.

Analysis

Possible reasons include:

- A communication failure exists between the NAS and the RADIUS server.

- The NAS is not configured with the IP address of the RADIUS server.
- The authentication and accounting UDP ports configured on the NAS are incorrect.
- The RADIUS server's authentication and accounting port numbers are being used by other applications.

Solution

To resolve the problem:

1. Verify the following items:
   - The link between the NAS and the RADIUS server works well at both the physical and data link layers.
   - The IP address of the RADIUS server is correctly configured on the NAS.
   - The authentication and accounting UDP port numbers configured on the NAS are the same as those of the RADIUS server.
   - The RADIUS server's authentication and accounting port numbers are available.
2. If the problem persists, contact H3C Support.

RADIUS accounting error

Symptom

A user is authenticated and authorized, but accounting for the user is not normal.

Analysis

The accounting server configuration on the NAS is not correct. Possible reasons include:

- The accounting port number configured on the NAS is incorrect.
- The accounting server IP address configured on the NAS is incorrect. For example, the NAS is configured to use a single server to provide authentication, authorization, and accounting services, but in fact the services are provided by different servers.

Solution

To resolve the problem:

1. Verify the following items:
   - The accounting port number is correctly configured.
   - The accounting server IP address is correctly configured on the NAS.
2. If the problem persists, contact H3C Support.

Troubleshooting HWTACACS

Similar to RADIUS troubleshooting. See "RADIUS authentication failure," "RADIUS packet delivery failure," and "RADIUS accounting error."

LDAP authentication failure

Symptom

User authentication fails.

Analysis

Possible reasons include:

- A communication failure exists between the NAS and the LDAP server.

- The LDAP server IP address or port number configured on the NAS is not correct.
- The username is not in the *userid@isp-name* format, or the ISP domain is not correctly configured on the NAS.
- The user is not configured on the LDAP server.
- The password entered by the user is incorrect.
- The administrator DN or password is not configured.
- Some user attributes (for example, the username attribute) configured on the NAS are not consistent with those configured on the server.
- No user search base DN is specified for the LDAP scheme.

Solution

To resolve the problem:

1. Verify the following items:
   - The NAS and the LDAP server can ping each other.
   - The IP address and port number of the LDAP server configured on the NAS match those of the server.
   - The username is in the correct format and the ISP domain for the user authentication is correctly configured on the NAS.
   - The user is configured on the LDAP server.
   - The correct password is entered.
   - The administrator DN and the administrator password are correctly configured.
   - The user attributes (for example, the username attribute) configured on the NAS are consistent with those configured on the LDAP server.
   - The user search base DN for authentication is specified.
2. If the problem persists, contact H3C Support.

Appendixes

Appendix A Commonly used RADIUS attributes

Commonly used RADIUS attributes are defined in RFC 2865, RFC 2866, RFC 2867, and RFC 2868.

Table 4 Commonly used RADIUS attributes

No.	Attribute	No.	Attribute
1	User-Name	45	Acct-Authentic
2	User-Password	46	Acct-Session-Time
3	CHAP-Password	47	Acct-Input-Packets
4	NAS-IP-Address	48	Acct-Output-Packets
5	NAS-Port	49	Acct-Terminate-Cause
6	Service-Type	50	Acct-Multi-Session-Id
7	Framed-Protocol	51	Acct-Link-Count
8	Framed-IP-Address	52	Acct-Input-Gigawords
9	Framed-IP-Netmask	53	Acct-Output-Gigawords
10	Framed-Routing	54	(unassigned)

No.	Attribute	No.	Attribute
11	Filter-ID	55	Event-Timestamp
12	Framed-MTU	56-59	(unassigned)
13	Framed-Compression	60	CHAP-Challenge
14	Login-IP-Host	61	NAS-Port-Type
15	Login-Service	62	Port-Limit
16	Login-TCP-Port	63	Login-LAT-Port
17	(unassigned)	64	Tunnel-Type
18	Reply-Message	65	Tunnel-Medium-Type
19	Callback-Number	66	Tunnel-Client-Endpoint
20	Callback-ID	67	Tunnel-Server-Endpoint
21	(unassigned)	68	Acct-Tunnel-Connection
22	Framed-Route	69	Tunnel-Password
23	Framed-IPX-Network	70	ARAP-Password
24	State	71	ARAP-Features
25	Class	72	ARAP-Zone-Access
26	Vendor-Specific	73	ARAP-Security
27	Session-Timeout	74	ARAP-Security-Data
28	Idle-Timeout	75	Password-Retry
29	Termination-Action	76	Prompt

44	Acct-Session-Id	91	Tunnel-Server-Auth-id

Appendix B Descriptions for commonly used standard RADIUS attributes

No.	Attribute	Description
1	User-Name	Name of the user to be authenticated.
2	User-Password	User password for PAP authentication, only present in Access-Request packets when PAP authentication is used.
3	CHAP-Password	Digest of the user password for CHAP authentication, only present in Access-Request packets when CHAP authentication is used.
4	NAS-IP-Address	IP address for the server to use to identify the client. Typically, a client is identified by the IP address of its access interface. This attribute is only present in Access-Request packets.
5	NAS-Port	Physical port of the NAS that the user accesses.
6	Service-Type	Type of service that the user has requested or type of service to be provided.
7	Framed-Protocol	Encapsulation protocol for framed access.
8	Framed-IP-Address	IP address assigned to the user.
11	Filter-ID	Name of the filter list. If the name is a string of all digits, it indicates an ACL number. If the name is not a string of all digits and the H3c-ACL-Version attribute is issued next to this attribute, the name is an ACL name. If the name is not a string of all digits and the H3c-ACL-Version attribute is not issued next to this attribute, the name is a user profile name.
12	Framed-MTU	MTU for the data link between the user and NAS. For example, this attribute can be used to define the maximum size of EAP packets allowed to be processed in 802.1X EAP authentication.
14	Login-IP-Host	IP address of the NAS interface that the user accesses.
15	Login-Service	Type of service that the user uses for login.
18	Reply-Message	Text to be displayed to the user, which can be used by the server to communicate information, for example, the cause of the authentication failure.
26	Vendor-Specific	Vendor-specific proprietary attribute. A packet can contain one or more proprietary attributes, each of which can contain one or more subattributes.
27	Session-Timeout	Maximum service duration for the user before termination of the session.
28	Idle-Timeout	Maximum idle time permitted for the user before termination of the session.
31	Calling-Station-Id	User identification that the NAS sends to the server. For the LAN access service provided by an H3C device, this attribute includes the MAC address of the user.
32	NAS-Identifier	Identification that the NAS uses to identify itself to the RADIUS server.
40	Acct-Status-Type	Type of the Accounting-Request packet. Possible values include: • **1**—Start. • **2**—Stop. • **3**—Interim-Update.

No.	Attribute	Description
		• **4**—Reset-Charge. • **7**—Accounting-On. (Defined in the 3rd Generation Partnership Project.) • **8**—Accounting-Off. (Defined in the 3rd Generation Partnership Project.) • **9 to 14**—Reserved for tunnel accounting. • **15**—Reserved for failed.
45	Acct-Authentic	Authentication method used by the user. Possible values include: • **1**—RADIUS. • **2**—Local. • **3**—Remote.
60	CHAP-Challenge	CHAP challenge generated by the NAS for MD5 calculation during CHAP authentication.
61	NAS-Port-Type	Type of the physical port of the NAS that is authenticating the user. Possible values include: • **15**—Ethernet. • **16**—Any type of ADSL. • **17**—Cable. (With cable for cable TV.) • **19**—WLAN-IEEE 802.11. • **201**—VLAN. • **202**—ATM. If the port is an ATM or Ethernet one and VLANs are implemented on it, the value of this attribute is 201.
64	Tunnel-Type	Tunneling protocols used. The value **13** represents VLAN. If the value is 13, the device interprets the Tunnel-Type, Tunnel-Medium-Type, and Tunnel-Private-Group-ID attributes as attributes to assign VLANs.
65	Tunnel-Medium-Type	Transport medium type to use for creating a tunnel. For VLAN assignment, the value must be **6** to indicate the 802 media plus Ethernet.
79	EAP-Message	Used to encapsulate EAP packets to allow RADIUS to support EAP authentication.
80	Message-Authenticator	Used for authentication and verification of authentication packets to prevent spoofing Access-Requests. This attribute is present when EAP authentication is used.
81	Tunnel-Private-Group-ID	Group ID for a tunnel session. To assign VLANs, the NAS conveys VLAN IDs by using this attribute.
87	NAS-Port-Id	String for describing the port of the NAS that is authenticating the user.
168	Framed-IPv6-Address	Server-assigned IPv6 address for the NAS to assign to the host. The address must be unique.

Appendix C RADIUS subattributes (vendor ID 25506)

Table 5 lists all RADIUS subattributes with a vendor ID of 25506. Support for these subattributes depends on the device model.

Table 5 RADIUS subattributes (vendor ID 25506)

No.	Subattribute	Description
1	Input-Peak-Rate	Peak rate in the direction from the user to the NAS, in bps.
2	Input-Average-Rate	Average rate in the direction from the user to the NAS, in bps.
3	Input-Basic-Rate	Basic rate in the direction from the user to the NAS, in bps.
4	Output-Peak-Rate	Peak rate in the direction from the NAS to the user, in bps.
5	Output-Average-Rate	Average rate in the direction from the NAS to the user, in bps.
6	Output-Basic-Rate	Basic rate in the direction from the NAS to the user, in bps.
15	Remanent_Volume	Total amount of data available for the connection, in different units for different server types.
17	ISP-ID	ISP domain where the user obtains authorization information.
20	Command	Operation for the session, used for session control. Possible values include: • **1**—Trigger-Request. • **2**—Terminate-Request. • **3**—SetPolicy. • **4**—Result. • **5**—PortalClear.
25	Result_Code	Result of the Trigger-Request or SetPolicy operation, zero for success and any other value for failure.
26	Connect_ID	Index of the user connection.
27	PortalURL	PADM redirect URL assigned to PPPoE users.
28	Ftp_Directory	FTP, SFTP, or SCP user working directory. When the RADIUS client acts as the FTP, SFTP, or SCP server, this attribute is used to set the working directory for an FTP, SFTP, or SCP user on the RADIUS client.
29	Exec_Privilege	EXEC user priority.
32	NAT-IP-Address	Public IP address assigned to the user when the source IP address and port are translated.
33	NAT-Start-Port	Start port number of the port range assigned to the user when the source IP address and port are translated.
34	NAT-End-Port	End port number of the port range assigned to the user when the source IP address and port are translated.
59	NAS_Startup_Timestamp	Startup time of the NAS in seconds, which is represented by the time elapsed after 00:00:00 on Jan. 1, 1970 (UTC).
60	Ip_Host_Addr	User IP address and MAC address included in authentication and accounting requests, in the format A.B.C.D hh:hh:hh:hh:hh:hh. A space is required between the IP address and the MAC address.
61	User_Notify	Information that must be sent from the server to the client transparently.
62	User_HeartBeat	Hash value assigned after an 802.1X user passes authentication, which is a 32-byte string. This attribute is stored in the user list on the NAS and verifies the handshake packets from the 802.1X user. This attribute only exists in Access-Accept and Accounting-Request packets.
98	Multicast_Receive_Group	IP address of the multicast group that the user's host joins as a

No.	Subattribute	Description
		receiver. This subattribute can appear multiple times in a multicast packet to indicate that the user belongs to multiple multicast groups.
100	IP6_Multicast_Receive_Group	IPv6 address of the multicast group that the user's host joins as a receiver. This subattribute can appear multiple times in a multicast packet to indicate that the user belongs to multiple multicast groups.
101	MLD-Access-Limit	Maximum number of MLD multicast groups that the user can join concurrently.
102	local-name	L2TP local tunnel name.
103	IGMP-Access-Limit	Maximum number of IGMP multicast groups that the user can join concurrently.
105	ANCP-Profile	ANCP profile name.
135	Client-Primary-DNS	IP address of the primary DNS server.
136	Client-Secondary-DNS	IP address of the secondary DNS server.
140	User_Group	User groups assigned after the user passes authentication. Typically, a user can belong to only one user group.
144	Acct_IPv6_Input_Octets	Bytes of IPv6 packets in the inbound direction. The measurement unit depends on the configuration on the device.
145	Acct_IPv6_Output_Octets	Bytes of IPv6 packets in the outbound direction. The measurement unit depends on the configuration on the device.
146	Acct_IPv6_Input_Packets	Number of IPv6 packets in the inbound direction. The measurement unit depends on the configuration on the device.
147	Acct_IPv6_Output_Packets	Number of IPv6 packets in the outbound direction. The measurement unit depends on the configuration on the device.
148	Acct_IPv6_Input_Gigawords	Bytes of IPv6 packets in the inbound direction. The measurement unit is 4G bytes.
149	Acct_IPv6_Output_Gigawords	Bytes of IPv6 packets in the outbound direction. The measurement unit is 4G bytes.
155	User-Roles	List of space-separated user roles.
210	Av-Pair	User-defined attribute pair. Available attribute pairs include: • Server-assigned voice VLAN in the format of device-traffic-class=voice. • Server-assigned user role in the format of shell:role=xxx. • Server-assigned ACL in the format of url-redirect-acl=xxx. • Server-assigned Web redirect URL in the format of url-redirect=xxx. • Server-deployed command to reboot a port, in the format of subscriber:command=bounce-host-port. • Server-assigned port shutdown duration in the format of bounce:seconds=xxx. • Server-deployed command to shut down a port, in the format of subscriber:command=disable-host-port. • Server-assigned blackhole MAC address attribute in the format of mac:block-mac=xxx. • Server-assigned MAC authentication offline detect timer (in seconds) in the format of mac-authentication: offline-detect-time=xxx. Value 0 of xxx indicates that MAC authentication offline detection is disabled.

No.	Subattribute	Description
		• Server-assigned MAC authentication offline detection flag in the format of mac-authentication: offline-detect-check=x. x has the following values: ○ **0**—The device does not search for the ARP snooping entry or ND snooping entry of the MAC address. ○ **1**—The device searches for the ARP snooping entry or ND snooping entry of the MAC address. • Server-assigned dynamic ACL. For more information about the format of this attribute, see "Appendix D Format of dynamic authorization ACLs." Support for this attribute in 802.1X authentication and MAC authentication depends on the device model. If the server assigns a user both this attribute and the Filter-ID attribute, the device will ignore this attribute. The device does not support using CoA messages to change the content assigned by this attribute or assign another ACL to the user.
215	Accounting-Level	ITA traffic level in the range of 1 to 8.
216	Ita-Policy	ITA policy name.
230	NAS-Port-Name	Interface through which the user is connected to the NAS.
246	Auth_Detail_Result	Accounting details. The server sends Access-Accept packets with subattributes 246 and 250 in the following situations: • **1**—The subscriber charge is overdue. The subscriber is allowed to access network resources in the whitelist. If the subscriber accesses other network resources, the device redirects it to the URL specified by subattribute 250. • **2**—The broadband lease of the subscriber expires. The device redirects the subscriber to the URL specified by subattribute 250 when the subscriber requests to access webpages for the first time.
247	Input-Committed-Burst-Size	Committed burst size from the user to the NAS, in bits. The total length cannot exceed 4 bytes for this field. This subattribute must be assigned together with the Input-Average-Rate attribute.
248	Output-Committed-Burst-Size	Committed burst size from the NAS to the user, in bits. The total length cannot exceed 4 bytes for this field. This subattribute must be assigned together with the Output-Average-Rate attribute.
249	authentication-type	Authentication type. The value can be: • **1**—Intranet access authentication. • **2**—Internet access authentication. If the packet does not contain this subattribute, common authentication applies.
250	WEB-URL	Redirect URL for users. In single-stack scenarios, use this attribute to assign the authorized IPv4 URL or IPv6 URL. In dual-stack scenarios, use this attribute to assign the authorized IPv4 URL and use user-defined attribute pair **urlipv6-redirect** to assign the authorized IPv6 URL.
251	Subscriber-ID	Family plan ID.
252	Subscriber-Profile	QoS policy name for the family plan of the subscriber.
255	Product_ID	Product name.

Appendix D Format of dynamic authorization ACLs

The server might assign a dynamic authorization ACL that contains multiple rules to a user in different ways:

- Assign only one Av-Pair subattribute to the user. In this subattribute, the dynamic ACL contains multiple rules separated by question marks (?).
- Assign multiple Av-Pair subattributes to the user. All the subattributes contain the same dynamic ACL and a different rule. Support for this method depends on the server model.

The format of a dynamic ACL rule is as follows:

aclrule?same?*acl-name*?*acl-type*?*ver-type*?*rule-id*?protocol=*protocol-type*?counting?dst-ip=*ip-addr*?src-ip=*ip-addr*?dst-port=*port-value*?src-port=*port-value*?action=*action-type*

The fields in the rule are described in Table 6. The following is an example of a dynamic ACL rule:

aclrule?same?test?1?1?1?protocol=3?counting?dst-ip=1.1.1.1/1.1.1.1?src-ip=1.1.1.1/0?dst-port=1.2000?src-port=5.2000-3000?action=1

Table 6 Fields in a dynamic ACL rule

Field	Description	Remarks
aclrule	Indicates that the following part is information about a dynamic ACL rule.	Required
same	Indicates that the current user will inherit the dynamic ACL rules that have been successfully assigned to another authenticated user. If the server assigns one user the same dynamic ACL as another user but the rules are different for the two users, the device applies the dynamic ACL rules of the user that comes online first to the other user.	Required
acl-name	ACL name, a case-insensitive string of 1 to 63 characters. The ACL name must begin with a letter and it cannot be **all** or the same as an existing static ACL on the device.	Required
acl-type	ACL type. **1** indicates an advanced ACL. In the current software version, only advanced ACLs are supported.	Required
ver-type	IP protocol type: • **1**—IPv4. • **2**—IPv6.	Required
rule-id	ACL rule number, in the range of 0 to 65534.	Required
protocol-type	Protocol type: • **1**—IP. • **2**—ICMP. • **3**—TCP. • **4**—UDP. • **5**—ICMPv6. • **6**—IPv6.	Optional
counting	Indicates that rule match statistics is enabled. If a rule does not include this field, rule match statistics is disabled for the rule.	Optional
ip-addr	IP address information. For example, 1.1.1.1/1.1.1.1, 1.1.1.1/0, or 3::3/128. If the value is **any**, the rule matches any IP address.	Optional
port-value	TCP or UDP port information, in the *X*.*YYY* format. • ***X***—Operator.	Optional

Field	Description	Remarks
	○ **1**—Equal to. ○ **2**—Greater than. ○ **3**—Smaller than. ○ **4**—Not equal to. ○ **5**—In the range of. • ***YYY***—Port number information. For example, 1.3000 and 5.2000-3000.	
action-type	Action type: • **1**—Deny. • **2**—Permit.	Optional

The following restrictions apply to dynamic authorization ACLs:

- For the former six fields (aclrule?same?*acl-name*?*acl-type*?*ver-type*?*rule-id*) of a dynamic ACL rule, their positions are fixed. The device cannot interpret a dynamic ACL rule if the positions of the six fields are changed. For the other fields, position changes are allowed.
- The settings for all the fields in the rules must meet the configuration logic of ACL rules on the device so the device can correctly interpret the rules.
- All dynamic ACL rules in one authorization must belong to the same ACL name.
- A dynamic ACL must have rules and the format of the rules must be valid.

Appendix E HWTACACS attributes

HWTACACS authorization and accounting packets include the HWTACACS attributes assigned by the server to a user and the HWTACACS attributes uploaded by a user to the server. Table 7 shows the HWTACACS attributes supported by the device. The device ignores an HWTACACS attribute if it does not support that attribute.

Table 7 Supported HWTACACS attributes

Attribute name	Description
acl	Number of the ACL assigned to the user.
idletime	Idle timeout period, in seconds.
priv-lvl	User privilege level in the range of level 0 to level 15.
ftp-directory	Initial working directory of the FTP user.
addr	IP address assigned to the user.
addr-pool	IP address pool assigned to the user.
tunnel-type	Type of the tunnel to be established. Only L2TP is supported.
ip-addresses	LNS IP addresses.
tunnel-id	Group ID of the L2TP tunnel.
gw-password	Authentication password of the L2TP tunnel.
roles	User roles assigned to the user.
allowed-roles	Roles for which the user is allowed to obtain temporary authorization.

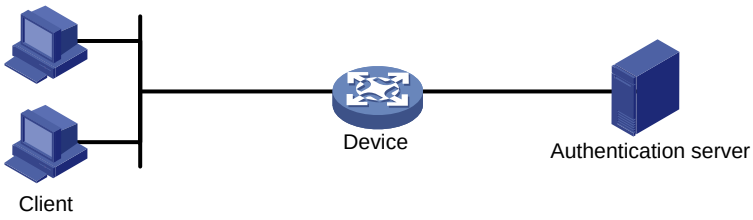
802.1X overview

About the 802.1X protocol



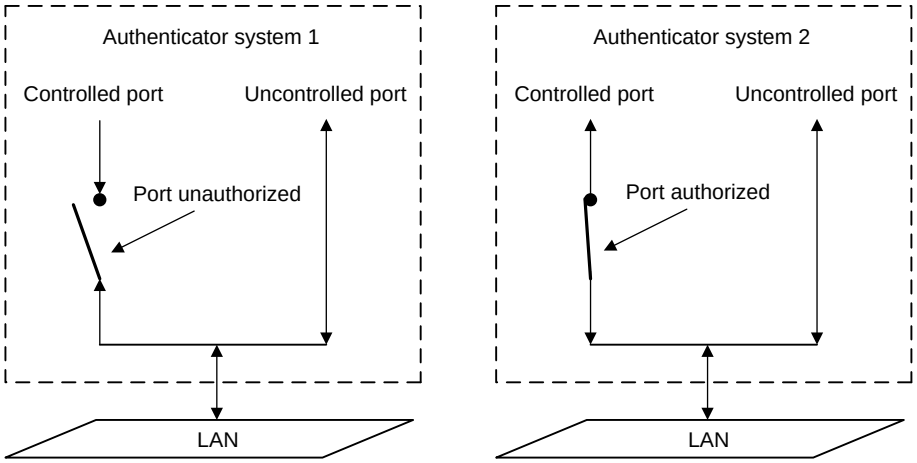
802.1X is a port-based network access control protocol widely used on Ethernet networks. The protocol controls network access by authenticating the devices connected to 802.1X-enabled LAN ports.

802.1X architecture

802.1X operates in the client/server model. As shown in Figure 1, 802.1X authentication includes the following entities:

- **Client (supplicant)**—A user terminal seeking access to the LAN. The terminal must have 802.1X software to authenticate to the access device.
- **Access device (authenticator)**—Authenticates the client to control access to the LAN. In a typical 802.1X environment, the access device uses an authentication server to perform authentication.
- **Authentication server**—Provides authentication services for the access device. The authentication server first authenticates 802.1X clients by using the data sent from the access device. Then, the server returns the authentication results to the access device to make access decisions. The authentication server is typically a RADIUS server. In a small LAN, you can use the access device as the authentication server.

Figure 1 802.1X architecture



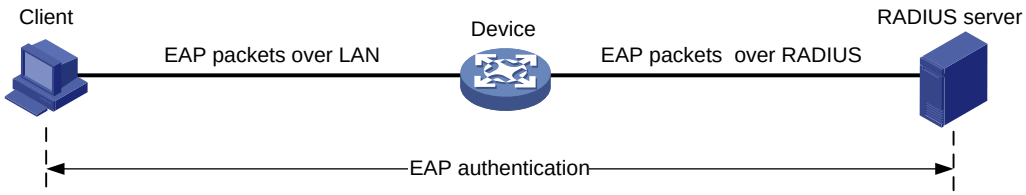
Controlled/uncontrolled port and port authorization status

802.1X defines two logical ports for the network access port: controlled port and uncontrolled port. Any packet arriving at the network access port is visible to both logical ports.

- **Uncontrolled port**—Is always open to receive and transmit authentication packets.
- **Controlled port**—Filters packets depending on the port state.
  - **Authorized state**—The controlled port is in authorized state when the client has passed authentication. The port allows traffic to pass through.
  - **Unauthorized state**—The port is in unauthorized state when the client has failed authentication. The port controls traffic by using one of the following methods:
    - Performs bidirectional traffic control to deny traffic to and from the client.
    - Performs unidirectional traffic control to deny traffic from the client. The device supports only unidirectional traffic control.

Figure 2 Authorization state of a controlled port

Packet exchange methods



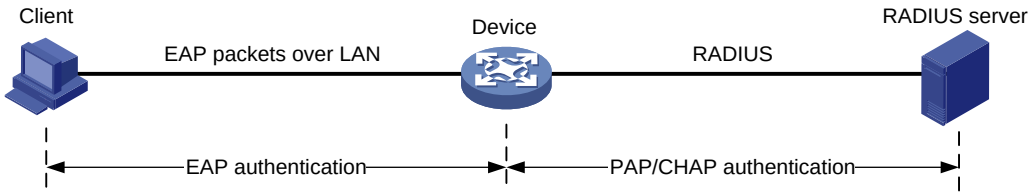
802.1X uses the Extensible Authentication Protocol (EAP) to transport authentication information for the client, the access device, and the authentication server. EAP is an authentication framework that uses the client/server model. The framework supports a variety of authentication methods, including MD5-Challenge, EAP-Transport Layer Security (EAP-TLS), and Protected EAP (PEAP).

802.1X defines EAP over LAN (EAPOL) for passing EAP packets between the client and the access device over a wired or wireless LAN. Between the access device and the authentication server, 802.1X delivers authentication information by either EAP relay or EAP termination.

EAP relay

EAP relay is defined in IEEE 802.1X. In this mode, the network device uses EAP over RADIUS (EAPOR) packets to send authentication information to the RADIUS server, as shown in Figure 3.

Figure 3 EAP relay



In EAP relay mode, the client must use the same authentication method as the RADIUS server. On the access device, you only need to use the **dot1x authentication-method eap** command to enable EAP relay.

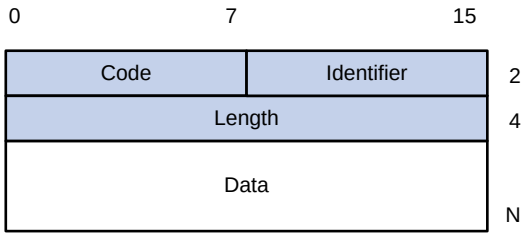
EAP termination

As shown in Figure 4, the access device performs the following operations in EAP termination mode:

1. Terminates the EAP packets received from the client.
2. Encapsulates the client authentication information in standard RADIUS packets.
3. Uses PAP or CHAP to authenticate to the RADIUS server.

Figure 4 EAP termination

Comparing EAP relay and EAP termination



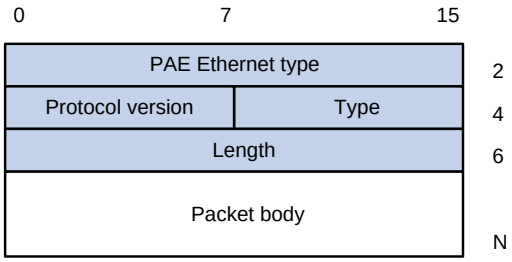
Packet exchange method	Benefits	Limitations
EAP relay	• Supports various EAP authentication methods. • The configuration and processing are simple on the access device.	The RADIUS server must support the EAP-Message and Message-Authenticator attributes, and the EAP authentication method used by the client.
EAP termination	Works with any RADIUS server that supports PAP or CHAP authentication.	• Supports only the following EAP authentication methods: ○ MD5-Challenge EAP authentication. ○ The username and password EAP authentication initiated by an iNode 802.1X client. • The processing is complex on the access device.

Packet formats

EAP packet format

Figure 5 shows the EAP packet format.

Figure 5 EAP packet format



- **Code**—Type of the EAP packet. Options include Request (1), Response (2), Success (3), or Failure (4).
- **Identifier**—Used for matching Responses with Requests.
- **Length**—Length (in bytes) of the EAP packet. The EAP packet length is the sum of the Code, Identifier, Length, and Data fields.
- **Data**—Content of the EAP packet. This field appears only in a Request or Response EAP packet. The **Data** field contains the request type (or the response type) and the type data. Type 1 (Identity) and type 4 (MD5-Challenge) are two examples for the type field.

EAPOL packet format

Figure 6 shows the EAPOL packet format.

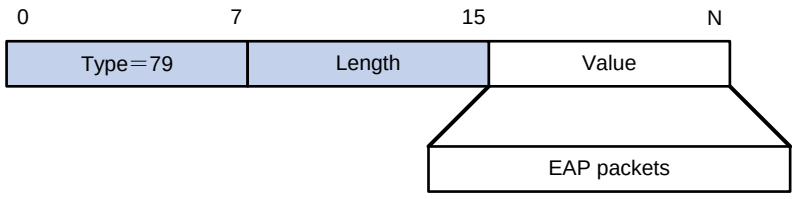
Figure 6 EAPOL packet format

- **PAE Ethernet type**—Protocol type. It takes the value 0x888E for EAPOL.
- **Protocol version**—The EAPOL protocol version used by the EAPOL packet sender.
- **Type**—Type of the EAPOL packet. Table 1 lists the types of EAPOL packets supported by the 802.1X implementation of the device.

  Table 1 Types of EAPOL packets

Value	Type	Description
0x00	EAP-Packet	The client and the access device uses EAP-Packets to transport authentication information.
0x01	EAPOL-Start	The client sends an EAPOL-Start message to initiate 802.1X authentication to the access device.
0x02	EAPOL-Logoff	The client sends an EAPOL-Logoff message to tell the access device that the client is logging off.

- **Length**—Data length in bytes, or length of the Packet body. If packet type is EAPOL-Start or EAPOL-Logoff, this field is set to 0, and no Packet body field follows.
- **Packet body**—Content of the packet. When the EAPOL packet type is EAP-Packet, the Packet body field contains an EAP packet.



EAP over RADIUS

RADIUS adds two attributes, EAP-Message and Message-Authenticator, for supporting EAP authentication. For the RADIUS packet format, see "Configuring AAA."

- EAP-Message.

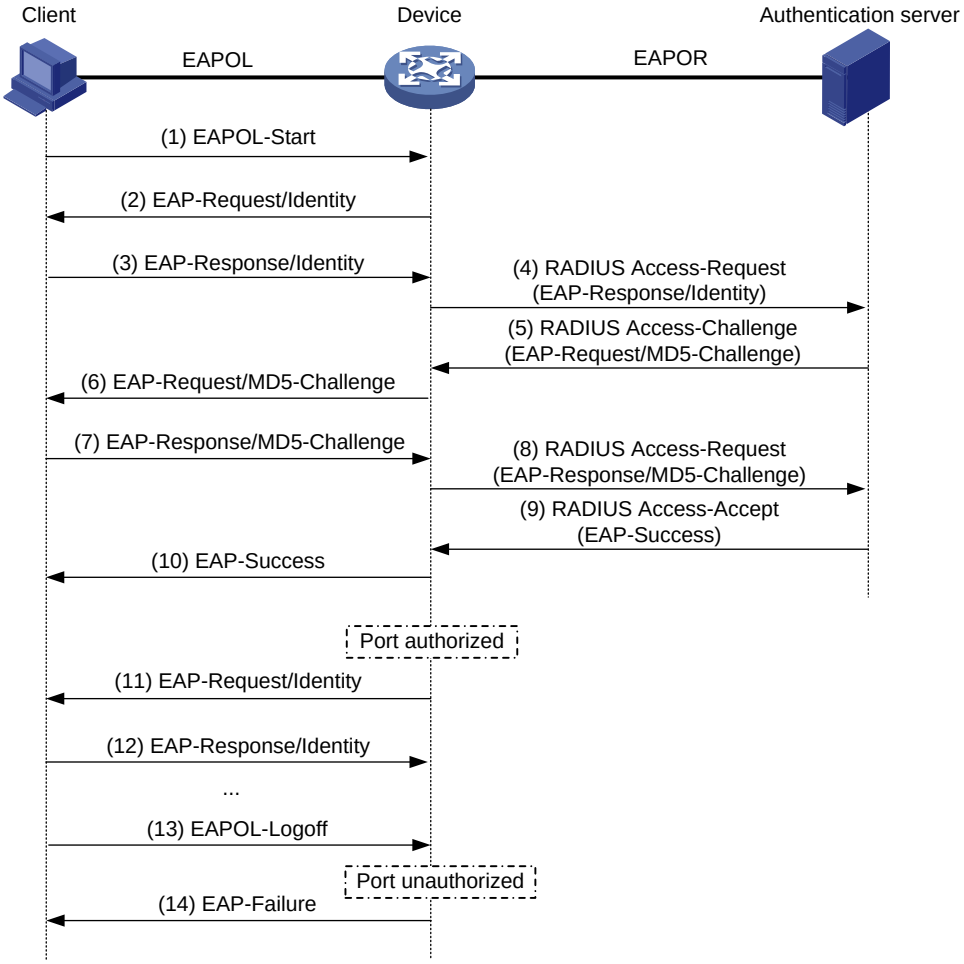
  RADIUS encapsulates EAP packets in the EAP-Message attribute, as shown in Figure 7. The Type field takes 79, and the Value field can be up to 253 bytes. If an EAP packet is longer than 253 bytes, RADIUS encapsulates it in multiple EAP-Message attributes.

  Figure 7 EAP-Message attribute format

- Message-Authenticator.

  As shown in Figure 8, RADIUS includes the Message-Authenticator attribute in all packets that have an EAP-Message attribute to check their integrity. The packet receiver drops the packet if the calculated packet integrity checksum is different from the Message-Authenticator attribute value. The Message-Authenticator prevents EAP authentication packets from being tampered with during EAP authentication.

Figure 8 Message-Authenticator attribute format



802.1X authentication procedures

802.1X authentication has two methods: EAP relay and EAP termination. You choose either mode depending on support of the RADIUS server for EAP packets and EAP authentication methods.

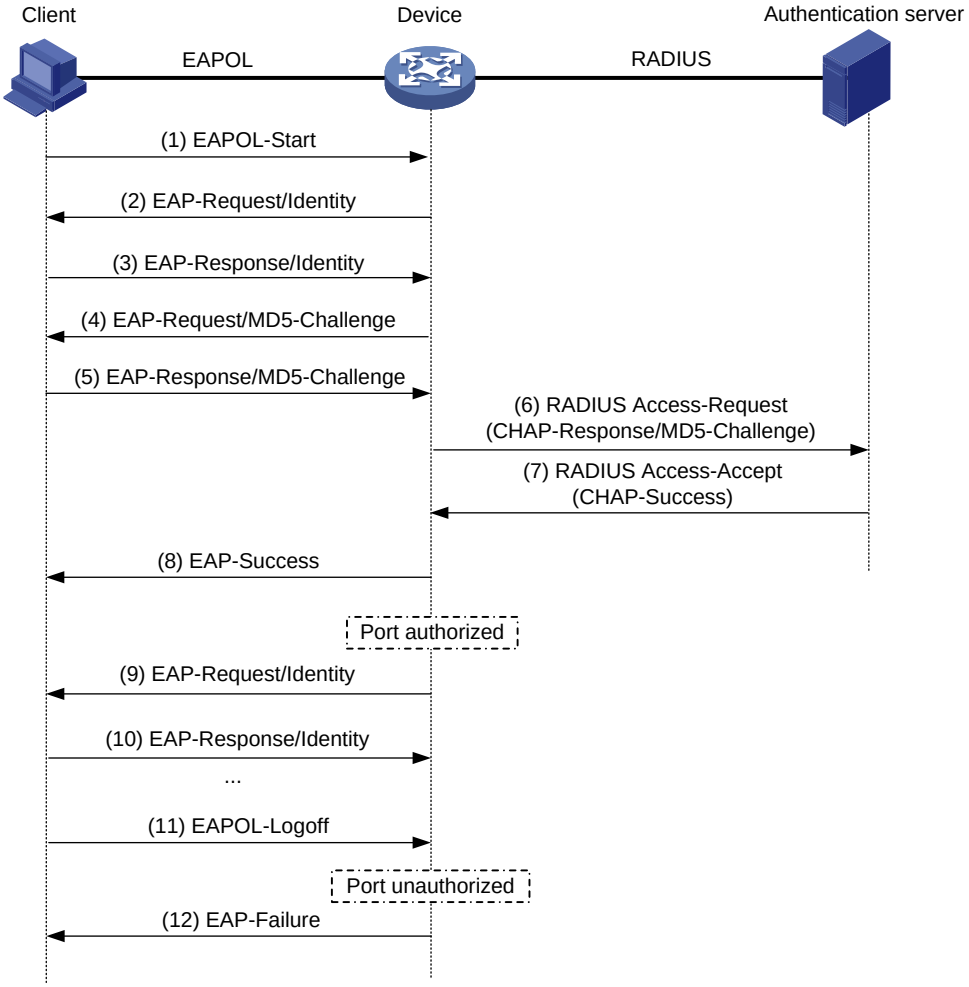
EAP relay

Figure 9 shows the basic 802.1X authentication procedure in EAP relay mode, assuming that MD5-Challenge EAP authentication is used.

Figure 9 802.1X authentication procedure in EAP relay mode

The following steps describe the 802.1X authentication procedure:

1. When a user launches the 802.1X client and enters a registered username and password, the 802.1X client sends an EAPOL-Start packet to the access device.
2. The access device responds with an EAP-Request/Identity packet to ask for the client username.
3. In response to the EAP-Request/Identity packet, the client sends the username in an EAP-Response/Identity packet to the access device.



4. The access device relays the EAP-Response/Identity packet in a RADIUS Access-Request packet to the authentication server.
5. The authentication server uses the identity information in the RADIUS Access-Request to search its user database. If a matching entry is found, the server uses a randomly generated challenge (EAP-Request/MD5-Challenge) to encrypt the password in the entry. Then, the server sends the challenge in a RADIUS Access-Challenge packet to the access device.
6. The access device transmits the EAP-Request/MD5-Challenge packet to the client.
7. The client uses the received challenge to encrypt the password, and sends the encrypted password in an EAP-Response/MD5-Challenge packet to the access device.
8. The access device relays the EAP-Response/MD5-Challenge packet in a RADIUS Access-Request packet to the authentication server.
9. The authentication server compares the received encrypted password with the encrypted password it generated at step 5. If the two passwords are identical, the server considers the client valid and sends a RADIUS Access-Accept packet to the access device.
10. Upon receiving the RADIUS Access-Accept packet, the access device performs the following operations:
    a. Sends an EAP-Success packet to the client.
    b. Sets the controlled port in authorized state.

    The client can access the network.
11. After the client comes online, the access device periodically sends handshake requests to check whether the client is still online. By default, if two consecutive handshake attempts fail, the device logs off the client.
12. Upon receiving a handshake request, the client returns a response. If the client fails to return a response after a number of consecutive handshake attempts (two by default), the access device logs off the client. This handshake mechanism enables timely release of the network resources used by 802.1X users that have abnormally gone offline.
13. The client can also send an EAPOL-Logoff packet to ask the access device for a logoff.
14. In response to the EAPOL-Logoff packet, the access device changes the status of the controlled port from authorized to unauthorized. Then, the access device sends an EAP-Failure packet to the client.

EAP termination

Figure 10 shows the basic 802.1X authentication procedure in EAP termination mode, assuming that CHAP authentication is used.

Figure 10 802.1X authentication procedure in EAP termination mode

In EAP termination mode, the access device rather than the authentication server generates an MD5 challenge for password encryption. The access device then sends the MD5 challenge together with the username and encrypted password in a standard RADIUS packet to the RADIUS server.

802.1X authentication initiation

Both the 802.1X client and the access device can initiate 802.1X authentication.

802.1X client as the initiator

The client sends an EAPOL-Start packet to the access device to initiate 802.1X authentication. The destination MAC address of the packet is the IEEE 802.1X specified multicast address 01-80-C2-00-00-03 or the broadcast MAC address. If any intermediate device between the client and the authentication server does not support the multicast address, you must use an 802.1X client that can send broadcast EAPOL-Start packets. For example, you can use the iNode 802.1X client.

Access device as the initiator

If the client cannot send EAPOL-Start packets, configure the access device to initiate authentication.

The access device supports the following modes:

- **Multicast trigger mode**—The access device multicasts EAP-Request/Identity packets to initiate 802.1X authentication at the identity request interval.

- **Unicast trigger mode**—Upon receiving a frame from an unknown MAC address, the access device sends an EAP-Request/Identity packet out of the receiving port to the MAC address. The device retransmits the packet if no response has been received within the identity request timeout interval. This process continues until the maximum number of request attempts set by using the **`dot1x retry`** command is reached.

The username request timeout timer sets both the identity request interval for the multicast trigger and the identity request timeout interval for the unicast trigger.

Access control methods

The device implements port-based access control as defined in the 802.1X protocol, and extends the protocol to support MAC-based access control.

- **Port-based access control**—Once an 802.1X user passes authentication on a port, any subsequent user can access the network through the port without authentication. When the authenticated user logs off, all other users are logged off.
- **MAC-based access control**—Each user is separately authenticated on a port. When a user logs off, no other online users are affected.

802.1X VLAN manipulation

Authorization VLAN

The authorization VLAN controls the access of an 802.1X user to authorized network resources. The device supports authorization VLANs assigned locally or by a remote server.

IMPORTANT:

Only remote servers can assign tagged authorization VLANs.

Remote VLAN authorization

In remote VLAN authorization, you must configure an authorization VLAN for a user on the remote server. After the user authenticates to the server, the server assigns authorization VLAN information to the device. Then, the device assigns the user access port to the authorization VLAN as a tagged or untagged member.

The device supports assignment of the following authorization VLAN information by the remote server:

- VLAN ID.
- VLAN name, which must be the same as the VLAN description on the access device.
- A string of VLAN IDs and VLAN names.

  In the string, some VLANs are represented by their IDs, and some VLANs are represented by their names.
- VLAN group name.

  For more information about VLAN groups, see *Layer 2—LAN Switching Configuration Guide*.
- VLAN ID with a suffix of **t** or **u**.

  The **t** and **u** suffixes require the device to assign the access port to the VLAN as a tagged or untagged member, respectively. For example, **2u** indicates assigning the port to VLAN 2 as an untagged member.

If a VLAN name or VLAN group name is assigned, the device converts the information into a VLAN ID before VLAN assignment.

IMPORTANT:

For a VLAN represented by its VLAN name to be assigned successfully, you must make sure the VLAN has been created on the device.

To assign VLAN IDs with suffixes, make sure the user access port is a hybrid or trunk port that performs port-based access control.

To ensure a successful assignment, the authorization VLANs assigned by the remote server cannot be any of the following types:

- Dynamically learned VLANs.
- Reserved VLANs.
- Private VLANs.

If the server assigns a group of VLANs, the access device selects a VLAN as described in Table 2.

Table 2 Authorization VLAN selection from a group of VLANs

VLAN information	Authorization VLAN selection
VLANs by IDs VLANs by names VLAN group name	If the 802.1X-enabled port performs MAC-based access control, the device selects an authorization VLAN from the VLAN group for a user according to the following rules: • On a hybrid port with MAC-based VLAN enabled: ○ If the port does not have online users, the device selects the VLAN with the lowest ID. ○ If the port has online users, the device selects the VLAN that has the fewest online users. If two VLANs have the same number of online 802.1X users, the device selects the VLAN with the lower ID. • On an access, trunk, or MAC-based VLAN disabled hybrid port: ○ If the port does not have online users, the device selects the VLAN with the lowest ID. ○ If the port has online users, the device examines the VLAN group for the VLAN of the online users. If the VLAN is found, the VLAN is assigned to the user as the authorization VLAN. If the VLAN is not found, VLAN authorization fails. If the 802.1X-enabled port performs port-based access control, the device selects the VLAN with the lowest ID from the VLAN group. All subsequent 802.1X users are assigned to that VLAN.
VLAN IDs with suffixes	**1.** The device selects the leftmost VLAN ID without a suffix, or the leftmost VLAN ID suffixed by **u** as an untagged VLAN, whichever is more leftmost. **2.** The device assigns the untagged VLAN to the port as the PVID, and it assigns the remaining as tagged VLANs. If no untagged VLAN is assigned, the PVID of the port does not change. The port permits traffic from these tagged and untagged VLANs to pass through. For example, the authentication server sends the string **1u 2t 3** to the access device for a user. The device assigns VLAN 1 as an untagged VLAN and all remaining VLANs (including VLAN 3) as tagged VLANs. VLAN 1 becomes the PVID.

Local VLAN authorization

To perform local VLAN authorization for a user, specify the VLAN ID in the authorization attribute list of the local user account for that user. For each local user, you can specify only one authorization VLAN ID. The user access port is assigned to the VLAN as an untagged member.

IMPORTANT:

Local VLAN authorization does not support assignment of tagged VLANs.

For more information about local user configuration, see "Configuring AAA."

Authorization VLAN manipulation on an 802.1X-enabled port

Table 3 describes how the access device handles VLANs (except for the VLANs specified with suffixes) on an 802.1X-enabled port.

Table 3 VLAN manipulation

Port access control method	VLAN manipulation
Port-based	The device assigns the port to the first authenticated user's authorization VLAN. All subsequent 802.1X users can access the VLAN without authentication. If the authorization VLAN has the untagged attribute, the device assigns the port to the authorization VLAN as an untagged member and sets the VLAN as the PVID. If the authorization VLAN has the tagged attribute, the device assigns the port to the VLAN as a tagged member without changing the PVID. **NOTE:** The tagged attribute is supported only on trunk and hybrid ports.
MAC-based	On a hybrid port with MAC-based VLAN enabled, the device maps the MAC address of each user to its own authorization VLAN. The PVID of the port does not change. On an access, trunk, or MAC-based VLAN disabled hybrid port: • The device assigns the port to the first authenticated user's authorization VLAN and sets the VLAN as the PVID if that authorization VLAN has the untagged attribute. • If the authorization VLAN has the tagged attribute, the device assigns the port to the authorization VLAN without changing its PVID.

IMPORTANT:

- If the users are attached to a port whose link type is access, make sure the authorization VLAN assigned by the server has the untagged attribute. VLAN assignment will fail if the server issues a VLAN that has the tagged attribute.
- When you assign VLANs to users attached to a trunk port or a MAC-based VLAN disabled hybrid port, make sure there is only one untagged VLAN. If a different untagged VLAN is assigned to a subsequent user, the user cannot pass authentication.
- As a best practice to enhance network security, do not use the **`port hybrid vlan`** command to assign a hybrid port to an authorization VLAN as a tagged member.

The VLAN assigned by the server to a user as an authorization VLAN might have been configured on the user access port but with a different tagging mode. For example, the server assigns an authorization VLAN with the tagged attribute, but the same VLAN configured on the port has the untagged attribute. In this situation, the VLAN settings that take effect on the user depend on the link type of the port.

- If the link type of the port is access or trunk, the authorization VLAN settings assigned by the server always take effect on the user as long as the user is online. After the user goes offline, the VLAN settings on the port take effect.
- If the link type of the port is hybrid, the VLAN settings configured on the port take effect. For example, the server assigns VLAN 30 with the untagged attribute to a user on the hybrid port. However, VLAN 30 has been configured on the port with the tagged attribute by using the **`port hybrid vlan tagged`** command. Then, the VLAN has the tagged attribute on the port.

For an 802.1X authenticated user to access the network on a hybrid port when no authorization VLAN is configured for the user, perform one of the following tasks:

- If the port receives tagged authentication packets from the user in a VLAN, use the **port hybrid vlan** command to configure the port as a tagged member in the VLAN.
- If the port receives untagged authentication packets from the user in a VLAN, use the **port hybrid vlan** command to configure the port as an untagged member in the VLAN.

On a port with periodic online user reauthentication enabled, the MAC-based VLAN feature does not take effect on a user that has been online since before this feature was enabled. The access device creates a MAC-to-VLAN mapping for the user when the following requirements are met:

- The user passes reauthentication.
- The authorization VLAN for the user is changed.

For more information about VLAN configuration and MAC-based VLANs, see *Layer 2—LAN Switching Configuration Guide*.

Guest VLAN

The 802.1X guest VLAN on a port accommodates users that have not performed 802.1X authentication. Users in the guest VLAN can access a limited set of network resources, such as a software server, to download antivirus software and system patches. Once a user in the guest VLAN passes 802.1X authentication, it is removed from the guest VLAN and can access authorized network resources.

The access device handles VLANs on an 802.1X-enabled port based on its 802.1X access control method.

Port-based access control

Authentication status	VLAN manipulation
A user accesses the 802.1X-enabled port when the port is in auto state.	The device assigns the port to the 802.1X guest VLAN. All 802.1X users on this port can access only resources in the guest VLAN. The guest VLAN assignment varies by port link mode. For more information, see Table 3 in "Authorization VLAN."
A user in the 802.1X guest VLAN fails 802.1X authentication.	If an 802.1X Auth-Fail VLAN is available, the device assigns the port to the Auth-Fail VLAN. All users on this port can access only resources in the Auth-Fail VLAN. If no Auth-Fail VLAN is configured, the port is still in the 802.1X guest VLAN. All users on the port are in the guest VLAN. For information about the 802.1X Auth-Fail VLAN, see "Auth-Fail VLAN."
A user in the 802.1X guest VLAN passes 802.1X authentication.	The device removes the port from the 802.1X guest VLAN and assigns the port to the authorization VLAN of the user. If the authentication server does not assign an authorization VLAN, the initial PVID of the port applies. The user and all subsequent 802.1X users are assigned to the initial port VLAN. After the user logs off, the port is assigned to the guest VLAN again. **NOTE:** The initial PVID of an 802.1X-enabled port refers to the PVID used by the port before the port is assigned to any 802.1X VLANs.

IMPORTANT:

When the port receives a packet with a VLAN tag, the packet will be forwarded within the tagged VLAN if the VLAN is not the guest VLAN.

MAC-based access control

Authentication status	VLAN manipulation
A user accesses the 802.1X-enabled port and has not performed 802.1X authentication.	The device creates a mapping between the MAC address of the user and the 802.1X guest VLAN. The user can access only resources in the guest VLAN.
A user in the 802.1X guest VLAN fails 802.1X authentication.	If an 802.1X Auth-Fail VLAN is available, the device remaps the MAC address of the user to the Auth-Fail VLAN. The user can access only resources in the Auth-Fail VLAN. If no 802.1X Auth-Fail VLAN is configured, the user is removed from the guest VLAN and added to the initial PVID.
A user in the 802.1X guest VLAN passes 802.1X authentication.	The device remaps the MAC address of the user to the authorization VLAN. If the authentication server does not assign an authorization VLAN, the device remaps the MAC address of the user to the initial PVID on the port.

Auth-Fail VLAN

The 802.1X Auth-Fail VLAN on a port accommodates users that have failed 802.1X authentication because of the failure to comply with the organization's security policy. For example, the VLAN accommodates users that have entered a wrong password. Users in the Auth-Fail VLAN can access a limited set of network resources, such as a software server, to download antivirus software and system patches.

The access device handles VLANs on an 802.1X-enabled port based on its 802.1X access control method.

Port-based access control

Authentication status	VLAN manipulation
A user accesses the port and fails 802.1X authentication.	The device assigns the port to the Auth-Fail VLAN. All 802.1X users on this port can access only resources in the Auth-Fail VLAN. The Auth-Fail VLAN assignment varies by port link mode. For more information, see Table 3 in "Authorization VLAN."
A user in the 802.1X Auth-Fail VLAN fails 802.1X authentication.	The port is still in the Auth-Fail VLAN, and all 802.1X users on this port are in this VLAN.
A user in the 802.1X Auth-Fail VLAN passes 802.1X authentication.	The device assigns the port to the authorization VLAN of the user, and it removes the port from the Auth-Fail VLAN. If the authentication server does not assign an authorization VLAN, the initial PVID of the port applies. The user and all subsequent 802.1X users are assigned to the initial PVID. After the user logs off, the port is assigned to the guest VLAN. If no guest VLAN is configured, the port is assigned to the initial PVID of the port.

MAC-based access control

Authentication status	VLAN manipulation
A user accesses the port and fails 802.1X authentication.	The device maps the MAC address of the user to the 802.1X Auth-Fail VLAN. The user can access only resources in the Auth-Fail VLAN.
A user in the 802.1X Auth-Fail VLAN fails 802.1X authentication.	The user is still in the Auth-Fail VLAN.

Authentication status	VLAN manipulation
A user in the 802.1X Auth-Fail VLAN passes 802.1X authentication.	The device remaps the MAC address of the user to the authorization VLAN. If the authentication server does not assign an authorization VLAN, the device remaps the MAC address of the user to the initial PVID on the port.

Critical VLAN

The 802.1X critical VLAN on a port accommodates 802.1X users that have failed authentication because none of the RADIUS servers in their ISP domain are reachable. Users in the critical VLAN can access a limited set of network resources depending on the configuration.

The critical VLAN feature takes effect when 802.1X authentication is performed only through RADIUS servers. If an 802.1X user fails local authentication after RADIUS authentication, the user is not assigned to the critical VLAN. For more information about the authentication methods, see "Configuring AAA."

The access device handles VLANs on an 802.1X-enabled port based on its 802.1X access control method.

Port-based access control

Authentication status	VLAN manipulation
A user accesses the port and fails 802.1X authentication because all the RADIUS servers are unreachable.	The device assigns the port to the critical VLAN. The 802.1X user and all subsequent 802.1X users on this port can access only resources in the 802.1X critical VLAN. The critical VLAN assignment varies by port link mode. For more information, see Table 3 in "Authorization VLAN."
A user in the 802.1X critical VLAN fails authentication because all the RADIUS servers are unreachable.	The port is still in the critical VLAN.
A user in the 802.1X critical VLAN fails authentication for any reason other than unreachable servers.	If an 802.1X Auth-Fail VLAN has been configured, the port is assigned to the Auth-Fail VLAN. If no 802.1X Auth-Fail VLAN is configured, the port is assigned to the initial PVID of the port.
A user in the 802.1X critical VLAN passes 802.1X authentication.	The device assigns the port to the authorization VLAN of the user, and it removes the port from the 802.1X critical VLAN. If the authentication server does not assign an authorization VLAN, the initial PVID of the port applies. The user and all subsequent 802.1X users are assigned to this port VLAN. After the user logs off, the port is assigned to the guest VLAN. If no 802.1X guest VLAN is configured, the initial PVID of the port is restored.
A user in the 802.1X guest VLAN fails authentication because all the RADIUS servers are unreachable.	The device assigns the port to the 802.1X critical VLAN, and all 802.1X users on this port are in this VLAN.
A user in the 802.1X Auth-Fail VLAN fails authentication because all the RADIUS servers are unreachable.	The port is still in the 802.1X Auth-Fail VLAN. All 802.1X users on this port can access only resources in the 802.1X Auth-Fail VLAN.
A user that has passed authentication fails reauthentication because all the RADIUS servers are unreachable, and the user is logged out of the device.	The device assigns the port to the 802.1X critical VLAN.

If the port is added to the critical VLAN because no RADIUS servers are reachable, the device performs the following operations after it detects a reachable RADIUS server:

1. Removes the port from the critical VLAN.
2. Sends a multicast EAP-Request/Identity message out of the port to trigger authentication.

MAC-based access control

Authentication status	VLAN manipulation
A user accesses the port and fails 802.1X authentication because all the RADIUS servers are unreachable.	The device maps the MAC address of the user to the 802.1X critical VLAN. The user can access only resources in the 802.1X critical VLAN.
A user in the 802.1X critical VLAN fails authentication because all the RADIUS servers are unreachable.	The user is still in the critical VLAN.
A user in the 802.1X critical VLAN fails 802.1X authentication for any reason other than unreachable servers.	If an 802.1X Auth-Fail VLAN has been configured, the device remaps the MAC address of the user to the Auth-Fail VLAN ID. If no 802.1X Auth-Fail VLAN has been configured, the device remaps the MAC address of the user to the initial PVID.
A user in the 802.1X critical VLAN passes 802.1X authentication.	The device remaps the MAC address of the user to the authorization VLAN. If the authentication server does not assign an authorization VLAN to the user, the device remaps the MAC address of the user to the initial PVID on the port.
A user in the 802.1X guest VLAN fails authentication because all the RADIUS servers are unreachable.	The device remaps the MAC address of the user to the 802.1X critical VLAN. The user can access only resources in the 802.1X critical VLAN.
A user in the 802.1X Auth-Fail VLAN fails authentication because all the RADIUS servers are unreachable.	The user remains in the 802.1X Auth-Fail VLAN.

If a user is added to the critical VLAN because no RADIUS servers are reachable, the device performs the following operations after it detects a reachable RADIUS server:

1. Removes the user from the critical VLAN.
2. Sends a unicast EAP-Request/Identity message out of the port to the user for reauthentication.

Critical voice VLAN

The 802.1X critical voice VLAN on a port accommodates 802.1X voice users that have failed authentication because none of the RADIUS servers in their ISP domain are reachable.

The critical voice VLAN feature takes effect when 802.1X authentication is performed only through RADIUS servers. If an 802.1X voice user fails local authentication after RADIUS authentication, the voice user is not assigned to the critical voice VLAN. For more information about the authentication methods, see "Configuring AAA."

When a reachable RADIUS server is detected, the device performs operations on a port based on its 802.1X access control method.

Port-based access control

When a reachable RADIUS server is detected, the device removes the port from the critical voice VLAN. The port sends a multicast EAP-Request/Identity packet to all 802.1X voice users on the port to trigger authentication.

MAC-based access control

When a reachable RADIUS server is detected, the device removes 802.1X voice users from the critical voice VLAN. The port sends a unicast EAP-Request/Identity packet to each 802.1X voice user that was assigned to the critical voice VLAN to trigger authentication.

ACL assignment

You can specify an authorization ACL for an 802.1X user on a remote server or the access device to control the user's access to network resources. After the user passes 802.1X authentication, the server or access device assigns the authorization ACL to the user access port. Then, the port permits or drops the matching traffic for the user depending on the rules in the ACL.

In R1132 and later versions, the device supports assignment of static and dynamic authorization ACLs.

- **Assignment of static authorization ACLs**—Static ACLs can be assigned by a RADIUS server or the access device. When the server or access device assigns a static ACL to a user, it assigns only the ACL number. You must manually create the ACL and configure its rules on the access device.

  To change the access permissions of a user, you can use one of the following methods:

  - Modify ACL rules in the authorization ACL on the access device.
  - Assign another ACL to the user as the authorization ACL from the RADIUS server or the access device.

  Static ACLs and their rules can be manually deleted from the access device.
- **Assignment of dynamic authorization ACLs**—Dynamic ACLs and their rules are automatically deployed by a RADIUS server, which are not configurable on the access device. Dynamic ACLs can only be named ACLs. After the device receives a server-deployed dynamic ACL and its rules, it automatically creates the ACL and configures its rules.

  If the dynamic ACL assigned by the server to a user has the same name as a static ACL, the dynamic ACL cannot be issued and the user cannot come online.

  A dynamic ACL and its rules are automatically deleted from the access device after all its users go offline.

  Dynamic ACLs and their rules cannot be manually modified or deleted on the access device. To display information about dynamic ACLs and their rules, use the **`display dot1x connection`** or **`display acl`** command.

IMPORTANT:

The supported authorization ACLs include the following types:

- Basic ACLs, which are numbered in the range of 2000 to 2999.
- Advanced ACLs, which are numbered in the range of 3000 to 3999.
- Layer 2 ACLs, which are numbered in the range of 4000 to 4999.

For an authorization ACL to take effect, make sure the ACL exists with rules and none of the rules contains the **`counting`**, **`established`**, **`fragment`**, **`source-mac`**, or **`logging`** keyword.

For more information about ACLs, see *ACL and QoS Configuration Guide*.

User profile assignment

You can specify a user profile for an 802.1X user on the authentication server to control the user's access to network resources. After the user passes 802.1X authentication, the authentication server assigns the user profile to the user for filtering traffic.

The authentication server can be the local access device or a RADIUS server. In either case, the server only specifies the user profile name. You must configure the user profile on the access device.

To change the user's access permissions, use one of the following methods:

- Modify the user profile configuration on the access device.
- Specify another user profile for the user on the authentication server.

For more information about user profiles, see "Configuring user profiles."

Periodic 802.1X reauthentication

Periodic 802.1X reauthentication tracks the connection status of online users and updates the authorization attributes (such as ACL and VLAN) assigned by the server.

The device reauthenticates online 802.1X users at the periodic reauthentication interval when the periodic online user reauthentication feature is enabled. The interval is controlled by a timer and the timer is user configurable. A change to the periodic reauthentication timer applies to online users only after the old timer expires and the users pass authentication.

The server-assigned session timeout timer (Session-Timeout attribute) and termination action (Termination-Action attribute) together can affect the periodic online user reauthentication feature. To display the server-assigned Session-Timeout and Termination-Action attributes, use the **`display dot1x connection`** command (see *Security Command Reference*).

- If the termination action is **Default** (logoff), periodic online user reauthentication on the device takes effect only when the periodic reauthentication timer is shorter than the session timeout timer.
- If the termination action is **Radius-request**, the periodic online user reauthentication settings on the device do not take effect. The device reauthenticates the online 802.1X users after the session timeout timer expires.

If no session timeout timer is assigned by the server, whether the device performs periodic 802.1X reauthentication depends on the periodic reauthentication configuration on the device. Support for the assignment of Session-Timeout and Termination-Action attributes depends on the server model.

With the RADIUS DAS feature enabled, the device immediately reauthenticates a user upon receiving a CoA message that carries the reauthentication attribute from a RADIUS authentication server. In this case, reauthentication will be performed regardless of whether 802.1X periodic reauthentication is enabled on the device. For more information about RADIUS DAS configuration, see "Configuring AAA."

By default, the device logs off online 802.1X users if no server is reachable for 802.1X reauthentication. The keep-online feature keeps authenticated 802.1X users online when no server is reachable for 802.1X reauthentication.

The VLANs assigned to an online user before and after reauthentication can be the same or different.

EAD assistant

Endpoint Admission Defense (EAD) is an integrated endpoint access control solution to improve the threat defensive capability of a network. The solution enables the security client, security policy server, access device, and third-party server to operate together. If a terminal device seeks to access an EAD network, it must have an EAD client, which performs 802.1X authentication.

The EAD assistant feature enables the access device to redirect the HTTP or HTTPS requests of a user to a redirect URL for downloading and installing an EAD client. This feature eliminates the administrative task to deploy EAD clients.

EAD assistant is implemented by the following functionality:

- Free IP.

  A free IP is a freely accessible network segment, which has a limited set of network resources such as software and DHCP servers. To ensure security policy compliance, an unauthenticated user can access only this segment to perform operations. For example, the user can download EAD client from a software server or obtain a dynamic IP address from a DHCP server.

- Redirect URL.

  If an unauthenticated 802.1X user is using a Web browser to access the network, EAD assistant redirects the network access requests of the user to a specific URL. For example, you can use this feature to redirect the user to the EAD client software download page.

The EAD assistant feature creates an ACL-based EAD rule automatically to open access to the redirect URL for each redirected user.

EAD rules are implemented by using ACL resources. When the EAD rule timer expires or the user passes authentication, the rule is removed. If users fail to download EAD client or fail to pass authentication before the timer expires, they must reconnect to the network to access the free IP or microsegment.

Configuring 802.1X

Restrictions and guidelines: 802.1X configuration

You can configure the port security feature to perform 802.1X. Port security combines and extends 802.1X and MAC authentication. It applies to a network (a WLAN, for example) that requires different authentication methods for different users on a port. For more information about the port security feature, see "Configuring port security."

When you configure 802.1X settings on an interface, follow these restrictions and guidelines:

- Do not change the link type of a port when the 802.1X guest VLAN, Auth-Fail VLAN, or critical VLAN on the port has users.

As a best practice, do not use Web authentication in conjunction with 802.1X guest VLAN, Auth-Fail VLAN, and critical VLAN settings on a port.

To ensure a successful HTTPS redirect for users in the following situations, make sure VLAN interfaces exist for the VLANs that transport their packets:

- The server has assigned a redirect URL to the users.
- EAD assistant is enabled.

802.1X tasks at a glance

To configure 802.1X authentication, perform the following tasks:

1. Enabling 802.1X
2. Configuring basic 802.1X features
   - Enabling EAP relay or EAP termination
   - Setting the port authorization state
   - Specifying an access control method
   - (Optional.) Specifying a mandatory authentication domain on a port
   - (Optional.) Setting the 802.1X authentication timeout timers
   - (Optional.) Configuring 802.1X reauthentication
   - (Optional.) Setting the quiet timer
3. (Optional.) Configuring 802.1X VLAN assignment
   - Configuring an 802.1X guest VLAN
   - Enabling 802.1X guest VLAN assignment delay
   - Configuring an 802.1X Auth-Fail VLAN
   - Configuring an 802.1X critical VLAN
   - Enabling the 802.1X critical voice VLAN feature
4. (Optional.) Setting the upper limit for 802.1X parameters
   - Setting the maximum number of concurrent 802.1X users on a port
   - Setting the maximum number of authentication request attempts
   - Setting the maximum number of 802.1X authentication attempts for MAC authenticated users
5. (Optional.) Configuring other 802.1X features
   - Sending EAP-Success packets on assignment of users to the 802.1X critical VLAN
   - Enabling 802.1X online user synchronization

- Configuring the authentication trigger feature

  Perform this task when 802.1X clients cannot initiate authentication.
- Discarding duplicate 802.1X EAPOL-Start requests
- Configuring online user handshake
- Configuring 802.1X offline detection
- Specifying supported domain name delimiters
- Removing the VLAN tags of 802.1X protocol packets sent out of a port
- Enabling 802.1X user IP freezing
- Enabling generation of dynamic IPSG binding entries for 802.1X authenticated users
- Configuring 802.1X MAC address binding
- Configuring the EAD assistant feature
- Sending EAP-Success packets to 802.1X clients after successful authorization
- Setting the maximum size of EAP-TLS fragments sent to the server

  Use this feature to reduce the size of authentication packets sent to the server when the device uses EAP-TLS authentication method in EAP relay mode.
- Logging off 802.1X users
- Enabling 802.1X user logging

Prerequisites for 802.1X

Before you configure 802.1X, complete the following tasks:

- Configure an ISP domain and AAA scheme (local or RADIUS authentication) for 802.1X users.
- If RADIUS authentication is used, create user accounts on the RADIUS server.
- If local authentication is used, create local user accounts on the access device and set the service type to **lan-access**.

Enabling 802.1X

Restrictions and guidelines

For 802.1X to take effect on a port, you must enable it both globally and on the port.

If the PVID is a voice VLAN, the 802.1X feature cannot take effect on the port. For more information about voice VLANs, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   `system-view`
2. Enable 802.1X globally.

   `dot1x`

   By default, 802.1X is disabled globally.
3. Enter interface view.

   `interface` *`interface-type interface-number`*
4. Enable 802.1X on a port.

   `dot1x`

   By default, 802.1X is disabled on a port.

Enabling EAP relay or EAP termination

About this task

Consider the following factors to select a proper EAP mode:

- Support of the RADIUS server for EAP packets.
- Authentication methods supported by the 802.1X client and the RADIUS server.

Restrictions and guidelines

- If EAP relay mode is used, the **user-name-format** command configured in RADIUS scheme view does not take effect. The access device sends the authentication data from the client to the server without any modification. For more information about the **user-name-format** command, see *Security Command Reference*.
- You can use both EAP termination and EAP relay in any of the following situations:
  - The client is using only MD5-Challenge EAP authentication. If EAP termination is used, you must enable CHAP authentication on the access device.
  - The client is an iNode 802.1X client and initiates only the username and password EAP authentication. If EAP termination is used, you can enable either PAP or CHAP authentication on the access device. However, for the purpose of security, you must use CHAP authentication on the access device.
- To use EAP-TLS, PEAP, or any other EAP authentication methods, you must use EAP relay. When you make your decision, see "Comparing EAP relay and EAP termination" for help.

Procedure

1. Enter system view.

   system-view
2. Configure EAP relay or EAP termination.

   dot1x authentication-method { **chap** | **eap** | **pap** }

   By default, the access device performs EAP termination and uses CHAP to communicate with the RADIUS server.

Setting the port authorization state

About this task

The port authorization state determines whether the client is granted access to the network. You can control the following authorization states of a port:

- **Authorized**—Places the port in the authorized state, enabling users on the port to access the network without authentication.
- **Unauthorized**—Places the port in the unauthorized state, denying any access requests from users on the port.
- **Auto**—Places the port initially in unauthorized state to allow only EAPOL packets to pass. After a user passes authentication, sets the port in the authorized state to allow access to the network. You can use this option in most scenarios.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*

3. Set the port authorization state.
   dot1x port-control { **authorized-force** | **auto** | **unauthorized-force** }
   By default, the **auto** state applies.

Specifying an access control method

About this task

The device supports port-based and MAC-based access control methods.

Restrictions and guidelines

If online 802.1X users are present on a port, changing its access control method will cause the online users to go offline.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify an access control method.
   dot1x port-method { **macbased** | **portbased** }
   By default, MAC-based access control applies.

Specifying a mandatory authentication domain on a port

About this task

You can place all 802.1X users in a mandatory authentication domain for authentication, authorization, and accounting on a port. No user can use an account in any other domain to access the network through the port. The implementation of a mandatory authentication domain enhances the flexibility of 802.1X access control deployment.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify a mandatory 802.1X authentication domain on the port.
   dot1x mandatory-domain *domain-name*
   By default, no mandatory 802.1X authentication domain is specified.

Setting the 802.1X authentication timeout timers

About this task

The network device uses the following 802.1X authentication timeout timers:

- **Client timeout timer**—Starts when the access device sends an EAP-Request/MD5-Challenge packet to a client. If no response is received when this timer expires, the access device retransmits the request to the client.
- **Server timeout timer**—Starts when the access device sends a RADIUS Access-Request packet to the authentication server. If no response is received when this timer expires, the 802.1X authentication fails.

Restrictions and guidelines

In most cases, the default settings are sufficient. You can edit the timers, depending on the network conditions.

- In a low-speed network, increase the client timeout timer.
- In a network with authentication servers of different performance, adjust the server timeout timer.

To avoid forced logoff before the server timeout timer expires, set the server timeout timer to a value that is lower than or equal to the product of the following values:

- The maximum number of RADIUS packet transmission attempts set by using the **retry** command in RADIUS scheme view.
- The RADIUS server response timeout timer set by using the **timer response-timeout** command in RADIUS scheme view.

For information about setting the maximum number of RADIUS packet transmission attempts and the RADIUS server response timeout timer, see "Configuring AAA."

Procedure

1. Enter system view.

   system-view
2. Set the client timeout timer.

   dot1x timer supp-timeout *supp-timeout-value*

   The default is 30 seconds.
3. Set the server timeout timer.

   dot1x timer server-timeout *server-timeout-value*

   The default is 100 seconds.

Configuring 802.1X reauthentication

Restrictions and guidelines

The device selects a periodic reauthentication timer for 802.1X reauthentication in the following order:

1. Server-assigned reauthentication timer.
2. Port-specific reauthentication timer.
3. Global reauthentication timer.
4. Default reauthentication timer.

After you perform a manual reauthentication, the device reauthenticates all online 802.1X users on a port regardless of the server-assigned reauthentication attribute and the periodic reauthentication feature on the port.

Modification to the mandatory authentication domain or EAP message handling method setting does not affect the reauthentication of online 802.1X users. The modified setting takes effect only on 802.1X users that come online after the modification.

If periodic reauthentication is triggered for a user while that user is waiting for online synchronization, the system performs online synchronization and does not perform reauthentication for the user.

Procedure

1. Enter system view.
   system-view
2. Set the periodic reauthentication timer.
   - Set a global periodic reauthentication timer.
     dot1x timer reauth-period *reauth-period-value*
     The default setting is 3600 seconds.
   - Execute the following commands in sequence to set a port-specific periodic reauthentication timer:
     interface *interface-type interface-number*
     dot1x timer reauth-period *reauth-period-value*
     quit
     By default, no periodic reauthentication timer is set on a port. The port uses the global 802.1X periodic reauthentication timer.
3. Enter interface view.
   interface *interface-type interface-number*
4. Enable periodic online user reauthentication.
   dot1x re-authenticate
   By default, the feature is disabled.
5. (Optional.) Manually reauthenticate all online 802.1X users on the port.
   dot1x re-authenticate manual
6. (Optional.) Enable the keep-online feature for 802.1X users.
   dot1x re-authenticate server-unreachable keep-online
   By default, this feature is disabled. The device logs off online 802.1X users if no authentication server is reachable for 802.1X reauthentication.
   Use the keep-online feature according to the actual network condition. In a fast-recovery network, you can use the keep-online feature to prevent 802.1X users from coming online and going offline frequently.

Setting the quiet timer

About this task

The quiet timer enables the access device to wait a period of time before it can process any authentication request from a client that has failed an 802.1X authentication.

Restrictions and guidelines

You can edit the quiet timer, depending on the network conditions.

- In a vulnerable network, set the quiet timer to a high value.
- In a high-performance network with quick authentication response, set the quiet timer to a low value.

Procedure

1. Enter system view.
   system-view

2. Enable the quiet timer.
   dot1x quiet-period
   By default, the timer is disabled.
3. Set the quiet timer.
   dot1x timer quiet-period *quiet-period-value*
   The default is 60 seconds.

Configuring an 802.1X guest VLAN

Restrictions and guidelines

- You can configure only one 802.1X guest VLAN on a port. The 802.1X guest VLANs on different ports can be different.
- Assign different IDs to the port VLAN, the voice VLAN, and the 802.1X guest VLAN on a port. The assignment makes sure the port can correctly process incoming VLAN-tagged traffic.
- For the 802.1X guest VLAN feature to work correctly, do not configure this feature together with EAD assistant.
- On a hybrid port, the guest VLAN can only be an untagged VLAN.
- If a voice VLAN and an 802.1X guest VLAN are both configured on a hybrid port, the voice VLAN has higher priority than the 802.1X guest VLAN. A packet is forwarded out of the voice VLAN if it matches the voice VLAN settings. If it does not match the voice VLAN settings, its source MAC address might be added to the 802.1X guest VLAN.
- When you configure multiple security features on a port, follow the guidelines in Table 4.

Table 4 Relationships of the 802.1X guest VLAN and other security features

Feature	Relationship description	Reference
802.1X Auth-Fail VLAN on a port that performs MAC-based access control	The 802.1X Auth-Fail VLAN has a higher priority than the 802.1X guest VLAN.	See "802.1X VLAN manipulation."
Port intrusion protection actions on a port that performs MAC-based access control	The 802.1X guest VLAN feature has higher priority than the block MAC action. The 802.1X guest VLAN feature has lower priority than the shutdown port action of the port intrusion protection feature.	See "Configuring port security."

Prerequisites

Before you configure an 802.1X guest VLAN, complete the following tasks:

- Create the VLAN to be specified as the 802.1X guest VLAN.
- If the 802.1X-enabled port performs MAC-based access control, perform the following operations for the port:
  - Configure the port as a hybrid port.
  - Enable MAC-based VLAN on the port. For more information about MAC-based VLANs, see *Layer 2—LAN Switching Configuration Guide*.
- If the port type is hybrid, verify that the VLAN to be specified as the guest VLAN is not in the tagged VLAN list on the port.

Procedure

1. Enter system view.

system-view

2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the 802.1X guest VLAN on the port.
   dot1x guest-vlan *guest-vlan-id*
   By default, no 802.1X guest VLAN exists on a port.

Enabling 802.1X guest VLAN assignment delay

About this task

This feature delays assigning an 802.1X-enabled port to the 802.1X guest VLAN when 802.1X authentication is triggered on the port.

This feature applies only to situations where 802.1X authentication is triggered by EAPOL-Start packets from 802.1X clients or packets from unknown MAC addresses.

To use this feature, the 802.1X-enabled port must perform MAC-based access control. To use the new MAC-triggered 802.1X guest VLAN assignment delay, you must also configure 802.1X unicast trigger on the port.

When 802.1X authentication is triggered on a port, the device performs the following operations:

1. Sends a unicast EAP-Request/Identity packet to the MAC address that triggers the authentication.
2. Retransmits the packet if no response is received within the username request timeout interval set by using the **dot1x timer tx-period** command.
3. Assigns the port to the 802.1X guest VLAN after the maximum number of request attempts set by using the **dot1x retry** command is reached.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable 802.1X guest VLAN assignment delay on the port.
   dot1x guest-vlan-delay { **eapol** | **new-mac** }
   By default, 802.1X guest VLAN assignment delay is disabled on a port.

Configuring an 802.1X Auth-Fail VLAN

Restrictions and guidelines

- Assign different IDs to the port VLAN, the voice VLAN, and the 802.1X Auth-Fail VLAN on a port. The assignment makes sure the port can correctly process VLAN-tagged incoming traffic.
- You can configure only one 802.1X Auth-Fail VLAN on a port. The 802.1X Auth-Fail VLANs on different ports can be different.
- On a hybrid port, the Auth-Fail VLAN can only be an untagged VLAN.
- When you configure multiple security features on a port, follow the guidelines in Table 5.

Table 5 Relationships of the 802.1X Auth-Fail VLAN with other features

Feature	Relationship description	Reference
MAC authentication guest VLAN on a port that performs MAC-based access control	The 802.1X Auth-Fail VLAN has a high priority.	See "Configuring MAC authentication."
Port intrusion protection actions on a port that performs MAC-based access control	The 802.1X Auth-Fail VLAN feature has higher priority than the block MAC action. The 802.1X Auth-Fail VLAN feature has lower priority than the shutdown port action of the port intrusion protection feature.	See "Configuring port security."

Prerequisites

Before you configure an 802.1X Auth-Fail VLAN, complete the following tasks:

- Create the VLAN to be specified as the 802.1X Auth-Fail VLAN.
- If the 802.1X-enabled port performs MAC-based access control, perform the following operations for the port:
  - Configure the port as a hybrid port.
  - Enable MAC-based VLAN on the port. For more information about MAC-based VLANs, see *Layer 2—LAN Switching Configuration Guide*.
- If the port type is hybrid, verify that the VLAN to be specified as the Auth-Fail VLAN is not in the tagged VLAN list on the port.

Procedure

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
3. Configure the 802.1X Auth-Fail VLAN on the port.
   `dot1x auth-fail vlan` *`authfail-vlan-id`*
   By default, no 802.1X Auth-Fail VLAN exists on a port.

Configuring an 802.1X critical VLAN

Restrictions and guidelines

- Assign different IDs to the PVID, the voice VLAN, and the 802.1X critical VLAN on a port. The assignment makes sure the port can correctly process VLAN-tagged incoming traffic.
- You can configure only one 802.1X critical VLAN on a port. The 802.1X critical VLANs on different ports can be different.
- On a hybrid port, the critical VLAN can only be an untagged VLAN.

Prerequisites

Before you configure an 802.1X critical VLAN, complete the following tasks:

- Create the VLAN to be specified as a critical VLAN.
- If the 802.1X-enabled port performs MAC-based access control, perform the following operations for the port:
  - Configure the port as a hybrid port.

    - Enable MAC-based VLAN on the port. For more information about MAC-based VLANs, see *Layer 2—LAN Switching Configuration Guide*.
- If the port type is hybrid, verify that the VLAN to be specified as the critical VLAN is not in the tagged VLAN list on the port.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the 802.1X critical VLAN on the port.
   dot1x critical vlan *critical-vlan-id*
   By default, no 802.1X critical VLAN exists on a port.

Enabling the 802.1X critical voice VLAN feature

Restrictions and guidelines

The feature does not take effect if the voice user has been in the 802.1X Auth-Fail VLAN.

Prerequisites

Before you enable the 802.1X critical voice VLAN feature on a port, complete the following tasks:

- Enable LLDP both globally and on the port.
  The device uses LLDP to identify voice users. For information about LLDP, see *Layer 2—LAN Switching Configuration Guide*.
- Enable voice VLAN on the port.
  For information about voice VLANs, see *Layer 2—LAN Switching Configuration Guide*.
- Specify an 802.1X critical VLAN on the port. This setting ensures that a voice user is assigned to the critical VLAN if it has failed authentication for unreachability of RADIUS servers before the device recognizes it as a voice user. If an 802.1X critical VLAN is not available, the voice user might be logged off instead.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable the 802.1X critical voice VLAN feature on a port.
   dot1x critical-voice-vlan
   By default, the 802.1X critical voice VLAN feature is disabled on a port.

Configuring 802.1X unauthenticated user aging

About this task

802.1X unauthenticated user aging applies to users added to an 802.1X guest, critical, or Auth-Fail VLAN because they have not been authenticated or have failed authentication.

When a user in one of those VLANs ages out, the device removes the user from the VLAN and deletes the MAC address entry for the user from the access port.

For users in one of those VLANs on one port to be authenticated successfully and come online on another port, enable this feature. In any other scenarios, disable this feature as a best practice.

The 802.1X user aging mechanism on a port depends on its access control mode.

- If the port uses port-based access control, a user aging timer starts when the port is assigned to the critical or Auth-Fail VLAN. When the aging timer expires, the port is removed from the VLAN and all MAC address entries for users in the VLAN are also removed.
- If the port uses MAC-based access control, a user aging timer starts for each 802.1X user when they are assigned to the Auth-Fail, critical, or guest VLAN. When the aging timer for a user expires, the device removes that user from the VLAN.

The removed users will be unable to access any network resources until after another authentication is triggered.

Restrictions and guidelines

As a best practice, use this feature on a port only if you want to have its unauthenticated users to be authenticated and come online on a different port.

Procedure

1. Enter system view.

   system-view

2. Set the user aging timer for a type of 802.1X VLAN.

   dot1x timer user-aging { **auth-fail-vlan** | **critical-vlan** | **guest-vlan** } *aging-time-value*

   By default, the user aging timers for all applicable types of 802.1X VLANs are 1000 seconds.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable 802.1X unauthenticated user aging.

   dot1x unauthenticated-user aging enable

   By default, 802.1X unauthenticated user aging is enabled.

Sending EAP-Success packets on assignment of users to the 802.1X Auth-Fail VLAN

About this task

By default, the device sends EAP-Failure packets to 802.1X clients when the client users are assigned to the 802.1X Auth-Fail VLAN on a port. However, some 802.1X clients cannot send DHCP requests for IP addresses after they receive EAP-Failure packets.

To have these clients obtain IP addresses and access resources after they are assigned to the 802.1X Auth-Fail VLAN, perform this task.

This task enables the device to send EAP-Success packets instead of EAP-Failure packets to 802.1X clients when the client users are assigned to the 802.1X Auth-Fail VLAN on the port.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the device to send an EAP-Success packet to a client when the client user is assigned to the 802.1X Auth-Fail VLAN on the port.

dot1x auth-fail eapol

By default, the device sends an EAP-Failure packet to a client when the client user is assigned to the 802.1X Auth-Fail VLAN.

Sending EAP-Success packets on assignment of users to the 802.1X critical VLAN

About this task

By default, the device sends EAP-Failure packets to 802.1X clients when the client users are assigned to the 802.1X critical VLAN. Some 802.1X clients cannot respond to the EAP-Request/Identity packet from the device for reauthentication if they have received an EAP-Failure packet. As a result, reauthentication for these clients will fail after the authentication server becomes reachable.

To avoid this situation, enable the device to send EAP-Success packets instead of EAP-Failure packets to 802.1X clients when the client users are assigned to the 802.1X critical VLAN.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Configure the device to send an EAP-Success packet to an 802.1X client when its client user is assigned to the critical VLAN on the port.

   dot1x critical eapol

   By default, the device sends an EAP-Failure packet to an 802.1X client when its client user is assigned to the critical VLAN.

Enabling 802.1X online user synchronization

About this task

IMPORTANT:

This feature takes effect only when the device uses an IMC RADIUS server to authenticate 802.1X users.

To ensure that the RADIUS server maintains the same online 802.1X user information as the device after the server state changes from unreachable to reachable, use this feature.

This feature synchronizes online 802.1X user information between the device and the RADIUS server when the RADIUS server state is detected having changed from unreachable to reachable.

When synchronizing online 802.1X user information on a port with the RADIUS server, the device initiates 802.1X authentication in turn for each authenticated online 802.1X user to the RADIUS server.

If synchronization fails for an online user, the device logs off that user unless the failure occurs because the server has become unreachable again.

Restrictions and guidelines

The amount of time required to complete online user synchronization increases as the number of online users grows. This might result in an increased delay for new 802.1X users and users in the critical VLAN to authenticate or reauthenticate to the RADIUS server and come online.

To have this feature take effect, you must use it in conjunction with the RADIUS server status detection feature, which is configurable with the **radius-server test-profile** command. When you configure this feature, make sure the detection interval is shorter than the RADIUS server quiet timer configured by using the **timer quiet** command in RADIUS scheme view. The server state changes to active on expiration of the quiet timer regardless of its actual reachability. Setting a shorter detection interval than the quiet timer prevents the RADIUS server status detection feature from falsely reporting the server reachability.

For more information about the RADIUS server status detection feature, see "Configuring AAA."

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable 802.1X online user synchronization.
   dot1x server-recovery online-user-sync
   By default, 802.1X online user synchronization is disabled.

Configuring the authentication trigger feature

About this task

The authentication trigger feature enables the access device to initiate 802.1X authentication when 802.1X clients cannot initiate authentication.

This feature provides the multicast trigger and unicast trigger (see 802.1X authentication initiation in "802.1X overview").

Restrictions and guidelines

- Enable the multicast trigger on a port when the clients attached to the port cannot send EAPOL-Start packets to initiate 802.1X authentication.
- As a best practice to conserve link bandwidth, disable the multicast trigger if a lot of VLANs are configured on the port.
- Enable the unicast trigger on a port if only a few 802.1X clients are attached to the port and these clients cannot initiate authentication.
- To avoid duplicate authentication packets, do not enable both triggers on a port.
- As a best practice, do not use the unicast trigger on a port that performs port-based access control. If you do so, users on the port might fail to come online.

Procedure

1. Enter system view.
   system-view
2. (Optional.) Set the username request timeout timer.
   dot1x timer tx-period *tx-period-value*
   The default is 30 seconds.
3. Enter interface view.
   interface *interface-type interface-number*
4. Enable an authentication trigger.
   dot1x { **multicast-trigger** | **unicast-trigger** }
   By default, the multicast trigger is enabled, and the unicast trigger is disabled.

Setting the maximum number of concurrent 802.1X users on a port

About this task

Perform this task to prevent the system resources from being overused.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the maximum number of concurrent 802.1X users on a port.
   dot1x max-user *max-number*
   The default is 4294967295.

Setting the maximum number of authentication request attempts

About this task

The access device retransmits an authentication request if it does not receive any responses to the request from the client within a period of time. To set the time, use the **dot1x timer tx-period** *tx-period-value* command or the **dot1x timer supp-timeout** *supp-timeout-value* command. The access device stops retransmitting the request if it has made the maximum number of request transmission attempts but still receives no response.

Procedure

1. Enter system view.
   system-view
2. Set the maximum number of attempts for sending an authentication request.
   dot1x retry *retries*
   The default setting is 2.

Discarding duplicate 802.1X EAPOL-Start requests

About this task

During 802.1X authentication, the device might receive duplicate EAPOL-Start requests from an 802.1X user. By default, the device delivers the duplicate EAPOL-Start requests to the authentication server as long as they are legal. However, this mechanism might result in authentication failure if the authentication server cannot respond to duplicate EAPOL-Start requests. To resolve this issue, perform this task on the user access interface to discard duplicate EAPOL-Start requests.

Restrictions and guidelines

As a best practice, perform this task only if the server cannot respond to duplicate EAPOL-Start requests. Do not perform this task in other situations.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Discard duplicate EAPOL-Start requests on the interface.
   dot1x duplicate-eapol-start discard
   By default, the device does not discard duplicate EAPOL-Start requests on an interface if the requests are legal.

Configuring online user handshake

About this task

The online user handshake feature checks the connectivity status of online 802.1X users. The access device sends handshake requests (EAP-Request/Identity) to online users at the interval specified by the **dot1x timer handshake-period** command. If the device does not receive any EAP-Response/Identity packets from an online user after it has made the maximum handshake attempts, the device sets the user to offline state. To set the maximum handshake attempts, use the **dot1x retry** command.

Typically, the device does not reply to 802.1X clients' EAP-Response/Identity packets with EAP-Success packets. Some 802.1X clients will go offline if they do not receive the EAP-Success packets for handshake. To avoid this issue, enable the online user handshake reply feature.

If iNode clients are deployed, you can also enable the online user handshake security feature to check authentication information in the handshake packets from clients. This feature can prevent 802.1X users that use illegal client software from bypassing iNode security check, such as dual network interface cards (NICs) detection. If a user fails the handshake security checking, the device sets the user to the offline state.

Restrictions and guidelines

- If the network has 802.1X clients that cannot exchange handshake packets with the access device, disable the online user handshake feature. This operation prevents the 802.1X connections from being incorrectly torn down.
- To use the online user handshake security feature, make sure the online user handshake feature is enabled.
- The online user handshake security feature takes effect only on the network where the iNode client and IMC server are used.
- Enable the online user handshake reply feature only if 802.1X clients will go offline without receiving EAP-Success packets from the device.
- To ensure online user handshake and new user authentication when a large number of users are present, set the following parameters to a large value:
  - Handshake timer (set by using the **dot1x timer handshake-period** command).
  - Maximum number of attempts to send an authentication request to a client (set by using the **dot1x retry** command).

Procedure

1. Enter system view.

system-view

2. (Optional.) Set the handshake timer.
   dot1x timer handshake-period *handshake-period-value*
   The default is 15 seconds.
3. Enter interface view.
   interface *interface-type interface-number*
4. Enable the online user handshake feature.
   dot1x handshake
   By default, the feature is enabled.
5. (Optional.) Enable the online user handshake security feature.
   dot1x handshake secure
   By default, the feature is disabled.
6. (Optional.) Enable the 802.1X online user handshake reply feature.
   dot1x handshake reply enable
   By default, the device does not reply to 802.1X clients' EAP-Response/Identity packets during the online handshake process.

Configuring 802.1X offline detection

About this task

The 802.1X offline detection feature monitors the online status of 802.1X users. This feature uses an offline detect timer to set the interval that the device must wait for traffic from a user before the device determines that the user is idle. If the device has not received traffic from a user before the timer expires, the device logs off that user and requests the accounting server to stop accounting for the user.

The traffic monitored by this feature includes 802.1X protocol packets sent from 802.1X clients.

Restrictions and guidelines

The 802.1X offline detection feature takes effect only on a port that performs MAC-based access control. If you change the port access mode to port-based, the 802.1X offline detection feature cannot take effect.

For this feature to operate as expected, do not set the offline detect timer to the same value as either of the following timers:

- Handshake timer (set by using the **dot1x timer handshake-period** command).
- Periodic reauthentication timer (set by using the **dot1x timer reauth-period** command).

Procedure

1. Enter system view.
   system-view
2. Set the 802.1X offline detect timer.
   dot1x timer offline-detect *offline-detect-value*
   By default, the 802.1X offline detect timer is 300 seconds.
3. Enter interface view.
   interface *interface-type interface-number*
4. Enable 802.1X offline detection.
   dot1x offline-detect enable

By default, 802.1X offline detection is disabled.

Specifying supported domain name delimiters

About this task

By default, the access device supports the at sign (@) as the delimiter. You can also configure the access device to accommodate 802.1X users that use other domain name delimiters. The configurable delimiters include the at sign (@), backslash (\), dot (.), and forward slash (/). Usernames that include domain names can use the format of *username@domain-name*, *domain-name******username*, *username***.***domain-name*, or *username***/***domain-name*.

If an 802.1X username string contains multiple configured delimiters, the rightmost delimiter is the domain name delimiter. For example, if you configure the backslash (\), dot (.), and forward slash (/) as delimiters, the domain name delimiter for the username string 121.123/22\@abc is the backslash (\). The username is **@abc** and the domain name is **121.123/22**.

Restrictions and guidelines

If a username string contains none of the delimiters, the access device authenticates the user in the mandatory or default ISP domain.

If you configure the access device to send usernames with domain names to the RADIUS server, make sure the domain delimiter can be recognized by the RADIUS server. For username format configuration, see the **user-name-format** command in *Security Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Specify a set of domain name delimiters for 802.1X users.

   dot1x domain-delimiter *string*

   By default, only the at sign (@) delimiter is supported.

Removing the VLAN tags of 802.1X protocol packets sent out of a port

About this task

This feature operates on a hybrid port to have it send 802.1X protocol packets with their VLAN tags removed, regardless of whether the port is a tagged or untagged member of a VLAN.

Use this feature if the 802.1X-enabled hybrid port is a tagged member of its PVID and the attached 802.1X clients cannot recognize VLAN-tagged 802.1X protocol packets.

Restrictions and guidelines

This feature removes the VLAN tags of all 802.1X protocol packets sent out of the port to 802.1X clients. Do not use this feature if VLAN-aware 802.1X clients are attached to the port. As a best practice, perform this task only in the described applicable scenario.

Prerequisites

Set the link type of the 802.1X-enabled port to hybrid. For more information, see VLAN configuration in *Layer 2 LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Remove the VLAN tags of all 802.1X protocol packets sent out of the port to 802.1X clients.

   dot1x eapol untag

   By default, whether the device removes the VLAN tags of all 802.1X protocol packets sent out of a port to 802.1X clients depends on the configuration in the VLAN module.

CAUTION:

This command removes the VLAN tags of all 802.1X protocol packets sent out of the port to 802.1X clients. Do not use this command if VLAN-aware 802.1X clients are attached to the port. As a best practice, use this command only in the described applicable scenario.

Setting the maximum number of 802.1X authentication attempts for MAC authenticated users

About this task

When a port uses both 802.1X authentication and MAC authentication, the device accepts 802.1X authentication requests from MAC authenticated users. If a MAC authenticated user passes 802.1X authentication, the user will come online as an 802.1X user. If the user fails 802.1X authentication, the user continues to make 802.1X authentication attempts depending on client configuration.

Perform this task to limit the number of 802.1X authentication attempts made by a MAC authenticated user.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Set the maximum number of 802.1X authentication attempts for MAC authenticated users on the port.

   dot1x after-mac-auth max-attempt *max-attempts*

   By default, the number of 802.1X authentication attempts for MAC authenticated users is not limited on a port.

Enabling 802.1X user IP freezing

About this task

This feature works with the IP source guard feature. 802.1X-based IP source guard requires that 802.1X clients support sending user IP addresses to the access device. The device uses information such as user MAC addresses and IP addresses obtained through 802.1X to generate IPSG bindings to filter out IPv4 packets from unauthenticated 802.1X users. For information about IP source guard, see "Configuring IP source guard."

This feature prevents any authenticated 802.1X users on a port from changing their IP addresses. After you enable this feature, the port does not update the IP addresses in dynamic IPSG bindings for 802.1X users. If an 802.1X user uses an IP address different from the IP address in its IPSG binding entry, the port denies the user access.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable 802.1X user IP freezing.
   dot1x user-ip freeze
   By default, 802.1X user IP freezing is disabled.

Enabling generation of dynamic IPSG binding entries for 802.1X authenticated users

About this task

IMPORTANT:
This feature must operate in conjunction with the IP source guard (IPSG) feature.

By default, the device generates a dynamic IPv4SG or IPv6SG binding entry for an 802.1X authenticated user after the user obtains a static or DHCP assigned IP address.

To allow only 802.1X users with DHCP assigned IP addresses to access the network, perform the following operations:

- Enable IPSG.
- Disable generation of dynamic IPv4SG or IPv6SG binding entries for 802.1X authenticated users.
- Enable DHCP snooping. The device will generate IPv4SG or IPv6SG binding entries for the users based on DHCP snooping.

For more information about IPSG, see IP source guard in *Security Configuration Guide*.

Restrictions and guidelines

This feature takes effect only on 802.1X users that come online after the feature is enabled. If the IP address of an online 802.1X user changes, the device will update the dynamic IPv4SG or IPv6SG binding entry for the user.

Disabling this feature does not delete the existing dynamic IPv4SG or IPv6SG binding entries for online 802.1X users. If the IP address of an online 802.1X user changes after the feature is disabled, the device will delete the dynamic IPv4SG or IPv6SG binding entry for the user.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable generation of dynamic IPv4SG or IPv6SG binding entries for 802.1X authenticated users.
   dot1x { **ip-verify-source** | **ipv6-verify-source** } **enable**
   By default, generation of dynamic IPv4SG or IPv6SG binding entries for 802.1X authenticated users is enabled.

Configuring 802.1X MAC address binding

About this task

This feature can automatically bind MAC addresses of authenticated 802.1X users to the users' access port and generate 802.1X MAC address binding entries. You can also use the **dot1x mac-binding** *mac-address* command to manually add 802.1X MAC address binding entries.

802.1X MAC address binding entries never age out. They can survive a user logoff or a device reboot. If users in the 802.1X MAC address binding entries perform 802.1X authentication on another port, they cannot pass authentication.

Restrictions and guidelines

The 802.1X MAC address binding feature takes effect only when the port performs MAC-based access control.

To delete an 802.1X MAC address binding entry, use the **undo dot1x mac-binding** *mac-address* command. An 802.1X MAC address binding entry cannot be deleted when the user in the entry is online.

After the number of 802.1X MAC address binding entries reaches the upper limit of concurrent 802.1X users (set by using the **dot1x max-user** command), the following restrictions exist:

- Users not in the binding entries will fail authentication even after users in the binding entries go offline.
- New 802.1X MAC address binding entries are not allowed.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable the 802.1X MAC address binding feature.
   dot1x mac-binding enable
   By default, the feature is disabled.
4. (Optional.) Manually add an 802.1X MAC address binding entry.
   dot1x mac-binding *mac-address*
   By default, no 802.1X MAC address binding entries exist on a port.

Configuring the EAD assistant feature

Restrictions and guidelines

- You must disable MAC authentication globally before you enable the EAD assistant feature.
- If you enable EAD assistant in conjunction with port security, EAD assistant cannot take effect on ports operating in autoLearn port security mode.
- To make the EAD assistant feature take effect on an 802.1X-enabled port, you must set the port authorization mode to **auto**.
- When global MAC authentication is enabled, the free IPs cannot take effect.
- When port security is enabled, the free IPs cannot take effect.

- EAD assistant might cause malfunction of 802.1X Auth-Fail VLANs and critical VLANs. To ensure that users can correctly access Auth-Fail VLANs and critical VLANs, execute the **dot1x ead-assistant permit authentication-escape** command.
- If you use free IP and Auth-Fail VLAN features together, make sure the resources in the Auth-Fail VLAN are on the free IP segments.
- When you use both EAD assistant and MAC authentication on the device, follow these restrictions and guidelines:
  - If both EAD assistant and MAC authentication are configured, the device does not mark the MAC address of a user that has failed MAC authentication as a silent MAC address. If the user has never passed MAC authentication, packets from the user can trigger MAC authentication again only after the user's EAD entry ages out.
  - EAD assistant might cause malfunction of MAC authentication critical VLANs. For the critical VLANs to function correctly for MAC authentication users, execute the **dot1x ead-assistant permit authentication-escape** command.
  - As a best practice, do not configure the Web authentication or IP source guard feature. These features might fail to work correctly when both EAD assistant and MAC authentication are configured on the device.
- The server that provides the redirect URL must be on the free IP accessible to unauthenticated users.

Procedure

1. Enter system view.

   system-view

2. Enable the EAD assistant feature.

   dot1x ead-assistant enable

   By default, this feature is disabled.

3. Configure a free IP.

   dot1x ead-assistant free-ip *ip-address* { *mask-length* | *mask-address* }

   Repeat this command to configure multiple free IPs.

4. (Optional.) Configure the redirect URL if users will use Web browsers to access the network.

   dot1x ead-assistant url *url-string*

   By default, no redirect URL exists.

   By default, the device listens to port 6654 for HTTPS requests to be redirected. To change the redirect listening port number, see configuring HTTP redirect in *Layer 3—IP Services Configuration Guide*.

5. (Optional.) Set the EAD rule timer.

   dot1x timer ead-timeout *ead-timeout-value*

   The default setting is 30 minutes.

   To avoid using up ACL resources when a large number of EAD users exist, you can shorten the EAD rule timer.

6. (Optional.) Enable support for correctly using Auth-Fail VLANs and critical VLANs when 802.1X EAD assistant is enabled.

   dot1x ead-assistant permit authentication-escape

   By default, 802.1X Auth-Fail VLANs and critical VLANs cannot function correctly when 802.1X EAD assistant is enabled.

   This command is supported only in R1122 and later.

Sending EAP-Success packets to 802.1X clients after successful authorization

About this task

By default, the device sends an EAP-Success packet to a client after it receives a RADIUS Access-Accept packet sent by the RADIUS server for the user of that client. After that, the device grants the user access to the network through the user's access port. Upon receiving the EAP-Success packet, the client immediately initiates a DHCP request to obtain an IP address. However, if the device has not yet received authorization information assigned by the RADIUS server, the client directly obtains an IP address from its access network segment. If its access network segment is different from its authorization network segment after the RADIUS server assigns the authorization information, the client will be unable to come online.

To ensure that each 802.1X client obtains an IP address from the authorization network segment, use this feature to configure the device to send EAP-Success packets to 802.1X clients after authorization for the users of the clients succeeds.

Software version and feature compatibility

This feature is supported only in R1122 and later.

Restrictions and guidelines

When this feature is configured, authentication for some users might fail due to untimely authorization if the RADIUS server or device needs to process a large number of authentication processes, resulting in authentication response timeout. As a best practice, use this feature based on the service processing capabilities of the device and the RADIUS server in the actual application scenario.

Procedure

1. Enter system view.

   `system-view`

2. Configure the device to send EAP-Success packets to 802.1X clients after authorization for the users of the clients succeeds.

   `dot1x eap-success post-authorization`

   By default, the device sends EAP-Success packets to 802.1X clients immediately after authentication for the users of the clients succeeds.

Setting the maximum size of EAP-TLS fragments sent to the server

About this task

When the device uses EAP-TLS authentication method in EAP relay mode, the RADIUS packets might exceed the maximum packet size supported by the RADIUS server. This situation typically occurs when long EAP-TLS messages are encapsulated in the EAP-Message attribute of the RADIUS packet sent to the RADIUS server.

To avoid authentication failures caused by oversized packets, fragment the EAP-TLS messages depending on the maximum RADIUS packet size supported by the remote RADIUS server.

For example, the maximum packet length allowed by the server is 1200 bytes and the length of a RADIUS packet (excluding the EAP-Message attribute) is 800 bytes. To make sure the maximum length of a RADIUS packet does not exceed 1200 bytes, you must set the maximum length of an EAP-TLS fragment to a value less than 400 bytes.

Restrictions and guidelines

802.1X EAP-TLS fragmentation takes effect only when EAP relay mode is used. For more information about enabling EAP relay, see "Enabling EAP relay or EAP termination."

Procedure

1. Enter system view.

   system-view

2. Enable 802.1X EAP-TLS fragmentation and set the maximum EAP-TLS fragment size.

   dot1x eap-tls-fragment to-server *eap-tls-max-length*

   By default, EAP-TLS messages are not fragmented.

Logging off 802.1X users

About this task

Perform this task to log off specified 802.1X users and clear information about these users from the device. These users must perform 802.1X authentication to come online again.

Procedure

To log off 802.1X users, execute the following command in user view:

reset dot1x access-user [**interface** *interface-type interface-number* | **mac** *mac-address* | **username** *username* | **vlan** *vlan-id*]

Enabling 802.1X user logging

About this task

This feature enables the device to generate logs about 802.1X users and send the logs to the information center. For the logs to be output correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

To prevent excessive 802.1X user log entries, use this feature only if you need to analyze abnormal 802.1X user logins or logouts.

Procedure

1. Enter system view.

   system-view

2. Enable 802.1X user logging.

   dot1x access-user log enable [**abnormal-logoff** | **failed-login** | **normal-logoff** | **successful-login**] *

   By default, 802.1X user logging is disabled.

   If you do not specify any parameters, this command enables all types of 802.1X user logs.

Display and maintenance commands for 802.1X

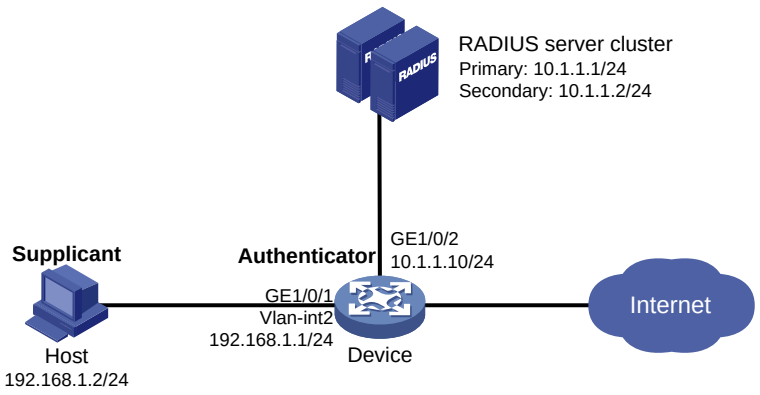
Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display 802.1X session information, statistics, or configuration information of specified or all ports.	**display dot1x** [**sessions** | **statistics**] [**interface** *interface-type interface-number*]
Display online 802.1X user information.	**display dot1x connection** [**open**] [**interface** *interface-type interface-number* | **slot** *slot-number* | **user-mac** *mac-address* | **user-name** *name-string*]
Display the MAC addresses of 802.1X users in a type of 802.1X VLAN.	**display dot1x mac-address** { **auth-fail-vlan** | **critical-vlan** | **guest-vlan** } [**interface** *interface-type interface-number*]
Remove users from the 802.1X guest VLAN on a port.	**reset dot1x guest-vlan interface** *interface-type interface-number* [**mac-address** *mac-address*]
Clear 802.1X statistics.	**reset dot1x statistics** [**interface** *interface-type interface-number*]

802.1X authentication configuration examples

Example: Configuring basic 802.1X authentication

Network configuration



As shown in Figure 11, the access device performs 802.1X authentication for users that connect to GigabitEthernet 1/0/1. Implement MAC-based access control on the port, so the logoff of one user does not affect other online 802.1X users.

Use RADIUS servers to perform authentication, authorization, and accounting for the 802.1X users. If RADIUS authentication fails, perform local authentication on the access device.

Configure the RADIUS server at 10.1.1.1/24 as the primary authentication and accounting server, and the RADIUS server at 10.1.1.2/24 as the secondary authentication and accounting server. Assign all users to ISP domain **bbb**.

Set the shared key to **name** for packets between the access device and the authentication server. Set the shared key to **money** for packets between the access device and the accounting server.

Figure 11 Network diagram

Procedure

For information about the RADIUS commands used on the access device in this example, see *Security Command Reference*.

1. Configure the RADIUS servers and add user accounts for the 802.1X users. Make sure the RADIUS servers can provide authentication, authorization, and accounting services. (Details not shown.)
2. Assign an IP address to each interface. (Details not shown.)
3. Configure user accounts for the 802.1X users on the access device:

   # Add a local network access user with username **localuser** and password **123456TESTplat&!** in plaintext. (Make sure the username and password are the same as those configured on the RADIUS servers.)

   ```
   <Device> system-view
   [Device] local-user localuser class network
   [Device-luser-network-localuser] password simple 123456TESTplat&!
   ```

   # Set the service type to **lan-access**.

   ```
   [Device-luser-network-localuser] service-type lan-access
   [Device-luser-network-localuser] quit
   ```

4. Configure a RADIUS scheme on the access device:

   # Create a RADIUS scheme named **radius1** and enter RADIUS scheme view.

   ```
   [Device] radius scheme radius1
   ```

   # Specify the IP addresses of the primary authentication and accounting RADIUS servers.

   ```
   [Device-radius-radius1] primary authentication 10.1.1.1
   [Device-radius-radius1] primary accounting 10.1.1.1
   ```

   # Configure the IP addresses of the secondary authentication and accounting RADIUS servers.

   ```
   [Device-radius-radius1] secondary authentication 10.1.1.2
   [Device-radius-radius1] secondary accounting 10.1.1.2
   ```

   # Specify the shared key between the access device and the authentication server.

   ```
   [Device-radius-radius1] key authentication simple name
   ```

   # Specify the shared key between the access device and the accounting server.

   ```
   [Device-radius-radius1] key accounting simple money
   ```

   # Exclude the ISP domain names from the usernames sent to the RADIUS servers.

   ```
   [Device-radius-radius1] user-name-format without-domain
   [Device-radius-radius1] quit
   ```

   NOTE:

   The access device must use the same username format as the RADIUS server. If the RADIUS server includes the ISP domain name in the username, so must the access device.

5. Configure an ISP domain on the access device:

   # Create an ISP domain named **bbb** and enter ISP domain view.

   ```
   [Device] domain bbb
   ```

   # Apply RADIUS scheme **radius1** to the ISP domain, and specify local authentication as the secondary authentication method.

   ```
   [Device-isp-bbb] authentication lan-access radius-scheme radius1 local
   [Device-isp-bbb] authorization lan-access radius-scheme radius1 local
   [Device-isp-bbb] accounting lan-access radius-scheme radius1 local
   [Device-isp-bbb] quit
   ```

6. Configure 802.1X on the access device:

Enable 802.1X on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] dot1x
```

Enable MAC-based access control on the port. By default, the port uses MAC-based access control.

```
[Device-GigabitEthernet1/0/1] dot1x port-method macbased
```

Specify ISP domain **bbb** as the mandatory domain.

```
[Device-GigabitEthernet1/0/1] dot1x mandatory-domain bbb
[Device-GigabitEthernet1/0/1] quit
```

Enable 802.1X globally.

```
[Device] dot1x
```

7. Configure the 802.1X client. If an iNode client is used, do not select the **Carry version info** option in the client configuration. (Details not shown.)

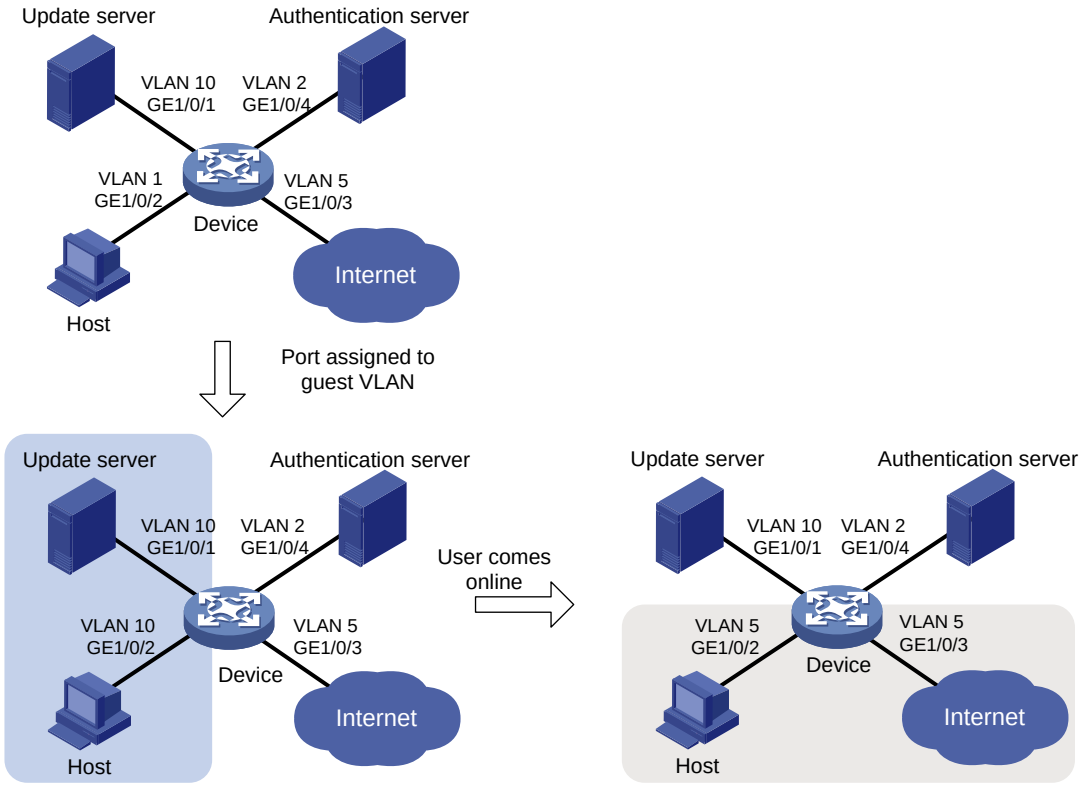
Verifying the configuration

Verify the 802.1X configuration on GigabitEthernet 1/0/1.

```
[Device] display dot1x interface gigabitethernet 1/0/1
```

Display the user connection information after an 802.1X user passes authentication.

```
[Device] display dot1x connection
```



Example: Configuring 802.1X guest VLAN and authorization VLAN

Network configuration

As shown in Figure 12:

- Use RADIUS servers to perform authentication, authorization, and accounting for 802.1X users that connect to GigabitEthernet 1/0/2. Implement port-based access control on the port.
- Configure VLAN 10 as the 802.1X guest VLAN on GigabitEthernet 1/0/2. The host and the update server are both in VLAN 10, and the host can access the update server and download the 802.1X client software.
- Configure a QoS policy to deny packets destined for the Internet (5.1.1.1) and apply the QoS policy to the outbound direction of VLAN 10. The configuration prevents users in the 802.1X guest VLAN from accessing the Internet before they pass 802.1X authentication.
- After the host passes 802.1X authentication, the access device assigns the host to VLAN 5 where GigabitEthernet 1/0/3 is. The host can access the Internet.

Figure 12 Network diagram

Procedure

For information about the RADIUS commands used on the access device in this example, see *Security Command Reference*.

1. Configure the RADIUS server to provide authentication, authorization, and accounting services. Configure user accounts and authorization VLAN (VLAN 5 in this example) for the users. (Details not shown.)
2. Create VLANs, and assign ports to the VLANs on the access device.

NOTE:

By default, VLAN 1 exists and all ports belong to the VLAN. You do not need to create the VLAN or assign GigabitEthernet 1/0/2 to the VLAN.

```
<Device> system-view
[Device] vlan 10
[Device-vlan10] port gigabitethernet 1/0/1
[Device-vlan10] quit
[Device] vlan 2
[Device-vlan2] port gigabitethernet 1/0/4
[Device-vlan2] quit
[Device] vlan 5
[Device-vlan5] port gigabitethernet 1/0/3
[Device-vlan5] quit
```

3. Configure a QoS policy:

   # Configure advanced ACL 3000 to match packets destined for 5.1.1.1.

```
[Device] acl advanced 3000
```

```
[Device-acl-ipv4-adv-3000] rule permit ip destination 5.1.1.1 0.0.0.255
[Device-acl-ipv4-adv-3000] quit
```

Specify advanced ACL 3000 in traffic class **classifier_1** to match traffic.

```
[Device] traffic classifier classifier_1
[Device-classifier-classifier_1] if-match acl 3000
[Device-classifier-classifier_1] quit
```

Configure traffic behavior **behavior_1** to deny matching packets.

```
[Device] traffic behavior behavior_1
[Device-behavior-behavior_1] filter deny
[Device-behavior-behavior_1] quit
```

Configure QoS policy **policy_1** to associate traffic class **classifier_1** with traffic behavior **behavior_1**.

```
[Device] qos policy policy_1
[Device-qospolicy-policy_1] classifier classifier_1 behavior behavior_1
[Device-qospolicy-policy_1] quit
```

Apply QoS policy **policy_1** to the outbound direction of VLAN 10.

```
[Device] qos vlan-policy policy_1 vlan 10 outbound
```

4. Configure a RADIUS scheme on the access device:

Create RADIUS scheme **2000** and enter RADIUS scheme view.

```
[Device] radius scheme 2000
```

Specify the server at 10.11.1.1 as the primary authentication server, and set the authentication port to 1812.

```
[Device-radius-2000] primary authentication 10.11.1.1 1812
```

Specify the server at 10.11.1.1 as the primary accounting server, and set the accounting port to 1813.

```
[Device-radius-2000] primary accounting 10.11.1.1 1813
```

Set the shared key to **abc** in plain text for secure communication between the authentication server and the device.

```
[Device-radius-2000] key authentication simple abc
```

Set the shared key to **abc** in plain text for secure communication between the accounting server and the device.

```
[Device-radius-2000] key accounting simple abc
```

Exclude the ISP domain names from the usernames sent to the RADIUS server.

```
[Device-radius-2000] user-name-format without-domain
[Device-radius-2000] quit
```

5. Configure an ISP domain on the access device:

Create ISP domain **bbb** and enter ISP domain view.

```
[Device] domain bbb
```

Apply RADIUS scheme 2000 to the ISP domain for authentication, authorization, and accounting.

```
[Device-isp-bbb] authentication lan-access radius-scheme 2000
[Device-isp-bbb] authorization lan-access radius-scheme 2000
[Device-isp-bbb] accounting lan-access radius-scheme 2000
[Device-isp-bbb] quit
```

6. Configure 802.1X on the access device:

Enable 802.1X on GigabitEthernet 1/0/2.

```
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] dot1x
```

Implement port-based access control on the port.

```
[Device-GigabitEthernet1/0/2] dot1x port-method portbased
```

Set the port authorization mode to **auto**. By default, the port uses the auto mode.

```
[Device-GigabitEthernet1/0/2] dot1x port-control auto
```

Specify VLAN 10 as the 802.1X guest VLAN on GigabitEthernet 1/0/2.

```
[Device-GigabitEthernet1/0/2] dot1x guest-vlan 10
[Device-GigabitEthernet1/0/2] quit
```

Enable 802.1X globally.

```
[Device] dot1x
```

7. Configure the 802.1X client. Make sure the 802.1X client can update its IP address after the access port is assigned to the guest VLAN or an authorization VLAN. (Details not shown.)

Verifying the configuration

Verify the 802.1X guest VLAN configuration on GigabitEthernet 1/0/2.

```
[Device] display dot1x interface gigabitethernet 1/0/2
```

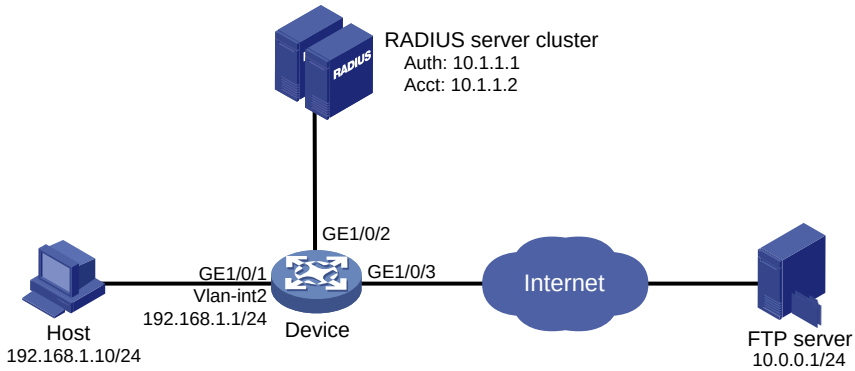
Verify that GigabitEthernet 1/0/2 is assigned to VLAN 10 before any user passes authentication on the port.

```
[Device] display vlan 10
```

After a user passes authentication, display information on GigabitEthernet 1/0/2. Verify that GigabitEthernet 1/0/2 is assigned to VLAN 5.

```
[Device] display interface gigabitethernet 1/0/2
```

Example: Configuring 802.1X with ACL assignment



Network configuration

As shown in Figure 13, the host that connects to GigabitEthernet 1/0/1 must pass 802.1X authentication to access the Internet.

Perform 802.1X authentication on GigabitEthernet 1/0/1. Use the RADIUS server at 10.1.1.1 as the authentication and authorization server, and the RADIUS server at 10.1.1.2 as the accounting server.

Configure ACL assignment on GigabitEthernet 1/0/1 to deny access of 802.1X users to the FTP server from 8:00 to 18:00 on weekdays.

Figure 13 Network diagram

Procedure

For information about the RADIUS commands used on the access device in this example, see *Security Command Reference*.

1. Configure the RADIUS servers to provide authentication, authorization, and accounting services. Add user accounts and specify the ACL (ACL 3000 in this example) for the users. (Details not shown.)
2. Assign an IP address to each interface, as shown in Figure 13. (Details not shown.)
3. Configure a RADIUS scheme on the access device:

   # Create RADIUS scheme **2000** and enter RADIUS scheme view.

   ```
   <Device> system-view
   [Device] radius scheme 2000
   ```

   # Specify the server at 10.1.1.1 as the primary authentication server, and set the authentication port to 1812.

   ```
   [Device-radius-2000] primary authentication 10.1.1.1 1812
   ```

   # Specify the server at 10.1.1.2 as the primary accounting server, and set the accounting port to 1813.

   ```
   [Device-radius-2000] primary accounting 10.1.1.2 1813
   ```

   # Set the shared key to **abc** in plain text for secure communication between the authentication server and the device.

   ```
   [Device-radius-2000] key authentication simple abc
   ```

   # Set the shared key to **abc** in plain text for secure communication between the accounting server and the device.

   ```
   [Device-radius-2000] key accounting simple abc
   ```

   # Exclude the ISP domain names from the usernames sent to the RADIUS server.

   ```
   [Device-radius-2000] user-name-format without-domain
   [Device-radius-2000] quit
   ```

4. Configure an ISP domain on the access device:

   # Create ISP domain **bbb** and enter ISP domain view.

   ```
   [Device] domain bbb
   ```

   # Apply RADIUS scheme 2000 to the ISP domain for authentication, authorization, and accounting.

   ```
   [Device-isp-bbb] authentication lan-access radius-scheme 2000
   [Device-isp-bbb] authorization lan-access radius-scheme 2000
   [Device-isp-bbb] accounting lan-access radius-scheme 2000
   [Device-isp-bbb] quit
   ```

5. Configure a time range named **ftp** from 8:00 to 18:00 on weekdays on the access device.

   ```
   [Device] time-range ftp 8:00 to 18:00 working-day
   ```

6. Configure ACL 3000 to deny packets destined for the FTP server at 10.0.0.1 during the specified time range on the access device.

   ```
   [Device] acl advanced 3000
   [Device-acl-ipv4-adv-3000] rule 0 deny ip destination 10.0.0.1 0 time-range ftp
   [Device-acl-ipv4-adv-3000] quit
   ```

7. Configure 802.1X on the access device:

   # Enable 802.1X on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] dot1x
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Enable 802.1X globally.

   ```
   [Device] dot1x
   ```

8. Configure the 802.1X client. Make sure the client is able to update its IP address after the access port is assigned to the 802.1X guest VLAN or an authorization VLAN. (Details not shown.)

Verifying the configuration

Use the user account to pass authentication. (Details not shown.)

Verify that the user cannot ping the FTP server at any time from 8:00 to 18:00 on any weekday.

```
C:\>ping 10.0.0.1

Pinging 10.0.0.1 with 32 bytes of data:

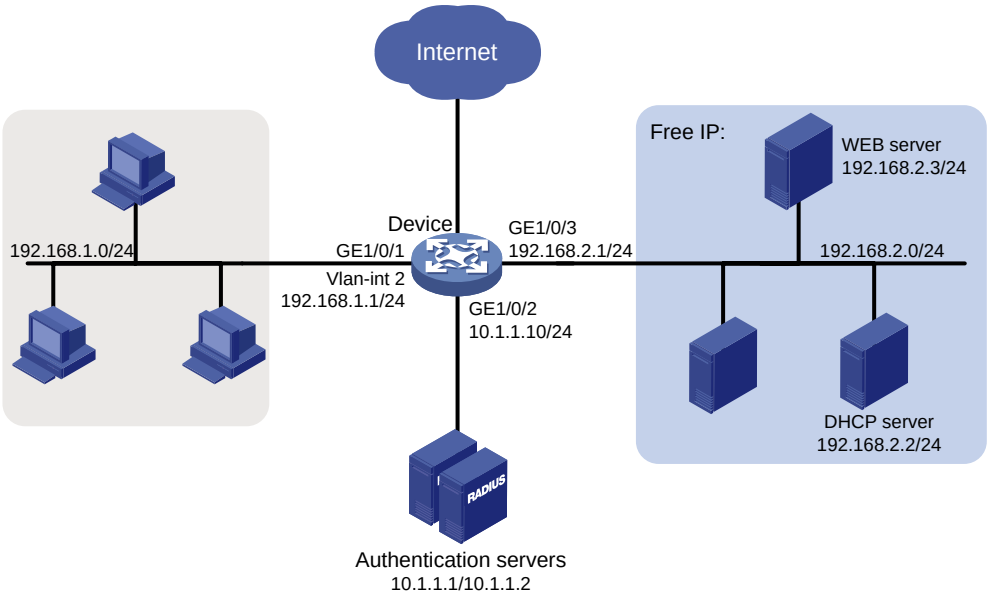
Request timed out.
Request timed out.
Request timed out.
Request timed out.

Ping statistics for 10.0.0.1:
    Packets: Sent = 4, Received = 0, Lost = 4 (100% loss),
```

The output shows that ACL 3000 is active on the user, and the user cannot access the FTP server.

Example: Configuring 802.1X with EAD assistant (with DHCP relay agent)

Network configuration



As shown in Figure 14:

- The intranet 192.168.1.0/24 is attached to GigabitEthernet 1/0/1 of the access device.
- The hosts use DHCP to obtain IP addresses.
- A DHCP server and a Web server are deployed on the 192.168.2.0/24 subnet for users to obtain IP addresses and download client software.

Deploy an EAD solution for the intranet to meet the following requirements:

- Allow unauthenticated users and users that have failed 802.1X authentication to access 192.168.2.0/24. The users can obtain IP addresses and download software.
- If these users use a Web browser to access a network other than 192.168.2.0/24, redirect them to the Web server for 802.1X client downloading.
- Allow authenticated 802.1X users to access the network.

Figure 14 Network diagram

Procedure

1. Make sure the DHCP server, the Web server, and the authentication servers have been configured correctly. (Details not shown.)
2. Configure an IP address for each interface. (Details not shown.)
3. Configure DHCP relay:

   # Enable DHCP.

   ```
   <Device> system-view
   [Device] dhcp enable
   ```

   # Enable the DHCP relay agent on VLAN-interface 2.

   ```
   [Device] interface vlan-interface 2
   [Device-Vlan-interface2] dhcp select relay
   ```

   # Specify the DHCP server 192.168.2.2 on the relay agent interface VLAN-interface 2.

   ```
   [Device-Vlan-interface2] dhcp relay server-address 192.168.2.2
   [Device-Vlan-interface2] quit
   ```

4. Configure a RADIUS scheme:

   # Create RADIUS scheme **2000** and enter RADIUS scheme view.

   ```
   [Device] radius scheme 2000
   ```

   # Specify the server at 10.1.1.1 as the primary authentication server, and set the authentication port to 1812.

   ```
   [Device-radius-2000] primary authentication 10.1.1.1 1812
   ```

   # Specify the server at 10.1.1.2 as the primary accounting server, and set the accounting port to 1813.

   ```
   [Device-radius-2000] primary accounting 10.1.1.2 1813
   ```

   # Set the shared key to **abc** in plain text for secure communication between the authentication server and the device.

   ```
   [Device-radius-2000] key authentication simple abc
   ```

   # Set the shared key to **abc** in plain text for secure communication between the accounting server and the device.

   ```
   [Device-radius-2000] key accounting simple abc
   ```

Exclude the ISP domain names from the usernames sent to the RADIUS server.

```
[Device-radius-2000] user-name-format without-domain
[Device-radius-2000] quit
```

5. Configure an ISP domain:

   # Create ISP domain **bbb** and enter ISP domain view.

   ```
   [Device] domain bbb
   ```

   # Apply RADIUS scheme 2000 to the ISP domain for authentication, authorization, and accounting.

   ```
   [Device-isp-bbb] authentication lan-access radius-scheme 2000
   [Device-isp-bbb] authorization lan-access radius-scheme 2000
   [Device-isp-bbb] accounting lan-access radius-scheme 2000
   [Device-isp-bbb] quit
   ```

6. Configure 802.1X:

   # Configure the free IP.

   ```
   [Device] dot1x ead-assistant free-ip 192.168.2.0 24
   ```

   # Configure the redirect URL for client software download.

   ```
   [Device] dot1x ead-assistant url https://192.168.2.3
   ```

   # Enable the EAD assistant feature.

   ```
   [Device] dot1x ead-assistant enable
   ```

   # Enable 802.1X on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] dot1x
   [Device-GigabitEthernet1/0/1] quit
   ```

   # Enable 802.1X globally.

   ```
   [Device] dot1x
   ```

Verifying the configuration

Verify the 802.1X configuration.

```
[Device] display dot1x
```

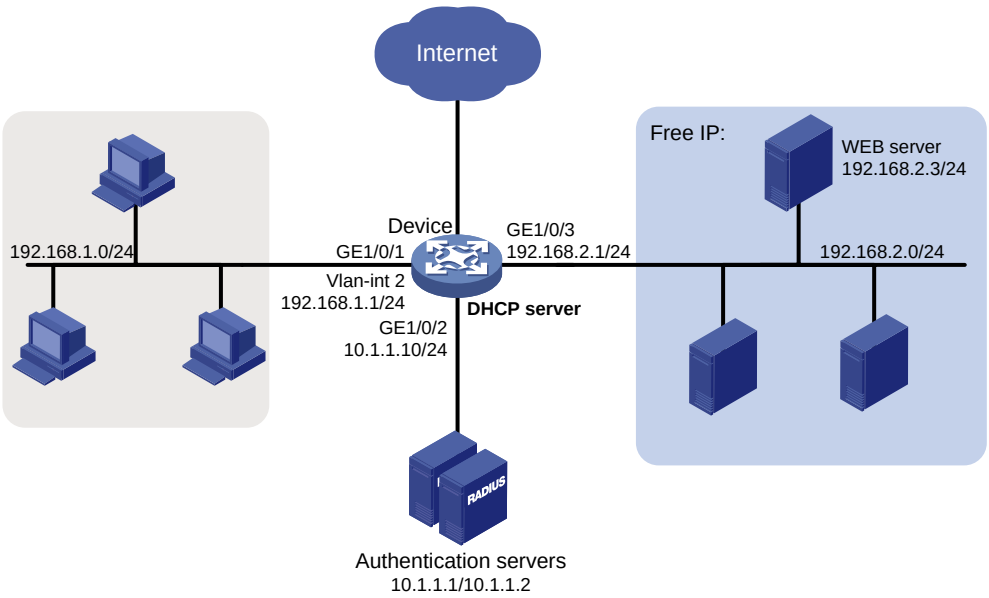
Verify that you can ping an IP address on the free IP subnet from a host. (Details not shown.)

Verify that you are redirected to the Web server when you enter in your Web browser an IP address not on the free IP. (Details not shown.)

Example: Configuring 802.1X with EAD assistant (with DHCP server)

Network configuration

As shown in Figure 15:



- The intranet 192.168.1.0/24 is attached to GigabitEthernet 1/0/1 of the access device.
- The hosts use DHCP to obtain IP addresses.
- A Web server is deployed on the 192.168.2.0/24 subnet for users to download client software.

Deploy an EAD solution for the intranet to meet the following requirements:

- Allow unauthenticated users and users that have failed 802.1X authentication to access 192.168.2.0/24. The users can download software.
- If these users use a Web browser to access a network other than 192.168.2.0/24, redirect them to the Web server for 802.1X client downloading.

- Allow authenticated 802.1X users to access the network.

Figure 15 Network diagram

Procedure

1. Make sure the Web server and the authentication servers have been configured correctly. (Details not shown.)
2. Configure an IP address for each interface. (Details not shown.)
3. Configure the DHCP server:

   # Enable DHCP.

   ```
   <Device> system-view
   [Device] dhcp enable
   ```

   # Enable the DHCP server on VLAN-interface 2.

   ```
   [Device] interface vlan-interface 2
   [Device-Vlan-interface2] dhcp select server
   [Device-Vlan-interface2] quit
   ```

   # Create DHCP address pool **0**.

   ```
   [Device] dhcp server ip-pool 0
   ```

   # Specify subnet 192.168.1.0/24 in DHCP address pool 0.

   ```
   [Device-dhcp-pool-0] network 192.168.1.0 mask 255.255.255.0
   ```

   # Specify the gateway address 192.168.1.1 in DHCP address pool 0.

   ```
   [Device-dhcp-pool-0] gateway-list 192.168.1.1
   [Device-dhcp-pool-0] quit
   ```

4. Configure a RADIUS scheme:

   # Create RADIUS scheme **2000** and enter RADIUS scheme view.

   ```
   [Device] radius scheme 2000
   ```

   # Specify the server at 10.1.1.1 as the primary authentication server, and set the authentication port to 1812.

   ```
   [Device-radius-2000] primary authentication 10.1.1.1 1812
   ```

   # Specify the server at 10.1.1.2 as the primary accounting server, and set the accounting port to 1813.

   ```
   [Device-radius-2000] primary accounting 10.1.1.2 1813
   ```

Set the shared key to **abc** in plain text for secure communication between the authentication server and the device.

```
[Device-radius-2000] key authentication simple abc
```

Set the shared key to **abc** in plain text for secure communication between the accounting server and the device.

```
[Device-radius-2000] key accounting simple abc
```

Exclude the ISP domain names from the usernames sent to the RADIUS server.

```
[Device-radius-2000] user-name-format without-domain
[Device-radius-2000] quit
```

5. Configure an ISP domain:

Create ISP domain **bbb** and enter ISP domain view.

```
[Device] domain bbb
```

Apply RADIUS scheme 2000 to the ISP domain for authentication, authorization, and accounting.

```
[Device-isp-bbb] authentication lan-access radius-scheme 2000
[Device-isp-bbb] authorization lan-access radius-scheme 2000
[Device-isp-bbb] accounting lan-access radius-scheme 2000
[Device-isp-bbb] quit
```

6. Configure 802.1X:

Configure the free IP.

```
[Device] dot1x ead-assistant free-ip 192.168.2.0 24
```

Configure the redirect URL for client software download.

```
[Device] dot1x ead-assistant url https://192.168.2.3
```

Enable the EAD assistant feature.

```
[Device] dot1x ead-assistant enable
```

Enable 802.1X on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] dot1x
[Device-GigabitEthernet1/0/1] quit
```

Enable 802.1X globally.

```
[Device] dot1x
```

Verifying the configuration

Verify the 802.1X configuration.

```
[Device] display dot1x
```

Verify that you can ping an IP address on the free IP subnet from a host. (Details not shown.)

Verify that you are redirected to the Web server when you enter in your Web browser an IP address not on the free IP. (Details not shown.)

Troubleshooting 802.1X

EAD assistant URL redirection failure

Symptom

Unauthenticated users are not redirected to the specified redirect URL after they enter external website addresses in their Web browsers.

Analysis

Redirection will not happen for one of the following reasons:

- The address is in the string format. The operating system of the host regards the string as a website name and tries to resolve the string. If the resolution fails, the operating system sends an ARP request, but the target address is not in the dotted decimal notation. The redirection feature does redirect this kind of ARP request.
- The address is within a free IP segment. No redirection will take place, even if no host is present with the address.
- The redirect URL is not in a free IP segment.
- No server is using the redirect URL, or the server with the URL does not provide Web services.

Solution

To resolve the issue:

1. Enter a dotted decimal IP address that is not in any free IP segments.
2. Verify that the access device and the server are configured correctly.
3. If the issue persists, contact H3C Support.

Configuring MAC authentication

About MAC authentication

MAC authentication controls network access by authenticating source MAC addresses on a port. The feature does not require client software, and users do not have to enter a username and password for network access. The device initiates a MAC authentication process when it detects an unknown source MAC address on a MAC authentication-enabled port. If the MAC address passes authentication, the user can access authorized network resources. If the authentication fails, the device marks the MAC address as a silent MAC address, drops the packet, and starts a quiet timer. The device drops all subsequent packets from the MAC address within the quiet time. The quiet mechanism avoids repeated authentication during a short time.

User account policies

MAC authentication supports the following user account policies:

- **Global user account policy**, which can be either of the following options:
  - **MAC-based user account policy**—One MAC-based user account for each user. As shown in Figure 1, the access device uses the source MAC addresses in packets as the usernames and passwords of users for MAC authentication. This policy is suitable for an insecure environment.

    NOTE:

    MAC-based user account policy also supports configuring a password shared by all MAC-based user accounts.

  - **Shared user account policy**—One shared user account for all users. You specify one username and password (which are not necessarily a MAC address) for all MAC authentication users on the access device, as shown in Figure 2. This policy is suitable for a secure environment.
- **MAC range-specific user account policy**—One shared user account for users in a specific MAC address range. You specify one username and password (which are not necessarily a MAC address) for users in a specific MAC address range on the access device, as shown in Figure 3. For example, you can specify a username and password for users with a specific OUI for MAC authentication.

IMPORTANT:

- You can use global and MAC range-specific user account policies together. For users in a MAC address range, the MAC range-specific user account settings have higher priority than the global user account settings.
- If a RADIUS server is used for MAC authentication, you must create the user accounts on the RADIUS server based on the user account policy on the access device.

Figure 1 MAC-based user account policy

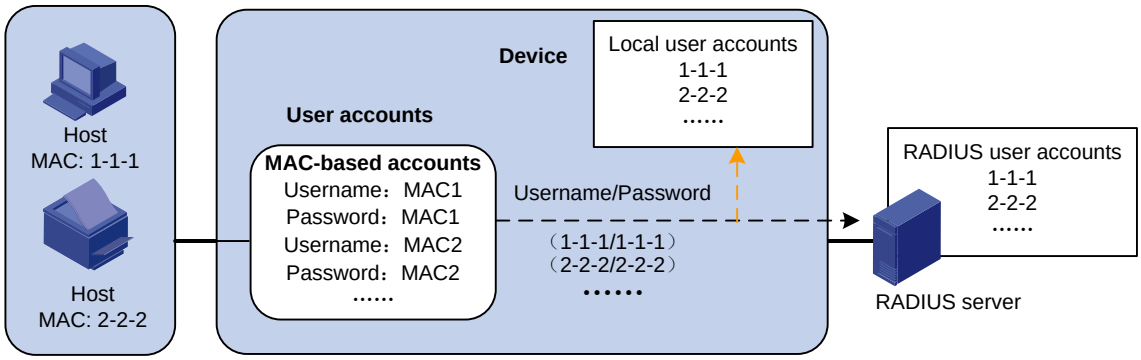

Figure 2 Shared user account policy (global)

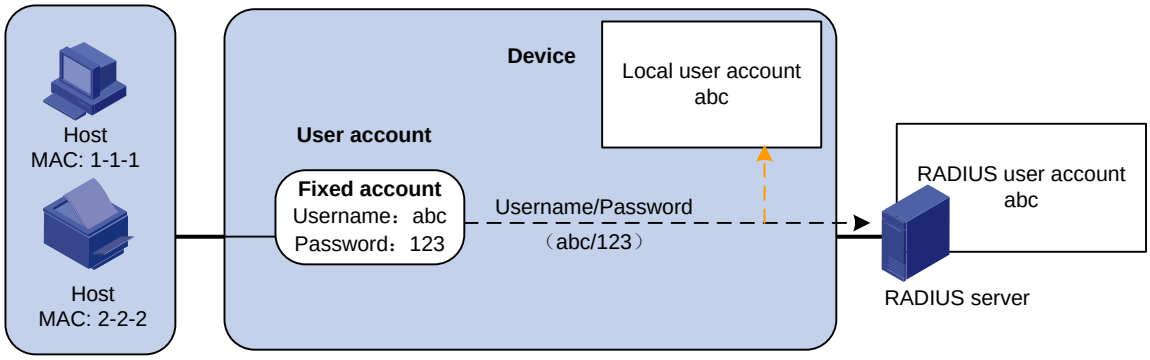

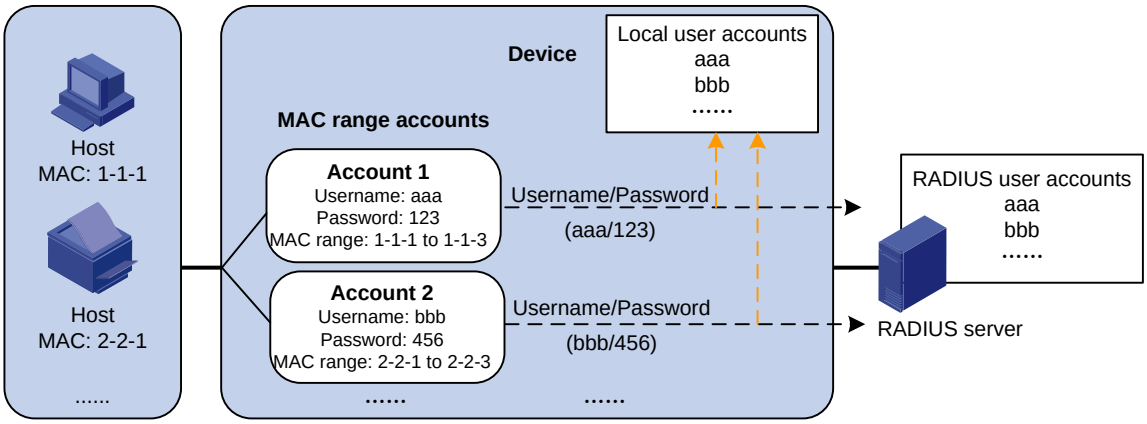

Figure 3 Shared user account policy (specific to MAC address ranges)

Authentication methods

You can perform MAC authentication on the access device (local authentication) or through a RADIUS server.

For more information about configuring local authentication and RADIUS authentication, see "Configuring AAA."

RADIUS authentication

If MAC-based accounts are used, the access device by default sends the source MAC address of a packet as the username and password to the RADIUS server for authentication. If a password is

configured for MAC-based accounts, the access device sends the configured password as the password to the RADIUS server.

If a shared account is used, the access device sends the shared account username and password to the RADIUS server for authentication.

The access device and the RADIUS server use Password Authentication Protocol (PAP) or Challenge Handshake Authentication Protocol (CHAP) for communication.

Local authentication

If MAC-based accounts are used, the access device by default uses the source MAC address of a packet as the username and password to search the local account database for a match. If a password is configured for MAC-based accounts, the device uses the configured password to search the local account database for a match.

If a shared account is used, the access device uses the shared account username and password to search the local account database for a match.

VLAN assignment

Authorization VLAN

The authorization VLAN controls the access of a MAC authentication user to authorized network resources. The device supports authorization VLANs assigned locally or by a remote server.

IMPORTANT:

Only remote servers can assign tagged authorization VLANs.

Remote VLAN authorization

In remote VLAN authorization, you must configure an authorization VLAN for a user on the remote server. After the user authenticates to the server, the server assigns authorization VLAN information to the device. Then, the device assigns the user access port to the authorization VLAN as a tagged or untagged member.

The device supports assignment of the following authorization VLAN information by the remote server:

- VLAN ID.
- VLAN name, which must be the same as the VLAN description on the access device.
- A string of VLAN IDs and VLAN names.

  In the string, some VLANs are represented by their IDs, and some VLANs are represented by their names.
- VLAN group name.

  For more information about VLAN groups, see *Layer 2—LAN Switching Configuration Guide*.
- VLAN ID with a suffix of **t** or **u**.

  The **t** and **u** suffixes require the device to assign the access port to the VLAN as a tagged or untagged member, respectively. For example, **2u** indicates assigning the port to VLAN 2 as an untagged member.

If a VLAN name or VLAN group name is assigned, the device converts the information into a VLAN ID before VLAN assignment.

IMPORTANT:

For a VLAN represented by its VLAN name to be assigned successfully, you must make sure the VLAN has been created on the device.

To assign VLAN IDs with suffixes, make sure the user access port is a hybrid or trunk port.

IMPORTANT:

To ensure a successful assignment, the authorization VLANs assigned by the remote server cannot be any of the following types:

- Dynamically learned VLANs.
- Reserved VLANs.
- Super VLANs.
- Private VLANs.

If the server assigns a group of VLANs, the access device selects a VLAN as described in Table 1.

Table 1 Authorization VLAN selection from a group of VLANs

VLAN information	Authorization VLAN selection
VLANs by IDs VLANs by names VLAN group name	The device selects an authorization VLAN from the VLAN group for a user according to the following rules: • On a hybrid port with MAC-based VLAN enabled: ○ If the port does not have online users, the device selects the VLAN with the lowest ID. ○ If the port has online users, the device selects the VLAN that has the fewest online users. If two VLANs have the same number of online MAC authentication users, the device selects the VLAN with the lower ID. • On an access, trunk, or MAC-based VLAN disabled hybrid port: ○ If the port does not have online users, the device selects the VLAN with the lowest ID. ○ If the port has online users, the device examines the VLAN group for the VLAN of the online users. If the VLAN is found, the VLAN is assigned to the user as the authorization VLAN. If the VLAN is not found, VLAN authorization fails.
VLAN IDs with suffixes	**1.** The device selects the leftmost VLAN ID without a suffix, or the leftmost VLAN ID suffixed by **u** as an untagged VLAN, whichever is more leftmost. **2.** The device assigns the untagged VLAN to the port as the PVID, and it assigns the remaining as tagged VLANs. If no untagged VLAN is assigned, the PVID of the port does not change. The port permits traffic from these tagged and untagged VLANs to pass through. For example, the authentication server sends the string **1u 2t 3** to the access device for a user. The device assigns VLAN 1 as an untagged VLAN and all remaining VLANs (including VLAN 3) as tagged VLANs. VLAN 1 becomes the PVID.

Local VLAN authorization

To perform local VLAN authorization for a user, specify the VLAN ID in the authorization attribute list of the local user account for that user. For each local user, you can specify only one authorization VLAN ID. The user access port is assigned to the VLAN as an untagged member.

IMPORTANT:

Local VLAN authorization does not support assignment of tagged VLANs.

For more information about local user configuration, see "Configuring AAA."

Authorization VLAN manipulation on a MAC authentication-enabled port

Table 2 describes the way the network access device handles authorization VLANs (except for the VLANs specified with suffixes) for MAC authenticated users on a port.

Table 2 VLAN manipulation

Port type	VLAN manipulation
• Access port • Trunk port • Hybrid port with MAC-based VLAN disabled	• The device assigns the port to the first authenticated user's authorization VLAN and sets the VLAN as the PVID if that authorization VLAN has the untagged attribute. • If the authorization VLAN has the tagged attribute, the device assigns the port to the authorization VLAN without changing its PVID. **NOTE:** The tagged attribute is supported only on trunk and hybrid ports.
Hybrid port with MAC-based VLAN enabled	The device maps the MAC address of each user to its own authorization VLAN regardless of whether the port is a tagged member. The PVID of the port does not change.

IMPORTANT:

- If the users are attached to a port whose link type is access, make sure the authorization VLAN assigned by the server has the untagged attribute. VLAN assignment will fail if the server issues a VLAN that has the tagged attribute.
- When you assign VLANs to users attached to a trunk port or a MAC-based VLAN disabled hybrid port, make sure there is only one untagged VLAN. If a different untagged VLAN is assigned to a subsequent user, the user cannot pass authentication.
- As a best practice to enhance network security, do not use the **`port hybrid vlan`** command to assign a hybrid port to an authorization VLAN as a tagged member.

The VLAN assigned by the server to a user as an authorization VLAN might have been configured on the user access port but with a different tagging mode. For example, the server assigns an authorization VLAN with the tagged attribute, but the same VLAN configured on the port has the untagged attribute. In this situation, the VLAN settings that take effect on the user depend on the link type of the port.

- If the link type of the port is access or trunk, the authorization VLAN settings assigned by the server always take effect on the user as long as the user is online. After the user goes offline, the VLAN settings on the port take effect.
- If the link type of the port is hybrid, the VLAN settings configured on the port take effect. For example, the server assigns VLAN 30 with the untagged attribute to a user on the hybrid port. However, VLAN 30 has been configured on the port with the tagged attribute by using the **`port hybrid vlan tagged`** command. Then, the VLAN has the tagged attribute on the port.

For a MAC authenticated user to access the network on a hybrid port when no authorization VLAN is configured for the user, perform one of the following tasks:

- If the port receives tagged authentication packets from the user in a VLAN, use the **`port hybrid vlan`** command to configure the port as a tagged member in the VLAN.
- If the port receives untagged authentication packets from the user in a VLAN, use the **`port hybrid vlan`** command to configure the port as an untagged member in the VLAN.

Guest VLAN

The MAC authentication guest VLAN on a port accommodates users that have failed MAC authentication for any reason other than server unreachable. For example, the VLAN accommodates users with invalid passwords entered.

You can deploy a limited set of network resources in the MAC authentication guest VLAN. For example, a software server for downloading software and system patches.

A hybrid port is always assigned to a MAC authentication guest VLAN as an untagged member. After the assignment, do not reconfigure the port as a tagged member in the VLAN.

The device reauthenticates users in the MAC authentication guest VLAN at a specific interval. Table 3 shows the way that the network access device handles guest VLANs for MAC authentication users.

Table 3 VLAN manipulation

Authentication status	VLAN manipulation
A user in the MAC authentication guest VLAN fails MAC authentication.	The user is still in the MAC authentication guest VLAN.
A user in the MAC authentication guest VLAN passes MAC authentication.	The device remaps the MAC address of the user to the authorization VLAN assigned by the authentication server. If no authorization VLAN is configured for the user on the authentication server, the device remaps the MAC address of the user to the PVID of the port.

Critical VLAN

The MAC authentication critical VLAN on a port accommodates users that have failed MAC authentication because no RADIUS authentication servers are reachable. Users in a MAC authentication critical VLAN can access only network resources in the critical VLAN.

The critical VLAN feature takes effect when MAC authentication is performed only through RADIUS servers. If a MAC authentication user fails local authentication after RADIUS authentication, the user is not assigned to the critical VLAN. For more information about the authentication methods, see "Configuring AAA."

Table 4 shows the way that the network access device handles critical VLANs for MAC authentication users.

Table 4 VLAN manipulation

Authentication status	VLAN manipulation
A user fails MAC authentication because all the RADIUS servers are unreachable.	The device maps the MAC address of the user to the MAC authentication critical VLAN. The user is still in the MAC authentication critical VLAN if the user fails MAC reauthentication because all the RADIUS servers are unreachable. If no MAC authentication critical VLAN is configured, the device maps the MAC address of the user to the PVID of the port.
A user in the MAC authentication guest VLAN fails authentication because all the RADIUS servers are unreachable.	The user remains in the MAC authentication guest VLAN.
A user in the MAC authentication critical VLAN fails MAC authentication for any reason other than server unreachable.	If a guest VLAN has been configured, the device maps the MAC address of the user to the guest VLAN. If no guest VLAN is configured, the device maps the MAC address of the user to the PVID of the port.
A user in the MAC authentication critical VLAN passes MAC authentication.	The device remaps the MAC address of the user to the authorization VLAN assigned by the authentication server. If no authorization VLAN is configured for the user on the authentication server, the device remaps the MAC address of the user to the PVID of the access port.

Critical voice VLAN

The MAC authentication critical voice VLAN on a port accommodates MAC authentication voice users that have failed authentication because none of the RADIUS servers in their ISP domain are reachable.

The critical voice VLAN feature takes effect when MAC authentication is performed only through RADIUS servers. If a MAC authentication voice user fails local authentication after RADIUS authentication, the user is not assigned to the critical voice VLAN. For more information about the authentication methods, see "Configuring AAA."

Table 5 shows the way that the network access device handles critical voice VLANs for MAC authentication voice users.

Table 5 VLAN manipulation

Authentication status	VLAN manipulation
A voice user fails MAC authentication because all the RADIUS servers are unreachable.	The device maps the MAC address of the voice user to the MAC authentication critical voice VLAN. The voice user is still in the MAC authentication critical voice VLAN if the voice user fails MAC reauthentication because all the RADIUS servers are unreachable. If no MAC authentication critical voice VLAN is configured, the device maps the MAC address of the voice user to the PVID of the port.
A voice user in the MAC authentication critical voice VLAN fails MAC authentication for any reason other than server unreachable.	If a guest VLAN has been configured, the device maps the MAC address of the voice user to the guest VLAN. If no guest VLAN is configured, the device maps the MAC address of the voice user to the PVID of the port.
A voice user in the MAC authentication critical voice VLAN passes MAC authentication.	The device remaps the MAC address of the voice user to the authorization VLAN assigned by the authentication server. If no authorization VLAN is configured for the voice user on the authentication server, the device remaps the MAC address of the voice user to the PVID of the access port.

ACL assignment

You can specify an authorization ACL for a MAC authentication user on a remote server or the access device to control the user's access to network resources. After the user passes MAC authentication, the server or access device assigns the authorization ACL to the user access port. Then, the port permits or drops the matching traffic for the user depending on the rules in the ACL.

In R1132 and later versions, the device supports assignment of static and dynamic authorization ACLs.

- **Assignment of static authorization ACLs**—Static ACLs can be assigned by a RADIUS server or the access device. When the server or access device assigns a static ACL to a user, it assigns only the ACL number. You must manually create the ACL and configure its rules on the access device.

  To change the access permissions of a user, use one of the following methods:

  - Modify ACL rules in the authorization ACL on the access device.
  - Assign another ACL to the user as the authorization ACL from the RADIUS server or the access device.

  Static ACLs and their rules can be manually deleted from the access device.
- **Assignment of dynamic authorization ACLs**—Dynamic ACLs and their rules are automatically deployed by a RADIUS server, which are not configurable on the access device.

Dynamic ACLs can only be named ACLs. After the device receives a server-deployed dynamic ACL and its rules, it automatically creates the ACL and configures its rules.

If a dynamic ACL assigned by the server to a user has the same name as a static ACL, the dynamic ACL cannot be issued and the user cannot come online.

A dynamic ACL and its rules are automatically deleted from the access device after all its users go offline.

Dynamic ACLs and their rules cannot be manually modified or deleted on the access device. To display information about dynamic ACLs and their rules, use the **display mac-authentication connection** or **display acl** command.

IMPORTANT:

The supported authorization ACLs include the following types:

- Basic ACLs, which are numbered in the range of 2000 to 2999.
- Advanced ACLs, which are numbered in the range of 3000 to 3999.
- Layer 2 ACLs, which are numbered in the range of 4000 to 4999.

For an authorization ACL to take effect, make sure the ACL exists with rules and none of the rules contains the **counting**, **established**, **fragment**, **source-mac**, **cos**, **dest-mac**, **lsap**, or **logging** keyword.

For more information about ACLs, see *ACL and QoS Configuration Guide*.

User profile assignment

You can specify a user profile in the user account for a MAC authentication user on the authentication server to control the user's access to network resources. After the user passes MAC authentication, the authentication server assigns the user profile to the user to filter traffic for this user.

The authentication server can be the local access device or a RADIUS server. In either case, the server only specifies the user profile name. You must configure the user profile on the access device.

To change the user's access permissions, use one of the following methods:

- Modify the user profile configuration on the access device.
- Specify another user profile for the user on the authentication server.

For more information about user profiles, see "Configuring user profiles."

Redirect URL assignment

The device supports the URL attribute assigned by a RADIUS server. During MAC authentication, the HTTP or HTTPS requests of a user are redirected to the Web interface specified by the server-assigned URL attribute. After the user passes the Web authentication, the RADIUS server records the MAC address of the user and uses a DM (Disconnect Message) to log off the user. When the user initiates MAC authentication again, it will pass the authentication and come online successfully.

By default, the device listens to port 6654 for HTTPS requests to be redirected. To change the redirect listening port number, see configuring HTTP redirect in *Layer 3—IP Services Configuration Guide*.

CAR attribute assignment

The device can use the CAR attributes assigned through RADIUS extended attributes to control the access rates of online MAC authenticated users. For information about extended RADIUS attributes, see "Configuring AAA."

The following CAR attributes are available:

- **Input-Peak-Rate**—Peak rate of inbound traffic in bps.
- **Input-Average-Rate**—Average rate of inbound traffic in bps.
- **Output-Peak-Rate**—Peak rate of outbound traffic in bps.
- **Output-Average-Rate**—Average rate of outbound traffic in bps.

If the server assigns CAR attributes for controlling both the peak and average rates, the device implements double-rate traffic policing on user traffic. If the server does not assign the Input-Peak-Rate or Output-Peak-Rate attribute, the device implements single-rate traffic policing on user traffic. For more information about traffic policing, see QoS configuration in *ACL and QoS Configuration Guide*.

Blackhole MAC attribute assignment

The device supports the blackhole MAC attribute assigned by the RADIUS authentication server through CoA messages for users that have passed MAC authentication. Upon receiving a CoA message that contains the blackhole MAC attribute for a user that has passed MAC authentication, the device performs the following operations:

1. Logs off the user.
2. Marks the MAC address of the user as a silent MAC address and starts a quiet timer for the MAC address.

The quiet timer is 10 minutes and is not user configurable. The device drops all packets from the MAC address after the quiet timer starts, and it will not authenticate the MAC address until the quiet timer expires.

To display silent MAC addresses, use the **`display mac-authentication`** command.

Periodic MAC reauthentication

Periodic MAC reauthentication tracks the connection status of online users, and updates the authorization attributes assigned by the RADIUS server. The attributes include the ACL and VLAN.

The device reauthenticates online MAC authentication users at the periodic reauthentication interval when the periodic MAC reauthentication feature is enabled. The interval is controlled by a timer and the timer is user configurable. A change to the periodic reauthentication timer applies to online MAC authentication users only after the old timer expires and the MAC authentication users pass authentication.

The server-assigned RADIUS Session-Timeout (attribute 27) and Termination-Action (attribute 29) attributes together can affect the periodic MAC reauthentication feature. To display the server-assigned Session-Timeout and Termination-Action attributes, use the **`display mac-authentication connection`** command.

- If the termination action is to log off users, periodic MAC reauthentication takes effect only when the periodic reauthentication timer is shorter than the session timeout timer. If the session timeout timer is shorter, the device logs off online authenticated users when the session timeout timer expires.
- If the termination action is to reauthenticate users, the periodic MAC reauthentication configuration on the device cannot take effect. The device reauthenticates online MAC authentication users after the server-assigned session timeout timer expires.

If no session timeout timer is assigned by the server, whether the device performs periodic MAC reauthentication depends on the periodic MAC reauthentication configuration on the device. Support for the assignment of Session-Timeout and Termination-Action attributes depends on the server model.

With the RADIUS DAS feature enabled, the device immediately reauthenticates a user upon receiving a CoA message that carries the reauthentication attribute from a RADIUS authentication server. In this case, reauthentication will be performed regardless of whether periodic MAC reauthentication is enabled on the device. For more information about RADIUS DAS configuration, see "Configuring AAA."

By default, the device logs off online MAC authentication users if no server is reachable for MAC reauthentication. The keep-online feature keeps authenticated MAC authentication users online when no server is reachable for MAC reauthentication.

The VLANs assigned to an online user before and after reauthentication can be the same or different.

RESTful server-assisted MAC authentication user recovery

Applicable scenario

After online dumb terminals such as printers go offline, they cannot reauthenticate to come online until after they send a service packet. This might cause the dumb terminals to stay offline for a long time after the device or their attached interface module reboots or after their attached interfaces fail.

To avoid this situation, you can configure the device to work with the authentication server and a RESTful server to trigger MAC reauthentication for dumb terminals or retain their online state.

NOTE:

This feature is available only when you use IMC server as the authentication server and the RESTful server.

Working mechanism

The following information describes how RESTful server-assisted MAC authentication user recovery works:

1. The authentication server includes the **shutdown-keep-online** proprietary attribute in the authorization attributes assigned to a dumb terminal after it passes authentication.
2. After receiving the authentication result from the authentication server, the device allows the dumb terminal user to come online and marks it as a dumb terminal user.
3. When a device or interface issue occurs, the device handles the dumb terminal user as follows:
   - If the interface is physical down, the device retains the online state of the dumb terminal user.
   - If the device or the interface module reboots or if the interface recovers from a failure, the device obtains MAC authentication user information from the RESTful server to perform MAC reauthentication.

Restrictions and guidelines: MAC authentication configuration

When you configure MAC authentication on an interface, follow these restrictions and guidelines:

- Do not change the link type of a port when the MAC authentication guest VLAN or critical VLAN on the port has users.

- As a best practice, do not use Web authentication in conjunction with MAC authentication guest VLAN and critical VLAN settings on a port.

To ensure a successful HTTPS redirect for users who have received a server-assigned redirect URL, make sure VLAN interfaces exist for the VLANs that transport their packets.

If the MAC address that has failed authentication is a static MAC address or a MAC address that has passed any security authentication, the device does not mark the MAC address as a silent address.

MAC authentication tasks at a glance

To configure MAC authentication, perform the following tasks:

1. Enabling MAC authentication
2. Configure basic MAC authentication features
   - Specifying a MAC authentication method
   - Specifying a MAC authentication domain
   - Configuring user account policy
   - (Optional.) Configuring MAC authentication timers
   - (Optional.) Configuring periodic MAC reauthentication
3. (Optional.) Configuring MAC authentication VLAN assignment
   - Configuring a MAC authentication guest VLAN
   - Configuring a MAC authentication critical VLAN
   - Enabling the MAC authentication critical voice VLAN feature
4. (Optional.) Configuring other MAC authentication features
   - Configuring MAC authentication offline detection
   - Enabling online user synchronization for MAC authentication
   - Setting the maximum number of concurrent MAC authentication users on a port
   - Enabling MAC authentication multi-VLAN mode on a port

     Perform this task to not reauthenticate online users when VLAN changes occur on a port.
   - Configuring MAC authentication delay
   - Including user IP addresses in MAC authentication requests
   - Enabling parallel MAC authentication and 802.1X authentication
   - Configuring RESTful server-assisted MAC authentication user recovery
   - Configuring Web proxy ports for URL redirection in MAC authentication
   - Logging off MAC authentication users
   - Enabling MAC authentication user logging

Prerequisites for MAC authentication

Before you configure MAC authentication, complete the following tasks:

1. Make sure the port security feature is disabled. For more information about port security, see "Configuring port security."
2. Configure an ISP domain and specify an AAA method. For more information, see "Configuring AAA."
   - For local authentication, you must also create local user accounts (including usernames and passwords) and specify the **lan-access** service for local users.

- For RADIUS authentication, make sure the device and the RADIUS server can reach each other and create user accounts on the RADIUS server. If you are using MAC-based accounts, make sure the username and password for each account are the same as the MAC address of each MAC authentication user.

Enabling MAC authentication

Restrictions and guidelines

For MAC authentication to take effect on a port, you must enable this feature globally and on the port.

MAC authentication cannnot take effect on a port if the device has run out of ACL resources when you perform either of the following operations:

- Enable MAC authentication on the port while MAC authentication has been enabled globally.
- Enable MAC authentication globally in system while MAC authentication has been enabled on the port.

Procedure

1. Enter system view.
   `system-view`
2. Enable MAC authentication globally.
   `mac-authentication`
   By default, MAC authentication is disabled globally.
3. Enter interface view.
   `interface` *`interface-type interface-number`*
4. Enable MAC authentication on the port.
   `mac-authentication`
   By default, MAC authentication is disabled on a port.

Specifying a MAC authentication method

About this task

RADIUS-based MAC authentication supports the following authentication methods:

- **PAP**—Transports usernames and passwords in plain text. The authentication method applies to scenarios that do not require high security.
- **CHAP**—Transports usernames in plain text and passwords in encrypted form over the network. CHAP is more secure than PAP.

Restrictions and guidelines

The device must use the same authentication method as the RADIUS server.

Procedure

1. Enter system view.
   `system-view`
2. Specify an authentication method for MAC authentication.
   `mac-authentication authentication-method` { **`chap`** | **`pap`** }
   By default, the device uses PAP for MAC authentication.

Specifying a MAC authentication domain

About this task

By default, MAC authentication users are in the system default authentication domain. To implement different access policies for users, you can use one of the following methods to specify authentication domains for MAC authentication users:

- Specify a global authentication domain in system view. This domain setting applies to all ports enabled with MAC authentication.
- Specify an authentication domain for an individual port in interface view.

MAC authentication chooses an authentication domain for users on a port in this order: the port-specific domain, the global domain, and the default domain. For more information about authentication domains, see "Configuring AAA."

Procedure

1. Enter system view.

   system-view
2. Specify an authentication domain for MAC authentication users.
   - In system view:

     mac-authentication domain *domain-name*
   - In interface view:

     interface *interface-type interface-number*

     mac-authentication domain *domain-name*

   By default, the system default authentication domain is used for MAC authentication users.

Configuring user account policy

Restrictions and guidelines

For users in a MAC address range, the MAC address range-specific user account has higher priority than the global user account settings.

You can configure a maximum of 16 MAC address ranges and must make sure the MAC address ranges do not overlap.

If you configure user account settings multiple times for the same MAC address range, the most recent configuration overwrites the previous configuration.

The MAC range-specific accounts apply only to unicast MAC addresses.

- If you specify a MAC address range that contains only multicast MAC addresses, execution of this command will fail.
- If you specify a MAC address range that contains both unicast and multicast MAC addresses, the command takes effect only on unicast MAC addresses.

The all-zero MAC address is invalid for MAC authentication. Users with the all-zero MAC address cannot pass MAC authentication.

Procedure

1. Enter system view.

   system-view
2. Configure the global MAC authentication user account policy.
   - Use one MAC-based user account for each user.

mac-authentication user-name-format mac-address [{ **with-hyphen** | **without-hyphen** } [**lowercase** | **uppercase**]] [**password** { **cipher** | **simple** } *string*]

- Use one shared user account for all users.

  mac-authentication user-name-format fixed [**account** *name*] [**password** { **cipher** | **simple** } *string*]

By default, the device uses the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hexadecimal notation without hyphens, and letters are in lower case.

3. Specify one shared user account specific to a MAC address range.

   mac-authentication mac-range-account mac-address *mac-address* **mask** { *mask* | *mask-length* } **account** *name* **password** { **cipher** | **simple** } *string*

   By default, no username or password is configured specific to a MAC address range. The global user account policy applies to the users.

Configuring MAC authentication timers

About this task

MAC authentication uses the following timers:

- **Offline detect timer**—Sets the interval that the device must wait for traffic from a user before the device determines that the user is idle. If the device has not received traffic from a user before the timer expires, the device logs off that user and requests the accounting server to stop accounting for the user. This timer takes effect only when the MAC authentication offline detection feature is enabled.

  As a best practice, set the MAC address aging timer to the same value as the offline detect timer. This operation prevents a MAC authenticated user from being logged off within the offline detect interval because of MAC address entry expiration.
- **Quiet timer**—Sets the interval that the device must wait before the device can perform MAC authentication for a user that has failed MAC authentication. All packets from the MAC address are dropped during the quiet time. This quiet mechanism prevents repeated authentication from affecting system performance.
- **Server timeout timer**—Sets the interval that the device waits for a response from a RADIUS server before the device determines that the RADIUS server is unavailable. If the timer expires during MAC authentication, the user fails MAC authentication.

Restrictions and guidelines

To avoid forced logoff before the server timeout timer expires, set the server timeout timer to a value that is lower than or equal to the product of the following values:

- The maximum number of RADIUS packet transmission attempts set by using the **retry** command in RADIUS scheme view.
- The RADIUS server response timeout timer set by using the **timer response-timeout** command in RADIUS scheme view.

For information about setting the maximum number of RADIUS packet transmission attempts and the RADIUS server response timeout timer, see "Configuring AAA."

Procedure

1. Enter system view.

   system-view

2. Configure MAC authentication timers.

mac-authentication timer { **offline-detect** *offline-detect-value* | **quiet** *quiet-value* | **server-timeout** *server-timeout-value* }

By default, the offline detect timer is 300 seconds, the quiet timer is 60 seconds, and the server timeout timer is 100 seconds.

Configuring periodic MAC reauthentication

Restrictions and guidelines

The device selects a periodic reauthentication timer for MAC reauthentication in the following order:

1. Server-assigned reauthentication timer.
2. Port-specific reauthentication timer.
3. Global reauthentication timer.
4. Default reauthentication timer.

Modification to the MAC authentication domain, MAC authentication method, or user account format setting does not affect the reauthentication of online MAC authentication users. The modified setting takes effect only on MAC authentication users that come online after the modification.

If periodic reauthentication is triggered for a user while that user is waiting for online synchronization, the system performs online synchronization and does not perform reauthentication for the user.

Procedure

1. Enter system view.

   system-view

2. Set the periodic MAC reauthentication timer.
   - Set a global periodic reauthentication timer.

     mac-authentication timer reauth-period *reauth-period-value*

     The default setting is 3600 seconds.
   - Execute the following commands in sequence to set a port-specific periodic reauthentication timer:

     interface *interface-type interface-number*

     mac-authentication timer reauth-period *reauth-period-value*

     quit

     By default, no periodic MAC reauthentication timer is set on a port. The port uses the global periodic MAC reauthentication timer.
3. Enter interface view.

   interface *interface-type interface-number*

4. Enable periodic MAC reauthentication.

   mac-authentication re-authenticate

   By default, periodic MAC reauthentication is disabled on a port.

5. (Optional.) Enable the keep-online feature for MAC authenticated users on the port.

   mac-authentication re-authenticate server-unreachable keep-online

   By default, the keep-online feature is disabled. The device logs off online MAC authentication users if no server is reachable for MAC reauthentication.

   In a fast-recovery network, you can use the keep-online feature to prevent MAC authentication users from coming online and going offline frequently.

Configuring a MAC authentication guest VLAN

Specifying a MAC authentication guest VLAN on a port

Restrictions and guidelines

When you configure the MAC authentication guest VLAN on a port, follow the guidelines in Table 6.

Table 6 Relationships of the MAC authentication guest VLAN with other security features

Feature	Relationship description	Reference
Quiet feature of MAC authentication	The MAC authentication guest VLAN feature has higher priority. When a user fails MAC authentication, the user can access the resources in the guest VLAN. The user's MAC address is not marked as a silent MAC address.	See "Configuring MAC authentication timers."
Super VLAN	You cannot specify a VLAN as both a super VLAN and a MAC authentication guest VLAN.	See *Layer 2—LAN Switching Configuration Guide*.
Port intrusion protection	The guest VLAN feature has higher priority than the block MAC action but lower priority than the shutdown port action of the port intrusion protection feature.	See "Configuring port security."

Prerequisites

Before you configure the MAC authentication guest VLAN on a port, complete the following tasks:

- Create the VLAN to be specified as the MAC authentication guest VLAN.
- Configure the port as a hybrid port, and configure the VLAN as an untagged member on the port.
- Enable MAC-based VLAN on the port.

For information about VLAN configuration, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
3. Specify the MAC authentication guest VLAN on the port.
   `mac-authentication guest-vlan` *`guest-vlan-id`*
   By default, no MAC authentication guest VLAN is specified on a port.
   You can configure only one MAC authentication guest VLAN on a port. The MAC authentication guest VLANs on different ports can be different.

Enabling guest VLAN reauthentication in MAC authentication

About this task

The guest VLAN reauthentication feature of MAC authentication enables the device to reauthenticate users in the MAC authentication guest VLAN on a port at reauthentication intervals.

By default, this feature is enabled. You can disable it as needed to suppress excessive authentication failure log messages, which might occur when a network issue results in a large number of reauthentication failures.

If guest VLAN reauthentication is disabled on a port, the device does not reauthenticate users in the MAC authentication guest VLAN on the port. The guest VLAN users will stay in the guest VLAN until they age out. To control guest VLAN user aging functionality, use the **mac-authentication unauthenticated-user aging enable** command. To configure the aging timer, use the **mac-authentication timer user-aging guest-vlan** *aging-time-value* command.

Restrictions and guidelines

As a best practice, set the reauthentication interval to a value greater than 30 seconds if the number of concurrent MAC authentication users on a port is likely to exceed 300.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable the guest VLAN reauthentication feature of MAC authentication on the port.
   mac-authentication guest-vlan re-authenticate
   By default, the guest VLAN reauthentication feature of MAC authentication is enabled on a port.
4. Set the authentication interval for users in the MAC authentication guest VLAN.
   mac-authentication guest-vlan auth-period *period-value*
   The default setting is 30 seconds.

Configuring a MAC authentication critical VLAN

Restrictions and guidelines

When you configure the MAC authentication critical VLAN on a port, follow the guidelines in Table 7.

Table 7 Relationships of the MAC authentication critical VLAN with other security features

Feature	Relationship description	Reference
Quiet feature of MAC authentication	The MAC authentication critical VLAN feature has higher priority. When a user fails MAC authentication because no RADIUS authentication server is reachable, the user can access the resources in the critical VLAN. The user's MAC address is not marked as a silent MAC address.	See "Configuring MAC authentication timers."
Port intrusion protection	The critical VLAN feature has higher priority than the block MAC action but lower priority than the shutdown port action of the port intrusion protection feature.	See "Configuring port security."

Prerequisites

Before you configure the MAC authentication critical VLAN on a port, complete the following tasks:

- Create the VLAN to be specified as the MAC authentication critical VLAN.
- Configure the port as a hybrid port, and configure the VLAN as an untagged member on the port.

- Enable MAC-based VLAN on the port.

For information about VLAN configuration, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Specify the MAC authentication critical VLAN on the port.

   mac-authentication critical vlan *critical-vlan-id*

   By default, no MAC authentication critical VLAN is specified on a port.

   You can configure only one MAC authentication critical VLAN on a port. The MAC authentication critical VLANs on different ports can be different.

Enabling the MAC authentication critical voice VLAN feature

Prerequisites

Before you enable the MAC authentication critical voice VLAN feature on a port, complete the following tasks:

- Enable LLDP both globally and on the port.

  The device uses LLDP to identify voice users. For information about LLDP, see *Layer 2—LAN Switching Configuration Guide*.
- Enable voice VLAN on the port.

  For information about voice VLANs, see *Layer 2—LAN Switching Configuration Guide*.
- Specify a MAC authentication critical VLAN on the port. This setting ensures that a voice user is assigned to the critical VLAN if it has failed authentication for unreachability of RADIUS servers before the device recognizes it as a voice user. If a MAC authentication critical VLAN is not available, the voice user might be logged off instead.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable the MAC authentication critical voice VLAN feature on a port.

   mac-authentication critical-voice-vlan

   By default, the MAC authentication critical voice VLAN feature is disabled on a port.

Configuring unauthenticated MAC authentication user aging

About this task

Unauthenticated MAC authentication user aging applies to users added to a MAC authentication guest or critical VLAN because they have not been authenticated or have failed authentication.

When a user in one of those VLANs ages out, the device removes the user from the VLAN and deletes the MAC address entry for the user from the access port.

For users in one of those VLANs on one port to be authenticated successfully and come online on another port, enable this feature. In any other scenarios, disable this feature as a best practice.

Restrictions and guidelines

As a best practice, use this feature on a port only if you want to have its unauthenticated users to be authenticated and come online on a different port.

Procedure

1. Enter system view.

   system-view

2. Set the user aging timer for a type of MAC authentication VLAN.

   mac-authentication timer user-aging { **critical-vlan** | **guest-vlan** } *aging-time-value*

   By default, the user aging timer is 1000 seconds for all applicable types of MAC authentication VLANs.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable unauthenticated MAC authentication user aging.

   mac-authentication unauthenticated-user aging enable

   By default, unauthenticated MAC authentication user aging is enabled.

Configuring MAC authentication offline detection

About this task

Enable MAC authentication offline detection to detect idle users on a port. If the port has not received traffic from a user when the offline detect timer expires, the device logs off that user and requests the accounting server to stop accounting for the users. For information about setting the offline detect timer in system view, see "Configuring MAC authentication timers."

Disabling this feature disables the device from inspecting the online user status.

In addition to port-based MAC authentication offline detection, you can configure offline detection parameters on a per-user basis, as follows:

- Set an offline detect timer specific to a user and control whether to use the ARP snooping or ND snooping table to determine the offline state of the user.
  - If the ARP snooping or ND snooping table is used, the device searches the ARP snooping or ND snooping table before it checks for traffic from the user within the detection interval. If a matching ARP snooping or ND snooping entry is found, the device resets the offline detect timer and the user stays online. If the offline detect timer expires because the device has not found a matching snooping entry for the user or received traffic from the user, the device disconnects the user.
  - If the ARP or ND snooping table is not used, the device disconnects the user if it has not received traffic from that user before the offline detect timer expires.

  When disconnecting the user, the device also notifies the RADIUS server (if any) to stop user accounting.
- Skip offline detection for the user. You can choose this option if the user is a dumb terminal. A dumb terminal might fail to come online again after it is logged off by the offline detection feature.

The device uses the offline detection settings for a user in the following sequence:

1. User-specific offline detection settings.
2. Offline detection settings assigned to the user by the RADIUS server. The settings include the offline detect timer, use of the ARP or ND snooping table in offline detection, and whether to ignore offline detection.
3. Port-based offline detection settings.

Restrictions and guidelines

For the user-specific offline detection feature to take effect on a user, make sure the MAC authentication offline detection feature is enabled on the user's access port.

The user-specific offline detection settings take effect on the online users immediately after they are configured.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Configure MAC authentication offline detection for a user.

   mac-authentication offline-detect mac-address *mac-address* { **ignore** | **timer** *offline-detect-value* [**check-arp-or-nd-snooping**] }

   By default, offline detection settings configured on access ports take effect and the offline detect timer set in system view is used.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable MAC authentication offline detection.

   mac-authentication offline-detect enable

   By default, MAC authentication offline detection is enabled on a port.

Enabling online user synchronization for MAC authentication

About this task

IMPORTANT:

This feature takes effect only when the device uses an IMC RADIUS server to authenticate MAC authentication users.

To ensure that the RADIUS server maintains the same online MAC authentication user information as the device after the server state changes from unreachable to reachable, use this feature.

This feature synchronizes online MAC authentication user information between the device and the RADIUS server when the RADIUS server state is detected having changed from unreachable to reachable.

When synchronizing online MAC authentication user information on a port with the RADIUS server, the device initiates MAC authentication in turn for each authenticated online MAC authentication user to the RADIUS server.

If synchronization fails for an online user, the device logs off that user unless the failure occurs because the server has become unreachable again.

Restrictions and guidelines

The amount of time required to complete online user synchronization increases as the number of online users grows. This might result in an increased delay for new MAC authentication users and users in the critical VLAN to authenticate or reauthenticate to the RADIUS server and come online.

To have this feature take effect, you must use it in conjunction with the RADIUS server status detection feature, which is configurable with the **radius-server test-profile** command. For more information about the RADIUS server status detection feature, see "Configuring AAA."

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable online user synchronization for MAC authentication.
   mac-authentication server-recovery online-user-sync
   By default, online user synchronization for MAC authentication is disabled.

Setting the maximum number of concurrent MAC authentication users on a port

About this task

Perform this task to prevent the system resources from being overused.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the maximum number of concurrent MAC authentication users on the port.
   mac-authentication max-user *max-number*
   The default setting is 4294967295.

Enabling MAC authentication multi-VLAN mode on a port

About this task

By default, MAC authentication single-VLAN mode applies on a port. In this mode, traffic from an online user cannot be sent in different VLANs on a port without service interruption. To accommodate applications that are sensitive to delay or service interruption in a multi-VLAN environment, for example, IP phones, enable MAC authentication multi-VLAN mode.

In multi-VLAN mode, the port forwards traffic from a user in different VLANs without reauthentication if the user has been authenticated and come online in any VLAN on the port. Free of reauthentication, traffic from an online user can be sent in different VLANs without delay or service interruption.

In single-VLAN mode, the port reauthenticates an online user when traffic received from that user contains a VLAN tag different from the VLAN in which the user was authenticated. The

authentication process differs depending on the MAC move setting in port security and the authorization VLAN assignment status, as follows:

- If no authorization VLAN has been assigned to the online user, the device first logs off the user and then reauthenticates the user in the new VLAN.
- If the online user has been assigned an authorization VLAN, the device handles the user depending on the MAC move setting in port security.
  - If MAC move is disabled in port security, the user cannot pass authentication and come online from the new VLAN until after it goes offline from the port.
  - If MAC move is enabled in port security, the user can pass authentication on the new VLAN and come online without having to first go offline from the port. After the user passes authentication on the new VLAN, the original authentication session of the user is deleted from the port.

To enable the port security MAC move feature, use the **port-security mac-move permit** command.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable MAC authentication multi-VLAN mode.
   mac-authentication host-mode multi-vlan
   By default, MAC authentication operates in single-VLAN mode on a port.

Configuring MAC authentication delay

About this task

When both 802.1X authentication and MAC authentication are enabled on a port, you can delay MAC authentication so that 802.1X authentication is preferentially triggered.

If no 802.1X authentication is triggered or 802.1X authentication fails within the delay period, the port continues to process MAC authentication.

Restrictions and guidelines

Do not set the port security mode to **mac-else-userlogin-secure** or **mac-else-userlogin-secure-ext** when you use MAC authentication delay. The delay does not take effect on a port in either of the two modes. For more information about port security modes, see "Configuring port security."

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable MAC authentication delay and set the delay timer.
   mac-authentication timer auth-delay *time*
   By default, MAC authentication delay is disabled.

Including user IP addresses in MAC authentication requests

About this task

IMPORTANT:

This feature can only operate in conjunction with an IMC server.

To avoid IP conflicts that result from changes to static IP addresses, use this feature on a port that has MAC authentication users with static IP addresses.

This feature adds user IP addresses to the MAC authentication requests sent to the authentication server. When MAC authentication is triggered for a user, the device checks the user's IP address for invalidity.

- If the IP address is valid, the device sends a MAC authentication request with the IP address included.
- If the IP address is not a valid host IP address or the triggering packet does not contain an IP address, the device does not initiate MAC authentication.
- If the packet is a DHCP packet with a source IP address of all zeros, the device sends a MAC authentication request without including the IP address. In this case, the IMC server does not examine the user IP address when it performs authentication.

Upon receipt of the authentication request that includes a user's IP address, the IMC server compares the user's IP and MAC addresses with its local IP-MAC mappings.

- If an exact match is found or if no match is found, the user passes MAC authentication. In the latter case, the server creates an IP-MAC mapping for the user.
- If a mapping is found for the MAC address but the IP addresses do not match, the user fails the MAC authentication.

Restrictions and guidelines

Do not use this feature in conjunction with the MAC authentication guest VLAN on a port. If both features are used, the device cannot perform MAC authentication for a user once that user is added to the MAC authentication guest VLAN.

You can specify an ACL to identify source IP addresses that can or cannot trigger MAC authentication. When you configure the ACL, follow these guidelines:

- The specified ACL number represents an IPv4 ACL and an IPv6 ACL with the same number. For example, if the ACL number is 2000, you specify both IPv4 ACL 2000 and IPv6 ACL 2000. The IPv4 ACL and the IPv6 ACL will be used to process IPv4 packets and IPv6 packets, respectively.
- Use permit rules to identify source IP addresses that are valid for MAC authentication. Use deny rules to identify source IP addresses that cannot trigger MAC authentication.
- In the rules, only the action keyword (permit or deny) and the source IP match criteria can take effect.
- As a best practice, configure a deny rule to exclude the IPv6 IP addresses that start with fe80 from triggering MAC authentication.
- If you configure permit rules, add a **`deny all`** rule at the bottom of the ACL.

IMPORTANT:

If the user host is configured with IPv6, the device might receive packets that contain an IPv6 link-local address, which starts with fe80. MAC authentication failure or incorrect MAC-IP binding will occur if this address is used in MAC authentication. To avoid these issues, configure an ACL to exclude the IPv6 IP addresses that start with fe80.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Include user IP addresses in MAC authentication requests.

   mac-authentication carry user-ip [**exclude-ip acl** *acl-number*]

   By default, a MAC authentication request does not include the user IP address.

Enabling parallel MAC authentication and 802.1X authentication

About this task

This feature enables a port to perform MAC authentication in parallel with 802.1X authentication when it receives a packet from an unknown MAC address.

This feature applies to the following situation in which MAC authentication can be performed only after 802.1X authentication is completed:

- The port is configured with both 802.1X authentication and MAC authentication and performs MAC-based access control for 802.1X authentication.
- The port is enabled with the 802.1X unicast trigger.

With parallel authentication enabled, the port performs MAC authentication while sending a unicast EAP-Request/Identity packet to trigger 802.1 authentication when it receives a packet from an unknown MAC address.

If MAC authentication succeeds before 802.1X authentication is completed, the port is assigned to the MAC authentication authorization VLAN. When 802.1X authentication completes, the device manipulates VLAN assignment depending on the authentication result, as follows:

- If 802.1X authentication fails, the MAC authentication result takes effect.
- If 802.1X authentication succeeds, the device manipulates VLAN assignment based on the 802.1X authentication result.

For the port to perform MAC authentication before it is assigned to the 802.1X guest VLAN, you must also enable new MAC-triggered 802.1X guest VLAN assignment delay. For information about new MAC-triggered 802.1X guest VLAN assignment delay, see "Configuring 802.1X."

Restrictions and guidelines

To configure both 802.1X authentication and MAC authentication on a port, use one of the following methods:

- Enable the 802.1X and MAC authentication features separately on the port.
- Enable port security on the port. The port security mode must be **userlogin-secure-or-mac** or **userlogin-secure-or-mac-ext**.

  For information about port security mode configuration, see "Configuring port security."

For the parallel authentication feature to work correctly, do not enable MAC authentication delay on the port. This feature will delay MAC authentication after 802.1X authentication is triggered.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable parallel MAC authentication and 802.1X authentication on the port.
   mac-authentication parallel-with-dot1x
   By default, this feature is disabled.

Configuring RESTful server-assisted MAC authentication user recovery

About this task

RESTful server-assisted MAC authentication user recovery supports the following methods:

- **Automatic recovery**—The device automatically obtains MAC authentication user information and performs a reauthentication after the device or an interface module reboots or after an interface recovers from a failure. This feature recovers the online state of MAC authenticated users quickly without waiting for packets from the MAC authentication users to trigger a reauthentication. It is helpful when the network has a large number of dumb terminals or the operation of dumb terminals is important for services.
- **Manual recovery**—You trigger a recovery manually. Then, the device obtains MAC authentication user information from the RESTful server and performs reauthentication. This method is helpful when automatic recovery fails to recover the online state of all MAC authenticated users because of link flapping.

With this feature, you can configure a maximum of 16 profiles for MAC authentication user recovery. Each profile contains a set of parameters for accessing a RESTful server and the URI from which you obtain MAC authentication user information.

Restrictions and guidelines

To use this feature, you must use an IMC server to act as both authentication and RESTful servers.

This feature is mutually exclusive with the RADIUS accounting-on feature. Do not use the two features together. For more information about the RADIUS accounting-on feature, see "Configuring AAA."

To ensure that the MAC authentication user entries obtained from the RESTful server contain user IP addresses, configure the device to include user IP addresses in the MAC authentication requests sent to the authentication server. For more information about this feature, see "Including user IP addresses in MAC authentication requests."

Procedure

1. Enter system view.
   system-view
2. Configure a MAC authentication user-recovery profile:
   a. Create a profile for MAC authentication user recovery and enter its view.
      mac-authentication user-recovery-profile *profile-name*
   b. Configure the IP address and port number of the RESTful server.

server-address { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port-number*] [**vpn-instance** *vpn-instance-name*]

By default, no RESTful servers are configured.

c. Configure the username and password for accessing the RESTful server.

login-name *username* [**password** { **cipher** | **simple** } *string*]

By default, no username or password is configured for accessing the RESTful server.

d. Configure the NAS IP address used by the device to communicate with the RESTful server.

nas-ip { *ipv4-address* | **ipv6** *ipv6-address* }

By default, no NAS IP address is configured for the device to communicate with the RESTful server.

The NAS IP address must be the same as that configured in the authentication RADIUS scheme for the MAC authentication users.

e. Specify the URI for obtaining MAC authentication user information from the RESTful server.

uri *uri-string*

By default, no URIs are specified.

The URI can only be **imcrs/uam/online/notAgingMuteTerminal**. Other URIs cannot take effect.

3. Return to system view.

quit

4. Enable automatic MAC authentication user recovery.

mac-authentication auto-recover-user profile *profile-name*

By default, automatic MAC authentication user recovery is disabled.

5. Return to user view.

quit

6. (Optional.) Manually recover MAC authentication users.

mac-authentication recover-user profile *profile-name* [**interface** *interface-type interface-number*

Configuring Web proxy ports for URL redirection in MAC authentication

About this task

By default, the device redirects the HTTP or HTTPS requests from a MAC authenticated user to the authorized URL only if the requests are sent from a browser with Web proxy disabled. The device discards these requests if they are sent from a browser configured with a Web proxy.

To prevent the HTTP or HTTPS requests from being discarded, add the TCP port numbers of the Web proxy for HTTP and HTTPS to the device. These TCP port numbers are called Web proxy ports in this document.

Restrictions and guidelines

You can configure a maximum of 64 Web proxy ports for MAC authenticated users.

Specify different Web proxy port numbers for HTTP and HTTPS requests.

Adding or removing a Web proxy port will cause the device to log off all online MAC authenticated users that have been assigned an authorization redirect URL.

Procedure

1. Enter system view.
   system-view
2. Specify a Web proxy port used by MAC authentication users for HTTP or HTTPS.
   mac-authentication web-proxy { **http** | **https** } **port** *port-number*
   By default, no Web proxy ports are specified.

Logging off MAC authentication users

About this task

Perform this task to log off specified MAC authentication users and clear information about these users from the device. These users must perform MAC authentication to come online again.

Procedure

To log off MAC authentication users, execute the following command in user view:

reset mac-authentication access-user [**interface** *interface-type interface-number* | **mac** *mac-address* | **username** *username* | **vlan** *vlan-id*]

Enabling MAC authentication user logging

About this task

This feature enables the device to generate logs about MAC authentication users and send the logs to the information center. For the logs to be output correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

To prevent excessive MAC authentication user log entries, use this feature only if you need to analyze abnormal MAC authentication user logins or logouts.

Procedure

1. Enter system view.
   system-view
2. Enable MAC authentication user logging.
   mac-authentication access-user log enable [**failed-login** | **logoff** | **successful-login**] *
   By default, MAC authentication user logging is disabled.
   If you do not specify any parameters, this command enables all types of MAC authentication user logs.

Display and maintenance commands for MAC authentication

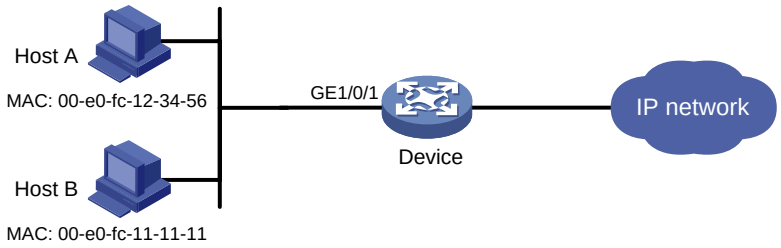
Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display MAC authentication information.	**display mac-authentication** [**interface**

Task	Command
	interface-type interface-number]
Display MAC authentication connections.	**display mac-authentication connection** [**open**] [**interface** *interface-type interface-number* | **slot** *slot-number* | **user-mac** *mac-address* | **user-name** *user-name*]
Display the MAC addresses of MAC authentication users in a type of MAC authentication VLAN.	**display mac-authentication mac-address** { **critical-vlan** | **guest-vlan** } [**interface** *interface-type interface-number*]
Clear MAC authentication statistics.	**reset mac-authentication statistics** [**interface** *interface-type interface-number*]
Remove users from the MAC authentication critical VLAN on a port.	**reset mac-authentication critical vlan interface** *interface-type interface-number* [**mac-address** *mac-address*]
Remove users from the MAC authentication critical voice VLAN on a port.	**reset mac-authentication critical-voice-vlan interface** *interface-type interface-number* [**mac-address** *mac-address*]
Remove users from the MAC authentication guest VLAN on a port.	**reset mac-authentication guest-vlan interface** *interface-type interface-number* [**mac-address** *mac-address*]

MAC authentication configuration examples

Example: Configuring local MAC authentication



Network configuration

As shown in Figure 4, the device performs local MAC authentication on GigabitEthernet 1/0/1 to control Internet access of users.

Configure the device to meet the following requirements:

- Detect whether a user has gone offline every 180 seconds.
- Deny a user for 180 seconds if the user fails MAC authentication.
- Authenticate all users in ISP domain **bbb**.
- Use the MAC address of each user as both the username and password for authentication. The MAC addresses are in hexadecimal notation with hyphens, and letters are in lower case.

Figure 4 Network diagram

Procedure

Add a network access local user. In this example, configure both the username and password as Host A's MAC address 08-00-27-12-34-56.

```
<Device> system-view
[Device] local-user 08-00-27-12-34-56 class network
[Device-luser-network-08-00-27-12-34-56] password simple 08-00-27-12-34-56
```

Specify the LAN access service for the user.

```
[Device-luser-network-08-00-27-12-34-56] service-type lan-access
[Device-luser-network-08-00-27-12-34-56] quit
```

Configure ISP domain **bbb** to perform local authentication for LAN users.

```
[Device] domain bbb
[Device-isp-bbb] authentication lan-access local
[Device-isp-bbb] quit
```

Enable MAC authentication on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] mac-authentication
[Device-GigabitEthernet1/0/1] quit
```

Specify ISP domain **bbb** as the MAC authentication domain.

```
[Device] mac-authentication domain bbb
```

Configure MAC authentication timers.

```
[Device] mac-authentication timer offline-detect 180
[Device] mac-authentication timer quiet 180
```

Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hexadecimal notation with hyphens, and letters are in lower case.

```
[Device] mac-authentication user-name-format mac-address with-hyphen lowercase
```

Enable MAC authentication globally.

```
[Device] mac-authentication
```

Verifying the configuration

Display MAC authentication settings and statistics to verify your configuration.

```
[Device] display mac-authentication
 Global MAC authentication parameters:
   MAC authentication                        : Enabled
   Authentication method                     : PAP
   User name format                        : MAC address in lowercase(xx-xx-xx-xx-xx-xx)
           Username                          : mac
           Password                          : Not configured
   Offline detect period                     : 180 s
```

```

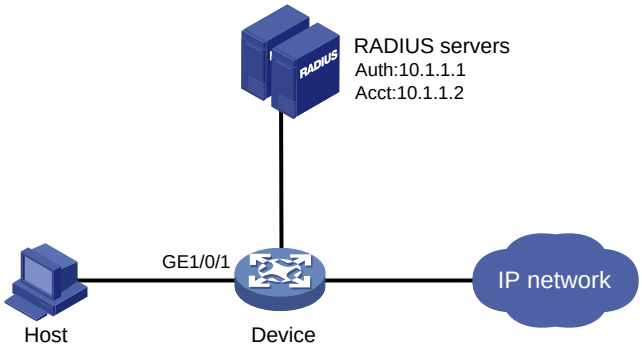
  Critical VLAN                   : Not configured
  Critical voice VLAN             : Disabled
  Host mode                       : Single VLAN
  Offline detection               : Enabled
  Authentication order            : Default
  User aging                      : Enabled
  Server-recovery online-user-sync : Enabled

  URL user logoff                 : No
  Auto-tag feature                : Disabled
  VLAN tag configuration ignoring  : Disabled
  Max online users                : 4294967295
  Authentication attempts         : successful 1, failed 0
  Current online users            : 1
         MAC address       Auth state
         0800-2712-3456    Authenticated
```

The output shows that Host A has passed MAC authentication and has come online. Host B failed MAC authentication and its MAC address is marked as a silent MAC address.

Example: Configuring RADIUS-based MAC authentication



Network configuration

As shown in Figure 5, the device uses RADIUS servers to perform authentication, authorization, and accounting for users. The RADIUS servers use the CHAP authentication method.

To control user access to the Internet by MAC authentication, perform the following tasks:

- Enable MAC authentication globally and on GigabitEthernet 1/0/1.
- Configure the device to use CHAP for MAC authentication.
- Configure the device to detect whether a user has gone offline every 180 seconds.
- Configure the device to deny a user for 180 seconds if the user fails MAC authentication.
- Configure all users to belong to ISP domain **bbb**.
- Use a shared user account for all users, with username **aaa** and password **123456**.

Figure 5 Network diagram

Procedure

Make sure the RADIUS servers and the access device can reach each other.

1. Configure the RADIUS servers to provide authentication, authorization, and accounting services. Create a shared account with username **aaa** and password **123456** for MAC authentication users. (Details not shown.)
2. Configure RADIUS-based MAC authentication on the device:

   # Configure a RADIUS scheme.

   ```

Example: Configuring ACL assignment for MAC authentication

Network configuration

As shown in Figure 6, configure the device to meet the following requirements:

- Use RADIUS servers to perform authentication, authorization, and accounting for users.
- Perform MAC authentication on GigabitEthernet 1/0/1 to control Internet access.
- Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hexadecimal notation with hyphens, and letters are in lower case.
- Use an ACL to deny authenticated users to access the FTP server at 10.0.0.1.

Figure 6 Network diagram

Procedure

Make sure the RADIUS servers and the access device can reach each other.

1. Configure the RADIUS servers:

   # Configure the RADIUS servers to provide authentication, authorization, and accounting services. (Details not shown.)

   # Add a user account with **08-00-27-12-34-56** as both the username and password on each RADIUS server. (Details not shown.)

   # Specify ACL 3000 as the authorization ACL for the user account. (Details not shown.)

2. Configure ACL 3000 to deny packets destined for 10.0.0.1 on the device.

```
<Device> system-view
```

```
[Device] acl advanced 3000
[Device-acl-ipv4-adv-3000] rule 0 deny ip destination 10.0.0.1 0
[Device-acl-ipv4-adv-3000] quit
```

3. Configure RADIUS-based MAC authentication on the device:

Configure a RADIUS scheme.

```
[Device] radius scheme 2000
[Device-radius-2000] primary authentication 10.1.1.1 1812
[Device-radius-2000] primary accounting 10.1.1.2 1813
[Device-radius-2000] key authentication simple abc
[Device-radius-2000] key accounting simple abc
[Device-radius-2000] user-name-format without-domain
[Device-radius-2000] quit
```

Apply the RADIUS scheme to an ISP domain for authentication, authorization, and accounting.

```
[Device] domain bbb
[Device-isp-bbb] authentication default radius-scheme 2000
[Device-isp-bbb] authorization default radius-scheme 2000
[Device-isp-bbb] accounting default radius-scheme 2000
[Device-isp-bbb] quit
```

Specify the ISP domain for MAC authentication.

```
[Device] mac-authentication domain bbb
```

Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hexadecimal notation with hyphens, and letters are in lower case.

```
[Device] mac-authentication user-name-format mac-address with-hyphen lowercase
```

Enable MAC authentication on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] mac-authentication
[Device-GigabitEthernet1/0/1] quit
```

Enable MAC authentication globally.

```
[Device] mac-authentication
```

Verifying the configuration

Verify the MAC authentication configuration.

```
[Device] display mac-authentication
 Global MAC authentication parameters:
   MAC authentication                        : Enable
   Authentication method                     : PAP
   Username format                       : MAC address in lowercase(xx-xx-xx-xx-xx-xx)
           Username                          : mac
           Password                          : Not configured
   Offline detect period                     : 300 s
   Quiet period                              : 60 s
   Server timeout                            : 100 s
   Reauth period                             : 3600 s
   User aging period for critical VLAN       : 1000 s
   User aging period for guest VLAN          : 1000 s
   Authentication domain                     : bbb
   HTTP proxy port list                      : Not configured
```

```
  HTTPS proxy port list                     : Not configured
 Online MAC-auth wired users                : 1

 Silent MAC users:
         MAC address       VLAN ID  From port               Port index

 GigabitEthernet1/0/1  is link-up
   MAC authentication               : Enabled
   Carry User-IP                    : Disabled
   Authentication domain            : Not configured
   Auth-delay timer                 : Disabled
   Periodic reauth                  : Disabled
   Re-auth server-unreachable       : Logoff
   Guest VLAN                       : Not configured
   Guest VLAN reauthentication      : Enabled
     Guest VLAN auth-period         : 30 s
   Critical VLAN                    : Not configured
   Critical voice VLAN              : Disabled
   Host mode                        : Single VLAN
   Offline detection                : Enabled
   Authentication order             : Default
   User aging                       : Enabled
   Server-recovery online-user-sync : Enabled

   URL user logoff                  : No
   Auto-tag feature                 : Disabled
   VLAN tag configuration ignoring  : Disabled
   Max online users                 : 4294967295
   Authentication attempts          : successful 1, failed 0
   Current online users             : 1
          MAC address       Auth state
          08-00-2712-3456    Authenticated
```

Verify that you cannot ping the FTP server from the host.

```
C:\>ping 10.0.0.1

Pinging 10.0.0.1 with 32 bytes of data:

Request timed out.
Request timed out.
Request timed out.
Request timed out.

Ping statistics for 10.0.0.1:
   Packets: Sent = 4, Received = 0, Lost = 4 (100% loss),
```

The output shows that ACL 3000 has been assigned to GigabitEthernet 1/0/1 to deny access to the FTP server.

Configuring portal authentication

About portal authentication

Portal authentication controls user access to networks. Portal authenticates a user by the username and password the user enters on a portal authentication page. Typically, portal authentication is deployed on the access layer and vital data entries.

In a portal-enabled network, users can actively initiate portal authentication by visiting the authentication website provided by the portal Web server. Or, they are redirected to the portal authentication page for authentication when they visit other websites.

The device supports Portal 1.0, Portal 2.0, and Portal 3.0.

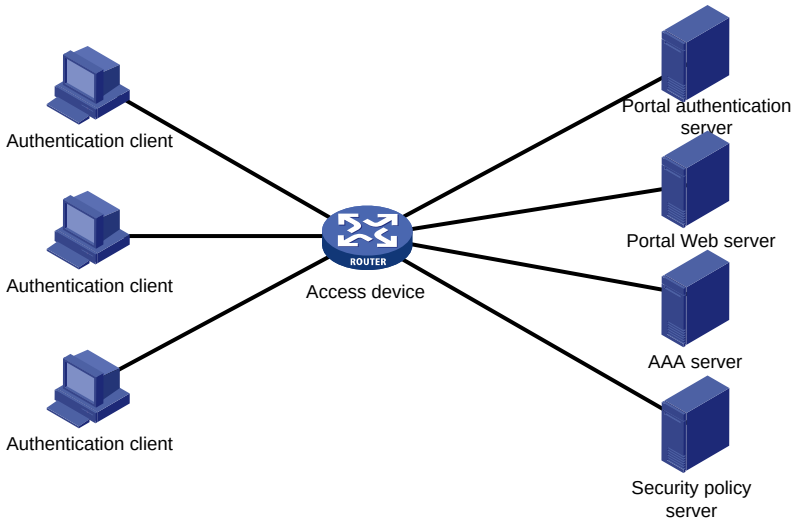
Advantages of portal authentication

Portal authentication has the following advantages:

- Allows users to perform authentication through a Web browser without installing client software.
- Provides ISPs with diversified management choices and extended functions. For example, the ISPs can place advertisements, provide community services, and publish information on the authentication page.
- Supports multiple authentication modes. For example, re-DHCP authentication implements a flexible address assignment scheme and saves public IP addresses. Cross-subnet authentication can authenticate users who reside in a different subnet than the access device.

Extended portal functions

By forcing patching and anti-virus policies, extended portal functions help hosts to defend against viruses. Portal supports the following extended functions:



- **Security check**—Detects after authentication whether or not a user host installs anti-virus software, virus definition file, unauthorized software, and operating system patches.
- **Resource access restriction**—Allows an authenticated user to access certain network resources such as the virus server and the patch server. Users can access more network resources after passing security check.

Security check must cooperate with the IMC security policy server and the iNode client.

Portal system

A typical portal system consists of these basic components: authentication client, access device, portal authentication server, portal Web server, AAA server, and security policy server.

Figure 1 Portal system

Authentication client

An authentication client is a Web browser that runs HTTP/HTTPS or a user host that runs a portal client. Security check for the user host is implemented through the interaction between the portal client and the security policy server. Only the iNode client is supported.

Access device

An access device provides access services. It has the following functions:

- Redirects all HTTP or HTTPS requests of unauthenticated users to the portal Web server.
- Interacts with the portal authentication server and the AAA server to complete authentication, authorization, and accounting.
- Allows users that pass portal authentication to access authorized network resources.

Portal server

A portal server collectively refers to a portal authentication server and portal Web server.

The portal Web server pushes the Web authentication page to authentication clients and forwards user authentication information (username and password) to the portal authentication server. The portal authentication server receives authentication requests from authentication clients and interacts with the access device to authenticate users. The portal Web server is typically integrated with the portal authentication server and it can also be an independent server.

AAA server

The AAA server interacts with the access device to implement authentication, authorization, accounting for portal users. In a portal system, a RADIUS server can perform authentication, authorization, accounting for portal users, and an LDAP server can perform authentication for portal users.

Security policy server

The security policy server interacts with the portal client and the access device for security check and authorization for users. Only hosts that run portal clients can interact with the security policy server.

Portal authentication using a remote portal server

The components of a portal system interact as follows:

1. An unauthenticated user initiates authentication by accessing an Internet website through a Web browser. When receiving the HTTP or HTTPS request, the access device redirects it to the

Web authentication page provided by the portal Web server. The user can also visit the authentication website to log in. The user must log in through the iNode client for extended portal functions.

2. The user enters the authentication information on the authentication page/dialog box and submits the information. The portal Web server forwards the information to the portal authentication server. The portal authentication server processes the information and forwards it to the access device.
3. The access device interacts with the AAA server to implement authentication, authorization, accounting for the user.
4. If security policies are not imposed on the user, the access device allows the authenticated user to access networks.

   If security policies are imposed on the user, the portal client, the access device, and the security policy server interact to check the user host. If the user passes the security check, the security policy server authorizes the user to access resources based on the check result.

Local portal service

System components

As shown in Figure 2, a local portal system consists of an authentication client, access device, and AAA server. The access device acts as both the portal Web server and the portal authentication server to provide the local portal Web service for the authentication client. The authentication client can only be a Web browser, and it cannot be a user host that runs a portal client. Therefore, extended portal functions are not supported and no security policy server is required.

Figure 2 System components

Portal page customization

The portal system pushes different authentication pages to portal users at different stages. The local portal service supports portal page customization. You can customize one or more sets of authentication pages, compress each set of authentication pages to a .zip file, and upload the compressed files to the storage medium of the device.

For more information about authentication page customization, see "Customizing authentication pages."

Portal authentication modes

Portal authentication has three modes: direct authentication, re-DHCP authentication, and cross-subnet authentication. In direct authentication and re-DHCP authentication, no Layer 3 forwarding devices exist between the authentication client and the access device. In cross-subnet authentication, Layer 3 forwarding devices can exist between the authentication client and the access device.

Direct authentication

A user manually configures a public IP address or obtains a public IP address through DHCP. Before authentication, the user can access only the portal Web server and predefined authentication-free websites. After passing authentication, the user can access other network resources. The process of direct authentication is simpler than that of re-DHCP authentication.

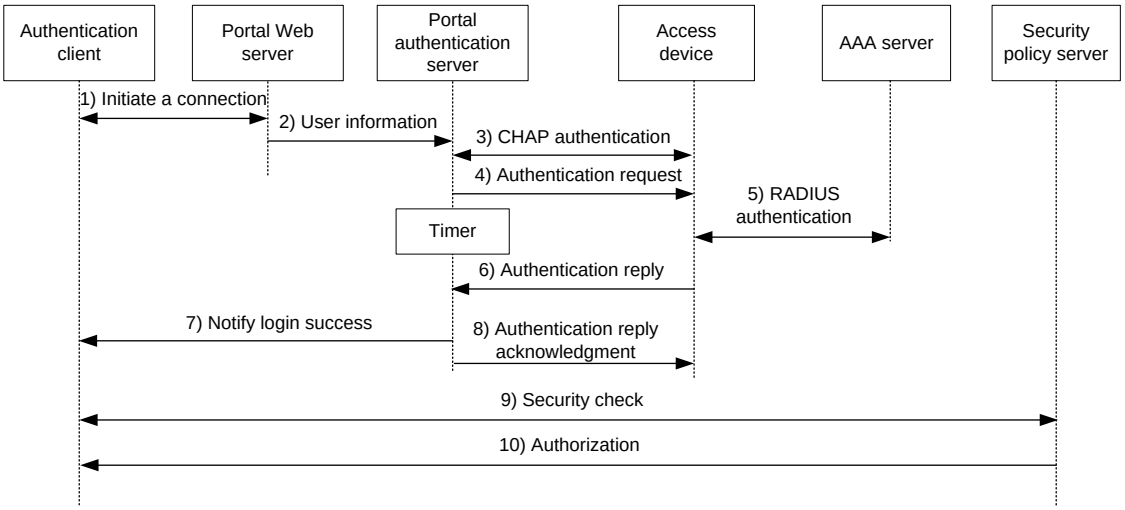
Re-DHCP authentication

Before a user passes authentication, DHCP allocates an IP address (a private IP address) to the user. The user can access only the portal Web server and predefined authentication-free websites. After the user passes authentication, DHCP reallocates an IP address (a public IP address) to the user. The user then can access other network resources. No public IP address is allocated to users who fail authentication. Re-DHCP authentication saves public IP addresses. For example, an ISP can allocate public IP addresses to broadband users only when they access networks beyond the residential community network.

Only the iNode client supports re-DHCP authentication. IPv6 portal authentication does not support the re-DHCP authentication mode.

Cross-subnet authentication

Cross-subnet authentication is similar to direct authentication, except it allows Layer 3 forwarding devices to exist between the authentication client and the access device.



In direct authentication, re-DHCP authentication, and cross-subnet authentication, a user's IP address uniquely identifies the user. After a user passes authentication, the access device generates an ACL for the user based on the user's IP address to control forwarding of the packets from the user. Because no Layer 3 forwarding device exists between authentication clients and the access device in direct authentication and re-DHCP authentication, the access device can learn the user MAC addresses. The access device can enhance its capability of controlling packet forwarding by using the learned MAC addresses.

Portal authentication process

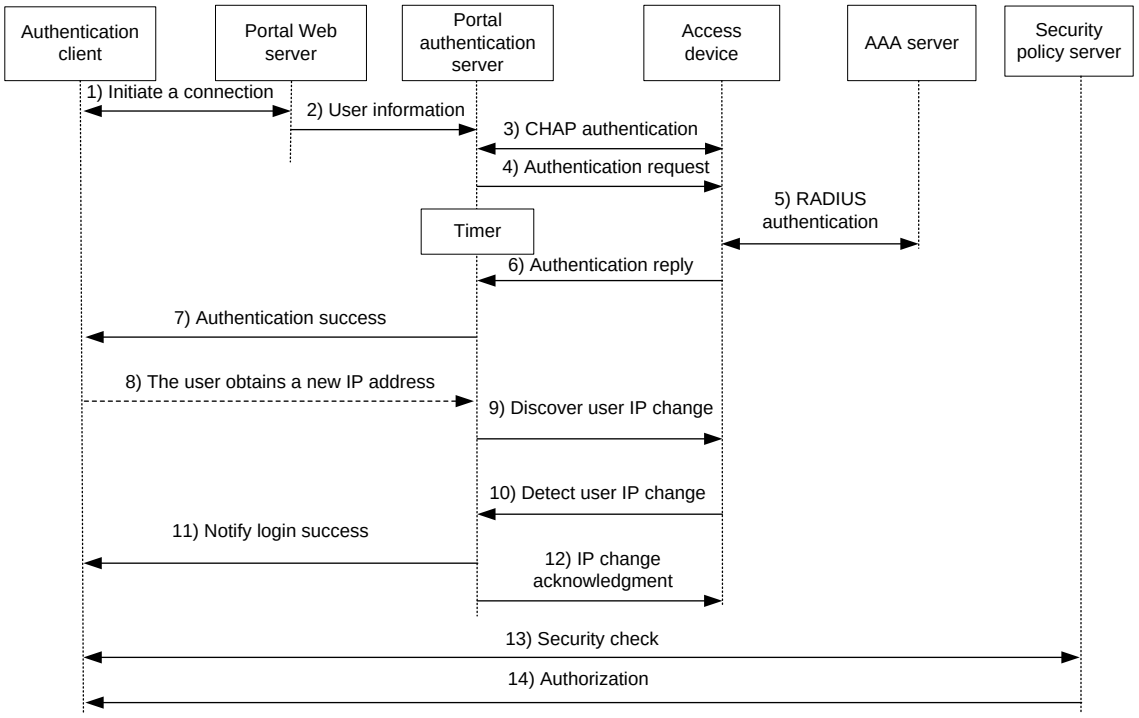
Direct authentication and cross-subnet authentication share the same authentication process. Re-DHCP authentication has a different process as it has two address allocation procedures.

Direct authentication/cross-subnet authentication process (with CHAP/PAP authentication)

Figure 3 Direct authentication/cross-subnet authentication process

The direct/cross-subnet authentication process is as follows:

1. A portal user access the Internet through HTTP or HTTPS, and the HTTP or HTTPS packet arrives at the access device.
   - If the packet matches a portal free rule, the access device allows the packet to pass.
   - If the packet does not match any portal-free rule, the access device redirects the packet to the portal Web server. The portal Web server pushes the Web authentication page to the user for him to enter his username and password.



2. The portal Web server submits the user authentication information to the portal authentication server.
3. The portal authentication server and the access device exchange CHAP messages. This step is skipped for PAP authentication. The portal authentication server decides the method (CHAP or PAP) to use.
4. The portal authentication server adds the username and password into an authentication request packet and sends it to the access device. Meanwhile, the portal authentication server starts a timer to wait for an authentication reply packet.
5. The access device and the RADIUS server exchange RADIUS packets.
6. The access device sends an authentication reply packet to the portal authentication server to notify authentication success or failure.
7. The portal authentication server sends an authentication success or failure packet to the client.
8. If the authentication is successful, the portal authentication server sends an authentication reply acknowledgment packet to the access device.

If the client is an iNode client, the authentication process includes step 9 and step 10 for extended portal functions. Otherwise the authentication process is complete.

9. The client and the security policy server exchange security check information. The security policy server detects whether or not the user host installs anti-virus software, virus definition files, unauthorized software, and operating system patches.
10. The security policy server authorizes the user to access certain network resources based on the check result. The access device saves the authorization information and uses it to control access of the user.

Re-DHCP authentication process (with CHAP/PAP authentication)

Figure 4 Re-DHCP authentication process

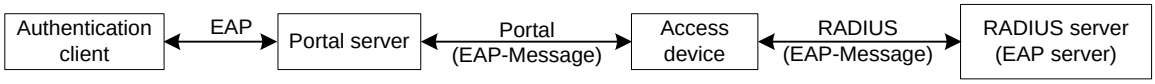
The re-DHCP authentication process is as follows:

Step 1 through step 7 are the same as those in the direct authentication/cross-subnet authentication process.

8. After receiving the authentication success packet, the client obtains a public IP address through DHCP. The client then notifies the portal authentication server that it has a public IP address.
9. The portal authentication server notifies the access device that the client has obtained a public IP address.
10. The access device detects the IP change of the client through DHCP and then notifies the portal authentication server that it has detected an IP change of the client IP.
11. After receiving the IP change notification packets sent by the client and the access device, the portal authentication server notifies the client of login success.
12. The portal authentication server sends an IP change acknowledgment packet to the access device.

Step 13 and step 14 are for extended portal functions.

13. The client and the security policy server exchanges security check information. The security policy server detects whether or not the user host installs anti-virus software, virus definition files, unauthorized software, and operating system patches.
14. The security policy server authorizes the user to access certain network resources based on the check result. The access device saves the authorization information and uses it to control access of the user.



Portal support for EAP

To use portal authentication that supports EAP, the portal authentication server and client must be the IMC portal server and the iNode portal client. Local portal authentication does not support EAP authentication.

Compared with username and password based authentication, digital certificate-based authentication ensures higher security.

The Extensible Authentication Protocol (EAP) supports several digital certificate-based authentication methods, for example, EAP-TLS. Working together with EAP, portal authentication can implement digital certificate-based user authentication.

Figure 5 Portal support for EAP working flow diagram

As shown in Figure 5, the authentication client and the portal authentication server exchange EAP authentication packets. The portal authentication server and the access device exchange portal authentication packets that carry the EAP-Message attributes. The access device and the RADIUS server exchange RADIUS packets that carry the EAP-Message attributes. The RADIUS server that supports the EAP server function processes the EAP packets encapsulated in the EAP-Message attributes, and provides the EAP authentication result.

The access device does not process but only transports EAP-Message attributes between the portal authentication server and the RADIUS server. Therefore, the access device requires no additional configuration to support EAP authentication.

Portal filtering rules

The access device uses portal filtering rules to control user traffic forwarding.

Based on the configuration and authentication status of portal users, the device generates the following categories of portal filtering rules:

- **Category 1**—The rule permits user packets that are destined for the portal Web server and packets that match the portal-free rules to pass through.

- **Category 2**—For an authenticated user with no ACL authorized, the rule allows the user to access any destination network resources. For an authenticated user with an ACL authorized, the rule allows users to access resources permitted by the ACL. The device adds the rule when a user comes online and deletes the rule when the user goes offline.

  The device supports the following types of authorization ACLs:

  - Basic ACLs (ACL 2000 to ACL 2999).
  - Advanced ACLs (ACL 3000 to ACL 3999).
  - Layer 2 ACLs (ACL 4000 to ACL 4999).

  For an authorization ACL to take effect, make sure the ACL exists and has ACL rules. Configuring the ACL rules with the **`established`**, **`fragment`**, **`source-mac`**, or **`source-ip`** keyword will cause users to be offline.
- **Category 3**—The rule redirects all HTTP or HTTPS requests from unauthenticated users to the portal Web server.
- **Category 4**—For direct authentication and cross-subnet authentication, the rule forbids any user packets to pass through. For re-DHCP authentication, the device forbids user packets with private source addresses to pass.

After receiving a user packet, the device compares the packet against the filtering rules from category 1 to category 4. Once the packet matches a rule, the matching process completes.

Restrictions and guidelines: Portal configuration

Portal authentication through Web does not support security check for users. To implement security check, the client must be the iNode client.

Portal authentication supports NAT traversal whether it is initiated by a Web client or an iNode client. NAT traversal must be configured when the portal client is on a private network and the portal server is on a public network.

If the portal clients and the portal server belong to different VPNs, the Rule ARP entry feature will cause the portal clients to go offline abnormally. To avoid this issue, execute the **`undo portal refresh arp enable`** command to disable the Rule ARP entry feature for portal clients.

IPv6 portal authentication is not supported.

Portal authentication tasks at a glance

To configure portal authentication, perform the following tasks:

1. Configuring a remote portal service

   Perform this task if the access device does not act as a portal authentication server or portal Web server.

   - Configuring a remote portal authentication server
   - Configuring a portal Web server
2. Configuring a local portal service

   Perform this task if the access device acts as a portal authentication server and portal Web server.

   - Configuring local portal service features
   - Configuring a portal Web server
3. Enabling portal authentication and specifying a portal Web server
   - Enabling portal authentication on an interface
   - Specifying a portal Web server on an interface

4. (Optional.) Specifying a preauthentication IP address pool
5. (Optional.) Specifying a portal authentication domain
6. (Optional.) Controlling portal user access
   - Configuring a portal-free rule
   - Configuring an authentication source subnet
   - Configuring an authentication destination subnet
   - Configuring support of Web proxy for portal authentication
   - Checking the issuing of category-2 portal filtering rules
   - Setting the maximum number of portal users
   - Enabling strict-checking on portal authorization information
   - Allowing only users with DHCP-assigned IP addresses to pass portal authentication
   - Enabling portal roaming
   - Configuring the portal fail-permit feature
7. (Optional.) Configuring portal detection features
   - Configuring online detection of portal users
   - Configuring portal authentication server detection
   - Configuring portal Web server detection
   - Configuring portal user synchronization
8. (Optional.) Configuring attributes for portal packets and RADIUS packets
   - Configuring portal packet attributes

     You can configure the BAS-IP or BAS-IPv6 attribute for portal packets and specify the device ID.
   - Configuring attributes for RADIUS packets

     You can configure the NAS-Port-Id and NAS-Port-Type attributes and apply a NAS-ID profile to an interface.
9. (Optional.) Configuring online and offline related features for portal users
   - Logging out online portal users
   - Enabling portal user login/logout logging
10. (Optional.) Configuring extended portal authentication features
    - Disabling the Rule ARP or ND entry feature for portal clients
    - Configuring Web redirect
11. Obtaining user access information from ARP or ND entries

    This task is required in a remote Web authentication network.

Prerequisites for portal authentication

The portal feature provides a solution for user identity authentication and security check. To complete user identity authentication, portal must cooperate with RADIUS.

Before you configure portal, you must complete the following tasks:

- The portal authentication server, portal Web server, and RADIUS server have been installed and configured correctly.
- To use the re-DHCP portal authentication mode, make sure the DHCP relay agent is enabled on the access device, and the DHCP server is installed and configured correctly.
- The portal client, access device, and servers can reach each other.

- To use the remote RADIUS server, configure usernames and passwords on the RADIUS server, and configure the RADIUS client on the access device. For information about RADIUS client configuration, see "Configuring AAA."
- To implement extended portal functions, install and configure IMC EAD. Make sure the ACLs configured on the access device correspond to the isolation ACL and the security ACL on the security policy server. For installation and configuration about the security policy server, see *IMC EAD Security Policy Help*.

Configuring a remote portal authentication server

About this task

With portal authentication enabled, the device searches for a portal authentication server for a received portal request packet according to the source IP address and VPN information of the packet.

- If a matching portal authentication server is found, the device regards the packet valid and sends an authentication response packet to the portal authentication server. After a user logs in to the device, the user interacts with the portal authentication server as needed.
- If no matching portal authentication server is found, the device drops the packet.

Restrictions and guidelines

Do not delete a portal authentication server in use. Otherwise, users authenticated by that server cannot log out correctly.

Procedure

1. Enter system view.

   system-view

2. Create a portal authentication server and enter its view.

   portal server *server-name*

   You can create multiple portal authentication servers.

3. Specify the IP address of the portal authentication server.

   IPv4:

   ip *ipv4-address* [**vpn-instance** *vpn-instance-name*] [**key** { **cipher** | **simple** } *string*]

   IPv6:

   ipv6 *ipv6-address* [**vpn-instance** *vpn-instance-name*] [**key** { **cipher** | **simple** } *string*]

4. (Optional.) Set the destination UDP port number used by the device to send unsolicited portal packets to the portal authentication server.

   port *port-number*

   By default, the UDP port number is 50100.

   This port number must be the same as the listening port number specified on the portal authentication server.

5. (Optional.) Specify the portal authentication server type.

   server-type { **cmcc** | **imc** }

   By default, the portal authentication server type is IMC.

   The specified server type must be the same as the type of the portal authentication server actually used.

6. (Optional.) Configure the device to periodically register with the portal authentication server.

   server-register [**interval** *interval-value*]

By default, the device does not register with a portal authentication server.

Configuring a portal Web server

Portal Web server tasks at a glance

To configure a portal Web server, perform the following tasks:

1. Configure basic parameters for a portal Web server
2. (Optional.) Enabling the captive-bypass feature
3. (Optional.) Configuring a match rule for URL redirection

Configure basic parameters for a portal Web server

1. Enter system view.
   system-view
2. Create a portal Web server and enter its view.
   portal web-server *server-name*
   You can create multiple portal Web servers.
3. Specify the VPN instance to which the portal Web server belongs.
   vpn-instance *vpn-instance-name*
   By default, the portal Web server belongs to the public network.
4. Specify the URL of the portal Web server.
   url *url-string*
   By default, no URL is specified for a portal Web server.
5. Configure the parameters to be carried in the URL when the device redirects it to users.
   url-parameter *param-name* { **nas-id** | **nas-port-id** | **original-url** | **source-address** | **source-mac** [**encryption** { **aes** | **des** } **key** { **cipher** | **simple** } *string*] | **value** *expression* }
   Only the S5570S-EI series switches support the **nas-id** and **nas-port-id** keywords.
   By default, no redirection URL parameters are configured.
6. (Optional.) Specify the portal Web server type.
   server-type { **cmcc** | **imc** }
   By default, the portal Web server type is IMC.
   This configuration is applicable to only to the remote portal service.
   The specified server type must be the same as the type of the portal Web server actually used.

Enabling the captive-bypass feature

About this task

By default, the device automatically pushes the portal authentication page to iOS devices and some Android devices when they are connected to the network. The captive-bypass feature enables the device to push the portal authentication page to iOS devices and some Android devices only when they access the Internet by using browsers.

Procedure

1. Enter system view.

system-view

2. Enter portal Web server view.
   portal web-server *server-name*
3. Enable the captive-pass feature.
   captive-bypass enable
   By default, the captive-bypass feature is disabled.

Configuring a match rule for URL redirection

About this task

A URL redirection match rule matches HTTP or HTTPS requests by user-requested URL or User-Agent information, and redirects the matching requests to the specified redirection URL. Therefore, URL redirection match rules allow for more flexible URL redirection than the **url** command. The **url** command is only used to redirect HTTP or HTTPS requests from unauthenticated users to the portal Web server for authentication.

Restrictions and guidelines

For a user to successfully access a redirection URL, configure a portal-free rule to allow HTTP or HTTPS requests destined for the redirection URL to pass. For information about configuring portal-free rules, see the **portal free-rule** command.

If both the **url** and **if-match** commands are executed, the **if-match** command takes priority to perform URL redirection.

Procedure

1. Enter system view.
   system-view
2. Enter portal Web server view.
   portal web-server *server-name*
3. Configure a match rule for URL redirection.
   if-match { **original-url** *url-string* **redirect-url** *url-string* [**url-param-encryption** { **aes** | **des** } **key** { **cipher** | **simple** } *string*] | **user-agent** *string* **redirect-url** *url-string* }

Configuring local portal service features

About the local portal service

After a local portal service is configured, the device acts as the portal Web server and portal authentication server to perform portal authentication on users. The portal authentication page file is saved in the root directory of the device.

Restrictions and guidelines for configuring local portal service features

For an interface to use the local portal service, the URL of the portal Web server specified for the interface must meet the following requirements:

- The IP address in the URL must be the IP address of a Layer 3 interface (except 127.0.0.1) on the device, and the IP address must be reachable to portal clients.

- The URL must be ended with **/portal/**. For example: **http://1.1.1.1/portal/**.

The device provides a default authentication page file. To use customized authentication pages, you must edit the authentication pages, compress them to a file, and then upload the file to the device. On the device, specify the file as the default authentication page file.

Customizing authentication pages

About this task

Authentication pages are HTML files. Local portal authentication requires the following authentication pages:

- Logon page
- Logon success page
- Logon failure page
- Online page
- System busy page
- Logoff success page

You must customize the authentication pages, including the page elements that the authentication pages will use, for example, **back.jpg** for authentication page **Logon.htm**.

Follow the authentication page customization rules when you edit the authentication page files.

File name rules

The names of the main authentication page files are fixed (see Table 1). You can define the names of the files other than the main authentication page files. File names and directory names are case insensitive.

Table 1 Main authentication page file names

Main authentication page	File name
Logon page	logon.htm
Logon success page	logonSuccess.htm
Logon failure page	logonFail.htm
Online page Pushed after the user gets online for online notification	online.htm
System busy page Pushed when the system is busy or the user is in the logon process	busy.htm
Logoff success page	logoffSuccess.htm

Page request rules

The local portal Web server supports only Get and Post requests.

- **Get requests**—Used to get the static files in the authentication pages and allow no recursion. For example, if file **Logon.htm** includes contents that perform Get action on file **ca.htm**, file **ca.htm** cannot include any reference to file **Logon.htm**.
- **Post requests**—Used when users submit username and password pairs, log in, and log out.

Post request attribute rules

1. Observe the following requirements when editing a form of an authentication page:

- An authentication page can have multiple forms, but there must be one and only one form whose action is **logon.cgi**. Otherwise, user information cannot be sent to the access device.
- The username attribute is fixed as **PtUser**. The password attribute is fixed as **PtPwd**.
- The value of the **PtButton** attribute is either **Logon** or **Logoff**, which indicates the action that the user requests.
- A logon Post request must contain **PtUser**, **PtPwd**, and **PtButton** attributes.
- A logoff Post request must contain the **PtButton** attribute.

2. Authentication pages **logon.htm** and **logonFail.htm** must contain the logon Post request.

The following example shows part of the script in page **logon.htm**.

```
<form action=logon.cgi method = post >
<p>User name:<input type="text" name = "PtUser" style="width:160px;height:22px"
maxlength=64>
<p>Password :<input type="password" name = "PtPwd" style="width:160px;height:22px"
maxlength=32>
<p><input type=SUBMIT value="Logon" name = "PtButton" style="width:60px;"
onclick="form.action=form.action+location.search;">
</form>
```

3. Authentication pages **logonSuccess.htm** and **online.htm** must contain the logoff Post request.

The following example shows part of the script in page **online.htm**.

```
<form action=logon.cgi method = post >
<p><input type=SUBMIT value="Logoff" name="PtButton" style="width:60px;">
</form>
```

Page file compression and saving rules

You must compress the authentication pages and their page elements into a standard zip file.

- The name of a zip file can contain only letters, numbers, and underscores.
- The authentication pages must be placed in the root directory of the zip file.
- Zip files can be transferred to the device through FTP or TFTP and must be saved in the root directory of the device.

  Examples of zip files on the device:

```
<Sysname> dir
Directory of flash:
   1     -rw-      1405  Feb 28 2008 15:53:20   ssid1.zip
   0     -rw-      1405  Feb 28 2008 15:53:31   ssid2.zip
   2     -rw-      1405  Feb 28 2008 15:53:39   ssid3.zip
   3     -rw-      1405  Feb 28 2008 15:53:44   ssid4.zip
2540 KB total (1319 KB free)
```

Redirecting authenticated users to a specific webpage

To make the device automatically redirect authenticated users to a specific webpage, do the following in logon.htm and logonSuccess.htm:

1. In logon.htm, set the target attribute of Form to _**blank**.

See the contents in gray:

```
<form method=post action=logon.cgi target="_blank">
```

2. Add the function for page loading pt_init() to LogonSuccess.htm.

See the contents in gray:

```
<html>
```

```
    <head>
    <title>LogonSuccess</title>
    <script type="text/javascript" language="javascript"
src="pt_private.js"></script>
    </head>
    <body onload="pt_init();" onbeforeunload="return pt_unload();">
    ... ...
    </body>
</html>
```

Configuring a local portal Web service

Prerequisites

Before you configure an HTTPS-based local portal Web service, you must complete the following tasks:

- Configure a PKI policy, obtain the CA certificate, and request a local certificate. For more information, see "Configuring PKI."
- Configure an SSL server policy, and specify the PKI domain configured in the PKI policy.

  During SSL connection establishment, the user browser might display a message that it cannot verify server identity by certificate. For users to perform portal authentication without checking such a message, configure an SSL server policy to request a client-trusted certificate on the device. The name of the policy must be **https_redirect**. For more information about SSL server policy configuration, see "Configuring SSL."

Procedure

1. Enter system view.

   system-view
2. Enable HTTP- or HTTPS-based local portal Web service and enter its view.

   portal local-web-server { **http** | **https ssl-server-policy** *policy-name* [**tcp-port** *port-number*] }
3. Specify the default authentication page file for the local portal Web service.

   default-logon-page *filename*

   By default, the default authentication page file for a local portal Web service is file **defaultfile.zip**.
4. (Optional.) Configure the HTTP or HTTPS listening TCP port for the local portal Web service.

   tcp-port *port-number*

   By default, the HTTP service listening port number is 80 and the HTTPS service listening port number is the TCP port number set by the **portal local-web-server** command.

Enabling portal authentication on an interface

Restrictions and guidelines

When you enable portal authentication on an interface, follow these restrictions and guidelines:

- Cross-subnet authentication mode (**layer3**) does not require Layer 3 forwarding devices between the access device and the portal authentication clients. However, if a Layer 3 forwarding device exists between the authentication client and the access device, you must use the cross-subnet portal authentication mode.
- You can enable both IPv4 portal authentication and IPv6 portal authentication on an interface.

When you configure re-DHCP portal authentication on an interface, follow these restrictions and guidelines:

- Make sure the interface has a valid IP address before you enable re-DHCP portal authentication on the interface.
- With re-DHCP portal authentication, configure authorized ARP on the interface as a best practice to make sure only valid users can access the network. With authorized ARP configured on the interface, the interface learns ARP entries only from the users who have obtained a public address from DHCP.
- For successful re-DHCP portal authentication, make sure the BAS-IP or BAS-IPv6 attribute value is the same as the device IP address specified on the portal authentication server. To configure the attribute, use the **portal** { **bas-ip** | **bas-ipv6** } command.
- An IPv6 portal server does not support re-DHCP portal authentication.

Portal authentication supports both HTTP redirect and HTTPS redirect. The default HTTPS redirect listening port number on the device is 6654. To change the HTTPS redirect listening port number, see HTTP redirect configuration in *Layer 3—IP Services Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Enter Layer 3 interface view.

   interface *interface-type interface-number*
3. Enable portal authentication.

   IPv4:

   portal enable method { **direct** | **layer3** | **redhcp** }

   IPv6:

   portal ipv6 enable method { **direct** | **layer3** }

   By default, portal authentication is disabled.

Specifying a portal Web server on an interface

About this task

With a portal Web server specified on an interface, the device redirects the HTTP requests of portal users on the interface to the portal Web server.

You can specify both an IPv4 portal Web server and an IPv6 portal Web server on an interface.

Procedure

1. Enter system view.

   system-view
2. Enter Layer 3 interface view.

   interface *interface-type interface-number*
3. Specify a portal Web server on the interface.

   portal [**ipv6**] **apply web-server** *server-name* [**fail-permit**]

   By default, no portal Web servers are specified on an interface.

Specifying a preauthentication IP address pool

About this task

You must specify a preauthentication IP address pool on a portal-enabled interface in the following situation:

- Portal users access the network through a subinterface of the portal-enabled interface.
- The subinterface does not have an IP address.
- Portal users need to obtain IP addresses through DHCP.

After a user connects to a portal-enabled interface, the user uses an IP address for portal authentication according to the following rules:

- If the interface is configured with a preauthentication IP address pool, the user uses the following IP address:
  - If the client is configured to obtain an IP address automatically through DHCP, the user obtains an address from the specified IP address pool.
  - If the client is configured with a static IP address, the user uses the static IP address.
- If the interface has an IP address but no preauthentication IP pool specified, the user uses the static IP address or the IP address obtained from a DHCP server.
- If the interface has no IP address or preauthentication IP pool specified, the user cannot perform portal authentication.

After the user passes portal authentication, the AAA server authorizes an IP address pool for re-assigning an IP address to the user. If no authorized IP address pool is deployed, the user continues using the previous IP address.

Restrictions and guidelines

This configuration takes effect only when the direct IPv4 portal authentication is enabled on the interface.

Make sure the specified IP address pool exists and is complete. Otherwise, the user cannot obtain the IP address and cannot perform portal authentication.

If the portal user does not perform authentication or fails to pass authentication, the assigned IP address is still retained.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Specify a preauthentication IP address pool on the interface.
   portal [**ipv6**] **pre-auth ip-pool** *pool-name*
   By default, no preauthentication IP address pool is specified on an interface.

Specifying a portal authentication domain

About portal authentication domains

An authentication domain defines a set of authentication, authorization, and accounting policies. Each portal user belongs to an authentication domain and is authenticated, authorized, and accounted in the domain.

With an authentication domain specified on an interface, the device uses the authentication domain for AAA of portal users. This allows for flexible portal access control.

Restrictions and guidelines for specifying a portal authentication domain

The device selects the authentication domain for a portal user in this order:

1. ISP domain specified for the interface.
2. ISP domain carried in the username.
3. System default ISP domain.

If the chosen domain does not exist on the device, the device searches for the ISP domain configured to accommodate users assigned to nonexistent domains. If no such ISP domain is configured, user authentication fails. For information about ISP domains, see "Configuring AAA."

For the authorization ACL in the authentication domain, the following rules apply:

- If the user traffic matches a rule in the ACL, the device processes the traffic based on the permit or deny statement of the rule.
- If the user traffic does not match any rule in the ACL, the device permits the traffic. To deny such traffic, configure the last rule in the ACL to deny all packets by using the **rule deny ip** command.
- If the ACL contains rules that specify a source address, users might not be able to get online. Do not specify a source IPv4, IPv6, or MAC address when you configure a rule in the ACL.

Specifying a portal authentication domain on an interface

1. Enter system view.

   system-view
2. Enter Layer 3 interface view.

   interface *interface-type interface-number*
3. Specify an portal authentication domain on the interface.

   portal [**ipv6**] **domain** *domain-name*

   By default, no portal authentication domain is specified on an interface.

   You can specify both an IPv4 portal authentication domain and an IPv6 portal authentication domain on an interface.

Controlling portal user access

Configuring a portal-free rule

About this task

A portal-free rule allows specified users to access specified external websites without portal authentication.

The matching items for a portal-free rule include the host name, source/destination IP address, TCP/UDP port number, source MAC address, access interface, and VLAN. Packets matching a portal-free rule will not trigger portal authentication, so users sending the packets can directly access the specified external websites.

Restrictions and guidelines for configuring a portal-free rule

If you specify both a VLAN and an interface, the interface must belong to the VLAN. If the interface does not belong to the VLAN, the portal-free rule does not take effect.

You cannot configure two or more portal-free rules with the same filtering criteria. Otherwise, the system prompts that the rule already exists.

Regardless of whether portal authentication is enabled or not, you can only add or remove a portal-free rule. You cannot modify it.

Configuring an IP-based portal-free rule

1. Enter system view.

   system-view

2. Configure an IP-based portal-free rule.

   IPv4:

   portal free-rule *rule-number* { **destination ip** { *ipv4-address* { *mask-length* | *mask* } | **any** } [**tcp** *tcp-port-numbe*r | **udp** *udp-port-number*] | **source ip** { *ipv4-address* { *mask-length* | *mask* } | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] } * [**interface** *interface-type interface-number*]

   IPv6:

   portal free-rule *rule-number* { **destination ipv6** { *ipv6-address prefix-length* | **any** } [**tcp** *tcp-port-numbe*r | **udp** *udp-port-number*] | **source ipv6** { *ipv6-address prefix-length* | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] } * [**interface** *interface-type interface-number*]

Configuring a source-based portal-free rule

1. Enter system view.

   system-view

2. Configure a source-based portal-free rule.

   portal free-rule *rule-number* **source** { **interface** *interface-type interface-number* | **mac** *mac-address* | **vlan** *vlan-id* } *

   The **vlan** *vlan-id* option takes effect only on portal users that access the network through VLAN interfaces.

Configuring a destination-based portal-free rule

1. Enter system view.

   system-view

2. Configure a destination-based portal-free rule.

   portal free-rule *rule-number* **destination** *host-name*

   Before you configure destination-based portal-free rules, make sure a DNS server is deployed on the network.

Configuring an authentication source subnet

About this task

By configuring authentication source subnets, you specify that only HTTP or HTTPS packets from users on the authentication source subnets can trigger portal authentication. HTTP or HTTPS packets from users not in authentication source subnets will be discarded if the packets do not match any portal-free rules.

Restrictions and guidelines

Authentication source subnets are used only for cross-subnet authentication.

In direct or re-DHCP portal authentication mode, a portal user and its access interface (portal-enabled) are on the same subnet. It is not necessary to specify the subnet as the authentication source subnet.

- In direct mode, the access device regards the authentication source subnet as any source IP address.
- In re-DHCP mode, the access device regards the authentication source subnet on an interface as the subnet to which the private IP address of the interface belongs.

If both authentication source subnets and destination subnets are configured on an interface, only the authentication destination subnets take effect.

You can configure multiple authentication source subnets. If the source subnets overlap, the subnet with the largest address scope (with the smallest mask or prefix) takes effect.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Configure a portal authentication source subnet.

   IPv4:

   portal layer3 source *ipv4-network-address* { *mask-length* | *mask* }

   IPv6:

   portal ipv6 layer3 source *ipv6-network-address prefix-length*.

   By default, no portal authentication source subnets are configured, and users from any subnets can trigger portal authentication.

Configuring an authentication destination subnet

About this task

After authentication destination subnets are configured, the device performs portal authentication on portal users only when they access the specified subnets (excluding the destination IP addresses and subnets specified in portal-free rules). Users can access other subnets without portal authentication.

Restrictions and guidelines

If both authentication source subnets and destination subnets are configured on an interface, only the authentication destination subnets take effect.

You can configure multiple authentication destination subnets. If the destination subnets overlap, the subnet with the largest address scope (with the smallest mask or prefix) takes effect.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Configure a portal authentication destination subnet.

   IPv4:

portal free-all except destination *ipv4-network-address* { *mask-length* | *mask* }

IPv6:

portal ipv6 free-all except destination *ipv6-network-address prefix-length*

By default, no authentication destination subnets are configured, and users accessing any subnets must pass portal authentication.

Configuring support of Web proxy for portal authentication

About this task

To allow HTTP requests proxied by a Web proxy server to trigger portal authentication, specify the port number of the Web proxy server on the device. If a Web proxy server port is not specified on the device, HTTP requests proxied by the Web proxy server are dropped, and portal authentication cannot be triggered.

Restrictions and guidelines

If a user's browser uses the Web Proxy Auto-Discovery (WPAD) protocol to discover Web proxy servers, you must perform the following tasks on the device:

- Specify port numbers of the Web proxy servers.
- Configure portal-free rules to allow user packets destined for the WPAD server to pass without authentication.

If portal users enable Web proxy in their browsers, the users must add the IP address of the portal authentication server as a proxy exception in their browsers. Thus, HTTP packets that the users send to the portal authentication server will not be sent to Web proxy servers.

You cannot specify Web proxy server port 443 on the device.

You can execute this command multiple times to specify multiple port numbers of Web proxy servers.

Procedure

1. Enter system view.

   system-view

2. Specify the port number of a Web proxy server.

   portal web-proxy port *port-number*

   By default, no port numbers of Web proxy servers are specified. Proxied HTTP requests are dropped.

Checking the issuing of category-2 portal filtering rules

About this task

Category-2 portal filtering rules permit authenticated users to access authorized network resources. By default, the device allows an authenticated user to come online as long as a member device has issued a category-2 portal filtering rule for the user. Users coming online from global interfaces might fail to access network resources because some member ports might not have category-2 rules for the users. To resolve this issue, enable the device to check the issuing of category-2 portal filtering rules. Then, the device allows users to come online only when all member devices have issued category-2 portal filtering rules for the users.

As a best practice, perform this task when portal authentication is enabled on a global interface.

Procedure

1. Enter system view.
   system-view
2. Enable the device to check the issuing of category-2 portal filtering rules.
   portal user-rule assign-check enable
   By default, the device does not check the issuing of category-2 portal filtering rules.

Setting the maximum number of portal users

About this task

Perform this task to control the total number of portal users in the system, and the maximum number of IPv4 or IPv6 portal users on an interface.

Restrictions and guidelines for setting the maximum number of portal users

Make sure the maximum combined number of IPv4 and IPv6 portal users specified on all interfaces does not exceed the global maximum number. Otherwise, the exceeding number of portal users will not be able to log in to the device.

Make sure the sum of the maximum number of portal users for IPv4 and IPv6 on an interface does not exceed the maximum number of all portal users set on the interface. Otherwise, the exceeding number of portal users cannot come online from the interface.

You can set the maximum number of portal users in interface view or system view. The effective value on an interface is as follows:

- If portal does not support IPv4/IPv6 dual stack on the interface, the maximum number of portal users allowed on the interface is the smallest value among the following items:
  - Maximum number of IPv4 or IPv6 portal users allowed on the interface.
  - Maximum number of all portal users allowed on the interface.
  - Global maximum number of portal users.
- If portal supports IPv4/IPv6 dual stack on the interface, the maximum number of portal users allowed on the interface is the smallest value among the following items:
  - Maximum number of all portal users allowed on the interface.
  - Global maximum number of portal users.

Setting the global maximum number of portal users

1. Enter system view.
   system-view
2. Set the global maximum number of portal users.
   portal max-user *max-number*
   By default, no limit is set on the global number of portal users.
   If you set the global maximum number smaller than the number of current online portal users on the device, this configuration still takes effect. The online users are not affected but the system forbids new portal users to log in.

Setting the maximum number of portal users on an interface

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Set the maximum number of portal users.

portal { **ipv4-max-user** | **ipv6-max-user** | **max-user** } *max-number*

By default, no limit is set on the number of portal users on an interface.

If you set the maximum number smaller than the current number of portal users on an interface, this configuration still takes effect. The online users are not affected but the system forbids new portal users to log in from the interface.

Enabling strict-checking on portal authorization information

About this task

The strict checking feature allows a portal user to stay online only when the authorization information for the user is successfully deployed.

Enabling strict checking on portal authentication information on an interface

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Enable strict checking on portal authorization information.
   portal authorization acl strict-checking

CAUTION:

The device logs out a portal user if the authorized ACL does not exist on the device or the device fails to deploy the authorized ACL.

By default, strict checking on portal authorization information is disabled on an interface. Portal users stay online even when the authorized ACL does not exist.

Allowing only users with DHCP-assigned IP addresses to pass portal authentication

About this task

This feature allows only users with DHCP-assigned IP addresses to pass portal authentication. Use this feature to ensure that only users with valid IP addresses can access the network.

Restrictions and guidelines

This feature takes effect only when the device acts as both the access device and the DHCP server.

Configuration of this feature does not affect the online portal users.

Allowing only users with DHCP-assigned IP addresses to pass portal authentication on an interface

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Allow only users with DHCP-assigned IP addresses to pass portal authentication.
   portal [**ipv6**] **user-dhcp-only**

CAUTION:

- After this feature is enabled, users with static IP addresses cannot pass portal authentication to come online.
- If this feature is configured, to ensure that IPv6 users can pass portal authentication, disable the temporary IPv6 address feature. Otherwise, IPv6 users will use temporary IPv6 addresses to access the IPv6 network and will fail portal authentication.

By default, both users with IP addresses obtained through DHCP and users with static IP addresses can pass authentication to come online.

Enabling portal roaming

About this task

If portal roaming is enabled on a VLAN interface, an online portal user can access resources from any Layer 2 port in the VLAN without re-authentication.

If portal roaming is disabled, to access external network resources from a Layer 2 port different from the current access port in the VLAN, the user must do the following:

1. Logs out from the current port.
2. Re-authenticates on the new Layer 2 port.

Restrictions and guidelines

Portal roaming takes effect only on portal users logging in from VLAN interfaces. It does not take effect on portal users logging in from common Layer 3 interface.

You cannot enable portal roaming when online portal users exist on the device.

For portal roaming to take effect, you must disable the Rule ARP or ND entry feature by using the **`undo portal refresh { arp | nd } enable`** command.

Procedure

1. Enter system view.
   `system-view`
2. Enable portal roaming.
   `portal roaming enable`
   By default, portal roaming is disabled.

Configuring the portal fail-permit feature

About this task

Perform this task to configure the portal fail-permit feature on an interface. When the access device detects that the portal authentication server or portal Web server is unreachable, it allows users on the interface to have network access without portal authentication.

If you enable fail-permit for both a portal authentication server and a portal Web server on an interface, the interface does the following:

- Disables portal authentication when either server is unreachable.
- Resumes portal authentication when both servers are reachable.

After portal authentication resumes, unauthenticated users must pass portal authentication to access the network. Users who have passed portal authentication before the fail-permit event can continue accessing the network.

When portal authentication is enabled to support IPv4/IPv6 dual stack, this feature takes effect on only one IP stack (the first stack used by portal users for passing authentication. When the portal users use the second stack to come line, this feature does not take effect on the users.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Enable portal fail-permit for a portal authentication server.
   portal [**ipv6**] **fail-permit server** *server-name*
   By default, portal fail-permit is disabled for a portal authentication server.
4. Enable portal fail-permit for portal Web servers.
   portal [**ipv6**] **apply web-server** *server-name* [**fail-permit**]
   By default, portal fail-permit is disabled for portal Web servers.

Configuring portal detection features

Configuring online detection of portal users

About this task

Use the online detection feature to quickly detect abnormal logouts of portal users. Configure ARP or ICMP detection for IPv4 portal users. Configure ND or ICMPv6 detection for IPv6 portal users.

If the device receives no packets from a portal user within the idle time, the device detects the user's online status as follows:

- **ICMP or ICMPv6 detection**—Sends ICMP or ICMPv6 requests to the user at configurable intervals to detect the user status.
  - If the device receives a reply within the maximum number of detection attempts, it considers that the user is online and stops sending detection packets. Then the device resets the idle timer and repeats the detection process when the timer expires.
  - If the device receives no reply after the maximum number of detection attempts, the device logs out the user.
- **ARP or ND detection**—Sends ARP or ND requests to the user and detects the ARP or ND entry status of the user at configurable intervals.
  - If the ARP or ND entry of the user is refreshed within the maximum number of detection attempts, the device considers that the user is online and stops detection. Then the device resets the idle timer and repeats the detection process when the timer expires.
  - If the ARP or ND entry of the user is not refreshed after the maximum number of detection attempts, the device logs out the user.

Restrictions and guidelines

ARP detection and ND detection apply only to direct and re-DHCP portal authentication. ICMP detection applies to all portal authentication modes.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*

3. Configure online detection of portal users.

   IPv4:

   portal user-detect type { **arp** | **icmp** } [**retry** *retries*] [**interval** *interval*] [**idle** *time*]

   IPv6:

   portal ipv6 user-detect type { **icmpv6** | **nd** } [**retry** *retries*] [**interval** *interval*] [**idle** *time*]

   By default, online detection is disabled for portal users on an interface.

Configuring portal authentication server detection

About this task

During portal authentication, if the communication between the access device and portal authentication server is broken, new portal users are not able to log in. Online portal users are not able to log out normally.

To address this problem, the access device needs to be able to detect the reachability changes of the portal server quickly and take corresponding actions to deal with the changes.

The portal authentication server detection feature enables the device to periodically detect portal packets sent by a portal authentication server to determine the reachability of the server. If the device receives a portal packet within a detection timeout (**timeout** *timeout*) and the portal packet is valid, the device considers the portal authentication server to be reachable. Otherwise, the device considers the portal authentication server to be unreachable.

Portal packets include user login packets, user logout packets, and heartbeat packets. Heartbeat packets are periodically sent by a server. By detecting heartbeat packets, the device can detect the server's actual status more quickly than by detecting other portal packets.

Restrictions and guidelines

The portal authentication server detection feature takes effect only when the device has a portal-enabled interface.

Only the IMC portal authentication server supports sending heartbeat packets. To test server reachability by detecting heartbeat packets, you must enable the server heartbeat feature on the IMC portal authentication server.

You can configure the device to take one or more of the following actions when the server reachability status changes:

- Sending a log message, which contains the name, the current state, and the original state of the portal authentication server.
- Enabling portal fail-permit. When the portal authentication server is unreachable, the portal fail-permit feature on an interface allows users on the interface to have network access. When the server recovers, it resumes portal authentication on the interface. For more information, see "Configuring the portal fail-permit feature."
- Make sure the detection timeout configured on the device is greater than the server heartbeat interval configured on the portal authentication server.

Procedure

1. Enter system view.

   system-view

2. Enter portal authentication server view.

   portal server *server-name*

3. Configure portal authentication server detection.

server-detect [**timeout** *timeout*] **log**

By default, portal authentication server detection is disabled.

Configuring portal Web server detection

About this task

A portal authentication process cannot complete if the communication between the access device and the portal Web server is broken. To address this problem, you can enable portal Web server detection on the access device.

With the portal Web server detection feature, the access device simulates a Web access process to initiate a TCP connection to the portal Web server. If the TCP connection can be established successfully, the access device considers the detection successful, and the portal Web server is reachable. Otherwise, it considers the detection to have failed.

You can configure the following detection parameters:

- **Detection interval**—Interval at which the device detects the server reachability.
- **Maximum number of consecutive failures**—If the number of consecutive detection failures reaches this value, the access device considers that the portal Web server is unreachable.

You can configure the device to take one or more of the following actions when the server reachability status changes:

- Sending a log message, which contains the name, the current state, and the original state of the portal Web server.
- Enabling portal fail-permit. When the portal Web server is unreachable, the portal fail-permit feature on an interface allows users on the interface to have network access. When the server recovers, it resumes portal authentication on the interface. For more information, see "Configuring the portal fail-permit feature."

Restrictions and guidelines

The portal Web server detection feature takes effect only when the URL of the portal Web server is specified and the device has a portal-enabled interface.

Procedure

1. Enter system view.

   system-view

2. Enter portal Web server view.

   portal web-server *server-name*

3. Configure portal Web server detection.

   server-detect [**interval** *interval*] [**retry** *retries*] **log**

   By default, portal Web server detection is disabled.

Configuring portal user synchronization

About this task

Once the access device loses communication with a portal authentication server, the portal user information on the access device and that on the portal authentication server might be inconsistent after the communication resumes. To address this problem, the device provides the portal user synchronization feature. This feature is implemented by sending and detecting portal synchronization packets, as follows:

1. The portal authentication server sends the online user information to the access device in a synchronization packet at the user heartbeat interval.

The user heartbeat interval is set on the portal authentication server.

2. Upon receiving the synchronization packet, the access device compares the users carried in the packet with its own user list and performs the following operations:
   - If a user contained in the packet does not exist on the access device, the access device informs the portal authentication server to delete the user. The access device starts the synchronization detection timer (**timeout** *timeout*) immediately when a user logs in.
   - If the user does not appear in any synchronization packet within a synchronization detection interval, the access device considers the user does not exist on the portal authentication server and logs the user out.

Restrictions and guidelines

Portal user synchronization requires a portal authentication server to support the portal user heartbeat function. Only the IMC portal authentication server supports the portal user heartbeat function. To implement the portal user synchronization feature, you also need to configure the user heartbeat function on the portal authentication server. Make sure the user heartbeat interval configured on the portal authentication server is not greater than the synchronization detection timeout configured on the access device.

Deleting a portal authentication server on the access device also deletes the user synchronization configuration for the portal authentication server.

Procedure

1. Enter system view.
   system-view
2. Enter portal authentication server view.
   portal server *server-name*
3. Configure portal user synchronization.
   user-sync timeout *timeout*

   By default, portal user synchronization is disabled.

Configuring portal packet attributes

Configuring the BAS-IP or BAS-IPv6 attribute

About this task

If the device runs Portal 2.0, the unsolicited packets sent to the portal authentication server must carry the BAS-IP attribute. If the device runs Portal 3.0, the unsolicited packets sent to the portal authentication server must carry the BAS-IP or BAS-IPv6 attribute.

After this attribute is configured, the source IP address for unsolicited notification portal packets the device sends to the portal authentication server is the configured BAS-IP or BAS-IPv6 address. If the attribute is not configured, the source IP address of the portal packets is the IP address of the packet output interface.

Restrictions and guidelines

During a re-DHCP portal authentication or mandatory user logout process, the device sends portal notification packets to the portal authentication server. For the authentication or logout process to complete, make sure the BAS-IP/BAS-IPv6 attribute is the same as the device IP address specified on the portal authentication server.

You must configure the BAS-IP or BAS-IPv6 attribute on a portal authentication-enabled interface if the following conditions are met:

- The portal authentication server is an IMC server.

- The portal device IP address specified on the portal authentication server is not the IP address of the portal packet output interface.

Configuring the BAS-IP or BAS-IPv6 attribute on an interface

1. Enter system view.

   system-view

2. Enter Layer 3 interface view.

   interface *interface-type interface-number*

3. Configure the BAS-IP or BAS-IPv6 attribute.

   IPv4:

   portal bas-ip *ipv4-address*

   By default, the BAS-IP attribute of an IPv4 portal reply packet is the source IPv4 address of the packet. The BAS-IP attribute of an IPv4 portal notification packet is the IPv4 address of the packet's output interface.

   IPv6:

   portal bas-ipv6 *ipv6-address*

   By default, the BAS-IPv6 attribute of an IPv6 portal reply packet is the source IPv6 address of the packet. The BAS-IPv6 attribute of an IPv6 portal notification packet is the IPv6 address of the packet's output interface.

Specifying the device ID

About this task

The portal authentication server uses device IDs to identify the devices that send protocol packets to the portal server.

Restrictions and guidelines

Make sure the configured device ID is different than any other access devices communicating with the same portal authentication server.

Procedure

1. Enter system view.

   system-view

2. Specify the device ID.

   portal device-id *device-id*

   By default, a device is not configured with a device ID.

Configuring attributes for RADIUS packets

Specifying a format for the NAS-Port-Id attribute

About this task

RADIUS servers from different vendors might require different formats of the NAS-Port-Id attribute in the RADIUS packets. You can specify the NAS-Port-Id attribute format as required.

The device supports predefined formats (format 1, 2, 3, and 4). For more information about the formats, see portal commands in *Security Command Reference*.

Procedure

1. Enter system view.
   system-view
2. Specify the format for the NAS-Port-Id attribute.
   portal nas-port-id format { **1** | **2** | **3** | **4** }
   By default, the format for the NAS-Port-Id attribute is format 2.

Configuring the NAS-Port-Type attribute

About this task

The NAS-Port-Type attribute in a RADIUS request represents the type of a user's access interface.

The access device might not be able to correctly obtain the type of users' access interfaces when multiple network devices exist between the access device and the portal client. For the access device to send the correct access interface type to the RADIUS server, perform this task to configure the NAS-Port-Type attribute.

Restrictions and guidelines

This configuration takes effect only on portal users that newly come online.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the NAS-Port-Type attribute carried in outgoing RADIUS requests on the interface.
   portal nas-port-type { **802.11** | **adsl-cap** | **adsl-dmt** | **async** | **cable** | **ethernet** | **g.3-fax** | **hdlc** | **idsl** | **isdn-async-v110** | **isdn-async-v120** | **isdn-sync** | **piafs** | **sdsl** | **sync** | **virtual** | **wireless-other** | **x.25** | **x.75** | **xdsl** }
   By default, the NAS-Port-Type carried in outgoing RADIUS requests is Ethernet (attribute value 15).

Applying a NAS-ID profile to an interface

About this task

By default, the device sends its device name in the NAS-Identifier attribute of all RADIUS requests.

A NAS-ID profile enables you to send different NAS-Identifier attribute strings in RADIUS requests from different VLANs. The strings can be organization names, service names, or any user categorization criteria, depending on the administrative requirements.

For example, map the NAS-ID **companyA** to all VLANs of company A. The device will send **companyA** in the NAS-Identifier attribute for the RADIUS server to identify requests from any Company A users.

Restrictions and guidelines

You can apply a NAS-ID profile to a portal-enabled interface. If no NAS-ID profile is specified on the interface or no matching NAS-ID is found in the specified profile, the device uses the device name as the interface NAS-ID.

Procedure

1. Enter system view.
   system-view
2. Create a NAS-ID profile and enter NAS-ID profile view.
   aaa nas-id profile *profile-name*
   For more information about this command, see *Security Command Reference*.
3. Configure a NAS ID and VLAN binding in the profile.
   nas-id *nas-identifier* **bind vlan** *vlan-id*
   For more information about this command, see *Security Command Reference*. Portal access matches only the inner VLAN ID of QinQ packets. For more information about QinQ, see *Layer 2—LAN Switching Configuration Guide*.
4. Specify the NAS-ID profile on the interface.
   a. Return to system view.
      quit
   b. Enter Layer 3 interface view.
      interface *interface-type interface-number*
   c. Specify the NAS-ID profile on the interface.
      portal nas-id-profile *profile-name*
      By default, no NAS-ID profile is specified for an interface.

Logging out online portal users

About this task

This feature deletes users that have passed portal authentication and terminates ongoing portal authentications.

Restrictions and guidelines

When the number of online users exceeds 2000, executing the **portal delete-user** command takes a few minutes.

To ensure successful logout of online users, do not disable portal authentication or perform master/subordinate device switchover on the portal-enabled interface during the command execution.

Procedure

1. Enter system view.
   system-view
2. Log out online portal users.
   portal delete-user { *ipv4-address* | **all** | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* | **mac** *mac-address* }

Enabling portal user login/logout logging

About this task

This feature logs information about user login and logout events. The information includes the username, user IP address and MAC address, user access interface, VLAN, and login result. The logs are sent to the information center of the device. For the logs to be output correctly, you must

also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable portal user login/logout logging.

   portal log enable

   By default, portal user login/logout logging is disabled.

Disabling the Rule ARP or ND entry feature for portal clients

About this task

When the Rule ARP or ND entry feature is enabled for portal clients, ARP or ND entries for portal clients are Rule entries after the clients come online. The Rule entries will not age out and will be deleted immediately after the portal clients go offline. If a portal client goes offline and then tries to get online before the ARP or ND entry is relearned for the client, the client will fail the authentication. To avoid such authentication failure, disable this feature. Then, ARP or ND entries for portal clients are dynamic entries after the clients come online and are deleted only when they age out.

Restrictions and guidelines

Enabling or disabling of this feature does not affect existing Rule/dynamic ARP or ND entries.

If the portal clients and the portal server belong to different VPNs, the Rule ARP entry feature will cause the portal clients to go offline abnormally. To avoid this issue, execute the **undo portal refresh arp enable** command to disable the Rule ARP entry feature for portal clients.

Procedure

1. Enter system view.

   system-view

2. Disable the Rule ARP or ND entry feature for portal clients.

   undo portal refresh { **arp** | **nd** } **enable**

   By default, the Rule ARP or ND entry feature is enabled for portal clients.

Configuring Web redirect

About this task

Web redirect is a simplified portal feature. With Web redirect, a user does not perform portal authentication but is directly redirected to the specified URL on the first Web access attempt in a browser. After the specified redirect interval, the user is redirected from the visiting website to the specified URL again.

Web redirect can provide ISPs with extended services. For example, the ISPs can place advertisements and publish information on the redirected webpage.

Restrictions and guidelines

The Web redirect feature takes effect only on HTTP packets that use the default port number 80.

If the device supports Etherchannel interfaces, you can enable both Web redirect and portal authentication on supporting interfaces. If the device does not support Etherchannel interfaces, Web redirect does not work when both Web redirect and portal authentication are enabled on an interface.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 3 interface view.
   interface *interface-type interface-number*
3. Configure Web redirect.
   web-redirect [**ipv6**] **url** *url-string* [**interval** *interval*]
   By default, Web redirect is disabled.

Obtaining user access information from ARP or ND entries

About this task

In a remote Web authentication network, the device cannot obtain user access information from FIB entries upon receiving portal packets from the portal authentication server. This will cause users to fail Web authentication.

To resolve this issue, you can perform this task on the device. When this feature is enabled, the device first attempts to obtain user access information from ARP or ND entries during Web authentication.

Procedure

1. Enter system view.
   system-view
2. Configure the device to obtain user information from ARP or ND entries.
   portal access-info trust { **arp** | **nd** }
   By default, the device obtains user information from FIB entries.

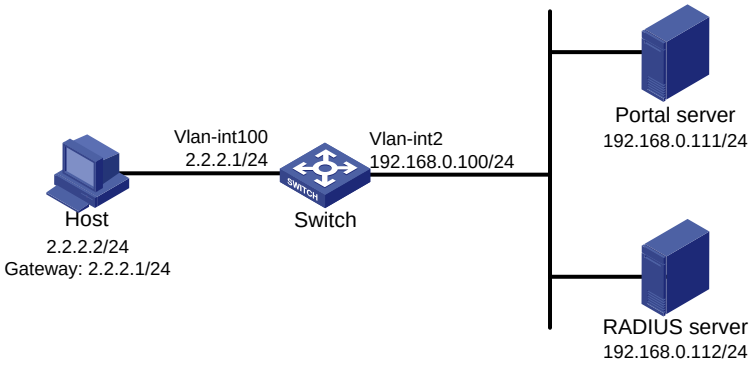
Display and maintenance commands for portal

Execute **display** commands in any view and the **reset** command in user view.

Task	Command
Display portal configuration and portal running state.	**display portal interface** *interface-type interface-number*
Display packet statistics for portal authentication servers.	**display portal packet statistics** [**server** *server-name*]
Display portal rules.	**display portal rule** { **all** | **dynamic** | **static** } **interface** *interface-type interface-number* [**slot** *slot-number*]
Display portal authentication server information.	**display portal server** [*server-name*]
Display session information for portal users or portal-based Web authentication users.	**display portal session user-type** { **portal** | **web-auth** }
Display portal user information.	**display portal user** { **all** | **interface** *interface-type interface-number* | **ip**

Task	Command
	ipv4-address | **ipv6** *ipv6-address* | **mac** *mac-address* | **pre-auth** [**interface** *interface-type interface-number* | **ip** *ipv4-address* | **ipv6** *ipv6-address*] } [**verbose**]
Display portal Web server information.	**display portal web-server** [*server-name*]
Display Web redirect rule information.	**display web-redirect rule interface** *interface-type interface-number* [**slot** *slot-number*]
Clear packet statistics for portal authentication servers.	**reset portal packet statistics** [**server** *server-name*]

Portal configuration examples



Example: Configuring direct portal authentication

Network configuration

As shown in Figure 6, the host is directly connected to the switch (the access device). The host is assigned a public IP address either manually or through DHCP. An IMC server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server. In this example, the IMC server runs IMC 7.1 (E0303) and IMC UAM 7.1 (E0304).

Configure direct portal authentication, so the host can access only the portal server before passing the authentication and access other network resources after passing the authentication.

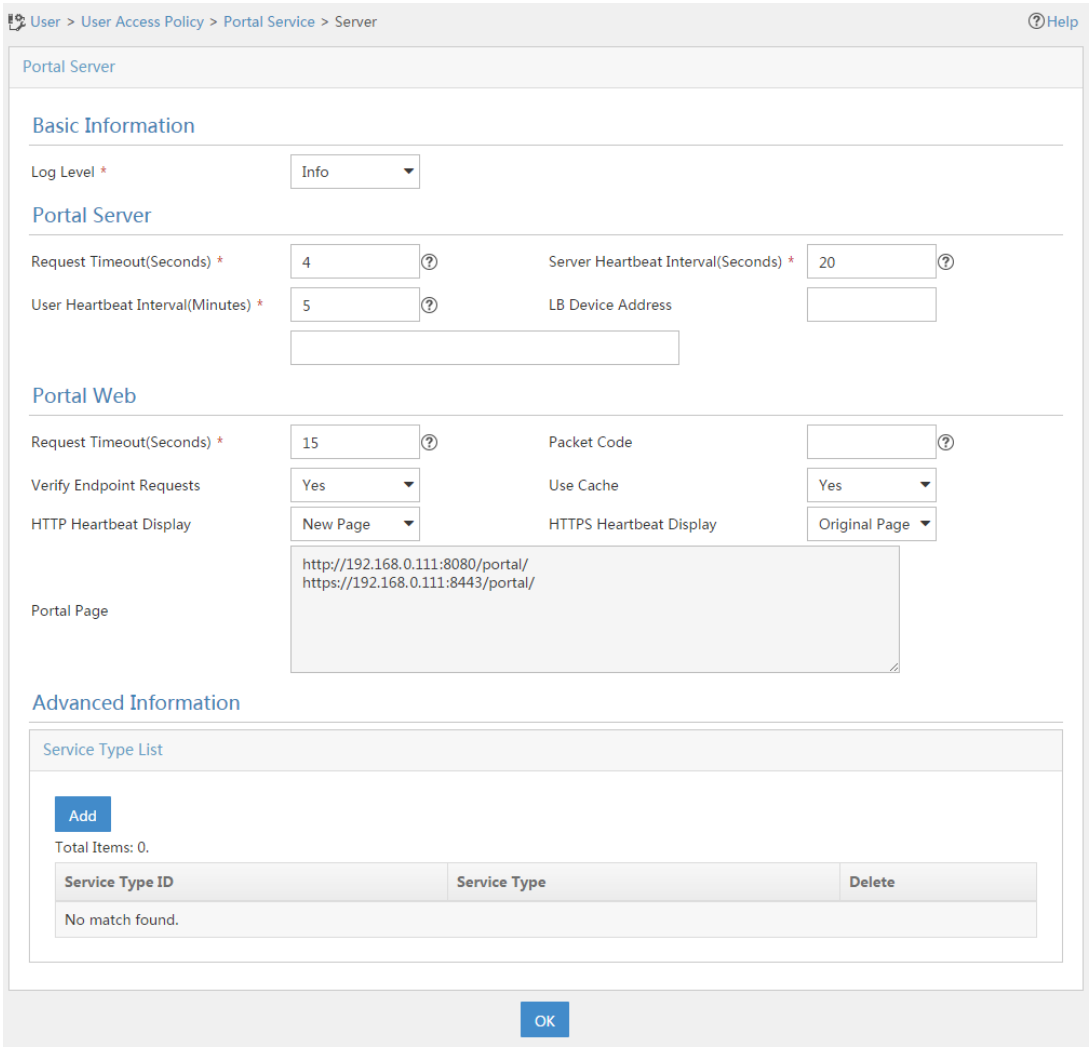
Figure 6 Network diagram

Prerequisites

- Configure IP addresses for the host, switch, and servers as shown in Figure 6 and make sure they can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.

Configuring the portal server

1. Configure the portal server:
   a. Log in to IMC and click the **User** tab.



b. Select **User Access Policy** > **Portal Service** > **Server** from the navigation tree to open the portal server configuration page, as shown in Figure 7.

c. Configure the portal server parameters as needed.

   This example uses the default settings.

d. Click **OK**.

Figure 7 Portal server configuration

2. Configure the IP address group:

   a. Select **User Access Policy** > **Portal Service** > **IP Group** from the navigation tree to open the portal IP address group configuration page.

   b. Click **Add** to open the page as shown in Figure 8.

   c. Enter the IP group name.

   d. Enter the start IP address and end IP address of the IP group.

      Make sure the host IP address is in the IP group.

   e. Select a service group.

      This example uses the default group **Ungrouped**.

   f. Select **Normal** from the **Action** list.

   g. Click **OK**.

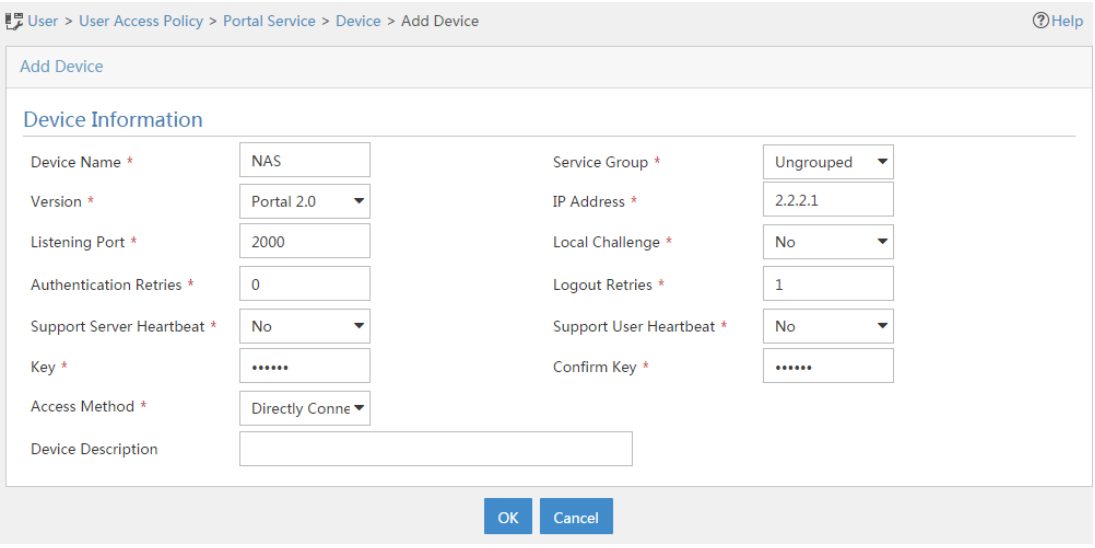


Figure 8 Adding an IP address group

3. Add a portal device:
   a. Select **User Access Policy** > **Portal Service** > **Device** from the navigation tree to open the portal device configuration page.
   b. Click **Add** to open the page as shown in Figure 9.
   c. Enter device name **NAS**.
   d. Enter the IP address of the switch's interface connected to the host.
   e. Set whether to support the portal server heartbeat and user heartbeat functions.

      In this example, select **No** for both **Support Server Heartbeat** and **Support User Heartbeat**.
   f. Enter the key, which must be the same as that configured on the switch.
   g. Select **Directly Connected** from the **Access Method** list.
   h. Use the default settings for other parameters.
   i. Click **OK**.

Figure 9 Adding a portal device

4. Associate the portal device with the IP address group:
   a. As shown in Figure 10, click the **Port Group Information Management** icon for device **NAS** to open the port group configuration page.
   b. Click **Add** to open the page as shown in Figure 11.

c. Enter the port group name.

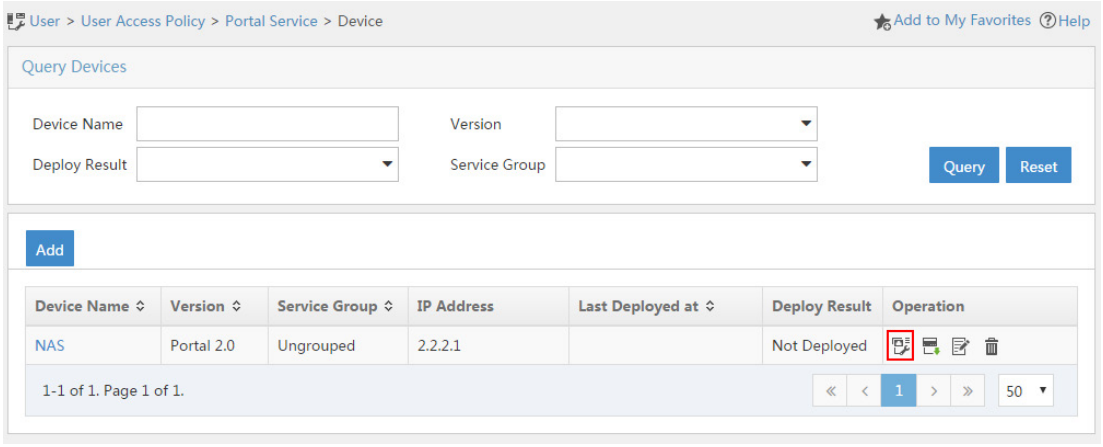
d. Select the configured IP address group.

   The IP address used by the user to access the network must be within this IP address group.

e. Use the default settings for other parameters.

f. Click **OK**.

Figure 10 Device list



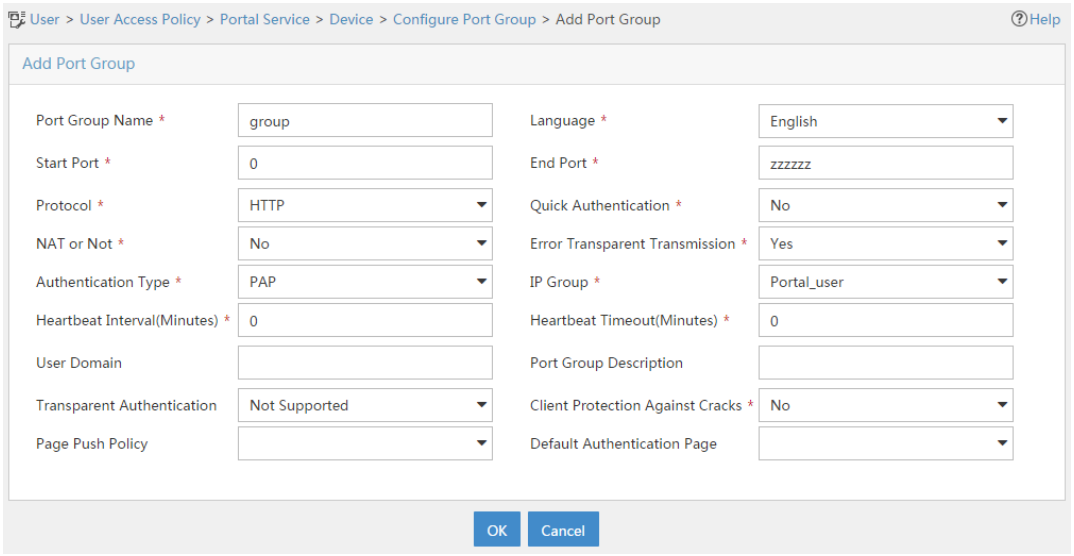


Figure 11 Adding a port group

Configuring the switch

1. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rs1** and enter its view.

   ```
   <Switch> system-view
   [Switch] radius scheme rs1
   ```

   # Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

   ```
   [Switch-radius-rs1] primary authentication 192.168.0.112
   [Switch-radius-rs1] primary accounting 192.168.0.112
   [Switch-radius-rs1] key authentication simple radius
   ```

```
[Switch-radius-rs1] key accounting simple radius
```

Exclude the ISP domain name from the username sent to the RADIUS server.

```
[Switch-radius-rs1] user-name-format without-domain
[Switch-radius-rs1] quit
```

Enable RADIUS session control.

```
[Switch] radius session-control enable
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[Switch] domain dm1
```

Configure AAA methods for the ISP domain.

```
[Switch-isp-dm1] authentication portal radius-scheme rs1
[Switch-isp-dm1] authorization portal radius-scheme rs1
[Switch-isp-dm1] accounting portal radius-scheme rs1
[Switch-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

```
[Switch] domain default enable dm1
```

3. Configure portal authentication:

Configure a portal authentication server.

```
[Switch] portal server newpt
[Switch-portal-server-newpt] ip 192.168.0.111 key simple portal
[Switch-portal-server-newpt] port 50100
[Switch-portal-server-newpt] quit
```

Configure a portal Web server.

```
[Switch] portal web-server newpt
[Switch-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Switch-portal-websvr-newpt] quit
```

Enable direct portal authentication on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] portal enable method direct
```

Specify portal Web server **newpt** on VLAN-interface 100.

```
[Switch–Vlan-interface100] portal apply web-server newpt
```

Configure the BAS-IP as 2.2.2.1 for portal packets sent from VLAN-interface 100 to the portal authentication server.

```
[Switch–Vlan-interface100] portal bas-ip 2.2.2.1
[Switch–Vlan-interface100] quit
```

Verifying the configuration

Verify that the portal configuration has taken effect.

```
[Switch] display portal interface vlan-interface 100
 Portal information of Vlan-interface100
     NAS-ID profile: Not configured
     Authorization : Strict checking
     ACL           : Disabled
     User profile  : Disabled
     Dual stack    : Disabled
     Max users     : Not configured
```

```
 IPv4:
     Portal status: Enabled
     Portal authentication method: Direct
     Portal web server: newpt
     Portal mac-trigger-server: Not configured

     Destination authenticate subnet:
         IP address                                         Prefix length
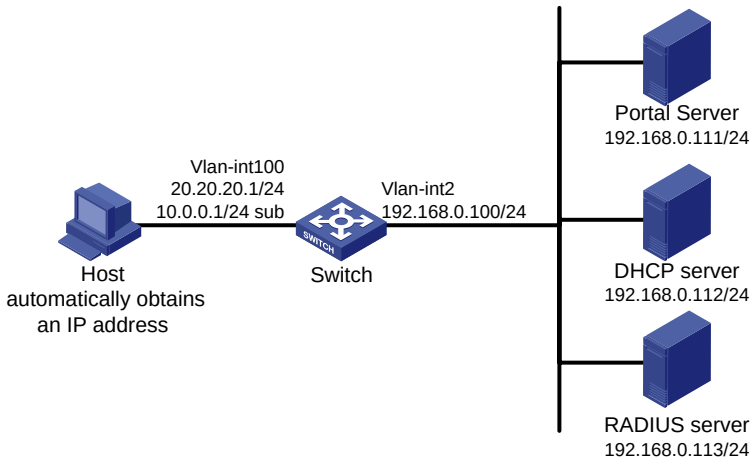
```

A user can perform portal authentication by using the iNode client or through a Web browser. Before passing the authentication, the user can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user will be redirected to the authentication page. After passing the authentication, the user can access other network resources.

After the user passes authentication, use the following command to display information about the portal user.

```
[Switch] display portal user interface vlan-interface 100
 Total portal users: 1
  Username: abc
```

```
Portal server: newpt
State: Online
VPN instance: N/A
MAC                IP                VLAN   Interface
0015-e9a6-7cfe     2.2.2.2           100    Vlan-interface100
Authorization information:
  DHCP IP pool: N/A
  User profile: N/A
  Session group profile: N/A
  ACL number: N/A
  Inbound CAR: N/A
  Outbound CAR: N/A
```



Example: Configuring re-DHCP portal authentication

Network configuration

As shown in Figure 12, the host is directly connected to the switch (the access device). The host obtains an IP address through the DHCP server. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure re-DHCP portal authentication. Before passing the authentication, the host is assigned a private IP address. After passing the authentication, the host gets a public IP address and can access network resources.

Figure 12 Network diagram

Restrictions and guidelines

- For re-DHCP portal authentication, configure a public address pool (20.20.20.0/24) and a private address pool (10.0.0.0/24) on the DHCP server. (Details not shown.)
- For re-DHCP portal authentication:
  - The switch must be configured as a DHCP relay agent.
  - The portal-enabled interface must be configured with a primary IP address (a public IP address) and a secondary IP address (a private IP address).

  For information about DHCP relay agent configuration, see *Layer 3—IP Services Configuration Guide*.
- Make sure the IP address of the portal device added on the portal server is the public IP address (20.20.20.1) of the switch's interface connecting the host. The private IP address range

for the IP address group associated with the portal device is the private subnet 10.0.0.0/24 where the host resides. The public IP address range for the IP address group is the public subnet 20.20.20.0/24.

Prerequisites

- Configure IP addresses for the switch and servers as shown in Figure 12 and make sure the host, switch, and servers can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.

Procedure

1. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rs1** and enter its view.

   ```
   <Switch> system-view
   [Switch] radius scheme rs1
   ```

   # Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

   ```
   [Switch-radius-rs1] primary authentication 192.168.0.113
   [Switch-radius-rs1] primary accounting 192.168.0.113
   [Switch-radius-rs1] key authentication simple radius
   [Switch-radius-rs1] key accounting simple radius
   ```

   # Exclude the ISP domain name from the username sent to the RADIUS server.

   ```
   [Switch-radius-rs1] user-name-format without-domain
   [Switch-radius-rs1] quit
   ```

   # Enable RADIUS session control.

   ```
   [Switch] radius session-control enable
   ```

2. Configure an authentication domain:

   # Create an ISP domain named **dm1** and enter its view.

   ```
   [Switch] domain dm1
   ```

   # Configure AAA methods for the ISP domain.

   ```
   [Switch-isp-dm1] authentication portal radius-scheme rs1
   [Switch-isp-dm1] authorization portal radius-scheme rs1
   [Switch-isp-dm1] accounting portal radius-scheme rs1
   [Switch-isp-dm1] quit
   ```

   # Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

   ```
   [Switch] domain default enable dm1
   ```

3. Configure DHCP relay and authorized ARP:

   # Configure DHCP relay.

   ```
   [Switch] dhcp enable
   [Switch] dhcp relay client-information record
   [Switch] interface vlan-interface 100
   [Switch–Vlan-interface100] ip address 20.20.20.1 255.255.255.0
   [Switch–Vlan-interface100] ip address 10.0.0.1 255.255.255.0 sub
   [Switch-Vlan-interface100] dhcp select relay
   [Switch-Vlan-interface100] dhcp relay server-address 192.168.0.112
   ```

   # Enable authorized ARP.

   ```
   [Switch-Vlan-interface100] arp authorized enable
   [Switch-Vlan-interface100] quit
   ```

4. Configure portal authentication:

Configure a portal authentication server.

```
[Switch] portal server newpt
[Switch-portal-server-newpt] ip 192.168.0.111 key simple portal
[Switch-portal-server-newpt] port 50100
[Switch-portal-server-newpt] quit
```

Configure a portal Web server.

```
[Switch] portal web-server newpt
[Switch-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Switch-portal-websvr-newpt] quit
```

Enable re-DHCP portal authentication on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] portal enable method redhcp
```

Specify portal Web server **newpt** on VLAN-interface 100.

```
[Switch–Vlan-interface100] portal apply web-server newpt
```

Configure the BAS-IP as 20.20.20.1 for portal packets sent from VLAN-interface 100 to the portal authentication server.

```
[Switch–Vlan-interface100] portal bas-ip 20.20.20.1
[Switch–Vlan-interface100] quit
```

Verifying the configuration

Verify that the portal configuration has taken effect.

```
[Switch] display portal interface vlan-interface 100
 Portal information of Vlan-interface100

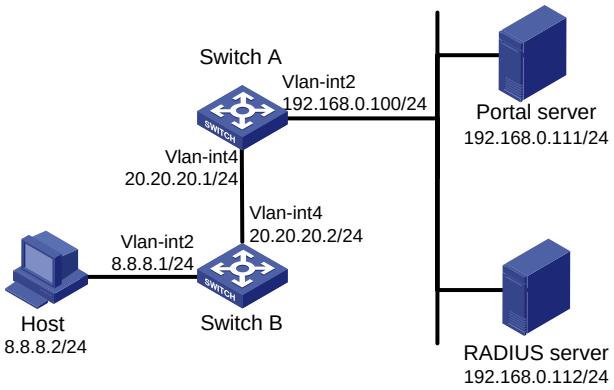
  0015-e9a6-7cfe    20.20.20.2        100    Vlan-interface100
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number: N/A
    Inbound CAR: N/A
    Outbound CAR: N/A
```



Example: Configuring cross-subnet portal authentication

Network configuration

As shown in Figure 13, Switch A supports portal authentication. The host accesses Switch A through Switch B. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure Switch A for cross-subnet portal authentication. Before passing the authentication, the host can access only the portal Web server. After passing the authentication, the user can access other network resources.

Figure 13 Network diagram

Restrictions and guidelines

Make sure the IP address of the portal device added on the portal authentication server is the IP address (20.20.20.1) of the switch's interface connecting the host. The IP address group associated with the portal device is the subnet of the host (8.8.8.0/24).

Prerequisites

- Configure IP addresses for the switch and servers as shown in Figure 13 and make sure the host, switch, and servers can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.

Procedure

1. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rs1** and enter its view.

   ```
   <SwitchA> system-view
   [SwitchA] radius scheme rs1
   ```

   # Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

   ```
   [SwitchA-radius-rs1] primary authentication 192.168.0.112
   [SwitchA-radius-rs1] primary accounting 192.168.0.112
   [SwitchA-radius-rs1] key authentication simple radius
   [SwitchA-radius-rs1] key accounting simple radius
   ```

   # Exclude the ISP domain name from the username sent to the RADIUS server.

   ```
   [SwitchA-radius-rs1] user-name-format without-domain
   [SwitchA-radius-rs1] quit
   ```

   # Enable RADIUS session control.

   ```
   [SwitchA] radius session-control enable
   ```

2. Configure an authentication domain:

   # Create an ISP domain named **dm1** and enter its view.

   ```
   [SwitchA] domain dm1
   ```

   # Configure AAA methods for the ISP domain.

   ```
   [SwitchA-isp-dm1] authentication portal radius-scheme rs1
   [SwitchA-isp-dm1] authorization portal radius-scheme rs1
   [SwitchA-isp-dm1] accounting portal radius-scheme rs1
   [SwitchA-isp-dm1] quit
   ```

Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

```
[SwitchA] domain default enable dm1
```

3. Configure portal authentication:

Configure a portal authentication server.

```
[SwitchA] portal server newpt
[SwitchA-portal-server-newpt] ip 192.168.0.111 key simple portal
[SwitchA-portal-server-newpt] port 50100
[SwitchA-portal-server-newpt] quit
```

Configure a portal Web server.

```
[SwitchA] portal web-server newpt
[SwitchA-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[SwitchA-portal-websvr-newpt] quit
```

Enable cross-subnet portal authentication on VLAN-interface 4.

```
[SwitchA] interface vlan-interface 4
[SwitchA–Vlan-interface4] portal enable method layer3
```

Specify portal Web server **newpt** on VLAN-interface 4.

```
[SwitchA–Vlan-interface4] portal apply web-server newpt
```

Configure the BAS-IP as 20.20.20.1 for portal packets sent from VLAN-interface 4 to the portal authentication server.

```
[SwitchA–Vlan-interface4] portal bas-ip 20.20.20.1
[SwitchA–Vlan-interface4] quit
```

Verifying the configuration

Verify that the portal configuration has taken effect.

```
[SwitchA] display portal interface vlan-interface 4
 Portal information of Vlan-interface4
     NAS-ID profile: Not configured

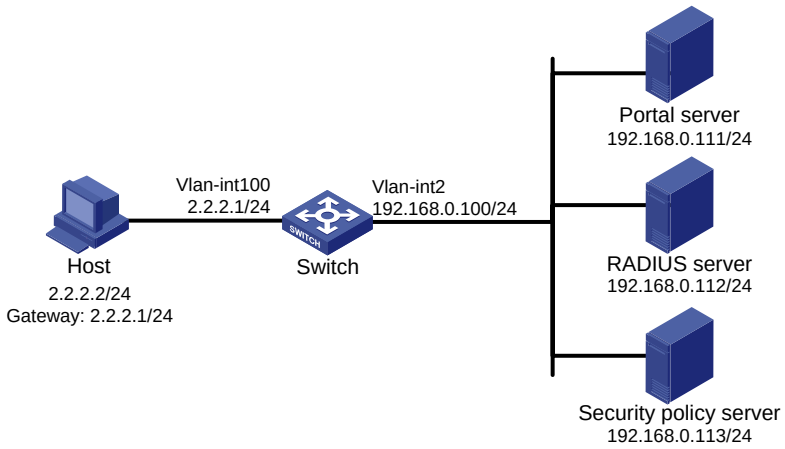
         Server type    Server name                     Action
         --             --                              --
     Layer3 source network:
         IP address                                     Prefix length

     Destination authenticate subnet:
         IP address                                     Prefix length
```

A user can perform portal authentication by using the iNode client or through a Web browser. Before passing the authentication, the user can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user will be redirected to the authentication page. After passing the authentication, the user can access other network resources.

After the user passes authentication, use the following command to display information about the portal user.

```
[SwitchA] display portal user interface vlan-interface 4
Total portal users: 1
Username: abc
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  0000-0000-0000    8.8.8.2           4      Vlan-interface4
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number: N/A
    Inbound CAR: N/A
    Outbound CAR: N/A
```



Example: Configuring extended direct portal authentication

Network configuration

As shown in Figure 14, the host is directly connected to the switch (the access device). The host is assigned a public IP address either manually or through DHCP. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure extended direct portal authentication. If the host fails security check after passing identity authentication, it can access only subnet 192.168.0.0/24. After passing security check, the host can access other network resources.

Figure 14 Network diagram

Prerequisites

- Configure IP addresses for the host, switch, and servers as shown in Figure 14 and make sure they can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.

Procedure

1. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rs1** and enter its view.

   ```
   <Switch> system-view
   [Switch] radius scheme rs1
   ```

   # Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

   ```
   [Switch-radius-rs1] primary authentication 192.168.0.112
   [Switch-radius-rs1] primary accounting 192.168.0.112
   [Switch-radius-rs1] key accounting simple radius
   [Switch-radius-rs1] key authentication simple radius
   [Switch-radius-rs1] user-name-format without-domain
   ```

   # Enable RADIUS session control.

   ```
   [Switch] radius session-control enable
   ```

   # Specify a session-control client with IP address 192.168.0.112 and shared key 12345 in plaintext form.

   ```
   [Switch] radius session-control client ip 192.168.0.112 key simple 12345
   ```

2. Configure an authentication domain:

Create an ISP domain named dm1 and enter its view.

```
[Switch] domain dm1
```

Configure AAA methods for the ISP domain.

```
[Switch-isp-dm1] authentication portal radius-scheme rs1
[Switch-isp-dm1] authorization portal radius-scheme rs1
[Switch-isp-dm1] accounting portal radius-scheme rs1
[Switch-isp-dm1] quit
```

Configure domain dm1 as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

```
[Switch] domain default enable dm1
```

3. Configure ACL 3000 as the isolation ACL and ACL 3001 as the security ACL.

```
[Switch] acl advanced 3000
[Switch-acl-ipv4-adv-3000] rule permit ip destination 192.168.0.0 0.0.0.255
[Switch-acl-ipv4-adv-3000] rule deny ip
[Switch-acl-ipv4-adv-3000] quit
[Switch] acl advanced 3001
[Switch-acl-ipv4-adv-3001] rule permit ip
[Switch-acl-ipv4-adv-3001] quit
```

NOTE:

Make sure you specify ACL 3000 as the isolation ACL and ACL 3001 as the security ACL on the security policy server.

4. Configure portal authentication:

Configure a portal authentication server.

```
[Switch] portal server newpt
[Switch-portal-server-newpt] ip 192.168.0.111 key simple portal
[Switch-portal-server-newpt] port 50100
[Switch-portal-server-newpt] quit
```

Configure a portal Web server.

```
[Switch] portal web-server newpt
[Switch-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Switch-portal-websvr-newpt] quit
```

Enable direct portal authentication on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] portal enable method direct
```

Specify portal Web server **newpt** on VLAN-interface 100.

```
[Switch–Vlan-interface100] portal apply web-server newpt
```

Configure the BAS-IP as 2.2.2.1 for portal packets sent from VLAN-interface 100 to the portal authentication server.

```
[Switch–Vlan-interface100] portal bas-ip 2.2.2.1
[Switch–Vlan-interface100] quit
```

Verifying the configuration

Verify that the portal configuration has taken effect.

```
[Switch] display portal interface vlan-interface 100
 Portal information of Vlan-interface100
     NAS-ID profile: Not configured
```

```
    Authorization : Strict checking

    Layer3 source network:
        IP address                                        Prefix length

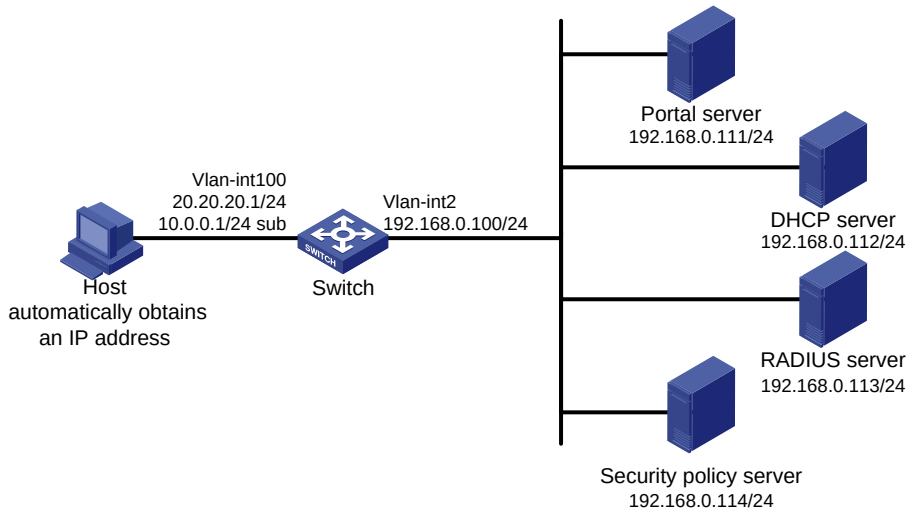
    Destination authenticate subnet:
        IP address                                        Prefix length
```

Before passing portal authentication, a user that uses the iNode client can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user will be redirected to the authentication page.

- The user can access the resources permitted by ACL 3000 after passing only identity authentication.
- The user can access network resources permitted by ACL 3001 after passing both identity authentication and security check.

After the user passes identity authentication and security check, use the following command to display information about the portal user.

```
[Switch] display portal user interface vlan-interface 100
Total portal users: 1
Username: abc
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC                IP                VLAN   Interface
  0015-e9a6-7cfe     2.2.2.2           100    Vlan-interface100
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL: 3001
    Inbound CAR: N/A
    Outbound CAR: N/A
```



Example: Configuring extended re-DHCP portal authentication

Network configuration

As shown in Figure 15, the host is directly connected to the switch (the access device). The host obtains an IP address through the DHCP server. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure extended re-DHCP portal authentication. Before passing portal authentication, the host is assigned a private IP address. After passing portal identity authentication, the host obtains a public IP address and accepts security check. If the host fails the security check, it can access only subnet 192.168.0.0/24. After passing the security check, the host can access other network resources.

Figure 15 Network diagram

Restrictions and guidelines

- For re-DHCP portal authentication, configure a public address pool (20.20.20.0/24) and a private address pool (10.0.0.0/24) on the DHCP server. (Details not shown.)

- For re-DHCP portal authentication:
  - The switch must be configured as a DHCP relay agent.
  - The portal-enabled interface must be configured with a primary IP address (a public IP address) and a secondary IP address (a private IP address).

  For information about DHCP relay agent configuration, see *Layer 3—IP Services Configuration Guide*.
- Make sure the IP address of the portal device added on the portal server is the public IP address (20.20.20.1) of the switch's interface connecting the host. The private IP address range for the IP address group associated with the portal device is the private subnet 10.0.0.0/24 where the host resides. The public IP address range for the IP address group is the public subnet 20.20.20.0/24.

Prerequisites

- Configure IP addresses for the switch and servers as shown in Figure 15 and make sure the host, switch, and servers can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.

Procedure

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1** and enter its view.

```
<Switch> system-view
[Switch] radius scheme rs1
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Switch-radius-rs1] primary authentication 192.168.0.113
[Switch-radius-rs1] primary accounting 192.168.0.113
[Switch-radius-rs1] key accounting simple radius
[Switch-radius-rs1] key authentication simple radius
[Switch-radius-rs1] user-name-format without-domain
```

Enable RADIUS session control.

```
[Switch] radius session-control enable
```

Specify a session-control client with IP address 192.168.0.113 and shared key 12345 in plaintext form.

```
[Switch] radius session-control client ip 192.168.0.113 key simple 12345
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[Switch] domain dm1
```

Configure AAA methods for the ISP domain.

```
[Switch-isp-dm1] authentication portal radius-scheme rs1
[Switch-isp-dm1] authorization portal radius-scheme rs1
[Switch-isp-dm1] accounting portal radius-scheme rs1
[Switch-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

```
[Switch] domain default enable dm1
```

3. Configure ACL 3000 as the isolation ACL and ACL 3001 as the security ACL.

```
[Switch] acl advanced 3000
[Switch-acl-ipv4-adv-3000] rule permit ip destination 192.168.0.0 0.0.0.255
[Switch-acl-ipv4-adv-3000] rule deny ip
```

```
[Switch-acl-ipv4-adv-3000] quit
[Switch] acl advanced 3001
[Switch-acl-ipv4-adv-3001] rule permit ip
[Switch-acl-ipv4-adv-3001] quit
```

NOTE:

Make sure you specify ACL 3000 as the isolation ACL and ACL 3001 as the security ACL on the security policy server.

4. Configure DHCP relay and authorized ARP:

   # Configure DHCP relay.

```
[Switch] dhcp enable
[Switch] dhcp relay client-information record
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] ip address 20.20.20.1 255.255.255.0
[Switch–Vlan-interface100] ip address 10.0.0.1 255.255.255.0 sub
[Switch-Vlan-interface100] dhcp select relay
[Switch-Vlan-interface100] dhcp relay server-address 192.168.0.112
```

   # Enable authorized ARP.

```
[Switch-Vlan-interface100] arp authorized enable
[Switch-Vlan-interface100] quit
```

5. Configure portal authentication:

   # Configure a portal authentication server.

```
[Switch] portal server newpt
[Switch-portal-server-newpt] ip 192.168.0.111 key simple portal
[Switch-portal-server-newpt] port 50100
[Switch-portal-server-newpt] quit
```

   # Configure a portal Web server.

```
[Switch] portal web-server newpt
[Switch-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Switch-portal-websvr-newpt] quit
```

   # Enable re-DHCP portal authentication on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] portal enable method redhcp
```

   # Specify portal Web server **newpt** on VLAN-interface 100.

```
[Switch–Vlan-interface100] portal apply web-server newpt
```

   # Configure the BAS-IP as 20.20.20.1 for portal packets sent from VLAN-interface 100 to the portal authentication server.

```
[Switch–Vlan-interface100] portal bas-ip 20.20.20.1
[Switch–Vlan-interface100] quit
```

Verifying the configuration

Verify that the portal configuration has taken effect.

```
[Switch] display portal interface vlan-interface 100
 Portal information of Vlan-interface100
     NAS-ID profile: Not configured
     Authorization : Strict checking
     ACL           : Disabled
     User profile  : Disabled
```

```
    Max users     : Not configured

    Action for server detection:
        Server type    Server name                          Action
        --             --                                   --
    Layer3 source network:
        IP address                                          Prefix length

    Destination authenticate subnet:
        IP address                                          Prefix length
```

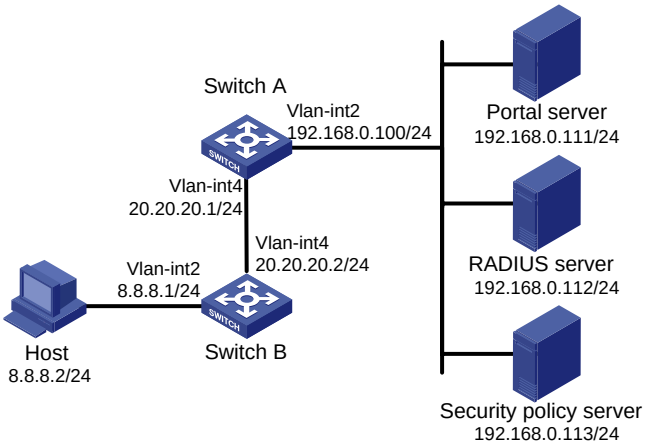
Before passing portal authentication, a user that uses the iNode client can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user will be redirected to the authentication page.

- The user can access the resources permitted by ACL 3000 after passing only identity authentication.
- The user can access network resources permitted by ACL 3001 after passing both identity authentication and security check.

After the user passes identity authentication and security check, use the following command to display information about the portal user.

```
[Switch] display portal user interface vlan-interface 100
```

```
Total portal users: 1
Username: abc
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  0015-e9a6-7cfe    20.20.20.2        100    Vlan-interface100
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number: 3001 (active)
    Inbound CAR: N/A
    Outbound CAR: N/A
```



Example: Configuring extended cross-subnet portal authentication

Network configuration

As shown in Figure 16, Switch A supports portal authentication. The host accesses Switch A through Switch B. A portal server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure Switch A for extended cross-subnet portal authentication. Before passing portal authentication, the host can access only the portal server. After passing portal identity authentication, the host accepts security check. If the host fails the security check it can access only the subnet 192.168.0.0/24. After passing the security check, the host can access other network resources.

Figure 16 Network diagram

Restrictions and guidelines

Make sure the IP address of the portal device added on the portal server is the IP address (20.20.20.1) of the switch's interface connecting the host. The IP address group associated with the portal device is the subnet of the host (8.8.8.0/24).

Prerequisites

- Configure IP addresses for the switch and servers as shown in Figure 16 and make sure the host, switch, and servers can reach each other.

- Configure the RADIUS server correctly to provide authentication and accounting functions.

Procedure

1. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rs1** and enter its view.

   ```
   <SwitchA> system-view
   [SwitchA] radius scheme rs1
   ```

   # Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

   ```
   [SwitchA-radius-rs1] primary authentication 192.168.0.112
   [SwitchA-radius-rs1] primary accounting 192.168.0.112
   [SwitchA-radius-rs1] key accounting simple radius
   [SwitchA-radius-rs1] key authentication simple radius
   [SwitchA-radius-rs1] user-name-format without-domain
   ```

   # Enable RADIUS session control.

   ```
   [SwitchA] radius session-control enable
   ```

   # Specify a session-control client with IP address 192.168.0.112 and shared key 12345 in plaintext form.

   ```
   [SwitchA] radius session-control client ip 192.168.0.112 key simple 12345
   ```

2. Configure an authentication domain:

   # Create an ISP domain named **dm1** and enter its view.

   ```
   [SwitchA] domain dm1
   ```

   # Configure AAA methods for the ISP domain.

   ```
   [SwitchA-isp-dm1] authentication portal radius-scheme rs1
   [SwitchA-isp-dm1] authorization portal radius-scheme rs1
   [SwitchA-isp-dm1] accounting portal radius-scheme rs1
   [SwitchA-isp-dm1] quit
   ```

   # Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

   ```
   [SwitchA] domain default enable dm1
   ```

3. Configure ACL 3000 as the isolation ACL and ACL 3001 as the security ACL.

   ```
   [SwitchA] acl advanced 3000
   [SwitchA-acl-ipv4-adv-3000] rule permit ip destination 192.168.0.0 0.0.0.255
   [SwitchA-acl-ipv4-adv-3000] rule deny ip
   [SwitchA-acl-ipv4-adv-3000] quit
   [SwitchA] acl advanced 3001
   [SwitchA-acl-ipv4-adv-3001] rule permit ip
   [SwitchA-acl-ipv4-adv-3001] quit
   ```

   NOTE:

   Make sure you specify ACL 3000 as the isolation ACL and ACL 3001 as the security ACL on the security policy server.

4. Configure portal authentication:

   # Configure a portal authentication server.

   ```
   [SwitchA] portal server newpt
   [SwitchA-portal-server-newpt] ip 192.168.0.111 key simple portal
   [SwitchA-portal-server-newpt] port 50100
   ```

```
[SwitchA-portal-server-newpt] quit
```

Configure a portal Web server.

```
[SwitchA] portal web-server newpt
[SwitchA-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[SwitchA-portal-websvr-newpt] quit
```

Enable cross-subnet portal authentication on VLAN-interface 4.

```
[SwitchA] interface vlan-interface 4
[SwitchA–Vlan-interface4] portal enable method layer3
```

Specify portal Web server **newpt** on VLAN-interface 4.

```
[SwitchA–Vlan-interface4] portal apply web-server newpt
```

Configure the BAS-IP as 20.20.20.1 for portal packets sent from VLAN-interface 4 to the portal authentication server.

```
[SwitchA–Vlan-interface4] portal bas-ip 20.20.20.1
[SwitchA–Vlan-interface4] quit
```

Verifying the configuration

Verify that the portal configuration has taken effect.

```
[SwitchA] display portal interface vlan-interface 4
 Portal information of Vlan-interface4
     NAS-ID profile: Not configured
     Authorization : Strict checking
     ACL           : Disabled

Layer3 source network:
    IP address                                     Prefix length

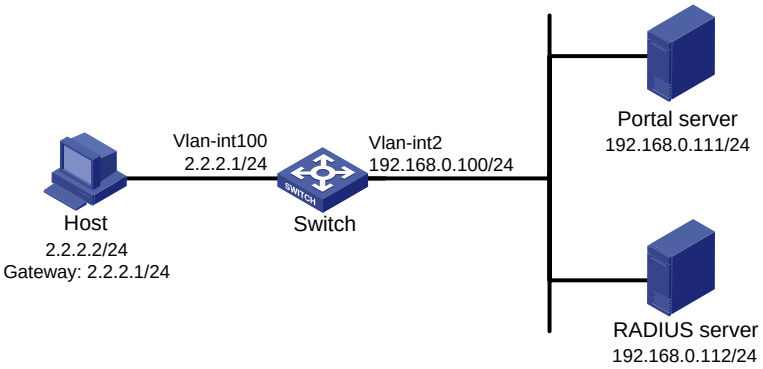
Destination authenticate subnet:
    IP address                                     Prefix length
```

Before passing portal authentication, a user that uses the iNode client can access only the authentication page **http://192.168.0.111:8080/portal**. All Web requests from the user will be redirected to the authentication page.

- The user can access the resources permitted by ACL 3000 after passing only identity authentication.
- The user can access network resources permitted by ACL 3001 after passing both identity authentication and security check.

After the user passes identity authentication and security check, use the following command to display information about the portal user.

```
[SwitchA] display portal user interface vlan-interface 4
Total portal users: 1
Username: abc
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  0015-e9a6-7cfe    8.8.8.2           4    Vlan-interface4
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number: 3001 (active)
    Inbound CAR: N/A
    Outbound CAR: N/A
```



Example: Configuring portal server detection and portal user synchronization

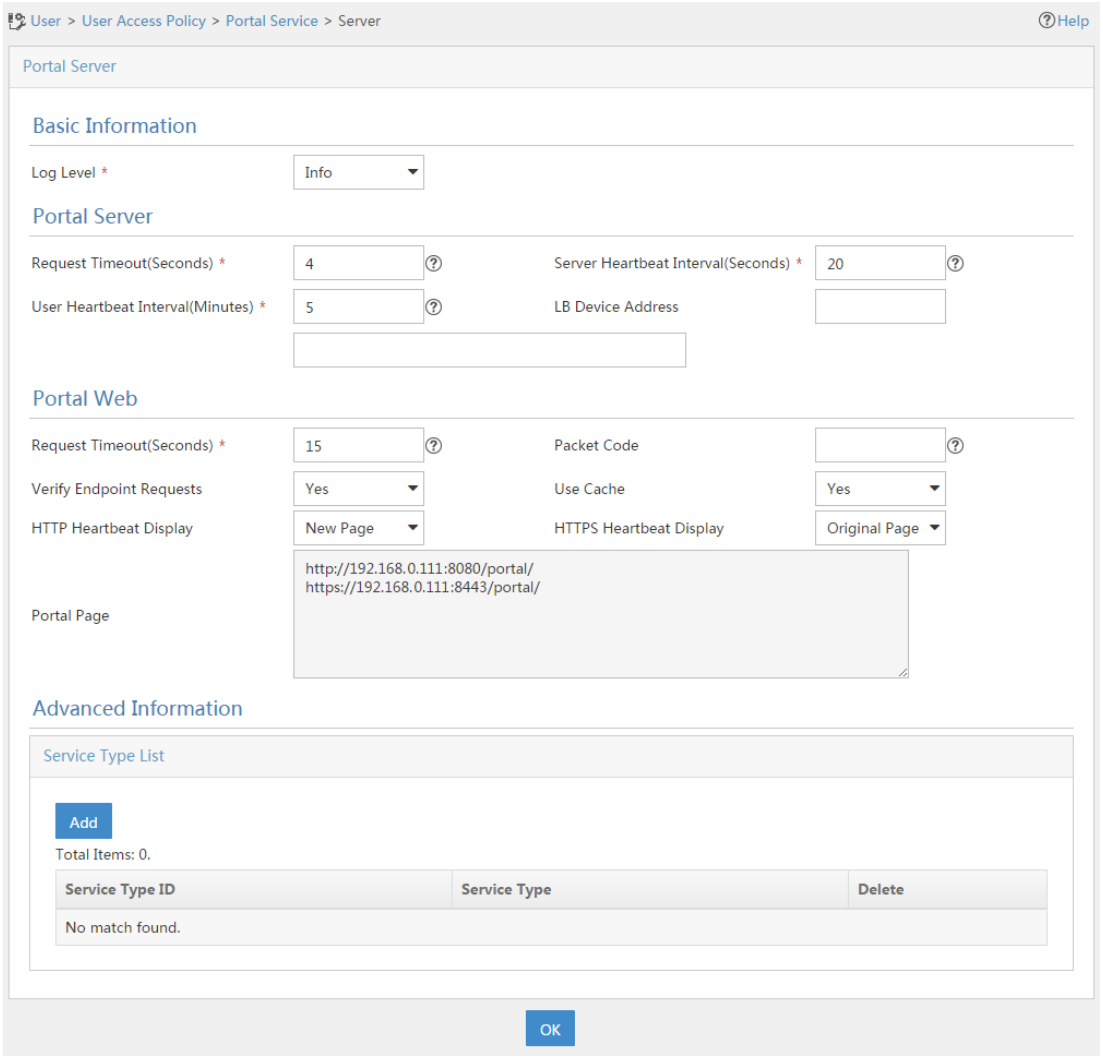
Network configuration

As shown in Figure 17, the host is directly connected to the switch (the access device). The host is assigned a public IP address either manually or through DHCP. An IMC server acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server. In this example, the IMC server runs IMC 7.1 (E0303) and IMC UAM 7.1 (E0304).

- Configure direct portal authentication on the switch, so the host can access only the portal server before passing the authentication and access other network resources after passing the authentication.
- Configure the switch to detect the reachability state of the portal authentication server, send log messages upon state changes, and disable portal authentication when the authentication server is unreachable.
- Configure the switch to synchronize portal user information with the portal server periodically.

Figure 17 Network diagram

Prerequisites



- Configure IP addresses for the switch and servers as shown in Figure 17 and make sure the host, switch, and servers can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.

Configuring the portal server

1. Configure the portal server:
   a. Log in to IMC and click the **User** tab.
   b. Select **User Access Policy** > **Portal Service** > **Server** from the navigation tree to open the portal server configuration page, as shown in Figure 18.
   c. Configure the portal server parameters as needed.

      This example uses the default settings.
   d. Click **OK**.

Figure 18 Portal server configuration

2. Configure the IP address group:
   a. Select **User Access Policy** > **Portal Service** > **IP Group** from the navigation tree to open the portal IP address group configuration page.
   b. Click **Add** to open the page as shown in Figure 19.
   c. Enter the IP group name.
   d. Enter the start IP address and end IP address of the IP group.
      Make sure the host IP address is in the IP group.
   e. Select a service group.
      This example uses the default group **Ungrouped**.
   f. Select **Normal** from the **Action** list.
   g. Click **OK**.

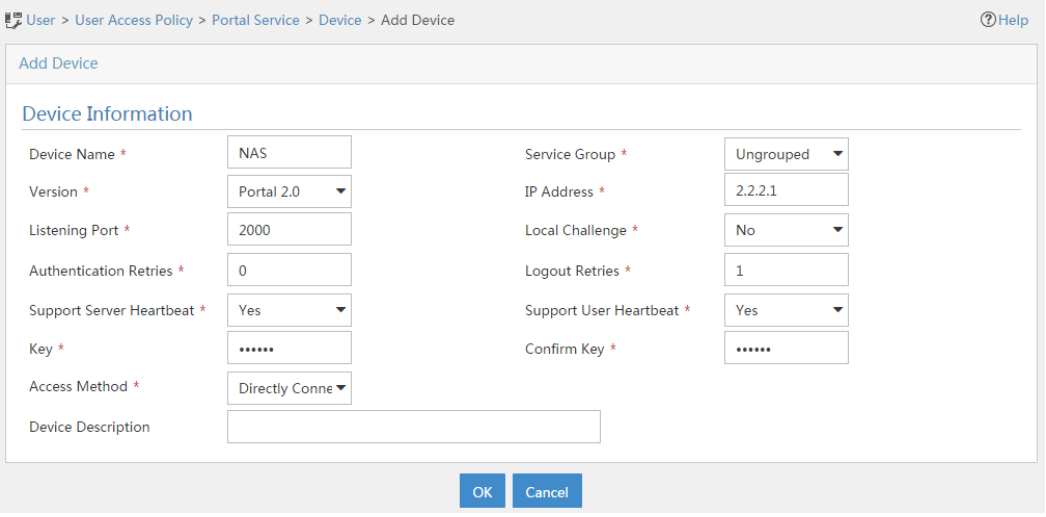


Figure 19 Adding an IP address group

3. Add a portal device:
   a. Select **User Access Policy** > **Portal Service** > **Device** from the navigation tree to open the portal device configuration page.
   b. Click **Add** to open the page as shown in Figure 20.
   c. Enter device name **NAS**.
   d. Enter the IP address of the switch's interface connected to the host.
   e. Set whether to support the portal server heartbeat and user heartbeat functions.

      In this example, select **Yes** for both **Support Server Heartbeat** and **Support User Heartbeat**.
   f. Enter the key, which must be the same as that configured on the switch.
   g. Select **Directly Connected** from the **Access Method** list.
   h. Use the default settings for other parameters.
   i. Click **OK**.

Figure 20 Adding a portal device

4. Associate the portal device with the IP address group:
   a. As shown in Figure 21, click the **Port Group Information Management** icon for device **NAS** to open the port group configuration page.
   b. Click **Add** to open the page as shown in Figure 22.
   c. Enter the port group name.

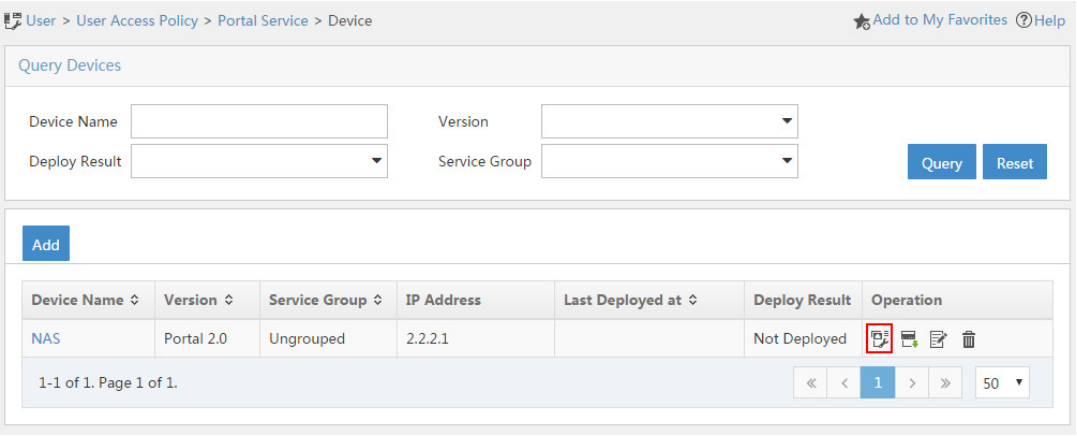
d. Select the configured IP address group.

The IP address used by the user to access the network must be within this IP address group.

e. Use the default settings for other parameters.

f. Click **OK**.

Figure 21 Device list



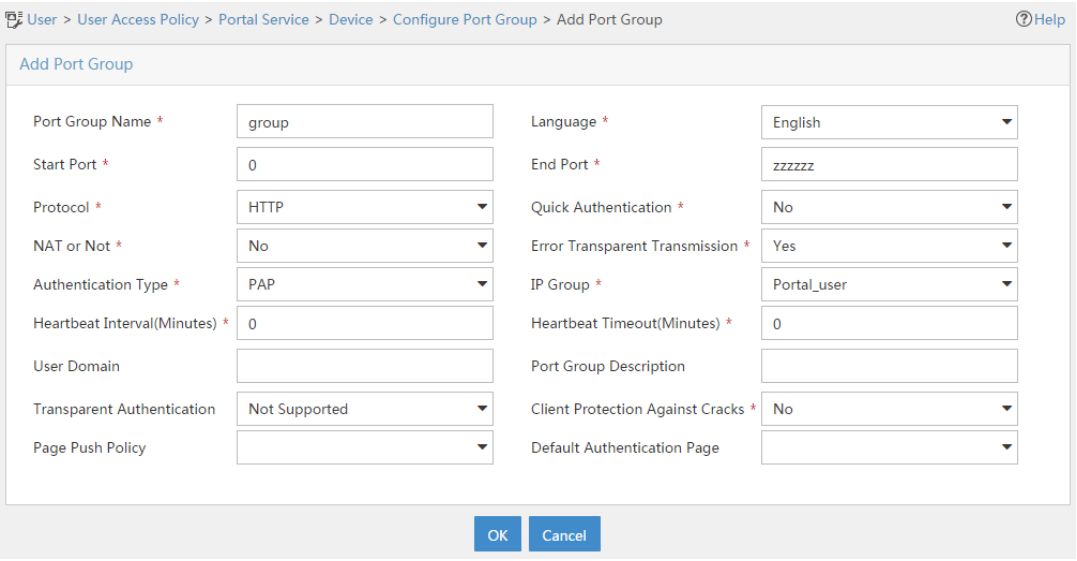


Figure 22 Adding a port group

Configuring the switch

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1** and enter its view.

```
<Switch> system-view
[Switch] radius scheme rs1
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Switch-radius-rs1] primary authentication 192.168.0.112
[Switch-radius-rs1] primary accounting 192.168.0.112
[Switch-radius-rs1] key authentication simple radius
[Switch-radius-rs1] key accounting simple radius
```

Exclude the ISP domain name from the username sent to the RADIUS server.

```
[Switch-radius-rs1] user-name-format without-domain
[Switch-radius-rs1] quit
```

Enable RADIUS session control.

```
[Switch] radius session-control enable
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[Switch] domain dm1
```

Configure AAA methods for the ISP domain.

```
[Switch-isp-dm1] authentication portal radius-scheme rs1
[Switch-isp-dm1] authorization portal radius-scheme rs1
[Switch-isp-dm1] accounting portal radius-scheme rs1
[Switch-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

```
[Switch] domain default enable dm1
```

3. Configure portal authentication:

Configure a portal authentication server.

```
[Switch] portal server newpt
[Switch-portal-server-newpt] ip 192.168.0.111 key simple portal
[Switch-portal-server-newpt] port 50100
```

Configure reachability detection of the portal authentication server: set the server detection interval to 40 seconds, and send log messages upon reachability status changes.

```
[Switch-portal-server-newpt] server-detect timeout 40 log
```

NOTE:

The value of **timeout** must be greater than or equal to the portal server heartbeat interval.

Configure portal user synchronization with the portal authentication server, and set the synchronization detection interval to 600 seconds.

```
[Switch-portal-server-newpt] user-sync timeout 600
[Switch-portal-server-newpt] quit
```

NOTE:

The value of **timeout** must be greater than or equal to the portal user heartbeat interval.

Configure a portal Web server.

```
[Switch] portal web-server newpt
[Switch-portal-websvr-newpt] url http://192.168.0.111:8080/portal
[Switch-portal-websvr-newpt] quit
```

Enable direct portal authentication on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] portal enable method direct
```

Enable portal fail-permit for the portal authentication server **newpt**.

```
[Switch–Vlan-interface100] portal fail-permit server newpt
```

Specify portal Web server **newpt** on VLAN-interface 100.

```
[Switch–Vlan-interface100] portal apply web-server newpt
```

Configure the BAS-IP as 2.2.2.1 for portal packets sent from VLAN-interface 100 to the portal authentication server.

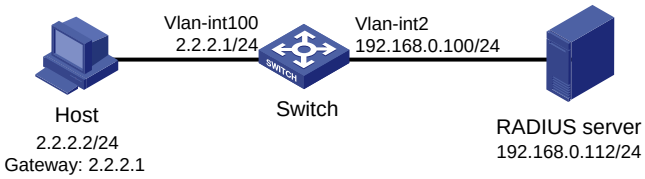
```
[Switch–Vlan-interface100] portal bas-ip 2.2.2.1
[Switch–Vlan-interface100] quit
```

Verifying the configuration

Use the following command to display information about the portal authentication server.

```
[Switch] display portal server newpt
Portal server: newpt
  Type                  : IMC
  IP                    : 192.168.0.111
  VPN instance          : Not configured
  Port                  : 50100
  Server Detection      : Timeout 40s  Action: log
  User synchronization  : Timeout 600s
  Status                : Up
```

The **Up** status of the portal authentication server indicates that the portal authentication server is reachable. If the access device detects that the portal authentication server is unreachable, the **Status** field in the command output displays **Down**. The access device generates a server unreachable log "Portal server newpt turns down from up." and disables portal authentication on the access interface, so the host can access the external network without authentication.



Example: Configuring direct portal authentication using a local portal Web service

Network configuration

As shown in Figure 23, the host is directly connected to the switch (the access device). The host is assigned a public IP address either manually or through DHCP. The switch acts as both a portal authentication server and a portal Web server. A RADIUS server acts as the authentication and accounting server.

Configure direct portal authentication on the switch. Before a user passes portal authentication, the user can access only the portal Web server. After passing portal authentication, the user can access other network resources.

Figure 23 Network diagram

Prerequisites

- Configure IP addresses for the host, switch, and server as shown in Figure 23 and make sure they can reach each other.
- Configure the RADIUS server correctly to provide authentication and accounting functions.

Procedure

1. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rs1** and enter its view.

   ```
   <Switch> system-view
   ```

```
[Switch] radius scheme rs1
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Switch-radius-rs1] primary authentication 192.168.0.112
[Switch-radius-rs1] primary accounting 192.168.0.112
[Switch-radius-rs1] key authentication simple radius
[Switch-radius-rs1] key accounting simple radius
```

Exclude the ISP domain name from the username sent to the RADIUS server.

```
[Switch-radius-rs1] user-name-format without-domain
[Switch-radius-rs1] quit
```

Enable RADIUS session control.

```
[Switch] radius session-control enable
```

2. Configure an authentication domain:

Create an ISP domain named **dm1** and enter its view.

```
[Switch] domain dm1
```

Configure AAA methods for the ISP domain.

```
[Switch-isp-dm1] authentication portal radius-scheme rs1
[Switch-isp-dm1] authorization portal radius-scheme rs1
[Switch-isp-dm1] accounting portal radius-scheme rs1
[Switch-isp-dm1] quit
```

Configure domain **dm1** as the default ISP domain. If a user enters the username without the ISP domain name at login, the authentication and accounting methods of the default domain are used for the user.

```
[Switch] domain default enable dm1
```

3. Configure portal authentication:

Configure a portal Web server named **newpt** and specify **http://2.2.2.1:2331/portal** as the URL of the portal Web server. The IP address in the URL must be the IP address of a Layer 3 interface reachable to portal clients or a loopback interface (except 127.0.0.1) on the device.

```
[Switch] portal web-server newpt
[Switch-portal-websvr-newpt] url http://2.2.2.1:2331/portal
[Switch-portal-websvr-newpt] quit
```

Enable direct portal authentication on VLAN-interface 100.

```
[Switch] interface vlan-interface 100
[Switch–Vlan-interface100] portal enable method direct
```

Specify portal Web server **newpt** on VLAN-interface 100.

```
[Switch–Vlan-interface100] portal apply web-server newpt
[Switch–Vlan-interface100] quit
```

Create an HTTP-based local portal Web service and enter its view.

```
[Switch] portal local-web-server http
```

Specify file **defaultfile.zip** as the default authentication page file for the local portal Web service. (Make sure the file exists under the root directory of the switch.)

```
[Switch–portal-local-websvr-http] default-logon-page defaultfile.zip
```

Set the HTTP listening port number to 2331 for the local portal Web service.

```
[Switch–portal-local-webserver-http] tcp-port 2331
[Switch–portal-local-websvr-http] quit
```

Verifying the configuration

Verify that the portal configuration has taken effect.

```
[Switch] display portal interface vlan-interface 100
 Portal information of Vlan-interface 100
     Authorization                   Strict checking
     ACL                             Disabled
     User profile                    Disabled
 IPv4:
     Portal status: Enabled
     Portal authentication method: Direct
     Portal web server: newpt
     Portal mac-trigger-server: Not configured
     Authentication domain: Not configured
     User-dhcp-only: Disabled
     Pre-auth IP pool: Not configured
     Max users: Not configured
     Bas-ip: Not configured
     User detection:  Not configured
     Action for server detection:
         Server type    Server name                      Action
         --             --                               --
     Layer3 source network:
         IP address              Mask

     Destination authenticate subnet:
         IP address              Mask
IPv6:
     Portal status: Disabled
     Portal authentication method: Disabled
     Portal web server: Not configured
     Portal mac-trigger-server: Not configured
     Authentication domain: Not configured
     User-dhcp-only: Disabled
     Pre-auth IP pool: Not configured
     Max users: Not configured
     Bas-ipv6: Not configured
     User detection: Not configured
     Action for server detection:
         Server type    Server name                      Action
         --             --                               --
     Layer3 source network:
         IP address                                      Prefix length

     Destination authenticate subnet:
         IP address                                      Prefix length
```

A user can perform portal authentication through a Web page. Before passing the authentication, the user can access only the authentication page **http://2.2.2.1:2331/portal** and all Web requests will be redirected to the authentication page. After passing the authentication, the user can access other network resources.

After the user passes authentication, use the following command to display information about the portal user.

```
[Switch] display portal user interface vlan-interface 100
Total portal users: 1
Username: abc
  Portal server: newpt
  State: Online
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  0015-e9a6-7cfe    2.2.2.2           100     Vlan-interface100
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number: N/A
    Inbound CAR: N/A
    Outbound CAR: N/A
```

Troubleshooting portal

No portal authentication page is pushed for users

Symptom

When a user is redirected to the IMC portal authentication server, no portal authentication page or error message is prompted for the user. The login page is blank.

Analysis

The key configured on the portal access device and that configured on the portal authentication server are inconsistent. As a result, packet verification fails, and the portal authentication server refuses to push the authentication page.

Solution

Use the **display this** command in portal authentication server view on the access device to check whether a key is configured for the portal authentication server.

- If no key is configured, configure the right key.
- If a key is configured, use the **ip** or **ipv6** command in the portal authentication server view to correct the key, or correct the key configured for the access device on the portal authentication server.

Cannot log out portal users on the access device

Symptom

You cannot use the **portal delete-user** command on the access device to log out a portal user, but the portal user can log out by clicking the **Disconnect** button on the portal authentication client.

Analysis

When you execute the **portal delete-user** command on the access device to log out a user, the access device sends an unsolicited logout notification message to the portal authentication server. The destination port number in the logout notification is the listening port number of the portal authentication server configured on the access device. If this listening port number is not the actual listening port number configured on the server, the server cannot receive the notification. As a result, the server does not log out the user.

When a user uses the **Disconnect** button on the authentication client to log out, the portal authentication server sends an unsolicited logout request message to the access device. The access device uses the source port in the logout request as the destination port in the logout ACK message. As a result, the portal authentication server can definitely receive the logout ACK message and log out the user.

Solution

1. Use the **display portal server** command to display the listening port of the portal authentication server configured on the access device.
2. Use the **portal server** command in system view to change the listening port number to the actual listening port of the portal authentication server.

Cannot log out portal users on the RADIUS server

Symptom

The access device uses the IMC server as the RADIUS server to perform identity authentication for portal users. You cannot log out the portal users on the RADIUS server.

Analysis

The IMC server uses session control packets to send disconnection requests to the access device. On the access device, the listening UDP port for session control packets is disabled by default. Therefore, the access device cannot receive the portal user logout requests from the RADIUS server.

Solution

On the access device, execute the **radius session-control enable** command in system view to enable the RADIUS session control function.

Users logged out by the access device still exist on the portal authentication server

Symptom

After you log out a portal user on the access device, the user still exists on the portal authentication server.

Analysis

When you execute the **portal delete-user** command on the access device to log out a user, the access device sends an unsolicited logout notification to the portal authentication server. If the BAS-IP or BAS-IPv6 address carried in the logout notification is different from the portal device IP address specified on the portal authentication server, the portal authentication server discards the logout notification. When sending of the logout notifications times out, the access device logs out the user. However, the portal authentication server does not receive the logout notification successfully, and therefore it regards the user is still online.

Solution

Configure the BAS-IP or BAS-IPv6 attribute on the interface enabled with portal authentication. Make sure the attribute value is the same as the portal device IP address specified on the portal authentication server.

Re-DHCP portal authenticated users cannot log in successfully

Symptom

The device performs re-DHCP portal authentication for users. A user enters the correct username and password, and the client successfully obtains the private and public IP addresses. However, the authentication result for the user is failure.

Analysis

When the access device detects that the client IP address is changed, it sends an unsolicited portal packet to notify of the IP change to the portal authentication server. The portal authentication server notifies of the authentication success only after it receives the IP change notification from both the access device and the client.

If the BAS-IP or BAS-IPv6 address carried in the portal notification packet is different from the portal device IP address specified on the portal authentication server, the portal authentication server discards the portal notification packet. As a result, the portal authentication server considers that the user has failed the authentication.

Solution

Configure the BAS-IP or BAS-IPv6 attribute on the interface enabled with portal authentication. Make sure the attribute value is the same as the portal device IP address specified on the portal authentication server.

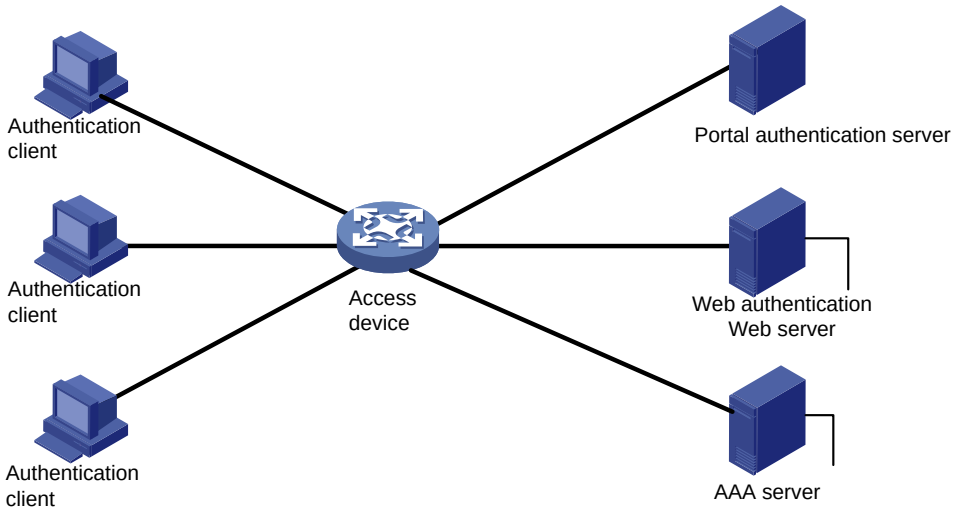
Configuring Web authentication

About Web authentication

Web authentication is deployed on Layer 2 interfaces of the access device to control user access to networks. The access device redirects unauthenticated users to the specified website. The users can access the resources on the website without authentication. If the users want to access other network resources, they must pass authentication.

Advantages of Web authentication



Web authentication has the following advantages:

- Allows users to perform authentication through webpages without installing client software.
- Provides ISPs with diversified management choices and extended functions. For example, the ISPs can place advertisements, provide community services, and publish information on the authentication page.

Web authentication system

A typical Web authentication system consists of four basic components: authentication client, access device, Web server for Web authentication, and AAA server.

Figure 1 Web authentication system using the local portal server

Authentication client

An authentication client is a Web browser that runs HTTP or HTTPS on the user endpoint.

Access device

An access device has the following functions:

- Redirects all user HTTP or HTTPS requests that do not match authentication-free rules to the Web authentication page before authentication.
- Interacts with the AAA server to complete authentication, authorization, and accounting. For more information about AAA, see "Configuring AAA."

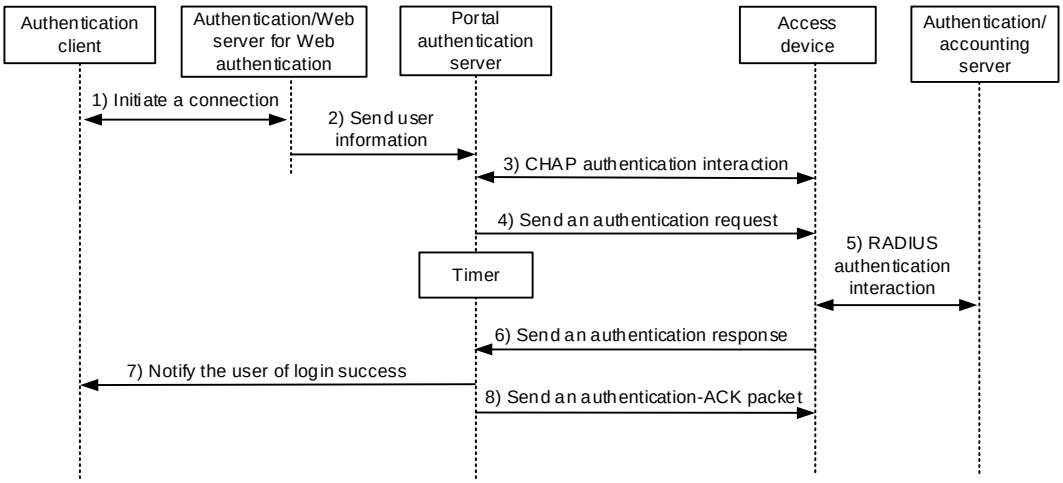
- Allows users that pass authentication to access authorized network resources.

Web server for Web authentication

A Web server pushes the Web authentication page to authentication clients and obtains user authentication information (username and password).

A Web server for Web authentication can be a local Web server or a remote Web server. A local Web server is usually integrated into the access device. A remote Web server is a portal Web server.

Portal authentication server



Web authentication uses a portal authentication server as the authentication server, which exchanges client authentication information with the access device.

AAA server

An AAA server interacts with the access device to implement user authentication, authorization, and accounting. A RADIUS server can perform authentication, authorization, and accounting for Web authentication users. An LDAP server can perform authentication for Web authentication users.

Web authentication process

Figure 2 Web authentication process

The Web authentication process is as follows:

1. An unauthenticated user sends an HTTP or HTTPS request. When the access device receives the HTTP or HTTPS request on a Layer 2 Ethernet interface enabled with Web authentication, the request, it redirects the request to the Web authentication page. The user enters the username and password on the Web authentication page.

   If the user requests the Web authentication page or free Web resources, the access device permits the request. No Web authentication is performed.
2. The Web server for Web authentication sends the user information to the portal authentication.
3. The portal authentication server and the access device interact with each other to perform CHAP authentication. This step is skipped if PAP authentication is used. The authentication interaction type is determined by the portal authentication server.
4. The portal authentication sends an authentication request that contains the username and password of the user to the access device and starts a timer to wait for an authentication response.
5. The access device and the AAA server exchange RADIUS packets to authenticate the user.

6. The access device sends an authentication response indicating authentication success or failure to the portal authentication server.
7. The portal authentication server notifies the authentication result to the client.
8. If the user passes RADIUS authentication, the portal authentication server also sends an authentication-ACK packet to the access device..

Web authentication support for VLAN assignment

Authorization VLAN

Web authentication uses VLANs authorized by the AAA server or the access device to control network resource access of authenticated users.

After a user passes Web authentication, the AAA server or the access device authorizes the user to access a VLAN. If the authorization VLAN does not exist, the access device first creates the VLAN and then assigns the user access interface as an untagged member to the VLAN. If the authorization VLAN already exists, the access device directly assigns the user access interface as an untagged member to the VLAN. Then, the user can access resources in the authorization VLAN.

Table 1 describes the way the access device handles authorization VLANs for Web authenticated users.

Table 1 VLAN manipulation

Port type	VLAN manipulation
• Access port • Trunk port • Hybrid port with MAC-based-VLAN disabled	The device assigns the port to the first authenticated user's authorization VLAN. The authorization VLAN becomes the PVID. All Web authentication users on the port must be assigned the same authorization VLAN. If a different authorization VLAN is assigned to a subsequent user, the user cannot pass Web authentication.
Hybrid port with MAC-based VLAN enabled	The device maps the MAC address of each user to its own authorization VLAN regardless of whether the port is a tagged member. The PVID of the port does not change.

Auth-Fail VLAN

An Auth-Fail VLAN is a VLAN assigned to users who fail authentication. The Auth-Fail VLAN provides network resources such as the patch server, virus definitions server, client software server, and anti-virus software server to the users. The users can use these resources to upgrade their client software or other programs.

Web authentication supports Auth-Fail VLAN on an interface that performs MAC-based access control. If a user on the interface fails authentication, the access devices creates a MAC VLAN entry based on the MAC address of the user and adds the user to the Auth-Fail VLAN. Then, the user can access the authentication-free IP resources in the Auth-Fail VLAN. All HTTP or HTTPS requests to non-authentication-free IP resources will be redirected to the authentication page. If the user still fails authentication, the interface remains in the Auth-Fail VLAN. If the user passes authentication, the access device removes the interface from the Auth-Fail VLAN and assigns the interface to a VLAN as follows:

- If the authentication server assigns an authorization VLAN to the user, the access device assigns the interface to the authorization VLAN.
- If the authentication server does not assign an authorization VLAN to the user, the access device assigns the interface to the default VLAN.

Web authentication multi-VLAN mode

Web authentication supports single-VLAN or multi-VLAN mode on a port.

In multi-VLAN mode, the port forwards traffic from a user in different VLANs without reauthentication if the user has been authenticated and come online in any VLAN on the port.

In single-VLAN mode, the port reauthenticates an online user when traffic received from that user contains a VLAN tag different from the VLAN in which the user was authenticated. The authentication process differs depending on the MAC move setting in port security and the authorization VLAN assignment status, as follows:

- If no authorization VLAN has been assigned to the online user, the device first logs off the user and then reauthenticates the user in the new VLAN.
- If the online user has been assigned an authorization VLAN, the device handles the user depending on the MAC move setting in port security.
  - If MAC move is disabled in port security, the user cannot pass authentication and come online from the new VLAN until after it goes offline from the port.
  - If MAC move is enabled in port security, the user can pass authentication on the new VLAN and come online without having to first go offline from the port. After the user passes authentication on the new VLAN, the original authentication session of the user is deleted from the port.

  To enable the port security MAC move feature, use the **`port-security mac-move permit`** command.

Web authentication support for authorization ACLs

Web authentication uses ACLs authorized by the AAA server or the access device to control user access to network resources and limit user access rights. When a user passes authentication, the AAA server and the access device assigns an authorization ACL to the access interface of the user. The access device filters traffic from the user on the access interface according to the authorized ACL.

You must configure the authorization ACLs on the access device if you specify authorization ACLs on the authentication server.

To change the access control criteria for the user, you can specify a different authorization ACL on the authentication server or change rules in the authorization ACL on the access device.

The device supports the following types of authorization ACLs:

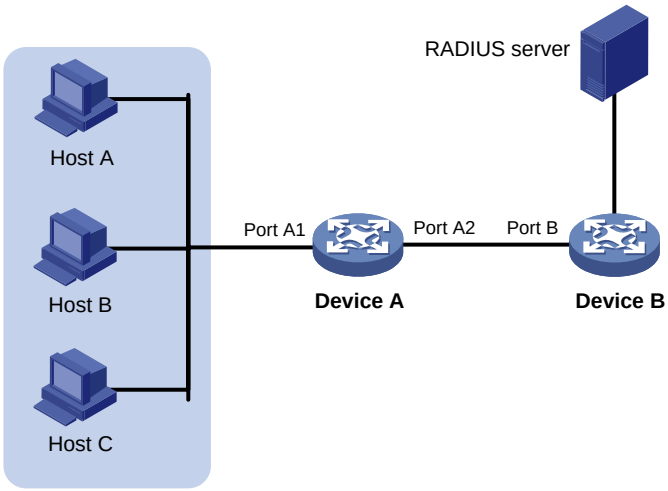
- Basic ACLs (ACL 2000 to ACL 2999).
- Advanced ACLs (ACL 3000 to ACL 3999).
- Layer 2 ACLs (ACL 4000 to ACL 4999).

For an authorization ACL to take effect, make sure the ACL exists and has ACL rules excluding rules configured with the **`counting`**, **`established`**, **`fragment`**, **`source-mac`**, or **`logging`** keyword. For more information about ACL rules, see ACL commands in *ACL and QoS Command Reference*.

Restrictions and guidelines: Web authentication configuration

When you configure Web authentication, follow these restrictions and guidelines:

- Web authentication cannot be configured in conjunction with the guest, Auth-Fail, and critical VLAN settings of 802.1X authentication.
- Web authentication cannot be configured in conjunction with the guest and critical VLAN settings of MAC authentication.



To access the resources in the authorization or Auth-Fail VLAN, a user must update the IP address of the client after being assigned to the authorization or Auth-Fail VLAN.

To redirect HTTPS requests for unauthenticated users correctly, make sure the packet incoming VLANs have Layer 3 interfaces (VLAN interfaces) configured.

As a best practice, perform Web authentication on users directly connected to the device. As shown in Figure 3, if you enable Web authentication on Port B to authenticate non-directly connected users (the hosts), you must follow these restrictions and guidelines:

- If the RADIUS server assigns an authorization VLAN to the users, make sure the following conditions are met:
  - The link between Device A and Device B is a trunk link.
  - The PVIDs of Port A1 and Port B are the same as the authorization VLAN ID.
- If the RADIUS server does not assign an authorization VLAN to the users, make sure the PVIDs of Port A1 and Port B are the same.

Figure 3 Web authentication for non-directly connected users

Web authentication tasks at a glance

To configure Web authentication, perform the following tasks:

1. Configuring a remote Web authentication service

   Perform this task if a remote Web server is deployed on the network for Web authentication.

   a. Configuring a remote portal authentication server
   b. Configuring a remote Web server for Web authentication
   c. Obtaining user information from ARP or ND entries
2. Configuring a local Web authentication service

   Perform this task if the device is used as the local Web server for Web authentication.

   a. Configuring a local Web server for Web authentication
   b. Configuring a local portal service
3. Enabling Web authentication
4. (Optional.) Specifying a Web authentication domain
5. (Optional.) Setting the redirection wait time
6. (Optional.) Configuring a Web authentication-free subnet
7. (Optional.) Setting the maximum number of Web authentication users
8. (Optional.) Configuring online Web authentication user detection
9. (Optional.) Configuring an Auth-Fail VLAN

10. (Optional.) Configuring Web authentication to support Web proxy

Prerequisites for Web authentication

The device supports two methods for Web authentication, which are local authentication and RADIUS authentication.

To use the RADIUS authentication method, you must complete the following tasks:

- Install a RADIUS server and configure the RADIUS server properly.
- Make sure the authentication client, the access device, and the RADIUS server can reach each other.
- Configure user accounts on the RADIUS server and configure the RADIUS client information on the access device.

To use the local authentication method, you must configure local users on the access device.

For more information about RADIUS clients and local users, see "Configuring AAA."

Configuring a remote Web server for Web authentication

About this task

In the view of a remote Web server, you can configure the Web server IP address, redirection URL, and the parameters to be carried in the redirection URL.

By default, the state of the Web server specified by the redirection URL is always **active**. The device cannot obtain the real server state. When primary and secondary Web servers are deployed for continuous authentication service, the device needs to quickly obtain the primary server's state changes to perform primary/secondary switchovers accordingly.

You can associate the Web server with a track entry that is associated with NQA, so the device can periodically detect the reachability of the server through NQA.

- The Track module changes the state of the track entry according to the NQA detection result. The device changes the state of the Web server according to the state of the track entry.
- In this way, if NQA detects that the Web server becomes reachable, the device will set the server state to active. If NQA detects that the Web server becomes unreachable, the device will set the server state to inactive.

For more information about the Track configuration, see *High Availability Configuration Guide*.

Restrictions and guidelines

To deploy both primary and secondary Web servers, you must associate the primary Web server with a track entry to monitor the reachability status of the server. Otherwise, the device cannot sense the reachability state changes of the primary server to perform primary/secondary switchovers.

The NQA detection for server reachability is performed according to the **`nqa schedule`** configuration, which schedules the NQA operation associated with the track entry. Configure the NQA operation time and other detection parameters as needed.

Procedure

1. Enter system view.

   `system-view`

2. Create a remote Web server for Web authentication and enter Web authentication remote Web server view.

web-auth remote server *server-name*

The local and remote Web servers cannot use the same name.

3. Specify the IP address of the remote Web server for Web authentication.

   IPv4:

   ip *ipv4-address*

   IPv6:

   ipv6 *ipv6-address*

   By default, no IP address is specified for the remote Web server for Web authentication.

   The IP address of the remote Web server must be the IP address of the portal Web server used for Web authentication.

   You can configure one IPv4 address and one IPv6 address for a remote Web server.

4. Configure the redirection URL of the remote Web server for Web authentication.

   url *url-string* [**track** *track-entry-number*]

   By default, no redirection URL is specified for a Web server for Web authentication.

   To provide Web authentication pages for both IPv4 and IPv6 Web authentication users, configure the redirection URL to carry the domain name of the Web server. For example: **http://abc.com**, where **abc.com** is the domain name of the Web server.

   A Web server can be associated with only one track entry. If you associate Track with the Web server multiple times, the most recent configuration takes effect.

5. (Optional.) Add parameters to the redirection URL of the remote Web server.

   url-parameter *parameter-name* { **original-url** | **source-address** | **source-mac** | **value** *expression* }

   By default, no parameters are added to the redirection URL of a Web server.

   You must use the URL parameter name supported by the Web browser. Different Web browsers support different URL parameter names.

Configuring a remote portal authentication server

For information about configuring a remote portal authentication server, see "Configuring portal authentication."

Obtaining user information from ARP or ND entries

About this task

By default, the device obtains user information required by the portal authentication server from MIB entries. However, MIB entries do not contain the Layer 2 user information (such as MAC address and Layer 2 access interface) required for Web authentication. Users will fail the Web authentication as a result.

To resolve this issue, configure the device to obtain user information from ARP or ND entries.

Procedure

1. Enter system view.

   system-view

2. Configure the device to obtain portal user information from ARP or ND entries.

   portal access-info trust { **arp** | **nd** }

By default, the device obtains user information from FIB entries.

For more information about the configuration, see "Configuring portal authentication."

Configuring a local Web server for Web authentication

Restrictions and guidelines

Specify the IP address of a Layer 3 interface on the device that is routable to the Web client as the listening IP address of the local Web server for Web authentication. As a best practice, use the IP address of a loopback interface. A loopback interface has the following advantages:

- The status of a loopback interface is stable. There will be no authentication page access failures caused by interface failures.
- A loopback interface does not forward received packets to any networks, avoiding impact on system performances when there are many network access requests.

Procedure

1. Enter system view.

   system-view

2. Create a local Web server for Web authentication and enter Web authentication local Web server view.

   web-auth server *server-name*

   The local and remote Web servers cannot use the same name.

3. Specify the IP address and port number of the local Web server.

   IPv4:

   ip *ipv4-address* **port** *port-number*

   IPv6:

   ipv6 *ipv6-address* **port** *port-number*

   The port number of the local Web server must be the same as the listening port number of the local portal Web service.

   You can configure one IPv4 address and one IPv6 address for a local Web server.

4. Specify the redirection URL for the local Web server.

   url *url-string*

   By default, no redirection URL is specified for a Web server for Web authentication.

   The redirection URL must start with **http://** or **https://**. The IP address and port number in the specified redirection URL must be the same as those of the local Web server for Web authentication.

   To provide Web authentication pages for both IPv4 and IPv6 Web authentication users, configure the redirection URL to carry the domain name of the Web server.

5. (Optional.) Add parameters to the redirection URL of the local Web server.

   url-parameter *parameter-name* { **original-url** | **source-address** | **source-mac** | **value** *expression* }

   By default, no parameters are added to the redirection URL of a Web server.

   You must use the URL parameter name supported by the Web browser. Different Web browsers support different URL parameter names.

Configuring a local portal service

For information about the local portal service configuration, see "Configuring portal authentication."

Enabling Web authentication

Restrictions and guidelines

For Web authentication to operate correctly, do not enable port security or configure the port security mode on the Layer 2 interface enabled with Web authentication. For more information about port security, see "Configuring port security."

To deploy both primary and secondary Web servers, follow these restrictions and guidelines:

- Only a remote Web server can be used as the primary Web server. A remote or local Web server can be used as the secondary Web server.
- Associate the primary Web server with a track entry (by using the **url** *url-string* **track** *track-entry-number* command) to monitor the reachability status of the server. Otherwise, the device cannot sense the reachability state changes of the primary server to perform primary/secondary switchovers.

The default HTTPS redirect listening port number on the device is 6654. To change the HTTPS redirect listening port number, see HTTP redirect configuration in *Layer 3—IP Services Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable Web authentication and specify Web servers for Web authentication.

   web-auth enable apply server *primary-server-name* [**secondary-server** *secondary-server-name*]

   By default, Web authentication is disabled.

Specifying a Web authentication domain

About this task

You can specify different authentication domains for Web authentication users on different interfaces. After you specify a Web authentication domain on an interface, the device uses the authentication domain for AAA of all Web authentication users on the interface, ignoring the domain names carried in the usernames.

The device selects the authentication domain for a Web authentication user on an interface in this order:

1. The authentication domain specified for the interface.
2. The authentication domain carried in the username.
3. The system default authentication domain.
4. The ISP domain configured to accommodate users assigned to nonexistent domains.

If the selected domain does not exist on the device, user authentication fails. For information about ISP domains, see "Configuring AAA."

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify an authentication domain for Web authentication users on the interface.
   web-auth domain *domain-name*
   By default, no authentication domain is specified for Web authentication users.

Setting the redirection wait time

About this task

The redirection wait time determines the length of time that the device waits to redirect a user to the specified webpage after the user passes Web authentication.

You need to change the redirection wait time in some scenarios, for example, when a user needs to update the client IP address after passing local Web authentication. To ensure that the specified webpage can be successfully opened, set the redirection wait time to be greater than the time that the user takes to update the IP address of the client.

Procedure

1. Enter system view.
   system-view
2. Enter Web authentication local Web server view.
   web-auth server *server-name*
3. Set the redirection wait time.
   redirect-wait-time *period*
   By default, the redirection wait time for authenticated users is 5 seconds.

Configuring a Web authentication-free subnet

About this task

You can configure a Web authentication-free subnet so that users can freely access the network resources in the subnet without being authenticated.

Restrictions and guidelines

As a best practice, do not configure the same address value for a Web authentication-free subnet and a 802.1X free IP. Otherwise, when you cancel one of the configuration, the other configuration does not take effect, either.

Procedure

1. Enter system view.
   system-view
2. Configure a Web authentication-free subnet.
   web-auth free-ip *ip-address* { *mask-length* | *mask* }

Setting the maximum number of Web authentication users

Restrictions and guidelines

If the maximum number of online Web authentication users you set is less than that of the current online Web authentication users, the limit can be set successfully and does not impact the online Web authentication users. However, the system does not allow new Web authentication users to log in until the number drops down below the limit.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the maximum number of Web authentication users on the interface.
   web-auth max-user *max-number*
   By default, the maximum number of Web authentication users is 1024.

Configuring online Web authentication user detection

About this task

This feature enables the device to detect packets of an online user at the specified detection interval. If no packet from the user is received within the interval, the device logs out the user and notifies the RADIUS server to stop accounting for the user.

Restrictions and guidelines

To prevent the device from mistakenly logging out users, set the detection interval to be the same as the aging time of MAC address entries.

On a Layer 2 aggregate interface, the real interval for logging out a user is greater than the specified detection interval. The maximum delay is 300 seconds.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable online Web authentication user detection.
   web-auth offline-detect interval *interval*
   By default, online Web authentication user detection is disabled.

Configuring an Auth-Fail VLAN

Restrictions and guidelines

To make the Auth-Fail VLAN take effect, you must also enable MAC-based VLAN on the interface, and set the subnet of the Auth-Fail VLAN as the Web authentication-free subnet.

Because MAC-based VLAN takes effect only on Hybrid ports, Auth-Fail VLAN also takes effect only on Hybrid ports.

If a VLAN is specified as the super VLAN, do not configure the VLAN as an Auth-Fail VLAN of an interface. If a VLAN is specified as an Auth-Fail VLAN of an interface, do not configure the VLAN as a super VLAN.

Do not delete the VLAN that has been configured as an Auth-Fail VLAN. To delete this VLAN, first cancel the Auth-Fail VLAN configuration by using **undo web-auth auth-fail vlan** command.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure an Auth-Fail VLAN.
   web-auth auth-fail vlan *authfail-vlan-id*
   By default, no Auth-Fail VLAN is configured on an interface.

Configuring Web authentication multi-VLAN mode

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable the multi-VLAN mode for Web authentication on the port.
   web-auth host-mode multi-vlan
   By default, Web authentication operates in single-VLAN mode on a port.

Configuring Web authentication to support Web proxy

About this task

By default, proxied HTTP or HTTPS requests cannot trigger Web authentication but are silently dropped. To allow such HTTP or HTTPS requests to trigger Web authentication, specify the port numbers of the Web proxy servers on the device.

Restrictions and guidelines

If a user's browser uses the Web Proxy Auto-Discovery (WPAD) protocol to discover Web proxy servers, follow these restrictions and guidelines:

- Add the port numbers of the Web proxy servers on the device.

- Configure a Web authentication-free rule on the device to allow user packets destined for the IP address of the WPAD server to pass without authentication.
- Users must add the IP address of the Web server for Web authentication as a proxy exception in their browsers. Then, HTTP or HTTPS packets that the users send to the Web server for Web authentication will not be sent to Web proxy servers.

Procedure

1. Enter system view.

   system-view
2. Add a Web proxy server port number.

   web-auth proxy [**https**] **port** *port-number*

   By default, no Web proxy server port numbers are configured on the device.

   Do not specify port number 80 or 443 because 80 and 443 are port numbers reserved for Web authentication.

   Do not specify the same Web proxy server port number for HTTP and HTTPS.

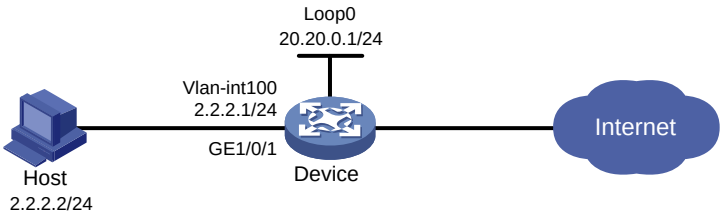
Display and maintenance commands for Web authentication

Execute **display** commands in any view.

Task	Command
Display Web authentication configuration information on interfaces.	**display web-auth** [**interface** *interface-type interface-number*]
Display Web authentication-free subnets.	**display web-auth free-ip**
Display information about Web servers for Web authentication.	**display web-auth server** [*server-name*]
Display Web authentication user information.	**display web-auth user** [**interface** *interface-type interface-number* | **slot** *slot-number*]

Web authentication configuration examples

Example: Configuring local Web authentication by using the AAA local authentication method



Network configuration

As shown in Figure 4, the host is directly connected to the device through GigabitEthernet 1/0/1.

Configure local Web authentication on GigabitEthernet 1/0/1, and configure the device to perform local authentication and authorization for the local Web authentication users.

Configure a local Web server on the device that uses the IP address of Loopback 0 and port 80 for Web authentication. Configure the device to use HTTP to transfer the authentication data.

Figure 4 Network diagram

Prerequisites

Create VLANs, assign IP addresses to the VLAN interfaces, and assign interfaces to the VLANs.

Procedure

1. Configure a local user:

   # Create a local network access user named **localuser**.

   ```
   <Device>system-view
   [Device] local-user localuser class network
   ```

   # Set the password for user **localuser.**

   ```
   [Device-luser-network-localuser] password simple 123456TESTplat&!
   ```

   # Authorize the user to use LAN access services.

   ```
   [Device-luser-network-localuser] service-type lan-access
   [Device-luser-network-localuser] quit
   ```

2. Configure an ISP domain:

   # Create an ISP domain named **local**.

   ```
   [Device] domain local
   ```

   # Configure the ISP domain to perform local authentication, authorization, and accounting for LAN access users.

   ```
   [Device-isp-local] authentication lan-access local
   [Device-isp-local] authorization lan-access local
   [Device-isp-local] accounting lan-access local
   [Device-isp-local] quit
   ```

3. Configure a local portal Web service:

   # Create an HTTP-based local portal Web service and enter its view.

   ```
   [Device] portal local-web-server http
   ```

   # Specify file **defaultfile.zip** as the default authentication page file for the local portal Web service. (Make sure the authentication page file already exists in the root directory of the storage medium on the device.)

   ```
   [Device-portal-local-websvr-http] default-logon-page defaultfile.zip
   ```

   # Specify the HTTP listening port number as 80 for the portal Web service.

   ```
   [Device–portal-local-websvr-http] tcp-port 80
   [Device-portal-local-websvr-http] quit
   ```

4. Configure local Web authentication:

   # Create a local Web server named **user** for Web authentication and enter its view.

   ```
   [Device] web-auth server user
   ```

   # Configure the redirection URL for the local Web server as **http://20.20.0.1:80/portal/**.

   ```
   [Device-web-auth-server-user] url http://20.20.0.1:80/portal/
   ```

   # Specify the IP address of the local Web server as 20.20.0.1 (the IP address of Loopback 0) and the port number as 80.

```
[Device-web-auth-server-user] ip 20.20.0.1 port 80
[Device-web-auth-server-user] quit
```

Specify ISP domain **local** as the Web authentication domain.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] web-auth domain local
```

Enable Web authentication that uses local Web server **user**.

```
[Device-GigabitEthernet1/0/1] web-auth enable apply server user
[Device-GigabitEthernet1/0/1] quit
```

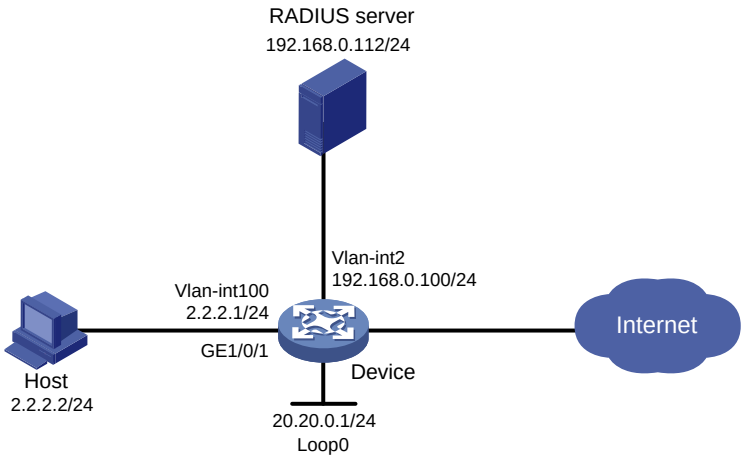
Verifying the configuration

Display online Web authentication user information after user **localuser** passes Web authentication.

```
[Device] display web-auth user
  Total online web-auth users: 1

User Name: localuser
  MAC address: acf1-df6c-f9ad
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 100
  Authorization VLAN: N/A
  Authorization ACL ID: N/A
  Authorization user profile: N/A
```

Example: Configuring local Web authentication by using the AAA remote authentication method



Network configuration

As shown in Figure 5, the host is directly connected to the device through GigabitEthernet 1/0/1.

Configure local Web authentication on GigabitEthernet 1/0/1, and use a remote RADIUS server to perform authentication, authorization, and accounting for the local Web authentication users.

Configure a local Web server on the device that uses the IP address of Loopback 0 and port 80 for Web authentication. Configure the device to use HTTP to transfer the authentication data.

Figure 5 Network diagram

Prerequisites

Configure the RADIUS server properly to provide authentication, authorization, and accounting functions for users. In this example, the username is configured as **user1** on the RADIUS server.

Create VLANs, assign IP addresses to the VLAN interfaces, and assign interfaces to the VLANs. Make sure the host, the RADIUS server, and the device can reach each other.

Procedure

1. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1**.

```
<Device> system-view
[Device] radius scheme rs1
```

Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

```
[Device-radius-rs1] primary authentication 192.168.0.112
[Device-radius-rs1] primary accounting 192.168.0.112
[Device-radius-rs1] key authentication simple radius
[Device-radius-rs1] key accounting simple radius
```

Exclude the ISP domain name from the username sent to the RADIUS server.

```
[Device-radius-rs1] user-name-format without-domain
[Device-radius-rs1] quit
```

2. Configure an authentication domain:

Create an ISP domain named **dm1**.

```
[Device] domain dm1
```

Configure AAA methods for the ISP domain

```
[Device-isp-dm1] authentication lan-access radius-scheme rs1
[Device-isp-dm1] authorization lan-access radius-scheme rs1
[Device-isp-dm1] accounting lan-access radius-scheme rs1
[Device-isp-dm1] quit
```

3. Configure a local portal Web service:

Create an HTTP-based local portal Web service.

```
[Device] portal local-web-server http
```

Specify the file **defaultfile.zip** as the default authentication page file for the local portal Web service. (Make sure the authentication page file already exists in the root directory of the storage medium on the device.)

```
[Device-portal-local-websvr-http] default-logon-page defaultfile.zip
```

Specify 80 as the port number listened by the local portal Web service.

```
[Device–portal-local-websvr-http] tcp-port 80
[Device-portal-local-websvr-http] quit
```

4. Configure local Web authentication:

Create a local Web server named **user** for Web authentication and enter its view.

```
[Device] web-auth server user
```

Specify **http://20.20.0.1:80/portal/** as the redirection URL for the local Web server.

```
[Device-web-auth-server-user] url http://20.20.0.1:80/portal/
```

Specify the IP address of the local Web server as 20.20.0.1 (the IP address of Loopback 0) and the port number as 80.

```
[Device-web-auth-server-user] ip 20.20.0.1 port 80
[Device-web-auth-server-user] quit
```

Specify domain **dml** as the Web authentication domain.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] web-auth domain dm1
```

Enable Web authentication that uses local Web server **user**.

```
[Device-GigabitEthernet1/0/1] web-auth enable apply server user
[Device-GigabitEthernet1/0/1] quit
```

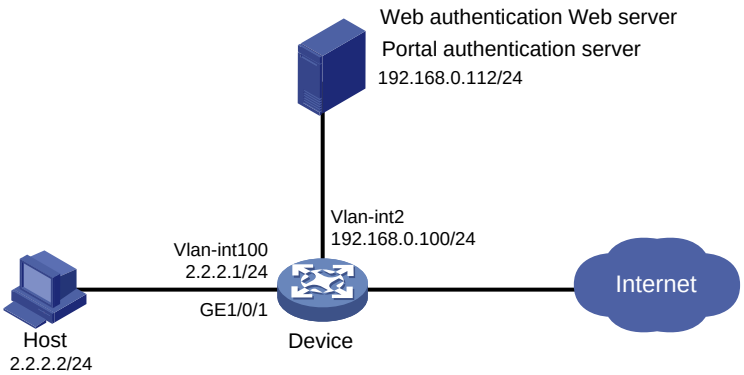
Verifying the configuration

Display Web authentication user information after user **user1** passes Web authentication.

```
[Device] display web-auth user
  Total online web-auth users: 1

User Name: user1
  MAC address: acf1-df6c-f9ad
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 100
  Authorization VLAN: N/A
  Authorization ACL ID: N/A
  Authorization user profile: N/A
```

Example: Configuring remote Web authentication by using the AAA local authentication method



Network configuration

As shown in Figure 6, the host is directly connected to the device through GigabitEthernet 1/0/1.

Configure remote Web authentication on GigabitEthernet 1/0/1, and configure the device to perform local authentication and authorization for the remote Web authentication users.

The remote Web server pushes Web authentication pages to users.

Figure 6 Network diagram

Prerequisites

Configure the portal authentication server properly to provide normal portal functions for users.

Create VLANs, assign IP addresses to the VLAN interfaces, and assign interfaces to the VLANs. Make sure the host, the RADIUS server, and the device can reach each other.

Procedure

1. Configure a local user:

Create a local network access user named **localuser**.

```
<Device>system-view
[Device] local-user localuser class network
```

Set the password for user **localuser.**

```
[Device-luser-network-localuser] password simple 123456TESTplat&!
```

Authorize the user to use LAN access services.

```
[Device-luser-network-localuser] service-type lan-access
[Device-luser-network-localuser] quit
```

2. Configure an ISP domain:

Create an ISP domain named **local**.

```
[Device] domain local
```

Configure the ISP domain to perform local authentication, authorization, and accounting for LAN access users.

```
[Device-isp-local] authentication lan-access local
[Device-isp-local] authorization lan-access local
[Device-isp-local] accounting lan-access local
[Device-isp-local] quit
```

3. Configure the portal authentication server:

```
[Device] portal server newpt
[Device-portal-server-newpt] ip 192.168.0.112 key simple portal
[Device-portal-server-newpt] port 50100
[Device-portal-server-newpt] quit
```

4. Configure remote Web authentication:

Create a remote Web server named **user** for Web authentication and enter its view.

```
[Device] web-auth remote server user
```

Configure the redirection URL of the remote Web server as **http://192.168.0.112:8080/portal/**.

```
[Device-web-auth-remote-server-user] url http://192.168.0.112:8080/portal/
```

Configure the IP address of the remote Web server as 192.168.0.112.

```
[Device-web-auth-remote-server-user] ip 192.168.0.112
[Device-web-auth-remote-server-user] quit
```

Specify an authentication domain for Web authentication users.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] web-auth domain local
```

Enable Web authentication that uses remote Web server **user**.

```
[Device-GigabitEthernet1/0/1] web-auth enable apply server user
[Device-GigabitEthernet1/0/1] quit
```

5. Configure the device to obtain user information from ARP entries.

```
[Device] portal access-info trust arp
```

Verifying the configuration

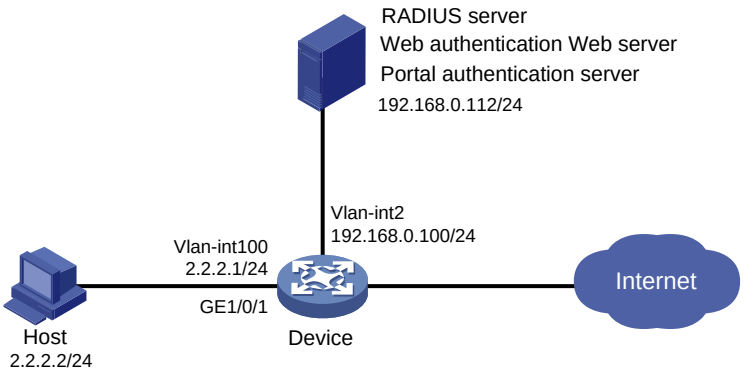
Display Web authentication user information after user **user1** passes Web authentication.

```
[Device] display web-auth user
  Total online web-auth users: 1

User Name: user1
  MAC address: acf1-df6c-f9ad
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 100
```

```
Authorization VLAN: N/A
Authorization ACL ID: N/A
Authorization user profile: N/A
```

Example: Configuring remote Web authentication by using the AAA remote authentication method



Network configuration

As shown in Figure 7, the host is directly connected to the device through GigabitEthernet 1/0/1.

Configure remote Web authentication on GigabitEthernet 1/0/1, and use a remote RADIUS server to perform authentication, authorization, and accounting for the remote Web authentication users.

The remote Web server pushes Web authentication pages to users.

Figure 7 Network diagram

Prerequisites

Configure the RADIUS server properly to provide authentication, authorization, and accounting functions for users. In this example, the username is configured as **user1** on the RADIUS server.

Configure the portal authentication server properly to provide normal portal functions for users.

Create VLANs, assign IP addresses to the VLAN interfaces, and assign interfaces to the VLANs. Make sure the host, the RADIUS server, and the device can reach each other.

Procedure

1. Configure a RADIUS scheme:

   # Create a RADIUS scheme named **rs1**.

   ```
   <Device> system-view
   [Device] radius scheme rs1
   ```

   # Specify the primary authentication server and primary accounting server, and configure the keys for communication with the servers.

   ```
   [Device-radius-rs1] primary authentication 192.168.0.112
   [Device-radius-rs1] primary accounting 192.168.0.112
   [Device-radius-rs1] key authentication simple radius
   [Device-radius-rs1] key accounting simple radius
   ```

   # Exclude the ISP domain name from the username sent to the RADIUS server.

   ```
   [Device-radius-rs1] user-name-format without-domain
   [Device-radius-rs1] quit
   ```

2. Configure an authentication domain:

Create an ISP domain named **dm1**.

```
[Device] domain dm1
```

Configure AAA methods for the ISP domain

```
[Device-isp-dm1] authentication lan-access radius-scheme rs1
[Device-isp-dm1] authorization lan-access radius-scheme rs1
[Device-isp-dm1] accounting lan-access radius-scheme rs1
[Device-isp-dm1] quit
```

3. Configure the portal authentication server:

```
[Device] portal server newpt
[Device-portal-server-newpt] ip 192.168.0.112 key simple portal
[Device-portal-server-newpt] port 50100
[Device-portal-server-newpt] quit
```

4. Configure remote Web authentication:

Create a remote Web server named **user** for Web authentication and enter its view.

```
[Device] web-auth remote server user
```

Configure the redirection URL of the remote Web server as **http://192.168.0.112:8080/portal/**.

```
[Device-web-auth-remote-server-user] url http://192.168.0.112:8080/portal/
```

Configure the IP address of the remote Web server as 192.168.0.112.

```
[Device-web-auth-remote-server-user] ip 192.168.0.112
[Device-web-auth-remote-server-user] quit
```

Specify an authentication domain for Web authentication users.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] web-auth domain dm1
```

Enable Web authentication that uses remote Web server **user**.

```
[Device-GigabitEthernet1/0/1] web-auth enable apply server user
[Device-GigabitEthernet1/0/1] quit
```

5. Configure the device to obtain user information from ARP entries.

```
[Device] portal access-info trust arp
```

Verifying the configuration

Display Web authentication user information after user **user1** passes Web authentication.

```
[Device] display web-auth user
  Total online web-auth users: 1

User Name: user1
  MAC address: acf1-df6c-f9ad
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 100
  Authorization VLAN: N/A
  Authorization ACL ID: N/A
  Authorization user profile: N/A
```

Troubleshooting Web authentication

Failure to come online (local authentication interface using the default ISP domain

Symptom

No authentication domain is specified for the local authentication interface. A user fails to pass Web authentication to come online.

Analysis

If no Web authentication domain is specified, the system default ISP domain (domain **system**) is used for Web authentication. The system default domain uses the local authentication method by default. Using these default domain settings, the local authentication should have operated correctly.

The local authentication fails might because that the authentication method of the system default domain is changed or the system default domain is changed.

Solution

To resolve the problem, perform the following tasks:

1. Use the **`display domain`** command to identify whether the AAA methods for Web users in the system default domain are local.
2. If the AAA methods for Web users in the system default domain are not local, reconfigure the AAA methods as local.

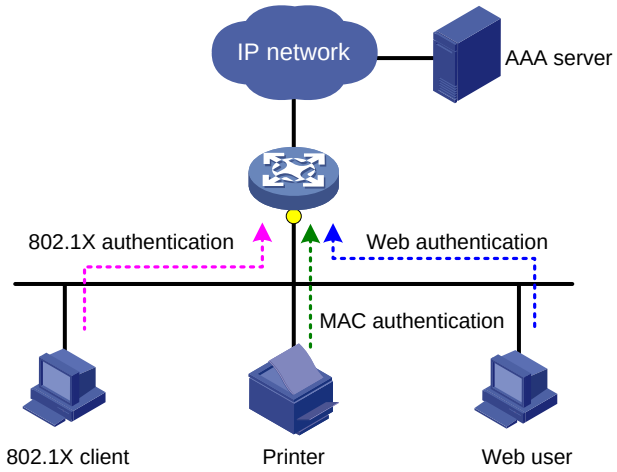
Configuring triple authentication



About triple authentication

Triple authentication enables an access port to perform Web, MAC, and 802.1X authentication. A terminal can access the network if it passes one type of authentication. For more information about 802.1X authentication, MAC authentication, and Web authentication, see "Configuring 802.1X authentication", "Configuring MAC authentication", and "Configuring Web authentication."

Typical network of triple authentication

Triple authentication is suitable for a LAN that comprises terminals that require different authentication services, as shown in Figure 1. The triple authentication-enabled access port can perform MAC authentication for the printer, 802.1X authentication for the PC installed with the 802.1X client, and Web authentication for the Web user.

Figure 1 Triple authentication network diagram

Triple authentication mechanism

The three types of authentication are triggered by different packets:

- The access port performs MAC authentication for a terminal when it receives an ARP or DHCP broadcast packet from the terminal for the first time. If the terminal passes MAC authentication, the terminal can access the network. If the MAC authentication fails, the access port performs 802.1X or Web authentication.
- The access port performs 802.1X authentication when it receives an EAP packet from an 802.1X client or a third-party client. If the unicast trigger feature of 802.1X is enabled on the access port, any packet from the client can trigger an 802.1X authentication.
- The access port performs Web authentication when it receives an HTTP packet from a terminal.

If a terminal triggers different types of authentication, the authentications are processed at the same time. The failure of one type of authentication does not affect the others. When a terminal passes one type of authentication, the other types of authentication are processed as follows:

- If the terminal first passes MAC authentication, Web authentication is terminated immediately, but 802.1X authentication will proceed. If the terminal also passes 802.1X authentication, the 802.1X authentication information will overwrite the MAC authentication information for the

terminal. If the terminal fails 802.1X authentication, the user stays online as a MAC authentication user, and only 802.1X authentication can be triggered again.

- If the terminal first passes 802.1X or Web authentication, the other types of authentication are terminated immediately and cannot be triggered again.

Triple authentication support for VLAN assignment

Authorization VLAN

After a user passes authentication, the authentication server assigns an authorization VLAN to the access port for the user. The user can then access the network resources in the authorized VLAN.

Authentication failure VLAN

The access port adds a user to an authentication failure VLAN configured on the port after the user fails authentication.

- For an 802.1X authentication user—Adds the user to the Auth-Fail VLAN configured for 802.1X authentication.
- For a Web authentication user—Adds the user to the Auth-Fail VLAN configured for Web authentication.
- For a MAC authentication user—Adds the user to the guest VLAN configured for MAC authentication.

The access port supports configuring all types of authentication failure VLANs at the same time. If a user fails more than one type of authentication, the authentication failure VLAN of the user changes as follows:

- If a user in the Web Auth-Fail VLAN fails MAC authentication, the user is moved to the MAC authentication guest VLAN.
- If a user in the Web Auth-Fail VLAN or MAC authentication guest VLAN fails 802.1X authentication, the user is moved to the 802.1X Auth-Fail VLAN.
- If a user in the 802.1X Auth-Fail VLAN fails MAC authentication or Web authentication, the user is still in the 802.1X Auth-Fail VLAN.

Server-unreachable VLAN

If a user fails authentication due to the unreachable server, the access port adds the user to an server-unreachable VLAN.

- For an 802.1X authentication user—Adds the user to the critical VLAN configured for 802.1X authentication.
- For a Web authentication user—Adds the user to the Auth-Fail VLAN configured for Web authentication.
- For a MAC authentication user—Adds the user to the critical VLAN configured for MAC authentication.

The access port supports configuring all types of server-unreachable VLANs at the same time. A user is added to the server-unreachable VLAN as follows:

- If the user does not undergo 802.1X authentication, the user is added to the server-unreachable VLAN configured for the last authentication.
- If the user in the Web Auth-Fail VLAN or the MAC authentication critical VLAN also fails 802.1X authentication, the user is added to the 802.1X authentication critical VLAN.

Triple authentication support for ACL authorization

After a user passes authentication, the authentication server assigns an authorization ACL to the access port for the user. The access port uses the ACL to filter traffic for the user.

To use ACL authorization, you must specify authorization ACLs on the authentication server and configure the ACLs on the access device. You can change the user's access authorization by changing the authorization ACL on the authentication server or changing rules of the authorization ACL on the access device.

Triple authentication support for online user detection

You can configure the following features to detect the online status of users:

- Enable online user detection for Web authentication users.
- Enable the online user handshake or periodic online user reauthentication feature for 802.1X users.
- Enable offline detection for MAC authentication users.

Restrictions and guidelines: Triple authentication

In triple authentication, 802.1X authentication must use the MAC-based access control method.

If Web authentication is enabled on a port, configure the subnets of the authentication failure VLANs and server-unreachable VLANs of the port as Web authentication-free subnets. This ensures that an authentication-failed user can access the authentication failure VLAN or server-unreachable VLAN.

Do not configure both Web authentication-free IPs and 802.1X free IPs. If you do so, only 802.1X free IPs take effect.

Triple authentication tasks at a glance

Choose the following tasks as needed:

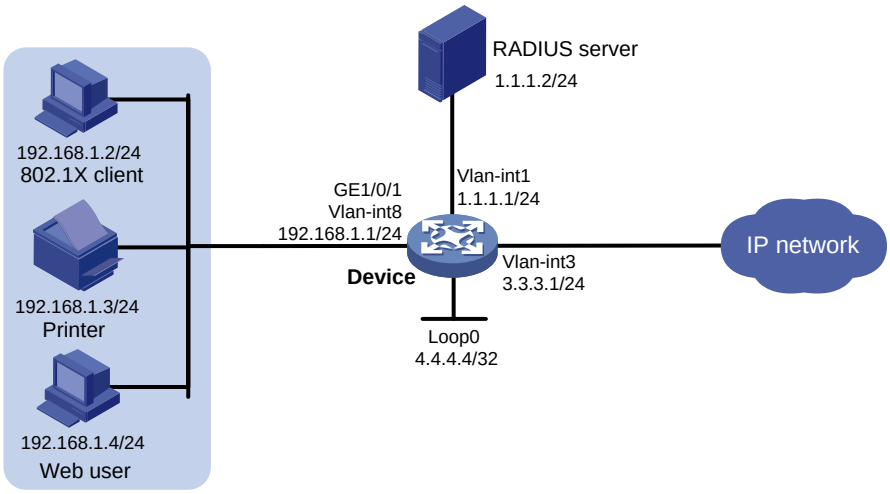
- Configure 802.1X authentication

  For more information, see "Configuring 802.1X."
- Configure MAC authentication

  For more information, see "Configuring MAC authentication."
- Configure Web authentication

  For more information, see "Configuring Web authentication."

Triple authentication configuration examples



Example: Configuring basic triple authentication

Network configuration

As shown in Figure 2, the terminals are connected to the device to access the IP network. Configure triple authentication on the device's Layer 2 interface that connects to the terminals. A terminal passing one of the three authentication methods, 802.1X authentication, Web authentication, and MAC authentication, can access the IP network.

- Assign IP addresses on subnet 192.168.1.0/24 to the terminals.
- Use the remote RADIUS server to perform authentication, authorization, and accounting. Configure the device to send usernames carrying no ISP domain names to the RADIUS server.
- Configure the local Web authentication server on the device to use listening IP address 4.4.4.4. Configure the device to send a default authentication page to the Web user and forward authentication data by using HTTP.

Figure 2 Network diagram

Procedure

1. Make sure that the terminals, the server, and the device can reach each other. (Details not shown.)
2. Configure the RADIUS server to provide normal authentication, authorization, and accounting for users. In this example, configure the following on the RADIUS server:
   - An 802.1X user with username **userdot**.
   - A Web authentication user with username **userpt**.
   - A MAC authentication user with a username and password both being the MAC address of the printer **f07d6870725f**.
3. Configure Web authentication:

   # Configure VLANs and IP addresses for the VLAN interfaces, and add ports to specific VLANs. (Details not shown.)

   # Create an HTTP-based local portal Web service, and specify file **defaultfile.zip** as the default authentication page file of the local portal Web service. (Make sure the authentication page file already exists in the root directory of the storage medium on the device.)

   ```
   <Device> system-view
   [Device] portal local-web-server http
   [Device-portal-local-websvr-http] default-logon-page defaultfile.zip
   [Device-portal-local-websvr-http] quit
   ```

   # Assign IP address 4.4.4.4 to Loopback 0.

   ```
   [Device] interface loopback 0
   [Device-LoopBack0] ip address 4.4.4.4 32
   [Device-LoopBack0] quit
   ```

   # Create a Web authentication server named **webserver** and enter its view.

   ```
   [Device] web-auth server webserver
   ```

   # Configure the redirection URL for the Web authentication server as **http://4.4.4.4/portal/**.

   ```
   [Device-web-auth-server-webserver] url http://4.4.4.4/portal/
   ```

   # Specify 4.4.4.4 as the IP address and 80 as the port number of the Web authentication server.

   ```
   [Device-web-auth-server-webserver] ip 4.4.4.4 port 80
   [Device-web-auth-server-webserver] quit
   ```

   # Enable Web authentication on GigabitEthernet 1/0/1 and specify Web authentication server **webserver** on the interface.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] web-auth enable apply server webserver
[Device–GigabitEthernet1/0/1] quit
```

4. Configure 802.1X authentication:

Enable 802.1X authentication globally.

```
[Device] dot1x
```

Enable 802.1X authentication (MAC-based access control required) on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] dot1x port-method macbased
[Device–GigabitEthernet1/0/1] dot1x
[Device–GigabitEthernet1/0/1] quit
```

5. Configure MAC authentication:

Enable MAC authentication globally.

```
[Device] mac-authentication
```

Enable MAC authentication on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] mac-authentication
[Device–GigabitEthernet1/0/1] quit
```

6. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1**.

```
[Device] radius scheme rs1
```

Specify the primary authentication and accounting servers and keys.

```
[Device-radius-rs1] primary authentication 1.1.1.2
[Device-radius-rs1] primary accounting 1.1.1.2
[Device-radius-rs1] key authentication simple radius
[Device-radius-rs1] key accounting simple radius
```

Specify usernames sent to the RADIUS server to carry no domain names.

```
[Device-radius-rs1] user-name-format without-domain
[Device-radius-rs1] quit
```

7. Configure an ISP domain:

Create an ISP domain named **triple**.

```
[Device] domain triple
```

Configure the domain to use RADIUS scheme **rs1** for authentication, authorization and accounting of LAN access users.

```
[Device-isp-triple] authentication lan-access radius-scheme rs1
[Device-isp-triple] authorization lan-access radius-scheme rs1
[Device-isp-triple] accounting lan-access radius-scheme rs1
[Device-isp-triple] quit
```

Configure domain **triple** as the default domain. If a username entered by a user includes no ISP domain name, the AAA method of the default domain is used.

```
[Device] domain default enable triple
```

Verifying the configuration

1. Verify that the Web user can pass Web authentication.

On the Web user terminal, use a Web browser to access an external network and then enter the correct username and password on the authentication page **http://4.4.4.4/portal/logon.html**. (Details not shown.)

Display information about online Web authentication users.

```
[Device] display web-auth user
  Total online web-auth users: 1
User Name: localuser
  MAC address: acf1-df6c-f9ad
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 8
  Authorization VLAN: N/A
  Authorization ACL ID: N/A
  Authorization user profile: N/A
```

2. Verify that the printer can pass MAC authentication.

Connect the printer to the network. (Details not shown.)

Display information about online MAC authentication users.

```
[Device] display mac-authentication connection
Total connections: 1
Slot ID: 1
User MAC address: f07d-6870-725f
Access interface: GigabitEthernet1/0/1
Username: f07d6870725f
User access state: Successful
Authentication domain: triple
Initial VLAN: 8
Authorization untagged VLAN: N/A
Authorization tagged VLAN: N/A
Authorization ACL ID: N/A
Authorization user profile: N/A
Authorization CAR: N/A
Authorization URL: N/A
Termination action: Default
Session timeout period: N/A
Online from: 2015/01/04 18:01:43
Online duration: 0h 0m 2s
```

3. Verify that the 802.1X client can pass 802.1X authentication.

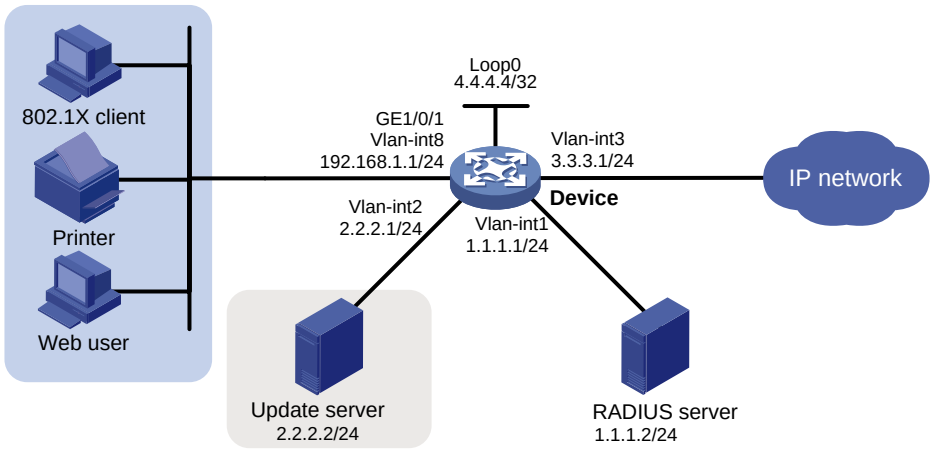
On the 802.1X client, initiate 802.1X authentication and then enter the correct username and password. (Details not shown.)

Display information about online 802.1X users.

```
[Device] display dot1x connection
Total connections: 1
Slot ID: 1
User MAC address: 7446-a091-84fe
Access interface: GigabitEthernet1/0/1
Username: userdot
User access state: Successful
Authentication domain: triple
IPv4 address: 192.168.1.2
Authentication method: CHAP
Initial VLAN: 8
Authorization untagged VLAN: N/A
```

```
Authorization tagged VLAN list: N/A
Authorization ACL ID: N/A
Authorization user profile: N/A
Authorization CAR: N/A
Authorization URL: N/A
Termination action: Default
Session timeout period: N/A
Online from: 2015/01/04 18:13:01
Online duration: 0h 0m 14s
```

Example: Configuring triple authentication to support authorization VLAN and authentication failure VLAN



Network configuration

As shown in Figure 3, the terminals are connected to the device to access the IP network. Configure triple authentication on the device's Layer 2 interface connected to the terminals. A terminal passing one of the three authentication methods, 802.1X authentication, Web authentication, and MAC authentication, can access the IP network.

- The Web authentication terminal uses DHCP to get an IP address in 192.168.1.0/24 before authentication and in 3.3.3.0/24 after passing authentication. If the terminal fails authentication, it requests IP addresses in 2.2.2.0/24 through DHCP.

  You can use the access device or an attached device as the DHCP server. In this example, the access device (the device) provides the DHCP service.
- The 802.1X terminal uses DHCP to get an IP address in 192.168.1.0/24 before authentication and in 3.3.3.0/24 after passing authentication. If the terminal fails authentication, it requests IP addresses in 2.2.2.0/24 through DHCP.
- After passing authentication, the printer obtains IP address 3.3.3.111/24 that is bound with its MAC address through DHCP.
- Use the remote RADIUS server to perform authentication, authorization, and accounting. Configure the device to remove the ISP domain names from usernames sent to the RADIUS server.
- Configure the local Web authentication server on the device to use listening IP address 4.4.4.4. Configure the device to forward authentication data by using HTTP.
- Configure VLAN 3 as the authorization VLAN. Users passing authentication are added to this VLAN.
- Configure VLAN 2 as the authentication failure VLAN. Users failing authentication are added to this VLAN.

Figure 3 Network diagram

Procedure

1. Make sure the terminals, the servers, and the device can reach each other. (Details not shown.)
2. Configure the RADIUS server to provide normal authentication, authorization, and accounting for users. In this example, configure the following on the RADIUS server:
   - An 802.1X user with username **userdot**.
   - A Web authentication user with username **userpt**.
   - A MAC authentication user with a username and password both being the MAC address of the printer **f07d6870725f**.
   - An authorization VLAN (VLAN 3).
3. Configure the IP address of the update server as an authentication-free IP address.

   ```
   <Device> system-view
   [Device] web-auth free-ip 2.2.2.2 24
   ```
4. Configure DHCP:

   # Configure VLANs and IP addresses for the VLAN interfaces, and add ports to specific VLANs. (Details not shown.)

   # Enable DHCP.

   ```
   [Device] dhcp enable
   ```

   # Exclude the IP address of the update server from dynamic address assignment.

   ```
   [Device] dhcp server forbidden-ip 2.2.2.2
   ```

   # Configure DHCP address pool 1 to assign IP addresses and other configuration parameters to clients on subnet 192.168.1.0.

   ```
   [Device] dhcp server ip-pool 1
   [Device-dhcp-pool-1] network 192.168.1.0 mask 255.255.255.0
   [Device-dhcp-pool-1] expired day 0 hour 0 minute 1
   [Device-dhcp-pool-1] gateway-list 192.168.1.1
   [Device-dhcp-pool-1] quit
   ```

   # Configure DHCP address pool 2 to assign IP address and other configuration parameters to clients on subnet 2.2.2.0.

   ```
   [Device] dhcp server ip-pool 2
   [Device-dhcp-pool-2] network 2.2.2.0 mask 255.255.255.0
   [Device-dhcp-pool-2] expired day 0 hour 0 minute 1
   [Device-dhcp-pool-2] gateway-list 2.2.2.1
   [Device-dhcp-pool-2] quit
   ```

Configure DHCP address pool 3 to assign IP address and other configuration parameters to clients on subnet 3.3.3.0.

```
[Device] dhcp server ip-pool 3
[Device-dhcp-pool-3] network 3.3.3.0 mask 255.255.255.0
[Device-dhcp-pool-3] expired day 0 hour 0 minute 1
[Device-dhcp-pool-3] gateway-list 3.3.3.1
[Device-dhcp-pool-3] quit
```

Configure DHCP address pool 4, and bind the printer's MAC address f07d-6870-725f to IP address 3.3.3.111/24 in this address pool.

```
[Device] dhcp server ip-pool 4
[Device-dhcp-pool-4] static-bind ip-address 3.3.3.111 mask 255.255.255.0
client-identifier f07d-6870-725f
[Device-dhcp-pool-4] quit
```

5. Configure Web authentication:

Create an HTTP-based local portal Web service, and specify file **defaultfile.zip** as the default authentication page file of the local portal Web service. (Make sure the authentication page file already exists in the root directory of the storage medium on the device.)

```
[Device] portal local-web-server http
[Device-portal-local-websvr-http] default-logon-page defaultfile.zip
[Device-portal-local-websvr-http] quit
```

Assign IP address 4.4.4.4 to Loopback 0.

```
[Device] interface loopback 0
[Device-LoopBack0] ip address 4.4.4.4 32
[Device-LoopBack0] quit
```

Create a Web authentication server named **webserver**.

```
[Device] web-auth server webserver
```

Configure the redirection URL of the Web authentication server as **http://4.4.4.4/portal/**.

```
[Device-web-auth-server-webserver] url http://4.4.4.4/portal/
```

Specify 4.4.4.4 as the IP address and 80 as the port number of the Web authentication server.

```
[Device-web-auth-server-webserver] ip 4.4.4.4 port 80
[Device-web-auth-server-webserver] quit
```

Configure the IP address of the update server as an authentication-free IP address.

```
[Device] web-auth free-ip 2.2.2.2 24
```

Enable Web authentication on GigabitEthernet 1/0/1 and specify VLAN 2 as the Auth-Fail VLAN.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] port link-type hybrid
[Device–GigabitEthernet1/0/1] mac-vlan enable
[Device–GigabitEthernet1/0/1] web-auth enable apply server webserver
[Device–GigabitEthernet1/0/1] web-auth auth-fail vlan 2
[Device–GigabitEthernet1/0/1] quit
```

6. Configure 802.1X authentication:

Enable 802.1X authentication globally.

```
[Device] dot1x
```

Enable 802.1X authentication (MAC-based access control required) on GigabitEthernet 1/0/1, and specify VLAN 2 as the Auth-Fail VLAN.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] dot1x port-method macbased
```

```
[Device–GigabitEthernet1/0/1] dot1x
[Device–GigabitEthernet1/0/1] dot1x auth-fail vlan 2
[Device–GigabitEthernet1/0/1] quit
```

7. Configure MAC authentication:

Enable MAC authentication globally.

```
[Device] mac-authentication
```

Enable MAC authentication on GigabitEthernet 1/0/1, and specify VLAN 2 as the guest VLAN.

```
[Device] interface gigabitethernet 1/0/1
[Device–GigabitEthernet1/0/1] mac-authentication
[Device–GigabitEthernet1/0/1] mac-authentication guest-vlan 2
[Device–GigabitEthernet1/0/1] quit
```

8. Configure a RADIUS scheme:

Create a RADIUS scheme named **rs1**.

```
[Device] radius scheme rs1
```

Specify the primary authentication and accounting servers and keys.

```
[Device-radius-rs1] primary authentication 1.1.1.2
[Device-radius-rs1] primary accounting 1.1.1.2
[Device-radius-rs1] key authentication simple radius
[Device-radius-rs1] key accounting simple radius
```

Specify usernames sent to the RADIUS server to carry no domain names.

```
[Device-radius-rs1] user-name-format without-domain
[Device-radius-rs1] quit
```

9. Configure an ISP domain:

Create an ISP domain named **triple**.

```
[Device] domain triple
```

Configure the domain to use RADIUS scheme **rs1** for authentication, authorization and accounting of LAN access users.

```
[Device-isp-triple] authentication lan-access radius-scheme rs1
[Device-isp-triple] authorization lan-access radius-scheme rs1
[Device-isp-triple] accounting lan-access radius-scheme rs1
[Device-isp-triple] quit
```

Configure domain **triple** as the default domain. If a username entered by a user includes no ISP domain name, the AAA methods of the default domain is used.

```
[Device] domain default enable triple
```

Verifying the configuration

1. Verify that the Web user can pass Web authentication.

On the Web user terminal, use a Web browser to access an external network and then enter the correct username and password on the authentication page **http://4.4.4.4/portal/logon.html**. (Details not shown.)

Use the **`display web-auth user`** command to display information about online users.

```
[Device] display web-auth user
  Total online web-auth users: 1

User Name: userpt
  MAC address: 6805-ca17-4a0b
  Access interface: GigabitEthernet1/0/1
  Initial VLAN: 8
```

```
  Authorization VLAN: 3
  Authorization ACL ID: N/A
  Authorization user profile: N/A
```

2. Verify that the printer can pass MAC authentication.

Connect the printer to the network. (Details not shown.)

Display information about online MAC authentication users.

```
[Device] display mac-authentication connection
Total connections: 1
Slot ID: 1
User MAC address: f07d-6870-725f
Access interface: GigabitEthernet1/0/1
Username: f07d6870725f
User access state: Successful
Authentication domain: triple
Initial VLAN: 8
Authorization untagged VLAN: 3
Authorization tagged VLAN: N/A
Authorization ACL ID: N/A
Authorization user profile: N/A
Authorization CAR: N/A
Authorization URL: N/A
Termination action: Default
Session timeout period: N/A
Online from: 2015/01/04 18:01:43
Online duration: 0h 0m 2s
```

3. Verify that the 802.1X user can pass 802.1X authentication.

On the 802.1X client, initiate 802.1X authentication and enter the correct username and password. (Details not shown.)

Display information about online 802.1X users.

```
[Device] display dot1x connection
Total connections: 1
Slot ID: 1
User MAC address: 7446-a091-84fe
Access interface: GigabitEthernet1/0/1
Username: userdot
User access state: Successful
Authentication domain: triple
IPv4 address: 3.3.3.3
Authentication method: CHAP
Initial VLAN: 8
Authorization untagged VLAN: 3
Authorization tagged VLAN list: N/A
Authorization ACL ID: N/A
Authorization user profile: N/A
Authorization CAR: N/A
Authorization URL: N/A
Termination action: Default
Session timeout period: N/A
```

```
Online from: 2015/01/04 18:13:01
Online duration: 0h 0m 14s
```

4. Verify that users that pass authentication have been assigned authorization VLANs.

Display MAC-VLAN entries of online users.

```
[Device] display mac-vlan all
  The following MAC VLAN addresses exist:
  S:Static  D:Dynamic
  MAC ADDR         MASK             VLAN ID   PRIO   STATE
  ------------------------------------------------------
  6805-ca17-4a0b   ffff-ffff-ffff   3         0      D
  f07d-6870-725f   ffff-ffff-ffff   3         0      D
  7446-a091-84fe   ffff-ffff-ffff   3         0      D
  Total MAC VLAN address count:3
```

5. Verify that online users have been assigned IP addresses.

```
[Device] display dhcp server ip-in-use
IP address       Client-identifier/    Lease expiration          Type
                  Hardware address
 3.3.3.111        01f0-7d68-7072-5f     Jan  4 18:14:17 2015      Auto:(C)
 3.3.3.2          0168-05ca-174a-0b     Jan  4 18:15:01 2015      Auto:(C)
 3.3.3.3          0174-46a0-9184-fe     Jan  4 18:15:03 2015      Auto:(C)
```

6. When a terminal fails authentication, it is added to VLAN 2. You can use the previous display commands to display the MAC-VLAN entry and IP address of the terminal. (Details not shown.)

Configuring port security

About port security

Port security combines and extends 802.1X and MAC authentication to provide MAC-based network access control. The feature applies to ports that use different authentication methods for users.

Major functions

Port security provides the following functions:

- Prevents unauthorized access to a network by checking the source MAC address of inbound traffic.
- Prevents access to unauthorized devices or hosts by checking the destination MAC address of outbound traffic.
- Controls MAC address learning and authentication on a port to make sure the port learns only source trusted MAC addresses.

Port security features

NTK

The need to know (NTK) feature prevents traffic interception by checking the destination MAC address in the outbound frames. The feature ensures that frames are sent only to the following hosts:

- Hosts that have passed authentication.
- Hosts whose MAC addresses have been learned or configured on the access device.

Intrusion protection

The intrusion protection feature checks the source MAC address in inbound frames for illegal frames, and takes a predefined action on each detected illegal frame. The action can be disabling the port temporarily, disabling the port permanently, or blocking frames from the illegal MAC address for a period set by the MAC block timer.

A frame is illegal if its source MAC address cannot be learned in a port security mode or it is from a client that has failed 802.1X or MAC authentication.

Port security modes

Port security supports the following categories of security modes:

- **MAC learning control**—Includes two modes: autoLearn and secure. MAC address learning is permitted on a port in autoLearn mode and disabled in secure mode.
- **Authentication**—Security modes in this category implement MAC authentication, 802.1X authentication, or a combination of these two authentication methods.

Upon receiving a frame, the port in a security mode searches the MAC address table for the source MAC address. If a match is found, the port forwards the frame. If no match is found, the port learns the MAC address or performs authentication, depending on the security mode. If the frame is illegal, the port takes the predefined NTK or intrusion protection action, or sends SNMP notifications. Outgoing frames are not restricted by port security's NTK action unless they trigger the NTK feature.

Table 1 describes the port security modes and the security features.

Table 1 Port security modes

Purpose	Security mode		Features that can be triggered
Turning off the port security feature	noRestrictions (the default mode) In this mode, port security is disabled on the port and access to the port is not restricted.		N/A
Controlling MAC address learning	autoLearn		NTK/intrusion protection
	secure		
Performing 802.1X authentication	userLogin		NTK (**ntkauto** mode)
	userLoginSecure		NTK/intrusion protection
	userLoginSecureExt		
	userLoginWithOUI		
Performing MAC authentication	macAddressWithRadius		NTK/intrusion protection
Performing a combination of MAC authentication and 802.1X authentication	Or	macAddressOrUserLoginSecure	NTK/intrusion protection
		macAddressOrUserLoginSecureExt	
	Else	macAddressElseUserLoginSecure	
		macAddressElseUserLoginSecureExt	

The mode names are illustrated as follows:

- **userLogin** specifies 802.1X authentication and port-based access control. **userLogin** with **Secure** specifies 802.1X authentication and MAC-based access control. **Ext** indicates allowing multiple 802.1X users to be authenticated and serviced at the same time. A security mode without **Ext** allows only one user to pass 802.1X authentication.
- **macAddress** specifies MAC authentication.
- **Else** specifies that the authentication method before **Else** is applied first. If the authentication fails, whether to turn to the authentication method following **Else** depends on the protocol type of the authentication request.
- **Or** specifies that the authentication method following **Or** is applied first. If the authentication fails, the authentication method before **Or** is applied.

Controlling MAC address learning

- autoLearn.

  A port in this mode can learn MAC addresses. The automatically learned MAC addresses are not added to the MAC address table as dynamic MAC address. Instead, these MAC addresses are added to the secure MAC address table as secure MAC addresses. You can also configure secure MAC addresses by using the **`port-security mac-address security`** command.

  A port in autoLearn mode allows frames sourced from the following MAC addresses to pass:

  - Secure MAC addresses.
  - MAC addresses configured by using the **`mac-address dynamic`** and **`mac-address static`** commands.

  When the number of secure MAC addresses reaches the upper limit, the port transitions to secure mode.

- secure.

MAC address learning is disabled on a port in secure mode. You configure MAC addresses by using the **mac-address static** and **mac-address dynamic** commands. For more information about configuring MAC address table entries, see *Layer 2—LAN Switching Configuration Guide*.

A port in secure mode allows only frames sourced from the following MAC addresses to pass:

- Secure MAC addresses.
- MAC addresses configured by using the **mac-address dynamic** and **mac-address static** commands.

Performing 802.1X authentication

- userLogin.

  A port in this mode performs 802.1X authentication and implements port-based access control. The port can service multiple 802.1X users. Once an 802.1X user passes authentication on the port, any subsequent 802.1X users can access the network through the port without authentication.

- userLoginSecure.

  A port in this mode performs 802.1X authentication and implements MAC-based access control. The port services only one user passing 802.1X authentication.

- userLoginSecureExt.

  This mode is similar to the userLoginSecure mode except that this mode supports multiple online 802.1X users.

- userLoginWithOUI.

  This mode is similar to the userLoginSecure mode. The difference is that a port in this mode also permits frames from one user whose MAC address contains a specific OUI.

  In this mode, the port performs OUI check at first. If the OUI check fails, the port performs 802.1X authentication. The port permits frames that pass OUI check or 802.1X authentication.

NOTE:

An OUI is a 24-bit number that uniquely identifies a vendor, manufacturer, or organization. In MAC addresses, the first three octets are the OUI.

Performing MAC authentication

macAddressWithRadius: A port in this mode performs MAC authentication, and services multiple users.

Performing a combination of MAC authentication and 802.1X authentication

- macAddressOrUserLoginSecure.

  This mode is the combination of the macAddressWithRadius and userLoginSecure modes. The mode allows one 802.1X authentication user and multiple MAC authentication users to log in.

  In this mode, the port performs 802.1X authentication first. By default, if 802.1X authentication fails, MAC authentication is performed.

  However, the port in this mode processes authentication differently when the following conditions exist:

  - The port is enabled with parallel processing of MAC authentication and 802.1X authentication.
  - The port is enabled with the 802.1X unicast trigger.
  - The port receives a packet from an unknown MAC address.

  Under such conditions, the port sends a unicast EAP-Request/Identity packet to the MAC address to initiate 802.1X authentication. After that, the port immediately processes MAC authentication without waiting for the 802.1X authentication result.

- macAddressOrUserLoginSecureExt.

  This mode is similar to the macAddressOrUserLoginSecure mode, except that this mode supports multiple 802.1X and MAC authentication users.
- macAddressElseUserLoginSecure.

  This mode is the combination of the macAddressWithRadius and userLoginSecure modes, with MAC authentication having a higher priority as the **Else** keyword implies. The mode allows one 802.1X authentication user and multiple MAC authentication users to log in.

  In this mode, the port performs MAC authentication upon receiving non-802.1X frames. Upon receiving 802.1X frames, the port performs MAC authentication and then, if the authentication fails, 802.1X authentication.
- macAddressElseUserLoginSecureExt.

  This mode is similar to the macAddressElseUserLoginSecure mode except that this mode supports multiple 802.1X and MAC authentication users as the **Ext** keyword implies.

Restrictions and guidelines: Port security configuration

This feature applies to networks, such as a WLAN, that require different authentication methods for different users on a port.

As a best practice, use the 802.1X authentication or MAC authentication feature rather than port security for scenarios that require only 802.1X authentication or MAC authentication. For more information about 802.1X and MAC authentication, see "Configuring 802.1X" and "Configuring MAC authentication."

To ensure a successful HTTPS redirect for users in either of the following situations, make sure VLAN interfaces exist for the VLANs that transport their packets:

- The users are assigned a redirect URL.
- EAD assistant is enabled.

Port security tasks at a glance

To configure port security, perform the following tasks:

1. Configuring basic features of port security
   - Enabling port security
   - Setting the port security mode
   - (Optional.) Setting port security's limit on the number of secure MAC addresses on a port
   - (Optional.) Configuring secure MAC addresses
   - (Optional.) Enabling unified secure MAC address control for access users
   - (Optional.) Configuring NTK
   - (Optional.) Configuring intrusion protection
2. (Optional.) Configuring extended features of port security
   - Ignoring authorization information from the server
   - Configuring MAC move
   - Enabling the authorization-fail-offline feature
   - Setting port security's limit on the number of MAC addresses for specific VLANs on a port
   - Enabling open authentication mode
   - Configuring free VLANs for port security

- Applying a NAS-ID profile to port security
- Enabling traffic statistics for MAC authentication and 802.1X users

The extended port security features can also take effect when port security is disabled but 802.1X or MAC authentication is enabled.

3. (Optional.) Enabling SNMP notifications for port security
4. (Optional.) Enabling port security user logging

Enabling port security

Restrictions and guidelines

When you configure port security, follow these restrictions and guidelines:

- When port security is enabled, you cannot enable 802.1X or MAC authentication, or change the access control mode or port authorization state. Port security automatically modifies these settings in different security modes.
- You can use the **undo port-security enable** command to disable port security. Because the command logs off online users, make sure no online users are present.
- Enabling or disabling port security resets the following security settings to the default:
  - 802.1X access control mode, which is MAC-based.
  - Port authorization state, which is **auto**.

For more information about 802.1X authentication and MAC authentication configuration, see "Configuring 802.1X" and "Configuring MAC authentication."

Prerequisites

Before you enable port security, disable 802.1X and MAC authentication globally.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable port security.
   ```
   port-security enable
   ```
   By default, port security is disabled.

Setting the port security mode

Restrictions and guidelines

You can specify a port security mode when port security is disabled, but your configuration cannot take effect.

Changing the port security mode of a port logs off the online users of the port.

Do not enable 802.1X authentication or MAC authentication on a port where port security is enabled.

After enabling port security, you can change the port security mode of a port only when the port is operating in noRestrictions (the default) mode. To change the port security mode for a port in any other mode, first use the **undo port-security port-mode** command to restore the default port security mode.

The device supports the URL attribute assigned by a RADIUS server in the following port security modes:

- mac-authentication.

- mac-else-userlogin-secure.
- mac-else-userlogin-secure-ext.
- userlogin-secure.
- userlogin-secure-ext.
- userlogin-secure-or-mac.
- userlogin-secure-or-mac-ext.
- userlogin-withoui.

During authentication, the HTTP or HTTPS requests of a user are redirected to the Web interface specified by the server-assigned URL attribute. After the user passes the Web authentication, the RADIUS server records the MAC address of the user and uses a DM (Disconnect Message) to log off the user. When the user initiates 802.1X or MAC authentication again, it will pass the authentication and come online successfully.

To redirect the HTTPS requests of port security users, specify the HTTPS redirect listening port on the device. For more information, see HTTP redirect in *Layer 3—IP Services Configuration Guide*.

Prerequisites

Before you set a port security mode for a port, complete the following tasks:

- Disable 802.1X and MAC authentication.
- If you are configuring the autoLearn mode, set port security's limit on the number of secure MAC addresses. You cannot change the setting when the port is operating in autoLearn mode.

Procedure

1. Enter system view.

   system-view
2. Set an OUI value for user authentication.

   port-security oui index *index-value* **mac-address** *oui-value*

   By default, no OUI values are configured for user authentication.

   This command is required only for the **userlogin-withoui** mode.

   You can set multiple OUIs, but when the port security mode is **userlogin-withoui**, the port allows one 802.1X user and only one user that matches one of the specified OUIs.
3. Enter interface view.

   interface *interface-type interface-number*
4. Set the port security mode.

   port-security port-mode { **autolearn** | **mac-authentication** | **mac-else-userlogin-secure** | **mac-else-userlogin-secure-ext** | **secure** | **userlogin** | **userlogin-secure** | **userlogin-secure-ext** | **userlogin-secure-or-mac** | **userlogin-secure-or-mac-ext** | **userlogin-withoui** }

   By default, a port operates in noRestrictions mode.

Setting port security's limit on the number of secure MAC addresses on a port

About this task

You can set the maximum number of secure MAC addresses that port security allows on a port for the following purposes:

- Controlling the number of concurrent users on the port.

For a port operating in a security mode (except for autoLearn and secure), the upper limit equals the smaller of the following values:

- The limit of the secure MAC addresses that port security allows.
- The limit of concurrent users allowed by the authentication mode in use.

- Controlling the number of secure MAC addresses on the port in autoLearn mode.

  You can also set the maximum number of secure MAC addresses that port security allows for specific VLANs or each VLAN on a port.

Port security's limit on the number of secure MAC addresses on a port is independent of the MAC learning limit described in MAC address table configuration. For more information about MAC address table configuration, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Set the maximum number of secure MAC addresses allowed on a port.

   port-security max-mac-count *max-count*[**vlan** [*vlan-id-list*]]

   By default, port security does not limit the number of secure MAC addresses on a port.

Configuring secure MAC addresses

About secure MAC addresses

Secure MAC addresses are configured or learned in autoLearn mode. If the secure MAC addresses are saved, they can survive a device reboot. You can bind a secure MAC address only to one port in a VLAN.

Secure MAC addresses include static, sticky, and dynamic secure MAC addresses.

Table 2 Comparison of static, sticky, and dynamic secure MAC addresses

Type	Address sources	Aging mechanism	Can be saved and survive a device reboot?
Static	Manually added (by using the **port-security mac-address security** command without the **sticky** keyword).	Not available. The static secure MAC addresses never age out unless you perform any of the following tasks: • Manually remove these MAC addresses. • Change the port security mode. • Disable the port security feature.	Yes.
Sticky	• Manually added (by using the **port-security mac-address security** command with the **sticky** keyword). • Converted from dynamic secure MAC	By default, sticky MAC addresses do not age out. However, you can configure an aging timer or use the aging timer together with the inactivity aging feature to remove old sticky MAC addresses. • If only the aging timer is configured, the aging timer counts up regardless of whether traffic data has been sent from the sticky	Yes. The secure MAC aging timer restarts at a reboot.

Type	Address sources	Aging mechanism	Can be saved and survive a device reboot?
	addresses. • Automatically learned when the dynamic secure MAC feature is disabled.	MAC addresses. • If both the aging timer and the inactivity aging feature are configured, the aging timer restarts once traffic data is detected from the sticky MAC addresses.	
Dynamic	• Converted from sticky MAC addresses. • Automatically learned after the dynamic secure MAC feature is enabled.	Same as sticky MAC addresses.	No. All dynamic secure MAC addresses are lost at reboot.

When the maximum number of secure MAC address entries is reached, the port changes to secure mode. In secure mode, the port cannot add or learn any more secure MAC addresses. The port allows only frames sourced from secure MAC addresses or MAC addresses configured by using the **mac-address dynamic** or **mac-address static** command to pass through.

Prerequisites

Before you configure secure MAC addresses, complete the following tasks:

- Set port security's limit on the number of MAC addresses on the port. Perform this task before you enable autoLearn mode.
- Set the port security mode to autoLearn.
- Configure the port to permit packets of the specified VLAN to pass or add the port to the VLAN. Make sure the VLAN already exists.

Adding secure MAC addresses

1. Enter system view.

   system-view
2. Set the secure MAC aging timer.

   port-security timer autolearn aging [**second**] *time-value*

   By default, secure MAC addresses do not age out.
3. Configure a secure MAC address.
   - Configure a secure MAC address in system view.

     port-security mac-address security [**sticky**] *mac-address* **interface** *interface-type interface-number* **vlan** *vlan-id*
   - Execute the following commands in sequence to configure a secure MAC address in interface view:

     interface *interface-type interface-number*

     port-security mac-address security [**sticky**] *mac-address* **vlan** *vlan-id*

   By default, no manually configured secure MAC addresses exist.

   In a VLAN, a MAC address cannot be specified as both a static secure MAC address and a sticky MAC address.

4. (Optional.) Execute the following commands in sequence to configure the secure MAC aging timer in interface view.

   interface *interface-type interface-number*

   port-security timer autolearn aging second *time-value*

   This command is available only in R1132 and later.

   By default, secure MAC addresses do not age out.

Enabling inactivity aging for secure MAC addresses

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable inactivity aging for secure MAC addresses.

   port-security mac-address aging-type inactivity

   By default, the inactivity aging feature is disabled for secure MAC addresses.

Enabling the dynamic secure MAC feature

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable the dynamic secure MAC feature.

   port-security mac-address dynamic

   By default, the dynamic secure MAC feature is disabled. Sticky MAC addresses can be saved to the configuration file. Once saved, they can survive a device reboot.

Enabling unified secure MAC address control for access users

About this task

By default, only the MAC addresses manually configured or automatically learned in the port security autoLearn mode are considered secure MAC addresses and are subject to related security features. To enhance network access security, the device now supports unified secure MAC management for various access users on a port.

With this feature enabled on a port, the MAC addresses of 802.1X authentication users, MAC authentication users, Web authentication users, and voice VLAN users who have been successfully authenticated on the port will be added to the secure MAC table and controlled by related secure MAC functions. For example, the number of online users depends on the maximum number of secure MAC addresses allowed by port security, intrusion protection support, and whether the entries can be manually deleted.

The secure MAC addresses generated by this feature are sticky MAC addresses. You can use the **port-security mac-address dynamic** command to convert them into dynamic secure MAC addresses.

In contrast to sticky MAC entries generated in autoLearn mode, the sticky MAC entries for authenticated users and voice VLAN users do not age while they are online. These entries are only affected by timing and traffic aging mechanisms after the users go offline.

Software and feature compatibility

This feature is supported only in F1127 and later versions.

Restrictions and guidelines

Before configuring this feature, you must first set the maximum number of secure MAC addresses allowed on a port by executing the **port-security max-mac-count** command in interface view. After this feature is configured, you cannot change the limit on the number of secure MAC addresses on a port.

When the **dot1x port-method portbased** or **mac-authentication host-mode multi-vlan** command is executed on a port, only the MAC address of the first authenticated user is added as a secure MAC address entry.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Enable unified secure MAC address control for access users.
   port-security user-mac control enable
   By default, unified secure MAC address control for access users is disabled.

Configuring NTK

About this task

The NTK feature checks the destination MAC address in outbound frames to make sure frames are forwarded only to trustworthy devices.

The NTK feature supports the following modes:

- **ntkonly**—Forwards only unicast frames with a known destination MAC address.
- **ntk-withbroadcasts**—Forwards only broadcast and unicast frames with a known destination MAC address.
- **ntk-withmulticasts**—Forwards only broadcast, multicast, and unicast frames with a known destination MAC address.
- **ntkauto**—Forwards only broadcast, multicast, and unicast frames with a known destination MAC address, and only when the port has online users.

Restrictions and guidelines

The NTK feature drops any unicast frame with an unknown destination MAC address.

Not all port security modes support triggering the NTK feature. For more information, see Table 1.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the NTK feature.

port-security ntk-mode { **ntk-withbroadcasts** | **ntk-withmulticasts** | **ntkauto** | **ntkonly** }

By default, NTK is disabled on a port and all frames are allowed to be sent.

Configuring intrusion protection

About this task

Intrusion protection takes one of the following actions on a port in response to illegal frames:

- **blockmac**—Adds the source MAC addresses of illegal frames to the blocked MAC address list, and then discards frames sourced from blocked MAC addresses for a period set by the block timer. A blocked MAC address will be unblocked when the block timer expires.
- **disableport**—Disables the port until you bring it up manually.
- **disableport-temporarily**—Disables the port for a period of time. The period can be configured with the **port-security timer disableport** command.

If the action is **disableport** or **disableport-temporarily**, you can also enable strict intrusion protection to enhance security. With strict intrusion protection, the port shuts down when it receives a frame whose source MAC address is a secure MAC address on another port in the same VLAN.

Restrictions and guidelines

On a port operating in either macAddressElseUserLoginSecure mode or macAddressElseUserLoginSecureExt mode, intrusion protection is triggered only after both MAC authentication and 802.1X authentication fail for the same frame.

Strict intrusion protection takes effect only when the intrusion protection action is **disableport** or **disableport-temporarily**. When strict intrusion protection is enabled on a port, you cannot change the intrusion protection action to **blockmac** on that port. To change the intrusion protection action to **blockmac**, you must first disable strict intrusion protection on that port.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the intrusion protection feature.

   port-security intrusion-mode { **blockmac** | **disableport** | **disableport-temporarily** }

   By default, intrusion protection is disabled.

4. (Optional.) Enable strict intrusion protection.

   port-security strict-intrusion-protection enable

   By default, strict intrusion protection is disabled.

5. Return to system view.

   quit

6. (Optional.) Set the silence timeout period during which a port remains disabled.

   port-security timer disableport *time-value*

   By default, the port silence timeout period is 20 seconds.

7. (Optional.) Set the block timer for blocked MAC addresses.

   port-security timer blockmac *time-value*

   By default, the block timer is 180 seconds.

Ignoring authorization information from the server

About this task

You can configure a port to ignore the authorization information received from the server (local or remote) after an 802.1X or MAC authentication user passes authentication.

Procedure

1. Enter system view.
   `system-view`
2. Enter interface view.
   `interface` *`interface-type interface-number`*
3. Ignore the authorization information received from the authentication server.
   `port-security authorization ignore`
   By default, a port uses the authorization information received from the authentication server.

Configuring MAC move

About this task

Port security MAC move takes effect in the following scenarios:

- **Inter-port move on a device**—An online user authenticated through 802.1X authentication, MAC authentication, or Web authentication moves between ports on the device. The user VLAN or authentication method might change or stay unchanged after the move.
- **Inter-VLAN move on a port**—An online user authenticated through 802.1X authentication, MAC authentication, or Web authentication moves between VLANs on a trunk or hybrid port. In addition, the packets that trigger authentication have VLAN tags.

Port security MAC move allows an authenticated online user on one port or VLAN to be reauthenticated and come online on another port or VLAN without going offline first. After the user passes authentication on the new port or VLAN, the system removes the authentication session of the user on the original port or VLAN.

NOTE:

For MAC authentication, the MAC move feature applies only when MAC authentication single-VLAN mode is used. The MAC move feature does not apply to MAC authentication users that move between VLANs on a port with MAC authentication multi-VLAN mode enabled.

If this feature is disabled, authenticated users must go offline first before they can be reauthenticated successfully on a new port or VLAN to come online.

For a user moving between ports, the port from which the user moves is called the source port and the port to which the user moves is called the destination port.

On the destination port, an 802.1X, MAC, or Web authentication user will reauthenticate in the VLAN authorized on the source port if the source port is enabled with MAC-based VLAN. If that VLAN is not permitted to pass through on the destination port, reauthentication will fail. To avoid this situation, enable VLAN check bypass on the destination port.

Restrictions and guidelines

As a best practice to minimize security risks, enable MAC move only if user roaming between ports is required.

802.1X, MAC, or Web authenticated users cannot move between ports on a device or between VLANs on a port if the maximum number of online users on the authentication server has been reached.

MAC authentication multi-VLAN mode has higher priority than MAC move for users moving between VLANs on a port. If MAC authentication multi-VLAN mode is enabled, these users can come online in the new VLAN without being reauthenticated. To enable MAC authentication multi-VLAN mode, use the **mac-authentication host-mode multi-vlan** command. For more information about MAC authentication multi-VLAN mode, see "Configuring MAC authentication."

When you configure VLAN check bypass for users moving between ports, follow these guidelines:

- To ensure a successful reauthentication, enable VLAN check bypass on a destination port if the source port is enabled with MAC-based VLAN.
- If the destination port is an 802.1X-enabled trunk port, you must configure it to send 802.1X protocol packets without VLAN tags. For more information, see "Configuring 802.1X."

Procedure

1. Enter system view.
   system-view
2. Enable MAC move.
   port-security mac-move permit [**port** | **vlan**]
   By default, MAC move is disabled.
3. (Optional.) Enable VLAN check bypass for users moving between ports.
   a. Enter interface view.
      interface *interface-type interface-number*
   b. Enable VLAN check bypass for users moving to the port from other ports.
      port-security mac-move bypass-vlan-check
      By default, the VLAN check bypass feature is disabled.

Enabling the authorization-fail-offline feature

About the authorization-fail-offline feature

IMPORTANT:
The authorization-fail-offline feature takes effect only on port security users that have failed ACL, CAR, or user profile authorization.

The authorization-fail-offline feature logs off port security users that have failed authorization.

A user fails authorization in the following situations:

- The device or server fails to assign the specified authorization attribute to the user.
- The device or server assigns authorization information that does not exist on the device to the user.

This feature does not apply to users that have failed VLAN authorization. The device logs off these users directly.

You can also enable the quiet timer feature for 802.1X or MAC authentication users that are logged off by the authorization-fail-offline feature. The device adds these users to the 802.1X or MAC authentication quiet queue. Within the quiet timer, the device does not process packets from these users or authenticate them. If you do not enable the quiet timer feature, the device immediately authenticates these users upon receiving packets from them.

Prerequisites

For the quiet timer feature to take effect, complete the following tasks:

- For 802.1X users, use the **dot1x quiet-period** command to enable the quiet timer and use the **dot1x timer quiet-period** command to set the timer.
- For MAC authentication users, use the **mac-authentication timer quiet** command to set the quiet timer for MAC authentication.

Procedure

1. Enter system view.

   system-view
2. Enable the authorization-fail-offline feature.

   port-security authorization-fail offline [**quiet-period**]

   By default, this feature is disabled, and the device does not log off users that have failed authorization.

Setting port security's limit on the number of MAC addresses for specific VLANs on a port

About this task

Typically, port security allows the access of the following types of MAC addresses on a port:

- MAC addresses that pass 802.1X authentication, MAC authentication, or Web authentication.
- MAC addresses in the MAC authentication guest or critical VLAN.
- MAC addresses in the 802.1X guest, Auth-Fail, or critical VLAN.
- MAC addresses in the Web authentication Auth-Fail VLAN.

This feature limits the number of MAC addresses that port security allows to access a port through specific VLANs. Use this feature to prevent resource contentions among MAC addresses and ensure reliable performance for each access user on the port. When the number of MAC addresses in a VLAN on the port reaches the upper limit, the device denies any subsequent MAC addresses in the VLAN on the port.

Restrictions and guidelines

On a port, the maximum number of MAC addresses in a VLAN cannot be smaller than the number of existing MAC addresses in the VLAN. If the specified maximum number is smaller, the setting does not take effect.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Set port security's limit on the number of MAC addresses for specific VLANs on the port.

   port-security mac-limit *max-number* **per-vlan** *vlan-id-list*

   The default setting is 2147483647.

Enabling open authentication mode

About this task

This feature enables access users (802.1X or MAC authentication users) of a port to come online and access the network even if they use nonexistent usernames or incorrect passwords.

Access users that come online in open authentication mode are called open users. Authorization and accounting are not available for open users. To display open user information, use the following commands:

- **`display dot1x connection open`**.
- **`display mac-authentication connection open`**.

This feature does not affect the access of users that use correct user information.

Restrictions and guidelines

When you configure open authentication mode, follow these restrictions and guidelines:

- If global open authentication mode is enabled, all ports are enabled with open authentication mode regardless of the port-specific open authentication mode setting. If global open authentication mode is disabled, whether a port is enabled with open authentication mode depends on the port-specific open authentication mode setting.
- The open authentication mode setting has lower priority than the 802.1X Auth-Fail VLAN and the MAC authentication guest VLAN. Open authentication mode does not take effect on a port if the port is also configured with the 802.1X Auth-Fail VLAN or the MAC authentication guest VLAN. For information about 802.1X authentication and MAC authentication, see "802.1X overview," "Configuring 802.1X," and "Configuring MAC authentication."

Procedure

1. Enter system view.
   `system-view`
2. Enable global open authentication mode.
   `port-security authentication open global`
   By default, global open authentication mode is disabled.
3. Enter interface view.
   `interface` *`interface-type interface-number`*
4. Enable open authentication mode on the port.
   `port-security authentication open`
   By default, open authentication mode is disabled on a port.

Configuring free VLANs for port security

About this task

This feature allows packets from the specified VLANs to not trigger 802.1X or MAC authentication on a port configured with any of the following features:

- 802.1X authentication.
- MAC authentication.
- One of the following port security modes:
  - userLogin.
  - userLoginSecure.

- userLoginWithOUI.
- userLoginSecureExt.
- macAddressWithRadius.
- macAddressOrUserLoginSecure.
- macAddressElseUserLoginSecure.
- macAddressOrUserLoginSecureExt.
- macAddressElseUserLoginSecureExt.

Software version and feature compatibility

This feature is supported only in R1122 and later.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure free VLANs for port security.
   port-security free-vlan *vlan-id-list*
   By default, no free VLANs for port security exist on a port.

Applying a NAS-ID profile to port security

About this task

By default, the device sends its device name in the NAS-Identifier attribute of all RADIUS requests.

A NAS-ID profile enables you to send different NAS-Identifier attribute strings in RADIUS requests from different VLANs. The strings can be organization names, service names, or any user categorization criteria, depending on the administrative requirements.

For example, map the NAS-ID **companyA** to all VLANs of company A. The device will send **companyA** in the NAS-Identifier attribute for the RADIUS server to identify requests from any Company A users.

Restrictions and guidelines

You can apply a NAS-ID profile to port security globally or on a port. On a port, the device selects a NAS-ID profile in the following order:

1. The port-specific NAS-ID profile.
2. The NAS-ID profile applied globally.

If no NAS-ID profile is applied or no matching binding is found in the selected profile, the device uses the device name as the NAS-ID.

For more information about the NAS-ID profile configuration, see "Configuring AAA."

Procedure

1. Enter system view.
   system-view
2. Apply a NAS-ID profile.
   - Apply a NAS-ID profile globally.
     port-security nas-id-profile *profile-name*
   - Execute the following commands in sequence to apply a NAS-ID profile to an interface:

interface *interface-type interface-number*

port-security nas-id-profile *profile-name*

By default, no NAS-ID profile is applied in system view or in interface view.

Enabling traffic statistics for MAC authentication and 802.1X users

About this task

By default, 802.1X and MAC authentication user statistics collected and sent to the accounting server contain only the online duration of the users. To collect and send their traffic statistics to the accounting server in addition to their online duration, perform this task.

This feature takes effect on 802.1X and MAC authentication users when port security is enabled, or when 802.1X and MAC authentication are separately enabled on the device.

If a port performs MAC authentication or 802.1X authentication in MAC-based access control mode, this feature collects user traffic statistics on a per-MAC basis on the port.

If a port performs 802.1X authentication in port-based access control mode, this feature collects user traffic statistics on a per-port basis on the port.

With this feature enabled, the device requires more ACL resources for new 802.1X or MAC authentication users. If the device has run out of ACL resources, the authentication will fail for new 802.1X or MAC authentication users.

Restrictions and guidelines

This feature takes effect only on users that come online after the feature is enabled.

Enable this feature only if traffic accounting is required and only if there are sufficient ACL resources. When you enable this feature, make sure you are fully aware of its impact on the network. If the network has a large number of online 802.1X and MAC authentication users, ACL resources might become insufficient, causing authentication failure of new 802.1X and MAC authentication users. For more information about 802.1X and MAC authentication, see "Configuring 802.1X" and "Configuring MAC authentication."

Procedure

1. Enter system view.

   system-view

2. Enable traffic statistics for 802.1X and MAC authentication users.

   port-security traffic-statistics enable

   By default, the device does not collect traffic statistics for 802.1X and MAC authentication users.

Enabling SNMP notifications for port security

About this task

Use this feature to report critical port security events to an NMS. For port security event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications for port security.

   snmp-agent trap enable port-security [**address-learned** | **dot1x-failure** | **dot1x-logoff** | **dot1x-logon** | **intrusion** | **mac-auth-failure** | **mac-auth-logoff** | **mac-auth-logon**] *

   By default, SNMP notifications are disabled for port security.

Enabling port security user logging

About this task

This feature enables the device to generate logs about port security users and send the logs to the information center. For the logs to be output correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

To prevent excessive port security user log entries, use this feature only if you need to analyze abnormal port security user events.

Procedure

1. Enter system view.

   system-view

2. Enable port security user logging.

   port-security access-user log enable [**failed-authorization** | **mac-learning** | **violation** | **vlan-mac-limit**] *

   By default, port security user logging is disabled.

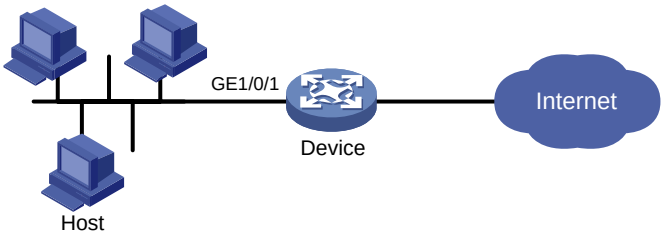
   If you do not specify any parameters, this command enables all types of port security user logs.

Display and maintenance commands for port security

Execute **display** commands in any view:

Task	Command
Display the port security configuration, operation information, and statistics.	**display port-security** [**interface** *interface-type interface-number*]
Display information about blocked MAC addresses.	**display port-security mac-address block** [**interface** *interface-type interface-number*] [**vlan** *vlan-id*] [**count**]
Display information about secure MAC addresses.	**display port-security mac-address security** [**interface** *interface-type interface-number*] [**vlan** *vlan-id*] [**count**]

Port security configuration examples



Example: Configuring port security in autoLearn mode

Network configuration

As shown in Figure 1, configure GigabitEthernet 1/0/1 on the device to meet the following requirements:

- Accept up to 64 users without authentication.
- Be permitted to learn and add MAC addresses as sticky MAC addresses, and set the secure MAC aging timer to 30 minutes.
- Stop learning MAC addresses after the number of secure MAC addresses reaches 64. If any frame with an unknown MAC address arrives, intrusion protection starts, and the port shuts down and stays silent for 30 seconds.

Figure 1 Network diagram

Procedure

Enable port security.

```
<Device> system-view
[Device] port-security enable
```

Set the secure MAC aging timer to 30 minutes.

```
[Device] port-security timer autolearn aging 30
```

Set port security's limit on the number of secure MAC addresses to 64 on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] port-security max-mac-count 64
```

Set the port security mode to autoLearn.

```
[Device-GigabitEthernet1/0/1] port-security port-mode autolearn
```

Configure the port to be silent for 30 seconds after the intrusion protection feature is triggered.

```
[Device-GigabitEthernet1/0/1] port-security intrusion-mode disableport-temporarily
[Device-GigabitEthernet1/0/1] quit
[Device] port-security timer disableport 30
```

Verifying the configuration

Verify the port security configuration.

```
[Device] display port-security interface gigabitethernet 1/0/1
Global port security parameters:
   Port security          : Enabled
   AutoLearn aging time   : 30 min
   Disableport timeout    : 30 s
   Blockmac timeout       : 180 s
```

```
   MAC move               : Denied
   Authorization fail     : Online
   NAS-ID profile         : Not configured
   Dot1x-failure trap     : Disabled
   Dot1x-logon trap       : Disabled
   Dot1x-logoff trap      : Disabled
   Intrusion trap         : Disabled
   Address-learned trap   : Disabled
   Mac-auth-failure trap  : Disabled
   Mac-auth-logon trap    : Disabled
   Mac-auth-logoff trap   : Disabled
   Open authentication    : Disabled
   Traffic-statistics     : Disabled
   OUI value list         :
    Index :  1           Value : 123401

 GigabitEthernet1/0/1 is link-up
   Port mode                      : autoLearn
   NeedToKnow mode                : Disabled
   AutoLearn aging time           : Not configured
   Intrusion protection mode      : DisablePortTemporarily
   Strict intrusion protection    : Disabled
   Security MAC address attribute
       Learning mode              : Sticky
       Aging type                 : Periodical
   Max secure MAC addresses       : 64
   Current secure MAC addresses   : 0
   Authorization                  : Permitted
   NAS-ID profile                 : Not configured
   Free VLANs                     : Not configured
   Open authentication            : Disabled
   MAC-move VLAN check bypass     : Disabled
```

The port allows for MAC address learning, and you can view the number of learned MAC addresses in the **Current secure MAC addresses** field.

Display additional information about the learned MAC addresses.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] display this
#
interface GigabitEthernet1/0/1
 port-security max-mac-count 64
 port-security port-mode autolearn
 port-security mac-address security sticky 0002-0000-0015 vlan 1
 port-security mac-address security sticky 0002-0000-0014 vlan 1
 port-security mac-address security sticky 0002-0000-0013 vlan 1
 port-security mac-address security sticky 0002-0000-0012 vlan 1
 port-security mac-address security sticky 0002-0000-0011 vlan 1
#
[Device-GigabitEthernet1/0/1] quit
```

Verify that the port security mode changes to **secure** after the number of MAC addresses learned by the port reaches 64.

```
[Device] display port-security interface gigabitethernet 1/0/1
```

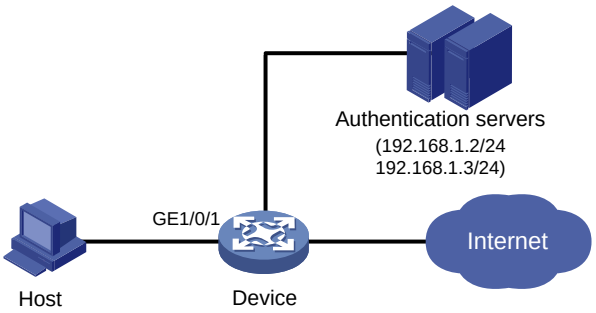
Verify that the port will be disabled for 30 seconds after it receives a frame with an unknown MAC address. (Details not shown.)

After the port is re-enabled, delete several secure MAC addresses.

```
[Device] undo port-security mac-address security sticky 0002-0000-0015 vlan 1
[Device] undo port-security mac-address security sticky 0002-0000-0014 vlan 1
...
```

Verify that the port security mode of the port changes to **autoLearn**, and the port can learn MAC addresses again. (Details not shown.)

Example: Configuring port security in userLoginWithOUI mode



Network configuration

As shown in Figure 2, a client is connected to the device through GigabitEthernet 1/0/1. The device authenticates the client with a RADIUS server in ISP domain **sun**. If the authentication succeeds, the client is authorized to access the Internet.

- The RADIUS server at 192.168.1.2 acts as the primary authentication server and the secondary accounting server. The RADIUS server at 192.168.1.3 acts as the secondary authentication server and the primary accounting server. The shared key for authentication is **name**, and the shared key for accounting is **money**.
- All users use the authentication, authorization, and accounting methods of ISP domain **sun**.
- The RADIUS server response timeout time is 5 seconds. The maximum number of RADIUS packet retransmission attempts is 5. The device sends real-time accounting packets to the RADIUS server at 15-minute intervals, and sends usernames without domain names to the RADIUS server.

Configure GigabitEthernet 1/0/1 to allow only one 802.1X user and a user that uses one of the specified OUI values to be authenticated.

Figure 2 Network diagram

Procedure

The following configuration steps cover some AAA/RADIUS configuration commands. For more information about the commands, see *Security Command Reference*.

Make sure the host and the RADIUS server can reach each other.

1. Configure AAA:

Configure a RADIUS scheme named **radsun**.

```
<Device> system-view
[Device] radius scheme radsun
[Device-radius-radsun] primary authentication 192.168.1.2
[Device-radius-radsun] primary accounting 192.168.1.3
[Device-radius-radsun] secondary authentication 192.168.1.3
[Device-radius-radsun] secondary accounting 192.168.1.2
[Device-radius-radsun] key authentication simple name
[Device-radius-radsun] key accounting simple money
[Device-radius-radsun] timer response-timeout 5
[Device-radius-radsun] retry 5
[Device-radius-radsun] timer realtime-accounting 15
[Device-radius-radsun] user-name-format without-domain
[Device-radius-radsun] quit
```

Configure ISP domain **sun**.

```
[Device] domain sun
[Device-isp-sun] authentication lan-access radius-scheme radsun
[Device-isp-sun] authorization lan-access radius-scheme radsun
[Device-isp-sun] accounting lan-access radius-scheme radsun
[Device-isp-sun] quit
```

2. Configure 802.1X:

Set the 802.1X authentication method to CHAP. By default, the authentication method for 802.1X is CHAP.

```
[Device] dot1x authentication-method chap
```

Specify ISP domain **sun** as the mandatory authentication domain for 802.1X users on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] dot1x mandatory-domain sun
[Device-GigabitEthernet1/0/1] quit
```

3. Configure port security:

Enable port security.

```
[Device] port-security enable
```

Add five OUI values. (You can add up to 16 OUI values. The port permits only one user matching one of the OUIs to pass authentication.)

```
[Device] port-security oui index 1 mac-address 1234-0100-1111
[Device] port-security oui index 2 mac-address 1234-0200-1111
[Device] port-security oui index 3 mac-address 1234-0300-1111
[Device] port-security oui index 4 mac-address 1234-0400-1111
[Device] port-security oui index 5 mac-address 1234-0500-1111
```

Set the port security mode to userLoginWithOUI.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] port-security port-mode userlogin-withoui
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Verify that GigabitEthernet 1/0/1 allows only one 802.1X user to be authenticated.

```
[Device] display port-security interface gigabitethernet 1/0/1
Global port security parameters:
   Port security          : Enabled

  MAC-move VLAN check bypass    : Disabled
```

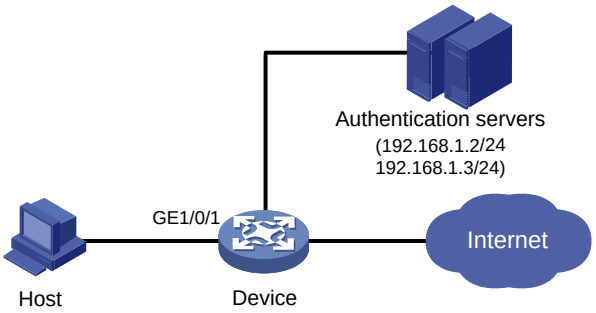
Display information about the online 802.1X user to verify 802.1X configuration.

```
[Device] display dot1x
```

Verify that the port also allows one user whose MAC address has an OUI among the specified OUIs to pass authentication.

```
[Device] display mac-address interface gigabitethernet 1/0/1
MAC Address     VLAN ID   State          Port/Nickname           Aging
1234-0300-0011  1         Learned        GE1/0/1                 Y
```

Example: Configuring port security in macAddressElseUserLoginSecure mode



Network configuration

As shown in Figure 3, a client is connected to the device through GigabitEthernet 1/0/1. The device authenticates the client by a RADIUS server in ISP domain **sun**. If the authentication succeeds, the client is authorized to access the Internet.

Configure GigabitEthernet 1/0/1 of the device to meet the following requirements:

- Allow more than one MAC authenticated user to log on.
- For 802.1X users, perform MAC authentication first and then, if MAC authentication fails, 802.1X authentication. Allow only one 802.1X user to log on.
- Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hexadecimal notation with hyphens, and letters are in upper case.
- Set the total number of MAC authenticated users and 802.1X authenticated users to 64.
- Enable NTK (**ntkonly** mode) to prevent frames from being sent to unknown MAC addresses.

Figure 3 Network diagram

Procedure

Make sure the host and the RADIUS server can reach each other.

1. Configure RADIUS authentication/accounting and ISP domain settings. (See "Example: Configuring port security in userLoginWithOUI mode.")
2. Configure port security:

   # Enable port security.

   ```
   <Device> system-view
   [Device] port-security enable
   ```

   # Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hexadecimal notation with hyphens, and letters are in upper case.

   ```
   [Device] mac-authentication user-name-format mac-address with-hyphen uppercase
   ```

   # Specify the MAC authentication domain.

   ```
   [Device] mac-authentication domain sun
   ```

   # Set the 802.1X authentication method to CHAP. By default, the authentication method for 802.1X is CHAP.

   ```
   [Device] dot1x authentication-method chap
   ```

   # Set port security's limit on the number of MAC addresses to 64 on the port.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] port-security max-mac-count 64
   ```

Set the port security mode to macAddressElseUserLoginSecure.

```
[Device-GigabitEthernet1/0/1] port-security port-mode mac-else-userlogin-secure
```

Specify ISP domain **sun** as the mandatory authentication domain for 802.1X users.

```
[Device-GigabitEthernet1/0/1] dot1x mandatory-domain sun
```

Set the NTK mode of the port to ntkonly.

```
[Device-GigabitEthernet1/0/1] port-security ntk-mode ntkonly
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Verify the port security configuration.

```
[Device] display port-security interface gigabitethernet 1/0/1
Global port security parameters:
   Port security          : Enabled
   AutoLearn aging time   : 30 min
   Disableport timeout    : 30 s
   Blockmac timeout       : 180 s
   MAC move               : Denied
   Authorization fail     : Online
   NAS-ID profile         : Not configured
   Dot1x-failure trap     : Disabled
   Dot1x-logon trap       : Disabled
   Dot1x-logoff trap      : Disabled
   Intrusion trap         : Disabled
   Address-learned trap   : Disabled
   Mac-auth-failure trap  : Disabled
   Mac-auth-logon trap    : Disabled
   Mac-auth-logoff trap   : Disabled
   Open authentication    : Disabled
   Traffic-statistics     : Disabled
   OUI value list

 GigabitEthernet1/0/1 is link-up
   Port mode                      : macAddressElseUserLoginSecure

        0002-0000-0011      Authenticated
```

Verify that frames with an unknown destination MAC address, multicast address, or broadcast address are discarded. (Details not shown.)

Troubleshooting port security

Cannot set the port security mode

Symptom

Cannot set the port security mode for a port.

Analysis

For a port operating in a port security mode other than noRestrictions, you cannot change the port security mode by using the **`port-security port-mode`** command.

Solution

To resolve the issue:

1. Set the port security mode to noRestrictions.
   ```
   [Device-GigabitEthernet1/0/1] undo port-security port-mode
   ```
2. Set a new port security mode for the port, for example, autoLearn.
   ```
   [Device-GigabitEthernet1/0/1] port-security port-mode autolearn
   ```
3. If the issue persists, contact H3C Support.

Cannot configure secure MAC addresses

Symptom

Cannot configure secure MAC addresses.

Analysis

No secure MAC address can be configured on a port operating in a port security mode other than autoLearn.

Solution

To resolve the issue:

1. Set the port security mode to autoLearn.

```
[Device-GigabitEthernet1/0/1] undo port-security port-mode
[Device-GigabitEthernet1/0/1] port-security max-mac-count 64
[Device-GigabitEthernet1/0/1] port-security port-mode autolearn
[Device-GigabitEthernet1/0/1] port-security mac-address security 1-1-2 vlan 1
```

2. If the issue persists, contact H3C Support.

Configuring user profiles

About user profiles

A user profile defines a set of parameters, such as a QoS policy, for a user or a class of users. A user profile can be reused when a user connected to the network on a different interface.

The user profile application allows flexible traffic policing on a per-user basis. Each time a user passes authentication, the server sends the device the name of the user profile specified for the user. The device applies the parameters in the user profile to the user.

User profiles are typically used for resource allocation per user. For example, the interface-based traffic policing limits the total amount of bandwidth available to a group of users. However, user-profile-based traffic policing can limit the amount of bandwidth available to a single user.

Prerequisites for user profile

A user profile works with authentication methods. You must configure authentication for a user profile. For information about supported authentication methods, see the configuration guides for the related authentication modules.

Configuring a user profile

1. Enter system view.

   system-view
2. Create a user profile and enter user profile view.

   user-profile *profile-name*
3. Configure the user profile. Choose the options to configure as needed:
   - Apply an existing QoS policy to the user profile.

     qos apply policy *policy-name* { **inbound** | **outbound** }

     By default, no QoS policy is applied to a user profile.
   - Configure a CAR policy for the user profile.

     qos car { **inbound** | **outbound** } **any cir** *committed-information-rate* [**cbs** *committed-burst-size* [**ebs** *excess-burst-size*]]

     qos car { **inbound** | **outbound** } **any cir** *committed-information-rate* [**cbs** *committed-burst-size*] **pir** *peak-information-rate* [**ebs** *excess-burst-size*]

     By default, no CAR policy is configured for a user profile.

   For more information about QoS policies and CAR policies, see *ACL and QoS Configuration Guide*.

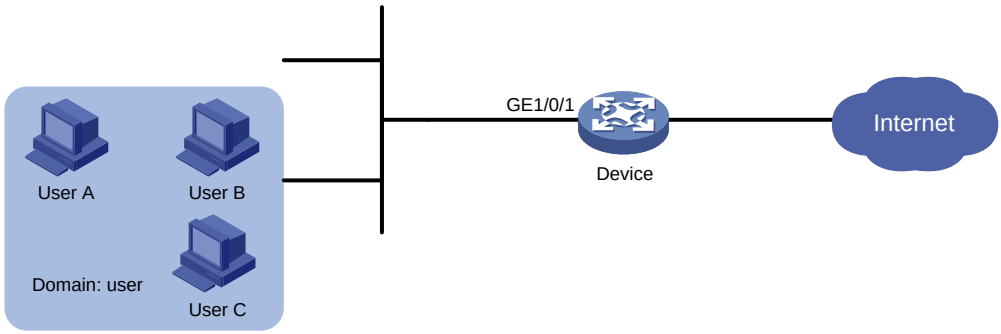
Display and maintenance commands for user profiles

Execute **display** commands in any view.

Task	Command
Display configuration and online user information for the specified user profile or all user profiles.	**display user-profile** [**name** *profile-name*] [**slot** *slot-number*]

User profile configuration examples

Example: Configuring user profiles and QoS policies



Network requirements

As shown in Figure 1, the device performs local 802.1X authentication on the users in domain **user** for authentication and authorization efficiency.

Configure user profiles and QoS policies on the device to meet the following requirements:

- User A cannot access the Internet during 8: 30 and 12:00 every day even if User A passes 802.1X authentication.
- User B has an upload speed of 2 Mbps after passing 802.1X authentication.
- User C has a download speed of 4 Mbps after passing 802.1X authentication.

Figure 1 Network diagram

Configuration procedure

1. Configure a QoS policy for User A:

   # Create a periodic time range from 8:30 to 12:00 every day.

   ```
   <Device> system-view
   [Device] time-range for_usera 8:30 to 12:00 daily
   ```

   # Create IPv4 basic ACL 2000, and configure a rule to match all packets during the time range **for_usera**.

   ```
   [Device] acl basic 2000
   [Device-acl-basic-2000] rule permit time-range for_usera
   [Device-acl-basic-2000] quit
   ```

   # Create a traffic class named **for_usera**, and use ACL 2000 as the match criterion.

   ```
   [Device] traffic classifier for_usera
   [Device-classifier-for_usera] if-match acl 2000
   [Device-classifier-for_usera] quit
   ```

   # Create a traffic behavior named **for_usera**, and configure the deny action.

   ```
   [Device] traffic behavior for_usera
   [Device-behavior-for_usera] filter deny
   ```

```
[Device-behavior-for_usera] quit
```

Create a QoS policy named **for_usera**, and associate traffic class **for_usera** and traffic behavior **for_usera** in the QoS policy.

```
[Device] qos policy for_usera
[Device-qospolicy-for_usera] classifier for_usera behavior for_usera
[Device-qospolicy-for_usera] quit
```

2. Create a user profile for User A and apply the QoS policy to the user profile:

Create a user profile named **usera**.

```
[Device] user-profile usera
```

Apply QoS policy **for_usera** to the inbound direction of user profile **usera**.

```
[[Device-user-profile-usera] qos apply policy for_usera inbound
[Device-user-profile-usera] quit
```

3. Configure a QoS policy for limiting the traffic rate for User B:

Create a traffic class named **class** to match all packets.

```
[Device] traffic classifier class
[Device-classifier-class] if-match any
[Device-classifier-class] quit
```

Create a traffic behavior named **for_userb**, and configure a traffic policing action (CIR 2000 kbps).

```
[Device] traffic behavior for_userb
[Device-behavior-for_userb] car cir 2000
[Device-behavior-for_userb] quit
```

Create a QoS policy named **for_userb**, and associate traffic class **class** and traffic behavior **for_userb** in the QoS policy.

```
[Device] qos policy for_userb
[Device-qospolicy-for_userb] classifier class behavior for_userb
[Device-qospolicy-for_userb] quit
```

4. Create a user profile for User B and apply the QoS policy to the user profile:

Create a user profile named **userb**.

```
[Device] user-profile userb
```

Apply QoS policy **for_userb** to the inbound direction of user profile **userb**.

```
[Device-user-profile-userb] qos apply policy for_userb inbound
[Device-user-profile-userb] quit
```

5. Configure a QoS policy for limiting the traffic rate for User C:

Create a traffic behavior named **for_userc**, and configure a traffic policing action (CIR 4000 kbps).

```
[Device] traffic behavior for_userc
[Device-behavior-for_userc] car cir 4000
[Device-behavior-for_userc] quit
```

Create a QoS policy named **for_userc**, and associate traffic class **class** and traffic behavior **for_userc** in the QoS policy.

```
[Device] qos policy for_userc
[Device-qospolicy-for_userc] classifier class behavior for_userc
[Device-qospolicy-for_userc] quit
```

6. Create a user profile for User C and apply the QoS policy to the user profile:

Create a user profile named **userc**.

```
[Device] user-profile userc
```

Apply QoS policy **for_userc** to the outbound direction of user profile **userc**.

```
[Device-user-profile-userc] qos apply policy for_userc outbound
[Device-user-profile-userc] quit
```

7. Configure local users:

Create a local user named **usera**.

```
[Device] local-user usera class network
New local user added.
```

Set the password to **123456TESTusera&!** for user **usera**.

```
[Device-luser-network-usera] password simple 123456TESTusera&!
```

Authorize user **usera** to use the LAN access service.

```
[Device-luser-network-usera] service-type lan-access
```

Specify user profile **usera** as the authorization user profile for user **usera**.

```
[Device-luser-network-usera] authorization-attribute user-profile usera
[Device-luser-network-usera] quit
```

Create a local user named **userb**.

```
[Device] local-user userb class network
New local user added.
```

Set the password to **123456TESTuserb&!** for user **userb**.

```
[Device-luser-network-userb] password simple 123456TESTuserb&!
```

Authorize user **userb** to use the LAN access service.

```
[Device-luser-network-userb] service-type lan-access
```

Specify user profile **userb** as the authorization user profile for user **userb**.

```
[Device-luser-network-userb] authorization-attribute user-profile userb
[Device-luser-network-userb] quit
```

Create a local user named **userc**.

```
[Device] local-user userc class network
New local user added.
```

Set the password to **123456TESTuserc&!** for user **userc**.

```
[Device-luser-network-userc] password simple 123456TESTuserc&!
```

Authorize user **userc** to use the LAN access service.

```
[Device-luser-network-userc] service-type lan-access
```

Specify user profile **userc** as the authorization user profile for user **userc**.

```
[Device-luser-network-userc] authorization-attribute user-profile userc
[Device-luser-network-userc] quit
```

8. Configure the authentication, authorization, and accounting methods for local users:

```
[Device] domain user
[Device-isp-user] authentication lan-access local
[Device-isp-user] authorization lan-access local
[Device-isp-user] accounting login none
[Device-isp-user] quit
```

9. Configure 802.1X:

Enable 802.1X on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] dot1x
```

Enable MAC-based access control on the port. By default, a port uses MAC-based access control.

```
[Device-GigabitEthernet1/0/1] dot1x port-method macbased
[Device-GigabitEthernet1/0/1] quit
```

Enable 802.1X globally.

```
[Device] dot1x
```

Verifying the configuration

Verify that the three users can pass 802.1X authentication and that QoS policies take effect on these users. (Details not shown.)

Display user profile information.

```
<Device> display user-profile
  User-Profile: usera
    Inbound:
      Policy: for_usera

    slot 1:
      User -:
        Authentication type: 802.1X
        Network attributes:
          Interface    : GigabitEthernet1/0/1
          MAC address  : 6805-ca06-557b
          Service VLAN : 1

  User-Profile: userb
    Inbound:
      Policy: for_userb

    slot 1:
      User -:
        Authentication type: 802.1X
        Network attributes:
          Interface    : GigabitEthernet1/0/1
          MAC address  : 80c1-6ee0-2664
          Service VLAN : 1

  User-Profile: userc
    Outbound:
      Policy: for_userc

    slot 1:
      User -:
        Authentication type: 802.1X
        Network attributes:
          Interface    : GigabitEthernet1/0/1
          MAC address  : 6805-ca05-3efa
          Service VLAN : 1
```

Configuring password control

About password control

Password control allows you to implement the following features:

- Manage login and super password setup, expirations, and updates for local users.
- Control user login status based on predefined policies.

For more information about local users, see "Configuring AAA." For information about super passwords, see RBAC in *Fundamentals Configuration Guide*.

Password setting

Minimum password length

You can define the minimum length of user passwords. The system rejects the setting of a password that is shorter than the configured minimum length.

Password composition policy

A password can be a combination of characters from the following types:

- Uppercase letters A to Z.
- Lowercase letters a to z.
- Digits 0 to 9.
- Special characters in Table 1.

Table 1 Special Characters

Character name	Symbol	Character name	Symbol
Ampersand sign	&	Apostrophe	'
Asterisk	*	At sign	@
Back quote	`	Back slash	\
Blank space	N/A	Caret	^
Colon	:	Comma	,
Dollar sign	$	Dot	.
Equal sign	=	Exclamation point	!
Left angle bracket	<	Left brace	{
Left bracket	[	Left parenthesis	(
Minus sign	-	Percent sign	%
Plus sign	+	Pound sign	#
Quotation marks	"	Right angle bracket	>
Right brace	}	Right bracket	]
Right parenthesis	)	Semi-colon	;
Slash	/	Tilde	~

Character name	Symbol	Character name	Symbol
Underscore	_	Vertical bar	|

Depending on the system's security requirements, you can set the minimum number of character types a password must contain and the minimum number of characters for each type, as shown in Table 2.

Table 2 Password composition policy

Password combination level	Minimum number of character types	Minimum number of characters for each type
Level 1	One	One
Level 2	Two	One
Level 3	Three	One
Level 4	Four	One

When a user sets or changes a password, the system checks if the password meets the combination requirement. If it does not, the operation fails.

Password complexity checking policy

A less complicated password is more likely to be cracked, such as a password containing the username or repeated characters. For higher security, you can configure a password complexity checking policy to ensure that all user passwords are relatively complicated. When a user configures a password, the system checks the complexity of the password. If the password is complexity-incompliant, the configuration will fail.

You can apply the following password complexity requirements:

- A password cannot contain the username or the reverse of the username. For example, if the username is **abc**, a password such as **abc982** or **2cba** is not complex enough.
- A minimum of three identical consecutive characters is not allowed. For example, password **a111** is not complex enough.

Password updating and expiration

Password updating

This feature allows you to set the minimum interval at which users can change their passwords. A user can only change the password once within the specified interval.

The minimum interval does not apply to the following situations:

- A user is prompted to change the password at first login.
- The password aging time expires.

Password expiration

Password expiration imposes a lifecycle on a user password. After the password expires, the user needs to change the password.

The system displays an error message for a login attempt with an expired password. The user is asked to provide a new password. The new password must be valid, and the user must enter exactly the same password when confirming it.

Web users, Telnet users, SSH users, and console users can change their own passwords. FTP users must have their passwords changed by the administrator.

Early notice on pending password expiration

When a user logs in, the system checks whether the password will expire in a time equal to or less than the specified notification period. If so, the system notifies the user when the password will expire and provides a choice for the user to change the password.

- If the user sets a new valid password, the system records the new password and the setup time.
- If the user does not or fails to change the password, the system allows the user to log in by using the current password until the password expires.

Web users, Telnet users, SSH users, and console users can change their own passwords. FTP users must have their passwords changed by the administrator.

Login with an expired password

You can allow a user to log in a certain number of times within a period of time after the password expires. For example, if you set the maximum number of logins with an expired password to 3 and the time period to 15 days, a user can log in three times within 15 days after the password expires.

Password history

This feature allows the system to store passwords that a user has used.

When a network access user changes the password, the system compares the new password with the current password and those stored in the password history records. The new password must be different from the current one and those stored in the history records by a minimum of four different characters. Otherwise, the system will display an error message, and the new password is not successfully set.

The local passwords and super passwords for device management users are stored in hash form and cannot be converted to plain texts. When a device management user changes a local password or super password, follow these rules:

- If the new password is set by using the hash method, the system will not compare the new password with the current one and those stored in the history password records.
- If the new password is set in plain text, the system compares the new password with the current password and those stored in the password history records. A new password must be different from those stored in the history password records. If the current password is required, the new password must also be different from the current one by a minimum of four different characters. Otherwise, the system will display an error message, and the new password is not successfully set.

You can set the maximum number of history password records for the system to maintain for each user. When the number of history password records exceeds the setting, the most recent record overwrites the earliest one.

Current login passwords are not stored in the password history for device management users. Device management users have their passwords saved in cipher text, which cannot be recovered to plaintext passwords.

User login control

First login

By default, if the global password control feature is enabled, users must change the password at first login before they can access the system. In this situation, password changes are not subject to the minimum password update interval. If it is not necessary for users to change the password at first login, disable the password change at first login feature.

Password control blacklist

The password control blacklist prevents abnormal users from logging in by recording the login failures and maintaining the status of blacklisted user accounts.

If an FTP, Web, or VTY user fails to log in, the system adds the user account and the user's IP address to the password control blacklist. If an AUX user fails to log in, the system adds the user account to the password control blacklist.

If a user uses the same user account to log in to the device from different IP addresses and fails the logins, the device will create a blacklist entry for each IP address for the user account. When the maximum number of blacklist entries for the user account is reached, a blacklist entry for a new IP address of the user account will overwrite the earliest blacklist entry for the user account.

Login attempt limit

Limiting the number of consecutive login failures can effectively prevent password guessing.

When a user fails the maximum number of consecutive attempts, login attempt limit limits the user and user account in any of the following ways:

- For an FTP, Web, or VTY user, the system prohibits the user from using the user account to log in through the user's IP address. For an AUX user, the system prohibits the user from logging in through AUX user line. The locked user can use their own account to log in to the device only after the account is manually removed from the password control blacklist.
- Allows the user to continue using the user account. The user account is removed from the password control blacklist when the user uses this account to successfully log in to the device.
- Locks the user account and the user's IP address for a period of time.

  The user can use the account to log in when either of the following conditions exists:
  - The locking timer expires.
  - The account is manually removed from the password control blacklist before the locking timer expires.

NOTE:

This account is locked only for the user at the locked IP address. A user from an unlocked IP address can still use this account, and the user at the locked IP address can use other unlocked user accounts.

Maximum account idle time

You can set the maximum account idle time for user accounts. When an account is idle for this period of time since the last successful login, the account becomes invalid.

Login control with a weak password

The system checks for weak passwords for Telnet, SSH, HTTP, or HTTPS device management users. A password is weak if it does not meet the following requirements:

- Password composition restriction.
- Minimum password length restriction.
- Password complexity username checking policy.

By default, the system displays a message about a weak password but does not force the user to change it. To improve the device security, you can enable the mandatory weak password change feature, which forces the users to change the identified weak passwords. The users can log in to the device only after their passwords meet the password requirements.

Password not displayed in any form

For security purposes, nothing is displayed when a user enters a password.

Logging

The system generates a log each time a user changes its password successfully or is added to the password control blacklist because of login failures.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

Restrictions and guidelines: Password control configuration

IMPORTANT:

To successfully enable the global password control feature and allow device management users to log in to the device, make sure the device have sufficient storage space.

The password control features can be configured in several different views, and different views support different features. The settings configured in different views or for different objects have the following application ranges:

- Settings for super passwords apply only to super passwords.
- Settings in local user view apply only to the password of the local user.
- Settings in user group view apply to the passwords of the local users in the user group if you do not configure password policies for these users in local user view.
- Global settings in system view apply to the passwords of the local users in all user groups if you do not configure password policies for these users in both local user view and user group view.

For local user passwords, the settings with a smaller application scope have higher priority. For local user passwords, the settings with a smaller application scope have higher priority. The system prefers to use the non-default setting in local user view for a local user.

- If the default setting is configured for the local user, the system uses the non-default setting for the user group to which the local user belongs.
- If the default setting is configured for the user group, the system uses the global setting.

Password control tasks at a glance

To configure password control, perform the following tasks:

1. Enabling password control
2. (Optional.) Setting global password control parameters
3. (Optional.) Setting user group password control parameters
4. (Optional.) Setting local user password control parameters
5. (Optional.) Setting super password control parameters

Enabling password control

About this task

Enabling global password control is a prerequisite for password control functions to take effect except for the following functions:

- Password composition policy.
- Minimum password length.
- Username checking.

For a specific password restriction setting (password expiration or password history management) to take effect, make sure you enable both the global password control feature and the specific password restriction.

Restrictions and guidelines

After global password control is enabled, follow these restrictions and guidelines:

- You cannot display the password and super password configurations for device management users by using the corresponding **display** commands.
- You cannot display the password configuration for network access users by using the corresponding **display** command.
- The passwords configured for local users must contain a minimum of four different characters.
- In FIPS mode, the global password control feature is enabled for device management users and cannot be disabled for them.
- To ensure correct function of password control, configure the device to use NTP to obtain the UTC time. After global password control is enabled, password control will record the UTC time when the password is set. The recorded UTC time might not be consistent with the actual UTC time due to power failure or device reboot. The inconsistency will cause the password expiration feature to malfunction. For information about NTP, see *Network Management and Monitoring Configuration Guide*.
- The device automatically generates a .dat file and saves the file to the storage media. The file is used to record authentication and login information of the local users. Do not manually delete or modify the file.
- The global password control feature enables the system to record history passwords. When the number of history password records of a user reaches the maximum number, the newest history record overwrites the earliest one. To delete the existing history password records, use one of the following methods:
  - Use the **undo password-control enable** command to disable the password control feature globally.
  - Use the **reset password-control history-record** command to clear the passwords manually.

Procedure

1. Enter system view.

   system-view

2. Enable the global password control feature.

   In non-FIPS mode:

   password-control enable [**network-class**]

   By default, the global password control feature is disabled for device management and network access users.

   In FIPS mode:

   password-control enable [**network-class**]

By default, the global password control feature is enabled for device management users and cannot be disabled. The global password control feature is disabled for network access users.

3. (Optional.) Enable a password restriction feature.

   password-control { **aging** | **composition** | **history** | **length** } **enable**

   By default, all four password restriction features are enabled.

Setting global password control parameters

Restrictions and guidelines

The global password control parameters in system view apply to all device management and network access local users.

You can configure all password control features for device management users. The password aging time, minimum password length, password complexity policy, password composition policy, and user login attempt limit can be configured in system view, user group view, and local user view.

You can configure only the following password control features for network access users:

- Minimum password length.
- Password complexity policy.
- Password composition policy.
- Minimum password update interval.
- Maximum number of history password records for each user.

Where, the minimum password length, password complexity policy, and password composition policy can be configured in system view, user group view, and local user view.

The password settings with a smaller application scope have higher priority. For local users, password settings configured in local user view have the highest priority, and global settings in system view have the lowest priority.

The **password-control login-attempt** command takes effect immediately and can affect the users already in the password control blacklist. Other password control configurations do not take effect on users that have been logged in or passwords that have been configured.

Procedure

1. Enter system view.

   system-view

2. Configure password settings.
   - Set the minimum password length.

     In non-FIPS mode:

     password-control length *length*

     The default setting is 10 characters.

     In FIPS mode:

     password-control length *length*

     The default length is 15 characters.
   - Configure the password composition policy.

     In non-FIPS mode:

     password-control composition type-number *type-number* [**type-length** *type-length*]

     By default, a password must contain a minimum of two character types and a minimum of one character for each type.

In FIPS mode:

password-control composition type-number *type-number* [**type-length** *type-length*]

By default, a password must contain a minimum of four character types and a minimum of one character for each type.

- Configure the password complexity checking policy.

  password-control complexity { **same-character** | **user-name** } **check**

  In non-FIPS mode:

  By default, the username checking is enabled but repeated character checking is disabled.

  In FIPS mode:

  By default, the system does not perform password complexity checking.

- Set the maximum number of history password records for each user.

  password-control history *max-record-number*

  The default setting is 4.

3. Configure password updating and expiration.

- Set the minimum password update interval.

  password-control update interval *interval*

  The default setting is 24 hours.

- Set the password aging time.

  password-control aging *aging-time*

  The default setting is 90 days.

- Set the number of days during which a user is notified of the pending password expiration.

  password-control alert-before-expire *alert-time*

  The default setting is 7 days.

- Set the maximum number of days and maximum number of times that a user can log in after the password expires.

  password-control expired-user-login delay *delay* **times** *times*

  By default, a user can log in three times within 30 days after the password expires.

4. Configure user login control.

- Enable the password control blacklist feature for all user line types.

  password-control blacklist all-line

  By default, the password control blacklist feature is disabled for all user line types. The password control blacklist feature is enabled only for FTP, Web, and VTY users when you enable the global password control feature.

- Set the maximum number of blacklist entries for a user account.

  password-control per-user blacklist-limit *max-number*

  By default, the maximum number of blacklist entries for a user account is 32.

- Configure the login attempt limit.

  password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

  By default, the maximum number of login attempts is 3 and a user failing to log in after the specified number of attempts must wait for 1 minute before trying again.

- Set the maximum account idle time.

  password-control login idle-time *idle-time*

  The default setting is 90 days.

If a user account is idle for this period of time, the account becomes invalid and can no longer be used to log in to the device. To disable the account idle time restriction, set the idle time value to 0.

- Set the user authentication timeout time.

  password-control authentication-timeout *timeout*

  The default setting is 600 seconds.

  This command takes effect only on Telnet and terminal users.

- Disable password change at first login.

  undo password-control change-password first-login enable

  By default, the password change at first login feature is enabled.

  In FIPS mode, the password change at first login feature cannot be disabled.

- Enable mandatory weak password change.

  password-control change-password weak-password enable

  In non-FIPS mode:

  By default, the mandatory weak password change feature is disabled.

  In FIPS mode:

  By default, the mandatory weak password change feature is enabled, and cannot be disabled.

Setting user group password control parameters

1. Enter system view.

   system-view

2. Create a user group and enter its view.

   user-group *group-name*

   For information about how to configure a user group, see "Configuring AAA."

3. Configure the password aging time for the user group.

   password-control aging *aging-time*

   By default, the password aging time of the user group equals the global password aging time.

4. Configure the minimum password length for the user group.

   password-control length *length*

   By default, the minimum password length of the user group equals the global minimum password length.

5. Configure the password composition policy for the user group.

   password-control composition type-number *type-number* [**type-length** *type-length*]

   By default, the password composition policy of the user group equals the global password composition policy.

6. Configure the password complexity checking policy for the user group.

   password-control complexity { **same-character** | **user-name** } **check**

   By default, the password complexity checking policy of the user group equals the global password complexity checking policy.

7. Configure the login attempt limit.

   password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

   By default, the login-attempt policy of the user group equals the global login-attempt policy.

Setting local user password control parameters

1. Enter system view.

   system-view

2. Create a device management or network access user and enter its view.
   - Create a device management user and enter its view.

     local-user *user-name* **class manage**
   - Create a network access user and enter its view.

     local-user *user-name* **class network**

   For information about local user configuration, see "Configuring AAA."

3. Configure the password aging time for the local user.

   password-control aging *aging-time*

   By default, the setting equals that for the user group to which the local user belongs. If no aging time is configured for the user group, the global setting applies to the local user.

   This command is available only for device management users.

4. Configure the minimum password length for the local user.

   password-control length *length*

   By default, the setting equals that for the user group to which the local user belongs. If no minimum password length is configured for the user group, the global setting applies to the local user.

5. Configure the password composition policy for the local user.

   password-control composition type-number *type-number* [**type-length** *type-length*]

   By default, the settings equal those for the user group to which the local user belongs. If no password composition policy is configured for the user group, the global settings apply to the local user.

6. Configure the password complexity checking policy for the local user.

   password-control complexity { **same-character** | **user-name** } **check**

   By default, the settings equal those for the user group to which the local user belongs. If no password complexity checking policy is configured for the user group, the global settings apply to the local user.

7. Configure the login attempt limit.

   password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

   By default, the settings equal those for the user group to which the local user belongs. If no login-attempt policy is configured for the user group, the global settings apply to the local user.

   This command is available only for device management users.

Setting super password control parameters

1. Enter system view.

   system-view

2. Set the password aging time for super passwords.

   password-control super aging *aging-time*

   The default setting is 90 days.

3. Configure the minimum length for super passwords.

In non-FIPS mode:

password-control super length *length*

The default setting is 10 characters.

In FIPS mode:

password-control super length *length*

The default setting is 15 characters.

4. Configure the password composition policy for super passwords.

   In non-FIPS mode:

   password-control super composition type-number *type-number* [**type-length** *type-length*]

   By default, a super password must contain a minimum of two character types and a minimum of one character for each type.

   In FIPS mode:

   password-control super composition type-number *type-number* [**type-length** *type-length*]

   By default, a super password must contain a minimum of four character types and a minimum of one character for each type.

Display and maintenance commands for password control

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display password control configuration.	**display password-control** [**super**]
Display information about users in the password control blacklist.	**display password-control blacklist** [**user-name** *user-name* | **ip** *ipv4-address* | **ipv6** *ipv6-address*]
Delete users from the password control blacklist.	**reset password-control blacklist** [**user-name** *user-name*]
Clear history password records.	**reset password-control history-record** [**user-name** *user-name* | **super** [**role** *role-name*] | **network-class** [**user-name** *user-name*]]

Password control configuration examples

Example: Configuring password control

Network configuration

Configure a global password control policy to meet the following requirements:

- A password must contain a minimum of 16 characters.
- A password must contain a minimum of four character types and a minimum of four characters for each type.

- An FTP or VTY user failing to provide the correct password in two successive login attempts is permanently prohibited from logging in with the current IP address.
- A user can log in five times within 60 days after the password expires.
- A password expires after 30 days.
- The minimum password update interval is 36 hours.
- The maximum account idle time is 30 days.
- A password cannot contain the username or the reverse of the username.
- A minimum of three identical consecutive characters is not allowed in a password.

Configure a super password control policy for user role **network-operator** to meet the following requirements:

- A super password must contain a minimum of 24 characters.
- A super password must contain a minimum of four character types and a minimum of five characters for each type.

Configure a password control policy for local Telnet user **test** to meet the following requirements:

- The password must contain a minimum of 24 characters.
- The password must contain a minimum of four character types and a minimum of five characters for each type.
- The password for the local user expires after 20 days.

Procedure

Enable the password control feature globally.

```
<Sysname> system-view
[Sysname] password-control enable
```

Allow a maximum of two consecutive login failures on a user account, and lock the user account and the user's IP address permanently if the limit is reached.

```
[Sysname] password-control login-attempt 2 exceed lock
```

Set all passwords to expire after 30 days.

```
[Sysname] password-control aging 30
```

Globally set the minimum password length to 16 characters.

```
[Sysname] password-control length 16
```

Set the minimum password update interval to 36 hours.

```
[Sysname] password-control update-interval 36
```

Specify that a user can log in five times within 60 days after the password expires.

```
[Sysname] password-control expired-user-login delay 60 times 5
```

Set the maximum account idle time to 30 days.

```
[Sysname] password-control login idle-time 30
```

Refuse any password that contains the username or the reverse of the username.

```
[Sysname] password-control complexity user-name check
```

Refuse a password that contains a minimum of three identical consecutive characters.

```
[Sysname] password-control complexity same-character check
```

Globally specify that all passwords must each contain a minimum of four character types and a minimum of four characters for each type.

```
[Sysname] password-control composition type-number 4 type-length 4
```

Set the minimum super password length to 24 characters.

```
[Sysname] password-control super length 24
```

Specify that a super password must contain a minimum of four character types and a minimum of five characters for each type.

```
[Sysname] password-control super composition type-number 4 type-length 5
```

Configure a super password used for switching to user role **network-operator** as **123456789ABGFTweuix@#$%!** in plain text.

```
[Sysname] super password role network-operator simple 123456789ABGFTweuix@#$%!
```

Create a device management user named **test**.

```
[Sysname] local-user test class manage
```

Set the service type of the user to **Telnet**.

```
[Sysname-luser-manage-test] service-type telnet
```

Set the minimum password length to 24 for the local user.

```
[Sysname-luser-manage-test] password-control length 24
```

Specify that the password of the local user must contain a minimum of four character types and a minimum of five characters for each type.

```
[Sysname-luser-manage-test] password-control composition type-number 4 type-length 5
```

Set the password for the local user to expire after 20 days.

```
[Sysname-luser-manage-test] password-control aging 20
```

Configure the password of the local user in interactive mode.

```
[Sysname-luser-manage-test] password
Password:
Confirm :
Updating user information. Please wait ... ...
[Sysname-luser-manage-test] quit
```

Verifying the configuration

Display the global password control configuration.

```
<Sysname> display password-control
 Global password control configurations:
 Password control:                    Enabled(device management users)
                                      Disabled (network access users)
 Password aging:                      Enabled (30 days)
 Password length:                     Enabled (16 characters)
 Password composition:                Enabled (4 types, 4 characters per type)
 Password history:                    Enabled (max history record:4)
 Early notice on password expiration: 7 days
 User authentication timeout:         600 seconds
 Maximum login attempts:              2
 Action for exceeding login attempts: Lock
 Minimum interval between two updates: 36 hours
 User account idle time:              30 days
 Logins with aged password:           5 times in 60 days
 Password complexity:                 Enabled (username checking)
                                      Enabled (repeated characters checking)
 Password change:                     Enabled (first login)
                                      Disabled (mandatory weak password change)
 All line:                            Disabled (all line blacklist)
```

Display the password control configuration for super passwords.

```
<Sysname> display password-control super
 Super password control configurations:
 Password aging:                       Enabled (90 days)
 Password length:                      Enabled (24 characters)
 Password composition:                 Enabled (4 types, 5 characters per type)
```

Display the password control configuration for local user **test**.

```
<Sysname> display local-user user-name test class manage
Total 1 local users matched.

Device management user test:
  State:                     Active
  Service type:              Telnet
  User group:                system
  Bind attributes:
  Authorization attributes:
    Work directory:          flash:
    User role list:          network-operator
  Password control configurations:
    Password aging:          20 days
    Password length:         24 characters
    Password composition:    4 types, 5 characters per type
```

Configuring keychains

About keychains

A keychain, a sequence of keys, provides dynamic authentication to ensure secure communication by periodically changing the key and authentication algorithm without service interruption.

A keychain operates in absolute time mode. In this mode, each time point during a key's lifetime is the UTC time and is not affected by the system's time zone or daylight saving time.

Each key in a keychain has a key string, authentication algorithm, sending lifetime, and receiving lifetime. When the system time is within the lifetime of a key in a keychain, an application uses the key to authenticate incoming and outgoing packets. The keys in the keychain take effect one by one according to the sequence of the configured lifetimes. In this way, the authentication algorithms and keys are dynamically changed to implement dynamic authentication.

Restrictions and guidelines: Keychain configuration

To make sure only one key in a keychain is used at a time to authenticate packets to a peer, set non-overlapping sending lifetimes for the keys in the keychain.

The keys used by the local device and the peer device must have the same authentication algorithm and key string.

Configuring a keychain

1. Enter system view.

   system-view

2. Create a keychain and enter keychain view.

   keychain *keychain-name* **mode absolute**

3. (Optional.) Configure TCP authentication.
   - Set the kind value in the TCP Enhanced Authentication Option.

     tcp-kind *kind-value*

     By default, the kind value is 254.
   - Set an algorithm ID for a TCP authentication algorithm.

     tcp-algorithm-id { **hmac-md5** | **md5** } *algorithm-id*

     By default, the algorithm ID is 3 for the MD5 authentication algorithm and 5 for the HMAC-MD5 authentication algorithm.

   When the local device uses TCP to communicate with a peer device from another vendor, make sure both devices have the same kind value and algorithm ID settings. If they do not, modify the settings on the local device.

4. (Optional.) Set a tolerance time for accept keys in the keychain.

   accept-tolerance { *value* | **infinite** }

   By default, no tolerance time is configured for accept keys in a keychain.

   If authentication information is changed, information mismatch occurs on the local and peer devices, and the service might be interrupted. Use this command to ensure continuous packet authentication.

5. Create a key and enter key view.

   key *key-id*

6. Configure the key.
   - Specify an authentication algorithm for the key.

     authentication-algorithm { **hmac-md5** | **hmac-sha-256** | **md5** }

     By default, no authentication algorithm is specified for a key.
   - Configure a key string for the key.

     key-string { **cipher** | **plain** } *string*

     By default, no key string is configured.
   - Set the sending lifetime in UTC mode for the key.

     send-lifetime utc *start-time start-date* { **duration** { *duration-value* | **infinite** } | **to** *end-time end-date* }

     By default, the sending lifetime is not configured for a key.
   - Set the receiving lifetime in UTC mode for the key.

     accept-lifetime utc *start-time start-date* { **duration** { *duration-value* | **infinite** } | **to** *end-time end-date* }

     By default, the receiving lifetime is not configured for a key.
   - (Optional.) Specify the key as the default send key.

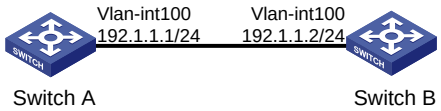
     default-send-key

     You can specify only one key as the default send key in a keychain.

Display and maintenance commands for keychain

Execute **display** commands in any view.

Task	Command
Display keychain information.	**display keychain** [**name** *keychain-name* [**key** *key-id*]]



Keychain configuration example

Example: Configuring keychains

Network configuration

As shown in Figure 1, establish an OSPF neighbor relationship between Switch A and Switch B, and use a keychain to authenticate packets between the switches. Configure key 1 and key 2 for the keychain and make sure key 2 is used immediately when key 1 expires.

Figure 1 Network diagram

Procedure

1. Configure Switch A:

Configure IP addresses for interfaces. (Details not shown.)

Configure OSPF.

```
<SwitchA> system-view
[SwitchA] ospf 1 router-id 1.1.1.1
[SwitchA-ospf-1] area 0
[SwitchA-ospf-1-area-0.0.0.0] network 192.1.1.0 0.0.0.255
[SwitchA-ospf-1-area-0.0.0.0] quit
[SwitchA-ospf-1] quit
```

Create a keychain named **abc**, and specify the absolute time mode for it.

```
[SwitchA] keychain abc mode absolute
```

Create key **1** for keychain **abc**, specify an authentication algorithm, and configure a key string and the sending and receiving lifetimes for the key.

```
[SwitchA-keychain-abc] key 1
[SwitchA-keychain-abc-key-1] authentication-algorithm md5
[SwitchA-keychain-abc-key-1] key-string plain 123456
[SwitchA-keychain-abc-key-1] send-lifetime utc 10:00:00 2015/02/06 to 11:00:00
2015/02/06
[SwitchA-keychain-abc-key-1] accept-lifetime utc 10:00:00 2015/02/06 to 11:00:00
2015/02/06
[SwitchA-keychain-abc-key-1] quit
```

Create key **2** for keychain **abc**, specify an authentication algorithm, and configure a key string and the sending and receiving lifetimes for the key.

```
[SwitchA-keychain-abc] key 2
[SwitchA-keychain-abc-key-2] authentication-algorithm hmac-md5
[SwitchA-keychain-abc-key-2] key-string plain pwd123
[SwitchA-keychain-abc-key-2] send-lifetime utc 11:00:00 2015/02/06 to 12:00:00
2015/02/06
[SwitchA-keychain-abc-key-2] accept-lifetime utc 11:00:00 2015/02/06 to 12:00:00
2015/02/06
[SwitchA-keychain-abc-key-2] quit
[SwitchA-keychain-abc] quit
```

Configure VLAN-interface 100 to use keychain **abc** for authentication.

```
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ospf authentication-mode keychain abc
[SwitchA-Vlan-interface100] quit
```

2. Configure Switch B:

Configure IP addresses for interfaces. (Details not shown.)

Configure OSPF.

```
[SwitchB] ospf 1 router-id 2.2.2.2
[SwitchB-ospf-1] area 0
[SwitchB-ospf-1-area-0.0.0.0] network 192.1.1.0 0.0.0.255
[SwitchB-ospf-1-area-0.0.0.0] quit
[SwitchB-ospf-1] quit
```

Create a keychain named **abc**, and specify the absolute time mode for it.

```
[SwitchB] keychain abc mode absolute
```

Create key **1** for keychain **abc**, specify an authentication algorithm, and configure a key string and the sending and receiving lifetimes for the key.

```
[SwitchB-keychain-abc] key 1
[SwitchB-keychain-abc-key-1] authentication-algorithm md5
[SwitchB-keychain-abc-key-1] key-string plain 123456
[SwitchB-keychain-abc-key-1] send-lifetime utc 10:00:00 2015/02/06 to 11:00:00 2015/02/06
[SwitchB-keychain-abc-key-1] accept-lifetime utc 10:00:00 2015/02/06 to 11:00:00 2015/02/06
[SwitchB-keychain-abc-key-1] quit
```

Create key **2** for keychain **abc**, specify an authentication algorithm, and configure a key string and the sending and receiving lifetimes for the key.

```
[SwitchB-keychain-abc] key 2
[SwitchB-keychain-abc-key-2] authentication-algorithm hmac-md5
[SwitchB-keychain-abc-key-2] key-string plain pwd123
[SwitchB-keychain-abc-key-2] send-lifetime utc 11:00:00 2015/02/06 to 12:00:00 2015/02/06
[SwitchB-keychain-abc-key-2] accept-lifetime utc 11:00:00 2015/02/06 to 12:00:00 2015/02/06
[SwitchB-keychain-abc-key-2] quit
[SwitchB-keychain-abc] quit
```

Configure VLAN-interface 100 to use keychain **abc** for authentication.

```
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ospf authentication-mode keychain abc
[SwitchB-Vlan-interface100] quit
```

Verifying the configuration

1. When the system time is within the lifetime from 10:00:00 to 11:00:00 on the day 2015/02/06, verify the status of the keys in keychain **abc**.

Display keychain information on Switch A. The output shows that key 1 is the valid key.

```
[SwitchA] display keychain

 Keychain name          : abc
   Mode                 : absolute
   Accept tolerance     : 0
   TCP kind value       : 254
   TCP algorithm value
     HMAC-MD5           : 5
     MD5                : 3
   Default send key ID  : None
   Active send key ID   : 1
   Active accept key IDs: 1

   Key ID               : 1
     Key string         : $c$3$dYTC8QeOKJkwFwP2k/rWL+1p6uMTw3MqNg==
     Algorithm          : md5
     Send lifetime      : 10:00:00 2015/02/06 to 11:00:00 2015/02/06
     Send status        : Active
     Accept lifetime    : 10:00:00 2015/02/06 to 11:00:00 2015/02/06
     Accept status      : Active
```

```
  Key ID               : 2
    Key string         : $c$3$7TSPbUxoP1ytOqkdcJ3K3x0BnXEWl4mOEw==
    Algorithm          : hmac-md5
    Send lifetime      : 11:00:00 2015/02/06 to 12:00:00 2015/02/06
    Send status        : Inactive
    Accept lifetime    : 11:00:00 2015/02/06 to 12:00:00 2015/02/06
    Accept status      : Inactive
```

Display keychain information on Switch B. The output shows that key 1 is the valid key.

```
[SwitchB]display keychain

 Keychain name          : abc
   Mode                 : absolute
   Accept tolerance     : 0
   TCP kind value       : 254
   TCP algorithm value
     HMAC-MD5           : 5
     MD5                : 3
   Default send key ID  : None
   Active send key ID   : 1
   Active accept key IDs: 1

   Key ID               : 1
     Key string         : $c$3$/G/Shnh6heXWprlSQy/XDmftHa2JZJBSgg==
     Algorithm          : md5
     Send lifetime      : 10:00:00 2015/02/06 to 11:00:00 2015/02/06
     Send status        : Active
     Accept lifetime    : 10:00:00 2015/02/06 to 11:00:00 2015/02/06
     Accept status      : Active

   Key ID               : 2
     Key string         : $c$3$t4qHAw1hpZYN0JKIEpXPcMFMVT81u0hiOw==
     Algorithm          : hmac-md5
     Send lifetime      : 11:00:00 2015/02/06 to 12:00:00 2015/02/06
     Send status        : Inactive
     Accept lifetime    : 11:00:00 2015/02/06 to 12:00:00 2015/02/06
     Accept status      : Inactive
```

2. When the system time is within the lifetime from 11:00:00 to 12:00:00 on the day 2015/02/06, verify the status of the keys in keychain **abc**.

Display keychain information on Switch A. The output shows that key 2 becomes the valid key.

```
[SwitchA]display keychain

 Keychain name          : abc
   Mode                 : absolute
   Accept tolerance     : 0
   TCP kind value       : 254
   TCP algorithm value
```

```
    HMAC-MD5           : 5
    MD5                : 3
  Default send key ID  : None
  Active send key ID   : 2
  Active accept key IDs: 2

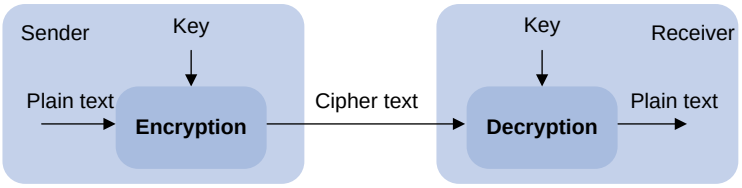
Managing public keys

About public key management



This chapter describes public key management for the following asymmetric key algorithms:

- Revest-Shamir-Adleman Algorithm (RSA).
- Digital Signature Algorithm (DSA).
- Elliptic Curve Digital Signature Algorithm (ECDSA).

Asymmetric key algorithm overview

Asymmetric key algorithms are used by security applications to secure communications between two parties, as shown in Figure 1. Asymmetric key algorithms use two separate keys (one public and one private) for encryption and decryption. Symmetric key algorithms use only one key.

Figure 1 Encryption and decryption

A key owner can distribute the public key in plain text on the network but must keep the private key in privacy. It is mathematically infeasible to calculate the private key even if an attacker knows the algorithm and the public key.

Usage of asymmetric key algorithms

Security applications (such as SSH, SSL, and PKI) use the asymmetric key algorithms for the following purposes:

- **Encryption and decryption**—Any public key receiver can use the public key to encrypt information, but only the private key owner can decrypt the information.
- **Digital signature**—The key owner uses the private key to digitally sign information to be sent. The receiver decrypts the information with the sender's public key to verify information authenticity.

RSA, DSA, and ECDSA can all perform digital signature, but only RSA can perform encryption and decryption.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

Public key management tasks at a glance

To manage public keys, perform the following tasks:

1. Creating a local key pair
2. Distributing a local host public key

   Choose one of the following tasks:

   - Exporting a host public key
   - Displaying a host public key

   To enable the peer device to authenticate the local device, you must distribute the local device's public key to the peer device.
3. Configuring a peer host public key

   Choose one of the following tasks:

   - Importing a peer host public key from a public key file
   - Entering a peer host public key

   To encrypt information sent to a peer device or authenticate the digital signature of the peer device, you must configure the peer device's public key on the local device.
4. (Optional.) Destroying a local key pair
5. (Optional.) Configuring master keys

Creating a local key pair

Restrictions and guidelines

When you create a local key pair, follow these guidelines:

- The key algorithm must be the same as required by the security application.
- When you create an RSA or DSA key pair, enter an appropriate key modulus length at the prompt. The longer the key modulus length, the higher the security, and the longer the key generation time.

  When you create an ECDSA key pair, choose the appropriate elliptic curve. The elliptic curve determines the ECDSA key length. The longer the key length, the higher the security, and the longer the key generation time.

  See Table 1 for more information about key modulus lengths and key lengths.
- If you do not assign the key pair a name, the system assigns the default name to the key pair and marks the key pair as **default**. You can also assign the default name to another key pair, but the system does not mark the key pair as **default**. The key pair name must be unique among all manually named key pairs that use the same key algorithm. If a name conflict occurs, the system asks whether you want to overwrite the existing key pair.
- The key pairs are automatically saved and can survive system reboots.

Table 1 A comparison of different types of asymmetric key algorithms

Type	Generated key pairs	Modulus/key length
RSA	• In non-FIPS mode: ○ One host key pair, if you specify a key pair name. ○ One server key pair and one host key pair, if you do not specify a key pair name. Both key pairs use their default names. • In FIPS mode: One host key pair. **NOTE:** Only SSH 1.5 uses the RSA server key pair.	RSA key modulus length: • In non-FIPS mode: 512 to 4096 bits, 1024 bits by default. To ensure security, use a minimum of 768 bits. • In FIPS mode: A multiple of 256 bits in the range of 2048 to 4096 bits, 2048 bits by default.
DSA	One host key pair.	DSA key modulus length:

Type	Generated key pairs	Modulus/key length
		• In non-FIPS mode: 512 to 2048 bits, 1024 bits by default. To ensure security, use a minimum of 768 bits. • In FIPS mode: 2048 bits.
ECDSA	One host key pair.	ECDSA key length: • In non-FIPS mode: 192, 256, 384, or 521 bits. • In FIPS mode: 256, 384, or 521 bits.

Procedure

1. Enter system view.

   system-view

2. Create a local key pair.

   In non-FIPS mode:

   public-key local create { **dsa** | **ecdsa** [**secp192r1** | **secp256r1** | **secp384r1** | **secp521r1**] | **rsa** } [**name** *key-name*]

   In FIPS mode:

   public-key local create { **dsa** | **ecdsa** [**secp256r1** | **secp384r1** | **secp521r1**] | **rsa** } [**name** *key-name*]

Distributing a local host public key

About distribution of local host public keys

You must distribute a local host public key to a peer device so the peer device can perform the following operations:

- Use the public key to encrypt information sent to the local device.
- Authenticate the digital signature signed by the local device.

To distribute a local host public key, you must first export or display the key.

- Export a host public key:
  - Export a host public key to a file.
  - Export a host public key to the monitor screen, and then save it to a file.

  After the key is exported to a file, transfer the file to the peer device. On the peer device, import the key from the file.
- Display a host public key.

  After the key is displayed, record the key, for example, copy it to an unformatted file. On the peer device, you must literally enter the key.

Exporting a host public key

Restrictions and guidelines

When you export a host public key, follow these restrictions and guidelines:

- If you specify a file name in the command, the command exports the key to the specified file.

- If you do not specify a file name, the command exports the key to the monitor screen. You must manually save the exported key to a file.

Procedure

1. Enter system view.

   system-view

2. Export a local host public key.
   - Export an RSA host public key:

     In non-FIPS mode:

     public-key local export rsa [**name** *key-name*] { **openssh** | **ssh1** | **ssh2** } [*filename*]

     In FIPS mode:

     public-key local export rsa [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]
   - Export an ECDSA host public key.

     public-key local export ecdsa [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]
   - Export a DSA host public key.

     public-key local export dsa [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]

Displaying a host public key

Perform the following tasks in any view:

- Display local RSA public keys.

  display public-key local rsa public [**name** *key-name*]

  Do not distribute the RSA server public key **serverkey (default)** to a peer device.
- Display local ECDSA public keys.

  display public-key local ecdsa public [**name** *key-name*]
- Display local DSA public keys.

  display public-key local dsa public [**name** *key-name*]

Configuring a peer host public key

About peer host public key configuration

To encrypt information sent to a peer device or authenticate the digital signature of the peer device, you must configure the peer device's public key on the local device.

You can configure the peer host public key by using the following methods:

- Import the peer host public key from a public key file (recommended).
- Manually enter (type or copy) the peer host public key.

For information about how to obtain the host public key of a device, see "Distributing a local host public key."

Restrictions and guidelines for peer host public key configuration

When you configure a peer host public key, follow these restrictions and guidelines:

- When you manually enter the peer host public key, make sure the entered key is in the correct format. To obtain the peer host public key in the correct format, use the **display public-key local public** command to display the public key on the peer device and record the key. The format of the public key displayed in any other way might be incorrect. If the key is not in the correct format, the system discards the key and displays an error message.
- Always import rather than enter the peer host public key if you are not sure whether the device supports the format of the recorded peer host public key.

Importing a peer host public key from a public key file

About this task

Before you perform this task, make sure you have exported the host public key to a file on the peer device and obtained the file from the peer device. For information about exporting a host public key, see "Exporting a host public key."

After you import the key, the system automatically converts the imported public key to a string in the Public Key Cryptography Standards (PKCS) format.

Procedure

1. Enter system view.

   system-view
2. Import a peer host public key from a public key file.

   public-key peer *keyname* **import sshkey** *filename*

   By default, no peer host public keys exist.

Entering a peer host public key

About this task

Before you perform this task, make sure you have displayed the key on the peer device and recorded the key. For information about displaying a host public key, see "Displaying a host public key."

Procedure

1. Enter system view.

   system-view
2. Specify a name for the peer host public key and enter public key view.

   public-key peer *keyname*
3. Type or copy the key.

   You can use spaces and carriage returns, but the system does not save them.
4. Exit public key view.

   peer-public-key end

   When you exit public key view, the system automatically saves the peer host public key.

Destroying a local key pair

About this task

To ensure security, destroy the local key pair and generate a new key pair in any of the following situations:

- The local key has leaked. An intrusion event might occur.
- The storage media of the device is replaced.
- The local certificate has expired. For more information about local certificates, see "Configuring PKI."

Procedure

1. Enter system view.

   system-view
2. Destroy a local key pair.

   public-key local destroy { **dsa** | **ecdsa** | **rsa** } [**name** *key-name*]

Configuring master keys

Setting a master key

About this task

By default, a device uses the unified default master key to encrypt the key strings configured for each service module on the device. After you load the exported configuration file of a device on another device, you can use the default master key to decrypt and obtain the configured key strings. In this way, keys can be copied between devices, bringing security risks.

To improve the security and reliability of data, you can set a master key for the device. After you configure this feature on the device, you need to configure the relevant settings as prompted:

1. Validate your identity:
   - If the login authentication mode is **password** or **scheme**, the CLI prompts you to enter your password for login. After you pass the authentication, you go to step 2.
   - If the login authentication mode is **none**, you do not need to perform identity authentication but go to step 2 directly.

     For more information about login authentication modes, see login management in *Fundamentals Configuration Guide*.
2. Select whether to enter the master key:
   - If you enter **N** or **n**, the device will automatically and randomly generate a master key.
   - If you enter **Y** or **y**, manually enter the prepared master key and confirm it.

The device stores the master key in the hard disk. Power-off or reboot of the device will not affect the set master key. The device uses the master key to encrypt the key strings configured for each service module on the device.

You can only use the **display master-key type** command to view the type of the master key. You cannot view or obtain the value of the master key by any means. This prevents copying the keys on the device to another device.

Restrictions and guidelines

When the storage space for master keys is insufficient, the device prompts whether to overwrite the oldest master key.

When the login authentication mode is **password** or **scheme**, you will be logged off after three consecutive authentication failures and thus cannot perform master key-related operations.

The minimum interval between setting master keys is 3 minutes.

Prerequisites

To manually enter a master key, prepare the master key and keep it safe before configuring this feature.

Procedure

1. Enter system view.
   system-view
2. Set a master key.
   set master-key

Clearing master keys

About this task

You can configure this feature to clear master keys in the following situations:

- You do not need to use the master key feature.
- The storage space for master keys is insufficient, and you want to clear existing master keys to release storage space.

The master keys cleared by this feature vary by the type of the device's default master key:

- If the default master key uses the fixed factory default value, this feature clears all set master keys and restores the default master key.
- If the default master key was generated randomly, this feature clears all history master keys and reserves only the current master key.

Procedure

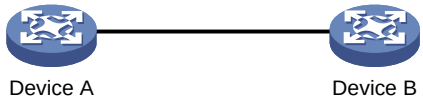
1. Enter system view.
   system-view
2. Clear master keys.
   clear master-key

Display and maintenance commands for public keys

Execute **display** commands in any view.

Task	Command
Display local public keys.	**display public-key local** { **dsa** | **ecdsa** | **rsa** } **public** [**name** *key-name*]
Display peer host public keys.	**display public-key peer** [**brief** | **name** *publickey-name*]
Display the type of the current master key.	**display master-key type**

Examples of public key management



Example: Entering a peer host public key

Network configuration

As shown in Figure 2, to prevent illegal access, Device B authenticates Device A through a digital signature. Before configuring authentication parameters on Device B, use the following procedure to configure the public key of Device A on Device B:

- Create RSA key pairs on Device A and display the public keys of the RSA key pairs.
- Manually specify the RSA host public key of Device A on Device B.

Figure 2 Network diagram

Procedure

1. Configure Device A:

   # Create local RSA key pairs with the default names on Device A, and use the default key modulus length (1024 bits).

```
<DeviceA> system-view
[DeviceA] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
...
Create the key pair successfully.
```

   # Display all local RSA public keys.

```
[DeviceA] display public-key local rsa public

Example: Importing a public key from a public key file

Network configuration

As shown in Figure 3, Device B authenticates Device A through a digital signature. Before configuring authentication parameters on Device B, use the following procedure to configure the public key of Device A on Device B:

- Create RSA key pairs on Device A and export the RSA host public key to a file.
- Import the RSA host public key of Device A from the public key file to Device B.

Figure 3 Network diagram

Procedure

1. Configure Device A:

Create local RSA key pairs with the default names on Device A, and use the default key modulus length (1024 bits).

```
<DeviceA> system-view
[DeviceA] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
...
Create the key pair successfully.
```

Display all local RSA public keys.

```
[DeviceA] display public-key local rsa public

Configuring PKI

About PKI

Public Key Infrastructure (PKI) is an asymmetric key infrastructure to encrypt and decrypt data for securing network services.

PKI uses digital certificates to distribute and employ public keys, and provides network communication and e-commerce with security services such as user authentication, data confidentiality, and data integrity. For more information about public keys, see "Managing public keys."

PKI terminology

Digital certificate

A digital certificate is an electronic document signed by a CA that binds a public key with the identity of its owner.

A digital certificate includes the following information:

- Issuer name (name of the CA that issued the certificate).
- Subject name (name of the individual or group to which the certificate is issued).
- Identity information of the subject.
- Subject's public key.
- Signature of the CA.
- Validity period.

A digital certificate must comply with the international standards of ITU-T X.509, of which X.509 v3 is the most commonly used.

This chapter covers the following types of certificates:

- **CA certificate**—Certificate of a CA. Multiple CAs in a PKI system form a CA tree, with the root CA at the top. The root CA generates a self-signed certificate, and each lower level CA holds a CA certificate issued by the CA immediately above it. The chain of these certificates forms a chain of trust.
- **Registration authority (RA) certificate**—Certificate issued by a CA to an RA. RAs act as proxies for CAs to process enrollment requests in a PKI system.
- **Local certificate**—Digital certificate issued by a CA to a local PKI entity, which contains the entity's public key.
- **Peer certificate**—CA-signed digital certificate of a peer, which contains the peer's public key.

Fingerprint of root CA certificate

Each root CA certificate has a unique fingerprint, which is the hash value of the certificate content. The fingerprint of a root CA certificate can be used to authenticate the validity of the root CA.

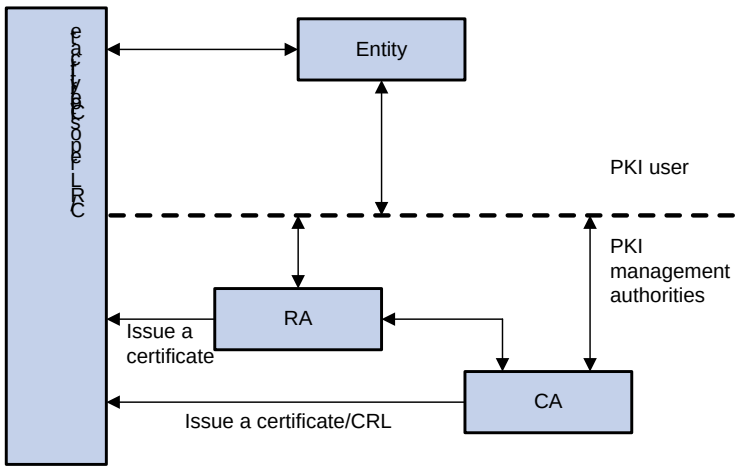
Certificate revocation list

A certificate revocation list (CRL) is a list of serial numbers for certificates that have been revoked. A CRL is created and signed by the CA that originally issued the certificates.

The CA publishes CRLs periodically to revoke certificates. Entities that are associated with the revoked certificates should not be trusted.

The CA must revoke a certificate when any of the following conditions occurs:

- The certificate subject name is changed.
- The private key is compromised.
- The association between the subject and CA is changed. For example, when an employee terminates employment with an organization.



CA policy

A CA policy is a set of criteria that a CA follows to process certificate requests, to issue and revoke certificates, and to publish CRLs. Typically, a CA advertises its policy in a certification practice statement (CPS). You can obtain a CA policy through out-of-band means such as phone, disk, and email. Make sure you understand the CA policy before you select a trusted CA for certificate request because different CAs might use different policies.

PKI architecture

A PKI system consists of PKI entities, CAs, RAs and a certificate/CRL repository, as shown in Figure 1.

Figure 1 PKI architecture

PKI entity

A PKI entity is an end user using PKI certificates. The PKI entity can be an operator, an organization, a device like a router or a switch, or a process running on a computer. PKI entities use SCEP to communicate with the CA or RA.

CA

Certification authority that grants and manages certificates. A CA issues certificates, defines the certificate validity periods, and revokes certificates by publishing CRLs.

RA

Registration authority, which offloads the CA by processing certificate enrollment requests. The RA accepts certificate requests, verifies user identity, and determines whether to ask the CA to issue certificates.

The RA is optional in a PKI system. In cases when there is security concern over exposing the CA to direct network access, it is advisable to delegate some of the tasks to an RA. Then, the CA can concentrate on its primary tasks of signing certificates and CRLs.

Certificate/CRL repository

A certificate distribution point that stores certificates and CRLs, and distributes these certificates and CRLs to PKI entities. It also provides the query function. A PKI repository can be a directory server using the LDAP or HTTP protocol, of which LDAP is commonly used.

Retrieval, usage, and maintenance of a digital certificate

The following workflow describes the retrieval, usage, and maintenance of a digital certificate. This example uses a CA which has an RA to process certificate enrollment requests.

1. A PKI entity generates an asymmetric key pair and submits a certificate request to the RA.

   The certificate request contains the public key and its identity information.
2. The RA verifies the identity of the entity and sends a digital signature containing the identity information and the public key to the CA.
3. The CA verifies the digital signature, approves the request, and issues a certificate.
4. After receiving the certificate from the CA, the RA sends the certificate to the certificate repository and notifies the PKI entity that the certificate has been issued.
5. The PKI entity obtains the certificate from the certificate repository.
6. To establish a secure connection for communication, two PKI entities exchange local certificates to authenticate each other. The connection can be established only if both entities verify that the peer's certificate is valid.
7. You can remove the local certificate of a PKI entity and request a new one when any of the following conditions occur:
   - The local certificate is about to expire.
   - The certificate's private key is compromised.

PKI applications

The PKI technology can meet security requirements of online transactions. As an infrastructure, PKI has a wide range of applications. H3C's PKI system can provide certificate management for IPsec and SSL.

The following are some application examples.

VPN

A VPN is a private data communication network built on the public communication infrastructure. A VPN can use network layer security protocols (for example, IPsec) in conjunction with PKI-based encryption and digital signature technologies for confidentiality.

Secure emails

PKI can address the email requirements for confidentiality, integrity, authentication, and non-repudiation. A common secure email protocol is Secure/Multipurpose Internet Mail Extensions (S/MIME), which is based on PKI and allows for transfer of encrypted mails with signature.

Web security

PKI can be used in the SSL handshake phase to verify the identities of the communicating parties by digital certificates.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

PKI tasks at a glance

To configure PKI, perform the following tasks:

1. Configuring a PKI entity
2. Configuring a PKI domain
3. (Optional.) Specifying the storage path for certificates and CRLs
4. Requesting a certificate

   Choose one of the following tasks:
   - Enabling the automatic online certificate request mode
   - Manually submitting an online certificate request
   - Manually submitting a certificate request in offline mode
5. (Optional.) Aborting a certificate request
6. (Optional.) Obtaining certificates

   You can obtain the CA certificate, local certificates, and peer certificates related to a PKI domain from a CA and save them locally for higher lookup efficiency.
7. (Optional.) Verifying PKI certificates
8. (Optional.) Exporting certificates
9. (Optional.) Removing a certificate
10. (Optional.) Configuring a certificate-based access control policy

    Certificate-based access control policies allow you to authorize access to a device (for example, an HTTPS server) based on the attributes of an authenticated client's certificate.

Configuring a PKI entity

About this task

A certificate applicant uses an entity to provide its identity information to a CA. A valid PKI entity must include one or more of following identity categories:

- Distinguished name (DN) of the entity, which further includes the common name, country code, locality, organization, unit in the organization, and state. If you configure the DN for an entity, a common name is required.
- FQDN of the entity.
- IP address of the entity.

Restrictions and guidelines

Follow these restrictions and guidelines when you configure a PKI entity:

- Whether the identity categories are required or optional depends on the CA policy. Follow the CA policy to configure the entity settings. For example, if the CA policy requires the entity DN, but you configure only the IP address, the CA rejects the certificate request from the entity.
- The SCEP add-on on the Windows 2000 CA server has restrictions on the data length of a certificate request. If a request from a PKI entity exceeds the data length limit, the CA server does not respond to the certificate request. In this case, you can use an out-of-band means to submit the request. Other types of CA servers, such as RSA servers and OpenCA servers, do not have such restrictions.

Procedure

1. Enter system view.

   system-view
2. Create a PKI entity and enter its view.

   pki entity *entity-name*
3. Set a common name for the entity.

   common-name *common-name-sting*

By default, the common name is not set.

4. Set the country code of the entity.
   country *country-code-string*
   By default, the country code is not set.
5. Set the locality of the entity.
   locality *locality-name*
   By default, the locality is not set.
6. Set the organization of the entity.
   organization *org-name*
   By default, the organization is not set.
7. Set the unit of the entity in the organization.
   organization-unit *org-unit-name*
   By default, the unit is not set.
8. Set the state where the entity resides.
   state *state-name*
   By default, the state is not set.
9. Set the FQDN of the entity.
   fqdn *fqdn-name-string*
   By default, the FQDN is not set.
10. Configure the IP address of the entity.
    ip { *ip-address* | **interface** *interface-type interface-number* }
    By default, the IP address is not configured.

Configuring a PKI domain

About PKI domain

A PKI domain contains enrollment information for a PKI entity. It is locally significant and is intended only for use by other applications like IKE and SSL.

PKI domain tasks at a glance

To configure a PKI domain, perform the following tasks:

1. Creating a PKI domain
2. Specifying the trusted CA
3. Specifying the PKI entity name
4. Specifying the certificate request reception authority
5. Specifying the certificate request URL
6. (Optional.) Setting the SCEP polling interval and maximum polling attempts
7. Specifying the LDAP server

   This task is required when either of the following conditions is met:
   - The device must obtain certificates from the CA by using the LDAP protocol.
   - An LDAP URL which does not contain the host name of the LDAP server is specified as the CRL repository URL.
8. Specifying the fingerprint for root CA certificate verification

This step is required if the auto certificate request mode is configured in the PKI domain.

If the manual certificate request mode is configured, you can skip this step and manually verify the fingerprint displayed during verification of the root CA certificate.

9. Specifying the key pair for certificate request
10. (Optional.) Specifying the intended purpose for the certificate
11. (Optional.) Specifying the source IP address for PKI protocol packets

Creating a PKI domain

1. Enter system view.
   system-view
2. Create a PKI domain and enter its view.
   pki domain *domain-name*

Specifying the trusted CA

About this task

The PKI domain must have a CA certificate before you can request a local certificate. To obtain a CA certificate, the trusted CA name must be specified. The trusted CA name uniquely identifies the CA to be used if multiple CAs exist on the CA server.

Procedure

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Specify the trusted CA name.
   ca identifier *name*

   By default, no trusted CA name is specified.

Specifying the PKI entity name

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Specify the PKI entity name.
   certificate request entity *entity-name*

   By default, no PKI entity name is specified.

Specifying the certificate request reception authority

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Specify the certificate request reception authority.

certificate request from { **ca** | **ra** }

By default, no certificate request reception authority is specified.

Specifying the certificate request URL

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Specify the URL of the certificate request reception authority to which the device sends certificate requests.

   certificate request url *url-string* [**vpn-instance** *vpn-instance-name*]

   By default, the certificate request URL is not specified.

Setting the SCEP polling interval and maximum polling attempts

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Set the SCEP polling interval and maximum number of polling attempts.

   certificate request polling { **count** *count* | **interval** *interval* }

   By default, the device polls the CA server for the certificate request status every 20 minutes. The maximum number of polling attempts is 50.

Specifying the LDAP server

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Specify the LDAP server.

   ldap-server host *hostname* [**port** *port-number*] [**vpn-instance** *vpn-instance-name*]

   By default, no LDAP server is specified.

Specifying the fingerprint for root CA certificate verification

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Configure the fingerprint for verifying the root CA certificate.

   In non-FIPS mode:

   root-certificate fingerprint { **md5** | **sha1** } *string*

In FIPS mode:

root-certificate fingerprint sha1 *string*

By default, no fingerprint is configured.

Specifying the key pair for certificate request

Restrictions and guidelines

You can specify a nonexistent key pair for certificate request. The PKI entity automatically creates the key pair before submitting a certificate request.

Procedure

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Specify the key pair for certificate request.
   - Specify an RSA key pair.

     public-key rsa { { **encryption name** *encryption-key-name* [**length** *key-length*] | **signature name** *signature-key-name* [**length** *key-length*] } * | **general name** *key-name* [**length** *key-length*] }
   - Specify an ECDSA key pair.

     In non-FIPS mode:

     public-key ecdsa name *key-name* [**secp192r1** | **secp256r1** | **secp384r1** | **secp521r1**]

     In FIPS mode:

     public-key ecdsa name *key-name* [**secp256r1** | **secp384r1** | **secp521r1**]
   - Specify a DSA key pair.

     public-key dsa name *key-name* [**length** *key-length*]

   By default, no key pair is specified.

Specifying the intended purpose for the certificate

About this task

An issued certificate contains the extensions which restrict the usage of the certificate to specific purposes. You can specify the intended purposes for a certificate, which will be included in the certificate request sent to the CA. However, the actual extensions contained in an issued certificate depend on the CA policy, and they might be different from those specified in the PKI domain. Whether an application will use the certificate during authentication depends on the application's policy.

Supported certificate extensions include:

- **ike**—Certificates carrying this extension can be used by IKE peers.
- **ssl-client**—Certificates carrying this extension can be used by SSL clients.
- **ssl-server**—Certificates carrying this extension can be used by SSL servers.

Procedure

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Specify the intended use for the certificate.

   usage { **ike** | **ssl-client** | **ssl-server** } *

   By default, the certificate can be used by all supported applications, including IKE, SSL client, and SSL server.

Specifying the source IP address for PKI protocol packets

About this task

This task is required if the CA policy requires that the CA server accept certificate requests from a specific IP address or subnet.

Procedure

1. Enter system view.

   system-view

2. Enter PKI domain view.

   pki domain *domain-name*

3. Specify a source IP address for the PKI protocol packets.

   IPv4:

   source ip { *ip-address* | **interface** *interface-type interface-number* }

   IPv6:

   source ipv6 { *ipv6-address* | **interface** *interface-type interface-number* }

   By default, the source IP address of PKI protocol packets is the IP address of their outgoing interface.

Specifying the storage path for certificates and CRLs

About this task

The device has a default storage path for certificates and CRLs. You can change the storage path and specify different paths for the certificates and CRLs.

After you change the storage path for certificates or CRLs, the certificate files and CRL files in the original path are moved to the new path. Certificate files use the .cer or .p12 file extension and CRL files use the .crl file extension.

Restrictions and guidelines

If you change the storage path, save the configuration before you reboot or shut down the device to avoid loss of certificates or CRLs.

Procedure

1. Enter system view.

   system-view

2. Specify the storage path for certificates and CRLs.

   pki storage { **certificates** | **crls** } *dir-path*

   By default, the device stores certificates and CRLs in the PKI directory on the storage media of the device.

Requesting a certificate

About certificate request configuration

To request a certificate, a PKI entity must provide its identity information and public key to a CA.

A certificate request can be submitted to a CA in offline or online mode.

- **Offline mode**—A certificate request is submitted by using an out-of-band method, such as phone, disk, or email.
- **Online mode**—A certificate request can be automatically or manually submitted to a CA through the Simple Certificate Enrollment Protocol (SCEP).

Restrictions and guidelines for certificate request configuration

When you request a local certificate in a PKI domain, follow these restrictions and guidelines:

- To prevent an existing local certificate from becoming invalid, do not perform the following tasks:
  - Create a key pair with the same name as the key pair contained in the certificate.

    To create a key pair, use the **`public-key local create`** command.
  - Destroy the key pair contained in the certificate.

    To destroy a key pair, use the **`public-key local destroy`** command.
- To manually request a new certificate in a PKI domain that already has a local certificate, use the following procedure:
  a. Use the **`pki delete-certificate`** command to delete the existing local certificate.
  b. Use the **`public-key local create`** command to generate a new key pair.
  c. Manually submit a certificate request.
- A PKI domain can have local certificates using only one type of cryptographic algorithms (DSA, ECDSA, or RSA). If DSA or ECDSA is used, a PKI domain can have only one local certificate. If RSA is used, a PKI domain can have one local certificate for signature, and one local certificate for encryption.

Prerequisites for certificate request configuration

Make sure the device is time synchronized with the CA server. If the device is not time synchronized with the CA server, the certificate request might fail because the certificate might be considered to be outside of the validity period. For information about configuring the system time, see *Fundamentals Configuration Guide*.

Enabling the automatic online certificate request mode

About this task

In auto request mode, a PKI entity with no local certificates automatically submits a certificate request to the CA when an application works with the PKI entity. For example, when IKE negotiation uses a digital signature for identity authentication, but no local certificate is available, the entity automatically submits a certificate request. It saves the certificate locally after obtaining the certificate from the CA.

A CA certificate must be present before you request a local certificate. If no CA certificate exists in the PKI domain, the PKI entity automatically obtains a CA certificate before sending a certificate request.

Restrictions and guidelines

In auto request mode, the device does not automatically request a new certificate if the current certificate is about to expire or has expired, which might cause service interruptions.

Procedure

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Enable the automatic online certificate request mode.
   certificate request mode auto [**password** { **cipher** | **simple** } *string*]
   By default, the manual request mode applies.
   If the CA policy requires a password for certificate revocation, specify the password in this command.

Manually submitting an online certificate request

About this task

In manual request mode, you must execute the **pki request-certificate domain** command to request a local certificate in a PKI domain. The certificate will be saved in the domain after it is obtained from the CA.

Procedure

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Set the certificate request mode to manual.
   certificate request mode manual
   By default, the manual request mode applies.
4. Return to system view.
   quit
5. Obtain a CA certificate.
   See "Obtaining certificates."
   This step is required if the PKI domain does not have a CA certificate. The CA certificate is used to verify the authenticity and validity of the obtained local certificate.
6. Manually submit an SCEP certificate request.
   pki request-certificate domain *domain-name* [**password** *password*]
   This command is not saved in the configuration file.
   If the CA policy requires a password for certificate revocation, specify the password in this command.

Manually submitting a certificate request in offline mode

About this task

Use this method if the CA does not support SCEP or if a network connection between the device and CA is not possible.

Procedure

1. Enter system view.

   system-view
2. Enter PKI domain view.

   pki domain *domain-name*
3. Set the certificate request mode to manual.

   certificate request mode manual

   By default, the manual request mode applies.
4. Return to system view.

   quit
5. Obtain the CA certificate.

   See "Obtaining certificates."

   This step is required if the PKI domain does not have a CA certificate. The CA certificate is used to verify the authenticity and validity of the obtained local certificate.
6. Print the certificate request in PKCS10 format on the terminal or save the certificate request to a PKCS10 file.

   pki request-certificate domain *domain-name* **pkcs10** [**filename** *filename*]

   This command is not saved in the configuration file.
7. Transfer certificate request information to the CA by using an out-of-band method.
8. Transfer the issued local certificate from the CA to the local device by using an out-of-band method.
9. Import the local certificate to the PKI domain.

   pki import domain *domain-name* { **der local filename** *filename* | **p12 local filename** *filename* | **pem local** [**filename** *filename*] }

Aborting a certificate request

About this task

Before the CA issues a certificate, you can abort a certificate request and change its parameters, such as the common name, country code, or FQDN. You can use the **display pki certificate request-status** command to display the status of a certificate request.

Alternatively, you also can remove a PKI domain to abort the associated certificate request.

Procedure

1. Enter system view.

   system-view
2. Abort a certificate request.

   pki abort-certificate-request domain *domain-name*

   This command is not saved in the configuration file.

Obtaining certificates

About this task

You can obtain the CA certificate, local certificates, and peer certificates related to a PKI domain from a CA and save them locally for higher lookup efficiency. To do so, use either the offline mode or the online mode:

- In offline mode, obtain the certificates by an out-of-band means like FTP, disk, or email, and then import them locally. Use this mode when the CRL repository is not specified, the CA server does not support SCEP, or the CA server generates the key pair for the certificates.
- In online mode, you can obtain the CA certificate through SCEP and obtain local certificates or peer certificates through LDAP.

Restrictions and guidelines

Follow these restrictions and guidelines when obtain certificates from a CA

- If a CA certificate already exists locally, you cannot obtain it again in online mode. If you want to obtain a new CA certificate, use the **pki delete-certificate** command to delete the existing CA certificate and local certificates first.
- If local or peer certificates already exist, you can obtain new local or peer certificates to overwrite the existing ones. If RSA is used, a PKI domain can have two local certificates, one for signature and the other for encryption.
- If CRL checking is enabled, obtaining a certificate triggers CRL checking. If the certificate to be obtained has been revoked, the certificate cannot be obtained.
- The device compares the validity period of a certificate with the local system time to determine whether the certificate is valid. Make sure the system time of the device is synchronized with the CA server.

Prerequisites

- Before you obtain local or peer certificates in online mode, make sure an LDAP server is correctly configured in the PKI domain.
- Before you import certificates in offline mode, complete the following tasks:
  - Use FTP or TFTP to upload the certificate files to the storage media of the device.

    If FTP or TFTP is not available, display and copy the contents of a certificate to a file on the device. Make sure the certificate is in PEM format because only certificates in PEM format can be imported.
  - Before you import a local certificate or peer certificate, obtain the CA certificate chain that signs the certificate.

    This step is required only if the CA certificate chain is neither available in the PKI domain nor contained in the certificate to be imported.
  - Before you import a local certificate that contains an encrypted key pair, contact the CA administrator to obtain the password required for importing the certificate.

Procedure

1. Enter system view.

   system-view
2. Obtain certificates.
   - Import certificates in offline mode.

     pki import domain *domain-name* { **der** { **ca** | **local** | **peer** } **filename** *filename* | **p12 local filename** *filename* | **pem** { **ca** | **local** | **peer** } [**filename** *filename*] }
   - Obtain certificates in online mode.

pki retrieve-certificate domain *domain-name* { **ca** | **local** | **peer** *entity-name* }

This command is not saved in the configuration file.

Verifying PKI certificates

About certification verification

A certificate is automatically verified when it is requested, obtained, or used by an application. If the certificate expires, if it is not issued by a trusted CA, or if it is revoked, the certificate cannot be used You can also manually verify a certificate.

You can enable or disable CRL checking in a PKI domain. CRL checking checks whether a certificate is in the CRL. If it is, the certificate has been revoked and its home entity is not trusted.

To use CRL checking, a CRL must be obtained from a CRL repository. The device selects a CRL repository in the following order:

1. CRL repository specified in the PKI domain by using the **crl url** command.
2. CRL repository in the certificate that is being verified.
3. CRL repository in the CA certificate or CRL repository in the upper-level CA certificate if the certificate being verified is a CA certificate

If no CRL repository is found after the selection process, the device obtains the CRL through SCEP. In this scenario, the CA certificate and the local certificates must have been obtained.

A certificate fails CRL checking in the following situations:

- A CRL cannot be obtained during CRL checking of the certificate.
- CRL checking verifies that the certificate has been revoked.

Restrictions and guidelines for certificate verification

When verifying the CA certificate of a PKI domain, the system needs to verify all the certificates in the CA certificate chain. To ensure a successful certificate verification process, the device must have all the PKI domains to which the CA certificates in the certificate chain belong.

The system verifies the CA certificates in the CA certificate chain as follows:

1. Identifies the parent certificate of the lowest-level certificate.

   Each CA certificate contains an issuer field that identifies the parent CA that issued the certificate.
2. Locates the PKI domain to which the parent certificate belongs.
3. Performs CRL checking in the PKI domain to check whether the parent certificate has been revoked. If it has been revoked, the certificate cannot be used.

   This step will not be performed when CRL checking is disabled in the PKI domain.
4. Repeats the previous steps for upper-level certificates in the CA certificate chain until the root CA certificate is reached.
5. Verifies that each CA certificate in the certificate chain is issued by the named parent CA, starting from the root CA.

Verifying certificates with CRL checking

1. Enter system view.

   system-view

2. Enter PKI domain view.
   pki domain *domain-name*
3. (Optional.) Specify the URL of the CRL repository.
   crl url *url-string* [**vpn-instance** *vpn-instance-name*]
   By default, the URL of the CRL repository is not specified.
4. Enable CRL checking.
   crl check enable
   By default, CRL checking is enabled.
5. Return to system view.
   quit
6. Obtain the CA certificate.
   See "Obtaining certificates."
   The PKI domain must have a CA certificate before you can verify certificates in it.
7. (Optional.) Obtain the CRL and save it locally.
   pki retrieve-crl domain *domain-name*
   To verify a non-root CA certificate and local certificates, the device automatically retrieves the CRL if the PKI domain has no CRL.
   The newly obtained CRL overwrites the old one, if any.
   The obtained CRL is issued by a CA in the CA certificate chain stored in the PKI domain.
8. Manually verify the validity of the certificates.
   pki validate-certificate domain *domain-name* { **ca** | **local** }

Verifying certificates without CRL checking

1. Enter system view.
   system-view
2. Enter PKI domain view.
   pki domain *domain-name*
3. Disable CRL checking.
   undo crl check enable
   By default, CRL checking is enabled.
4. Return to system view.
   quit
5. Obtain a CA certificate for the PKI domain.
   See "Obtaining certificates."
   The PKI domain must have a CA certificate before you can verify certificates in it.
6. Manually verify the certificate validity.
   pki validate-certificate domain *domain-name* { **ca** | **local** }
   This command is not saved in the configuration file.

Exporting certificates

About this task

You can export the CA certificate and the local certificates in a PKI domain to certificate files. The exported certificate files can then be imported back to the device or other PKI applications.

Restrictions and guidelines

To export all certificates in PKCS12 format, the PKI domain must have a minimum of one local certificate. If the PKI domain does not have any local certificates, the certificates in the PKI domain cannot be exported.

If you do not specify a file name when you export a certificate in PEM format, this command displays the certificate content on the terminal.

When you export a local certificate with RSA key pairs to a file, the certificate file name might be different from the file name specified in the command. The actual certificate file name depends on the purpose of the key pair contained in the certificate. For more information about the file naming rule, see the **pki export** command in *Security Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Export certificates.
   - Export certificates in DER format.

     pki export domain *domain-name* **der** { **all** | **ca** | **local** } **filename** *filename*
   - Export certificates in PKCS12 format.

     pki export domain *domain-name* **p12** { **all** | **local** } **passphrase** *p12-key* **filename** *filename*
   - Export certificates in PEM format.

     pki export domain *domain-name* **pem** { { **all** | **local** } [{ **3des-cbc** | **aes-128-cbc** | **aes-192-cbc** | **aes-256-cbc** | **des-cbc** } *pem-key*] | **ca** } [**filename** *filename*]

Removing a certificate

About this task

You can remove certificates from a PKI domain in the following situations:

- Remove a CA certificate, local certificate, or peer certificate if the certificate has expired or is about to expire.
- Remove a local certificate if the certificate's private key is compromised, or if you want to request a new local certificate to replace the existing one.

Restrictions and guidelines

After you remove the CA certificate, the system automatically removes the local certificates, peer certificates, and CRLs from the domain.

To remove a local certificate and request a new certificate, perform the following tasks:

1. Remove the local certificate.
2. Use the **public-key local destroy** command to destroy the existing local key pair.
3. Use the **public-key local create** command to generate a new key pair.
4. Request a new certificate.

For more information about the **public-key local destroy** and **public-key local create** commands, see *Security Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Remove a certificate.

   pki delete-certificate domain *domain-name* { **ca** | **local** | **peer** [**serial** *serial-num*] }

   If you use the **peer** keyword without specifying a serial number, this command removes all peer certificates.

Configuring a certificate-based access control policy

About certificate-based access control policies

Certificate-based access control policies allow you to authorize access to a device (for example, an HTTPS server) based on the attributes of an authenticated client's certificate.

Access control rules and certificate attribute groups

A certificate-based access control policy is a set of access control rules (permit or deny statements), each associated with a certificate attribute group. A certificate attribute group contains multiple attribute rules, each defining a matching criterion for an attribute in the certificate issuer name, subject name, or alternative subject name field.

Certificate matching mechanism

If a certificate matches all attribute rules in a certificate attribute group associated with an access control rule, the system determines that the certificate matches the access control rule. In this scenario, the match process stops, and the system performs the access control action defined in the access control rule.

The following conditions describe how a certificate-based access control policy verifies the validity of a certificate:

- If a certificate matches a permit statement, the certificate passes the verification.
- If a certificate matches a deny statement or does not match any statements in the policy, the certificate is regarded invalid.
- If a statement is associated with a non-existing attribute group, or the attribute group does not have attribute rules, the certificate matches the statement.
- If the certificate-based access control policy specified for a security application (for example, HTTPS) does not exist, all certificates in the application pass the verification.

Procedure

1. Enter system view.

   system-view

2. Create a certificate attribute group and enter its view.

   pki certificate attribute-group *group-name*

3. Configure an attribute rule for issuer name, subject name, or alternative subject name.

   attribute *id* { **alt-subject-name** { **fqdn** | **ip** } | { **issuer-name** | **subject-name** } { **dn** | **fqdn** | **ip** } } { **ctn** | **equ** | **nctn** | **nequ**} *attribute-value*

   By default, not attribute rules are configured.

4. Return to system view.

   quit

5. Create a certificate-based access control policy and enter its view.

pki certificate access-control-policy *policy-name*

By default, no certificate-based access control policies exist.

6. Create a certificate access control rule.

   rule [*id*] { **deny** | **permit** } *group-name*

   By default, no certificate access control rules are configured, and all certificates can pass the verification.

   You can create multiple certificate access control rules for a certificate-based access control policy.

Display and maintenance commands for PKI

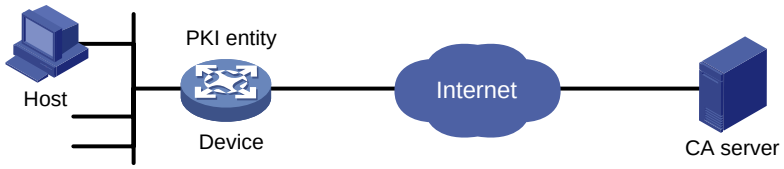
Execute **display** commands in any view.

Task	Command
Display certificate-based access control policy information.	**display pki certificate access-control-policy** [*policy-name*]
Display certificate attribute group information.	**display pki certificate attribute-group** [*group-name*]
Display the contents of a certificate.	**display pki certificate domain** *domain-name* { **ca** | **local** | **peer** [**serial** *serial-num*] }
Display certificate request status.	**display pki certificate request-status** [**domain** *domain-name*]
Display locally stored CRLs in a PKI domain.	**display pki crl domain** *domain-name*

PKI configuration examples

You can use different software applications, such as Windows server, RSA Keon, and OpenCA, to act as the CA server.

If you use Windows server or OpenCA, you must install the SCEP add-on for Windows server or enable SCEP for OpenCA. In either case, when you configure a PKI domain, you must use the **certificate request from ra** command to specify the RA to accept certificate requests.



If you use RSA Keon, the SCEP add-on is not required. When you configure a PKI domain, you must use the **certificate request from ca** command to specify the CA to accept certificate requests.

Example: Requesting a certificate from an RSA Keon CA server

Network configuration

Configure the PKI entity (the device) to request a local certificate from the CA server.

Figure 2 Network diagram

Configuring the RSA Keon CA server

1. Create a CA server named **myca**:

   In this example, you must configure these basic attributes on the CA server:

   - **Nickname**—Name of the trusted CA.
   - **Subject DN**—DN attributes of the CA, including the common name (CN), organization unit (OU), organization (O), and country (C).

   You can use the default values for other attributes.

2. Configure extended attributes:

   Configure parameters in the **Jurisdiction Configuration** section on the management page of the CA server:

   - Select the correct extension profiles.
   - Enable the SCEP autovetting function to enable the CA server to automatically approve certificate requests without manual intervention.
   - Specify the IP address list for SCEP autovetting.

Configuring the device

1. Synchronize the system time of the device with the CA server for the device to correctly request certificates or obtain CRLs. (Details not shown.)
2. Create an entity named **aaa** and set the common name to **Device**.

   ```
   <Device> system-view
   [Device] pki entity aaa
   [Device-pki-entity-aaa] common-name Device
   [Device-pki-entity-aaa] quit
   ```

3. Configure a PKI domain:

   # Create a PKI domain named **torsa** and enter its view.

   ```
   [Device] pki domain torsa
   ```

   # Specify the name of the trusted CA. The setting must be the same as CA name configured on the CA server. This example uses **myca**.

   ```
   [Device-pki-domain-torsa] ca identifier myca
   ```

   # Configure the URL of the CA server. The URL format is **http://***host:port*/*Issuing Jurisdiction ID*, where *Issuing Jurisdiction ID* is a hexadecimal string generated on the CA server.

   ```
   [Device-pki-domain-torsa] certificate request url
   http://1.1.2.22:446/80f6214aa8865301d07929ae481c7ceed99f95bd
   ```

   # Configure the device to send certificate requests to **ca**.

   ```
   [Device-pki-domain-torsa] certificate request from ca
   ```

   # Set the PKI entity name to **aaa**.

   ```
   [Device-pki-domain-torsa] certificate request entity aaa
   ```

   # Specify the URL of the CRL repository.

   ```
   [Device-pki-domain-torsa] crl url ldap://1.1.2.22:389/CN=myca
   ```

   # Specify a 1024-bit general-purpose RSA key pair named **abc** for certificate request.

```
[Device-pki-domain-torsa] public-key rsa general name abc length 1024
[Device-pki-domain-torsa] quit
```

4. Generate the RSA key pair.

```
[Device] public-key local create rsa name abc
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512,it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.........................++++++
.....................................++++++
Create the key pair successfully.
```

5. Request a local certificate:

Obtain the CA certificate and save it locally.

```
[Device] pki retrieve-certificate domain torsa ca
The trusted CA's finger print is:
    MD5  fingerprint:EDE9 0394 A273 B61A F1B3 0072 A0B1 F9AB
    SHA1 fingerprint: 77F9 A077 2FB8 088C 550B A33C 2410 D354 23B2 73A8
Is the finger print correct?(Y/N):y
Retrieved the certificates successfully.
```

Submit a certificate request manually and set the certificate revocation password to **1111**. The certificate revocation password is required when an RSA Keon CA server is used.

```
[Device] pki request-certificate domain torsa password 1111
Start to request general certificate ...
……
Request certificate of domain torsa successfully
```

Verifying the configuration

Display information about the local certificate in PKI domain **torsa**.

```
[Device] display pki certificate domain torsa local
Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number:

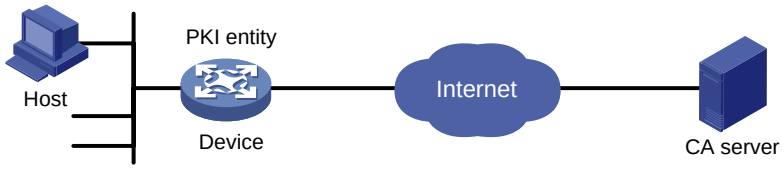
        1b:f5
```



To display detailed information about the CA certificate, use the **display pki certificate domain** command.

Example: Requesting a certificate from a Windows Server 2003 CA server

Network configuration

Configure the PKI entity (the device) to request a local certificate from a Windows Server 2003 CA server.

Figure 3 Network diagram

Configuring the Windows Server 2003 CA server

1. Install the certificate service component:
   a. Select **Control Panel** > **Add or Remove Programs** from the start menu.
   b. Select **Add/Remove Windows Components** > **Certificate Services**.
   c. Click **Next** to begin the installation.
   d. Set the CA name. In this example, set the CA name to **myca**.
2. Install the SCEP add-on:

   By default, Windows Server 2003 does not support SCEP. You must install the SCEP add-on on the server for a PKI entity to register and obtain a certificate from the server. After the SCEP

add-on installation is complete, you will see a URL. Specify this URL as the certificate request URL on the device.

3. Modify the certificate service attributes:
   a. Select **Control Panel** > **Administrative Tools** > **Certificate Authority** from the start menu.

      If the certificate service component and SCEP add-on have been installed successfully, there should be two certificates issued by the CA to the RA.

   b. Right-click the CA server in the navigation tree and select **Properties** > **Policy Module**.
   c. Click **Properties**, and then select **Follow the settings in the certificate template, if applicable. Otherwise, automatically issue the certificate**.
4. Modify the Internet information services attributes:
   a. Select **Control Panel** > **Administrative Tools** > **Internet Information Services (IIS) Manager** from the start menu.
   b. Select **Web Sites** from the navigation tree.
   c. Right-click **Default Web Site** and select **Properties** > **Home Directory**.
   d. Specify the path for certificate service in the **Local path** field.
   e. Specify a unique TCP port number for the default website to avoid conflict with existing services. This example uses port 8080.

Configuring the device

1. Synchronize the device's system time with the CA server for the device to correctly request certificates. (Details not shown.)
2. Create an entity named **aaa** and set the common name to **test**.

```
<Device> system-view
[Device] pki entity aaa
[Device-pki-entity-aaa] common-name test
[Device-pki-entity-aaa] quit
```

3. Configure a PKI domain:

   # Create a PKI domain named **winserver** and enter its view.

```
[Device] pki domain winserver
```

   # Set the name of the trusted CA to **myca**.

```
[Device-pki-domain-winserver] ca identifier myca
```

   # Configure the certificate request URL. The URL format is **http://***host:port***/certsrv/mscep/mscep.dll**, where *host:port* is the host IP address and port number of the CA server.

```
[Device-pki-domain-winserver] certificate request url
http://4.4.4.1:8080/certsrv/mscep/mscep.dll
```

   # Configure the device to send certificate requests to **ra**.

```
[Device-pki-domain-winserver] certificate request from ra
```

   # Set the PKI entity name to **aaa**.

```
[Device-pki-domain-winserver] certificate request entity aaa
```

   # Configure a 1024-bit general-purpose RSA key pair named **abc** for certificate request.

```
[Device-pki-domain-winserver] public-key rsa general name abc length 1024
[Device-pki-domain-winserver] quit
```

4. Generate RSA key pair **abc**.

```
[Device] public-key local create rsa name abc
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512,it will take a few minutes.
Press CTRL+C to abort.
```

```
Input the modulus length [default = 1024]:
Generating Keys...
.........................++++++
.....................................++++++
Create the key pair successfully.
```

5. Request a local certificate:

Obtain the CA certificate and save it locally.

```
[Device] pki retrieve-certificate domain winserver ca
The trusted CA's finger print is:
    MD5  fingerprint:766C D2C8 9E46 845B 4DCE 439C 1C1F 83AB
    SHA1 fingerprint:97E5 DDED AB39 3141 75FB DB5C E7F8 D7D7 7C9B 97B4
Is the finger print correct?(Y/N):y
Retrieved the certificates successfully.
```

Submit a certificate request manually.

```
[Device] pki request-certificate domain winserver
Start to request general certificate ...
…
Request certificate of domain winserver successfully
```

Verifying the configuration

Display information about the local certificate in PKI domain **winserver**.

```
[Device] display pki certificate domain winserver local
Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number:

```

To display detailed information about the CA certificate, use the **display pki certificate domain** command.

Example: Requesting a certificate from an OpenCA server

Network configuration

Configure the PKI entity (the device) to request a local certificate from the CA server.

Figure 4 Network diagram

Configuring the OpenCA server

Configure the OpenCA server as instructed in related manuals. (Details not shown.)

Make sure the version of the OpenCA server is later than version 0.9.2 because the earlier versions do not support SCEP.

Configuring the device

1. Synchronize the device's system time with the CA server for the device to correctly request certificates. (Details not shown.)
2. Create a PKI entity named **aaa** and configure the common name, country code, organization name, and OU for the entity.

```
<Device> system-view
[Device] pki entity aaa
[Device-pki-entity-aaa] common-name rnd
[Device-pki-entity-aaa] country CN
[Device-pki-entity-aaa] organization test
[Device-pki-entity-aaa] organization-unit software
[Device-pki-entity-aaa] quit
```

3. Configure a PKI domain:

   # Create a PKI domain named **openca** and enter its view.

```
[Device] pki domain openca
```

   # Set the name of the trusted CA to **myca**.

```
[Device-pki-domain-openca] ca identifier myca
```

   # Configure the certificate request URL. The URL is in the format **http://***host***/cgi-bin/pki/scep**, where *host* is the host IP address of the OpenCA server.

```
[Device-pki-domain-openca] certificate request url
http://192.168.222.218/cgi-bin/pki/scep
```

   # Configure the device to send certificate requests to the RA.

```
[Device-pki-domain-openca] certificate request from ra
```

   # Specify PKI entity **aaa** for certificate request.

```
[Device-pki-domain-openca] certificate request entity aaa
```

   # Configure a 1024-bit general-purpose RSA key pair named **abc** for certificate request.

```
[Device-pki-domain-openca] public-key rsa general name abc length 1024
[Device-pki-domain-openca] quit
```

4. Generate RSA key pair **abc**.

```
[Device] public-key local create rsa name abc
The range of public key modulus is (512 ~ 4096).
```

```
If the key modulus is greater than 512,it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.........................++++++
.....................................++++++
Create the key pair successfully.
```

5. Request a local certificate:

Obtain the CA certificate and save it locally.

```
[Device] pki retrieve-certificate domain openca ca
The trusted CA's finger print is:
    MD5  fingerprint:5AA3 DEFD 7B23 2A25 16A3 14F4 C81C C0FA
    SHA1 fingerprint:9668 4E63 D742 4B09 90E0 4C78 E213 F15F DC8E 9122
Is the finger print correct?(Y/N):y
Retrieved the certificates successfully.
```

Submit a certificate request manually.

```
[Device] pki request-certificate domain openca
Start to request general certificate ...
…
Request certificate of domain openca successfully
```

Verifying the configuration

Display information about the local certificate in PKI domain **openca**.

```
[Device] display pki certificate domain openca local

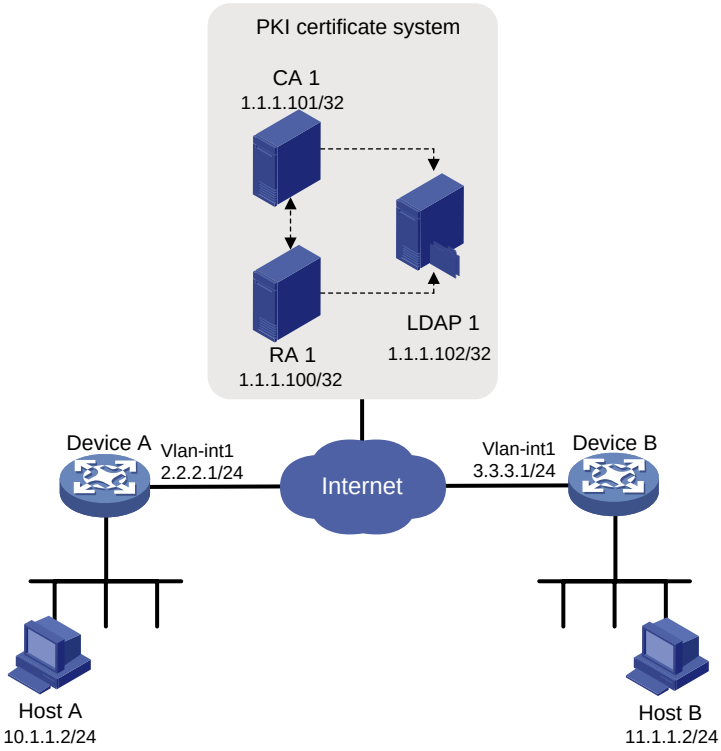
        81:99:31:89
```

To display detailed information about the CA certificate, use the **display pki certificate domain** command.

Example: Configuring IKE negotiation with RSA digital signature from a Windows Server 2003 CA server



Network configuration

As shown in the network diagram, an IPsec tunnel is required to be established between Device A and Device B. The IPsec tunnel protects the traffic between Host A on subnet 10.1.1.0/24 and Host B on subnet 1.1.1.0/24.

Device A and Device B use IKE to set up SAs, and the IKE proposal uses RSA digital signature for identity authentication.

Device A and Device B use the same CA.

Figure 5 Network diagram

Configuring the Windows Server 2003 CA server

See "Example: Requesting a certificate from a Windows Server 2003 CA server."

Configuring Device A

Configure a PKI entity.

```
<DeviceA> system-view
[DeviceA] pki entity en
[DeviceA-pki-entity-en] ip 2.2.2.1
[DeviceA-pki-entity-en] common-name devicea
[DeviceA-pki-entity-en] quit
```

Configure a PKI domain.

```
[DeviceA] pki domain 1
[DeviceA-pki-domain-1] ca identifier CA1
[DeviceA-pki-domain-1] certificate request url http://1.1.1.100/certsrv/mscep/mscep.dll
```

```
[DeviceA-pki-domain-1] certificate request entity en
[DeviceA-pki-domain-1] ldap-server host 1.1.1.102
```

Configure the device to send certificate requests to **ra**.

```
[DeviceA-pki-domain-1] certificate request from ra
```

Configure a 1024-bit general-purpose RSA key pair named **abc** for certificate request.

```
[DeviceA-pki-domain-1] public-key rsa general name abc length 1024
[DeviceA-pki-domain-1] quit
```

Generate the RSA key pair.

```
[DeviceA] public-key local create rsa name abc
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512,it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.........................++++++
.....................................++++++
Create the key pair successfully.
```

Obtain the CA certificate and save it locally.

```
[DeviceA] pki retrieve-certificate domain 1 ca
```

Submit a certificate request manually.

```
[DeviceA] pki request-certificate domain 1
```

Create IKE proposal 1, and configure the authentication method as RSA digital signature.

```
[DeviceA] ike proposal 1
[DeviceA-ike-proposal-1] authentication-method rsa-signature
[DeviceA-ike-proposal-1] quit
```

Specify the PKI domain used in IKE negotiation for IKE profile **peer**.

```
[DeviceA] ike profile peer
[DeviceA-ike-profile-peer] certificate domain 1
```

Configuring Device B

Configure a PKI entity.

```
<DeviceB> system-view
[DeviceB] pki entity en
[DeviceB-pki-entity-en] ip 3.3.3.1
[DeviceB-pki-entity-en] common-name deviceb
[DeviceB-pki-entity-en] quit
```

Configure a PKI domain.

```
[DeviceB] pki domain 1
[DeviceB-pki-domain-1] ca identifier CA1
[DeviceB-pki-domain-1] certificate request url http://1.1.1.100/certsrv/mscep/mscep.dll
[DeviceB-pki-domain-1] certificate request entity en
[DeviceB-pki-domain-1] ldap-server host 1.1.1.102
```

Configure the device to send certificate requests to **ra**.

```
[DeviceB-pki-domain-1] certificate request from ra
```

Configure a 1024-bit general-purpose RSA key pair named **abc** for certificate request.

```
[DeviceB-pki-domain-1] public-key rsa general name abc length 1024
```

```
[DeviceB-pki-domain-1] quit
```

Generate the RSA key pair.

```
[DeviceB] public-key local create rsa name abc
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512,it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.........................++++++
.....................................++++++
Create the key pair successfully.
```

Obtain the CA certificate and save it locally.

```
[DeviceB] pki retrieve-certificate domain 1 ca
The trusted CA's finger print is:
    MD5  fingerprint:5C41 E657 A0D6 ECB4 6BD6 1823 7473 AABC
    SHA1 fingerprint:1616 E7A5 D89A 2A99 9419 1C12 D696 8228 87BC C266
Is the finger print correct?(Y/N):y
Retrieved the certificates successfully.
```

Submit a certificate request manually.

```
[DeviceB] pki request-certificate domain 1
Start to request general certificate ...
...
Certificate requested successfully.
```

Create IKE proposal 1, and configure the authentication method as RSA digital signature.

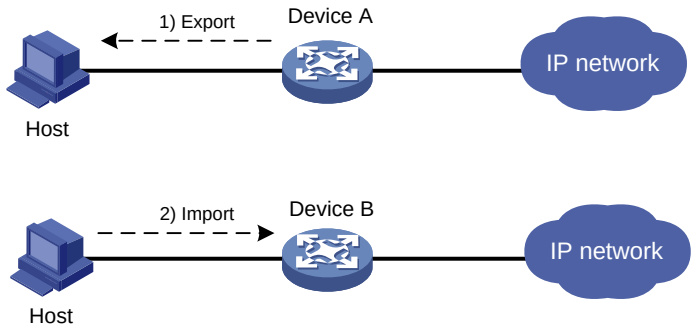
```
[DeviceB] ike proposal 1
[DeviceB-ike-proposal-1] authentication-method rsa-signature
[DeviceB-ike-proposal-1] quit
```

Specify the PKI domain used in IKE negotiation for IKE profile **peer**.

```
[DeviceB] ike profile peer
[DeviceB-ike-profile-peer] certificate domain 1
```

The configurations are for IKE negotiation with RSA digital signature. For information about how to configure IPsec SAs to be set up, see "Configuring IPsec."

Example: Importing and exporting certificates



Network configuration

As shown in Figure 6, Device B will replace Device A in the network. PKI domain **exportdomain** on Device A has two local certificates containing the private key and one CA certificate. To make sure the certificates are still valid after Device B replaces Device A, copy the certificates on Device A to Device B as follows:

1. Export the certificates in PKI domain **exportdomain** on Device A to .pem certificate files.

   During the export, encrypt the private key in the local certificates using 3DES_CBC with the password 11111.
2. Transfer the certificate files from Device A to Device B through the FTP host.
3. Import the certificate files to PKI domain **importdomain** on Device B.

Figure 6 Network diagram

Procedure

1. Export the certificates on Device A:

   # Export the CA certificate to a .pem file.

   ```
   <DeviceA> system-view
   [DeviceA] pki export domain exportdomain pem ca filename pkicachain.pem
   ```

   # Export the local certificate to a file named **pkilocal.pem** in PEM format, and use 3DES_CBC to encrypt the private key with the password **111111**.

   ```
   [DeviceA] pki export domain exportdomain pem local 3des-cbc 111111 filename
   pkilocal.pem
   ```

   Now, Device A has three certificate files in PEM format:

   - A CA certificate file named **pkicachain.pem**.
   - A local certificate file named **pkilocal.pem-signature**, which contains the private key for signature.
   - A local certificate file named **pkilocal.pem-encryption**, which contains the private key for encryption.

   # Display local certificate file **pkilocal.pem-signature**.

   ```
   [DeviceA] quit
   <DeviceA> more pkilocal.pem-signature

```

2. Download certificate files **pkicachain.pem**, **pkilocal.pem-signature**, and **pkilocal.pem-encryption** from Device A to the host through FTP. (Details not shown.)
3. Upload certificate files **pkicachain.pem**, **pkilocal.pem-signature**, and **pkilocal.pem-encryption** from the host to Device B through FTP. (Details not shown.)
4. Import the certificate files to Device B:

   # Disable CRL checking. (You can configure CRL checking as required. This example assumes CRL checking is not required.)

   ```
   <DeviceB> system-view
   [DeviceB] pki domain importdomain
   [DeviceB-pki-domain-importdomain] undo crl check enable
   ```

   # Specify RSA key pair **sign** for signature and RSA key pair **encr** for encryption.

   ```
   [DeviceB-pki-domain-importdomain] public-key rsa signature name sign encryption name encr
   [DeviceB-pki-domain-importdomain] quit
   ```

   # Import CA certificate file **pkicachain.pem** in PEM format to the PKI domain.

   ```
   [DeviceB] pki import domain importdomain pem ca filename pkicachain.pem
   ```

   # Import local certificate file **pkilocal.pem-signature** in PEM format to the PKI domain. The certificate file contains a key pair.

   ```
   [DeviceB] pki import domain importdomain pem local filename pkilocal.pem-signature
   Please input the password:
   ```

   # Import local certificate file **pkilocal.pem-encryption** in PEM format to the PKI domain. The certificate file contains a key pair.

   ```
   [DeviceB] pki import domain importdomain pem local filename pkilocal.pem-encryption
   Please input the password:
   ```

   # Display the imported local certificate information on Device B.

   ```
   [DeviceB] display pki certificate domain importdomain local

```

To display detailed information about the CA certificate, use the **`display pki certificate domain`** command.

Troubleshooting PKI configuration

This section provides troubleshooting information for common problems with PKI.

Failed to obtain the CA certificate

Symptom

The CA certificate cannot be obtained.

Analysis

- The network connection is down, for example, because the network cable is damaged or the connectors have bad contact.
- No trusted CA is specified.
- The certificate request URL is incorrect or not specified.
- The system time of the device is not synchronized with the CA server.
- The CA server does not accept the source IP address specified in the PKI domain, or no source IP address is specified.
- The fingerprint of the root CA certificate is illegal.

Solution

1. Fix the network connection problems, if any.
2. Configure the trusted CA and all other required parameters in the PKI domain.
3. Use the **ping** command to verify that the CA server is reachable.
4. Synchronize the system time of the device with the CA server.
5. Specify the correct source IP address that the CA server can accept. For the correct settings, contact the CA administrator.
6. Verify the fingerprint of the CA certificate on the CA server.
7. If the problem persists, contact H3C Support.

Failed to obtain local certificates

Symptom

The local certificates can be obtained.

Analysis

- The network connection is down.
- The PKI domain does not have a CA certificate before you submit the local certificate request.
- The LDAP server is not configured or is incorrectly configured.
- No key pair is specified for certificate request in the PKI domain, or the specified key pair does not match the one contained in the local certificates to the obtained.
- No PKI entity is configured in the PKI domain, or the PKI entity configuration is incorrect.
- CRL checking is enabled, but the PKI domain does not have a CRL and cannot obtain one.
- The CA server does not accept the source IP address specified in the PKI domain, or no source IP address is specified.
- The system time of the device is not synchronized with the CA server.

Solution

1. Fix the network connection problems, if any..
2. Obtain or import the CA certificate.
3. Configure the correct LDAP server parameters.

4. Specify the key pair for certificate request, or remove the existing key pair, specify a new key pair, and submit a local certificate request again.
5. Check the registration policy on the CA or RA, and make sure the attributes of the PKI entity meet the policy requirements.
6. Obtain the CRL from the CRL repository.
7. Specify the correct source IP address that the CA server can accept. For the correct settings, contact the CA administrator.
8. Synchronize the system time of the device with the CA server.
9. If the problem persists, contact H3C Support.

Failed to request local certificates

Symptom

Local certificate requests cannot be submitted.

Analysis

- The network connection is down, for example, because the network cable is damaged or the connectors have bad contact.
- The PKI domain does not have a CA certificate before the local certificate request is submitted.
- The certificate request URL is incorrect or is not specified.
- The certificate request reception authority is incorrect or is not specified.
- Required PKI entity parameters are not configured or are incorrectly configured.
- No key pair is specified in the PKI domain for certificate request, or the key pair is changed during a certificate request process.
- Exclusive certificate request applications are running in the PKI domain.
- The CA server does not accept the source IP address specified in the PKI domain, or no source IP address is specified.
- The system time of the device is not synchronized with the CA server.

Solution

1. Fix the network connection problems, if any.
2. Obtain or import the CA certificate.
3. Use the **ping** command to verify that the registration server is reachable.
4. Use the **certificate request from** command to specify the correct certificate request reception authority.
5. Configure the PKI entity parameters as required by the registration policy on the CA or RA.
6. Specify the key pair for certificate request, or remove the existing key pair, specify a new key pair, and submit a local certificate request again.
7. Use the **pki abort-certificate-request domain** command to abort the certificate request.
8. Specify the correct source IP address that the CA server can accept. For the correct settings, contact the CA administrator.
9. Synchronize the system time of the device with the CA server.
10. If the problem persists, contact H3C Support.

Failed to obtain CRLs

Symptom

CRLs cannot be obtained.

Analysis

- The network connection is down, for example, because the network cable is damaged or the connectors have bad contact.
- The PKI domain does not have a CA certificate before you try to obtain CRLs.
- The URL of the CRL repository is not configured and cannot be obtained from the CA certificate or local certificates in the PKI domain.
- The specified URL of the CRL repository is incorrect.
- The device tries to obtain CRLs through SCEP, but it experiences the following problems:
  - The PKI domain does not have local certificates.
  - The key pairs in the certificates have been changed.
  - The PKI domain has incorrect URL for certificate request.
- The CRL repository uses LDAP for CRL distribution. However, the IP address or host name of the LDAP server is neither contained in the CRL repository URL nor configured in the PKI domain.
- The CA does not issue CRLs.
- The CA server does not accept the source IP address specified in the PKI domain, or no source IP address is specified.

Solution

1. Fix the network connection problems, if any.
2. Obtain or import the CA certificate.
3. If the URL of the CRL repository cannot be obtained, verify that the following conditions exist:
   - The URL for certificate request is valid.
   - A local certificate has been successfully obtained.
   - The local certificate contains a public key that matches the locally stored key pair.
4. Make sure the LDAP server address is contained in the CRL repository URL, or is configured in the PKI domain.
5. Make sure the CA server support publishing CRLs.
6. Specify a correct source IP address that the CA server can accept. For the correct settings, contact the CA administrator.
7. If the problem persists, contact H3C Support.

Failed to import the CA certificate

Symptom

The CA certificate cannot be imported.

Analysis

- CRL checking is enabled, but the device does not have a CRL in the PKI domain and cannot obtain one.
- The specified format in which the CA certificate file is to be imported does not match actual certificate file format.

Solution

1. Use the **undo crl check enable** command to disable CRL checking in the PKI domain.
2. Make sure the format of the imported file is correct.
3. If the problem persists, contact H3C Support.

Failed to import the local certificate

Symptom

The local certificate cannot be imported.

Analysis

- The PKI domain does not have a CA certificate, and the local certificate file to be imported does not contain the CA certificate chain.
- CRL checking is enabled, but the device does not have a CRL in the PKI domain and cannot obtain one.
- The specified format in which the local certificate file is to be imported does not match actual certificate file format.
- The device and the certificate do not have the local key pair.
- The certificate has been revoked.
- The certificate is out of the validity period.
- The system time is incorrect.

Solution

1. Obtain or import the CA certificate.
2. Use the **undo crl check enable** command to disable CRL checking, or obtain the correct CRL before you import certificates.
3. Make sure the format of the file to be imported is correct.
4. Make sure the certificate file contains the private key.
5. Make sure the certificate is not revoked.
6. Make sure the certificate is valid.
7. Configure the correct system time for the device.
8. If the problem persists, contact H3C Support.

Failed to export certificates

Symptom

Certificates cannot be exported.

Analysis

- The PKI domain does not have local certificates when you export all certificates in PKCS12 format.
- The specified export path does not exist.
- The specified export path is illegal.
- The public key of the local certificate to be exported does not match the public key of the key pair configured in the PKI domain.
- The storage space of the device is full.

Solution

1. Obtain or request local certificates first.
2. Use the **mkdir** command to create the required path.
3. Specify a correct export path.
4. Configure the correct key pair in the PKI domain.
5. Clear up the storage space of the device.
6. If the problem persists, contact H3C Support.

Failed to set the storage path

Symptom

The storage path for certificates or CRLs cannot be set.

Analysis

- The specified storage path does not exist.
- The specified storage path is illegal.
- The storage space of the device is full.

Solution

1. Use the **mkdir** command to create the path.
2. Specify a valid storage path for certificates or CRLs.
3. Clear up the storage space of the device.
4. If the problem persists, contact H3C Support.

Configuring IPsec

About IPsec

IP Security (IPsec) is defined by the IETF to provide interoperable, high-quality, cryptography-based security for IP communications. It is a Layer 3 VPN technology that transmits data in a secure channel established between two endpoints (such as two security gateways). Such a secure channel is usually called an IPsec tunnel.

IPsec framework

IPsec is a security framework that has the following protocols and algorithms:

- Authentication Header (AH).
- Encapsulating Security Payload (ESP).
- Internet Key Exchange (IKE).
- Algorithms for authentication and encryption.

AH and ESP are security protocols that provide security services. IKE performs automatic key exchange. For more information about IKE, see "Configuring IKE."

IPsec security services

IPsec provides the following security services for data packets in the IP layer:

- **Confidentiality**—The sender encrypts packets before transmitting them over the Internet, protecting the packets from being eavesdropped en route.
- **Data integrity**—The receiver verifies the packets received from the sender to make sure they are not tampered with during transmission.
- **Data origin authentication**—The receiver verifies the authenticity of the sender.
- **Anti-replay**—The receiver examines packets and drops outdated and duplicate packets.

Benefits of IPsec

IPsec delivers the following benefits:

- Reduced key negotiation overhead and simplified maintenance by supporting the IKE protocol. IKE provides automatic key negotiation and automatic IPsec security association (SA) setup and maintenance.
- Good compatibility. You can apply IPsec to all IP-based application systems and services without modifying them.
- Encryption on a per-packet rather than per-flow basis. Per-packet encryption allows for flexibility and greatly enhances IP security.

Security protocols

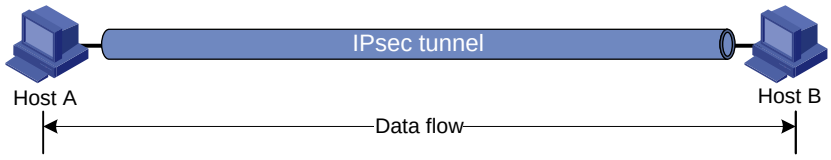
IPsec comes with two security protocols, AH and ESP. They define how to encapsulate IP packets and the security services that they can provide.

- AH (protocol 51) defines the encapsulation of the AH header in an IP packet, as shown in Figure 3. AH can provide data origin authentication, data integrity, and anti-replay services to

prevent data tampering, but it cannot prevent eavesdropping. Therefore, it is suitable for transmitting non-confidential data. The authentication algorithms supported by AH include HMAC-MD5 and HMAC-SHA1. AH does not support NAT traversal.

- ESP (protocol 50) defines the encapsulation of the ESP header and trailer in an IP packet, as shown in Figure 3. ESP can provide data encryption, data origin authentication, data integrity, and anti-replay services. Unlike AH, ESP can guarantee data confidentiality because it can encrypt the data before encapsulating the data to IP packets. ESP-supported encryption algorithms include DES, 3DES, and AES, and authentication algorithms include HMAC-MD5 and HMAC-SHA1.

Both AH and ESP provide authentication services, but the authentication service provided by AH is stronger. In practice, you can choose either or both security protocols. When both AH and ESP are used, an IP packet is encapsulated first by ESP and then by AH.



Encapsulation modes

IPsec supports the following encapsulation modes: transport mode and tunnel mode.

Transport mode

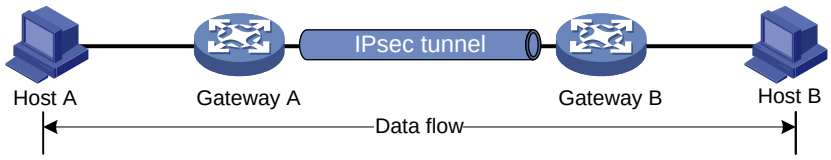
The security protocols protect the upper layer data of an IP packet. Only the transport layer data is used to calculate the security protocol headers. The calculated security protocol headers and the encrypted data (only for ESP encapsulation) are placed after the original IP header. You can use the transport mode when end-to-end security protection is required (the secured transmission start and end points are the actual start and end points of the data). The transport mode is typically used for protecting host-to-host communications, as shown in Figure 1.

Figure 1 IPsec protection in transport mode

Tunnel mode

The security protocols protect the entire IP packet. The entire IP packet is used to calculate the security protocol headers. The calculated security protocol headers and the encrypted data (only for ESP encapsulation) are encapsulated in a new IP packet. In this mode, the encapsulated packet has two IP headers. The inner IP header is the original IP header. The outer IP header is added by the network device that provides the IPsec service. You must use the tunnel mode when the secured transmission start and end points are not the actual start and end points of the data packets (for example, when two gateways provide IPsec but the data start and end points are two hosts behind the gateways). The tunnel mode is typically used for protecting gateway-to-gateway communications, as shown in Figure 2.

Figure 2 IPsec protection in tunnel mode



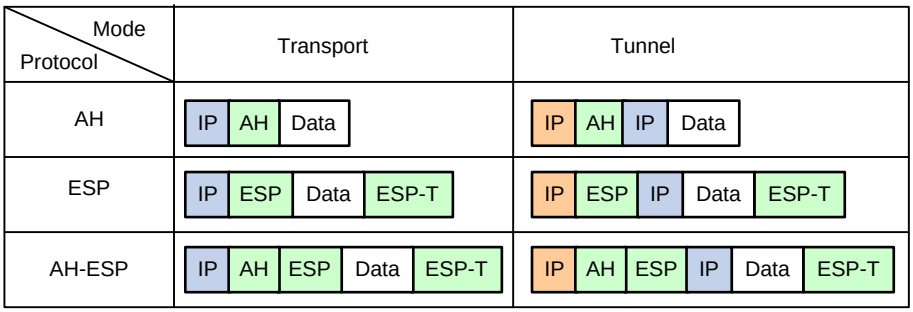


Figure 3 shows how the security protocols encapsulate an IP packet in different encapsulation modes.

Figure 3 Security protocol encapsulations in different modes

Security association

A security association (SA) is an agreement negotiated between two communicating parties called IPsec peers. An SA includes the following parameters for data protection:

- Security protocols (AH, ESP, or both).
- Encapsulation mode (transport mode or tunnel mode).
- Authentication algorithm (HMAC-MD5 or HMAC-SHA1).
- Encryption algorithm (DES, 3DES, or AES).
- Shared keys and their lifetimes.

An SA is unidirectional. At least two SAs are needed to protect data flows in a bidirectional communication. If two peers want to use both AH and ESP to protect data flows between them, they construct an independent SA for each protocol in each direction.

An SA is uniquely identified by a triplet, which consists of the security parameter index (SPI), destination IP address, and security protocol identifier. An SPI is a 32-bit number. It is transmitted in the AH/ESP header.

An SA can be set up manually or through IKE.

- **Manual mode**—Configure all parameters for the SA through commands. This configuration mode is complex and does not support some advanced features (such as periodic key update), but it can implement IPsec without IKE. This mode is mainly used in small and static networks or when the number of IPsec peers in the network is small.
- **IKE negotiation mode**—The peers negotiate and maintain the SA through IKE. This configuration mode is simple and has good expansibility. As a best practice, set up SAs through IKE negotiations in medium- and large-scale dynamic networks.

A manually configured SA never ages out. An IKE-created SA has a lifetime, which comes in two types:

- **Time-based lifetime**—Defines how long the SA can be valid after it is created.
- **Traffic-based lifetime**—Defines the maximum traffic that the SA can process.

If both lifetime timers are configured for an SA, the SA becomes invalid when either of the lifetime timers expires. Before the SA expires, IKE negotiates a new SA, which takes over immediately after its creation.

Authentication and encryption

Authentication algorithms

IPsec uses hash algorithms to perform authentication. A hash algorithm produces a fixed-length digest for an arbitrary-length message. IPsec peers respectively calculate message digests for each packet. The receiver compares the local digest with that received from the sender. If the digests are

identical, the receiver considers the packet intact and the sender's identity valid. IPsec uses the Hash-based Message Authentication Code (HMAC) based authentication algorithms, including HMAC-MD5 and HMAC-SHA1. Compared with HMAC-SHA1, HMAC-MD5 is faster but less secure.

Encryption algorithms

IPsec uses symmetric encryption algorithms, which encrypt and decrypt data by using the same keys. The following encryption algorithms are available for IPsec on the device:

- **DES**—Encrypts a 64-bit plaintext block with a 56-bit key. DES is the least secure but the fastest algorithm.
- **3DES**—Encrypts plaintext data with three 56-bit DES keys. The key length totals up to 168 bits. It provides moderate security strength and is slower than DES.
- **AES**—Encrypts plaintext data with a 128-bit, 192-bit, or 256-bit key. AES provides the highest security strength and is slower than 3DES.

IPsec-protected traffic

IPsec tunnels can protect the following types of traffic:

- Packets that match specific ACLs.
- Packets routed to a tunnel interface.
- Packets of IPv6 routing protocols.

Two peers use security policies (IPsec policies or IPsec profiles) to protect packets between them. A security policy defines the range of packets to be protected by IPsec and the security parameters used for the protection. For more information about IPsec policies and IPsec profiles, see "IPsec policy and IPsec profile."

The following information describes how IPsec protects packets:

- When an IPsec peer identifies the packets to be protected according to the security policy, it sets up an IPsec tunnel and sends the packet to the remote peer through the tunnel. The IPsec tunnel can be manually configured beforehand, or it can be set up through IKE negotiation triggered by the packet. The IPsec tunnels are actually the IPsec SAs. The inbound packets are protected by the inbound SA, and the outbound packets are protected by the outbound SA.
- When the remote IPsec peer receives the packet, it drops, de-encapsulates, or directly forwards the packet according to the configured security policy.

ACL-based IPsec

To implement ACL-based IPsec, configure an ACL to define the data flows to be protected, specify the ACL in an IPsec policy, and then apply the IPsec policy to an interface. You can apply an IPsec policy to physical interfaces such as Ethernet interfaces, or virtual interfaces such as tunnel interfaces.

ACL-based IPsec works as follows:

- When packets sent by the interface match a permit rule of the ACL, the packets are protected by the outbound IPsec SA and encapsulated with IPsec.
- When the interface receives an IPsec packet destined for the local device, it searches for the inbound IPsec SA according to the SPI in the IPsec packet header for de-encapsulation. If the de-encapsulated packet matches a permit rule of the ACL, the device processes the packet. If the de-encapsulated packet does not match any permit rule of the ACL, the device drops the packet.

The device supports the following data flow protection modes:

- **Standard mode**—One IPsec tunnel protects one data flow. The data flow permitted by an ACL rule is protected by one IPsec tunnel that is established solely for it.

- **Aggregation mode**—One IPsec tunnel protects all data flows permitted by all the rules of an ACL. This mode is only used to communicate with old-version devices.
- **Per-host mode**—One IPsec tunnel protects one host-to-host data flow. One host-to-host data flow is identified by one ACL rule and protected by one IPsec tunnel established solely for it. This mode consumes more system resources when multiple data flows exist between two subnets to be protected.

IPv6 routing protocol-based IPsec

You can implement IPv6 routing protocol-based IPsec by binding an IPsec profile to an IPv6 routing protocol. All packets of the protocol are encapsulated with IPsec. Supported IPv6 routing protocols include OSPFv3, IPv6 BGP, and RIPng.

All packets of the applications that are not bound to IPsec and the IPsec packets that failed to be de-encapsulated are dropped.

In one-to-many communication scenarios, you must configure the IPsec SAs for an IPv6 routing protocol in manual mode because of the following reasons:

- The automatic key exchange mechanism protects communications between two points. In one-to-many communication scenarios, automatic key exchange cannot be implemented.
- One-to-many communication scenarios require that all the devices use the same SA parameters (SPI and key) to receive and send packets. IKE negotiated SAs cannot meet this requirement.

IPsec policy and IPsec profile

IPsec policies and IPsec profiles define the parameters used to establish IPsec tunnels between two peers and the range of packets to be protected.

IPsec policy

An IPsec policy is a set of IPsec policy entries that have the same name but different sequence numbers.

An IPsec policy contains the following settings:

- An ACL that defines the range of data flows to be protected.
- An IPsec transform set that defines the security parameters used for IPsec protection.
- IPsec SA establishment mode.

  IPsec SAs can be established through manual configuration or IKE negotiation.
- Local and remote IP addresses that define the start and end points of the IPsec tunnel.

In the same IPsec policy, an IPsec policy entry with a smaller sequence number has a higher priority. When sending a packet, the interface applied with an IPsec policy looks through the IPsec policy's entries in ascending order of sequence numbers. If the packet matches the ACL of an IPsec policy entry, the interface encapsulates the packet according to the IPsec policy entry. If no match is found, the interface sends the packet out without IPsec protection.

When the interface receives an IPsec packet destined for the local device, it searches for the inbound IPsec SA according to the SPI in the IPsec packet header for de-encapsulation. If the de-encapsulated packet matches a permit rule of the ACL, the device processes the packet. If the de-encapsulated packet does not match a permit rule of the ACL, the device drops the packet.

IPsec profile

An IPsec profile has similar settings as an IPsec policy. It is uniquely identified by a name and does not support ACL configuration.

IPsec profiles can be classified into the following types:

- **Manual IPsec profile**—A manual IPsec profile is used to protect IPv6 routing protocols. It specifies the IPsec transform set used for protecting data flows, and the SPIs and keys used by the SAs.
- **IKE-based IPsec profile**—An IKE-based IPsec profile is applied to tunnel interfaces to protect tunneled traffic. It specifies the IPsec transform sets used for protecting data flows, and the IKE profile used for IKE negotiation.

Protocols and standards

- RFC 2401, *Security Architecture for the Internet Protocol*
- RFC 2402, *IP Authentication Header*
- RFC 2406, *IP Encapsulating Security Payload*
- RFC 4552, *Authentication/Confidentiality for OSPFv3*

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

Restrictions and guidelines: IPsec configuration

Typically, IKE uses UDP port 500 for communication, and AH and ESP use the protocol numbers 51 and 50, respectively. Make sure traffic of these protocols is not denied on the interfaces with IKE or IPsec configured.

Implementing ACL-based IPsec

ACLs for IPsec take effect only on traffic that is generated by the device and traffic that is destined for the device. They do not take effect on traffic forwarded through the device. For example, an ACL-based IPsec tunnel can protect log messages the device sends to a log server, but it does not protect data flows and voice flows that are forwarded by the device.

ACL-based IPsec tasks at a glance

To configure ACL-based IPsec, perform the following tasks:

1. Configuring an ACL
2. Configuring an IPsec transform set
3. Configuring an IPsec policy

   Choose one of the following tasks:
   - Configuring a manual IPsec policy
   - Configuring an IKE-based IPsec policy
4. Applying an IPsec policy to an interface
5. (Optional.) Configuring accessibility features for ACL-based IPsec
   - Enabling ACL checking for de-encapsulated packets
   - Configuring IPsec anti-replay
   - Configuring IPsec anti-replay redundancy

- Binding a source interface to an IPsec policy
- Enabling QoS pre-classify
- Configuring the DF bit of IPsec packets
- Configuring the global IPsec SA lifetime and idle timeout
- Configuring IPsec fragmentation
- Setting the maximum number of IPsec tunnels

6. (Optional.) Configuring logging and SNMP notification for IPsec.
   - Enabling logging for IPsec packets
   - Configuring SNMP notifications for IPsec

Configuring an ACL

IPsec uses ACLs to identify the traffic to be protected.

Keywords in ACL rules

An ACL is a collection of ACL rules. Each ACL rule is a deny or permit statement. A permit statement identifies a data flow protected by IPsec, and a deny statement identifies a data flow that is not protected by IPsec. IPsec compares a packet against the ACL rules and processes the packet according to the first rule it matches.

- Each ACL rule matches both the outbound traffic and the returned inbound traffic. Suppose there is a rule **rule 0 permit ip source 1.1.1.0 0.0.0.255 destination 2.2.2.0 0.0.0.255**. This rule matches both traffic from 1.1.1.0 to 2.2.2.0 and traffic from 2.2.2.0 to 1.1.1.0.
- In the outbound direction, if a permit statement is matched, IPsec considers that the packet requires protection and continues to process it. If a deny statement is matched or no match is found, IPsec considers that the packet does not require protection and delivers it to the next module.
- In the inbound direction:
  - Non-IPsec packets that match a permit statement are dropped.
  - IPsec packets destined for the device itself are de-encapsulated. By default, the de-encapsulated packets are compared against the ACL rules. Only those that match a permit statement are processed. Other packets are dropped. If ACL checking for de-encapsulated IPsec packets is disabled, the de-encapsulated packets are not compared against the ACL rules and are directly processed by other modules.

When defining ACL rules for IPsec, follow these guidelines:

- Permit only data flows that need to be protected and use the **any** keyword with caution. With the **any** keyword specified in a permit statement, all outbound traffic matching the permit statement will be protected by IPsec. All inbound IPsec packets matching the permit statement will be received and processed, but all inbound non-IPsec packets will be dropped. This will cause all the inbound traffic that does not need IPsec protection to be dropped.
- Avoid statement conflicts in the scope of IPsec policy entries. When creating a deny statement, be careful with its match scope and match order relative to permit statements. The policy entries in an IPsec policy have different match priorities. ACL rule conflicts between them are prone to cause mistreatment of packets. For example, when configuring a permit statement for an IPsec policy entry to protect an outbound traffic flow, you must avoid the situation that the traffic flow matches a deny statement in a higher priority IPsec policy entry. Otherwise, the packets will be sent out as normal packets. If they match a permit statement at the receiving end, they will be dropped by IPsec.

The following example shows how an improper statement causes unexpected packet dropping. Only the ACL-related configuration is presented.

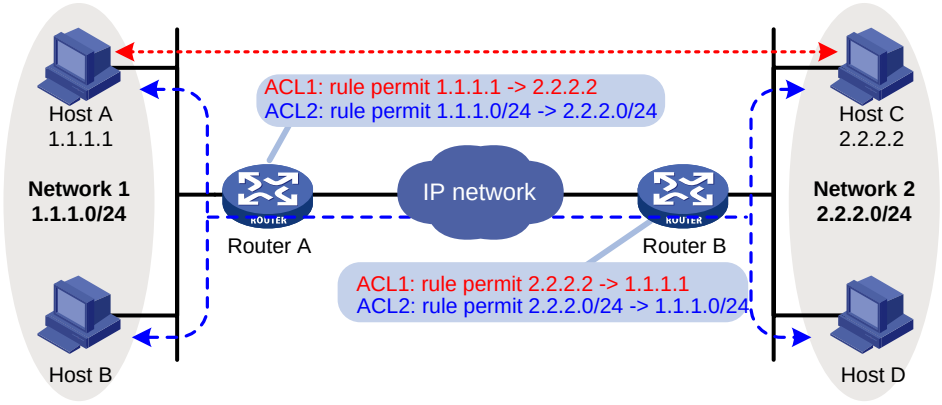
Assume Router A is connected to subnet 1.1.2.0/24 and Router B is connected to subnet 3.3.3.0/24, and the IPsec policy configuration on Router A and Router B is as follows:

- IPsec configuration on Router A:

```
acl advanced 3000
 rule 0 permit ip source 1.1.1.0 0.0.0.255 destination 2.2.2.0 0.0.0.255
 rule 1 deny ip
acl advanced 3001
 rule 0 permit ip source 1.1.2.0 0.0.0.255 destination 3.3.3.0 0.0.0.255
 rule 1 deny ip
#
ipsec policy testa 1 isakmp <---IPsec policy entry with a higher priority
 security acl 3000
 ike-profile aa
 transform-set 1
#
ipsec policy testa 2 isakmp <---IPsec policy entry with a lower priority
 security acl 3001
 ike-profile bb
 transform-set 1
```

- IPsec configuration on Router B:

```
acl advanced 3001
 rule 0 permit ip source 3.3.3.0 0.0.0.255 destination 1.1.2.0 0.0.0.255
 rule 1 deny ip
#
ipsec policy testb 1 isakmp
 security acl 3001
 ike-profile aa
 transform-set 1
```



On Router A, apply the IPsec policy **testa** to the outbound interface of Router A. The IPsec policy contains two policy entries, **testa 1** and **testa 2**. The ACLs used by the two policy entries each contain a rule that matches traffic from 1.1.2.0/24 to 3.3.3.0/24. The one used in the policy entry **testa 1** is a deny statement and the one used in the policy entry **testa 2** is a permit statement. Because **testa 1** is matched prior to **testa 2**, traffic from 1.1.2.0/24 to 3.3.3.0/24 will match the deny statement and be sent as normal traffic. When the traffic arrives at Router B, the traffic matches rule 0 (a permit statement) in ACL 3001 used in the applied IPsec policy **testb**. Because non-IPsec traffic that matches a permit statement must be dropped on the inbound interface, Router B drops the traffic.

To make sure subnet 1.1.2.0/24 can access subnet 3.3.3.0/24, you can delete the deny rule in ACL 3000 on Router A.

Mirror image ACLs

To make sure SAs can be set up and the traffic protected by IPsec can be processed correctly between two IPsec peers, create mirror image ACLs on the IPsec peers. As shown in Figure 4, ACL rules on Router B are mirror images of the rules on Router A. In this way, SAs can be created successfully for the traffic between Host A and Host C and for the traffic between Network 1 and Network 2.

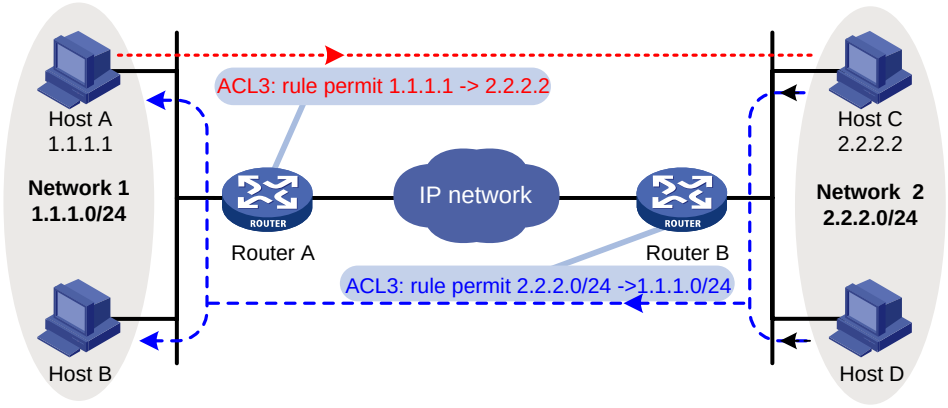


Figure 4 Mirror image ACLs

If the ACL rules on IPsec peers do not form mirror images of each other, SAs can be set up only when both of the following requirements are met:

- The range specified by an ACL rule on one peer is covered by its counterpart ACL rule on the other peer. As shown in Figure 5, the range specified by the ACL rule configured on Router A is covered by its counterpart on Router B.
- The peer with the narrower rule initiates SA negotiation. If a wider ACL rule is used by the SA initiator, the negotiation request might be rejected because the matching traffic is beyond the scope of the responder. As shown in Figure 5, the SA negotiation initiated by Host A to Host C is accepted but the SA negotiations from Host C to Host A, from Host C to Host B, and from Host D to Host A are rejected.

Figure 5 Non-mirror image ACLs

Configuring an IPsec transform set

About this task

An IPsec transform set, part of an IPsec policy, defines the security parameters for IPsec SA negotiation, including the security protocol, encryption algorithms, and authentication algorithms.

Restrictions and guidelines

Changes to an IPsec transform set affect only SAs negotiated after the changes. To apply the changes to existing SAs, execute the reset ipsec sa command to clear the SAs so that they can be set up by using the updated parameters.

In FIPS mode, you must specify both the ESP encryption algorithm and the ESP authentication algorithm for an IPsec transform set that uses the ESP security protocol.

When you set the packet encapsulation mode (tunnel or transport) for an IPsec transform set, follow these guidelines:

- The transport mode applies only when the source and destination IP addresses of data flows match those of the IPsec tunnel.
- IPsec for IPv6 routing protocols supports only the transport mode.

When you configure the Perfect Forward Secrecy (PFS) feature in an IPsec transform set, follow these guidelines:

- In IKEv1, the security level of the DH group of the initiator must be higher than or equal to that of the responder. This restriction does not apply to IKEv2.
- The end without the PFS feature performs SA negotiation according to the PFS requirements of the peer end.

You can specify multiple authentication or encryption algorithms for the same security protocol. The algorithm specified earlier has a higher priority.

Some algorithms are available only for IKEv2. See Table 1.

Table 1 Algorithms available only for IKEv2

Type	Algorithms
Encryption algorithm	aes-ctr-128 aes-ctr-192 aes-ctr-256 camellia-cbc-128 camellia-cbc-192 camellia-cbc-256 gmac-128 gmac-192 gmac-256 gcm-128 gcm-192 gcm-256
Authentication algorithm	aes-xcbc-mac
PFS algorithm	dh-group19 dh-group20

Procedure

1. Enter system view.

   system-view

2. Create an IPsec transform set and enter its view.

   ipsec transform-set *transform-set-name*

3. Specify the security protocol for the IPsec transform set.

   protocol { **ah** | **ah-esp** | **esp** }

   By default, the ESP security protocol is used.

4. Specify the encryption algorithms for ESP. Skip this step if the **protocol ah** command is configured.

   In non-FIPS mode:

   esp encryption-algorithm { **3des-cbc** | **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** | **aes-ctr-128** | **aes-ctr-192** | **aes-ctr-256** |

camellia-cbc-128 | **camellia-cbc-192** | **camellia-cbc-256** | **des-cbc** | **gmac-128** | **gmac-192** | **gmac-256** | **gcm-128** | **gcm-192** | **gcm-256** | **null** } *

By default, no encryption algorithm is specified for ESP.

In FIPS mode:

esp encryption-algorithm { **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** | **aes-ctr-128** | **aes-ctr-192** | **aes-ctr-256** | **gmac-128** | **gmac-192** | **gmac-256** | **gcm-128** | **gcm-192** | **gcm-256** } *

By default, no encryption algorithm is specified for ESP.

5. Specify the authentication algorithms for ESP. Skip this step if the **protocol ah** command is configured.

   In non-FIPS mode:

   esp authentication-algorithm { **aes-xcbc-mac** | **md5** | **sha1** | **sha256** | **sha384** | **sha512** } *

   By default, no authentication algorithm is specified for ESP.

   The **aes-xcbc-mac** algorithm is available only for IKEv2.

   In FIPS mode:

   esp authentication-algorithm { **sha1** | **sha256** | **sha384** | **sha512** } *

   By default, no authentication algorithm is specified for ESP.

6. Specify the authentication algorithms for AH. Skip this step if the **protocol esp** command is configured.

   In non-FIPS mode:

   ah authentication-algorithm { **aes-xcbc-mac** | **md5** | **sha1** | **sha256** | **sha384** | **sha512** } *

   By default, no authentication algorithm is specified for AH.

   The **aes-xcbc-mac** algorithm is available only for IKEv2.

   In FIPS mode:

   ah authentication-algorithm { **sha1** | **sha256** | **sha384** | **sha512** } *

   By default, no authentication algorithm is specified for AH.

7. Specify the packet encapsulation mode.

   encapsulation-mode { **transport** | **tunnel** }

   By default, the security protocol encapsulates IP packets in tunnel mode.

8. (Optional.) Enable the PFS feature.

   In non-FIPS mode:

   pfs { **dh-group1** | **dh-group2** | **dh-group5** | **dh-group14** | **dh-group24** | **dh-group19** | **dh-group20** }

   In FIPS mode:

   pfs { **dh-group14** | **dh-group19** | **dh-group20** }

   By default, the PFS feature is disabled.

   For more information about PFS, see "Configuring IKE."

9. (Optional.) Enable the Extended Sequence Number (ESN) feature.

   esn enable [**both**]

   By default, the ESN feature is disabled.

Configuring a manual IPsec policy

In a manual IPsec policy, the parameters are configured manually, such as the keys, the SPIs, and the IP addresses of the two ends in tunnel mode.

Restrictions and guidelines

When you configure a manual IPsec policy, make sure the IPsec configuration at both ends of the IPsec tunnel meets the following requirements:

- The IPsec policies at the two ends must have IPsec transform sets that use the same security protocols, security algorithms, and encapsulation mode.
- The remote IPv4 address configured on the local end must be the same as the primary IPv4 address of the interface applied with the IPsec policy at the remote end. The remote IPv6 address configured on the local end must be the same as the first IPv6 address of the interface applied with the IPsec policy at the remote end.
- At each end, configure parameters for both the inbound SA and the outbound SA, and make sure the SAs in each direction are unique: For an outbound SA, make sure its triplet (remote IP address, security protocol, and SPI) is unique. For an inbound SA, make sure its SPI is unique.
- The local inbound SA must use the same SPI and keys as the remote outbound SA. The same is true of the local outbound SA and remote inbound SA.
- The keys for the IPsec SAs at the two tunnel ends must be configured in the same format. For example, if the local end uses a key in hexadecimal format, the remote end must also use a key in hexadecimal format. If you configure a key in both the character and the hexadecimal formats, only the most recent configuration takes effect.
- If you configure a key in character format for ESP, the device automatically generates an authentication key and an encryption key for ESP.

Procedure

1. Enter system view.

   system-view

2. Create a manual IPsec policy entry and enter its view.

   ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* **manual**

3. (Optional.) Configure a description for the IPsec policy.

   description *text*

   By default, no description is configured.

4. Specify an ACL for the IPsec policy.

   security acl [**ipv6**] { *acl-number* | **name** *acl-name* }

   By default, no ACL is specified for an IPsec policy.

   You can specify only one ACL for an IPsec policy.

5. Specify an IPsec transform set for the IPsec policy.

   transform-set *transform-set-name*

   By default, no IPsec transform set is specified for an IPsec policy.

   You can specify only one IPsec transform set for a manual IPsec policy.

6. Specify the remote IP address of the IPsec tunnel.

   remote-address { *ipv4-address* | **ipv6** *ipv6-address* }

   By default, the remote IP address of the IPsec tunnel is not specified.

7. Configure an SPI for the inbound IPsec SA.

   sa spi inbound { **ah** | **esp** } *spi-number*

   By default, no SPI is configured for the inbound IPsec SA.

8. Configure an SPI for the outbound IPsec SA.

   sa spi outbound { **ah** | **esp** } *spi-number*

   By default, no SPI is configured for the outbound IPsec SA.

9. Configure keys for the IPsec SA.
   - Configure an authentication key in hexadecimal format for AH.

     sa hex-key authentication { **inbound** | **outbound** } **ah** { **cipher** | **simple** } *string*
   - Configure an authentication key in character format for AH.

     sa string-key { **inbound** | **outbound** } **ah** { **cipher** | **simple** } *string*
   - Configure a key in character format for ESP.

     sa string-key { **inbound** | **outbound** } **esp** { **cipher** | **simple** } *string*
   - Configure an authentication key in hexadecimal format for ESP.

     sa hex-key authentication { **inbound** | **outbound** } **esp** { **cipher** | **simple** }
   - Configure an encryption key in hexadecimal format for ESP.

     sa hex-key encryption { **inbound** | **outbound** } **esp** { **cipher** | **simple** } *string*

   By default, no keys are configured for the IPsec SA.

   Configure keys correctly for the security protocol (AH, ESP, or both) you have specified in the IPsec transform set used by the IPsec policy.

Configuring an IKE-based IPsec policy

About this task

In an IKE-based IPsec policy, the parameters are automatically negotiated through IKE.

To configure an IKE-based IPsec policy, use one of the following methods:

- Directly configure it by configuring the parameters in IPsec policy view.
- Configure it by using an existing IPsec policy template with the parameters to be negotiated configured.

  A device using an IPsec policy that is configured in this way cannot initiate an SA negotiation, but it can respond to a negotiation request. The parameters not defined in the template are determined by the initiator. For example, in an IPsec policy template, the ACL is optional. If you do not specify an ACL, the IPsec protection range has no limit. So the device accepts all ACL settings of the negotiation initiator.

  When the remote end's information (such as the IP address) is unknown, this method allows the remote end to initiate negotiations with the local end.

The configurable parameters for an IPsec policy template are the same as those when you directly configure an IKE-based IPsec policy. The difference is that more parameters are optional for an IPsec policy template. Except the IPsec transform sets and the IKE profile, all other parameters are optional.

Restrictions and guidelines for IKE-based IPsec policy configuration

The IPsec policies at the two tunnel ends must have IPsec transform sets that use the same security protocols, security algorithms, and encapsulation mode.

The IPsec policies at the two tunnel ends must have the same IKE profile parameters.

An IKE-based IPsec policy can use a maximum of six IPsec transform sets. During an IKE negotiation, IKE searches for a fully matched IPsec transform set at the two ends of the IPsec tunnel. If no match is found, no SA can be set up, and the packets expecting to be protected will be dropped.

The remote IP address of the IPsec tunnel is required on an IKE negotiation initiator and is optional on the responder. The remote IP address specified on the local end must be the same as the local IP address specified on the remote end.

The IPsec SA uses the local lifetime settings or those proposed by the peer, whichever are smaller.

The IPsec SA can have both a time-based lifetime and a traffic-based lifetime. The IPsec SA expires when either lifetime expires.

If you specify both an IKEv1 profile and an IKEv2 profile for an IPsec policy, the IKEv2 profile is used preferentially. For more information about IKEv1 and IKEv2 profiles, see "Configuring IKE" and "Configuring IKEv2."

Directly configuring an IKE-based IPsec policy

1. Enter system view.

   system-view

2. Create an IKE-based IPsec policy entry and enter its view.

   ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* **isakmp**

3. (Optional.) Configure a description for the IPsec policy.

   description *text*

   By default, no description is configured.

4. Specify an ACL for the IPsec policy.

   security acl [**ipv6**] { *acl-number* | **name** *acl-name* } [**aggregation** | **per-host**]

   By default, no ACL is specified for an IPsec policy.

   You can specify only one ACL for an IPsec policy.

5. Specify IPsec transform sets for the IPsec policy.

   transform-set *transform-set-name*&<1-6>

   By default, no IPsec transform sets are specified for an IPsec policy.

6. Specify an IKE profile or IKEv2 profile for the IPsec policy.
   - Specify an IKE profile.

     ike-profile *profile-name*

     By default, no IKE profile is specified for an IPsec policy.
   - Specify an IKEv2 profile.

     ikev2-profile *profile-name*

     By default, no IKEv2 profile is specified for an IPsec policy.

7. Specify the local IP address of the IPsec tunnel.

   local-address { *ipv4-address* | **ipv6** *ipv6-address* }

   By default, the local IPv4 address of the IPsec tunnel is the primary IPv4 address of the interface to which the IPsec policy is applied. The local IPv6 address of the IPsec tunnel is the first IPv6 address of the interface to which the IPsec policy is applied.

   The local IP address specified by this command must be the same as the IP address used as the local IKE identity.

   In a VRRP network, the local IP address must be the virtual IP address of the VRRP group to which the IPsec-applied interface belongs.

8. Specify the remote IP address of the IPsec tunnel.

   remote-address { [**ipv6**] *host-name* | *ipv4-address* | **ipv6** *ipv6-address* }

   By default, the remote IP address of the IPsec tunnel is not specified.

9. (Optional.) Set the lifetime or idle timeout for the IPsec SA.

- Set the IPsec SA lifetime.

  sa duration { **time-based** *seconds* | **traffic-based** *kilobytes* }

  By default, the global SA lifetime is used.
- Set the IPsec SA idle timeout.

  sa idle-time *seconds*

  By default, the global IPsec SA idle timeout is used.

10. (Optional.) Enable the Traffic Flow Confidentiality (TFC) padding feature.

tfc enable

By default, the TFC padding feature is disabled.

TFC padding applies only to IPsec SAs negotiated by IKEv2.

Configuring an IKE-based IPsec policy by using an IPsec policy template

1. Enter system view.

system-view

2. Create an IPsec policy template and enter its view.

ipsec { **ipv6-policy-template** | **policy-template** } *template-name seq-number*

3. (Optional.) Configure a description for the IPsec policy template.

description *text*

By default, no description is configured.

4. (Optional.) Specify an ACL for the IPsec policy template.

security acl [**ipv6**] { *acl-number* | **name** *acl-name* } [**aggregation** | **per-host**]

By default, no ACL is specified for an IPsec policy template.

You can specify only one ACL for an IPsec policy template.

5. Specify IPsec transform sets for the IPsec policy template.

transform-set *transform-set-name*&<1-6>

By default, no IPsec transform sets are specified for an IPsec policy template.

6. Specify an IKE profile or IKEv2 profile for the IPsec policy template.

- Specify an IKE profile.

  ike-profile *profile-name*

  By default, no IKE profile is specified for an IPsec policy template.

  Make sure the specified IKE profile is not used by another IPsec policy or IPsec policy template.
- Specify an IKEv2 profile.

  ikev2-profile *profile-name*

  By default, no IKEv2 profile is specified for an IPsec policy template.

7. Specify the local IP address of the IPsec tunnel.

local-address { *ipv4-address* | **ipv6** *ipv6-address* }

The default local IPv4 address and IPv6 address is the primary IPv4 address and first IPv6 address of the interface where the IPsec policy is applied.

The local IP address specified by this command must be the same as the IP address used as the local IKE identity.

In a VRRP network, the local IP address must be the virtual IP address of the VRRP group to which the IPsec-applied interface belongs.

8. Specify the remote IP address of the IPsec tunnel.

remote-address { [**ipv6**] *host-name* | *ipv4-address* | **ipv6** *ipv6-address* }

By default, the remote IP address of the IPsec tunnel is not specified.

9. (Optional.) Set the lifetime and idle timeout for the IPsec SA.
   - Set the IPsec SA lifetime.

     sa duration { **time-based** *seconds* | **traffic-based** *kilobytes* }

     By default, the global SA lifetime is used.
   - Set the IPsec SA idle timeout.

     sa idle-time *seconds*

     By default, the global IPsec SA idle timeout is used.
10. (Optional.) Enable the Traffic Flow Confidentiality (TFC) padding feature.

    tfc enable

    By default, the TFC padding feature is disabled.

    TFC padding applies only to IPsec SAs negotiated by IKEv2.
11. Return to system view.

    quit
12. Create an IPsec policy by using the IPsec policy template.

    ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* **isakmp template** *template-name*

Applying an IPsec policy to an interface

Restrictions and guidelines

You can apply an IPsec policy to interfaces to protect data flows.

- An IKE-based IPsec policy can be applied to multiple interfaces. As a best practice, apply an IKE-based IPsec policy to only one interface.
- A manual IPsec policy can be applied to only one interface.

To cancel the IPsec protection, remove the application of the IPsec policy.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Apply an IPsec policy to the interface.

   ipsec apply { **ipv6-policy** | **policy** } *policy-name*

   By default, no IPsec policy is applied to an interface.

   On one interface, you can apply a maximum of two IPsec policies: one IPv4 IPsec policy and one IPv6 IPsec policy.
4. Specify a traffic processing slot for the interface.

   service slot *slot-number*

   By default, no traffic processing slot is specified for an interface. Traffic on an interface is processed on the slot at which the traffic arrives.

   This step is required when the following conditions are met:
   - An IKE-based IPsec policy is applied to a global logical interface, such as VLAN interface and tunnel interface.

- The IPsec anti-replay feature is globally enabled.

Enabling ACL checking for de-encapsulated packets

About this task

This feature compares the de-encapsulated incoming IPsec packets against the ACL in the IPsec policy and discards those that do not match any permit rule of the ACL. This feature can protect networks against attacks using forged IPsec packets.

This feature applies only to tunnel-mode IPsec.

Procedure

1. Enter system view.

   `system-view`

2. Enable ACL checking for de-encapsulated packets.

   `ipsec decrypt-check enable`

   By default, ACL checking for de-encapsulated packets is enabled.

Configuring IPsec anti-replay

About this task

IPsec anti-replay protects networks against anti-replay attacks by using a sliding window mechanism called anti-replay window. This feature checks the sequence number of each received IPsec packet against the current IPsec packet sequence number range of the sliding window. If the sequence number is not in the current sequence number range, the packet is considered a replayed packet and is discarded.

IPsec packet de-encapsulation involves complicated calculation. De-encapsulation of replayed packets is not required, and the de-encapsulation process consumes large amounts of resources and degrades performance, resulting in DoS. IPsec anti-replay can check and discard replayed packets before de-encapsulation.

In some situations, service data packets are received in a different order than their original order. The IPsec anti-replay feature drops them as replayed packets, which impacts communications. If this happens, disable IPsec anti-replay checking or adjust the size of the anti-replay window as required.

Restrictions and guidelines

IPsec anti-replay does not affect manually created IPsec SAs. According to the IPsec protocol, only IKE-based IPsec SAs support anti-replay.

Set the anti-replay window size as small as possible to reduce the impact on system performance.

IPsec anti-replay requires that packets on the same interface be processed on the same slot. To perform IPsec anti-replay on a multichassis IRF fabric for a global interface, use the **`service`** command in interface view to specify a service processing slot for that interface. Global interfaces (such as VLAN or tunnel interfaces) are virtual interfaces that might have physical ports across the IRF member devices. For more information about the **`service`** command, see VLAN commands in *Layer 2—LAN Switching Command Reference* or tunneling commands in *Layer 3—IP Services Command Reference*.

Failure to detect anti-replay attacks might result in denial of services. If you want to disable IPsec anti-replay, make sure you understand the impact of the operation on network security.

Procedure

1. Enter system view.

system-view

2. Enable IPsec anti-replay.

   ipsec anti-replay check

   By default, IPsec anti-replay is enabled.

3. Set the size of the IPsec anti-replay window.

   ipsec anti-replay window *width*

   The default size is 64.

Configuring IPsec anti-replay redundancy

About this task

This feature synchronizes the following information from the active device to the standby device at configurable packet-based intervals:

- Lower bound values of the IPsec anti-replay window for inbound packets.
- IPsec anti-replay sequence numbers for outbound packets.

This feature, used together with IPsec redundancy, ensures uninterrupted IPsec traffic forwarding and anti-replay protection when the active device fails.

Procedure

1. Enter system view.

   system-view

2. Enable IPsec redundancy.

   ipsec redundancy enable

   By default, IPsec redundancy is disabled.

3. Enter IPsec policy view or IPsec policy template view.
   - Enter IPsec policy view.

     ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* [**isakmp** | **manual**]

   - Enter IPsec policy template view.

     ipsec { **ipv6-policy-template** | **policy-template** } *template-name seq-number*

4. Set the anti-replay window synchronization interval for inbound packets and the sequence number synchronization interval for outbound packets.

   redundancy replay-interval inbound *inbound-interval* **outbound** *outbound-interval*

   By default, the active device synchronizes the anti-replay window every time it receives 1000 packets and synchronizes the sequence number every time it sends 100000 packets.

Binding a source interface to an IPsec policy

About this task

For high availability, a core device is usually connected to an ISP through two links, which operate in backup or load sharing mode. The two interfaces negotiate with their peers to establish IPsec SAs respectively. When one interface fails and a link failover occurs, the other interface needs to take some time to renegotiate SAs, resulting in service interruption.

To solve these problems, bind a source interface to an IPsec policy and apply the policy to both interfaces. This enables the two physical interfaces to use the same source interface to negotiate

IPsec SAs. As long as the source interface is up, the negotiated IPsec SAs will not be removed and will keep working, regardless of link failover.

Restrictions and guidelines

Only the IKE-based IPsec policies can be bound to a source interface.

An IPsec policy can be bound to only one source interface.

A source interface can be bound to multiple IPsec policies.

If the source interface bound to an IPsec policy is removed, the IPsec policy becomes a common IPsec policy.

If no local address is specified for an IPsec policy that has been bound to a source interface, the IPsec policy uses the IP address of the bound source interface to perform IKE negotiation. If a local address is specified, the IPsec policy uses the local address to perform IKE negotiation.

Procedure

1. Enter system view.

   system-view

2. Bind a source interface to an IPsec policy.

   ipsec { **ipv6-policy** | **policy** } *policy-name* **local-address** *interface-type interface-number*

   By default, no source interface is bound to an IPsec policy.

Enabling QoS pre-classify

About this task

When both an IPsec policy and a QoS policy are applied to an interface, QoS classifies packets by using the new headers added by IPsec. If you want QoS to classify packets by using the headers of the original IP packets, enable the QoS pre-classify feature.

Restrictions and guidelines

If you configure both IPsec and QoS on an interface, make sure the IPsec traffic classification rules match the QoS traffic classification rules. If the rules do not match, QoS might classify the packets of one IPsec SA to different queues, causing packets to be sent out of order. When IPsec anti-replay is enabled, IPsec will drop the incoming packets that are out of the anti-replay window, resulting in packet loss.

IPsec traffic classification rules are determined by the rules of the specified ACL. For more information about QoS policy and classification, see *ACL and QoS Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter IPsec policy view or IPsec policy template view.

   - Enter IPsec policy view.

     ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* [**isakmp** | **manual**]

   - Enter IPsec policy template view.

     ipsec { **ipv6-policy-template** | **policy-template** } *template-name seq-number*

3. Enable QoS pre-classify.

   qos pre-classify

By default, QoS pre-classify is disabled.

Configuring the DF bit of IPsec packets

About this task

Perform this task to configure the Don't Fragment (DF) bit in the new IP header of IPsec packets in one of the following ways:

- **clear**—Clears the DF bit in the new header.
- **set**—Sets the DF bit in the new header.
- **copy**—Copies the DF bit in the original IP header to the new IP header.

You can configure the DF bit in system view and interface view. The interface-view DF bit setting takes precedence over the system-view DF bit setting. If the interface-view DF bit setting is not configured, the interface uses the system-view DF bit setting.

Restrictions and guidelines for DF bit configuration for IPsec packets

The DF bit setting takes effect only in tunnel mode, and it changes the DF bit in the new IP header rather than the original IP header.

Configure the same DF bit setting on the interfaces where the same IPsec policy bound to a source interface is applied.

If the DF bit is set, the devices on the path cannot fragment the IPsec packets. To prevent IPsec packets from being discarded, make sure the path MTU is larger than the IPsec packet size. As a best practice, clear the DF bit if you cannot make sure the path MTU is larger than the IPsec packet size.

Configuring the DF bit of IPsec packets on an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the DF bit of IPsec packets on the interface.
   ipsec df-bit { **clear** | **copy** | **set** }
   By default, the interface uses the global DF bit setting.

Configuring the DF bit of IPsec packets globally

1. Enter system view.
   system-view
2. Configure the DF bit of IPsec packets globally.
   ipsec global-df-bit { **clear** | **copy** | **set** }
   By default, IPsec copies the DF bit in the original IP header to the new IP header.

Configuring IPsec for IPv6 routing protocols

IPsec protection for IPv6 routing protocols tasks at a glance

To configure IPsec protection for IPv6 routing protocols, perform the following tasks:

1. Configuring an IPsec transform set
2. Configuring a manual IPsec profile

3. Applying the IPsec profile to an IPv6 routing protocol
4. (Optional.) Configuring IPsec fragmentation
5. (Optional.) Setting the maximum number of IPsec tunnels
6. (Optional.) Enabling logging for IPsec packets
7. (Optional.) Configuring SNMP notifications for IPsec

Configuring a manual IPsec profile

About this task

A manual IPsec profile specifies the IPsec transform set used for protecting data flows, and the SPIs and keys used by the SAs.

Restrictions and guidelines

When you configure a manual IPsec profile, make sure the IPsec profile configuration at both tunnel ends meets the following requirements:

- The IPsec transform set specified in the IPsec profile at the two tunnel ends must have the same security protocol, encryption and authentication algorithms, and packet encapsulation mode.
- The local inbound and outbound IPsec SAs must have the same SPI and key.
- The IPsec SAs on the devices in the same scope must have the same key. The scope is defined by protocols. For OSPFv3, the scope consists of OSPFv3 neighbors or an OSPFv3 area. For RIPng, the scope consists of directly-connected neighbors or a RIPng process. For BGP, the scope consists of BGP peers or a BGP peer group.
- The keys for the IPsec SAs at the two tunnel ends must be configured in the same format. For example, if the local end uses a key in hexadecimal format, the remote end must also use a key in hexadecimal format. If you configure a key in both the character and the hexadecimal formats, only the most recent configuration takes effect.
- If you configure a key in character format for ESP, the device automatically generates an authentication key and an encryption key for ESP.

Procedure

1. Enter system view.

   system-view
2. Create a manual IPsec profile and enter its view.

   ipsec profile *profile-name* **manual**

   The **manual** keyword is not needed if you enter the view of an existing IPsec profile.
3. (Optional.) Configure a description for the IPsec profile.

   description *text*

   By default, no description is configured.
4. Specify an IPsec transform set.

   transform-set *transform-set-name*

   By default, no IPsec transform set is specified in an IPsec profile.

   The specified IPsec transform set must use the transport mode.
5. Configure an SPI for an SA.

   sa spi { **inbound** | **outbound** } { **ah** | **esp** } *spi-number*

   By default, no SPI is configured for an SA.
6. Configure keys for the IPsec SA.
   - Configure an authentication key in hexadecimal format for AH.

sa hex-key authentication { **inbound** | **outbound** } **ah** { **cipher** | **simple** } *string*

- Configure an authentication key in character format for AH.

  sa string-key { **inbound** | **outbound** } **ah** { **cipher** | **simple** } *string*

- Configure a key in character format for ESP.

  sa string-key { **inbound** | **outbound** } **esp** { **cipher** | **simple** } *string*

- Configure an authentication key in hexadecimal format for ESP.

  sa hex-key authentication { **inbound** | **outbound** } **esp** { **cipher** | **simple** }

- Configure an encryption key in hexadecimal format for ESP.

  sa hex-key encryption { **inbound** | **outbound** } **esp** { **cipher** | **simple** } *string*

By default, no keys are configured for the IPsec SA.

Configure a key for the security protocol (AH, ESP, or both) you have specified.

Applying the IPsec profile to an IPv6 routing protocol

For information about the configuration procedure, see IPv6 BGP, OSPFv3, and RIPng configuration in *Layer 3—IP Routing Configuration Guide*.

Configuring the global IPsec SA lifetime and idle timeout

About this task

If the IPsec SA lifetime and idle timeout are not configured in an IPsec policy, IPsec policy template, or IPsec profile, the global settings are used.

When IKE negotiates IPsec SAs, it uses the local lifetime settings or those proposed by the peer, whichever are smaller.

An IPsec SA can have both a time-based lifetime and a traffic-based lifetime. The IPsec SA expires when either lifetime expires.

Procedure

1. Enter system view.

   system-view

2. Set the global IPsec SA lifetime or idle timeout.

   - Set the global IPsec SA lifetime.

     ipsec sa global-duration { **time-based** *seconds* | **traffic-based** *kilobytes* }

     By default, the time-based SA lifetime is 3600 seconds, and the traffic-based SA lifetime is 1843200 kilobytes.

   - Set the global SA idle timeout.

     ipsec sa idle-time *seconds*

     By default, the global IPsec SA idle timeout feature is disabled.

Configuring IPsec fragmentation

About this task

Perform this task to configure the device to fragment packets before or after IPsec encapsulation.

If you configure the device to fragment packets before IPsec encapsulation, the device predetermines the encapsulated packet size before the actual encapsulation. If the encapsulated packet size exceeds the MTU of the output interface, the device fragments the packets before encapsulation. If a packet's DF bit is set, the device drops the packet and sends an ICMP error message.

If you configure the device to fragment packets after IPsec encapsulation, the device directly encapsulates the packets and fragments the encapsulated packets in subsequent service modules.

Restrictions and guidelines

This feature takes effect on IPsec protected IPv4 packets.

Procedure

1. Enter system view.
   system-view
2. Configure IPsec fragmentation.
   ipsec fragmentation { **after-encryption** | **before-encryption** }
   By default, the device fragments packets before IPsec encapsulation.

Setting the maximum number of IPsec tunnels

Restrictions and guidelines

To maximize concurrent performance of IPsec when memory is sufficient, increase the maximum number of IPsec tunnels. To ensure service availability when memory is insufficient, decrease the maximum number of IPsec tunnels.

Procedure

1. Enter system view.
   system-view
2. Set the maximum number of IPsec tunnels.
   ipsec limit max-tunnel *tunnel-limit*
   The number of IPsec tunnels is not limited.

Enabling logging for IPsec packets

About this task

Perform this task to enable logging for IPsec packets that are discarded for reasons such as IPsec SA lookup failure, AH-ESP authentication failure, and ESP encryption failure. The log information includes the source and destination IP addresses, SPI value, and sequence number of a discarded IPsec packet, and the reason for the discard.

Procedure

1. Enter system view.
   system-view
2. Enable logging for IPsec packets.

ipsec logging packet enable

By default, logging for IPsec packets is disabled.

Configuring SNMP notifications for IPsec

About this task

After you enable SNMP notifications for IPsec, the IPsec module notifies the NMS of important module events. The notifications are sent to the device's SNMP module. For the notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP notifications, see *Network Management and Monitoring Configuration Guide*.

To generate and output SNMP notifications for a specific IPsec failure or event type, perform the following tasks:

1. Enable SNMP notifications for IPsec globally.
2. Enable SNMP notifications for the failure or event type.

Procedure

1. Enter system view.

   system-view
2. Enable SNMP notifications for IPsec globally.

   snmp-agent trap enable ipsec global

   By default, SNMP notifications for IPsec are disabled.
3. Enable SNMP notifications for the specified failure or event types.

   snmp-agent trap enable ipsec [**auth-failure** | **decrypt-failure** | **encrypt-failure** | **invalid-sa-failure** | **no-sa-failure** | **policy-add** | **policy-attach** | **policy-delete** | **policy-detach** | **tunnel-start** | **tunnel-stop**] *

   By default, SNMP notifications for all failure and event types are disabled.

Display and maintenance commands for IPsec

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display IPsec policy information.	**display ipsec** { **ipv6-policy** | **policy** } [*policy-name* [*seq-number*]]
Display IPsec policy template information.	**display ipsec** { **ipv6-policy-template** | **policy-template** } [*template-name* [*seq-number*]]
Display IPsec profile information.	**display ipsec profile** [*profile-name*]
Display IPsec SA information.	**display ipsec sa** [**brief** | **count** | **interface** *interface-type interface-number* | { **ipv6-policy** | **policy** } *policy-name* [*seq-number*] | **profile** *profile-name* | **remote** [**ipv6**] *ip-address*]
Display IPsec statistics.	**display ipsec statistics** [**tunnel-id** *tunnel-id*]

Task	Command
Display IPsec transform set information.	**display ipsec transform-set** [*transform-set-name*]
Display IPsec tunnel information.	**display ipsec tunnel** { **brief** | **count** | **tunnel-id** *tunnel-id* }
Clear IPsec SAs.	**reset ipsec sa** [{ **ipv6-policy** | **policy** } *policy-name* [*seq-number*] | **profile** *policy-name* | **remote** { *ipv4-address* | **ipv6** *ipv6-address* } | **spi** { *ipv4-address* | **ipv6** *ipv6-address* } { **ah** | **esp** } *spi-num*]
Clear IPsec statistics.	**reset ipsec statistics** [**tunnel-id** *tunnel-id*]

IPsec configuration examples

Example: Configuring a manual mode IPsec tunnel for IPv4 packets

Network configuration

As shown in Figure 6, establish an IPsec tunnel between Switch A and Switch B to protect data flows between the switches. Configure the tunnel as follows:

- Specify the encapsulation mode as tunnel, the security protocol as ESP, the encryption algorithm as AES-CBC-192, and the authentication algorithm as HMAC-SHA1.
- Manually set up IPsec SAs.

Figure 6 Network diagram

Procedure

1. Configure Switch A:

   # Configure an IP address for VLAN-interface 1.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 1
   [SwitchA-Vlan-interface1] ip address 2.2.2.1 255.255.255.0
   [SwitchA-Vlan-interface1] quit
   ```

   # Configure an IPv4 advanced ACL to identify the data flows between Switch A and Switch B.

   ```
   [SwitchA] acl advanced 3101
   [SwitchA-acl-ipv4-adv-3101] rule 0 permit ip source 2.2.2.1 0 destination 2.2.3.1 0
   [SwitchA-acl-ipv4-adv-3101] quit
   ```

   # Create an IPsec transform set named **tran1**.

   ```
   [SwitchA] ipsec transform-set tran1
   ```

Specify the encapsulation mode as **tunnel**.

```
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchA-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create a manual IPsec policy entry. Specify the policy name as **map1** and set the sequence number to 10.

```
[SwitchA] ipsec policy map1 10 manual
```

Specify ACL 3101.

```
[SwitchA-ipsec-policy-manual-map1-10] security acl 3101
```

Specify IPsec transform set **tran1**.

```
[SwitchA-ipsec-policy-manual-map1-10] transform-set tran1
```

Specify the remote IP address of the IPsec tunnel as 2.2.3.1.

```
[SwitchA-ipsec-policy-manual-map1-10] remote-address 2.2.3.1
```

Configure inbound and outbound SPIs for ESP.

```
[SwitchA-ipsec-policy-manual-map1-10] sa spi outbound esp 12345
[SwitchA-ipsec-policy-manual-map1-10] sa spi inbound esp 54321
```

Configure the inbound and outbound SA keys for ESP.

```
[SwitchA-ipsec-policy-manual-map1-10] sa string-key outbound esp simple abcdefg
[SwitchA-ipsec-policy-manual-map1-10] sa string-key inbound esp simple gfedcba
[SwitchA-ipsec-policy-manual-map1-10] quit
```

Apply IPsec policy **map1** to VLAN-interface 1.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ipsec apply policy map1
```

2. Configure Switch B:

Configure an IP address for VLAN-interface 1.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ip address 2.2.3.1 255.255.255.0
[SwitchB-Vlan-interface1] quit
```

Configure an IPv4 advanced ACL to identify the data flows between Switch B and Switch A.

```
[SwitchB] acl advanced 3101
[SwitchB-acl-ipv4-adv-3101] rule 0 permit ip source 2.2.3.1 0 destination 2.2.2.1 0
[SwitchB-acl-ipv4-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchB] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchB-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Create a manual IPsec policy entry. Specify the policy name as **use1** and set the sequence number to 10.

```
[SwitchB] ipsec policy use1 10 manual
```

Specify ACL 3101.

```
[SwitchB-ipsec-policy-manual-use1-10] security acl 3101
```

Specify IPsec transform set **tran1**.

```
[SwitchB-ipsec-policy-manual-use1-10] transform-set tran1
```

Specify the remote IP address of the IPsec tunnel as 2.2.2.1.

```
[SwitchB-ipsec-policy-manual-use1-10] remote-address 2.2.2.1
```

Configure the inbound and outbound SPIs for ESP.

```
[SwitchB-ipsec-policy-manual-use1-10] sa spi outbound esp 54321
[SwitchB-ipsec-policy-manual-use1-10] sa spi inbound esp 12345
```

Configure the inbound and outbound SA keys for ESP.

```
[SwitchB-ipsec-policy-manual-use1-10] sa string-key outbound esp simple gfedcba
[SwitchB-ipsec-policy-manual-use1-10] sa string-key inbound esp simple abcdefg
[SwitchB-ipsec-policy-manual-use1-10] quit
```

Apply IPsec policy **use1** to VLAN-interface 1.

```
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ipsec apply policy use1
```

Verifying the configuration

After the configuration is completed, an IPsec tunnel between Switch A and Switch B is established, and the traffic between the switches is IPsec-protected. This example uses Switch A to verify the configuration.

Use the **display ipsec sa** command to display IPsec SAs on Switch A.

```
[SwitchA] display ipsec sa
-------------------------------
Interface: Vlan-interface 1
-------------------------------

  ----------------------------
  IPsec policy: map1
  Sequence number: 10
  Mode: manual
  ----------------------------
    Tunnel id: 549
    Encapsulation mode: tunnel
    Path MTU: 1443
    Tunnel:
        local  address: 2.2.2.1
        remote address: 2.2.3.1
    Flow:
        as defined in ACL 3101
    [Inbound ESP SA]
      SPI: 54321 (0x0000d431)
      Transform set: ESP-ENCRYPT-AES-CBC-192 ESP-AUTH-SHA1
      No duration limit for this SA
    [Outbound ESP SA]
      SPI: 12345 (0x00003039)
```

```
Transform set: ESP-ENCRYPT-AES-CBC-192 ESP-AUTH-SHA1
No duration limit for this SA
```

Example: Configuring an IKE-based IPsec tunnel for IPv4 packets

Network configuration

As shown in Figure 7, establish an IPsec tunnel between Switch A and Switch B to protect data flows between them. Configure the IPsec tunnel as follows:

- Specify the encapsulation mode as tunnel, the security protocol as ESP, the encryption algorithm as AES-CBC-192, and the authentication algorithm as HMAC-SHA1.
- Set up SAs through IKE negotiation.

Figure 7 Network diagram

Procedure

1. Configure Switch A:

Configure an IP address for VLAN-interface 1.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ip address 2.2.2.1 255.255.255.0
[SwitchA-Vlan-interface1] quit
```

Configure an IPv4 advanced ACL to identify data flows from Switch A to Switch B.

```
[SwitchA] acl number 3101
[SwitchA-acl-adv-3101] rule 0 permit ip source 2.2.2.1 0 destination 2.2.3.1 0
[SwitchA-acl-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchA] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchA-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchA] ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 2.2.3.1.

```
[SwitchA-ike-keychain-keychain1] pre-shared-key address 2.2.3.1 255.255.255.0 key
simple 12345zxcvb!@#$%ZXCVB
[SwitchA-ike-keychain-keychain1] quit
```

Create and configure the IKE profile named **profile1**.

```
[SwitchA] ike profile profile1
[SwitchA-ike-profile-profile1] keychain keychain1
[SwitchA-ike-profile-profile1] match remote identity address 2.2.3.1 255.255.255.0
[SwitchA-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **map1** and set the sequence number to 10.

```
[SwitchA] ipsec policy map1 10 isakmp
```

Apply ACL 3101.

```
[SwitchA-ipsec-policy-isakmp-map1-10] security acl 3101
```

Apply IPsec transform set **tran1**.

```
[SwitchA-ipsec-policy-isakmp-map1-10] transform-set tran1
```

Specify the local and remote IP addresses of the IPsec tunnel as 2.2.2.1 and 2.2.3.1.

```
[SwitchA-ipsec-policy-isakmp-map1-10] local-address 2.2.2.1
[SwitchA-ipsec-policy-isakmp-map1-10] remote-address 2.2.3.1
```

Apply IKE profile **profile1**.

```
[SwitchA-ipsec-policy-isakmp-map1-10] ike-profile profile1
[SwitchA-ipsec-policy-isakmp-map1-10] quit
```

Apply IPsec policy **map1** to VLAN interface 1.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ipsec apply policy map1
```

2. Configure Switch B:

Configure an IP address for VLAN-interface 1.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ip address 2.2.3.1 255.255.255.0
[SwitchB-Vlan-interface1] quit
```

Configure an IPv4 advanced ACL to identify data flows from Switch B to Switch A.

```
[SwitchB] acl number 3101
[SwitchB-acl-adv-3101] rule 0 permit ip source 2.2.3.1 0 destination 2.2.2.1 0
[SwitchB-acl-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchB] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchB-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchB] ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 2.2.2.1.

```
[SwitchB-ike-keychain-keychain1] pre-shared-key address 2.2.2.1 255.255.255.0 key
simple 12345zxcvb!@#$%ZXCVB
```

```
[SwitchB-ike-keychain-keychain1] quit
```

Create and configure the IKE profile named **profile1**.

```
[SwitchB] ike profile profile1
[SwitchB-ike-profile-profile1] keychain keychain1
[SwitchB-ike-profile-profile1] match remote identity address 2.2.2.1 255.255.255.0
[SwitchB-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **use1** and set the sequence number to 10.

```
[SwitchB] ipsec policy use1 10 isakmp
```

Apply ACL 3101.

```
[SwitchB-ipsec-policy-isakmp-use1-10] security acl 3101
```

Apply IPsec transform set **tran1**.

```
[SwitchB-ipsec-policy-isakmp-use1-10] transform-set tran1
```

Specify the local and remote IP addresses of the IPsec tunnel as 2.2.3.1 and 2.2.2.1.

```
[SwitchB-ipsec-policy-isakmp-use1-10] local-address 2.2.3.1
[SwitchB-ipsec-policy-isakmp-use1-10] remote-address 2.2.2.1
```

Apply IKE profile **profile1**.

```
[SwitchB-ipsec-policy-isakmp-use1-10] ike-profile profile1
[SwitchB-ipsec-policy-isakmp-use1-10] quit
```

Apply IPsec policy **use1** to VLAN-interface 1.

```
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ipsec apply policy use1
```

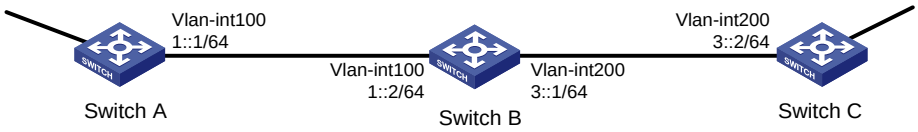
Verifying the configuration

Initiate a connection between Switch A and Switch B to trigger IKE negotiation. After IPsec SAs are successfully negotiated by IKE, the traffic between the two switches is IPsec-protected.



Example: Configuring IPsec for RIPng

Network configuration

As shown in Figure 8, Switch A, Switch B, and Switch C learn IPv6 routes through RIPng.

Establish an IPsec tunnel between the switches to protect the RIPng packets transmitted in between. Specify the security protocol as ESP, the encryption algorithm as 128-bit AES, and the authentication algorithm as HMAC-SHA1 for the IPsec tunnel.

Figure 8 Network diagram

Requirements analysis

To meet the network configuration requirements, perform the following tasks:

1. Configure basic RIPng.

   For more information about RIPng configurations, see *Layer 3—IP Routing Configuration Guide*.

2. Configure an IPsec profile.

- The IPsec profiles on all the switches must have IPsec transform sets that use the same security protocol, authentication and encryption algorithms, and encapsulation mode.
- The SPI and key configured for the inbound SA and those for the outbound SA must be the same on each switch.
- The SPI and key configured for the SAs on all the switches must be the same.

3. Apply the IPsec profile to a RIPng process or to an interface.

Procedure

1. Configure Switch A:

Configure IPv6 addresses for interfaces. (Details not shown.)

Configure basic RIPng.

```
<SwitchA> system-view
[SwitchA] ripng 1
[SwitchA-ripng-1] quit
[SwitchA] interface vlan-interface 100
[SwitchA-Vlan-interface100] ripng 1 enable
[SwitchA-Vlan-interface100] quit
```

Create and configure the IPsec transform set named **tran1**.

```
[SwitchA] ipsec transform-set tran1
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode transport
[SwitchA-ipsec-transform-set-tran1] protocol esp
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-128
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create and configure the IPsec profile named **profile001**.

```
[SwitchA] ipsec profile profile001 manual
[SwitchA-ipsec-profile-manual-profile001] transform-set tran1
[SwitchA-ipsec-profile-manual-profile001] sa spi outbound esp 123456
[SwitchA-ipsec-profile-manual-profile001] sa spi inbound esp 123456
[SwitchA-ipsec-profile-manual-profile001] sa string-key outbound esp simple abcdefg
[SwitchA-ipsec-profile-manual-profile001] sa string-key inbound esp simple abcdefg
[SwitchA-ipsec-profile-manual-profile001] quit
```

Apply the IPsec profile to RIPng process 1.

```
[SwitchA] ripng 1
[SwitchA-ripng-1] enable ipsec-profile profile001
[SwitchA-ripng-1] quit
```

2. Configure Switch B:

Configure IPv6 addresses for interfaces. (Details not shown.)

Configure basic RIPng.

```
<SwitchB> system-view
[SwitchB] ripng 1
[SwitchB-ripng-1] quit
[SwitchB] interface vlan-interface 200
[SwitchB-Vlan-interface200] ripng 1 enable
[SwitchB-Vlan-interface200] quit
[SwitchB] interface vlan-interface 100
[SwitchB-Vlan-interface100] ripng 1 enable
[SwitchB-Vlan-interface100] quit
```

Create and configure the IPsec transform set named **tran1**.

```
[SwitchB] ipsec transform-set tran1
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode transport
[SwitchB-ipsec-transform-set-tran1] protocol esp
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-128
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Create and configure the IPsec profile named **profile001**.

```
[SwitchB] ipsec profile profile001 manual
[SwitchB-ipsec-profile-manual-profile001] transform-set tran1
[SwitchB-ipsec-profile-manual-profile001] sa spi outbound esp 123456
[SwitchB-ipsec-profile-manual-profile001] sa spi inbound esp 123456
[SwitchB-ipsec-profile-manual-profile001] sa string-key outbound esp simple abcdefg
[SwitchB-ipsec-profile-manual-profile001] sa string-key inbound esp simple abcdefg
[SwitchB-ipsec-profile-manual-profile001] quit
```

Apply the IPsec profile to RIPng process 1.

```
[SwitchB] ripng 1
[SwitchB-ripng-1] enable ipsec-profile profile001
[SwitchB-ripng-1] quit
```

3. Configure Switch C:

Configure IPv6 addresses for interfaces. (Details not shown.)

Configure basic RIPng.

```
<SwitchC> system-view
[SwitchC] ripng 1
[SwitchC-ripng-1] quit
[SwitchC] interface vlan-interface 200
[SwitchC-Vlan-interface200] ripng 1 enable
[SwitchC-Vlan-interface200] quit
```

Create and configure the IPsec transform set named **tran1**.

```
[SwitchC] ipsec transform-set tran1
[SwitchC-ipsec-transform-set-tran1] encapsulation-mode transport
[SwitchC-ipsec-transform-set-tran1] protocol esp
[SwitchC-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-128
[SwitchC-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchC-ipsec-transform-set-tran1] quit
```

Create and configure the IPsec profile named **profile001**.

```
[SwitchC] ipsec profile profile001 manual
[SwitchC-ipsec-profile-manual-profile001] transform-set tran1
[SwitchC-ipsec-profile-manual-profile001] sa spi outbound esp 123456
[SwitchC-ipsec-profile-manual-profile001] sa spi inbound esp 123456
[SwitchC-ipsec-profile-manual-profile001] sa string-key outbound esp simple abcdefg
[SwitchC-ipsec-profile-manual-profile001] sa string-key inbound esp simple abcdefg
[SwitchC-ipsec-profile-manual-profile001] quit
```

Apply the IPsec profile to RIPng process 1.

```
[SwitchC] ripng 1
[SwitchC-ripng-1] enable ipsec-profile profile001
[SwitchC-ripng-1] quit
```

Verifying the configuration

After the configuration is completed, Switch A, Switch B, and Switch C learn IPv6 routing information through RIPng. IPsec SAs are set up successfully on the switches to protect RIPng packets. This example uses Switch A to verify the configuration.

Display the RIPng configuration. The output shows that IPsec profile **profile001** has been applied to RIPng process 1.

```
[SwitchA] display ripng 1
    RIPng process : 1
       Preference : 100
       Checkzero : Enabled
       Default Cost : 0
       Maximum number of load balanced routes : 8
       Update time   :   30 secs  Timeout time         :  180 secs
       Suppress time :  120 secs  Garbage-Collect time :  120 secs
       Update output delay:   20(ms)  Output count:    3
       Graceful-restart interval:   60 secs
       Triggered Interval : 5 50 200
       Number of periodic updates sent : 186
       Number of triggered updates sent : 1
       IPsec profile name: profile001
```

Display the established IPsec SAs.

```
[SwitchA] display ipsec sa
------------------------------
Global IPsec SA
------------------------------

  ----------------------------
  IPsec profile: profile001
  Mode: Manual
  ----------------------------
    Encapsulation mode: transport
    [Inbound ESP SA]
      SPI: 123456 (0x3039)
      Connection ID: 90194313219
      Transform set: ESP-ENCRYPT-AES-CBC-128 ESP-AUTH-SHA1
      No duration limit for this SA
    [Outbound ESP SA]
      SPI: 123456 (0x3039)
      Connection ID: 64424509441
      Transform set: ESP-ENCRYPT-AES-CBC-128ESP-AUTH-SHA1
      No duration limit for this SA
```

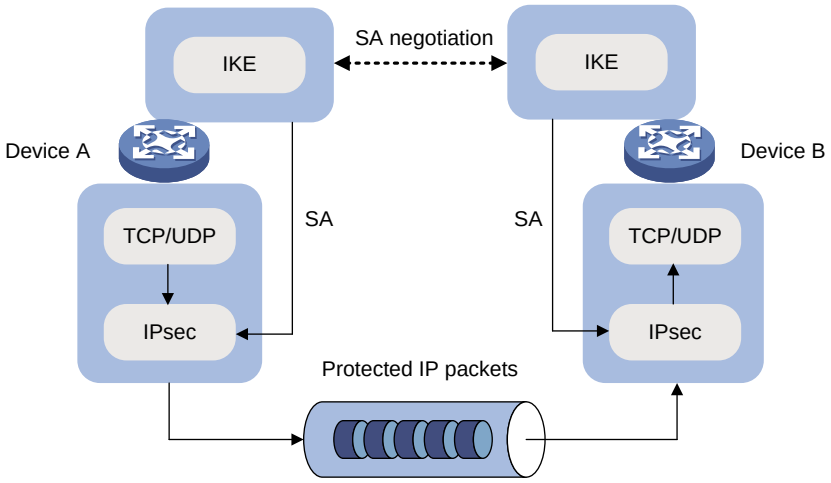
Configuring IKE

Unless otherwise specified, the term "IKE" in this chapter refers to IKEv1.

About IKE

Built on a framework defined by ISAKMP, Internet Key Exchange (IKE) provides automatic key negotiation and SA establishment services for IPsec.

Benefits of IKE



IKE provides the following benefits for IPsec:

- Automatically negotiates IPsec parameters.
- Performs DH exchanges to calculate shared keys, making sure each SA has a key that is independent of other keys.
- Automatically negotiates SAs when the sequence number in the AH or ESP header overflows, making sure IPsec can provide the anti-replay service by using the sequence number.

Relationship between IPsec and IKE

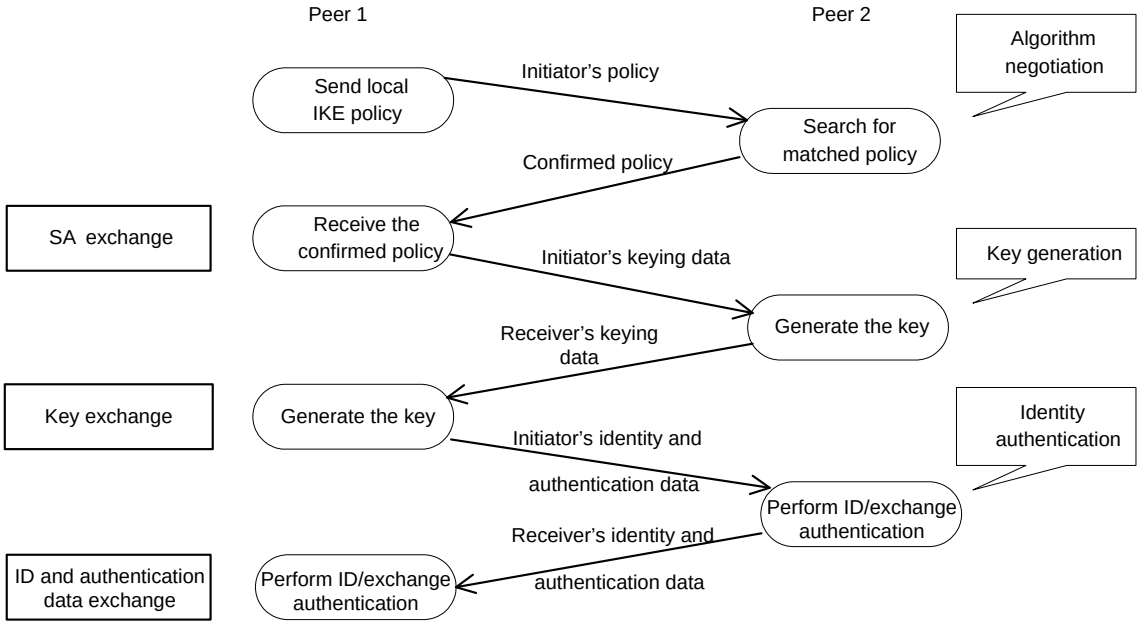
As shown in Figure 9, IKE negotiates SAs for IPsec and transfers the SAs to IPsec, and IPsec uses the SAs to protect IP packets.

Figure 9 Relationship between IKE and IPsec

IKE negotiation process

IKE negotiates keys and SAs for IPsec in two phases:

1. **Phase 1**—The two peers establish an IKE SA, a secure, authenticated channel for communication.
2. **Phase 2**—Using the IKE SA established in phase 1, the two peers negotiate to establish IPsec SAs.



Phase 1 negotiation can use either main mode or aggressive mode.

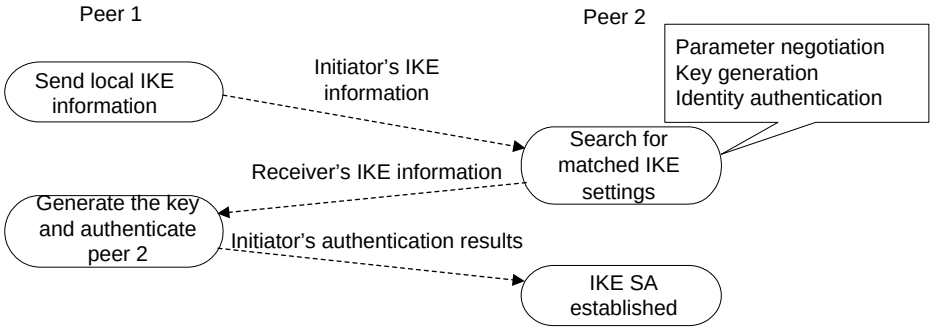
IKE exchange process in main mode

As shown in Figure 10, the main mode of IKE negotiation in phase 1 involves three pairs of messages:

- **SA exchange**—Used for negotiating the IKE security policy.
- **Key exchange**—Used for exchanging the DH public value and other values, such as the random number. The two peers use the exchanged data to generate key data and use the encryption key and authentication key to ensure the security of IP packets.
- **ID and authentication data exchange**—Used for identity authentication.

Figure 10 IKE exchange process in main mode

IKE exchange process in aggressive mode



As shown in Figure 11, the process of phase 1 IKE negotiation in aggressive mode is as follows:

1. The initiator (peer 1) sends a message containing the local IKE information to peer 2. The message includes parameters used for IKE SA establishment, keying data, and peer 1's identity information.
2. Peer 2 chooses the IKE establishment parameters to use, generate the key, and authenticate peer 1's identity. Then it sends the IKE data to peer 1.
3. Peer 1 generates the key, authenticates peer 2's identity, and sends the results to peer 1.

After the preceding process, an IKE SA is established between peer 1 and peer 2.

The aggressive mode is faster than the main mode but it does not provide identity information protection. The main mode provides identity information protection but is slower. Choose the appropriate negotiation mode according to your requirements.

Figure 11 IKE exchange process in aggressive mode

IKE security mechanism

IKE has a series of self-protection mechanisms and supports secure identity authentication, key distribution, and IPsec SA establishment on insecure networks.

Identity authentication

The IKE identity authentication mechanism is used to authenticate the identity of the communicating peers. The device supports the following identity authentication methods:

- **Preshared key authentication**—Two communicating peers use the pre-configured shared key for identity authentication.
- **RSA signature authentication** and **DSA signature authentication**—Two communicating peers use the digital certificates issued by the CA for identity authentication.

The preshared key authentication method does not require certificates and is easy to configure. It is usually deployed in small networks.

The signature authentication methods provide higher security and are usually deployed in networks with the headquarters and some branches. When deployed in a network with many branches, a signature authentication method can simplify the configuration because only one PKI domain is required. If you use the preshared key authentication method, you must configure a preshared key for each branch on the Headquarters node.

DH algorithm

The DH algorithm is a public key algorithm. With this algorithm, two peers can exchange keying material and then use the material to calculate the shared keys. Due to the decryption complexity, a third party cannot decrypt the keys even after intercepting all keying materials.

PFS

The Perfect Forward Secrecy (PFS) feature is a security feature based on the DH algorithm. After PFS is enabled, an additional DH exchange is performed in IKE phase 2 to make sure IPsec keys have no derivative relations with IKE keys and a broken key brings no threats to other keys.

Protocols and standards

- RFC 2408, *Internet Security Association and Key Management Protocol (ISAKMP)*
- RFC 2409, *The Internet Key Exchange (IKE)*
- RFC 2412, *The OAKLEY Key Determination Protocol*
- Internet Draft, *draft-ietf-ipsec-isakmp-xauth-06*
- Internet Draft, *draft-dukes-ike-mode-cfg-02*

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

IKE tasks at a glance

To configure IKE, perform the following tasks:

1. (Optional.) Configuring an IKE profile
   a. Creating an IKE profile
   b. Configuring peer IDs for the IKE profile
   c. Specifying the IKE keychain or PKI domain
   d. Configuring the IKE phase 1 negotiation mode
   e. Specifying IKE proposals for the IKE profile
   f. Configuring the local ID for the IKE profile
   g. Specifying an inside VPN instance for the IKE profile
   h. Configuring optional features for the IKE profile
2. Configuring an IKE proposal
3. Configuring an IKE keychain
4. (Optional.) Configuring the global identity information
5. (Optional.) Configuring the IKE keepalive feature
6. (Optional.) Configuring the IKE NAT keepalive feature
7. (Optional.) Configuring global IKE DPD
8. (Optional.) Enabling invalid SPI recovery
9. (Optional.) Setting the maximum number of IKE SAs
10. (Optional.) Configuring SNMP notifications for IKE

Prerequisites for IKE configuration

Determine the following parameters prior to IKE configuration:

- The algorithms to be used during IKE negotiation, including the identity authentication method, encryption algorithm, authentication algorithm, and DH group.
  - Different algorithms provide different levels of protection. A stronger algorithm provides more resistance to decryption but uses more resources.
  - A DH group that uses more bits provides higher security but needs more time for processing.
- The preshared key or PKI domain for IKE negotiation. For more information about PKI, see "Configuring PKI."
- The IKE-based IPsec policies for the communicating peers. If you do not specify an IKE profile in an IPsec policy, the device selects an IKE profile for the IPsec policy. If no IKE profile is configured, the globally configured IKE settings are used. For more information about IPsec, see "Configuring IPsec."

Configuring an IKE profile

Creating an IKE profile

About this task

Perform this task to create an IKE profile.

An IKE profile is intended to provide a set of parameters for IKE negotiation.

Procedure

1. Enter system view.
   system-view
2. Create an IKE profile and enter its view.
   ike profile *profile-name*

Configuring peer IDs for the IKE profile

About this task

Perform this task to configure the peer IDs for IKE profile matching. When the device needs to select an IKE profile for IKE negotiation with a peer, it compares the received peer ID with the peer IDs of its local IKE profiles. If a match is found, it uses the IKE profile with the matching peer ID for IKE negotiation.

Restrictions and guidelines

For an IKE profile, you can configure multiple peer IDs. A peer ID configured earlier has a higher priority.

Two IKE peers must both have or both not have peer IDs configured.

Procedure

1. Enter system view.
   system-view
2. Enter IKE profile view.
   ike profile *profile-name*
3. Configure a peer ID for the IKE profile.
   match remote { **certificate** *policy-name* | **identity** { **address** { { *ipv4-address* [*mask* | *mask-length*] | **range** *low-ipv4-address high-ipv4-address* } | **ipv6** { *ipv6-address* [*prefix-length*] | **range** *low-ipv6-address high-ipv6-address* } } [**vpn-instance** *vpn-instance-name*] | **fqdn** *fqdn-name* | **user-fqdn** *user-fqdn-name* } }

Specifying the IKE keychain or PKI domain

Restrictions and guidelines

Configure the IKE keychain or PKI domain for the IKE proposals to use. To use digital signature authentication, configure a PKI domain. To use preshared key authentication, configure an IKE keychain.

Procedure

1. Enter system view.

system-view

2. Enter IKE profile view.

   ike profile *profile-name*

3. Specify the keychain for preshared key authentication or the PKI domain used to request a certificate for digital signature authentication.

   - Specify the keychain.

     keychain *keychain-name*

   - Specify the PKI domain.

     certificate domain *domain-name*

   By default, no IKE keychain or PKI domain is specified in an IKE profile.

Configuring the IKE phase 1 negotiation mode

Restrictions and guidelines

Specify the IKE phase 1 negotiation mode (main or aggressive) that the device uses as the initiator. When the device acts as the responder, it uses the IKE negotiation mode of the initiator.

Procedure

1. Enter system view.

   system-view

2. Enter IKE profile view.

   ike profile *profile-name*

3. Specify the IKE negotiation mode for phase 1.

   In non-FIPS mode:

   exchange-mode { **aggressive** | **main** }

   In FIPS mode:

   exchange-mode main

   By default, IKE negotiation in phase 1 uses the main mode.

Specifying IKE proposals for the IKE profile

Restrictions and guidelines

Specify the IKE proposals that the device can use as the initiator. An IKE proposal specified earlier has a higher priority. When the device acts as the responder, it uses the IKE proposals configured in system view to match the IKE proposals received from the initiator. If no matching proposal is found, the negotiation fails.

Procedure

1. Enter system view.

   system-view

2. Enter IKE profile view.

   ike profile *profile-name*

3. Specify IKE proposals for the IKE profile.

   proposal *proposal-number*&<1-6>

   By default, no IKE proposals are specified for an IKE profile and the IKE proposals configured in system view are used for IKE negotiation.

Configuring the local ID for the IKE profile

Restrictions and guidelines

For digital signature authentication, the device can use an ID of any type. If the local ID is an IP address that is different from the IP address in the local certificate, the device uses the FQDN (the device name configured by using the **sysname** command) instead.

For preshared key authentication, the device can use an ID of any type other than the DN.

Procedure

1. Enter system view.

   system-view

2. Enter IKE profile view.

   ike profile *profile-name*

3. Configure the local ID.

   local-identity { **address** { *ipv4-address* | **ipv6** *ipv6-address* } | **dn** | **fqdn** [*fqdn-name*] | **user-fqdn** [*user-fqdn-name*] }

   By default, no local ID is configured for an IKE profile, and an IKE profile uses the local ID configured in system view. If the local ID is not configured in system view, the IKE profile uses the IP address of the interface to which the IPsec policy or IPsec policy template is applied as the local ID.

Specifying an inside VPN instance for the IKE profile

About this task

The inside MPLS L3VPN instance determines where the device should forward received IPsec protected data. If you specify an inside VPN instance, the device looks for a route in the specified VPN instance to forward the data. If you do not specify an inside VPN instance, the device looks for a route in the VPN instance where the receiving interface resides to forward the data.

Restrictions and guidelines

The inside VPN instance specified in an IKE profile takes effect only on IPsec policies that use the IKE profile. It does not take effect on IPsec profiles that use the IKE profile.

Procedure

1. Enter system view.

   system-view

2. Enter IKE profile view.

   ike profile *profile-name*

3. Specify an inside VPN instance.

   inside-vpn vpn-instance *vpn-instance-name*

   By default, no inside VPN instance is specified for an IKE profile, and the device forwards protected data to the VPN instance where the interface receiving the data resides.

Configuring optional features for the IKE profile

1. Enter system view.

   system-view

2. Enter IKE profile view.

ike profile *profile-name*

3. Configure optional features as needed.
   - Configure IKE DPD.

     dpd interval *interval* [**retry** *seconds*] { **on-demand** | **periodic** }

     By default, IKE DPD is not configured for an IKE profile and an IKE profile uses the DPD settings configured in system view. If IKE DPD is not configured in system view either, the device does not perform dead IKE peer detection.

     The IKE DPD settings configured in the IKE profile view take precedence over those configured in system view.
   - Specify the local interface or IP address to which the IKE profile can be applied.

     match local address { *interface-type interface-number* | { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] }

     By default, an IKE profile can be applied to any local interface or IP address.

     An IKE profile configured with this command has a higher priority over those not configured with this command.
   - Specify a priority for the IKE profile.

     priority *priority*

     By default, the priority of an IKE profile is 100.

     The device selects a local IKE profile for IKE negotiation as follows:
     - First, it selects an IKE profile with the **match local address** command configured.
     - If a tie exists, it selects the IKE profile with a smaller priority number.
     - If a tie still exists, it selects the IKE profile configured earlier.

Configuring an IKE proposal

About this task

An IKE proposal defines a set of attributes describing how IKE negotiation in phase 1 should take place. You can create multiple IKE proposals with different priorities. The priority of an IKE proposal is represented by its sequence number. The lower the sequence number, the higher the priority.

Two peers must have at least one matching IKE proposal for successful IKE negotiation. During IKE negotiation:

- The initiator sends its IKE proposals to the peer.
  - If the initiator is using an IPsec policy with an IKE profile, the initiator sends all IKE proposals specified in the IKE profile to the peer. An IKE proposal specified earlier for the IKE profile has a higher priority.
  - If the initiator is using an IPsec policy with no IKE profile, the initiator sends all its IKE proposals to the peer. An IKE proposal with a smaller number has a higher priority.
- The peer searches its own IKE proposals for a match. The search starts from the IKE proposal with the highest priority and proceeds in descending order of priority until a match is found. The matching IKE proposals are used to establish the IKE SA. If all user-defined IKE proposals are found mismatching, the two peers use their default IKE proposals to establish the IKE SA.

Two matching IKE proposals have the same encryption algorithm, authentication method, authentication algorithm, and DH group. The SA lifetime takes the smaller one of the two proposals' SA lifetime settings.

Procedure

1. Enter system view.

system-view

2. Create an IKE proposal and enter its view.

   ike proposal *proposal-number*

   By default, a default IKE proposal exists.

3. Configure a description for the IKE proposal.

   description

   By default, an IKE proposal does not have a description.

4. Specify an encryption algorithm for the IKE proposal.

   In non-FIPS mode:

   encryption-algorithm { **3des-cbc** | **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** | **des-cbc** }

   By default, the 56-bit DES encryption algorithm in CBC mode is used .

   In FIPS mode:

   encryption-algorithm { **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** }

   By default, the 128-bit AES encryption algorithm in CBC mode is used.

5. Specify an authentication method for the IKE proposal.

   authentication-method{ **dsa-signature** | **ecdsa-signature** | **pre-share** | **rsa-signature** }

   By default, the preshared key authentication method is used.

6. Specify an authentication algorithm for the IKE proposal.

   In non-FIPS mode:

   authentication-algorithm { **md5** | **sha** | **sha256** | **sha384** | **sha512** }

   By default, the HMAC-SHA1 authentication algorithm is used.

   In FIPS mode:

   authentication-algorithm { **sha** | **sha256** | **sha384** | **sha512** }

   By default, the HMAC-SHA256 authentication algorithm is used.

7. Specify a DH group for key negotiation in phase 1.

   In non-FIPS mode:

   dh{ **group1** | **group14** | **group19** | **group2** | **group20** | **group24** | **group5** }

   DH group 1 (the 768-bit DH group) is used by default.

   In FIPS mode:

   dh{ **group14** | **group19** | **group20** | **group24** }

   DH group 14 (the 2048-bit DH group) is used by default.

8. (Optional.) Set the IKE SA lifetime for the IKE proposal.

   sa duration *seconds*

   By default, the IKE SA lifetime is 86400 seconds.

Configuring an IKE keychain

About this task

Perform this task when you configure the IKE to use the preshared key for authentication.

Follow these guidelines when you configure an IKE keychain:

- Two peers must be configured with the same preshared key to pass preshared key authentication.

- You can specify the local address configured in IPsec policy or IPsec policy template view (using the **local-address** command) for the IKE keychain to be applied. If no local address is configured, specify the IP address of the interface that uses the IPsec policy.
- The device determines the priority of an IKE keychain as follows:
  a. The device examines the existence of the **match local address** command. An IKE keychain with the **match local address** command configured has a higher priority.
  b. If a tie exists, the device compares the priority numbers. An IKE keychain with a smaller priority number has a higher priority.
  c. If a tie still exists, the device prefers an IKE keychain configured earlier.

Procedure

1. Enter system view.
   system-view
2. Create an IKE keychain and enter its view.
   ike keychain *keychain-name* [**vpn-instance** *vpn-instance-name*]
3. Configure a preshared key.
   In non-FIPS mode:
   pre-shared-key { **address** { *ipv4-address* [*mask* | *mask-length*] | **ipv6** *ipv6-address* [*prefix-length*] } | **hostname** *host-name* } **key** { **cipher** | **simple** } *string*
   In FIPS mode:
   pre-shared-key { **address** { *ipv4-address* [*mask* | *mask-length*] | **ipv6** *ipv6-address* [*prefix-length*] } | **hostname** *host-name* } **key** [**cipher** *string*]
   By default, no preshared key is configured.
4. (Optional.) Specify a local interface or IP address to which the IKE keychain can be applied.
   match local address { *interface-type interface-number* | { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] }
   By default, an IKE keychain can be applied to any local interface or IP address.
5. (Optional.) Specify a priority for the IKE keychain.
   priority *priority*
   The default priority is 100.

Configuring the global identity information

Restrictions and guidelines

The global identity can be used by the device for all IKE SA negotiations, and the local identity (set by the **local-identity** command) can be used only by the device that uses the IKE profile.

When signature authentication is used, you can set any type of the identity information.

When preshared key authentication is used, you cannot set the DN as the identity.

Procedure

1. Enter system view.
   system-view
2. Configure the global identity to be used by the local end.
   ike identity { **address** { *ipv4-address* | **ipv6** *ipv6-address* }| **dn** | **fqdn** [*fqdn-name*] | **user-fqdn** [*user-fqdn-name*] }

By default, the IP address of the interface to which the IPsec policy or IPsec policy template is applied is used as the IKE identity.

3. (Optional.) Configure the local device to always obtain the identity information from the local certificate for signature authentication.

   ike signature-identity from-certificate

   By default, the local end uses the identity information specified by **local-identity** or **ike identity** for signature authentication.

   Configure this command when the aggressive mode and signature authentication are used and the device interconnects with a Comware 5-based peer device. Comware 5 supports only DN for signature authentication.

Configuring the IKE keepalive feature

About this task

IKE sends keepalive packets to query the liveness of the peer. If the peer is configured with the keepalive timeout time, you must configure the keepalive interval on the local device. If the peer receives no keepalive packets during the timeout time, the IKE SA is deleted along with the IPsec SAs it negotiated.

Restrictions and guidelines

Configure IKE DPD instead of IKE keepalive unless IKE DPD is not supported on the peer. The IKE keepalive feature sends keepalives at regular intervals, which consumes network bandwidth and resources.

The keepalive timeout time configured on the local device must be longer than the keepalive interval configured at the peer. Since it seldom occurs that more than three consecutive packets are lost on a network, you can set the keepalive timeout three times as long as the keepalive interval.

Procedure

1. Enter system view.

   system-view

2. Set the IKE SA keepalive interval.

   ike keepalive interval *interval*

   By default, no keepalives are sent to the peer.

3. Set the IKE SA keepalive timeout time.

   ike keepalive timeout *seconds*

   By default, IKE SA keepalive never times out.

Configuring the IKE NAT keepalive feature

About this task

If IPsec traffic passes through a NAT device, you must configure the NAT traversal feature. If no packet travels across an IPsec tunnel in a period of time, the NAT sessions are aged and deleted, disabling the tunnel from transmitting data to the intended end. To prevent NAT sessions from being aged, configure the NAT keepalive feature on the IKE gateway behind the NAT device to send NAT keepalive packets to its peer periodically to keep the NAT session alive.

Procedure

1. Enter system view.

   system-view

2. Set the IKE NAT keepalive interval.

   ike nat-keepalive *seconds*

   The default interval is 20 seconds.

Configuring global IKE DPD

About this task

DPD detects dead peers. It can operate in periodic mode or on-demand mode.

- **Periodic DPD**—Sends a DPD message at regular intervals. It features an earlier detection of dead peers, but consumes more bandwidth and CPU.
- **On-demand DPD**—Sends a DPD message based on traffic. When the device has traffic to send and is not aware of the liveness of the peer, it sends a DPD message to query the status of the peer. If the device has no traffic to send, it never sends DPD messages. As a best practice, use the on-demand mode.

The IKE DPD works as follows:

1. The local device sends a DPD message to the peer, and waits for a response from the peer.
2. If the peer does not respond within the retry interval specified by the **retry** *seconds* parameter, the local device resends the message.
3. If still no response is received within the retry interval, the local end sends the DPD message again. The system allows a maximum of two retries.
4. If the local device receives no response after two retries, the device considers the peer to be dead, and deletes the IKE SA along with the IPsec SAs it negotiated.
5. If the local device receives a response from the peer during the detection process, the peer is considered alive. The local device performs a DPD detection again when the triggering interval is reached or it has traffic to send, depending on the DPD mode.

Restrictions and guidelines

When DPD settings are configured in both IKE profile view and system view, the DPD settings in IKE profile view apply. If DPD is not configured in IKE profile view, the DPD settings in system view apply.

It is a good practice to set the triggering interval longer than the retry interval so that a DPD detection is not triggered during a DPD retry.

Procedure

1. Enter system view.

   system-view

2. Enable sending IKE DPD messages.

   ike dpd interval *interval* [**retry** *seconds*] { **on-demand** | **periodic** }

   By default, IKE DPD is disabled.

Enabling invalid SPI recovery

About this task

An IPsec "black hole" occurs when one IPsec peer fails (for example, a peer can fail if a reboot occurs). One peer fails and loses its SAs with the other peer. When an IPsec peer receives a data packet for which it cannot find an SA, an invalid SPI is encountered. The peer drops the data packet and tries to send an SPI invalid notification to the data originator. This notification is sent by using the IKE SA. Because no IKE SA is available, the notification is not sent. The originating peer continues sending the data by using the IPsec SA that has the invalid SPI, and the receiving peer keeps dropping the traffic.

The invalid SPI recovery feature enables the receiving peer to set up an IKE SA with the originator so that an SPI invalid notification can be sent. Upon receiving the notification, the originating peer deletes the IPsec SA that has the invalid SPI. If the originator has data to send, new SAs will be set up.

Restrictions and guidelines

Use caution when you enable the invalid SPI recovery feature because using this feature can result in a DoS attack. Attackers can make a great number of invalid SPI notifications to the same peer.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable invalid SPI recovery.
   ```
   ike invalid-spi-recovery enable
   ```
   By default, the invalid SPI recovery is disabled.

Setting the maximum number of IKE SAs

About this task

You can set the maximum number of half-open IKE SAs and the maximum number of established IKE SAs.

- The supported maximum number of half-open IKE SAs depends on the device's processing capability. Adjust the maximum number of half-open IKE SAs to make full use of the device's processing capability without affecting the IKE SA negotiation efficiency.
- The supported maximum number of established IKE SAs depends on the device's memory space. Adjust the maximum number of established IKE SAs to make full use of the device's memory space without affecting other applications in the system.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Set the maximum number of half-open IKE SAs and the maximum number of established IKE SAs.
   ike limit { **max-negotiating-sa** *negotiation-limit* | **max-sa** *sa-limit* }
   By default, there is no limit to the maximum number of IKE SAs.

Configuring SNMP notifications for IKE

About this task

After you enable SNMP notifications for IKE, the IKE module notifies the NMS of important module events. The notifications are sent to the device's SNMP module. For the notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP notifications, see *Network Management and Monitoring Configuration Guide*.

To generate and output SNMP notifications for a specific IKE failure or event type, perform the following tasks:

1. Enable SNMP notifications for IKE globally.
2. Enable SNMP notifications for the failure or event type.

Procedure

1. Enter system view

system-view

2. Enable SNMP notifications for IKE globally.

   snmp-agent trap enable ike global

   By default, SNMP notifications for IKE are disabled.

3. Enable SNMP notifications for the specified failure or event types.

   snmp-agent trap enable ike [**attr-not-support** | **auth-failure** | **cert-type-unsupport** | **cert-unavailable** | **decrypt-failure** | **encrypt-failure** | **invalid-cert-auth** | **invalid-cookie** | **invalid-id** | **invalid-proposal** | **invalid-protocol** | **invalid-sign** | **no-sa-failure** | **proposal-add** | **proposal–delete** | **tunnel-start** | **tunnel-stop** | **unsupport-exch-type**] *

   By default, SNMP notifications for all failure and event types are disabled.

Display and maintenance commands for IKE

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display configuration information about all IKE proposals.	**display ike proposal**
Display information about the current IKE SAs.	**display ike sa** [**verbose** [**connection-id** *connection-id* | **remote-address** [**ipv6**] *remote-address* [**vpn-instance** *vpn-instance-name*]]]
Display IKE statistics.	**display ike statistics**
Delete IKE SAs.	**reset ike sa** [**connection-id** *connection-id*]
Clear IKE MIB statistics.	**reset ike statistics**

IKE configuration examples

Example: Configuring main-mode IKE with preshared key authentication

Network configuration

As shown in Figure 12, configure an IKE-based IPsec tunnel between Switch A and Switch B to secure the communication between the switches.

- Configure the two switches to use the default IKE proposal for the IKE negotiation.
- Configure the two switches to use the preshared key authentication method for the IKE negotiation.

Figure 12 Network diagram

Procedure

1. Make sure Switch A and Switch B can reach each other.
2. Configure Switch A:

   # Configure an IP address for VLAN-interface 1.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 1
   [SwitchA-vlan-interface1] ip address 1.1.1.1 255.255.0.0
   [SwitchA-vlan-interface1] quit
   ```

   # Configure IPv4 advanced ACL 3101 to identify the traffic from Switch A to Switch B.

   ```
   [SwitchA] acl advanced 3101
   [SwitchA-acl-ipv4-adv-3101] rule 0 permit ip source 1.1.1.1 0 destination 2.2.2.2 0
   [SwitchA-acl-ipv4-adv-3101] quit
   ```

   # Create an IPsec transform set named **tran1**.

   ```
   [SwitchA] ipsec transform-set tran1
   ```

   # Set the packet encapsulation mode to **tunnel**.

   ```
   [SwitchA-ipsec-transform-set-tran1] encapsulation-mode tunnel
   ```

   # Use the ESP protocol for the IPsec transform set.

   ```
   [SwitchA-ipsec-transform-set-tran1] protocol esp
   ```

   # Specify the encryption and authentication algorithms.

   ```
   [SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
   [SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
   [SwitchA-ipsec-transform-set-tran1] quit
   ```

   # Create an IKE keychain named **keychain1**.

   ```
   [SwitchA] ike keychain keychain1
   ```

   # Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 2.2.2.2.

   ```
   [SwitchA-ike-keychain-keychain1] pre-shared-key address 2.2.2.2 255.255.0.0 key
   simple 12345zxcvb!@#$%ZXCVB
   [SwitchA-ike-keychain-keychain1] quit
   ```

   # Create an IKE profile named **profile1**.

   ```
   [SwitchA] ike profile profile1
   ```

   # Specify IKE keychain **keychain1**.

   ```
   [SwitchA-ike-profile-profile1] keychain keychain1
   ```

   # Configure a peer ID with the identity type as IP address and the value as **2.2.2.2/16**.

   ```
   [SwitchA-ike-profile-profile1] match remote identity address 2.2.2.2 255.255.0.0
   [SwitchA-ike-profile-profile1] quit
   ```

   # Create an IKE-based IPsec policy entry. Specify the policy name as **map1** and set the sequence number to 10.

   ```
   [SwitchA] ipsec policy map1 10 isakmp
   ```

   # Specify the remote IP address 2.2.2.2 for the IPsec tunnel.

   ```
   [SwitchA-ipsec-policy-isakmp-map1-10] remote-address 2.2.2.2
   ```

Specify ACL 3101 to identify the traffic to be protected.

```
[SwitchA-ipsec-policy-isakmp-map1-10] security acl 3101
```

Specify IPsec transform set **tran1** for the IPsec policy.

```
[SwitchA-ipsec-policy-isakmp-map1-10] transform-set tran1
```

Specify IKE profile **profile1** for the IPsec policy.

```
[SwitchA-ipsec-policy-isakmp-map1-10] ike-profile profile1
[SwitchA-ipsec-policy-isakmp-map1-10] quit
```

Apply IPsec policy **map1** to VLAN-interface 1.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ipsec apply policy map1
```

3. Configure Switch B:

Configure an IP address for VLAN-interface 1.

```
<SwitchB> system-view
[SwitchB] interface Vlan-interface1
[SwitchB-Vlan-interface1] ip address 2.2.2.2 255.255.0.0
[SwitchB-Vlan-interface1] quit
```

Configure IPv4 advanced ACL 3101 to identify the traffic from Switch B to Switch A.

```
[SwitchB] acl number 3101
[SwitchB-acl-adv-3101] rule 0 permit ip source 2.2.2.2 0 destination 1.1.1.1 0
[SwitchB-acl-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchB] ipsec transform-set tran1
```

Set the packet encapsulation mode to **tunnel**.

```
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Use the ESP protocol for the IPsec transform set.

```
[SwitchB-ipsec-transform-set-tran1] protocol esp
```

Specify the encryption and authentication algorithms.

```
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchB]ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 1.1.1.1.

```
[SwitchB-ike-keychain-keychain1] pre-shared-key address 1.1.1.1 255.255.0.0 key
simple 12345zxcvb!@#$%ZXCVB
[SwitchB-ike-keychain-keychain1] quit
```

Create an IKE profile named **profile1**.

```
[SwitchB] ike profile profile1
```

Specify IKE keychain **keychain1**

```
[SwitchB-ike-profile-profile1] keychain keychain1
```

Configure a peer ID with the identity type as IP address and the value as **1.1.1.1/16**.

```
[SwitchB-ike-profile-profile1] match remote identity address 1.1.1.1 255.255.0.0
[SwitchB-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **use1** and set the sequence number to 10.

```
[SwitchB] ipsec policy use1 10 isakmp
```

Specify the remote IP address 1.1.1.1 for the IPsec tunnel.

```
[SwitchB-ipsec-policy-isakmp-use1-10] remote-address 1.1.1.1
```

Specify ACL 3101 to identify the traffic to be protected.

```
[SwitchB-ipsec-policy-isakmp-use1-10] security acl 3101
```

Specify IPsec transform set **tran1** for the IPsec policy.

```
[SwitchB-ipsec-policy-isakmp-use1-10] transform-set tran1
```

Specify IKE profile **profile1** for the IPsec policy.

```
[SwitchB-ipsec-policy-isakmp-use1-10] ike-profile profile1
[SwitchB-ipsec-policy-isakmp-use1-10] quit
```

Apply IPsec policy **use1** to VLAN-interface 1.

```
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ipsec apply policy use1
```

Verifying the configuration

Initiate a connection between Switch A and Switch B to trigger IKE negotiation. After IPsec SAs are successfully negotiated by IKE, the traffic between the two switches is IPsec-protected.

Example: Configuring an IKE-based IPsec tunnel for IPv4 packets

Network configuration

As shown in Figure 13, establish an IPsec tunnel between Switch A and Switch B to protect data flows between the switches. Configure the IPsec tunnel as follows:

- Specify the encapsulation mode as tunnel, the security protocol as ESP, the encryption algorithm as AES-CBC-192, and the authentication algorithm as HMAC-SHA1.
- Set up SAs through IKE negotiation.

Figure 13 Network diagram

Procedure

1. Configure Switch A:

Configure an IP address for VLAN-interface 1.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ip address 2.2.2.1 255.255.255.0
[SwitchA-Vlan-interface1] quit
```

Configure an IPv4 advanced ACL to identify the data flows from Switch A to Switch B.

```
[SwitchA] acl advanced 3101
[SwitchA-acl-ipv4-adv-3101] rule 0 permit ip source 2.2.2.1 0 destination 2.2.3.1 0
[SwitchA-acl-ipv4-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchA] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchA-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchA-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchA-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchA-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchA-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchA] ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 2.2.3.1.

```
[SwitchA-ike-keychain-keychain1] pre-shared-key address 2.2.3.1 255.255.255.0 key
simple 12345zxcvb!@#$%ZXCVB
[SwitchA-ike-keychain-keychain1] quit
```

Create and configure an IKE profile named **profile1**.

```
[SwitchA] ike profile profile1
[SwitchA-ike-profile-profile1] keychain keychain1
[SwitchA-ike-profile-profile1] match remote identity address 2.2.3.1 255.255.255.0
[SwitchA-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **map1** and set the sequence number to 10.

```
[SwitchA] ipsec policy map1 10 isakmp
```

Specify ACL 3101.

```
[SwitchA-ipsec-policy-isakmp-map1-10] security acl 3101
```

Specify IPsec transform set **tran1**.

```
[SwitchA-ipsec-policy-isakmp-map1-10] transform-set tran1
```

Specify the local and remote IP addresses of the IPsec tunnel as 2.2.2.1 and 2.2.3.1.

```
[SwitchA-ipsec-policy-isakmp-map1-10] local-address 2.2.2.1
[SwitchA-ipsec-policy-isakmp-map1-10] remote-address 2.2.3.1
```

Specify IKE profile **profile1**.

```
[SwitchA-ipsec-policy-isakmp-map1-10] ike-profile profile1
[SwitchA-ipsec-policy-isakmp-map1-10] quit
```

Apply IPsec policy **map1** to VLAN-interface 1.

```
[SwitchA] interface vlan-interface 1
[SwitchA-Vlan-interface1] ipsec apply policy map1
```

2. Configure Switch B:

Configure an IP address for VLAN-interface 1.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ip address 2.2.3.1 255.255.255.0
[SwitchB-Vlan-interface1] quit
```

Configure an IPv4 advanced ACL to identify the data flows from Switch B to Switch A.

```
[SwitchB] acl advanced 3101
[SwitchB-acl-ipv4-adv-3101] rule 0 permit ip source 2.2.3.1 0 destination 2.2.2.1 0
[SwitchB-acl-ipv4-adv-3101] quit
```

Create an IPsec transform set named **tran1**.

```
[SwitchB] ipsec transform-set tran1
```

Specify the encapsulation mode as **tunnel**.

```
[SwitchB-ipsec-transform-set-tran1] encapsulation-mode tunnel
```

Specify the security protocol as **ESP**.

```
[SwitchB-ipsec-transform-set-tran1] protocol esp
```

Specify the ESP encryption and authentication algorithms.

```
[SwitchB-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-192
[SwitchB-ipsec-transform-set-tran1] esp authentication-algorithm sha1
[SwitchB-ipsec-transform-set-tran1] quit
```

Create an IKE keychain named **keychain1**.

```
[SwitchB] ike keychain keychain1
```

Specify **12345zxcvb!@#$%ZXCVB** in plain text as the preshared key to be used with the remote peer at 2.2.2.1.

```
[SwitchB-ike-keychain-keychain1] pre-shared-key address 2.2.2.1 255.255.255.0 key
simple 12345zxcvb!@#$%ZXCVB
[SwitchB-ike-keychain-keychain1] quit
```

Create and configure an IKE profile named **profile1**.

```
[SwitchB] ike profile profile1
[SwitchB-ike-profile-profile1] keychain keychain1
[SwitchB-ike-profile-profile1] match remote identity address 2.2.2.1 255.255.255.0
[SwitchB-ike-profile-profile1] quit
```

Create an IKE-based IPsec policy entry. Specify the policy name as **use1** and set the sequence number to 10.

```
[SwitchB] ipsec policy use1 10 isakmp
```

Specify ACL 3101.

```
[SwitchB-ipsec-policy-isakmp-use1-10] security acl 3101
```

Specify IPsec transform set **tran1**.

```
[SwitchB-ipsec-policy-isakmp-use1-10] transform-set tran1
```

Specify the local and remote IP addresses of the IPsec tunnel as 2.2.3.1 and 2.2.2.1.

```
[SwitchB-ipsec-policy-isakmp-use1-10] local-address 2.2.3.1
[SwitchB-ipsec-policy-isakmp-use1-10] remote-address 2.2.2.1
```

Specify IKE profile **profile1**.

```
[SwitchB-ipsec-policy-isakmp-use1-10] ike-profile profile1
[SwitchB-ipsec-policy-isakmp-use1-10] quit
```

Apply IPsec policy **use1** to VLAN-interface 1.

```
[SwitchB] interface vlan-interface 1
[SwitchB-Vlan-interface1] ipsec apply policy use1
```

Verifying the configuration

Initiate a connection between Switch A and Switch B to trigger IKE negotiation. After IPsec SAs are successfully negotiated by IKE, the traffic between the two switches is IPsec-protected.

Troubleshooting IKE

IKE negotiation failed because no matching IKE proposals were found

Symptom

1. The IKE SA is in Unknown state.

```
<Sysname> display ike sa
    Connection-ID   Remote                Flag         DOI
-------------------------------------------------------------------
    1               192.168.222.5         Unknown      IPsec
Flags:
RD--READY RL--REPLACED FD-FADING RK-REKEY
```

2. When IKE event debugging and packet debugging are enabled, the following messages appear:

   IKE event debugging message:

   ```
   The attributes are unacceptable.
   ```

   IKE packet debugging message:

   ```
   Construct notification packet: NO_PROPOSAL_CHOSEN.
   ```

Analysis

Certain IKE proposal settings are incorrect.

Solution

1. Examine the IKE proposal configuration to see whether the two ends have matching IKE proposals.
2. Modify the IKE proposal configuration to make sure the two ends have matching IKE proposals.

IKE negotiation failed because no IKE proposals or IKE keychains are specified correctly

Symptom

1. The IKE SA is in Unknown state.

   ```
   <Sysname> display ike sa
       Connection-ID   Remote                Flag         DOI
   -------------------------------------------------------------------
       1               192.168.222.5         Unknown      IPsec
   Flags:
   RD--READY RL--REPLACED FD-FADING RK-REKEY
   ```

2. The following IKE event debugging or packet debugging message appeared:

   IKE event debugging message:

   ```
   Notification PAYLOAD_MALFORMED is received.
   ```

   IKE packet debugging message:

   ```
   Construct notification packet: PAYLOAD_MALFORMED.
   ```

Analysis

- If the following debugging information appeared, the matched IKE profile is not using the matched IKE proposal:

  ```
  Failed to find proposal 1 in profile profile1.
  ```

- If the following debugging information appeared, the matched IKE profile is not using the matched IKE keychain:

  ```
  Failed to find keychain keychain1 in profile profile1.
  ```

Solution

- Verify that the matched IKE proposal (IKE proposal 1 in this debugging message example) is specified for the IKE profile (IKE profile 1 in the example).

- Verify that the matched IKE keychain (IKE keychain 1 in this debugging message example) is specified for the IKE profile (IKE profile 1 in the example).

IPsec SA negotiation failed because no matching IPsec transform sets were found

Symptom

1. The **display ike sa** command shows that the IKE SA negotiation succeeded and the IKE SA is in RD state, but the **display ipsec sa** command shows that the expected IPsec SA has not been negotiated yet.
2. The following IKE debugging message appeared:

   ```
   The attributes are unacceptable.
   ```

   Or:

   ```
   Construct notification packet: NO_PROPOSAL_CHOSEN.
   ```

Analysis

Certain IPsec policy settings are incorrect.

Solution

1. Examine the IPsec configuration to see whether the two ends have matching IPsec transform sets.
2. Modify the IPsec configuration to make sure the two ends have matching IPsec transform sets.

IPsec SA negotiation failed due to invalid identity information

Symptom

1. The **display ike sa** command shows that the IKE SA negotiation succeeded and the IKE SA is in RD state, but the **display ipsec sa** command shows that the expected IPsec SA has not been negotiated yet.
2. The following IKE debugging message appeared:

   ```
   Notification INVALID_ID_INFORMATION is received.
   ```

   Or:

   ```
   Failed to get IPsec policy when renegotiating IPsec SA. Delete IPsec SA.
   Construct notification packet: INVALID_ID_INFORMATION.
   ```

Analysis

Certain IPsec policy settings of the responder are incorrect. Verify the settings as follows:

1. Use the **display ike sa verbose** command to verify that matching IKE profiles were found in IKE negotiation phase 1. If no matching IKE profiles were found and the IPsec policy is using an IKE profile, the IPsec SA negotiation fails.

   # Identify whether matching IKE profiles were found in IKE negotiation phase 1. The following output shows that no matching IKE profile was found:

   ```
   <Sysname> display ike sa verbose
      ----------------------------------------------
      Connection ID: 3
      Outside VPN:
      Inside VPN:
      Profile:
      Transmitting entity: Responder
   ```

```
  ---------------------------------------------
  Local IP: 192.168.222.5
  Local ID type: IPV4_ADDR
  Local ID: 192.168.222.5

  Remote IP: 192.168.222.71
  Remote ID type: IPV4_ADDR
  Remote ID: 192.168.222.71

  Authentication-method: PRE-SHARED-KEY
  Authentication-algorithm: MD5
  Encryption-algorithm: 3DES-CBC

  Life duration(sec): 86400
  Remaining key duration(sec): 85847
  Exchange-mode: Main
  Diffie-Hellman group: Group 1
  NAT traversal: Not detected
```

Identify whether the IPsec policy is using an IKE profile. The following output shows that the IPsec policy is using an IKE profile.

```
[Sysname] display ipsec policy
-----------------------------------------
IPsec Policy: policy1
Interface: GigabitEthernet1/0/1
-----------------------------------------

  ----------------------------
  Sequence number: 1
  Mode: ISAKMP
  ----------------------------
  Description:
  Security data flow: 3000
  Selector mode: aggregation
  Local address: 192.168.222.5
  Remote address: 192.168.222.71
  Transform set:  transform1
  IKE profile: profile1
  SA duration(time based):
  SA duration(traffic based):
  SA idle time:
```

2. Verify that the ACL specified for the IPsec policy is correctly configured. If the flow range defined by the responder's ACL is smaller than that defined by the initiator's ACL, IPsec proposal matching will fail.

For example, if the initiator's ACL defines a flow from one network segment to another but the responder's ACL defines a flow from one host to another host, IPsec proposal matching will fail.

On the initiator:

```
[Sysname] display acl 3000
Advanced IPv4 ACL 3000, 1 rule,
ACL's step is 5
```

```
 rule 0 permit ip source 192.168.222.0 0.0.0.255 destination 192.168.222.0 0.0.0.255
```

On the responder:

```
[Sysname] display acl 3000
Advanced IPv4 ACL 3000, 1 rule,
ACL's step is 5
 rule 0 permit ip source 192.168.222.71 0 destination 192.168.222.5 0
```

3. Verify that the IPsec policy has a remote address and an IPsec transform set configured and that the IPsec transform set has all necessary settings configured.

   If, for example, the IPsec policy has no remote address configured, the IPsec SA negotiation will fail:

```
[Sysname] display ipsec policy
-----------------------------------------
IPsec Policy: policy1
Interface: GigabitEthernet1/0/1
-----------------------------------------

  ----------------------------
  Sequence number: 1
  Mode: ISAKMP
  ----------------------------
  Security data flow: 3000
  Selector mode: aggregation
  Local address: 192.168.222.5
  Remote address:
  Transform set:  transform1
  IKE profile: profile1
  SA duration(time based):
  SA duration(traffic based):
  SA idle time:
```

Solution

1. If the IPsec policy specifies an IKE profile but no matching IKE profiles was found in IKE negotiation, perform one of the following tasks on the responder:
   - Remove the specified IKE profile from the IPsec policy.
   - Modify the specified IKE profile to match the IKE profile of the initiator.
2. If the flow range defined by the responder's ACL is smaller than that defined by the initiator's ACL, modify the responder's ACL so the ACL defines a flow range equal to or greater than that of the initiator's ACL.

   For example:

```
[Sysname] display acl 3000
Advanced IPv4 ACL 3000, 2 rules,
ACL's step is 5
 rule 0 permit ip source 192.168.222.0 0.0.0.255 destination 192.168.222.0 0.0.0.255
```

3. Configure the missing settings (for example, the remote address).

Configuring IKEv2

About IKEv2

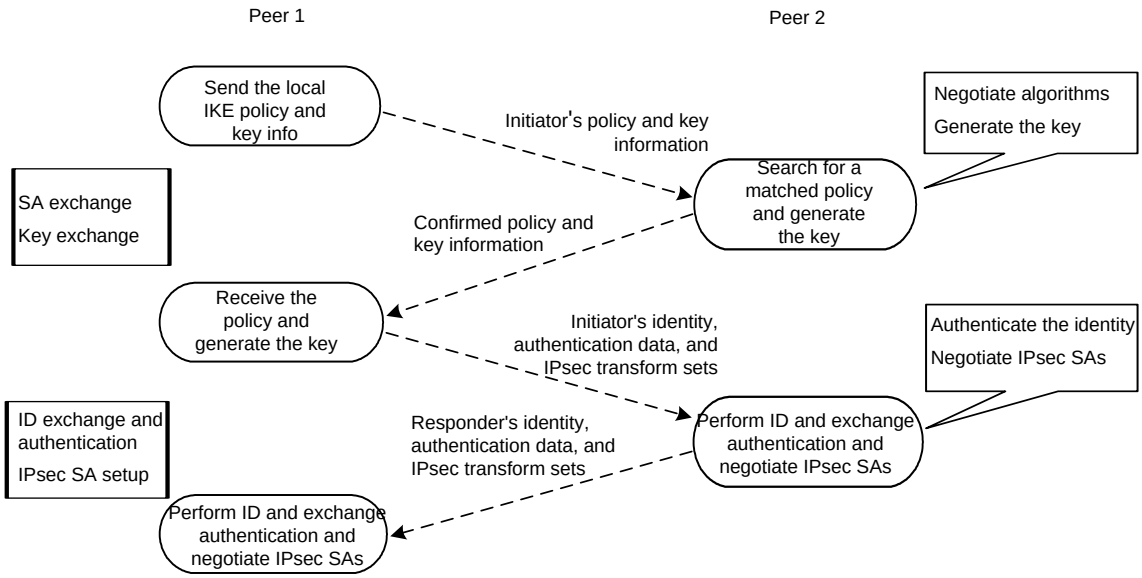
Internet Key Exchange version 2 (IKEv2) is an enhanced version of IKEv1. The same as IKEv1, IKEv2 has a set of self-protection mechanisms and can be used on insecure networks for reliable identity authentication, key distribution, and IPsec SA negotiation. IKEv2 provides stronger protection against attacks and higher key exchange ability and needs fewer message exchanges than IKEv1.

IKEv2 negotiation process

Compared with IKEv1, IKEv2 simplifies the negotiation process and is much more efficient.

IKEv2 defines three types of exchanges: initial exchanges, CREATE_CHILD_SA exchange, and INFORMATIONAL exchange.

As shown in Figure 14, IKEv2 uses two exchanges during the initial exchange process: IKE_SA_INIT and IKE_AUTH, each with two messages.



- **IKE_SA_INIT exchange**—Negotiates IKE SA parameters and exchanges keys.
- **IKE_AUTH exchange**—Authenticates the identity of the peer and establishes IPsec SAs.

After the four-message initial exchanges, IKEv2 sets up one IKE SA and one pair of IPsec SAs. For IKEv1 to set up one IKE SA and one pair of IPsec SAs, it must go through two phases that use a minimum of six messages.

To set up one more pair of IPsec SAs within the IKE SA, IKEv2 goes on to perform an additional two-message exchange—the CREATE_CHILD_SA exchange. One CREATE_CHILD_SA exchange creates one pair of IPsec SAs. IKEv2 also uses the CREATE_CHILD_SA exchange to rekey IKE SAs and Child SAs.

IKEv2 uses the INFORMATIONAL exchange to convey control messages about errors and notifications.

Figure 14 IKEv2 Initial exchange process

New features in IKEv2

DH guessing

In the IKE_SA_INIT exchange, the initiator guesses the DH group that the responder is most likely to use and sends it in an IKE_SA_INIT request message. If the initiator's guess is correct, the responder responds with an IKE_SA_INIT response message and the IKE_SA_INIT exchange is finished. If the guess is wrong, the responder responds with an INVALID_KE_PAYLOAD message that contains the DH group that it wants to use. The initiator then uses the DH group selected by the responder to reinitiate the IKE_SA_INIT exchange. The DH guessing mechanism allows for more flexible DH group configuration and enables the initiator to adapt to different responders.

Cookie challenging

Messages for the IKE_SA_INIT exchange are in plain text. An IKEv1 responder cannot confirm the validity of the initiators and must maintain half-open IKE SAs, which makes the responder susceptible to DoS attacks. An attacker can send a large number of IKE_SA_INIT requests with forged source IP addresses to the responder, exhausting the responder's system resources.

IKEv2 introduces the cookie challenging mechanism to prevent such DoS attacks. When an IKEv2 responder maintains a threshold number of half-open IKE SAs, it starts the cookie challenging mechanism. The responder generates a cookie and includes it in the response sent to the initiator. If the initiator initiates a new IKE_SA_INIT request that carries the correct cookie, the responder considers the initiator valid and proceeds with the negotiation. If the carried cookie is incorrect, the responder terminates the negotiation.

The cookie challenging mechanism automatically stops working when the number of half-open IKE SAs drops below the threshold.

IKEv2 SA rekeying

For security purposes, both IKE SAs and IPsec SAs have a lifetime and must be rekeyed when the lifetime expires. An IKEv1 SA lifetime is negotiated. An IKEv2 SA lifetime, in contrast, is configured. If two peers are configured with different lifetimes, the peer with the shorter lifetime always initiates the SA rekeying. This mechanism reduces the possibility that two peers will simultaneously initiate a rekeying. Simultaneous rekeying results in redundant SAs and SA status inconsistency on the two peers.

IKEv2 message retransmission

Unlike IKEv1 messages, IKEv2 messages appear in request/response pairs. IKEv2 uses the Message ID field in the message header to identify the request/response pair. If an initiator sends a request but receives no response with the same Message ID value within a specific period of time, the initiator retransmits the request.

It is always the IKEv2 initiator that initiates the retransmission, and the retransmitted message must use the same Message ID value.

Protocols and standards

- RFC 2408, *Internet Security Association and Key Management Protocol (ISAKMP)*
- RFC 4306, *Internet Key Exchange (IKEv2) Protocol*
- RFC 4718, *IKEv2 Clarifications and Implementation Guidelines*
- RFC 2412, *The OAKLEY Key Determination Protocol*
- RFC 5996, *Internet Key Exchange Protocol Version 2 (IKEv2)*

IKEv2 tasks at a glance

To configure IKEv2, perform the following tasks:

1. Configuring an IKEv2 profile
   a. Creating an IKEv2 profile
   b. Specifying the local and remote identity authentication methods
   c. Configuring the IKEv2 keychain or PKI domain
   d. Configuring the local ID for the IKEv2 profile
   e. Configuring peer IDs for the IKEv2 profile
   f. Specifying a VPN instance for the IKEv2 profile
   g. Specifying an inside VPN instance for the IKEv2 profile
   h. Configuring optional features for the IKEv2 profile
2. Configuring an IKEv2 policy
3. Configuring an IKEv2 proposal

   If you specify an IKEv2 proposal in an IKEv2 policy, you must configure the IKEv2 proposal.
4. Configuring an IKEv2 keychain

   This task is required when either end or both ends use the preshared key authentication method.
5. (Optional.) Enabling the cookie challenging feature

   The cookie challenging feature takes effect only on IKEv2 responders.
6. (Optional.) Configuring the IKEv2 DPD feature
7. (Optional.) Configuring the IKEv2 NAT keepalive feature

Prerequisites for IKEv2 configuration

Determine the following parameters prior to IKEv2 configuration:

- The strength of the algorithms for IKEv2 negotiation, including the encryption algorithms, integrity protection algorithms, PRF algorithms, and DH groups. Different algorithms provide different levels of protection. A stronger algorithm means better resistance to decryption of protected data but requires more resources. Typically, the longer the key, the stronger the algorithm.
- The local and remote identity authentication methods.
  - To use the preshared key authentication method, you must determine the preshared key.
  - To use the RSA digital signature authentication method, you must determine the PKI domain for the local end to use. For information about PKI, see "Configuring PKI."

Configuring an IKEv2 profile

Creating an IKEv2 profile

About this task

An IKEv2 profile is intended to provide a set of parameters for IKEv2 negotiation.

Procedure

1. Enter system view.

   `system-view`
2. Create an IKEv2 profile and enter its view.

   `ikev2 profile` *`profile-name`*

Specifying the local and remote identity authentication methods

Restrictions and guidelines

The local and remote identity authentication methods must both be specified and they can be different. You can specify only one local identity authentication method and multiple remote identity authentication methods.

Procedure

1. Enter system view.
   system-view
2. Enter IKEv2 profile view.
   ikev2 profile *profile-name*
3. Specify the local and remote identity authentication methods.
   authentication-method { **local** | **remote** } { **dsa-signature** | **ecdsa-signature** | **pre-share** | **rsa-signature** }
   By default, no local or remote identity authentication method is configured.

Configuring the IKEv2 keychain or PKI domain

Restrictions and guidelines

Configure the IKEv2 keychain or PKI domain for the IKEv2 profile to use. To use digital signature authentication, configure a PKI domain. To use preshared key authentication, configure an IKEv2 keychain.

Procedure

1. Enter system view.
   system-view
2. Enter IKEv2 profile view.
   ikev2 profile *profile-name*
3. Specify the keychain for preshared key authentication or the PKI domain used to request a certificate for digital signature authentication.
   - Specify the keychain.
     keychain *keychain-name*
   - Specify the PKI domain.
     certificate domain *domain-name* [**sign** | **verify**]

   By default, no IKEv2 keychain or PKI domain is specified for an IKEv2 profile.

Configuring the local ID for the IKEv2 profile

Restrictions and guidelines

For digital signature authentication, the device can use an ID of any type. If the local ID is an IP address that is different from the IP address in the local certificate, the device uses the FQDN as the local ID. The FQDN is the device name configured by using the **sysname** command.

For preshared key authentication, the device can use an ID of any type other than the DN.

Procedure

1. Enter system view.
   system-view
2. Enter IKEv2 profile view.
   ikev2 profile *profile-name*
3. Configure the local ID.
   identity local { **address** { *ipv4-address* | **ipv6** *ipv6-address* } | **dn** | **email** *email-string* | **fqdn** *fqdn-name* | **key-id** *key-id-string* }
   By default, no local ID is configured, and the device uses the IP address of the interface where the IPsec policy applies as the local ID.

Configuring peer IDs for the IKEv2 profile

About this task

Perform this task to configure the peer ID for IKEv2 profile matching. When the device needs to select an IKEv2 profile for IKEv2 negotiation with a peer, it compares the received peer ID with the peer IDs of its local IKE profiles. If a match is found, it uses the IKEv2 profile with the matching peer ID for negotiation. IKEv2 profiles will be compared in descending order of their priorities.

Procedure

1. Enter system view.
   system-view
2. Enter IKEv2 profile view.
   ikev2 profile *profile-name*
3. Configure a peer ID.
   match remote { **certificate** *policy-name* | **identity** { **address** { { *ipv4-address* [*mask* | *mask-length*] | **range** *low-ipv4-address high-ipv4-address* } | **ipv6** { *ipv6-address* [*prefix-length*] | **range** *low-ipv6-address high-ipv6-address* } } | **fqdn** *fqdn-name* | **email** *email-string* | **key-id** *key-id-string* } }
   You must configure a minimum of one peer ID on each of the two peers.

Specifying a VPN instance for the IKEv2 profile

About this task

After you specify a VPN instance for an IKEv2 profile, the IKEv2 profile can be used for IKEv2 negotiation only on the interfaces that belong to the VPN instance.

Procedure

1. Enter system view.
   system-view
2. Enter IKEv2 profile view.
   ikev2 profile *profile-name*
3. Specify a VPN instance for the IKEv2 profile.
   match vrf { **name** *vrf-name* | **any** }
   By default, an IKEv2 profile belongs to the public network.

Specifying an inside VPN instance for the IKEv2 profile

About this task

The inside VPN instance determines where the device should forward received IPsec packets after it de-encapsulates the packets. If you specify an inside VPN instance, the device looks for a route in the specified VPN instance to forward the packets. If you do not specify an inside VPN instance, the internal and external networks are in the same VPN instance. The device looks for a route in this VPN instance to forward the packets.

Restrictions and guidelines

The inside VPN instance specified in an IKEv2 profile takes effect only on IPsec policies that use the IKEv2 profile. It does not take effect on IPsec profiles that use the IKEv2 profile.

Procedure

1. Enter system view.
   system-view
2. Enter IKEv2 profile view.
   ikev2 profile *profile-name*
3. Specify an inside VPN instance.
   inside-vrf *vrf-name*

   By default, no inside VPN instance is specified for an IKEv2 profile. The internal and external networks are in the same VPN instance. The device forwards protected data to this VPN instance.

Configuring optional features for the IKEv2 profile

1. Enter system view.
   system-view
2. Enter IKEv2 profile view.
   ikev2 profile *profile-name*
3. Configure optional features as needed.
   - Configure IKEv2 DPD.
     dpd interval *interval* [**retry** *seconds*] { **on-demand** | **periodic** }

     By default, IKEv2 DPD is not configured for an IKEv2 profile and an IKEv2 profile uses the DPD settings configured in system view. If IKEv2 DPD is not configured in system view either, the device does not perform dead IKEv2 peer detection.
   - Specify the local interface or IP address to which the IKEv2 profile can be applied.
     match local address { *interface-type interface-number* | *ipv4-address* | **ipv6** *ipv6-address* }

     By default, an IKEv2 profile can be applied to any local interface or local IP address.

     Use this command to specify which address or interface can use the IKEv2 profile for IKEv2 negotiation. Specify the local address configured in IPsec policy or IPsec policy template view (using the **local-address** command) for this command. If no local address is configured, specify the IP address of the interface that uses the IPsec policy.
   - Specify a priority for the IKEv2 profile.
     priority *priority*

     By default, the priority of an IKEv2 profile is 100.

When the device needs to select an IKEv2 profile for IKEv2 negotiation with a peer, it compares the received peer ID with the peer ID of its local IKEv2 profiles in descending order of their priorities

- Set the IKEv2 SA lifetime for the IKEv2 profile.

  sa duration *seconds*

  By default, the IKEv2 SA lifetime is 86400 seconds.

  The local and remote ends can use different IKEv2 SA lifetimes and they do not negotiate the lifetime. The end with a smaller SA lifetime will initiate an SA negotiation when the lifetime expires.

- Set the IKEv2 NAT keepalive interval.

  nat-keepalive *seconds*

  By default, the global IKEv2 NAT keepalive setting is used.

  Configure this command when the device is behind a NAT gateway. The device sends NAT keepalive packets regularly to its peer to prevent the NAT session from being aged because of no matching traffic.

- Enable the configuration exchange feature.

  config-exchange { **request** | **set** { **accept** | **send** } }

  By default, all configuration exchange options are disabled.

  This feature applies to scenarios where the headquarters and branches communicate through virtual tunnels. It enables exchanges of IP address request and set messages between the IPsec gateway at a branch and the IPsec gateway at the headquarters.

  Table 2 Parameter descriptions

Parameter	Description
request	Enables the IPsec gateway at a branch to submit IP address request messages to the IPsec gateway at the headquarters.
set accept	Enables the IPsec gateway at a branch to accept the IP addresses pushed by the IPsec gateway at the headquarters.
set send	Enables the IPsec gateway at the headquarters to push IP addresses to IPsec gateways at branches.

Configuring an IKEv2 policy

About this task

During the IKE_SA_INIT exchange, each end tries to find a matching IKEv2 policy, using the IP address of the local security gateway as the matching criterion.

- If IKEv2 policies are configured, IKEv2 searches for an IKEv2 policy that uses the IP address of the local security gateway. If no IKEv2 policy uses the IP address or the policy is using an incomplete proposal, the IKE_SA_INIT exchange fails.
- If no IKEv2 policy is configured, IKEv2 uses the system default IKEv2 policy **default**.

The device matches IKEv2 policies in the descending order of their priorities. To determine the priority of an IKEv2 policy:

1. First, the device examines the existence of the **match local address** command. An IKEv2 policy with the **match local address** command configured has a higher priority.
2. If a tie exists, the device compares the priority numbers. An IKEv2 policy with a smaller priority number has a higher priority.
3. If a tie still exists, the device prefers an IKEv2 policy configured earlier.

Procedure

1. Enter system view.

   system-view

2. Create an IKEv2 policy and enter its view.

   ikev2 policy *policy-name*

   By default, an IKEv2 policy named **default** exists.

3. Specify the local interface or address used for IKEv2 policy matching.

   match local address { *interface-type interface-number* | *ipv4-address* | **ipv6** *ipv6-address* }

   By default, no local interface or address is used for IKEv2 policy matching, and the policy matches any local interface or address.

4. Specify a VPN instance for IKEv2 policy matching.

   match vrf { **name** *vrf-name* | **any** }

   By default, no VPN instance is specified for IKEv2 policy matching. The IKEv2 policy matches all local addresses in the public network.

5. Specify an IKEv2 proposal for the IKEv2 policy.

   proposal *proposal-name*

   By default, no IKEv2 proposal is specified for an IKEv2 policy.

6. Specify a priority for the IKEv2 policy.

   priority *priority*

   By default, the priority of an IKEv2 policy is 100.

Configuring an IKEv2 proposal

About this task

An IKEv2 proposal contains security parameters used in IKE_SA_INIT exchanges, including the encryption algorithms, integrity protection algorithms, PRF algorithms, and DH groups. An algorithm specified earlier has a higher priority.

Restrictions and guidelines

A complete IKEv2 proposal must have at least one set of security parameters, including one encryption algorithm, one integrity protection algorithm, one PRF algorithm, and one DH group.

You can specify multiple IKEv2 proposals for an IKEv2 policy. A proposal specified earlier has a higher priority.

Procedure

1. Enter system view.

   system-view

2. Create an IKEv2 proposal and enter its view.

   ikev2 proposal *proposal-name*

   By default, an IKEv2 proposal named **default** exists.

   In non-FIPS mode, the default proposal uses the following settings:

   - Encryption algorithms AES-CBC-128 and 3DES.
   - Integrity protection algorithms HMAC-SHA1 and HMAC-MD5.
   - PRF algorithms HMAC-SHA1 and HMAC-MD5.
   - DH groups 2 and 5.

In FIPS mode, the default proposal uses the following settings:

- Encryption algorithms AES-CBC-128 and AES-CTR-128.
- Integrity protection algorithms HMAC-SHA1 and HMAC-SHA256.
- PRF algorithms HMAC-SHA1 and HMAC-SHA256.
- DH groups 14 and 19.

3. Specify the encryption algorithms.

   In non-FIPS mode:

   encryption { **3des-cbc** | **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** | **aes-ctr-128** | **aes-ctr-192** | **aes-ctr-256** | **camellia-cbc-128** | **camellia-cbc-192** | **camellia-cbc-256** | **des-cbc** } *

   In FIPS mode:

   encryption { **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** | **aes-ctr-128** | **aes-ctr-192** | **aes-ctr-256** } *

   By default, an IKEv2 proposal does not have any encryption algorithms.

4. Specify the integrity protection algorithms.

   In non-FIPS mode:

   integrity { **aes-xcbc-mac** | **md5** | **sha1** | **sha256** | **sha384** | **sha512** } *

   In FIPS mode:

   integrity { **sha1** | **sha256** | **sha384** | **sha512** } *

   By default, an IKEv2 proposal does not have any integrity protection algorithms.

5. Specify the DH groups.

   In non-FIPS mode:

   dh { **group1** | **group14** | **group2** | **group24** | **group5** | **group19** | **group20** } *

   In FIPS mode:

   dh { **group14** | **group19** | **group20** } *

   By default, an IKEv2 proposal does not have any DH groups.

6. Specify the PRF algorithms.

   In non-FIPS mode:

   prf { **aes-xcbc-mac** | **md5** | **sha1** | **sha256** | **sha384** | **sha512** } *

   In FIPS mode:

   prf { **sha1** | **sha256** | **sha384** | **sha512** } *

   By default, an IKEv2 proposal uses the integrity protection algorithms as the PRF algorithms.

Configuring an IKEv2 keychain

About this task

An IKEv2 keychain specifies the preshared keys used for IKEv2 negotiation.

An IKEv2 keychain can have multiple IKEv2 peers. Each peer has a symmetric preshared key or an asymmetric preshared key pair, and information for identifying the peer (such as the peer's host name, IP address or address range, or ID).

An IKEv2 negotiation initiator uses the peer host name or IP address/address range as the matching criterion to search for a peer. A responder uses the peer host IP address/address range or ID as the matching criterion to search for a peer.

Procedure

1. Enter system view.
   system-view
2. Create an IKEv2 keychain and enter its view.
   ikev2 keychain *keychain-name*
3. Create an IKEv2 peer and enter its view.
   peer *name*
4. Configure a host name for the peer:
   hostname *name*
   By default, no host name is configured for an IKEv2 peer.
5. Configure a host IP address or address range for the peer:
   address { *ipv4-address* [*mask* | *mask-length*] | **ipv6** *ipv6-address* [*prefix-length*] }
   By default, no host IP address or address range is configured for an IKEv2 peer.
   You must configure different host IP addresses/address ranges for different peers.
6. Configure an ID for the peer:
   identity { **address** { *ipv4-address* | **ipv6** { *ipv6-address* } } | **fqdn** *fqdn-name* | **email** *email-string* | **key-id** *key-id-string* }
   By default, no identity information is configured for an IKEv2 peer.
7. Configure a preshared key for the peer.
   pre-shared-key [**local** | **remote**] { **ciphertext** | **plaintext** } *string*
   By default, an IKEv2 peer does not have a preshared key.

Configure global IKEv2 parameters

Enabling the cookie challenging feature

About this task

Enable cookie challenging on responders to protect them against DoS attacks that use a large number of source IP addresses to forge IKE_SA_INIT requests.

Procedure

1. Enter system view.
   system-view
2. Enable IKEv2 cookie challenging.
   ikev2 cookie-challenge *number*
   By default, IKEv2 cookie challenging is disabled.

Configuring the IKEv2 DPD feature

About this task

IKEv2 DPD detects dead IKEv2 peers in periodic or on-demand mode.

- **Periodic IKEv2 DPD**—Verifies the liveness of an IKEv2 peer by sending DPD messages at regular intervals.

- **On-demand IKEv2 DPD**—Verifies the liveness of an IKEv2 peer by sending DPD messages before sending data.
  - Before the device sends data, it identifies the time interval for which the last IPsec packet has been received from the peer. If the time interval exceeds the DPD interval, it sends a DPD message to the peer to detect its liveliness.
  - If the device has no data to send, it never sends DPD messages.

Restrictions and guidelines

If you configure IKEv2 DPD in both IKEv2 profile view and system view, the IKEv2 DPD settings in IKEv2 profile view apply. If you do not configure IKEv2 DPD in IKEv2 profile view, the IKEv2 DPD settings in system view apply.

Procedure

1. Enter system view.
   system-view
2. Configure global IKEv2 DPD.
   ikev2 dpd interval *interval* [**retry** *seconds*] { **on-demand** | **periodic** }
   By default, global DPD is disabled.

Configuring the IKEv2 NAT keepalive feature

About this task

Configure this feature on the IKEv2 gateway behind the NAT device. The gateway then sends NAT keepalive packets regularly to its peer to keep the NAT session alive, so that the peer can access the device.

The NAT keepalive interval must be shorter than the NAT session lifetime.

This feature takes effect after the device detects the NAT device.

Procedure

1. Enter system view.
   system-view
2. Set the IKEv2 NAT keepalive interval.
   ikev2 nat-keepalive *seconds*
   By default, the IKEv2 NAT keepalive interval is 10 seconds.

Display and maintenance commands for IKEv2

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the IKEv2 policy configuration.	**display ikev2 policy** [*policy-name* | **default**]
Display the IKEv2 profile configuration.	**display ikev2 profile** [*profile-name*]
Display the IKEv2 proposal configuration.	**display ikev2 proposal** [*name* | **default**]
Display the IKEv2 SA information.	**display ikev2 sa** [**count** | [{ **local** |

Task	Command
	remote } { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] [**verbose** [**tunnel** *tunnel-id*]]]
Display IKEv2 statistics.	**display ikev2 statistics**
Delete IKEv2 SAs and the child SAs negotiated through the IKEv2 SAs.	**reset ikev2 sa** [[{ **local** | **remote** } { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] | **tunnel** *tunnel-id*] [**fast**]
Clear IKEv2 statistics.	**reset ikev2 statistics**

Troubleshooting IKEv2

IKEv2 negotiation failed because no matching IKEv2 proposals were found

Symptom

The IKEv2 SA is in IN-NEGO status.

```
<Sysname> display ikev2 sa
Tunnel ID   Local                       Remote                      Status
  ------------------------------------------------------------------------------
  5           123.234.234.124/500         123.234.234.123/500         IN-NEGO
Status:
IN-NEGO: Negotiating, EST: Established, DEL:Deleting
```

Analysis

Certain IKEv2 proposal settings are incorrect.

Solution

1. Examine the IKEv2 proposal configuration to see whether the two ends have matching IKEv2 proposals.
2. Modify the IKEv2 proposal configuration to make sure the two ends have matching IKEv2 proposals.

IPsec SA negotiation failed because no matching IPsec transform sets were found

Symptom

The **display ikev2 sa** command shows that the IKEv2 SA negotiation succeeded and the IKEv2 SA is in EST status. The **display ipsec sa** command shows that the expected IPsec SAs have not been negotiated yet.

Analysis

Certain IPsec policy settings are incorrect.

Solution

1. Examine the IPsec configuration to see whether the two ends have matching IPsec transform sets.
2. Modify the IPsec configuration to make sure the two ends have matching IPsec transform sets.

IPsec tunnel establishment failed

Symptom

The ACLs and IKEv2 proposals are correctly configured on both ends. The two ends cannot establish an IPsec tunnel or cannot communicate through the established IPsec tunnel.

Analysis

The IKEv2 SA or IPsec SAs on either end are lost. The reason might be that the network is unstable and the device reboots.

Solution

1. Use the **`display ikev2 sa`** command to examine whether an IKEv2 SA exists on both ends. If the IKEv2 SA on one end is lost, delete the IKEv2 SA on the other end by using the **`reset ikev2 sa`** command and trigger new negotiation. If an IKEv2 SA exists on both ends, go to the next step.
2. Use the **`display ipsec sa`** command to examine whether IPsec SAs exist on both ends. If the IPsec SAs on one end are lost, delete the IPsec SAs on the other end by using the **`reset ipsec sa`** command and trigger new negotiation.

Configuring SSH

About SSH

Secure Shell (SSH) is a network security protocol. Using encryption and authentication, SSH can implement secure remote access and file transfer over an insecure network.

SSH uses the typical client-server model to establish a channel for secure data transfer based on TCP.

SSH includes two versions: SSH1.x and SSH2.0 (hereinafter referred to as SSH1 and SSH2), which are not compatible. SSH2 is better than SSH1 in performance and security.

SSH applications

The device supports the following SSH applications:

- **Secure Telnet**—Stelnet provides secure and reliable network terminal access services. Through Stelnet, a user can securely log in to a remote server. Stelnet can protect devices against attacks, such as IP spoofing and plain text password interception. The device can act as an Stelnet server or an Stelnet client.
- **Secure File Transfer Protocol**—Based on SSH2, SFTP uses SSH connections to provide secure file transfer. The device can act as an SFTP server, allowing a remote user to log in to the SFTP server for secure file management and transfer. The device can also act as an SFTP client, enabling a user to log in from the device to a remote device for secure file transfer.
- **Secure Copy**—Based on SSH2, SCP offers a secure method to copy files. The device can act as an SCP server, allowing a user to log in to the device for file upload and download. The device can also act as an SCP client, enabling a user to log in from the device to a remote device for secure file transfer.
- **NETCONF over SSH**—Based on SSH2, it enables users to securely log in to the device through SSH and perform NETCONF operations on the device through the NETCONF-over-SSH connections. The device can act only as a NETCONF-over-SSH server. For more information about NETCONF, see *Network Management and Monitoring Configuration Guide*.

When acting as an SSH server or client, the device supports the following SSH versions:

- When acting as an Stelnet, SFTP, or SCP server, the device supports both SSH2 and SSH1 in non-FIPS mode and only SSH2 in FIPS mode.
- When acting as an SSH client, the device supports only SSH2.
- When acting as a NETCONF-over-SSH server, the device supports only SSH2.

How SSH works

This section uses SSH2 as an example to describe the stages to establish an SSH session.

Table 1 Stages to establish an SSH session

Stages	Description
Connection establishment	The SSH server listens to connection requests on port 22. After a client initiates a connection request, the server and the client establish a TCP connection.
Version negotiation	The two parties determine a version to use.

Stages	Description
Algorithm negotiation	SSH supports multiple algorithms. Based on the local algorithms, the two parties negotiate the following algorithms: • Key exchange algorithm for generating session keys. • Encryption algorithm for encrypting data. • Public key algorithm for the digital signature and authentication. • HMAC algorithm for protecting data integrity.
Key exchange	The two parties use the DH exchange algorithm to dynamically generate the session keys and session ID. • The session keys are used for protecting data transfer. • The session ID is used for identifying the SSH connection. In this stage, the client also authenticates the server.
Authentication	The SSH server authenticates the client in response to the client's authentication request.
Session request	After passing the authentication, the client sends a session request to the server to request the establishment of a session (or request the Stelnet, SFTP, SCP, or NETCONF service).
Interaction	After the server grants the request, the client and the server start to communicate with each other in the session. In this stage, you can paste commands in text format and execute them at the CLI. The text pasted at one time must be no more than 2000 bytes. As a best practice to ensure the correct execution of commands, paste commands that are in the same view. To execute commands of more than 2000 bytes, save the commands in a configuration file, upload the file to the server through SFTP, and use it to restart the server.

SSH authentication methods

This section describes authentication methods that are supported by the device when it acts as an SSH server.

Password authentication

The SSH server authenticates a client through the AAA mechanism. The password authentication process is as follows:

1. The client sends the server an authentication request that includes the encrypted username and password.
2. The server performs the following operations:
   a. Decrypts the request to get the username and password in plain text.
   b. Verifies the username and password locally or through remote AAA authentication.
   c. Informs the client of the authentication result.

If the remote AAA server requires the user to enter a password for secondary authentication, it send the SSH server an authentication response carrying a prompt. The prompt is transparently transmitted to the client to notify the user to enter a specific password. When the user enters the correct password, the AAA sever examines the password validity. If the password is valid, the SSH server returns an authentication success message to the client.

SSH1 clients do not support secondary password authentication initiated by the AAA server.

For more information about AAA, see "Configuring AAA."

Keyboard-interactive authentication

In keyboard-interactive authentication, the remote authentication server and user exchanges information for authentication as follows:

1. The remote authentication server sends a prompt to the SSH server in an authentication response.

   The prompt indicates the information required to be provided by the user.
2. The SSH server transparently transmits the prompt to the client terminal.
3. The user enters the required information as prompted.

This process repeats multiple times if the remote authentication server requires more interactive information. The remote authentication server returns an authentication success message after the user provides all required interactive information.

If the remote authentication server does not require interactive information, the keyboard-interactive authentication process is the same as the password authentication.

Publickey authentication

The server authenticates a client by verifying the digital signature of the client. The publickey authentication process is as follows:

1. The client sends the server a publickey authentication request that includes the username, public key, and public key algorithm name.

   If the digital certificate of the client is required in authentication, the client also encapsulates the digital certificate in the authentication request. The digital certificate carries the public key information of the client.
2. The server verifies the client's public key.
   - If the public key is invalid, the server informs the client of the authentication failure.
   - If the public key is valid, the server requests the digital signature of the client. After receiving the signature, the server uses the public key to verify the signature and informs the client of the authentication result.

When acting as an SSH server, the device supports using the public key algorithms DSA, ECDSA, and RSA to verify digital signatures.

When acting as an SSH client, the device supports using the public key algorithms DSA, ECDSA, and RSA to generate digital signatures.

For more information about public key configuration, see "Managing public keys."

Password-publickey authentication

The server requires SSH2 clients to pass both password authentication and publickey authentication. However, an SSH1 client only needs to pass either authentication.

Any authentication

The server requires clients to pass keyboard-interactive authentication, password authentication, or publickey authentication. Success with any one authentication method is sufficient to connect to the server.

SSH support for Suite B

Suite B contains a set of encryption and authentication algorithms that meet high security requirements. Table 2 lists all algorithms in Suite B.

The SSH server and client support using the X.509v3 certificate for identity authentication in compliance with the algorithm, negotiation, and authentication specifications defined in RFC 6239.

Table 2 Suite B algorithms

Security level	Key exchange algorithm	Encryption algorithm and HMAC algorithm	Public key algorithm
128-bit	ecdh-sha2-nistp256	AES128-GCM	x509v3-ecdsa-sha2-nistp256
192-bit	ecdh-sha2-nistp384	AES256-GCM	x509v3-ecdsa-sha2-nistp384
Both	ecdh-sha2-nistp256 ecdh-sha2-nistp384	AES128-GCM AES256-GCM	x509v3-ecdsa-sha2-nistp256 x509v3-ecdsa-sha2-nistp384

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see "Configuring FIPS."

Configuring the device as an SSH server

SSH server tasks at a glance

To configure an SSH server, perform the following tasks:

1. Generating local key pairs
2. (Optional.) Specifying the SSH service port
3. Enabling the SSH server
   - Enabling the Stelnet server
   - Enabling the SFTP server
   - Enabling the SCP server
   - Enabling NETCONF over SSH
4. Configuring the user lines for SSH login

   Required only for Stelnet and NETCONF-over-SSH servers.
5. Configuring a client's host public key

   Required for authentication method **publickey**, **password-publickey,** or **any**.
6. Configuring an SSH user
   - Required for authentication method **keyboard-interactive**, **publickey**, **password-publickey,** or **any**.
   - Optional for the **password** authentication method.
7. (Optional.) Configuring the SSH management parameters

   SSH management settings, such as authentication and connection control settings, help improve security of SSH connections.
8. (Optional.) Specifying a PKI domain for the SSH server
9. (Optional.) Disconnecting SSH sessions

Generating local key pairs

About this task

The DSA, ECDSA, or RSA key pairs on the SSH server are required for generating the session keys and session ID in the key exchange stage. They can also be used by a client to authenticate the server. When a client authenticates the server, it compares the public key received from the server with the server's public key that the client saved locally. If the keys are consistent, the client uses the locally saved server's public key to decrypt the digital signature received from the server. If the decryption succeeds, the server passes the authentication.

To support SSH clients that use different types of key pairs, generate DSA, ECDSA, and RSA key pairs on the SSH server.

- **RSA key pairs**—The SSH server generates a server key pair and a host key pair for RSA. The RSA server key pair is only used in SSH1 to encrypt the session key for secure transmission of the session key. It is not used in SSH2, because no session key transmission is required in SSH2.
- **DSA key pair**—The SSH server generates only one DSA host key pair. SSH1 does not support the DSA algorithm.
- **ECDSA key pair**—The SSH server generates only one ECDSA host key pair.

Restrictions and guidelines

Local DSA, ECDSA, and RSA key pairs for SSH use default names. You cannot assign names to the key pairs.

If the device does not have RSA key pairs with default names, it automatically generates one RSA server key pair and one RSA host key pair when SSH starts. Both key pairs use their default names. The SSH application starts when you execute an SSH server command on the device.

The key modulus length must be less than 2048 bits when you generate the DSA key pair on the SSH server.

When you generate an ECDSA key pair, you can generate only a **secp256r1** or **secp384r1** ECDSA key pair.

The SSH server operating in FIPS mode supports only ECDSA and RSA key pairs. Do not generate a DSA key pair on the SSH server in FIPS mode.

Procedure

1. Enter system view.
   system-view
2. Generate local key pairs.
   public-key local create { **dsa** | **ecdsa** { **secp256r1** | **secp384r1** } | **rsa** }

Specifying the SSH service port

About this task

The default port of the SSH service is 22. You can specify another port for the SSH service to improve security of SSH connections.

Procedure

1. Enter system view.
   system-view
2. Specify the SSH service port.
   ssh server port *port-number*

CAUTION:

- If you modify the SSH port number when the SSH server is enabled, the SSH service is restarted and all SSH connections are terminated after the modification. SSH users must reconnect to the SSH server to access the server.
- If you set the SSH port to a well-known port number, the service that uses the well-known port number might fail to start. Well-known port numbers are in the range of 1 to 1024.

By default, the SSH service port is 22.

Enabling the Stelnet server

About this task

After you enable the Stelnet server on the device, a client can log in to the device through Stelnet.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable the Stelnet server.
   ```
   ssh server enable
   ```
   By default, the Stelnet server is disabled.

Enabling the SFTP server

About this task

After you enable the SFTP server on the device, a client can log in to the device through SFTP.

Restrictions and guidelines

When acting as an SFTP server, the device does not support SFTP connections initiated by SSH1 clients.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Enable the SFTP server.
   ```
   sftp server enable
   ```
   By default, the SFTP server is disabled.

Enabling the SCP server

About this task

After you enable the SCP server on the device, a client can log in to the device through SCP.

Restrictions and guidelines

When acting as an SCP server, the device does not support SCP connections initiated by SSH1 clients.

Procedure

1. Enter system view.
   ```
   system-view
   ```

2. Enable the SCP server.

   scp server enable

   By default, the SCP server is disabled.

Enabling NETCONF over SSH

About this task

After you enable NETCONF over SSH on the device, a client can perform NETCONF operations on the device through a NETCONF-over-SSH connection.

Restrictions and guidelines

When acting as a server in the NETCONF-over-SSH connection, the device does not support connection requests initiated by SSH1 clients.

Procedure

1. Enter system view.

   system-view

2. Enable NETCONF over SSH.

   netconf ssh server enable

   By default, NETCONF over SSH is disabled.

   For more information about NETCONF over SSH commands, see *Network Management and Monitoring Command Reference*.

Configuring the user lines for SSH login

About this task

Depending on the SSH application, an SSH client can be an Stelnet client, SFTP client, SCP client, or NETCONF-over-SSH client.

Only Stelnet and NETCONF-over-SSH clients require the user line configuration. The user line configuration takes effect on the clients at the next login.

Procedure

1. Enter system view.

   system-view

2. Enter VTY user line view.

   line vty *number* [*ending-number*]

3. Set the login authentication mode to scheme.

   authentication-mode scheme

   By default, the authentication mode is **password**.

   For more information about this command, see *Fundamentals Command Reference*.

Configuring a client's host public key

About this task

In publickey authentication, the server compares the SSH username and the client's host public key received from the client with the locally saved SSH username and the client's host public key. If they are the same, the server checks the digital signature that the client sends. The client generates the digital signature by using the private key that is paired with the client's host public key.

For publickey authentication, password-publickey authentication, or any authentication, you must perform the following tasks:

1. Configure the client's DSA, ECDSA, or RSA host public key on the server.
2. Specify the associated host private key on the client to generate the digital signature.

   If the device acts as an SSH client, specify the public key algorithm on the client. The algorithm determines the associated host private key for generating the digital signature.

Client public key configuration methods

You can configure the client host public key by using the following methods:

- Manually enter the content of a client's host public key on the server.
  a. Display the host public key on the client and record the key.
  b. Type the client's host public key character by character on the server, or use the copy and paste method.

  The manually entered key must be in DER format without being converted. For the displayed key to meet the requirement when the client is an H3C device, use the **display public-key local public** command. The format of the public key displayed in any other way (for example, by using the **public-key local export** command) might be incorrect. If the key is not in correct format, the system discards the key.
- Import the client host public key from a public key file.
  a. Save the client public key file to the server. For example, transfer the client public key file to the server in binary mode through FTP or TFTP.
  b. Import the client public key from the locally saved public key file.

     During the import process, the server automatically converts the host public key to a string in PKCS format.

Restrictions and guidelines

As a best practice, configure no more than 20 SSH client's host public keys on an SSH server.

Import the client's host public key as a best practice.

Entering a client's host public key

1. Enter system view.

   system-view
2. Enter public key view.

   public-key peer *keyname*
3. Configure a client's host public key.

   Enter the content of the client's host public key character by character, or use the copy and paste method.

   When you enter the content of a client's host public key, you can use spaces and carriage returns between characters but the system does not save them. For more information, see "Managing public keys."
4. Exit public key view and save the key.

   peer-public-key end

Importing a client's host public key from the public key file

1. Enter system view.

   system-view
2. Import a client's public key from the public key file.

   public-key peer *keyname* **import sshkey** *filename*

Configuring an SSH user

About this task

Configure an SSH user and a local user depending on the authentication method.

- If the authentication method is **publickey**, you must create an SSH user and a local user on the SSH server. The two users must have the same username, so that the SSH user can be assigned the correct working directory and user role.
- If the authentication method is **password**, you must perform one of the following tasks:
  - For local authentication, configure a local user on the SSH server.
  - For remote authentication, configure an SSH user on a remote authentication server, for example, a RADIUS server.

  You do not need to create an SSH user by using the **ssh user** command. However, if you want to display all SSH users, including the password-only SSH users, for centralized management, you can use this command to create them. If such an SSH user has been created, make sure you have specified the correct service type and authentication method.
- If the authentication method is **keyboard-interactive**, **password-publickey**, or **any**, you must create an SSH user on the SSH server and perform one of the following tasks:
  - For local authentication, configure a local user on the SSH server.
  - For remote authentication, configure an SSH user on a remote authentication server, for example, a RADIUS server.

  In either case, the local user or the SSH user configured on the remote authentication server must have the same username as the SSH user.

For information about configuring local users and remote authentication, see "Configuring AAA."

Restrictions and guidelines

If you change the authentication parameters for a logged-in SSH user, the change takes effect on the user at the next login.

When the device operates as an SSH server in FIPS mode, the device does not support authentication method **any** or **publickey**.

For an SFTP or SCP user, the working directory depends on the authentication method.

- If the authentication method is **publickey** or **password-publickey**, the working folder is specified by the **authorization-attribute** command in the associated local user view.
- If the authentication method is **keyboard-interactive** or **password**, the working directory is authorized by AAA.

For an SSH user, the user role also depends on the authentication method.

- If the authentication method is **publickey** or **password-publickey**, the user role is specified by the **authorization-attribute** command in the associated local user view.
- If the authentication method is **keyboard-interactive** or **password**, the user role is authorized by AAA.

For all authentication methods except keyboard-interactive authentication and password authentication, you must specify a client's host public key or digital certificate.

- For a client that sends the user's public key information directly to the server, specify the client's host public key on the server. The specified public key must already exist. For more information about public keys, see "Configuring a client's host public key." If you specify multiple client public keys, the device verifies the user identity by using the public keys in the order they are specified. The user is valid if the user passes one public key check.
- For a client that sends the user's public key information to the server through a digital certificate, specify the PKI domain on the server. This PKI domain verifies the client's digital certificate. For successful verification, the specified PKI domain must have the correct CA certificate. To

specify the PKI domain, use the **ssh user** or **ssh server pki-domain** command. For more information about configuring a PKI domain, see "Configuring PKI."

Procedure

1. Enter system view.

   system-view

2. Create an SSH user, and specify the service type and authentication method.

   In non-FIPS mode:

   ssh user *username* **service-type** { **all** | **netconf** | **scp** | **sftp** | **stelnet** } **authentication-type** { **keyboard-interactive** | **password** | { **any** | **password-publickey** | **publickey** } [**assign** { **pki-domain** *domain-name* | **publickey** *keyname*&<1-6> }] }

   In FIPS mode:

   ssh user *username* **service-type** { **all** | **netconf** | **scp** | **sftp** | **stelnet** } **authentication-type** { **keyboard-interactive** | **password** | **password-publickey** [**assign** { **pki-domain** *domain-name* | **publickey** *keyname*&<1-6> }] }

   An SSH server supports up to 1024 SSH users.

Configuring the SSH management parameters

Enabling the SSH server to support SSH1 clients

1. Enter system view.

   system-view

2. Enable the SSH server to support SSH1 clients.

   ssh server compatible-ssh1x enable

   By default, the SSH server does not support SSH1 clients.

   This command is not available in FIPS mode.

Enabling SSH algorithm renegotiation and key re-exchange

1. Enter system view.

   system-view

2. Enable SSH algorithm renegotiation and key re-exchange.

   ssh server key-re-exchange enable [**interval** *interval*]

   By default, SSH algorithm renegotiation and key re-exchange are disabled.

   This command is not available in FIPS mode.

   The command takes effect only on new SSH connections that are established after the command is configured, and it does not affect existing SSH connections.

Setting the minimum interval for updating the RSA server key pair

1. Enter system view.

   system-view

2. Set the minimum interval for updating the RSA server key pair.

   ssh server rekey-interval *interval*

   By default, the device does not update the RSA server key pair.

   This command is not available in FIPS mode.

   This configuration takes effect only on SSH1 clients.

Setting the SSH user authentication timeout timer

1. Enter system view.

   system-view

2. Set the SSH user authentication timeout timer.

   ssh server authentication-timeout *time-out-value*

   The default setting is 60 seconds.

   Perform this task to prevent malicious occupation of TCP connections. If a user does not finish the authentication when the timeout timer expires, the connection cannot be established.

Setting the maximum number of SSH authentication attempts

1. Enter system view.

   system-view

2. Set the maximum number of SSH authentication attempts.

   ssh server authentication-retries *retries*

   The default setting is 3.

   Perform this task to prevent malicious hacking of usernames and passwords. If the authentication method is **any**, the total number of publickey authentication attempts and password authentication attempts cannot exceed the upper limit.

Specifying an SSH login control ACL

1. Enter system view.

   system-view

2. Specify an SSH login control ACL.

   IPv4:

   ssh server acl { *advanced-acl-number* | *basic-acl-number* | **mac** *mac-acl-number* }

   IPv6:

   ssh server ipv6 acl { **ipv6** { *advanced-acl-number* | *basic-acl-number* } | **mac** *mac-acl-number* }

   This feature uses an ACL to filter SSH clients that initiate SSH connections to the server. By default, no ACLs are specified and all SSH users can initiate SSH connections to the server.

Enabling logging for SSH login attempts that are denied by the SSH login control ACL

1. Enter system view.

   system-view

2. Enable logging for SSH login attempts that are denied by the SSH login control ACL.

   ssh server acl-deny-log enable

   By default, logging is disabled for login attempts that are denied by the SSH login control ACL.

   This command enables SSH to generate log messages for SSH login attempts that are denied by the SSH login control ACL and send the messages to the information center.

Setting the DSCP value in the packets that the SSH server sends to SSH clients

1. Enter system view.

   system-view

2. Set the DSCP value in the packets that the SSH server sends to the SSH clients.

   IPv4:

   ssh server dscp *dscp-value*

   IPv6:

ssh server ipv6 dscp *dscp-value*

By default, the DSCP value of SSH packets is 48.

The DSCP value of a packet defines the priority of the packet and affects the transmission priority of the packet. A bigger DSCP value represents a higher priority.

Setting the SFTP connection idle timeout timer

1. Enter system view.

   system-view

2. Set the SFTP connection idle timeout timer.

   sftp server idle-timeout *time-out-value*

   By default, the SFTP connection idle timeout is 10 minutes.

   When the SFTP connection idle timeout timer expires, the system automatically tears the connection down and releases the connection resources.

Setting the maximum number of online SSH users

1. Enter system view.

   system-view

2. Set the maximum number of online SSH users.

   aaa session-limit ssh *max-sessions*

   The default setting is 32.

   When the number of online SSH users reaches the upper limit, the system denies new SSH connection requests. Changing the upper limit does not affect online SSH users.

   For more information about this command, see AAA commands in *Security Command Reference*.

Specifying a PKI domain for the SSH server

About this task

The PKI domain specified for the SSH server has the following functions:

- The SSH server uses the PKI domain to send its certificate to the client in the key exchange stage.
- The SSH server uses the PKI domain to authenticate the client's certificate if no PKI domain is specified for the client authentication by using the **ssh user** command.

Procedure

1. Enter system view.

   system-view

2. Specify a PKI domain for the SSH server.

   ssh server pki-domain *domain-name*

   By default, no PKI domain is specified for the SSH server.

Disconnecting SSH sessions

About this task

The device supports concurrent login sessions. To avoid an SSH login user interfering with your configuration, you can disconnect that SSH login user.

Procedure

Execute the following command in user view to disconnect SSH sessions:

free ssh { **user-ip** { *ip-address* | **ipv6** *ipv6-address* } [**port** *port-number*] | **user-pid** *pid-number* | **username** *username* }

Configuring the device as an Stelnet client

Stelnet client tasks at a glance

To configure an Stelnet client, perform the following tasks:

1. Generating local key pairs

   Only required for authentication method **publickey**, **password-publickey**, or **any**.
2. (Optional.) Specifying the source IP address for outgoing SSH packets
3. Establishing a connection to an Stelnet server
4. (Optional.) Deleting server public keys saved in the public key file on the Stelnet client
5. (Optional.) Establishing a connection to an Stelnet server based on Suite B

Generating local key pairs

About this task

You must generate local key pairs on Stelnet clients when the Stelnet server uses the **publickey**, **password-publickey**, or **any** authentication method.

Restrictions and guidelines

Local DSA, ECDSA, and RSA key pairs for SSH use default names. You cannot assign names to the key pairs.

The key modulus length must be less than 2048 bits when you generate a DSA key pair.

When you generate an ECDSA key pair, you can generate only a **secp256r1** or **secp384r1** ECDSA key pair.

The Stelnet client operating in FIPS mode supports only ECDSA and RSA key pairs.

Procedure

1. Enter system view.

   system-view
2. Generate local key pairs.

   public-key local create { **dsa** | **ecdsa** { **secp256r1** | **secp384r1** } | **rsa** }

Specifying the source IP address for outgoing SSH packets

About this task

After you specify the source IP address for outgoing SSH packets on an Stelnet client, the client uses the specified IP address to communicate with the Stelnet server.

Restrictions and guidelines

As a best practice, specify the IP address of a loopback interface as the source address of outgoing SSH packets for the following purposes:

- Ensuring the communication between the Stelnet client and the Stelnet server.

- Improving the manageability of Stelnet clients in authentication service.

Procedure

1. Enter system view.

   system-view

2. Specify the source address for outgoing SSH packets.

   IPv4:

   ssh client source { **interface** *interface-type interface-number* | **ip** *ip-address* }

   By default, an IPv4 Stelnet client uses the primary IPv4 address of the output interface in the matching route as the source address of the outgoing SSH packets.

   IPv6:

   ssh client ipv6 source { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

   By default, an IPv6 Stelnet client automatically selects a source IPv6 address for outgoing SSH packets in compliance with RFC 3484.

Establishing a connection to an Stelnet server

About this task

Perform this task to enable the Stelnet client feature on the device and establish a connection to the Stelnet server. You can specify the public key algorithm and the preferred encryption, HMAC, and key exchange algorithms to be used during the connection.

To access the server, a client must use the server's host public key to authenticate the server. As a best practice, configure the server's host public key on the device in an insecure network. If the server's host public key is not configured on the client, the client will notify you to confirm whether to continue with the access.

- If you choose to continue, the client accesses the server and downloads the server's host public key. The downloaded public key will be used to authenticate the server in subsequent accesses.

  If the server public key is not specified the when you connect to the server, the device saves the server public key to the public key file. It does not save the server public key to the configuration file.

- If you choose to not continue, the connection cannot be established.

Restrictions and guidelines for establishing a connection to an Stelnet server

An Stelnet client cannot establish connections to both IPv4 and IPv6 Stelnet servers.

Establishing a connection to an IPv4 Stelnet server

Execute the following command in user view to establish a connection with an IPv4 Stelnet server:

In non-FIPS mode:

ssh2 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm**

| **des-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | **escape** *character* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

In FIPS mode:

ssh2 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** } | **prefer-ctos-hmac** { **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** } | **prefer-stoc-hmac** { **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | **escape** *character* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

Establishing a connection to an IPv6 Stelnet server

Execute the following command in user view to establish a connection to an IPv6 Stelnet server:

In non-FIPS mode:

ssh2 ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | **escape** *character* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

In FIPS mode:

ssh2 ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** } | **prefer-ctos-hmac** { **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** } | **prefer-stoc-hmac** { **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | **escape** *character* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Deleting server public keys saved in the public key file on the Stelnet client

About this task

When the Stelnet client switches to FIPS mode but the locally saved server public key does not comply with FIPS, the client cannot connect to the server. To connect to the server, delete the server public key saved on the client and make sure a FIPS-compliant public key has been generated on the server.

Procedure

1. Enter system view.
   system-view
2. Delete server public keys saved in the public key file on the Stelnet client.
   delete ssh client server-public-key [**server-ip** *ip-address*]

Establishing a connection to an Stelnet server based on Suite B

Execute the following command in user view to establish a connection to an Stelnet server based on Suite B:

IPv4:

ssh2 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**dscp** *dscp-value* | **escape** *character* | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

IPv6:

ssh2 ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**dscp** *dscp-value* | **escape** *character* | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Configuring the device as an SFTP client

SFTP client tasks at a glance

To configure an SFTP client, perform the following tasks:

1. Generating local key pairs
   Only required for authentication method **publickey**, **password-publickey**, or **any**.
2. (Optional.) Specifying the source IP address for outgoing SFTP packets
3. Establishing a connection to an SFTP server
4. (Optional.) Deleting server public keys saved in the public key file on the SFTP client
5. (Optional.) Establishing a connection to an SFTP server based on Suite B
6. (Optional.) Working with SFTP directories
7. (Optional.) Working with SFTP files
8. (Optional.) Displaying help information

9. (Optional.) Terminating the connection with the SFTP server

Generating local key pairs

About this task

You must generate local key pairs on SFTP clients when the SFTP server uses the **publickey**, **password-publickey**, or **any** authentication method.

Restrictions and guidelines

Local DSA, ECDSA, and RSA key pairs for SSH use default names. You cannot assign names to the key pairs.

The key modulus length must be less than 2048 bits when you generate a DSA key pair.

When you generate an ECDSA key pair, you can generate only a **secp256r1** or **secp384r1** ECDSA key pair.

The SFTP client operating in FIPS mode supports only ECDSA and RSA key pairs.

Procedure

1. Enter system view.

   system-view

2. Generate local key pairs.

   public-key local create { **dsa** | **ecdsa** { **secp256r1** | **secp384r1** } | **rsa** }

Specifying the source IP address for outgoing SFTP packets

About this task

After you specify the source IP address for outgoing SFTP packets on an SFTP client, the client uses the specified IP address to communicate with the SFTP server.

Restrictions and guidelines

As a best practice, specify the IP address of a loopback interface as the source address of outgoing SFTP packets for the following purposes:

- Ensuring the communication between the SFTP client and the SFTP server.
- Improving the manageability of SFTP clients in authentication service.

Procedure

1. Enter system view.

   system-view

2. Specify the source address for outgoing SFTP packets.

   IPv4:

   sftp client source { **ip** *ip-address* | **interface** *interface-type interface-number* }

   By default, an SFTP client uses the primary IPv4 address of the output interface in the matching route as the source address of the outgoing SFTP packets.

   IPv6:

   sftp client ipv6 source { **ipv6** *ipv6-address* | **interface** *interface-type interface-number* }

   By default, an IPv6 SFTP client automatically selects a source IPv6 address for the outgoing SFTP packets in compliance with RFC 3484.

Establishing a connection to an SFTP server

About this task

Perform this task to enable the SFTP client feature on the device and establish a connection to the SFTP server. You can specify the public key algorithm and the preferred encryption, HMAC, and key exchange algorithms to be used during the connection.

To access the server, a client must use the server's host public key to authenticate the server. As a best practice, configure the server's host public key on the device in an insecure network. If the server's host public key is not configured on the client, the client will notify you to confirm whether to continue with the access.

- If you choose to continue, the client accesses the server and downloads the server's host public key. The downloaded public key will be used to authenticate the server in subsequent accesses.

  If the server public key is not specified when you connect to the server, the device saves the server public key to the public key file. It does not save the server public key to the configuration file.
- If you choose to not continue, the connection cannot be established.

Restrictions and guidelines for establishing a connection to an SFTP server

An SFTP client cannot establish connections to both IPv4 and IPv6 SFTP servers.

Establishing a connection to an IPv4 SFTP server

Execute the following command in user view to establish a connection to an IPv4 SFTP server:

In non-FIPS mode:

sftp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

In FIPS mode:

sftp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** } | **prefer-ctos-hmac** { **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** } | **prefer-stoc-hmac** { **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

Establishing a connection to an IPv6 SFTP server

Execute the following command in user view to establish a connection to an IPv6 SFTP server:

In non-FIPS mode:

sftp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

In FIPS mode:

sftp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** } | **prefer-ctos-hmac** { **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** } | **prefer-stoc-hmac** { **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [**dscp** *dscp-value* | { **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Deleting server public keys saved in the public key file on the SFTP client

About this task

When the SFTP client switches to FIPS mode but the locally saved server public key does not comply with FIPS, the client cannot connect to the server. To connect to the server, delete the server public key saved on the client and make sure a FIPS-compliant public key has been generated on the server.

Procedure

1. Enter system view.

   system-view

2. Delete server public keys saved in the public key file on the SFTP client.

   delete ssh client server-public-key [**server-ip** *ip-address*]

Establishing a connection to an SFTP server based on Suite B

Execute the following command in user view to establish a connection to an SFTP server based on Suite B:

IPv4:

sftp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress** **zlib**] [**dscp** *dscp-value* | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] *

IPv6:

sftp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress** **zlib**] [**dscp** *dscp-value* | **escape** *character* | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] *

Working with SFTP directories

About this task

After you establish a connection to an SFTP server, you can operate directories of the SFTP server.

Changing the working directory on the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Change the working directory on the SFTP server.

   cd [*remote-path*]
3. (Optional.) Return to the upper-level directory.

   cdup

Displaying the current working directory on the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Display the current working directory on the SFTP server.

   pwd

Displaying files under a directory

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Display files under a directory.
   - **dir** [**-a** | **-l**] [*remote-path*]
   - **ls** [**-a** | **-l**] [*remote-path*]

   The **dir** command has the same function as the **ls** command.

Changing the name of a directory on the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."

2. Change the name of a directory on the SFTP server.
   rename *oldname newname*

Creating a new directory on the SFTP server

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Create a new directory on the SFTP server.
   mkdir *remote-path*

Deleting directories on the SFTP server

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Delete one or more directories from the SFTP server.
   rmdir *remote-path*

Working with SFTP files

About this task

After you establish a connection to an SFTP server, you can operate files on the SFTP server.

Changing the name of a file on the SFTP server

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Change the name of a file on the SFTP server.
   rename *old-name new-name*

Downloading a file from the SFTP server and save it locally

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Download a file from the SFTP server and save it locally.
   get *remote-file* [*local-file*]

Uploading a local file to the SFTP server

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Upload a local file to the SFTP server.
   put *local-file* [*remote-file*]

Display files under a directory

1. Enter SFTP client view.
   For more information, see "Establishing a connection to an SFTP server."
2. Display files under a directory.
   - **dir** [**-a** | **-l**] [*remote-path*]
   - **ls** [**-a** | **-l**] [*remote-path*]

   The **dir** command has the same function as the **ls** command.

Deleting a file from the SFTP server

1. Enter SFTP client view.

For more information, see "Establishing a connection to an SFTP server."

2. Delete a file from the SFTP server.
   - **delete** *remote-file*
   - **remove** *remote-file*

   The **delete** command has the same function as the **remove** command.

Displaying help information

About this task

After you establish a connection to the SFTP server, you can display the help information of SFTP client commands, including the command syntax and parameter configuration.

Procedure

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Display SFTP client command help information.
   - **help**
   - **?**

   The **help** command has the same function as the **?** command.

Terminating the connection with the SFTP server

1. Enter SFTP client view.

   For more information, see "Establishing a connection to an SFTP server."
2. Terminate the connection with the SFTP server and return to user view.
   - **bye**
   - **exit**
   - **quit**

   The three commands have the same function.

Configuring the device as an SCP client

SCP client tasks at a glance

To configure an SCP client, perform the following tasks:

1. Generating local key pairs

   Only required for the **publickey**, **password-publickey**, or **any** authentication method.
2. (Optional.) Specifying the source IP address for outgoing SCP packets
3. Establishing a connection to an SCP server
4. (Optional.) Deleting server public keys saved in the public key file on the SCP client
5. (Optional.) Establishing a connection to an SCP server based on Suite B

Generating local key pairs

About this task

You must generate local key pairs on SCP clients when the SCP server uses the **publickey**, **password-publickey**, or **any** authentication method.

Restrictions and guidelines

Local DSA, ECDSA, and RSA key pairs for SSH use default names. You cannot assign names to the key pairs.

The key modulus length must be less than 2048 bits when you generate a DSA key pair.

When you generate an ECDSA key pair, you can generate only a **secp256r1** or **secp384r1** ECDSA key pair.

The SCP client operating in FIPS mode supports only ECDSA and RSA key pairs.

Procedure

1. Enter system view.
   system-view
2. Generate local key pairs.
   public-key local create { **dsa** | **ecdsa** { **secp256r1** | **secp384r1** } | **rsa** }

Specifying the source IP address for outgoing SCP packets

About this task

After you specify the source IP address for outgoing SCP packets on an SCP client, the client uses the specified IP address to communicate with the SCP server.

Restrictions and guidelines

As a best practice, specify the IP address of a loopback interface as the source address of outgoing SCP packets for the following purposes:

- Ensuring the communication between the SCP client and the SCP server.
- Improving the manageability of SCP clients in authentication service.

Procedure

1. Enter system view.
   system-view
2. Specify the source address for outgoing SCP packets.

   IPv4:

   scp client source { **interface** *interface-type interface-number* | **ip** *ip-address* }

   By default, an SCP client uses the primary IPv4 address of the output interface in the matching route as the source address of the outgoing SCP packets.

   IPv6:

   scp client ipv6 source { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

   By default, an SCP client automatically selects an IPv6 address as the source address of the outgoing packets in compliance with RFC 3484.

Establishing a connection to an SCP server

About this task

Perform this task to enable the SCP client feature on the device, establish a connection to the SCP server, and transfer files with the server. You can specify the public key algorithm and the preferred encryption, HMAC, and key exchange algorithms to be used during the connection.

To access the server, a client must use the server's host public key to authenticate the server. As a best practice, configure the server's host public key on the device in an insecure network. If the server's host public key is not configured on the client, the client will notify you to confirm whether to continue with the access.

- If you choose to continue, the client accesses the server and downloads the server's host public key. The downloaded public key will be used to authenticate the server in subsequent accesses.

  If the server public key is not specified when you connect to the server, the device saves the server public key to the public key file. It does not save the server public key to the configuration file.
- If you choose to not continue, the connection cannot be established.

Restrictions and guidelines for establishing a connection to an SCP server

An SCP client cannot establish connections to both IPv4 and IPv6 SCP servers.

Establishing a connection to an IPv4 SCP server

Execute the following command in user view to connect to an IPv4 SCP server, and transfer files with the server:

In non-FIPS mode:

scp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] { **put** | **get** } *source-file-name* [*destination-file-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [{ **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

In FIPS mode:

scp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] { **put** | **get** } *source-file-name* [*destination-file-name*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** } | **prefer-ctos-hmac** { **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** } | **prefer-stoc-hmac** { **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [{ **public-key** *keyname* | **server-pki-domain**

Establishing a connection to an IPv6 SCP server

Execute the following command in user view to connect to an IPv6 SCP server, and transfer files with the server.

In non-FIPS mode:

scp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] { **put** | **get** } *source-file-name* [*destination-file-name*] [**identity-key** { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-ctos-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } | **prefer-stoc-hmac** { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [{ **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

In FIPS mode:

scp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] { **put** | **get** } *source-file-name* [*destination-file-name*] [**identity-key** { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | { **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } **pki-domain** *domain-name* } | **prefer-compress zlib** | **prefer-ctos-cipher** { **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** } | **prefer-ctos-hmac** { **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } | **prefer-kex** { **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } | **prefer-stoc-cipher** { **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** } | **prefer-stoc-hmac** { **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }] * [{ **public-key** *keyname* | **server-pki-domain** *domain-name* } | **source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

Deleting server public keys saved in the public key file on the SCP client

About this task

When the SCP client switches to FIPS mode but the locally saved server public key does not comply with FIPS, the client cannot connect to the server. To connect to the server, delete the server public key saved on the client and make sure a FIPS-compliant public key has been generated on the server.

Procedure

1. Enter system view.

   system-view

2. Delete server public keys saved in the public key file on the SCP client.

delete ssh client server-public-key [**server-ip** *ip-address*]

Establishing a connection to an SCP server based on Suite B

Execute the following command in user view to establish a connection to an SCP server based on Suite B:

IPv4:

scp *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] { **put** | **get** } *source-file-name* [*destination-file-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**source** { **interface** *interface-type interface-number* | **ip** *ip-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

IPv6:

scp ipv6 *server* [*port-number*] [**vpn-instance** *vpn-instance-name*] [**-i** *interface-type interface-number*] { **put** | **get** } *source-file-name* [*destination-file-name*] **suite-b** [**128-bit** | **192-bit**] **pki-domain** *domain-name* [**server-pki-domain** *domain-name*] [**prefer-compress zlib**] [**source** { **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }] * [**user** *username* [**password** *password* [**no-more-input**]]]

Specifying algorithms for SSH2

About algorithms for SSH2

The SSH2 client and server use the following types of algorithms for algorithm negotiation during the Stelnet, SFTP, or SCP session establishment:

- Key exchange algorithms.
- Public key algorithms.
- Encryption algorithms.
- MAC algorithms.

If you specify algorithms, SSH2 uses only the specified algorithms for algorithm negotiation. The client uses the specified algorithms to initiate the negotiation, and the server uses the matching algorithms to negotiate with the client. If multiple algorithms of the same type are specified, the algorithm specified earlier has a higher priority during negotiation.

Specifying key exchange algorithms for SSH2

1. Enter system view.

   system-view

2. Specify key exchange algorithms for SSH2.

   In non-FIPS mode:

   ssh2 algorithm key-exchange { **dh-group-exchange-sha1** | **dh-group1-sha1** | **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } *

   By default, SSH2 uses the **ecdh-sha2-nistp256**, **ecdh-sha2-nistp384**, **dh-group-exchange-sha1**, **dh-group14-sha1**, and **dh-group1-sha1** key exchange algorithms in descending order of priority for algorithm negotiation.

   In FIPS mode:

ssh2 algorithm key-exchange { **dh-group14-sha1** | **ecdh-sha2-nistp256** | **ecdh-sha2-nistp384** } *

By default, SSH2 uses the **ecdh-sha2-nistp256**, **ecdh-sha2-nistp384**, and **dh-group14-sha1** key exchange algorithms in descending order of priority for algorithm negotiation.

Specifying public key algorithms for SSH2

1. Enter system view.

   system-view

2. Specify public key algorithms for SSH2.

   In non-FIPS mode:

   ssh2 algorithm public-key { **dsa** | **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } *

   By default, SSH2 uses the **x509v3-ecdsa-sha2-nistp256**, **x509v3-ecdsa-sha2-nistp384**, **ecdsa-sha2-nistp256**, **ecdsa-sha2-nistp384**, **rsa**, and **dsa** public key algorithms in descending order of priority for algorithm negotiation.

   In FIPS mode:

   ssh2 algorithm public-key { **ecdsa-sha2-nistp256** | **ecdsa-sha2-nistp384** | **rsa** | **x509v3-ecdsa-sha2-nistp256** | **x509v3-ecdsa-sha2-nistp384** } *

   By default, SSH2 uses the **x509v3-ecdsa-sha2-nistp256**, **x509v3-ecdsa-sha2-nistp384**, **ecdsa-sha2-nistp256**, **ecdsa-sha2-nistp384**, and **rsa** public key algorithms in descending order of priority for algorithm negotiation.

Specifying encryption algorithms for SSH2

1. Enter system view.

   system-view

2. Specify encryption algorithms for SSH2.

   In non-FIPS mode:

   ssh2 algorithm cipher { **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** | **des-cbc** } *

   By default, SSH2 uses the **aes128-ctr**, **aes192-ctr**, **aes256-ctr**, **aes128-gcm**, **aes256-gcm**, **aes128-cbc**, **3des-cbc**, **aes256-cbc**, **des-cbc** encryption algorithms in descending order of priority for algorithm negotiation.

   In FIPS mode:

   ssh2 algorithm cipher { **aes128-cbc** | **aes128-ctr** | **aes128-gcm** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **aes256-gcm** } *

   By default, SSH2 uses the **aes128-ctr**, **aes192-ctr**, **aes256-ctr**, **aes128-gcm**, **aes256-gcm**, **aes128-cbc**, and **aes256-cbc** encryption algorithms in descending order of priority for algorithm negotiation.

Specifying MAC algorithms for SSH2

1. Enter system view.

   system-view

2. Specify MAC algorithms for SSH2.

In non-FIPS mode:

ssh2 algorithm mac { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } *

By default, SSH2 uses the **sha2-256**, **sha2-512, sha1**, **md5**, **sha1-96**, and **md5-96** MAC algorithms in descending order of priority for algorithm negotiation.

In FIPS mode:

ssh2 algorithm mac { **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } *

By default, SSH2 uses the **sha2-256**, **sha2-512, sha1**, and **sha1-96** MAC algorithms in descending order of priority for algorithm negotiation.

Display and maintenance commands for SSH

Execute **display** commands in any view.

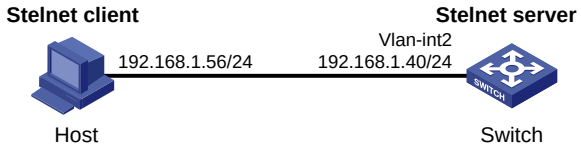
Task	Command
Display the public keys of the local key pairs.	**display public-key local** { **dsa** | **ecdsa** | **rsa** } **public** [**name** *publickey-name*]
Display information about peer public keys.	**display public-key peer** [**brief** | **name** *publickey-name*]
Display the source IP address configuration of the SCP client.	**display scp client source**
Display the source IP address configuration of the SFTP client.	**display sftp client source**
Display server public key information saved in the public key file on the SSH client.	**display ssh client server-public-key** [**server-ip** *ip-address*]
Display the source IP address configuration of the Stelnet client.	**display ssh client source**
Display SSH server status or sessions.	**display ssh server** { **session** | **status** }
Display SSH user information on the SSH server.	**display ssh user-information** [*username*]
Display algorithms used by SSH2 in the algorithm negotiation stage.	**display ssh2 algorithm**

For more information about the **display public-key local** and **display public-key peer** commands, see public key management commands in *Security Command Reference*.

Stelnet configuration examples

Unless otherwise noted, devices in the configuration examples operate in non-FIPS mode.

When the device acts as an Stelnet server operating in FIPS mode, only ECDSA and RSA key pairs are supported. Do not generate a DSA key pair on the Stelnet server.



Example: Configuring the device as an Stelnet server (password authentication)

Network configuration

As shown in Figure 1:

- The switch acts as the Stelnet server and uses password authentication to authenticate the Stelnet client. The username and password of the client are saved on the switch.
- The host acts as the Stelnet client, using Stelnet client software (SSH2). After the user on the host logs in to the switch through Stelnet, the user can configure and manage the switch as a network administrator.

Figure 1 Network diagram

Procedure

1. Configure the Stelnet server:

   # Generate RSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

   # Generate a DSA key pair.

```
[Switch] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
...+.................+..........+...+.
Create the key pair successfully.
```

   # Generate an ECDSA key pair.

```
[Switch] public-key local create ecdsa secp256r1
Generating Keys...
.
```

```
Create the key pair successfully.
```

Enable the Stelnet server.

```
[Switch] ssh server enable
```

Assign an IP address to VLAN-interface 2. The Stelnet client uses this address as the destination for SSH connection.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[Switch-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Create a local device management user named **client001**.

```
[Switch] local-user client001 class manage
```

Set a password for local user **client001**.

```
[Switch-luser-manage-client001] password simple 123456TESTplat&!
```

Authorize local user **client001** to use the **SSH** service.

```
[Switch-luser-manage-client001] service-type ssh
```

Assign the **network-admin** user role to local user **client001**.

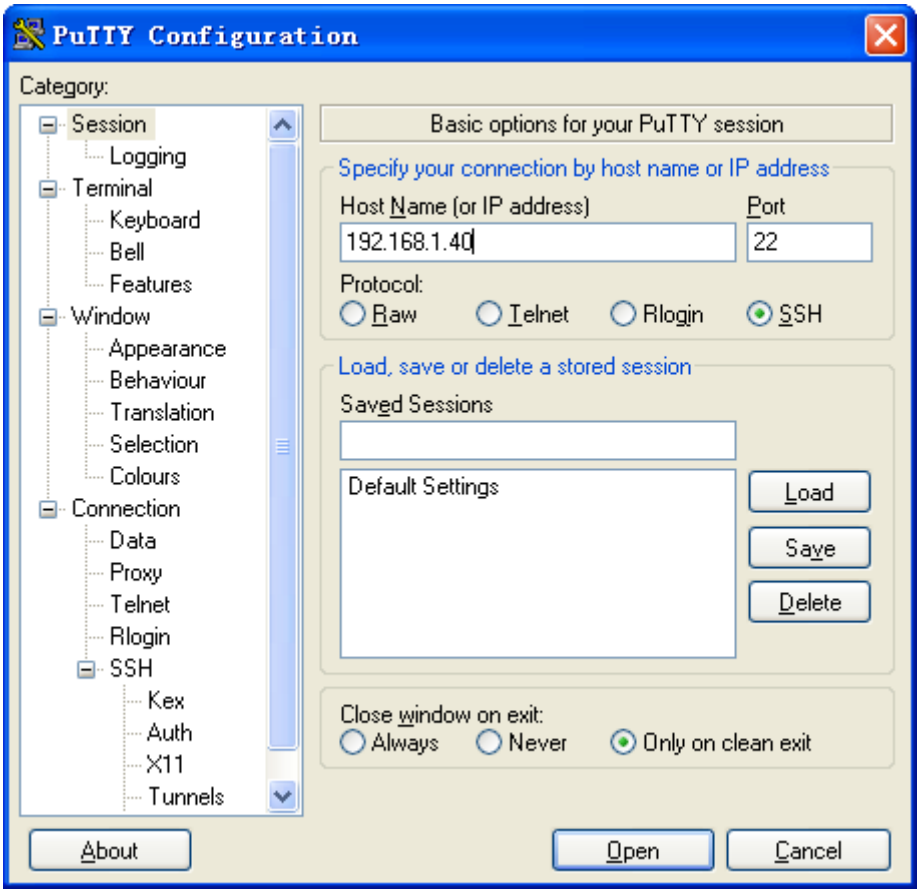
```
[Switch-luser-manage-client001] authorization-attribute user-role network-admin
[Switch-luser-manage-client001] quit
```

Create an SSH user named **client001**. Specify the service type as **stelnet** and the authentication method as **password** for the user.

```
[Switch] ssh user client001 service-type stelnet authentication-type password
```

2. Establish a connection to the Stelnet server:

There are different types of Stelnet client software, such as PuTTY and OpenSSH. This example uses an Stelnet client that runs PuTTY version 0.58.



To establish a connection to the Stelnet server:

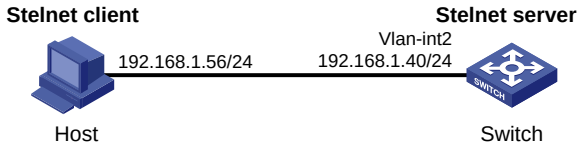
a. Launch PuTTY.exe to enter the interface shown in Figure 2.

b. In the **Host Name (or IP address)** field, enter IP address **192.168.1.40** of the Stelnet server.

c. Click **Open**.

Figure 2 Specifying the host name (or IP address)

d. Enter username **client001** and the password to log in to the Stelnet server.



Example: Configuring the device as an Stelnet server (publickey authentication)

Network configuration

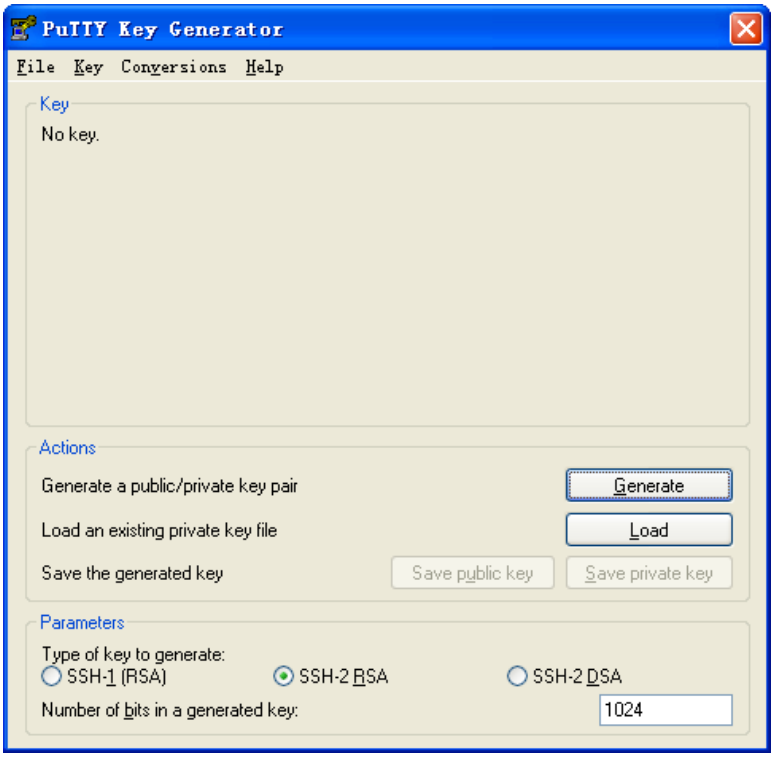
As shown in Figure 3:

- The switch acts as the Stelnet server, and it uses publickey authentication and the RSA public key algorithm.
- The host acts as the Stelnet client, using Stelnet client software (SSH2). After the user on the host logs in to the switch through Stelnet, the user can configure and manage the switch as a network administrator.

Figure 3 Network diagram

Procedure

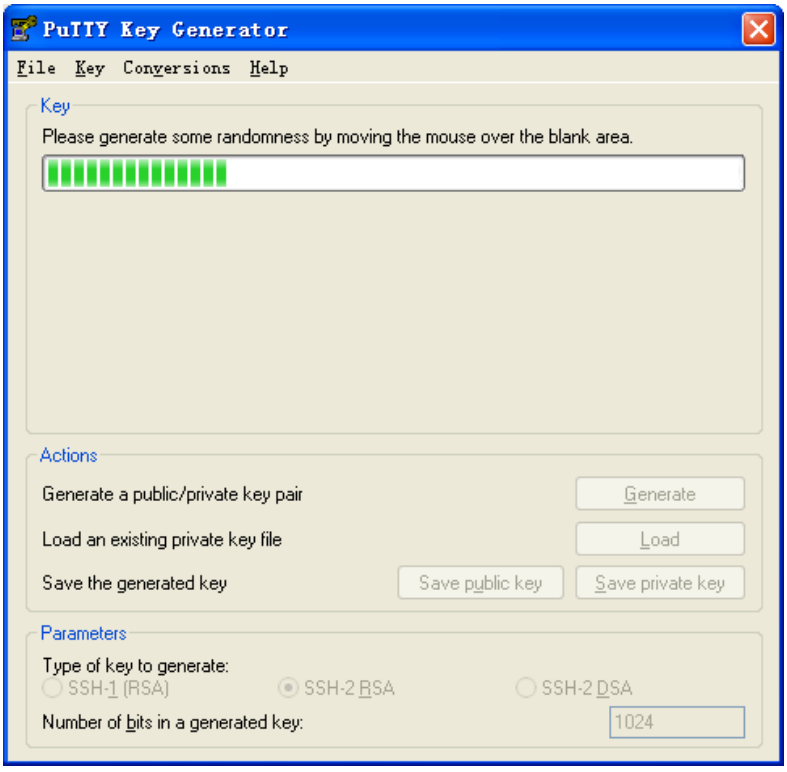
In the server configuration, the client's host public key is required. Use the client software to generate RSA key pairs on the client before configuring the Stelnet server.



There are different types of Stelnet client software, such as PuTTY and OpenSSH. This example uses an Stelnet client that runs PuTTY version 0.58.

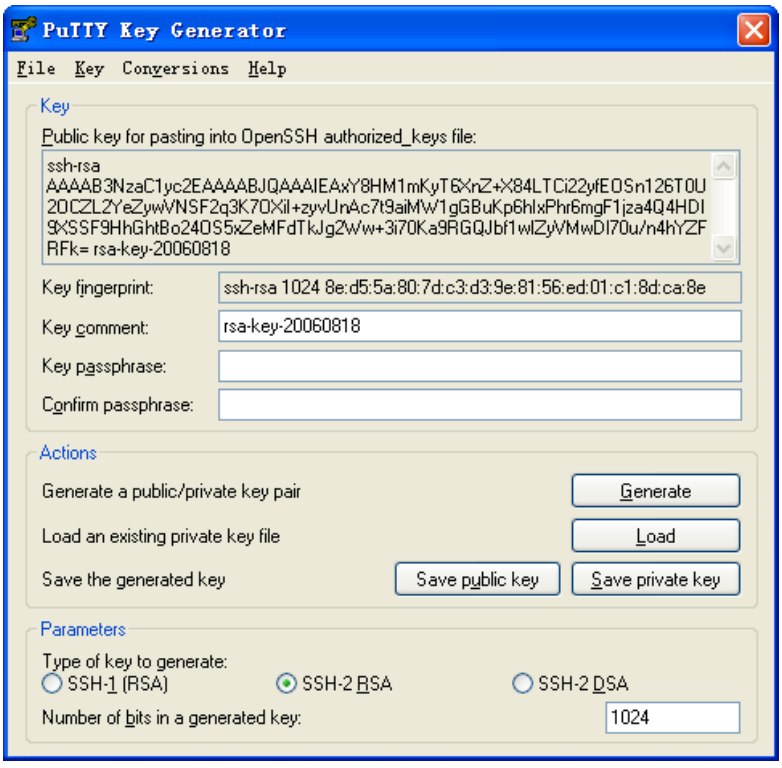
The configuration procedure is as follows:

1. Generate RSA key pairs on the Stelnet client:



a. Run PuTTYGen.exe on the client, select **SSH-2 RSA** and click **Generate**.

Figure 4 Generating a key pair on the client



b. Continue moving the mouse during the key generating process, but do not place the mouse over the green progress bar shown in Figure 5. Otherwise, the progress bar stops moving and the key pair generating progress stops.

Figure 5 Generating process

c. After the key pair is generated, click **Save public key** to save the public key. A file saving window appears.

Figure 6 Saving a key pair on the client

d. Enter a file name (**key.pub** in this example), and click **Save**.

e. On the page shown in Figure 6, click **Save private key** to save the private key.

A confirmation dialog box appears.

f. Click **Yes**.

A file saving window appears.

g. Enter a file name (**private.ppk** in this example), and click **Save**.

h. Transmit the public key file to the server through FTP or TFTP. (Details not shown.)

2. Configure the Stelnet server:

Generate RSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

Generate a DSA key pair.

```
[Switch] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.................................+
...+.................+..........+...+
Create the key pair successfully.
```

Generate an ECDSA key pair.

```
[Switch] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

Enable the Stelnet server.

```
[Switch] ssh server enable
```

Assign an IP address to VLAN-interface 2. The Stelnet client uses this IP address as the destination for SSH connection.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[Switch-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Import the client's public key from the public key file **key.pub** and name it **switchkey**.

```
[Switch] public-key peer switchkey import sshkey key.pub
```

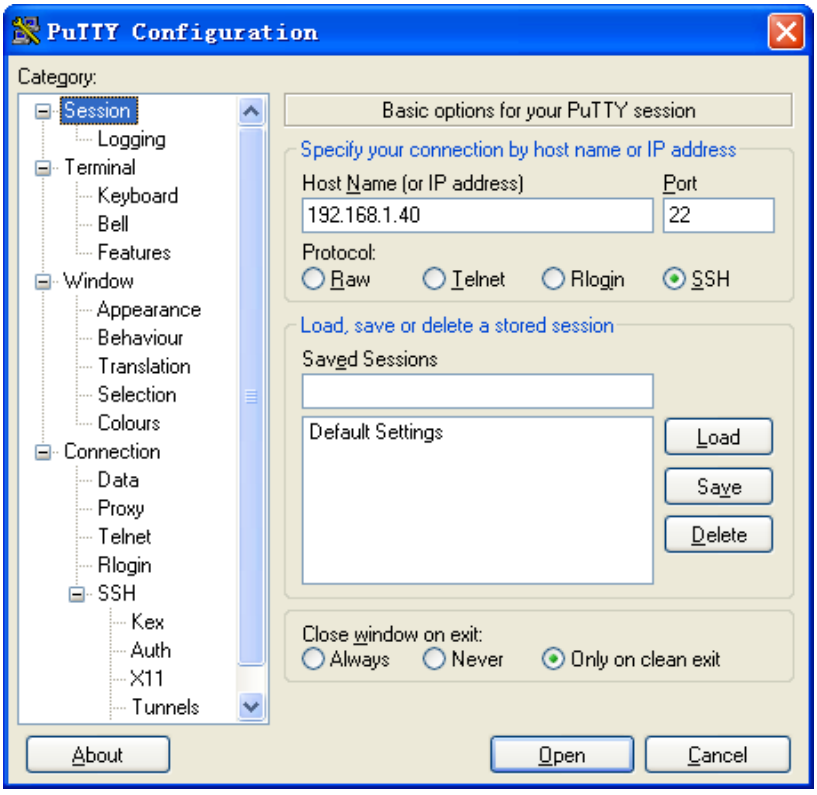
Create an SSH user named **client002**. Specify the authentication method as **publickey** for the user, and assign the public key **switchkey** to the user.

```
[Switch] ssh user client002 service-type stelnet authentication-type publickey assign publickey switchkey
```

Create a local device management user named **client002**.

```
[Switch] local-user client002 class manage
```

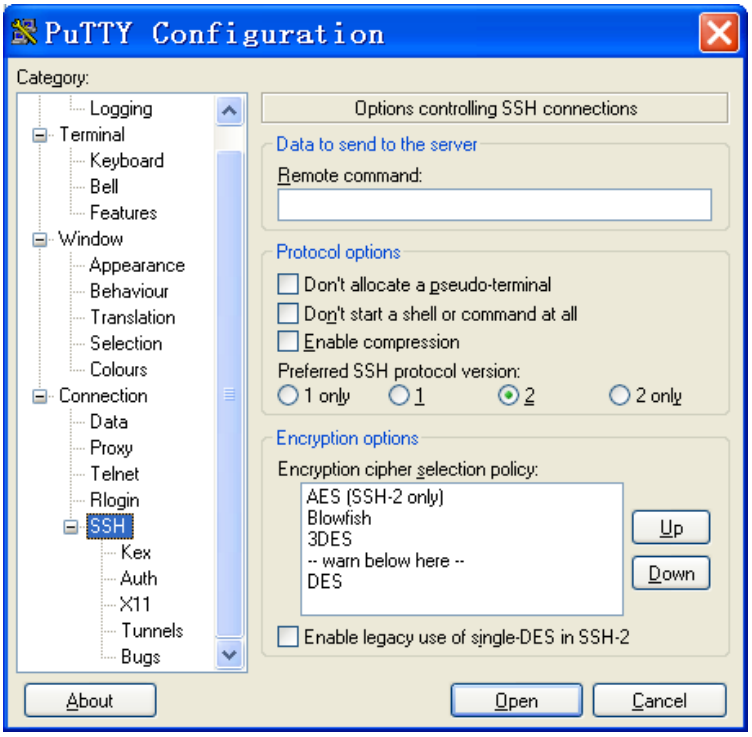
Authorize local user **client002** to use the **SSH** service.



```
[Switch-luser-manage-client002] service-type ssh
```

Assign the **network-admin** user role to local user **client002**.

```
[Switch-luser-manage-client002] authorization-attribute user-role network-admin
[Switch-luser-manage-client002] quit
```

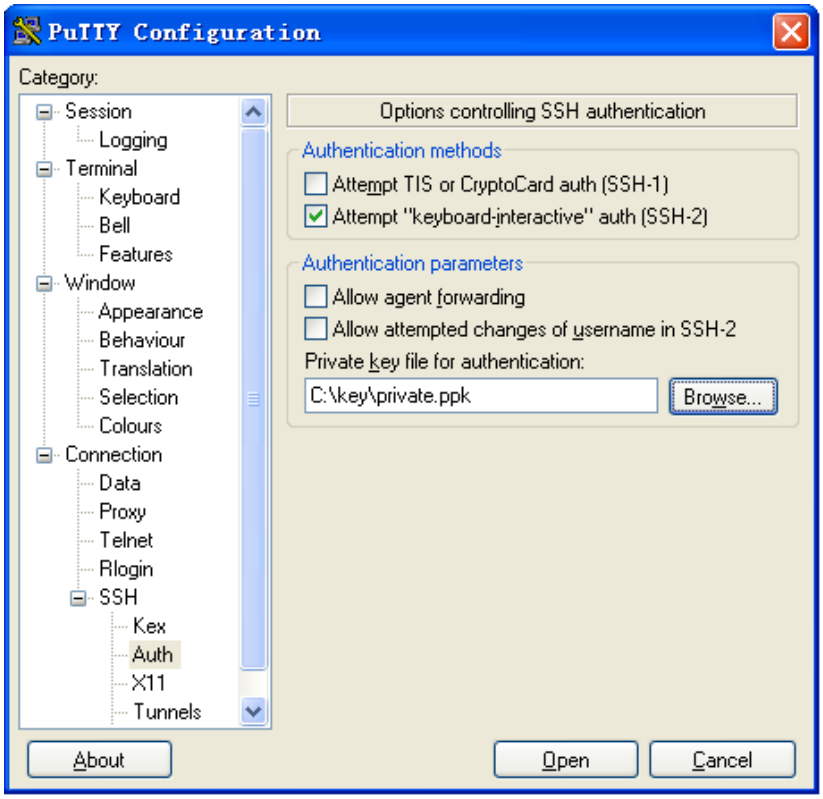


3. Specify the private key file and establish a connection to the Stelnet server:
   a. Launch PuTTY.exe on the Stelnet client to enter the interface shown in Figure 7.
   b. In the **Host Name (or IP address)** field, enter IP address **192.168.1.40** of the Stelnet server.

Figure 7 Specifying the host name (or IP address)

   c. From the navigation tree, select **Connection** > **SSH**.
      The window shown in Figure 8 appears.
   d. Set **Preferred SSH protocol version** to **2**.

Figure 8 Setting the preferred SSH version



e. From the navigation tree, select **Connection** > **SSH** > **Auth**.

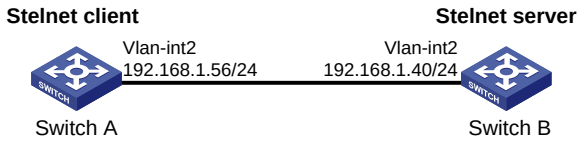
The window shown in Figure 9 appears.

f. Click **Browse…** to open the file selection window, and then select the private key file (**private.ppk** in this example).

g. Click **Open**.

Figure 9 Specifying the private key file

h. Entering username **client002** to log in to the Stelnet server.



Example: Configuring the device as an Stelnet client (password authentication)

Network configuration

As shown in Figure 10:

- Switch B acts as the Stelnet server and uses password authentication to authenticate the Stelnet client. The username and password of the client are saved on Switch B.
- Switch A acts as the Stelnet client. After the user on Switch A logs in to Switch B through Stelnet, the user can configure and manage Switch B as a network administrator.

Figure 10 Network diagram

Procedure

1. Configure the Stelnet server:

Generate RSA key pairs.

```
<SwitchB> system-view
[SwitchB] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
```

```
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

Generate a DSA key pair.

```
[SwitchB] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.................................+
...+.............+.........+...+
Create the key pair successfully.
```

Generate an ECDSA key pair.

```
[SwitchB] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

Enable the Stelnet server.

```
[SwitchB] ssh server enable
```

Assign an IP address to VLAN-interface 2. The Stelnet client uses this address as the destination address of the SSH connection.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[SwitchB] line vty 0 63
[SwitchB-line-vty0-63] authentication-mode scheme
[SwitchB-line-vty0-63] quit
```

Create a local device management user named **client001**.

```
[SwitchB] local-user client001 class manage
```

Set a password for local user **client001**.

```
[SwitchB-luser-manage-client001] password simple 123456TESTplat&!
```

Authorize local user **client001** to use the **SSH** service.

```
[SwitchB-luser-manage-client001] service-type ssh
```

Assign the **network-admin** user role to local user **client001**.

```
[SwitchB-luser-manage-client001] authorization-attribute user-role network-admin
[SwitchB-luser-manage-client001] quit
```

Create an SSH user named **client001**. Specify the service type as **stelnet** and the authentication method as **password** for the user.

```
[SwitchB] ssh user client001 service-type stelnet authentication-type password
```

Specify public key algorithm **dsa** for SSH2.

```
[SwitchB] ssh2 algorithm public-key dsa
```

2. Establish a connection to the Stelnet server:

Assign an IP address to VLAN-interface 2.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 192.168.1.56 255.255.255.0
[SwitchA-Vlan-interface2] quit
[SwitchA] quit
```

- If the client does not have the server's host public key, and is connected to the server for the first time:

  # Establish an SSH connection to server 192.168.1.40. Enter username **client001**, and then enter **y** to continue accessing the server without authenticating the server, and enter **y** to download and save the server's host public key.

```
<SwitchA> ssh2 192.168.1.40
Username: client001
Press CTRL+C to abort.
Connecting to 192.168.1.40 port 22.
The server is not authenticated. Continue? [Y/N]:y
Do you want to save the server public key? [Y/N]:y
client001@192.168.1.40's password:

Enter a character ~ and a dot to abort.

********************************************************************************

********************************************************************************
*

<SwitchB>
```

  After you enter the correct password, you can access Switch B successfully. At the next connection attempt, the client automatically authenticates the server by using the server's host public key that is saved on the client, and you only need to enter the password to log in to Switch B.

- If you configure the server's host public key on the client before establishing a connection to the server:

  # Use the **display public-key local dsa public** command on the server to display the server's host public key. (Details not shown.)

  # Enter public key view of the client and copy the host public key of the server to the client.

```
[SwitchA] public-key peer key1
Enter public key view. Return to system view with "peer-public-key end" command.

************************************************************************

<SwitchB>
```

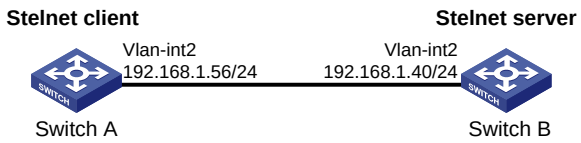
After you enter the correct username and password, you can successfully log in to Switch B.

- If the client already has the server's host public key:

Establish an SSH connection to server 192.168.1.40.

```
<SwitchA> ssh2 192.168.1.40
Username: client001
Press CTRL+C to abort.
Connecting to 192.168.1.40 port 22.
client001@192.168.1.40's password:
Enter a character ~ and a dot to abort.
************************************************************************
* Copyright (c) 2004-2017 New H3C Technologies Co., Ltd. All rights reserved.*
* Without the owner's prior written consent,                           *
* no decompiling or reverse-engineering shall be allowed.              *
************************************************************************
<SwitchB>
```

After you enter the correct username and password, you can successfully log in to Switch B.



Example: Configuring the device as an Stelnet client (publickey authentication)

Network configuration

As shown in Figure 11:

- Switch B acts as the Stelnet server, and it uses publickey authentication and the DSA public key algorithm.
- Switch A acts as the Stelnet client. After the user on Switch A logs in to Switch B through Stelnet, the user can configure and manage Switch B as a network administrator.

Figure 11 Network diagram

Procedure

In the server configuration, the client's host public key is required. Generate a DSA key pair on the client before configuring the Stelnet server.

1. Configure the Stelnet client:

   # Assign an IP address to VLAN-interface 2.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ip address 192.168.1.56 255.255.255.0
   [SwitchA-Vlan-interface2] quit
   ```

   # Generate a DSA key pair.

   ```
   [SwitchA] public-key local create dsa
   The range of public key modulus is (512 ~ 2048).
   If the key modulus is greater than 512, it will take a few minutes.
   Press CTRL+C to abort.
   Input the modulus length [default = 1024]:
   Generating Keys...
   ```

```
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
...+................+..........+...+
Create the key pair successfully.
```

Export the DSA host public key to a public key file named **key.pub**.

```
[SwitchA] public-key local export dsa ssh2 key.pub
[SwitchA] quit
```

Transmit the public key file **key.pub** to the server through FTP or TFTP. (Details not shown.)

2. Configure the Stelnet server:

Generate RSA key pairs.

```
<SwitchB> system-view
[SwitchB] public-key local create rsa
The range of public key modulus is (512 ~ 4096)
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.......................++++++
...................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

Generate a DSA key pair.

```
[SwitchB] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
...+................+..........+...+
Create the key pair successfully.
```

Generate an ECDSA key pair.

```
[SwitchB] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

Enable the Stelnet server.

```
[SwitchB] ssh server enable
```

Assign an IP address to VLAN-interface 2. The Stelnet client uses this address as the destination address for SSH connection.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[SwitchB] line vty 0 63
[SwitchB-line-vty0-63] authentication-mode scheme
```

```
[SwitchB-line-vty0-63] quit
```

Import the peer public key from the public key file **key.pub**, and name it **switchkey**.

```
[SwitchB] public-key peer switchkey import sshkey key.pub
```

Create an SSH user named **client002**. Specify the authentication method as **publickey** for the user. Assign the public key **switchkey** to the user.

```
[SwitchB] ssh user client002 service-type stelnet authentication-type publickey
assign publickey switchkey
```

Create a local device management user named **client002**.

```
[SwitchB] local-user client002 class manage
```

Authorize local user **client002** to use the **SSH** service.

```
[SwitchB-luser-manage-client002] service-type ssh
```

Assign the **network-admin** user role to local user **client002**.

```
[SwitchB-luser-manage-client002] authorization-attribute user-role network-admin
[SwitchB-luser-manage-client002] quit
```

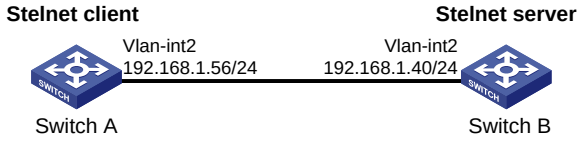
3. Establish an SSH connection to the Stelnet server.

```
<SwitchA> ssh2 192.168.1.40 identity-key dsa
Username: client002
Press CTRL+C to abort.
Connecting to 192.168.1.40 port 22.
The server is not authenticated. Continue? [Y/N]:y
Do you want to save the server public key? [Y/N]:n
Enter a character ~ and a dot to abort.

*****************************************************************************
* Copyright (c) 2004-2017 New H3C Technologies Co., Ltd. All rights reserved.*
* Without the owner's prior written consent,                                *
* no decompiling or reverse-engineering shall be allowed.                   *
*****************************************************************************

<SwitchB>
```

After you enter username **client002** and then enter **y** to continue accessing the server, you can log in to the server successfully.



Example: Configuring Stelnet based on 128-bit Suite B algorithms

Network configuration

As shown in Figure 12:

- Switch B acts as the Stelnet Suite B server (SSH2), and it uses publickey authentication to authenticate the Stelnet client.
- Switch A acts as an Stelnet Suite B client (SSH2). After the user on Switch A logs in to Switch B through the Stelnet Suite B client software, the user can configure and manage Switch B as an administrator.

Figure 12 Network diagram

Procedure

1. Generate the client's certificate and the server's certificate. (Details not shown.)

   You must first configure the certificates of the server and the client because they are required for identity authentication between the two parties.

   In this example, the server's certificate file is **ssh-server-ecdsa256.p12** and the client's certificate file is **ssh-client-ecdsa256.p12**.

2. Configure the Stelnet client:

   You can modify the pkix version of the client software OpenSSH to support Suite B. This example uses an H3C switch as an Stelnet client.

   # Upload the server's certificate file **ssh-server-ecdsa256.p12** and the client's certificate file **ssh-client-ecdsa256.p12** to the Stelnet client through FTP or TFTP. (Details not shown.)

   # Create a PKI domain named **server256** for verifying the server's certificate and enter its view.

   ```
   <SwitchA> system-view
   [SwitchA] pki domain server256
   ```

   # Disable CRL checking.

   ```
   [SwitchA-pki-domain-server256] undo crl check enable
   [SwitchA-pki-domain-server256] quit
   ```

   # Import local certificate file **ssh-server-ecdsa256.p12** to PKI domain **server256**.

   ```
   [SwitchA] pki import domain server256 p12 local filename ssh-server-ecdsa256.p12
   The system is going to save the key pair. You must specify a key pair name, which is
   a case-insensitive string of 1 to 64 characters. Valid characters include a to z, A
   to Z, 0 to 9, and hyphens (-).
   Please enter the key pair name[default name: server256]:
   ```

   # Display information about local certificates in PKI domain **server256**.

   ```
   [SwitchA] display pki certificate domain server256 local

```

Assign an IP address to VLAN-interface 2.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 192.168.1.56 255.255.255.0
[SwitchA-Vlan-interface2] quit
```

3. Configure the Stelnet server:

Upload the server's certificate file **ssh-server-ecdsa256.p12** and the client's certificate file **ssh-client-ecdsa256.p12** to the Stelnet server through FTP or TFTP. (Details not shown.)

Create a PKI domain named **client256** for verifying the client's certificate and import the file of the client's certificate to this domain. (Details not shown.)

Create a PKI domain named **server256** for the server's certificate and import the file of the server's certificate to this domain. (Details not shown.)

Specify Suite B algorithms for algorithm negotiation.

```
<SwitchB> system-view
[SwitchB] ssh2 algorithm key-exchange ecdh-sha2-nistp256
[SwitchB] ssh2 algorithm cipher aes128-gcm
[SwitchB] ssh2 algorithm public-key x509v3-ecdsa-sha2-nistp256
x509v3-ecdsa-sha2-nistp384
```

Specify **server256** as the PKI domain of the server's certificate.

```
[SwitchB] ssh server pki-domain server256
```

Enable the Stelnet server.

```
[SwitchB] ssh server enable
```

Assign an IP address to VLAN-interface 2.

```
[SwitchB] interface vlan-interface 2
```

```
[SwitchB-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[SwitchB] line vty 0 63
[SwitchB-line-vty0-63] authentication-mode scheme
[SwitchB-line-vty0-63] quit
```

Create a local device management user named **client001**. Authorize the user to use the **SSH** service and assign the **network-admin** user role to the user.

```
[SwitchB] local-user client001 class manage
[SwitchB-luser-manage-client001] service-type ssh
[SwitchB-luser-manage-client001] authorization-attribute user-role network-admin
[SwitchB-luser-manage-client001] quit
```

Create an SSH user named **client001**. Specify the **publickey** authentication method for the user and specify **client256** as the PKI domain for verifying the client's certificate.

```
[SwitchB] ssh user client001 service-type stelnet authentication-type publickey
assign pki-domain client256
```

4. Establish an SSH connection to the Stelnet server based on the 128-bit Suite B algorithms:

Establish an SSH connection to the server at 192.168.1.40.

```
<SwitchA>  ssh2 192.168.1.40 suite-b 128-bit pki-domain client256 server-pki-domain
server256
Username: client001
Press CTRL+C to abort.
Connecting to 192.168.1.40 port 22.
Enter a character ~ and a dot to abort.

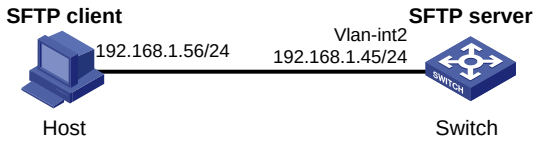
```

SFTP configuration examples

Unless otherwise noted, devices in the configuration examples operate in non-FIPS mode.

When the device acts as an SFTP server operating in FIPS mode, only ECDSA and RSA key pairs are supported. Do not generate a DSA key pair on the SFTP server.

Example: Configuring the device as an SFTP server (password authentication)



Network configuration

As shown in Figure 13:

- The switch acts as the SFTP server and uses password authentication to authenticate the SFTP client. The username and password of the client are saved on the switch.

- The host acts as the SFTP client. After the user on the client logs in to the switch through SFTP, the user can perform file management and transfer operations on the switch as a network administrator.

Figure 13 Network diagram

Procedure

1. Configure the SFTP server:

Generate RSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

Generate a DSA key pair.

```
[Switch] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.................................+
...+.................+..........+...+
Create the key pair successfully.
```

Generate an ECDSA key pair.

```
[Switch] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

Enable the SFTP server.

```
[Switch] sftp server enable
```

Assign an IP address to VLAN-interface 2. The client uses this address as the destination for SSH connection.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.1.45 255.255.255.0
[Switch-Vlan-interface2] quit
```

Create a local device management user named **client002**.

```
[Switch] local-user client002 class manage
```

Set a password for local user **client002**.

```
[Switch-luser-manage-client002] password simple 123456TESTplat&!
```

Authorize local user **client002** to use the **SSH** service.

```
[Switch-luser-manage-client002] service-type ssh
```

Assign the **network-admin** user role and working directory **flash:/** to local user **client002**.

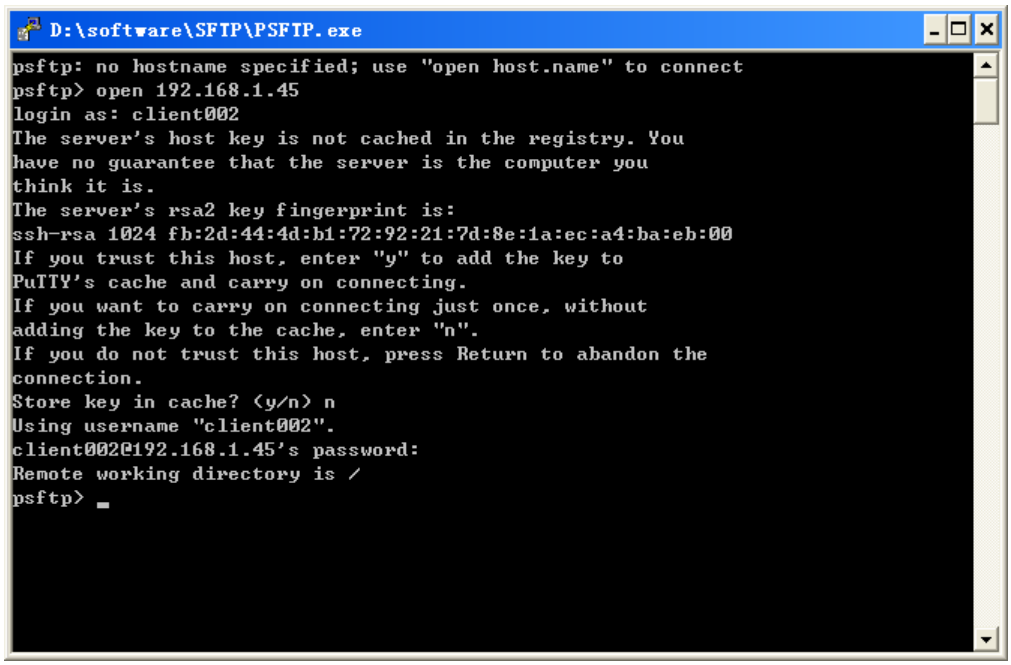
```
[Switch-luser-manage-client002] authorization-attribute user-role network-admin
work-directory flash:/
[Switch-luser-manage-client002] quit
```

Create an SSH user named **client002**. Specify the authentication method as **password** and service type as **sftp** for the user.

```
[Switch] ssh user client002 service-type sftp authentication-type password
```

2. Establish a connection between the SFTP client and the SFTP server:

This example uses an SFTP client that runs PSFTP of PuTTy version 0.58. PSFTP supports only password authentication.



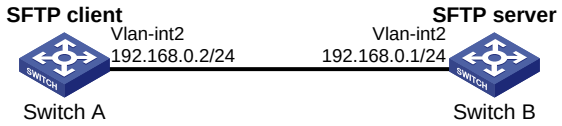
To establish a connection to the SFTP server:

a. Run the **psftp.exe** to launch the client interface shown in Figure 14, and enter the following command:

```
open 192.168.1.45
```

b. Enter username **client002** and the password to log in to the SFTP server.

Figure 14 SFTP client interface



Example: Configuring the device as an SFTP client (publickey authentication)

Network configuration

As shown in Figure 15:

- Switch B acts as the SFTP server, and it uses publickey authentication and the RSA public key algorithm.
- Switch A acts as the SFTP client. After the user on Switch A logs in to Switch B through SFTP, the user can perform file management and transfer operations on Switch B as a network administrator.

Figure 15 Network diagram

Procedure

In the server configuration, the client's host public key is required. Generate RSA key pairs on the client before configuring the SFTP server.

1. Configure the SFTP client:

Assign an IP address to VLAN-interface 2.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 192.168.0.2 255.255.255.0
[SwitchA-Vlan-interface2] quit
```

Generate RSA key pairs.

```
[SwitchA] public-key local create rsa
The range of public key size is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

Export the host public key to a public key file named **pubkey**.

```
[SwitchA] public-key local export rsa ssh2 pubkey
[SwitchA] quit
```

Transmit the public key file **pubkey** to the server through FTP or TFTP. (Details not shown.)

2. Configure the SFTP server:

Generate RSA key pairs.

```
<SwitchB> system-view
[SwitchB] public-key local create rsa
The range of public key size is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
```

```
.............++++++++
Create the key pair successfully.
```

Generate a DSA key pair.

```
[SwitchB] public-key local create dsa
The range of public key size is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
...+.................+..........+...+
Create the key pair successfully.
```

Generate an ECDSA key pair.

```
[SwitchB] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

Enable the SFTP server.

```
[SwitchB] sftp server enable
```

Assign an IP address to VLAN-interface 2. The SSH client uses this address as the destination for SSH connection.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 192.168.0.1 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Import the peer public key from the public key file **pubkey**, and name it **switchkey**.

```
[SwitchB] public-key peer switchkey import sshkey pubkey
```

Create an SSH user named **client001**. Specify the service type as **sftp** and the authentication method as **publickey** for the user. Assign the public key **switchkey** to the user.

```
[SwitchB] ssh user client001 service-type sftp authentication-type publickey assign
publickey switchkey
```

Create a local device management user named **client001**.

```
[SwitchB] local-user client001 class manage
```

Authorize local user **client001** to use the **SSH** service.

```
[SwitchB-luser-manage-client001] service-type ssh
```

Assign the **network-admin** user role and working directory **flash:/** to local user **client001**.

```
[SwitchB-luser-manage-client001] authorization-attribute user-role network-admin
work-directory flash:/
[SwitchB-luser-manage-client001] quit
```

3. Establish a connection to the SFTP server:

Establish a connection to the SFTP server and enter SFTP client view.

```
<SwitchA> sftp 192.168.0.1 identity-key rsa
Username: client001
Press CTRL+C to abort.
Connecting to 192.168.0.1 port 22.
The server is not authenticated. Continue? [Y/N]:y
Do you want to save the server public key? [Y/N]:n
sftp>
```

Display files under the current directory of the server, delete file **z**, and verify the result.

```
sftp> dir -l
-rwxrwxrwx   1 noone    nogroup      1759 Aug 23 06:52 config.cfg
-rwxrwxrwx   1 noone    nogroup       225 Aug 24 08:01 pubkey2
-rwxrwxrwx   1 noone    nogroup       283 Aug 24 07:39 pubkey
drwxrwxrwx   1 noone    nogroup         0 Sep 01 06:22 new
-rwxrwxrwx   1 noone    nogroup       225 Sep 01 06:55 pub
-rwxrwxrwx   1 noone    nogroup         0 Sep 01 08:00 z
sftp> delete z
Removing /z
sftp> dir -l
-rwxrwxrwx   1 noone    nogroup      1759 Aug 23 06:52 config.cfg
-rwxrwxrwx   1 noone    nogroup       225 Aug 24 08:01 pubkey2
-rwxrwxrwx   1 noone    nogroup       283 Aug 24 07:39 pubkey
drwxrwxrwx   1 noone    nogroup         0 Sep 01 06:22 new
-rwxrwxrwx   1 noone    nogroup       225 Sep 01 06:55 pub
```

Add a directory named **new1** and verify the result.

```
sftp> mkdir new1
sftp> dir -l
-rwxrwxrwx   1 noone    nogroup      1759 Aug 23 06:52 config.cfg
-rwxrwxrwx   1 noone    nogroup       225 Aug 24 08:01 pubkey2
-rwxrwxrwx   1 noone    nogroup       283 Aug 24 07:39 pubkey
drwxrwxrwx   1 noone    nogroup         0 Sep 01 06:22 new
-rwxrwxrwx   1 noone    nogroup       225 Sep 01 06:55 pub
drwxrwxrwx   1 noone    nogroup         0 Sep 02 06:30 new1
```

Change the name of directory **new1** to **new2** and verify the result.

```
sftp> rename new1 new2
sftp> dir -l
-rwxrwxrwx   1 noone    nogroup      1759 Aug 23 06:52 config.cfg
-rwxrwxrwx   1 noone    nogroup       225 Aug 24 08:01 pubkey2
-rwxrwxrwx   1 noone    nogroup       283 Aug 24 07:39 pubkey

```

```
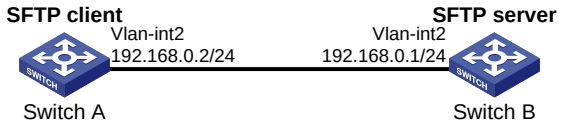
-rwxrwxrwx   1 noone    nogroup       283 Sep 02 06:36 puk
sftp>
```

Exit SFTP client view.

```
sftp> quit
<SwitchA>
```



Example: Configuring SFTP based on 192-bit Suite B algorithms

Network configuration

As shown in Figure 16:

- Switch B acts as the SFTP Suite B server (SSH2), and it uses publickey authentication to authenticate the SFTP client.
- Switch A acts as an SFTP Suite B client (SSH2). After the user on Switch A logs in to Switch B based on the SFTP Suite B client software, the user can manage and transfer files on Switch B as an administrator.

Figure 16 Network diagram

Procedure

1. Generate the client's certificate and the server's certificate. (Details not shown.)

   You must first configure the certificates of the server and the client because they are required for identity authentication between the two parties.

   In this example, the server's certificate file is **ssh-server-ecdsa384.p12** and the client's certificate file is **ssh-client-ecdsa384.p12**.

2. Configure the SFTP client:

   You can modify the pkix version of the client software OpenSSH to support Suite B. This example uses an H3C switch as an SFTP client.

   # Upload the server's certificate file **ssh-server-ecdsa384.p12** and the client's certificate file **ssh-client-ecdsa384.p12** to the SFTP client through FTP or TFTP. (Details not shown.)

   # Create a PKI domain named **server384** for verifying the server's certificate and enter its view.

   ```
   <SwitchA> system-view
   [SwitchA] pki domain server384
   ```

   # Disable CRL checking.

   ```
   [SwitchA-pki-domain-server384] undo crl check enable
   [SwitchA-pki-domain-server384] quit
   ```

   # Import local certificate file **ssh-server-ecdsa384.p12** to PKI domain **server384**.

   ```
   [SwitchA] pki import domain server384 p12 local filename ssh-server-ecdsa384.p12
   The system is going to save the key pair. You must specify a key pair name, which is
   a case-insensitive string of 1 to 64 characters. Valid characters include a to z, A
   to Z, 0 to 9, and hyphens (-).
   Please enter the key pair name[default name: server384]:
   ```

   # Display information about local certificates in PKI domain **server384**.

   ```
   [SwitchA] display pki certificate domain server384 local
   ```

```

         30:64:fe:14:ce:06:d5:0a:e2:cf:9a:69:19:ff
```

Assign an IP address to VLAN-interface 2.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 192.168.0.2 255.255.255.0
```

```
[SwitchA-Vlan-interface2] quit
[SwitchA] quit
```

3. Configure the SFTP server:

   # Upload the server's certificate file **ssh-server-ecdsa384.p12** and the client's certificate file **ssh-client-ecdsa384.p12** to the SFTP server through FTP or TFTP. (Details not shown.)

   # Create a PKI domain named **client384** for verifying the client's certificate and import the file of the client's certificate to this domain. (Details not shown.)

   # Create a PKI domain named **server384** for the server's certificate and import the file of the server's certificate to this domain. (Details not shown.)

   # Specify Suite B algorithms for algorithm negotiation.

   ```
   [SwitchB] ssh2 algorithm key-exchange ecdh-sha2-nistp384
   [SwitchB] ssh2 algorithm cipher aes256-gcm
   [SwitchB] ssh2 algorithm public-key x509v3-ecdsa-sha2-nistp384
   ```

   # Specify **server384** as the PKI domain of the server's certificate.

   ```
   [SwitchB] ssh server pki-domain server384
   ```

   # Enable the SFTP server.

   ```
   [SwitchB] sftp server enable
   ```

   # Assign an IP address to VLAN-interface 2.

   ```
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] ip address 192.168.0.1 255.255.255.0
   [SwitchB-Vlan-interface2] quit
   ```

   # Set the authentication mode to AAA for user lines.

   ```
   [SwitchB] line vty 0 63
   [SwitchB-line-vty0-63] authentication-mode scheme
   [SwitchB-line-vty0-63] quit
   ```

   # Create a local device management user named **client001**. Authorize the user to use the **SSH** service and assign the **network-admin** user role to the user.

   ```
   [SwitchB] local-user client001 class manage
   [SwitchB-luser-manage-client001] service-type ssh
   [SwitchB-luser-manage-client001] authorization-attribute user-role network-admin
   [SwitchB-luser-manage-client001] quit
   ```

   # Create an SSH user named **client001**. Specify the **publickey** authentication method for the user and specify **client384** as the PKI domain for verifying the client's certificate.

   ```
   [SwitchB] ssh user client001 service-type sftp authentication-type publickey assign
   pki-domain client384
   ```

4. Establish an SFTP connection to the SFTP server based on the 192-bit Suite B algorithms:

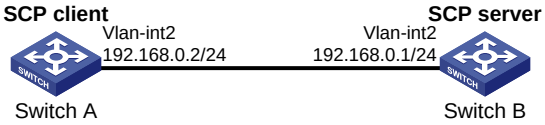
   # Establish an SFTP connection to the server at 192.168.0.1.

   ```
   <SwitchA> sftp 192.168.0.1 suite-b 192-bit pki-domain client384 server-pki-domain
   server384
   Username: client001
   Press CTRL+C to abort.
   Connecting to 192.168.0.1 port 22.
   sftp>
   ```

SCP configuration examples

Unless otherwise noted, devices in the configuration examples operate in non-FIPS mode.

When the device acts as an SCP server operating in FIPS mode, only ECDSA and RSA key pairs are supported. Do not generate a DSA key pair on the SCP server.



Example: Configuring SCP with password authentication

Network configuration

As shown in Figure 17:

- Switch B acts as the SCP server and uses password authentication to authenticate the SCP client. The client's username and password are saved on Switch B.
- Switch A acts as the SCP client. After the user on Switch A logs in to Switch B through SCP, the user can transfer files between switches as a network administrator.

Figure 17 Network diagram

Procedure

1. Configure the SCP server:

   # Generate RSA key pairs.

```
<SwitchB> system-view
[SwitchB] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

   # Generate a DSA key pair.

```
[SwitchB] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
...+.................+..........+...+.
Create the key pair successfully.
```

   # Generate an ECDSA key pair.

```
[SwitchB] public-key local create ecdsa secp256r1
Generating Keys...
.
```

```
Create the key pair successfully.
```

Enable the SCP server.

```
[SwitchB] scp server enable
```

Configure an IP address for VLAN-interface 2. The client uses this address as the destination for SCP connection.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 192.168.0.1 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Create a local device management user named **client001**.

```
[SwitchB] local-user client001 class manage
```

Set a password for local user **client001**.

```
[SwitchB-luser-manage-client001] password simple 123456TESTplat&!
```

Authorize local user **client001** to use the **SSH** service.

```
[SwitchB-luser-manage-client001] service-type ssh
```

Assign the **network-admin** user role to local user **client001**.

```
[SwitchB-luser-manage-client001] authorization-attribute user-role network-admin
[SwitchB-luser-manage-client001] quit
```

Create an SSH user named **client001**. Specify the service type as **scp** and the authentication method as **password** for the user.

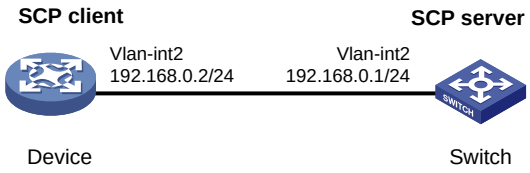
```
[SwitchB] ssh user client001 service-type scp authentication-type password
```

2. Configure an IP address for VLAN-interface 2 on the SCP client.

```
<SwitchA> system-view
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 192.168.0.2 255.255.255.0
[SwitchA-Vlan-interface2] quit
[SwitchA] quit
```

3. Connect to the SCP server, download file **remote.bin** from the server, and save it as a local file named **local.bin**.

```
<SwitchA> scp 192.168.0.1 get remote.bin local.bin
Username: client001
Press CTRL+C to abort.
Connecting to 192.168.0.1 port 22.
The server is not authenticated. Continue? [Y/N]:y
Do you want to save the server public key? [Y/N]:n
client001@192.168.0.1's password:
remote.bin                                    100% 2875     2.8KB/s   00:00
```



Example: Configuring SCP file transfer with a Linux SCP client

Network configuration

As shown in Figure 18, the switch acts as the SCP server and uses password authentication to authenticate the SCP client. The client's username and password are saved on the switch.

The device acts as the SCP client. After the user on the device logs in to the switch through SCP, the user can transfer files with the switch as a network administrator.

Figure 18 Network diagram

Procedure

1. Configure the SCP server:

   # Generate an RSA key pair.

```
<Switch> system-view
[Switch] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

   # Generate a DSA key pair.

```
[Switch] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.................................+
...+.................+..........+...+.
Create the key pair successfully.
```

   # Generate an ECDSA key pair.

```
[Switch] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

   # Enable the SCP server.

```
[Switch] scp server enable
```

   # Configure an IP address for VLAN interface 2. The SCP client uses this IP address as the destination address of the SCP connection.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.0.1 255.255.255.0
[Switch-Vlan-interface2] quit
```

   # Create a local device management user named **client001**. Set a password for the user, authorize the user to use the SSH service, assign the **network-admin** user role to the user, and specify the working directory as **flash:/**.

```
[Switch] local-user client001 class manage
[Switch-luser-manage-client001] password simple 123456TESTplat&!
[Switch-luser-manage-client001] service-type ssh
[Switch-luser-manage-client001] authorization-attribute user-role network-admin
work-directory flash:/
[Switch-luser-manage-client001] quit
```

Configure an SSH user named **client001**, specify the SCP service for the SSH user, and set the authentication method as password. (This step is optional.)

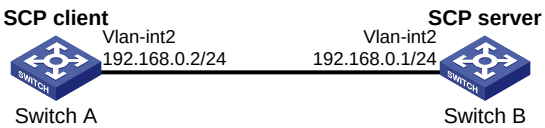
```
[Switch] ssh user client001 service-type scp authentication-type password
```

2. Configure the SCP client:

   The following uses the SCP client running on a Linux system as an example:

   # Connect to the SCP server, download the **remote.bin** file from the server, and save it as a local file named **local.bin**.

```
admin@device:~# scp client001@192.168.0.1:remote.bin local.bin
client001@192.168.0.1's password:
remote.bin                                                    100%   15
     0.0KB/s   00:00
```



Example: Configuring SCP based on Suite B algorithms

Network configuration

As shown in Figure 19:

- Switch B acts as the SCP Suite B server (SSH2), and it uses publickey authentication to authenticate the SCP client.
- Switch A acts as an SCP Suite B client (SSH2). After the user on Switch A logs in to Switch B through the SCP Suite B client software, the user can transfer files between switches as a network administrator.

Figure 19 Network diagram

Procedure

1. Generate the client's certificates and the server's certificates. (Details not shown.)

   You must first configure the certificates of the server and the client because they are required for identity authentication between the two parties.

   In this example, the server's certificate files are **ssh-server-ecdsa256.p12** and **ssh-server-ecdsa384.p12**. The client's certificate files are **ssh-client-ecdsa256.p12** and **ssh-client-ecdsa384.p12**.

2. Configure the SCP client:

   You can modify the pkix version of the client software OpenSSH to support Suite B. This example uses an H3C switch as an SCP client.

   # Upload the server's certificate files (**ssh-server-ecdsa256.p12** and **ssh-server-ecdsa384.p12**) and the client's certificate files (**ssh-client-ecdsa256.p12** and **ssh-client-ecdsa384.p12**) to the SCP client through FTP or TFTP. (Details not shown.)

   # Create a PKI domain named **server256** for verifying the server's certificate **ecdsa256** and enter its view.

```
<SwitchA> system-view
[SwitchA] pki domain server256
```

Disable CRL checking.

```
[SwitchA-pki-domain-server256] undo crl check enable
[SwitchA-pki-domain-server256] quit
```

Import local certificate file **ssh-server-ecdsa256.p12** to PKI domain **server256**.

```
[SwitchA] pki import domain server256 p12 local filename ssh-server-ecdsa256.p12
The system is going to save the key pair. You must specify a key pair name, which is
a case-insensitive string of 1 to 64 characters. Valid characters include a to z, A
to Z, 0 to 9, and hyphens (-).
Please enter the key pair name[default name: server256]:
```

Display information about local certificates in PKI domain **server256**.

```
[SwitchA] display pki certificate domain server256 local

Assign an IP address to VLAN-interface 2.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 192.168.0.2 255.255.255.0
[SwitchA-Vlan-interface2] quit
```

3. Configure the SCP server:

Upload the server's certificate files (**ssh-server-ecdsa256.p12** and **ssh-server-ecdsa384.p12**) and the client's certificate files (**ssh-client-ecdsa256.p12** and **ssh-client-ecdsa384.p12**) to the SCP server through FTP or TFTP. (Details not shown.)

Create a PKI domain named **client256** for verifying the client's certificate **ecdsa256** and import the file of this certificate to this domain. Create a PKI domain named **server256** for the server's certificate **ecdsa256** and import the file of this certificate to this domain. (Details not shown.)

Create a PKI domain named **client384** for verifying the client's certificate **ecdsa384** and import the file of this certificate to this domain. Create a PKI domain named **server384** for the server's certificate **ecdsa384** and import the file of this certificate to this domain. (Details not shown.)

Specify Suite B algorithms for algorithm negotiation.

```
<SwitchB> system-view
[SwitchB] ssh2 algorithm key-exchange ecdh-sha2-nistp256 ecdh-sha2-nistp384
[SwitchB] ssh2 algorithm cipher aes128-gcm aes256-gcm
[SwitchB] ssh2 algorithm public-key x509v3-ecdsa-sha2-nistp256
x509v3-ecdsa-sha2-nistp384
```

Enable the SCP server.

```
[SwitchB] scp server enable
```

Assign an IP address to VLAN-interface 2.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 192.168.0.1 255.255.255.0
[SwitchB-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[SwitchB] line vty 0 63
[SwitchB-line-vty0-63] authentication-mode scheme
[SwitchB-line-vty0-63] quit
```

Create a local device management user named **client001**. Authorize the user to use the **SSH** service and assign the **network-admin** user role to the user.

```
[SwitchB] local-user client001 class manage
[SwitchB-luser-manage-client001] service-type ssh
[SwitchB-luser-manage-client001] authorization-attribute user-role network-admin
[SwitchB-luser-manage-client001] quit
```

Create a local device management user named **client002**. Authorize the user to use the **SSH** service and assign the **network-admin** user role to the user.

```
[SwitchB] local-user client002 class manage
[SwitchB-luser-manage-client002] service-type ssh
[SwitchB-luser-manage-client002] authorization-attribute user-role network-admin
[SwitchB-luser-manage-client002] quit
```

4. Establish an SCP connection to the SCP server:

- Based on the 128-bit Suite B algorithms:

  # Specify **server256** as the PKI domain of the server's certificate.

  ```
  [SwitchB]ssh server pki-domain server256
  ```

  # Create an SSH user **client001**. Specify the **publickey** authentication method for the user and specify **client256** as the PKI domain for verifying the client's certificate.

  ```
  [SwitchB] ssh user client001 service-type scp authentication-type publickey assign pki-domain client256
  ```

  # Establish an SCP connection to the SCP server at 192.168.0.1 based on the 128-bit Suite B algorithms.

  ```
  <SwitchA> scp 192.168.0.1 get src.cfg suite-b 128-bit pki-domain client256 server-pki
  -domain server256
  Username: client001
  Press CTRL+C to abort.
  Connecting to 192.168.0.1 port 22.
  src.cfg                                       100% 4814     4.7KB/s   00:00
  <SwitchA>
  ```

- Based on the 192-bit Suite B algorithms:

  # Specify **server384** as the PKI domain of the server's certificate.

  ```
  [SwitchB] ssh server pki-domain server384
  ```

  # Create an SSH user **client002**. Specify the **publickey** authentication method for the user and specify **client384** as the PKI domain for verifying the client's certificate.

  ```
  [Switch] ssh user client002 service-type scp authentication-type publickey assign pki-domain client384
  ```

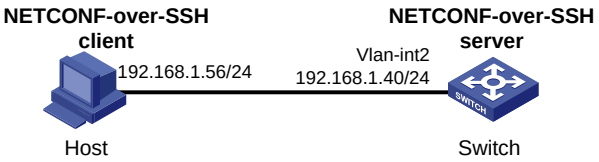
  # Establish an SCP connection to the SCP server at 192.168.0.1 based on the 192-bit Suite B algorithms.

  ```
  <SwitchA> scp 192.168.0.1 get src.cfg suite-b 192-bit pki-domain client384 server-pki
  -domain server384
  Username: client002
  Press CTRL+C to abort.
  Connecting to 192.168.0.1 port 22.
  src.cfg                                       100% 4814     4.7KB/s   00:00
  <SwitchA>
  ```

NETCONF over SSH configuration examples

Unless otherwise noted, devices in the configuration examples are in non-FIPS mode.

When the device acts as a NETCONF-over-SSH server operating in FIPS mode, only ECDSA and RSA key pairs are supported. Do not generate a DSA key pair on the NETCONF-over-SSH server.



Example: Configuring NETCONF over SSH with password authentication

Network configuration

As shown in Figure 20:

- The switch acts as the NETCONF-over-SSH server and uses password authentication to authenticate the client. The client's username and password are saved on the switch.
- The host acts as the NETCONF-over-SSH client, using SSH2 client software. After the user on the host logs in to the switch through NETCONF over SSH, the user can perform NETCONF operations on the switch as a network administrator.

Figure 20 Network diagram

Procedure

Generate RSA key pairs.

```
<Switch> system-view
[Switch] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....................++++++
.................++++++
..++++++++
............++++++++
Create the key pair successfully.
```

Generate a DSA key pair.

```
[Switch] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.++++++++++++++++++++++++++++++++++++++++++++++++++*
........+......+.....+.....................................+
```

```
...+.................+.........+...+.
Create the key pair successfully.
```

Generate an ECDSA key pair.

```
[Switch] public-key local create ecdsa secp256r1
Generating Keys...
.
Create the key pair successfully.
```

Enable NETCONF over SSH.

```
[Switch] netconf ssh server enable
```

Configure an IP address for VLAN-interface 2. The client uses this address as the destination for NETCONF-over-SSH connection.

```
[Switch] interface vlan-interface 2
[Switch-Vlan-interface2] ip address 192.168.1.40 255.255.255.0
[Switch-Vlan-interface2] quit
```

Set the authentication mode to AAA for user lines.

```
[Switch] line vty 0 63
[Switch-line-vty0-63] authentication-mode scheme
[Switch-line-vty0-63] quit
```

Create a local device management user named **client001**.

```
[Switch] local-user client001 class manage
```

Set a password for local user **client001**.

```
[Switch-luser-manage-client001] password simple 123456TESTplat&!
```

Authorize local user **client001** to use the **SSH** service.

```
[Switch-luser-manage-client001] service-type ssh
```

Assign the **network-admin** user role to local user **client001**.

```
[Switch-luser-manage-client001] authorization-attribute user-role network-admin
[Switch-luser-manage-client001] quit
```

Create an SSH user named **client001**. Specify the service type as **NETCONF** and the authentication method as **password** for the user.

```
[Switch] ssh user client001 service-type netconf authentication-type password
```

Verifying the configuration

Verify that you can perform NETCONF operations after logging in to the switch. (Details not shown.)

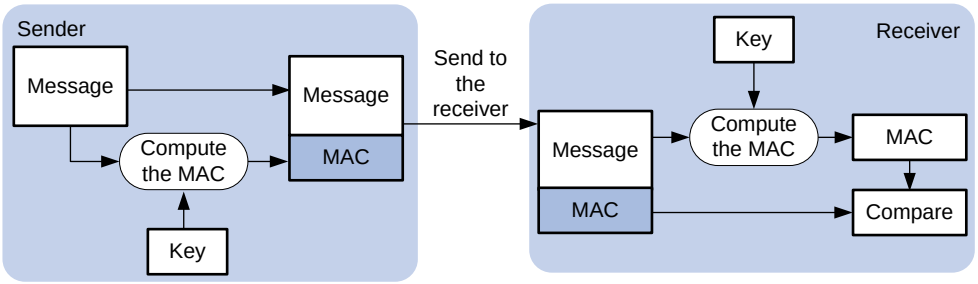
Configuring SSL

About SSL



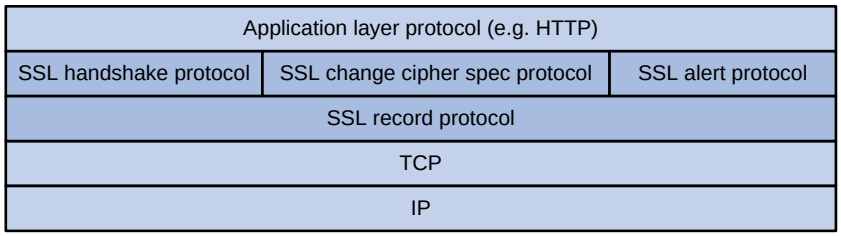
Secure Sockets Layer (SSL) is a cryptographic protocol that provides communication security for TCP-based application layer protocols such as HTTP. SSL has been widely used in applications such as e-business and online banking to provide secure data transmission over the Internet.

SSL security services

SSL provides the following security services:

- **Privacy**—SSL uses a symmetric encryption algorithm to encrypt data. It uses the asymmetric key algorithm of RSA to encrypt the key used by the symmetric encryption algorithm. For more information about RSA, see "Managing public keys."
- **Authentication**—SSL uses certificate-based digital signatures to authenticate the SSL server and client. The SSL server and client obtain digital certificates through PKI. For more information about PKI and digital certificates, see "Configuring PKI."
- **Integrity**—SSL uses the message authentication code (MAC) to verify message integrity. It uses a MAC algorithm and a key to transform a message of any length to a fixed-length message. Any change to the original message will result in a change to the calculated fixed-length message. As shown in Figure 1, the message integrity verification process is as follows:
  - **a.** The sender uses a MAC algorithm and a key to calculate a MAC value for a message. Then, it appends the MAC value to the message and sends the message to the receiver.
  - **b.** The receiver uses the same key and MAC algorithm to calculate a MAC value for the received message, and compares it with the MAC value appended to the message.
  - **c.** If the two MAC values match, the receiver considers the message intact. Otherwise, the receiver considers that the message was tampered with and it discards the message.

Figure 1 MAC algorithm diagram



SSL protocol stack

The SSL protocol stack includes the following protocols:

- SSL record protocol at the lower layer.
- SSL handshake protocol, SSL change cipher spec protocol, and SSL alert protocol at the upper layer.

Figure 2 SSL protocol stack

The following describes the major functions of SSL protocols:

- **SSL record protocol**—Fragments data received from the upper layer, computes and adds MAC to the data, and encrypts the data.
- **SSL handshake protocol**—Negotiates the cipher suite used for secure communication, authenticates the server and client, and securely exchanges the keys between the server and client. The cipher suite that needs to be negotiated includes the symmetric encryption algorithm, key exchange algorithm, and MAC algorithm.
- **SSL change cipher spec protocol**—Notifies the receiver that subsequent packets are to be protected based on the negotiated cipher suite and key.
- **SSL alert protocol**—Sends alert messages to the receiving party. An alert message contains the alert severity level and a description.

SSL protocol versions

SSL protocol versions include SSL 2.0, SSL 3.0, TLS 1.0 (or SSL 3.1), TLS 1.1, and TLS 1.2. Because SSL 3.0 is known to be insecure, you can disable SSL 3.0 for the SSL server to ensure security.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see "Configuring FIPS") and non-FIPS mode.

Restrictions and guidelines: SSL configuration

By default, the SSL server can communicate with clients running all SSL protocol versions. When the server receives an SSL 2.0 Client Hello message from a client, it notifies the client to use a later version for communication.

SSL tasks at a glance

Configuring the SSL server

- Configuring an SSL server policy
- (Optional.) Disabling SSL protocol versions for the SSL server
- (Optional.) Disabling SSL session renegotiation

Configuring the SSL client

Configuring an SSL client policy

Configuring an SSL server policy

About this task

An SSL server policy is a set of SSL parameters used by the device when the device acts as the SSL server. An SSL server policy takes effect only after it is associated with an application such as HTTPS.

Procedure

1. Enter system view.

   system-view

2. Create an SSL server policy and enter its view.

   ssl server-policy *policy-name*

3. Specify a PKI domain for the SSL server policy.

   pki-domain *domain-name*

   By default, no PKI domain is specified for an SSL server policy.

   If SSL server authentication is required, you must specify a PKI domain and request a local certificate for the SSL server in the domain.

   For information about configuring a PKI domain, see "Configuring PKI."

4. Specify the cipher suites that the SSL server policy supports.

   In non-FIPS mode:

   ciphersuite { **dhe_rsa_aes_128_cbc_sha** | **dhe_rsa_aes_128_cbc_sha256** | **dhe_rsa_aes_256_cbc_sha** | **dhe_rsa_aes_256_cbc_sha256** | **ecdhe_ecdsa_aes_128_cbc_sha256** | **ecdhe_ecdsa_aes_128_gcm_sha256** | **ecdhe_ecdsa_aes_256_cbc_sha384** | **ecdhe_ecdsa_aes_256_gcm_sha384** | **ecdhe_rsa_aes_128_cbc_sha256** | **ecdhe_rsa_aes_128_gcm_sha256** | **ecdhe_rsa_aes_256_cbc_sha384** | **ecdhe_rsa_aes_256_gcm_sha384** | **exp_rsa_des_cbc_sha** | **exp_rsa_rc2_md5** | **exp_rsa_rc4_md5** | **rsa_3des_ede_cbc_sha** | **rsa_aes_128_cbc_sha** | **rsa_aes_128_cbc_sha256** | **rsa_aes_256_cbc_sha** | **rsa_aes_256_cbc_sha256** | **rsa_des_cbc_sha** | **rsa_rc4_128_md5** | **rsa_rc4_128_sha** } *

   In FIPS mode:

   ciphersuite { **ecdhe_ecdsa_aes_128_cbc_sha256** | **ecdhe_ecdsa_aes_256_cbc_sha384** | **ecdhe_ecdsa_aes_128_gcm_sha256** | **ecdhe_ecdsa_aes_256_gcm_sha384** | **ecdhe_rsa_aes_128_cbc_sha256** | **ecdhe_rsa_aes_128_gcm_sha256** | **ecdhe_rsa_aes_256_cbc_sha384** | **ecdhe_rsa_aes_256_gcm_sha384** | **rsa_aes_128_cbc_sha** | **rsa_aes_128_cbc_sha256** | **rsa_aes_256_cbc_sha** | **rsa_aes_256_cbc_sha256** } *

   By default, an SSL server policy supports all cipher suites.

5. (Optional.) Set the maximum number of sessions that the SSL server can cache and the session cache timeout time.

   session { **cachesize** *size* | **timeout** *time* } *

   By default, the SSL server can cache a maximum of 500 sessions, and the session cache timeout time is 3600 seconds.

6. Enable mandatory or optional SSL client authentication.

client-verify { **enable** | **optional** }

By default, SSL client authentication is disabled. The SSL server does not perform digital certificate-based authentication on SSL clients.

When authenticating a client by using the digital certificate, the SSL server verifies the certificate chain presented by the client. It also verifies that the certificates in the certificate chain (except the root CA certificate) are not revoked.

7. (Optional.) Enable the SSL server to send the complete certificate chain to the client during SSL negotiation.

   certificate-chain-sending enable

   By default, the SSL server sends the server certificate rather than the complete certificate chain to the client during negotiation.

Configuring an SSL client policy

About this task

An SSL client policy is a set of SSL parameters used by the device when the device acts as the SSL client. The SSL client uses the settings in the client policy to establish a connection to the server. An SSL client policy takes effect only after it is associated with an application such as DDNS. For information about DDNS, see DNS configuration in *Layer 3—IP Services Configuration Guide*.

Restrictions and guidelines

As a best practice to enhance system security, do not specify SSL 3.0 for the SSL client policy.

Procedure

1. Enter system view.

   system-view

2. Create an SSL client policy and enter its view.

   ssl client-policy *policy-name*

3. Specify a PKI domain for the SSL client policy.

   pki-domain *domain-name*

   By default, no PKI domain is specified for an SSL client policy.

   If SSL client authentication is required, you must specify a PKI domain and request a local certificate for the SSL client in the PKI domain.

   For information about configuring a PKI domain, see "Configuring PKI."

4. Specify the preferred cipher suite for the SSL client policy.

   In non-FIPS mode:

   prefer-cipher { **dhe_rsa_aes_128_cbc_sha** | **dhe_rsa_aes_128_cbc_sha256** | **dhe_rsa_aes_256_cbc_sha** | **dhe_rsa_aes_256_cbc_sha256** | **ecdhe_ecdsa_aes_128_cbc_sha256** | **ecdhe_ecdsa_aes_128_gcm_sha256** | **ecdhe_ecdsa_aes_256_cbc_sha384** | **ecdhe_ecdsa_aes_256_gcm_sha384** | **ecdhe_rsa_aes_128_cbc_sha256** | **ecdhe_rsa_aes_128_gcm_sha256** | **ecdhe_rsa_aes_256_cbc_sha384** | **ecdhe_rsa_aes_256_gcm_sha384** | **exp_rsa_des_cbc_sha** | **exp_rsa_rc2_md5** | **exp_rsa_rc4_md5** | **rsa_3des_ede_cbc_sha** | **rsa_aes_128_cbc_sha** | **rsa_aes_128_cbc_sha256** | **rsa_aes_256_cbc_sha** | **rsa_aes_256_cbc_sha256** | **rsa_des_cbc_sha** | **rsa_rc4_128_md5** | **rsa_rc4_128_sha** }

   The default preferred cipher suite in non-FIPS mode is **rsa_rc4_128_md5**.

   In FIPS mode:

   prefer-cipher { **ecdhe_ecdsa_aes_128_cbc_sha256** | **ecdhe_ecdsa_aes_128_gcm_sha256** | **ecdhe_ecdsa_aes_256_cbc_sha384** |

ecdhe_ecdsa_aes_256_gcm_sha384 | **ecdhe_rsa_aes_128_cbc_sha256** | **ecdhe_rsa_aes_128_gcm_sha256** | **ecdhe_rsa_aes_256_cbc_sha384** | **ecdhe_rsa_aes_256_gcm_sha384** | **rsa_aes_128_cbc_sha** | **rsa_aes_128_cbc_sha256** | **rsa_aes_256_cbc_sha** | **rsa_aes_256_cbc_sha256** }

The default preferred cipher suite in FIPS mode is **rsa_aes_128_cbc_sha**.

5. Specify the SSL protocol version for the SSL client policy.

   In non-FIPS mode:

   version { **ssl3.0** | **tls1.0** | **tls1.1** | **tls1.2** }

   In FIPS mode:

   version { **tls1.0** | **tls1.1** | **tls1.2** }

   By default, an SSL client policy uses TLS 1.0.

6. Enable the SSL client to authenticate servers through digital certificates.

   server-verify enable

   By default, SSL server authentication is enabled.

Disabling SSL protocol versions for the SSL server

About this task

To enhance system security, you can disable the SSL server from using specific SSL protocol versions (SSL 3.0, TLS 1.0, and TLS 1.1) for session negotiation.

Restrictions and guidelines

Disabling an SSL protocol version does not affect the availability of earlier SSL protocol versions. For example, if you execute the **ssl version tls1.1 disable** command, TLS 1.1 is disabled but TLS 1.0 is still available for the SSL server.

Procedure

1. Enter system view.

   system-view

2. Disable SSL protocol versions for the SSL server.

   In non-FIPS mode:

   ssl version { **ssl3.0** | **tls1.0** | **tls1.1** } * **disable**

   By default, the SSL server supports SSL 3.0, TLS 1.0, TLS 1.1, and TLS 1.2.

   In FIPS mode:

   ssl version { **tls1.0** | **tls1.1** } * **disable**

   By default, the SSL server supports TLS 1.0, TLS 1.1, and TLS 1.2.

Disabling SSL session renegotiation

About this task

The SSL session renegotiation feature enables the SSL client and server to reuse a previously negotiated SSL session for an abbreviated handshake.

Disabling session renegotiation causes more computational overhead to the system but it can avoid potential risks.

Restrictions and guidelines

Disable SSL session renegotiation only when explicitly required.

Procedure

1. Enter system view.
   `system-view`
2. Disable SSL session renegotiation.
   `ssl renegotiation disable`
   By default, SSL session renegotiation is enabled.

Display and maintenance commands for SSL

Execute **`display`** commands in any view.

Task	Command
Display SSL client policy information.	**`display ssl client-policy`** [*`policy-name`*]
Display SSL server policy information.	**`display ssl server-policy`** [*`policy-name`*]

Configuring TCP attack prevention 1
About TCP attack prevention 1
Configuring Naptha attack prevention 1

Configuring TCP attack prevention

About TCP attack prevention

TCP attack prevention can detect and prevent attacks that exploit the TCP connection establishment process.

Configuring Naptha attack prevention

About this task

Naptha is a DDoS attack that targets operating systems. It exploits the resources consuming vulnerability in TCP/IP stack and network application process. The attacker establishes a large number of TCP connections in a short period of time and leaves them in certain states without requesting any data. These TCP connections starve the victim of system resources, resulting in a system breakdown.

After you enable Naptha attack prevention, the device periodically checks the number of TCP connections in each state (CLOSING, ESTABLISHED, FIN_WAIT_1, FIN_WAIT_2, and LAST_ACK). If the number of TCP connections in a state exceeds the limit, the device will accelerate the aging of the TCP connections in that state to mitigate the Naptha attack.

Procedure

1. Enter system view.

   system-view

2. Enable Naptha attack prevention.

   tcp anti-naptha enable

   By default, Naptha attack prevention is disabled.

3. (Optional.) Set the maximum number of TCP connections in a state.

   tcp state { **closing** | **established** | **fin-wait-1** | **fin-wait-2** | **last-ack** } **connection-limit** *number*

   By default, the maximum number of TCP connections in each state (CLOSING, ESTABLISHED, FIN_WAIT_1, FIN_WAIT_2, and LAST_ACK) is 50.

   To disable the device from accelerating the aging of the TCP connections in a state, set the value to 0.

4. (Optional.) Set the interval for checking the number of TCP connections in each state.

   tcp check-state interval *interval*

   By default, the interval for checking the number of TCP connections in each state is 30 seconds.

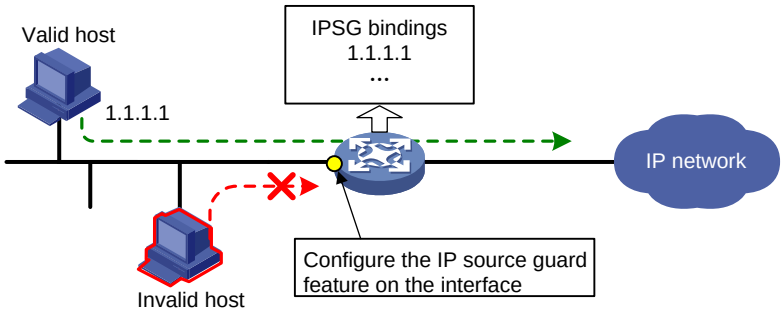
Configuring IP source guard

About IPSG

IP source guard (IPSG) prevents spoofing attacks by using an IPSG binding table to filter out illegitimate packets. This feature is typically configured on user-side interfaces.

IPSG operating mechanism



The IPSG binding table contains bindings that bind IP address, MAC address, VLAN, or any combinations. IPSG uses the bindings to match an incoming packet. If a match is found, the packet is forwarded. If no match is found, the packet is discarded.

IPSG is a per-interface packet filter. Configuring this feature on one interface does not affect packet forwarding on another interface.

IPSG bindings can be static or dynamic.

As shown in Figure 1, IPSG forwards only the packets that match an IPSG binding.

Figure 1 IPSG application

Static IPSG bindings

Static IPSG bindings are configured manually. They are suitable for scenarios where few hosts exist on a LAN and their IP addresses are manually configured. For example, you can configure a static IPSG binding on an interface that connects to a server. This binding allows the interface to receive packets only from the server.

Static IPSG bindings on an interface implement the following functions:

- Filter incoming IPv4 or IPv6 packets on the interface.
- Cooperate with ARP attack detection in IPv4 for user validity checking. For information about ARP attack detection, see "Configuring ARP attack protection."
- Cooperate with ND attack detection in IPv6 for user validity checking. For information about ND attack detection, see "Configuring ND attack defense."

Static IPSG bindings can be global or interface-specific.

- **Global static binding**—Binds the IP address and MAC address in system view. The binding takes effect on all interfaces to filter packets for user spoofing attack prevention.
- **Interface-specific static binding**—Binds the IP address, MAC address, VLAN, or any combination of the items in interface view. The binding takes effect only on the interface to check the validity of users who are attempting to access the interface.

Dynamic IPSG bindings

IPSG automatically obtains user information from other modules to generate dynamic bindings. A dynamic IPSG binding can contain MAC address, IPv4 or IPv6 address, VLAN tag, ingress interface, and binding type. The binding type identifies the source module for the binding, such as DHCP snooping, DHCPv6 snooping, DHCP relay agent, or DHCPv6 relay agent.

For example, DHCP-based IPSG bindings are suitable for scenarios where hosts on a LAN obtain IP addresses through DHCP. IPSG is configured on the DHCP server, the DHCP snooping device, or the DHCP relay agent. It generates dynamic bindings based on the client bindings on the DHCP server, the DHCP snooping entries, or the DHCP relay entries. IPSG allows only packets from the DHCP clients to pass through.

Dynamic IPv4SG

Dynamic bindings generated based on different source modules are for different usages:

Interface types	Source modules	Binding usage
Layer 2 Ethernet interface	DHCP snooping 802.1X	Packet filtering.
	ARP snooping	For cooperation with modules (such as the MFF module) to provide security services.
Layer 3 Ethernet interface VLAN interface	DHCP relay agent	Packet filtering.
	DHCP server	For cooperation with modules (such as the authorized ARP module) to provide security services.

For more information about 802.1X, see "Configuring 802.1X." For information about ARP snooping, DHCP snooping, DHCP relay, and DHCP server, see *Layer 3—IP Services Configuration Guide*.

Dynamic IPv6SG

Dynamic IPv6SG bindings generated based on different source modules are for different usages:

Interface types	Source modules	Binding usage
Layer 2 Ethernet interface	DHCPv6 snooping ND snooping 802.1X	Packet filtering.
Layer 3 Ethernet interface VLAN interface	DHCPv6 relay agent ND RA prefix entry recording	Packet filtering.
	DHCPv6 server	Reporting bindings to the controller to provide online and offline user information.

For more information about DHCPv6 snooping, see *Layer 3—IP Services Configuration Guide*. For more information about ND snooping, see IPv6 basics configuration in *Layer 3—IP Services Configuration Guide*. For more information about ND RA prefix entry recording, see IPv6 neighbor discovery in *Layer 3—IP Services Configuration Guide.* For more information about DHCPv6 relay agent, see *Layer 3—IP Services Configuration Guide*. For more information about DHCPv6 server, see *Layer 3—IP Services Configuration Guide.*

IPSG bindings synchronized by routing protocols

In addition to static and dynamic IPSG bindings, the device also supports IPSG bindings synchronized by routing protocols (such as BGP) from remote devices. These bindings are called remote IPSG bindings. By default, the remote IPSG bindings do not have interface information and cannot be used for packet filtering. When users roam from remote devices to the local device, the device learns interface information for the remote IPSG bindings through ARP or ND entries of the users. Then, the device converts the remote IPSG bindings into local IPSG bindings and uses these bindings for packet filtering.

For more information about BGP, see BGP overview in *Layer 3—IP Routing Configuration Guide*.

IPSG tasks at a glance

To configure IPv4SG, perform the following tasks:

1. Enabling IPv4SG
2. (Optional.) Configuring a static IPv4SG binding
3. (Optional.) Excluding IPv4 packets from IPSG filtering
4. (Optional.) Enabling IPv4SG alarming

To configure IPv6SG, perform the following tasks:

1. Enabling IPv6SG
2. (Optional.) Configuring a static IPv6SG binding
3. (Optional.) Setting the maximum number of IPv6SG bindings on an interface
4. (Optional.) Enabling IPv6SG alarming

Configuring the IPv4SG feature

Enabling IPv4SG

About this task

When you enable IPSG on an interface, the static and dynamic IPSG are both enabled.

- Static IPv4SG uses static bindings configured by using the **ip source binding** command. For more information, see "Configuring a static IPv4SG binding."
- Dynamic IPv4SG generates dynamic bindings from related source modules. IPv4SG uses the bindings to filter incoming IPv4 packets based on the matching criteria specified in the **ip verify source** command.

Restrictions and guidelines

To implement dynamic IPv4SG, make sure 802.1X, ARP snooping, DHCP snooping, DHCP relay agent, or DHCP server operates correctly on the network.

Enabling IPv4SG on an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
   The following interface types are supported:
   - Layer 2 Ethernet interface.

- Layer 3 Ethernet interface.
- Layer 3 aggregate interface.
- VLAN interface.

3. Enable the IPv4SG feature.

   ip verify source { **ip-address** | **ip-address** **mac-address** | **mac-address** }

   By default, the IPv4SG feature is disabled on an interface.

Configuring a static IPv4SG binding

About this task

You can configure global static and interface-specific static IPv4SG bindings. Interface-specific static and dynamic bindings take priority over global static bindings. An interface first uses the static and dynamic bindings on the interface to match packets. If no match is found, the interface uses the global bindings.

Restrictions and guidelines

Global static bindings take effect on all interfaces on the device.

To configure a static IPv4SG binding for the ARP attack detection feature, make sure the following conditions are met:

- The **ip-address** *ip-address* option, the **mac-address** *mac-address* option, and the **vlan** *vlan-id* option must be specified.
- ARP attack detection must be enabled for the specified VLAN.

Configuring a global static IPv4SG binding

1. Enter system view.

   system-view

2. Configure a global static IPv4SG binding.

   ip source binding ip-address *ip-address* **mac-address** *mac-address*

Configuring a static IPv4SG binding on an interface

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

   The following interface types are supported:

   - Layer 2 Ethernet interface.
   - Layer 3 Ethernet interface.
   - Layer 3 aggregate interface.
   - VLAN interface.

3. Configure a static IPv4SG binding.

   ip source binding { **ip-address** *ip-address* | **ip-address** *ip-address* **mac-address** *mac-address* | **mac-address** *mac-address* } [**vlan** *vlan-id*]

   You can configure the same static IPv4SG binding on different interfaces.

Excluding IPv4 packets from IPSG filtering

About this task

By default, IPv4SG processes all incoming IPv4 packets on an interface and discards the packets that do not match IPSG bindings. To allow specific IPv4 packets that do not match any IPSG binding to pass through the interface, you can specify source items of the packets for IPSG filtering exemption. All IPv4 packets with the specified source items are forwarded without being processed by IPSG.

Procedure

1. Enter system view.

   system-view
2. Exclude IPv4 packets with the specified source items from IPSG filtering.

   ip verify source exclude vlan *start-vlan-id* [to *end-vlan-id*]

   By default, no excluded source items are configured.

   You can execute this command multiple times to specify multiple excluded VLANs. The specified excluded VLANs cannot overlap.

Enabling IPv4SG alarming

About this task

This feature monitors the number of packets dropped by IPv4SG per second. When the packet dropping rate reaches or exceeds the alarm threshold, the device generates an alarm log. When the packet dropping rate drops below the alarm threshold, the device generates an alarm-cleared log.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Enable IPv4SG alarming on the interface.

   ip verify source alarm [*alarm-threshold*]

   By default, IPv4SG alarming is disabled on an interface.

Configuring the IPv6SG feature

Enabling IPv6SG

About this task

When you enable IPv6SG on an interface, the static and dynamic IPv6SG are both enabled.

- Static IPv6SG uses static bindings configured by using the **ipv6 source binding** command. For more information, see "Configuring a static IPv6SG binding."
- Dynamic IPv6SG generates dynamic bindings from related source modules. IPv6SG uses the bindings to filter incoming IPv6 packets based on the matching criteria specified in the **ipv6 verify source** command.

Restrictions and guidelines

To implement dynamic IPv6SG, make sure DHCPv6 snooping, DHCPv6 relay agent, or ND snooping operates correctly on the network.

Enabling IPv6SG on an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
   The following interface types are supported:
   - Layer 2 Ethernet interface.
   - Layer 3 Ethernet interface.
   - Layer 3 aggregate interface.
   - VLAN interface.
3. Enable the IPv6SG feature.
   ipv6 verify source { **ip-address** | **ip-address mac-address** | **mac-address** }
   By default, the IPv6SG feature is disabled on an interface.

Configuring a static IPv6SG binding

About this task

You can configure global static and interface-specific static IPv6SG bindings. Interface-specific static and dynamic bindings take priority over global static bindings. An interface first uses the static and dynamic bindings on the interface to match packets. If no match is found, the interface uses the global bindings.

Restrictions and guidelines

Global static bindings take effect on all interfaces on the device.

To configure a static IPv6SG binding for the ND attack detection feature, the **vlan** *vlan-id* option must be specified, and ND attack detection must be enabled for the specified VLAN.

Configuring a global static IPv6SG binding

1. Enter system view.
   system-view
2. Configure a global static IPv6SG binding.
   ipv6 source binding ip-address *ipv6-address* **mac-address** *mac-address*

Configuring a static IPv6SG binding on an interface

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
   The following interface types are supported:
   - Layer 2 Ethernet interface.
   - Layer 3 Ethernet interface.
   - Layer 3 aggregate interface.
   - VLAN interface.

3. Configure a static IPv6SG binding.

   ipv6 source binding { **ip-address** *ipv6-address* | **ip-address** *ipv6-address* **mac-address** *mac-address* | **mac-address** *mac-address* } [**vlan** *vlan-id*]

   You can configure the same static IPv6SG binding on different interfaces.

Setting the maximum number of IPv6SG bindings on an interface

About this task

You can set the maximum number of IPv6SG bindings on an interface to limit the total number of static and dynamic IPv6SG bindings on the interface. If the upper limit is reached, no more IPv6SG bindings can be added on the interface.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 2 Ethernet interface view.

   interface *interface-type interface-number*

3. Set the maximum number of IPv6SG bindings on the interface.

   ipv6 verify source max-entries *number*

   By default, the maximum number of IPv6SG bindings is not limited on an interface.

Enabling IPv6SG alarming

About this task

This feature enables the device to monitor the number of packets dropped by IPv6SG per second. When the packet dropping rate reaches or exceeds the alarm threshold, the device generates an alarm log. When the packet dropping rate drops below the alarm threshold, the device generates an alarm-cleared log.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Enable IPv6SG alarming on the interface.

   ipv6 verify source alarm [*alarm-threshold*]

   By default, IPv6SG alarming is disabled on an interface.

Display and maintenance commands for IPSG

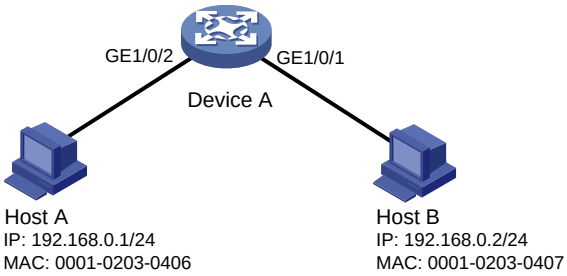
Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display IPv4SG bindings.	**display ip source binding** [**static** | [**vpn-instance** *vpn-instance-name*] [**arp-snooping-vlan** | **dhcp-relay** | **dhcp-server** | **dhcp-snooping** | **dot1x** | **remote**]]

Task	Command
	[**ip-address** *ip-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display local IPv4SG bindings that can be synchronized by routing protocols.	**display ip source binding-local** [**interface** *interface-type interface-number*] [**dhcp-relay**] [**ip-address** *ip-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**slot** *slot-number*]
Display remote IPv4SG bindings synchronized by routing protocols.	**display ip source binding-remote** [**router-id** *router-id*] [**dhcp-relay**] [**ip-address** *ip-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**slot** *slot-number*]
Display statistics about local and remote IPv4SG bindings that routing protocols synchronize.	**display ip source binding statistics**
Display source items that have been configured to be excluded from IPSG filtering.	**display ip verify source excluded** [**vlan** *start-vlan-id* [**to** *end-vlan-id*]] [**slot** *slot-number*]
Display IPv6SG address bindings.	**display ipv6 source binding** [**static** | [**vpn-instance** *vpn-instance-name*] [**dhcpv6-relay** | **dhcpv6-server** | **dhcpv6-snooping** | **dot1x** | **nd-snooping-vlan** | **remote**]] [**ip-address** *ipv6-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display local IPv6SG bindings that can be synchronized by routing protocols.	**display ipv6 source binding-local** [**interface** *interface-type interface-number*] [**dhcpv6-relay** | **nd-snooping-vlan**] [**ip-address** *ipv6-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**slot** *slot-number*]
Display remote IPv6SG bindings synchronized by routing protocols.	**display ipv6 source binding-remote** [**router-id** *router-id*] [**dhcpv6-relay** | **nd-snooping-vlan**] [**ip-address** *ipv6-address*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**slot** *slot-number*]
Display IPv6SG prefix bindings.	**display ipv6 source binding pd** [**vpn-instance** *vpn-instance-name*] [**prefix** *prefix/prefix-length*] [**mac-address** *mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**slot** *slot-number*]
Display statistics about local and remote IPv6SG bindings that routing protocols synchronize.	**display ipv6 source binding statistics**

IPSG configuration examples

Example: Configuring static IPv4SG



Network configuration

As shown in Figure 2, all hosts use static IP addresses.

Configure static IPv4SG bindings on Device A and Device B to meet the following requirements:

- All interfaces of Device A allow IP packets from Host A to pass.
- GigabitEthernet 1/0/1 of Device A allows IP packets from Host B to pass.

Figure 2 Network diagram

Procedure

Configure IP addresses for the interfaces. (Details not shown.)

Enable IPv4SG on GigabitEthernet 1/0/2.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] ip verify source ip-address mac-address
[DeviceA-GigabitEthernet1/0/2] quit
```

Configure a static IPv4SG binding for Host A.

```
[DeviceA] ip source binding ip-address 192.168.0.1 mac-address 0001-0203-0406
```

Enable IPv4SG on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] ip verify source ip-address mac-address
```

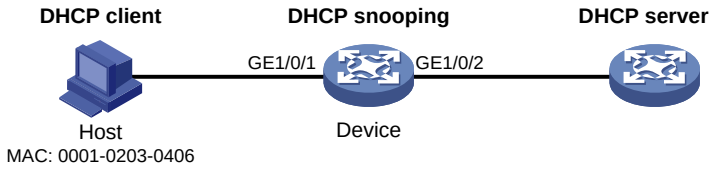
On GigabitEthernet 1/0/1, configure a static IPv4SG binding for Host B.

```
[DeviceA-GigabitEthernet1/0/1] ip source binding mac-address 0001-0203-0407
[DeviceA-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Verify that the static IPv4SG bindings are configured successfully on Device A.

```
<DeviceA> display ip source binding static
Total entries found: 2
IP address      MAC address    Interface               VLAN Type
192.168.0.1     0001-0203-0406 N/A                     N/A  Static
N/A             0001-0203-0407 GE1/0/1                 N/A  Static
```



Example: Configuring DHCP snooping-based dynamic IPv4SG

Network configuration

As shown in Figure 3, the host (the DHCP client) obtains an IP address from the DHCP server. Perform the following tasks:

- Enable DHCP snooping on the device to make sure the DHCP client obtains an IP address from the authorized DHCP server. To generate a DHCP snooping entry for the DHCP client, enable recording of client information in DHCP snooping entries.
- Enable dynamic IPv4SG on GigabitEthernet 1/0/1 to filter incoming packets by using the IPv4SG bindings generated based on DHCP snooping entries. Only packets from the DHCP client are allowed to pass.

Figure 3 Network diagram

Procedure

1. Configure the DHCP server.

   For information about DHCP server configuration, see *Layer 3—IP Services Configuration Guide*.

2. Configure the device:

   # Configure IP addresses for the interfaces. (Details not shown.)

   # Enable DHCP snooping.

   ```
   <Device> system-view
   [Device] dhcp snooping enable
   ```

   # Configure GigabitEthernet 1/0/2 as a trusted interface.

   ```
   [Device] interface gigabitethernet 1/0/2
   [Device-GigabitEthernet1/0/2] dhcp snooping trust
   [Device-GigabitEthernet1/0/2] quit
   ```

   # Enable IPv4SG on GigabitEthernet 1/0/1 and verify the source IP address and MAC address for dynamic IPSG.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ip verify source ip-address mac-address
   ```

   # Enable recording of client information in DHCP snooping entries on GigabitEthernet 1/0/1.

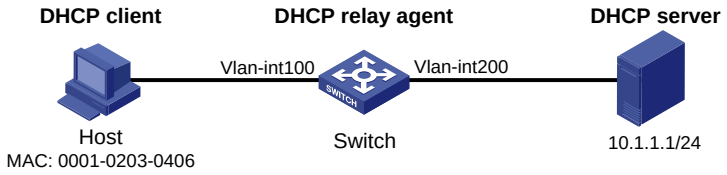
   ```
   [Device-GigabitEthernet1/0/1] dhcp snooping binding record
   [Device-GigabitEthernet1/0/1] quit
   ```

Verifying the configuration

Display dynamic IPv4SG bindings generated based on DHCP snooping entries.

```
[Device] display ip source binding dhcp-snooping
Total entries found: 1
IP address      MAC address    Interface               VLAN Type
192.168.0.1     0001-0203-0406 GE1/0/1                 1    DHCP snooping
```

GigabitEthernet 1/0/1 will filter packets based on the IPv4SG binding.



Example: Configuring DHCP relay agent-based dynamic IPv4SG

Network configuration

As shown in Figure 4, DHCP relay agent is enabled on the switch. The host obtains an IP address from the DHCP server through the DHCP relay agent.

Enable dynamic IPv4SG on VLAN-interface 100 to filter incoming packets by using the IPv4SG bindings generated based on DHCP relay entries.

Figure 4 Network diagram

Procedure

1. Configure dynamic IPv4SG:

   # Configure IP addresses for the interfaces. (Details not shown.)

   # Enable IPv4SG on VLAN-interface 100 and verify the source IP address and MAC address for dynamic IPSG.

   ```
   <Switch> system-view
   [Switch] interface vlan-interface 100
   [Switch-Vlan-interface100] ip verify source ip-address mac-address
   [Switch-Vlan-interface100] quit
   ```

2. Configure the DHCP relay agent:

   # Enable the DHCP service.

   ```
   [Switch] dhcp enable
   ```

   # Enable recording DHCP relay entries.

   ```
   [Switch] dhcp relay client-information record
   ```

   # Configure VLAN-interface 100 to operate in DHCP relay mode.

   ```
   [Switch] interface vlan-interface 100
   [Switch-Vlan-interface100] dhcp select relay
   ```

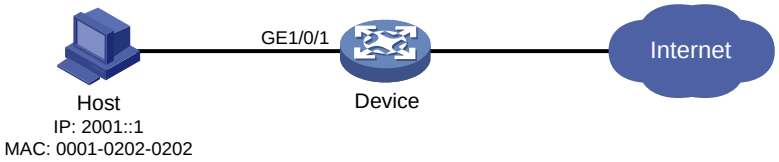
   # Specify the IP address of the DHCP server.

   ```
   [Switch-Vlan-interface100] dhcp relay server-address 10.1.1.1
   [Switch-Vlan-interface100] quit
   ```

Verifying the configuration

Display dynamic IPv4SG bindings generated based on DHCP relay entries.

```
[Switch] display ip source binding dhcp-relay
Total entries found: 1
IP address      MAC address    Interface               VLAN Type
192.168.0.1     0001-0203-0406 Vlan100                 100  DHCP relay
```



VLAN-interface 100 will filter packets based on the IPv4SG binding.

Example: Configuring static IPv6SG

Network configuration

As shown in Figure 5, configure a static IPv6SG binding on GigabitEthernet 1/0/1 of the device to allow only IPv6 packets from the host to pass.

Figure 5 Network diagram

Procedure

Enable IPv6SG on GigabitEthernet 1/0/1.

```
<Device> system-view
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ipv6 verify source ip-address mac-address
```

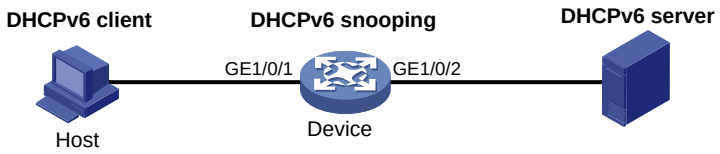
On GigabitEthernet 1/0/1, configure a static IPv6SG binding for the host.

```
[Device-GigabitEthernet1/0/1] ipv6 source binding ip-address 2001::1 mac-address
0001-0202-0202
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Verify that the static IPv6SG binding is configured successfully on the device.

```
[Device] display ipv6 source binding static
Total entries found: 1
IPv6 address         MAC address    Interface             VLAN Type
2001::1              0001-0202-0202 GE1/0/1               N/A  Static
```



Example: Configuring DHCPv6 snooping-based dynamic IPv6SG address bindings

Network configuration

As shown in Figure 6, the host (the DHCPv6 client) obtains an IP address from the DHCPv6 server. Perform the following tasks:

- Enable DHCPv6 snooping on the device to make sure the DHCPv6 client obtains an IPv6 address from the authorized DHCPv6 server. To generate a DHCPv6 snooping entry for the DHCPv6 client, enable recording of client information in DHCPv6 snooping entries.
- Enable dynamic IPv6SG on GigabitEthernet 1/0/1 to filter incoming packets by using the IPv6SG bindings generated based on DHCPv6 snooping entries. Only packets from the DHCPv6 client are allowed to pass.

Figure 6 Network diagram

Procedure

1. Configure DHCPv6 snooping:

   # Enable DHCPv6 snooping globally.

   ```
   <Device> system-view
   [Device] ipv6 dhcp snooping enable
   ```

   # Configure GigabitEthernet 1/0/2 as a trusted interface.

   ```
   [Device] interface gigabitethernet 1/0/2
   [Device-GigabitEthernet1/0/2] ipv6 dhcp snooping trust
   [Device-GigabitEthernet1/0/2] quit
   ```

2. Enable IPv6SG:

   # Enable IPv6SG on GigabitEthernet 1/0/1 and verify the source IP address and MAC address for dynamic IPv6SG.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] ipv6 verify source ip-address mac-address
   ```

   # Enable recording of client information in DHCPv6 snooping entries on GigabitEthernet 1/0/1.

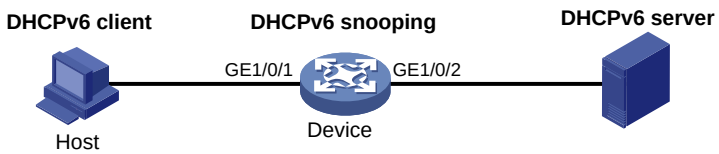
   ```
   [Device-GigabitEthernet1/0/1] ipv6 dhcp snooping binding record
   [Device-GigabitEthernet1/0/1] quit
   ```

Verifying the configuration

Display dynamic IPv6SG bindings generated based on DHCPv6 snooping entries.

```
[Device] display ipv6 source binding dhcpv6-snooping
Total entries found: 1
IPv6 address         MAC address    Interface              VLAN Type
2001::1              040a-0000-0001 GE1/0/1                1    DHCPv6 snooping
```

GigabitEthernet 1/0/1 will filter packets based on the IPv6SG binding.



Example: Configuring DHCPv6 snooping-based dynamic IPv6SG prefix bindings

Network configuration

As shown in Figure 7, the host (the DHCPv6 client) obtains an IPv6 prefix from the DHCPv6 server. Perform the following tasks:

- Enable DHCPv6 snooping on the device to make sure the DHCPv6 client obtains an IPv6 prefix from the authorized DHCPv6 server. To generate a DHCPv6 snooping prefix entry for the DHCPv6 client, enable recording IPv6 prefix information in DHCPv6 snooping entries.
- Enable dynamic IPv6SG on GigabitEthernet 1/0/1 to filter incoming packets by using the IPv6SG bindings generated based on DHCPv6 snooping prefix entries. Only packets from the DHCPv6 client are allowed to pass.

Figure 7 Network diagram

Procedure

1. Configure DHCPv6 snooping.

Enable DHCPv6 snooping globally.

```
<Device> system-view
[Device] ipv6 dhcp snooping enable
```

Configure GigabitEthernet 1/0/2 as a trusted interface.

```
[Device] interface gigabitethernet 1/0/2
[Device-GigabitEthernet1/0/2] ipv6 dhcp snooping trust
[Device-GigabitEthernet1/0/2] quit
```

Enable recording DHCPv6 snooping prefix entries on GigabitEthernet 1/0/1.

```
[Device] interface gigabitethernet 1/0/1
[Device-GigabitEthernet1/0/1] ipv6 dhcp snooping pd binding record
```

2. Enable IPv6SG.

Enable IPv6SG on GigabitEthernet 1/0/1 and verify the source IP address and MAC address for dynamic IPv6SG.

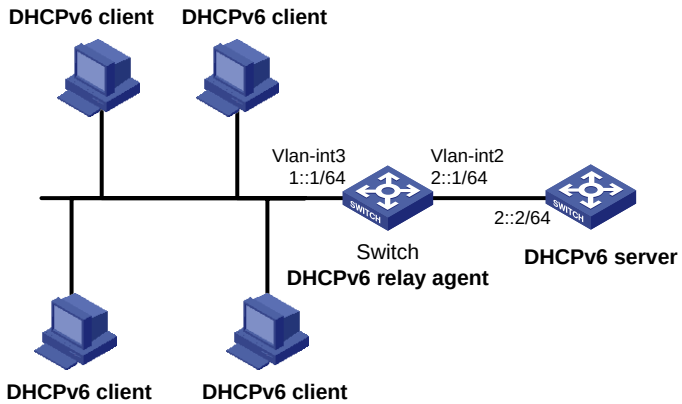
```
[Device-GigabitEthernet1/0/1] ipv6 verify source ip-address mac-address
[Device-GigabitEthernet1/0/1] quit
```

Verifying the configuration

Display dynamic IPv6SG bindings generated based on DHCPv6 snooping entries.

```
[Device] display ipv6 source binding pd
Total entries found: 1
IPv6 address         MAC address    Interface              VLAN Type
2001:410:1::/48      0010-9400-0004 GE1/0/1                1
```

GigabitEthernet 1/0/1 will filter packets based on the IPv6SG binding.



Example: Configuring DHCPv6 relay agent-based dynamic IPv6SG

Network configuration

As shown in Figure 8, DHCPv6 relay agent is enabled on the switch. The clients obtain IPv6 addresses from the DHCPv6 server through the DHCPv6 relay agent.

Enable dynamic IPv6SG on VLAN-interface 3 to filter incoming packets by using the IPv6SG bindings generated based on DHCPv6 relay entries.

Figure 8 Network diagram

Procedure

1. Configure the DHCPv6 relay agent:

Create VLAN 2 and VLAN 3, assign interfaces to the VLANs, and specify IP addresses for VLAN-interface 2 and VLAN-interface 3. (Details not shown.)

Enable the DHCPv6 relay agent on VLAN-interface 3.

```
[Switch] interface vlan-interface 3
[Switch-Vlan-interface3] ipv6 dhcp select relay
```

Enable recording of DHCPv6 relay entries on the interface.

```
[Switch-Vlan-interface3] ipv6 dhcp relay client-information record
```

Specify the DHCPv6 server address 2::2 on the relay agent.

```
[Switch-Vlan-interface3] ipv6 dhcp relay server-address 2::2
[Switch-Vlan-interface3] quit
```

2. Enable IPv6SG on VLAN-interface 3 and verify the source IP address and MAC address for dynamic IPv6SG.

```
<Switch> system-view
[Switch] interface vlan-interface 3
[Switch-Vlan-interface3] ipv6 verify source ip-address mac-address
[Switch-Vlan-interface3] quit
```

Verifying the configuration

Display dynamic IPv6SG bindings generated based on DHCPv6 relay entries.

```
[Switch] display ipv6 source binding dhcpv6-relay
Total entries found: 1
IP Address      MAC Address    Interface               VLAN Type
1::2            0001-0203-0406 Vlan3                   3    DHCPv6 relay
```

VLAN-interface 3 will filter packets based on the IPv6SG binding.

Configuring ARP attack protection

About ARP attack protection

The device can provide multiple features to detect and prevent ARP attacks and viruses in the LAN. An attacker can exploit ARP vulnerabilities to attack network devices in the following ways:

- Sends a large number of unresolvable IP packets to have the receiving device busy with resolving IP addresses until its CPU is overloaded. Unresolvable IP packets refer to IP packets for which ARP cannot find corresponding MAC addresses.
- Sends a large number of ARP packets to overload the CPU of the receiving device.
- Acts as a trusted user or gateway to send ARP packets so the receiving devices obtain incorrect ARP entries.

ARP attack protection tasks at a glance

All ARP attack protection tasks are optional.

- Preventing flood attacks
  - Configuring unresolvable IP attack protection
  - Configuring ARP packet rate limiting
  - Configuring source MAC-based ARP attack detection
- Preventing user and gateway spoofing attacks
  - Configuring ARP packet source MAC consistency check
  - Configuring ARP active acknowledgement
  - Configuring authorized ARP
  - Configuring ARP attack detection
  - Configuring ARP packet validity check
  - Configuring ARP restricted forwarding
  - Ignoring ingress ports of ARP packets during user validity check
  - Enabling ARP attack detection logging
  - Configuring ARP scanning and fixed ARP
  - Configuring ARP gateway protection
  - Example: Configuring ARP gateway protection
  - Configuring ARP filtering
  - Configuring ARP sender IP address checking

Configuring unresolvable IP attack protection

About unresolvable IP attack protection

If a device receives a large number of unresolvable IP packets from a host, the following situations can occur:

- The device sends a large number of ARP requests, overloading the target subnets.
- The device keeps trying to resolve the destination IP addresses, overloading its CPU.

To protect the device from such IP attacks, you can configure the following features:

- **ARP source suppression**—Stops resolving packets from an IP address if the number of unresolvable IP packets from the IP address exceeds the upper limit within 5 seconds. The device continues ARP resolution when the interval elapses. This feature is applicable if the attack packets have the same source addresses.
- **ARP blackhole routing**—Creates a blackhole route destined for an unresolved IP address. The device drops all matching packets until the blackhole route is deleted. A blackhole route is deleted when its aging timer is reached or the route becomes reachable.

  After a blackhole route is created for an unresolved IP address, the device immediately starts the first ARP blackhole route probe by sending an ARP request. If the resolution fails, the device continues probing according to the probe settings. If the IP address resolution succeeds in a probe, the device converts the blackhole route to a normal route. If an ARP blackhole route ages out before the device finishes all probes, the device deletes the blackhole route and does not perform the remaining probes.

  This feature is applicable regardless of whether the attack packets have the same source addresses.

Configuring ARP source suppression

1. Enter system view.

   system-view
2. Enable ARP source suppression.

   arp source-suppression enable

   By default, ARP source suppression is disabled.
3. Set the maximum number of unresolvable packets that the device can process per source IP address within 5 seconds.

   arp source-suppression limit *limit-value*

   By default, the maximum number is 10.

Configuring ARP blackhole routing

Restrictions and guidelines

Set the ARP blackhole route probe count to a big value, for example, 25. If the device fails to reach the destination IP address temporarily and the probe count is too small, all probes might finish before the problem is resolved. As a result, non-attack packets will be dropped. This setting can avoid such situation.

Procedure

1. Enter system view.

   system-view
2. Enable ARP blackhole routing.

   arp resolving-route enable

   By default, ARP blackhole routing is enabled.
3. (Optional.) Set the number of ARP blackhole route probes for each unresolved IP address.

   arp resolving-route probe-count *count*

   The default setting is three probes.
4. (Optional.) Set the interval at which the device probes ARP blackhole routes.

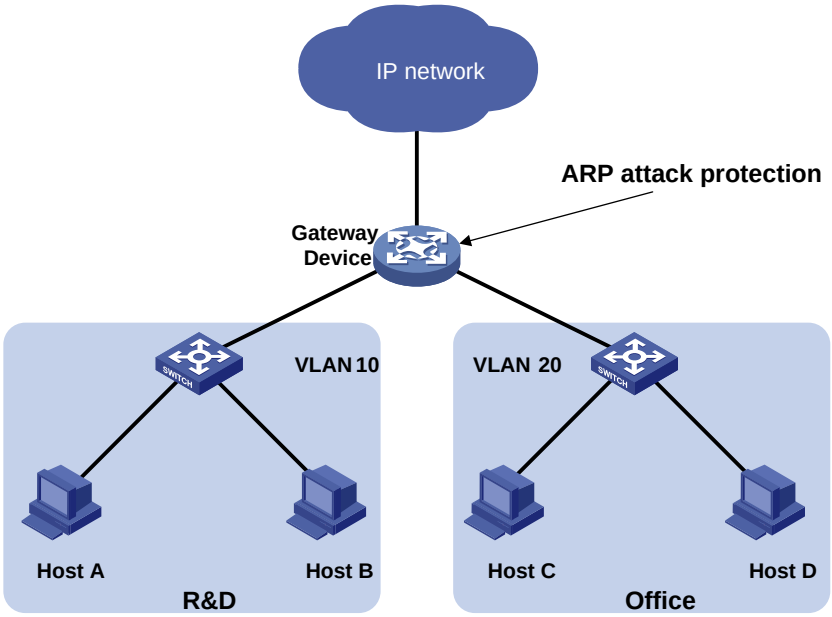
   arp resolving-route probe-interval *interval*

   The default setting is 1 second.

Display and maintenance commands for unresolvable IP attack protection

Execute **display** commands in any view.

Task	Command
Display ARP source suppression configuration information.	**display arp source-suppression**



Example: Configuring unresolvable IP attack protection

Network configuration

As shown in Figure 1, a LAN contains two areas: an R&D area in VLAN 10 and an office area in VLAN 20. Each area connects to the gateway (Device) through an access switch.

A large number of ARP requests are detected in the office area and are considered an attack caused by unresolvable IP packets. To prevent the attack, configure ARP source suppression or ARP blackhole routing.

Figure 1 Network diagram

Procedure

- If the attack packets have the same source address, configure ARP source suppression:

  # Enable ARP source suppression.

  ```
  <Device> system-view
  [Device] arp source-suppression enable
  ```

  # Configure the device to process a maximum of 100 unresolvable packets per source IP address within 5 seconds.

  ```
  [Device] arp source-suppression limit 100
  ```

- If the attack packets have different source addresses, configure ARP blackhole routing:

  # Enable ARP blackhole routing.

```
[Device] arp resolving-route enable
```

Configuring ARP packet rate limiting

About this task

The ARP packet rate limiting feature allows you to limit the rate of ARP packets delivered to the CPU. An ARP attack detection-enabled device will send all received ARP packets to the CPU for inspection. Processing excessive ARP packets will make the device malfunction or even crash. To solve this problem, configure ARP packet rate limiting. When the receiving rate of ARP packets on the interface exceeds the rate limit, those packets are discarded.

You can enable sending notifications to the SNMP module or enable logging for ARP packet rate limiting.

- If notification sending is enabled, the device sends the highest threshold-crossed ARP packet rate within the sending interval in a notification to the SNMP module. You must use the **snmp-agent target-host** command to set the notification type and target host. For more information about notifications, see *Network Management and Monitoring Command Reference*.
- If logging for ARP packet rate limiting is enabled, the device sends the highest threshold-crossed ARP packet rate within the sending interval in a log message to the information center. You can configure the information center module to set the log output rules. For more information about information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

As a best practice, configure this feature when ARP attack detection or ARP snooping is enabled, or when ARP flood attacks are detected.

If excessive notifications and log messages are sent for ARP packet rate limiting, you can increase notification and log message sending interval.

If you enable notification sending and logging for ARP packet rate limiting on an aggregate interface, the features apply to all aggregation member ports.

This feature is mutually exclusive with the source MAC-based ARP packet rate limiting feature configured by using the **arp rate-limit source-mac** command.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Enable SNMP notifications for ARP packet rate limiting.

   snmp-agent trap enable arp [**rate-limit**]

   By default, SNMP notifications for ARP packet rate limiting are disabled.

3. (Optional.) Enable logging for ARP packet rate limiting.

   arp rate-limit log enable

   By default, logging for ARP packet rate limiting is disabled.

4. (Optional.) Set the notification and log message sending interval.

   arp rate-limit log interval *interval*

   By default, the device sends notifications and log messages every 60 seconds.

5. Enter interface view.

   interface *interface-type interface-number*

   Supported interface types include Layer 2 Ethernet interface, Layer 3 Ethernet interface, Layer 3 aggregate interface, and Layer 2 aggregate interface.

6. Enable ARP packet rate limiting.

   arp rate-limit [*pps*]

   By default, ARP packet rate limiting is enabled.

Configuring source MAC-based ARP attack detection

About this task

This feature checks the number of ARP packets delivered to the CPU. If the number of packets from the same MAC address within 5 seconds exceeds a threshold, the device generates an ARP attack entry for the MAC address. If logging is enabled for source MAC-based ARP attack detection, the device handles the attack by using either of the following methods before the ARP attack entry ages out:

- **Monitor**—Only generates log messages.
- **Filter**—Generates log messages and filters out subsequent ARP packets from the MAC address.

To enable the ARP logging feature, use the **arp source-mac log enable** command. For information about the ARP logging feature, see ARP in *Layer 3—IP Services Configuration Guide*.

When an ARP attack entry ages out, ARP packets sourced from the MAC address in the entry can be processed correctly.

Restrictions and guidelines

When you change the handling method from monitor to filter, the configuration takes effect immediately. When you change the handling method from filter to monitor, the device continues filtering packets that match existing attack entries.

You can exclude the MAC addresses of some gateways and servers from this detection. This feature does not inspect ARP packets from those devices even if they are attackers.

Procedure

1. Enter system view.

   system-view

2. Enable source MAC-based ARP attack detection and specify the handling method.

   arp source-mac { **filter** | **monitor** }

   By default, this feature is disabled.

3. Set the threshold.

   arp source-mac threshold *threshold-value*

   By default, the threshold is 30.

4. Set the aging timer for ARP attack entries.

   arp source-mac aging-time *time*

   By default, the lifetime is 300 seconds.

5. (Optional.) Exclude specific MAC addresses from this detection.

   arp source-mac exclude-mac *mac-address*&<1-10>

   By default, no MAC address is excluded.

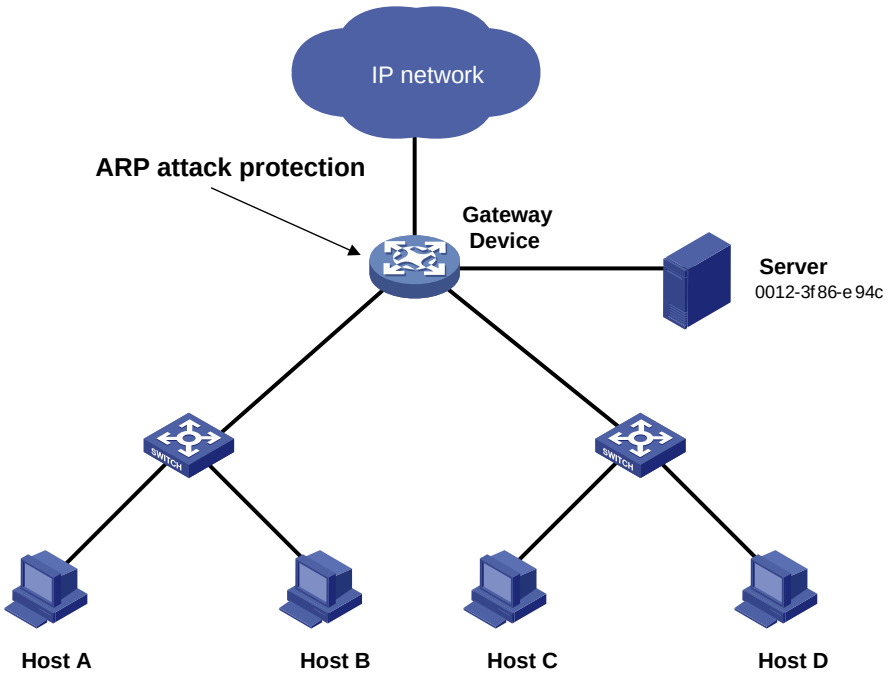
6. Enable logging for source MAC-based ARP attack detection.

   arp source-mac log enable

   By default, logging for source MAC-based ARP attack detection is disabled.

Display and maintenance commands for source MAC-based ARP attack detection

Execute **display** commands in any view.



Task	Command
Display ARP attack entries detected by source MAC-based ARP attack detection.	**display arp source-mac** { **interface** *interface-type interface-number* [**slot** *slot-number*] | **slot** *slot-number* }

Example: Configuring source MAC-based ARP attack detection

Network configuration

As shown in Figure 2, the hosts access the Internet through a gateway (Device). If malicious users send a large number of ARP requests to the gateway, the gateway might crash and cannot process requests from the clients. To solve this problem, configure source MAC-based ARP attack detection on the gateway.

Figure 2 Network diagram

Procedure

Enable source MAC-based ARP attack detection, and specify the handling method as filter.

```
<Device> system-view
[Device] arp source-mac filter
```

Set the threshold to 30.

```
[Device] arp source-mac threshold 30
```

Set the lifetime for ARP attack entries to 60 seconds.

```
[Device] arp source-mac aging-time 60
```

Exclude MAC address 0012-3f86-e94c from this detection.

```
[Device] arp source-mac exclude-mac 0012-3f86-e94c
```

Configuring ARP packet source MAC consistency check

About ARP packet source MAC consistency check

This feature enables a gateway to filter out ARP packets whose source MAC address in the Ethernet header is different from the sender MAC address in the message body. This feature allows the gateway to learn correct ARP entries.

Procedure

1. Enter system view.

   `system-view`

2. Enable ARP packet source MAC address consistency check.

   `arp valid-check enable`

   By default, ARP packet source MAC address consistency check is disabled.

Configuring ARP active acknowledgement

About this task

Use the ARP active acknowledgement feature on gateways to prevent user spoofing.

This feature enables the device to perform active acknowledgement before creating an ARP entry.

- Upon receiving an ARP request that requests the MAC address of the device, the device sends an ARP reply. Then, it sends an ARP request for the sender IP address in the received ARP request to determine whether to create an ARP entry for the sender IP address.
  - If the device receives an ARP reply within the probe interval, it creates the ARP entry.
  - If the device does not receive an ARP reply within the probe interval, it does not create the ARP entry.
- Upon receiving an ARP reply, the device examines whether it was the reply to the request that the device has sent.
  - If it was, the device creates an ARP entry for the sender IP address in the ARP reply.
  - If it was not, the device sends an ARP request for the sender IP address to determine whether to create an ARP entry for the sender IP address.
    - If the device receives an ARP reply within the probe interval, it creates the ARP entry.
    - If the device does not receive an ARP reply within the probe interval, it does not create the ARP entry.

To improve validity and reliability of ARP entries, you can enable ARP active acknowledgement in strict mode. In this mode, the device creates ARP entries only for the IP addresses that the device actively initiates the ARP resolution.

Procedure

1. Enter system view.

system-view

2. Enable ARP active acknowledgement.

   arp active-ack [**strict**] **enable**

   By default, ARP active acknowledgement is disabled.

   For ARP active acknowledgement to take effect in strict mode, make sure ARP blackhole routing is enabled.

Configuring authorized ARP

About authorized ARP

Authorized ARP entries are generated based on the DHCP clients' address leases on the DHCP server or dynamic client entries on the DHCP relay agent. For more information about DHCP server and DHCP relay agent, see *Layer 3—IP Services Configuration Guide*.

Use this feature to prevent user spoofing and to allow only authorized clients to access network resources.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

   Supported interface types include Layer 3 Ethernet interface, Layer 3 aggregate interface, and VLAN interface.

3. Enable authorized ARP on the interface.

   arp authorized enable

   By default, authorized ARP is disabled.

Configuring ARP attack detection

About ARP attack detection

ARP attack detection enables access devices to block ARP packets from unauthorized clients to prevent user spoofing and gateway spoofing attacks.

ARP attack detection provides the following features:

- User validity check.
- ARP packet validity check.
- ARP restricted forwarding.
- ARP packet ingress port ignoring during user validity check
- ARP attack detection logging.

If both ARP packet validity check and user validity check are enabled, the former one applies first, and then the latter applies.

Do not configure ARP attack detection together with ARP snooping. Otherwise, ARP snooping entries cannot be generated.

Configuring user validity check

About this task

User validity check does not check ARP packets received on ARP trusted interfaces. This feature compares the sender IP and sender MAC in the ARP packet received on an ARP untrusted interface with the matching criteria in the following order:

1. User validity check rules.
   - If a match is found, the device processes the ARP packet according to the rule.
   - If no match is found or no user validity check rule is configured, proceeds to step 2.
2. Static IPSG bindings, 802.1X security entries, and DHCP snooping entries.
   - If a match is found, the device determines that the ARP packet is valid, and then forwards the ARP packet.
     - If a match is found and the receiving interface is different from the interface in the entry with a matching sender IP address, the device performs Layer 3 forwarding.
     - If a match is found but the receiving interface is the same as the interface in the entry with a matching sender IP address, the device performs Layer 2 forwarding.
     - If no match is found, the device performs Layer 2 forwarding.
   - If no match is found, the device discards the ARP packet.

Static IP source guard bindings are created by using the **ip source binding** command. For more information, see "Configuring IP source guard."

DHCP snooping entries are automatically generated by DHCP snooping. For more information, see *Layer 3—IP Services Configuration Guide*.

802.1X security entries record the IP-to-MAC mappings for 802.1X clients. After a client passes 802.1X authentication and uploads its IP address to an ARP attack detection enabled device, the device automatically generates an 802.1X security entry. The 802.1X client must be enabled to upload its IP address to the device. For more information, see "Configuring 802.1X."

Restrictions and guidelines

When you configure user validity check, make sure one or more of the following items are configured:

- User validity check rules.
- Static IP source guard bindings.
- DHCP snooping.
- 802.1X.

If none of the items is configured, the device does not perform user validity check and cannot correctly forward the incoming ARP packets on ARP untrusted interfaces.

Specify an IP address, a MAC address, and a VLAN where ARP attack detection is enabled for an IP source guard binding. Otherwise, no ARP packets can match the IP source guard binding.

Configuring user validity check rules

1. Enter system view.

   system-view

2. Configure a user validity check rule.

   arp detection rule *rule-id* { **deny** | **permit** } **ip** { *ip-address* [*mask*] | **any** } **mac** { *mac-address* [*mask*] | **any** } [**vlan** *vlan-id*]

   By default, no user validity check rules are configured.

Enabling ARP attack detection in a VLAN

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable ARP attack detection.
   arp detection enable
   By default, ARP attack detection is disabled. The device does not perform ARP user validity check.
4. (Optional.) Configure an interface that does not require ARP user validity check as a trusted interface.
   a. Return to system view.
      quit
   b. Enter interface view.
      interface *interface-type interface-number*
      Supported interface types include Layer 2 Ethernet interface and Layer 2 aggregate interface.
   c. Configure the interface as a trusted interface excluded from ARP attack detection.
      arp detection trust
      By default, an interface is untrusted.

Configuring ARP packet validity check

About this task

ARP packet validity check does not check ARP packets received on ARP trusted interfaces. To check ARP packets received on untrusted interfaces, you can specify the following objects to be checked:

- **src-mac**—Checks whether the sender MAC address in the message body is identical to the source MAC address in the Ethernet header. If they are identical, the packet is forwarded. Otherwise, the packet is discarded.
- **dst-mac**—Checks the target MAC address of ARP replies. If the target MAC address is all-zero, all-one, or inconsistent with the destination MAC address in the Ethernet header, the packet is considered invalid and discarded.
- **ip**—Checks the sender and target IP addresses of ARP replies, and the sender IP address of ARP requests. All-one or multicast IP addresses are considered invalid and the corresponding packets are discarded.

Prerequisites

Before you configure ARP packet validity check, you must first configure user validity check. For more information about user validity check configuration, see "Configuring user validity check."

Enabling ARP packet validity check

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable ARP attack detection.
   arp detection enable

By default, ARP attack detection is disabled. The device does not perform ARP packet validity check.

4. Enable ARP packet validity check.
   a. Return to system view.
      quit
   b. Enable ARP packet validity check and specify the objects to be checked.
      arp detection validate { **dst-mac** | **ip** | **src-mac** } *
      By default, ARP packet validity check is disabled.

Enabling ARP attack detection in a VLAN

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable ARP attack detection.
   arp detection enable
   By default, ARP attack detection is disabled. The device does not perform ARP packet validity check.
4. (Optional.) Configure the interface that does not require ARP packet validity check as a trusted interface.
   a. Return to system view.
      quit
   b. Enter interface view.
      interface *interface-type interface-number*
      Supported interface types include Layer 2 Ethernet interface and Layer 2 aggregate interface.
   c. Configure the interface as a trusted interface excluded from ARP attack detection.
      arp detection trust
      By default, an interface is untrusted.

Configuring ARP restricted forwarding

About this task

ARP restricted forwarding does not take effect on ARP packets received on ARP trusted interfaces and forwards the ARP packets correctly. This feature controls the forwarding of ARP packets that are received on untrusted interfaces and have passed user validity check as follows:

- If the packets are ARP requests, they are forwarded through the trusted interface.
- If the packets are ARP replies, they are forwarded according to their destination MAC address. If no match is found in the MAC address table, they are forwarded through the trusted interface.

Restrictions and guidelines

ARP restricted forwarding does not apply to ARP packets that use multiport destination MAC addresses.

Prerequisites

Configure user validity check before you configure ARP restricted forwarding. For information about user validity check configuration, see "Configuring user validity check."

Procedure

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable ARP restricted forwarding.
   arp restricted-forwarding enable
   By default, ARP restricted forwarding is disabled.

Ignoring ingress ports of ARP packets during user validity check

About this task

ARP attack detection performs user validity check on ARP packets from ARP untrusted interfaces. The sender IP and sender MAC in the received ARP packet are compared with the entries used for user validity check. In addition, user validity check compares the ingress port of the ARP packet with the port in the entries. If no matching port is found, the ARP packet is discarded. For more information about user validity check, see "Configuring user validity check."

You can configure the device to ignore the ingress ports of ARP packets during user validity check. If an ARP packet passes user validity check, the device directly performs Layer 2 forwarding for the packet. It no longer searches for a matching static IPSG binding, 802.1X security entry, or DHCP snooping entry by the target IP address of the ARP packet.

Procedure

1. Enter system view.
   system-view
2. Ignore ingress ports of ARP packets during user validity check.
   arp detection port-match-ignore
   By default, ingress ports of ARP packets are checked during user invalidity.

Enabling ARP attack detection logging

About this task

The ARP attack detection logging feature enables a device to generate ARP attack detection log messages when illegal ARP packets are detected. An ARP attack detection log message contains the following information:

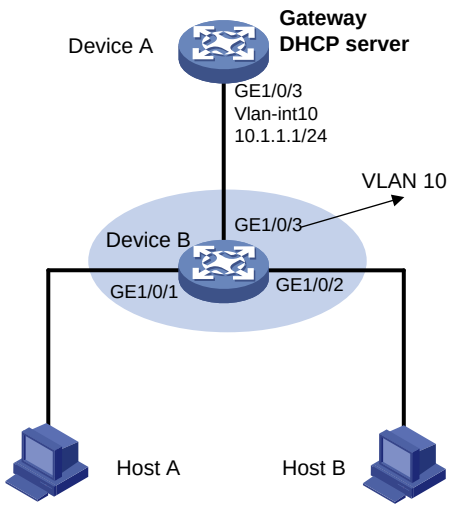
- Receiving interface of the ARP packets.
- Sender IP address.
- Total number of dropped ARP packets.

Procedure

1. Enter system view.
   system-view
2. Enable ARP attack detection logging.
   arp detection log enable [**interval** *interval* | **number** *number* | **threshold** *threshold-value*]*
   By default, ARP attack detection logging is disabled.

Display and maintenance commands for ARP attack detection

Execute **display** commands in any view and **reset** commands in user view.



Task	Command
Display the VLANs enabled with ARP attack detection.	**display arp detection**
Display ARP attack source statistics.	**display arp detection statistics attack-source slot** *slot-number*
Display statistics for packets dropped by ARP attack detection.	**display arp detection statistics packet-drop** [**interface** *interface-type interface-number*]
Clear ARP attack source statistics.	**reset arp detection statistics attack-source** [**slot** *slot-number*]
Clear statistics for packets dropped by ARP attack detection.	**reset arp detection statistics packet-drop** [**interface** *interface-type interface-number*]

Example: Configuring user validity check

Network configuration

As shown in Figure 3, configure Device B to perform user validity check based on 802.1X security entries for connected hosts.

Figure 3 Network diagram

Procedure

1. Add all interfaces on Device B to VLAN 10, and specify the IP address of VLAN-interface 10 on Device A. (Details not shown.)
2. Configure the DHCP server on Device A, and configure DHCP address pool 0.

```
<DeviceA> system-view
[DeviceA] dhcp enable
[DeviceA] dhcp server ip-pool 0
```

```
[DeviceA-dhcp-pool-0] network 10.1.1.0 mask 255.255.255.0
```

3. Configure Host A and Host B as 802.1X clients and configure them to upload IP addresses for ARP attack detection. (Details not shown.)
4. Configure Device B:

   # Enable 802.1X.

```
<DeviceB> system-view
[DeviceB] dot1x
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] dot1x
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] dot1x
[DeviceB-GigabitEthernet1/0/2] quit
```

   # Add a local user **test**.

```
[DeviceB] local-user test class network
[DeviceB-luser-network-test] service-type lan-access
[DeviceB-luser-network-test] password simple test
[DeviceB-luser-network-test] quit
```

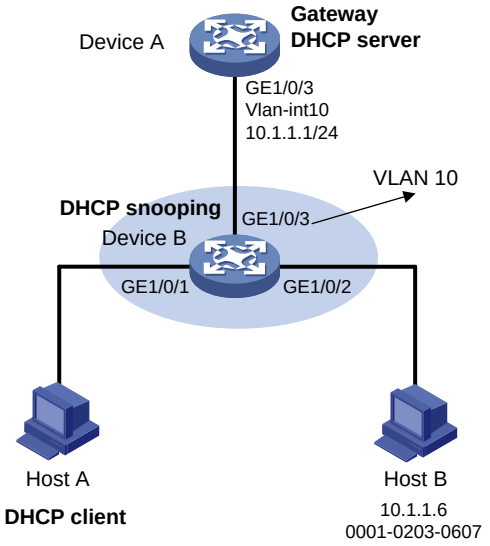
   # Enable ARP attack detection for VLAN 10 to check user validity based on 802.1X entries.

```
[DeviceB] vlan 10
[DeviceB-vlan10] arp detection enable
```

   # Configure the upstream interface as an ARP trusted interface. By default, an interface is an untrusted interface.

```
[DeviceB-vlan10] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] arp detection trust
[DeviceB-GigabitEthernet1/0/3] quit
```

Verifying the configuration



Verify that ARP packets received on interfaces GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are checked against 802.1X entries.

Example: Configuring user validity check and ARP packet validity check

Network configuration

As shown in Figure 4, configure Device B to perform ARP packet validity check and user validity check based on static IP source guard bindings and DHCP snooping entries for connected hosts.

Figure 4 Network diagram

Procedure

1. Add all interfaces on Device B to VLAN 10, and specify the IP address of VLAN-interface 10 on Device A. (Details not shown.)
2. Configure the DHCP server on Device A, and configure DHCP address pool 0.

```
<DeviceA> system-view
[DeviceA] dhcp enable
[DeviceA] dhcp server ip-pool 0
[DeviceA-dhcp-pool-0] network 10.1.1.0 mask 255.255.255.0
```

3. Configure Host A (DHCP client) and Host B. (Details not shown.)
4. Configure Device B:

   # Enable DHCP snooping.

```
<DeviceB> system-view
[DeviceB] dhcp snooping enable
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] dhcp snooping trust
[DeviceB-GigabitEthernet1/0/3] quit
```

   # Enable recording of client information in DHCP snooping entries on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] dhcp snooping binding record
[DeviceB-GigabitEthernet1/0/1] quit
```

   # Enable ARP attack detection for VLAN 10.

```
[DeviceB] vlan 10
[DeviceB-vlan10] arp detection enable
```

   # Configure the upstream interface as a trusted interface. By default, an interface is an untrusted interface.

```
[DeviceB-vlan10] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] arp detection trust
[DeviceB-GigabitEthernet1/0/3] quit
```

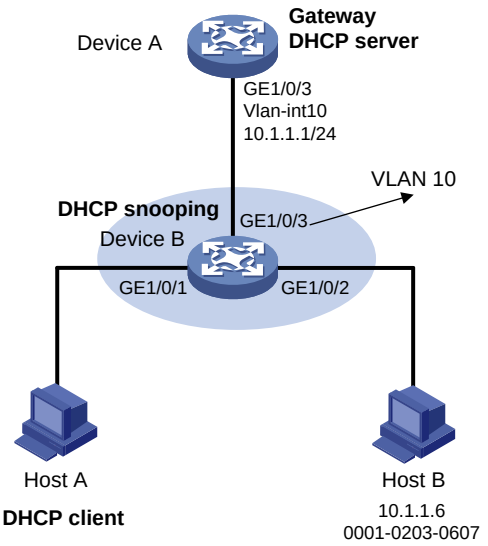
   # Configure a static IP source guard binding entry on interface GigabitEthernet 1/0/2 for user validity check.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] ip source binding ip-address 10.1.1.6 mac-address
0001-0203-0607 vlan 10
[DeviceB-GigabitEthernet1/0/2] quit
```

Enable ARP packet validity check by checking the MAC addresses and IP addresses of ARP packets.

```
[DeviceB] arp detection validate dst-mac ip src-mac
```

Verifying the configuration



Verify that Device B first checks the validity of ARP packets received on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2. If the ARP packets are confirmed valid, Device B performs user validity check by using the static IP source guard bindings and finally DHCP snooping entries.

Example: Configuring ARP restricted forwarding

Network configuration

As shown in Figure 5, configure ARP restricted forwarding on Device B where ARP attack detection is configured. Port isolation configured on Device B can take effect for broadcast ARP requests.

Figure 5 Network diagram

Procedure

1. Configure VLAN 10, add interfaces to VLAN 10, and specify the IP address of VLAN-interface 10 on Device A. (Details not shown.)
2. Configure the DHCP server on Device A, and configure DHCP address pool 0.

```
<DeviceA> system-view
[DeviceA] dhcp enable
[DeviceA] dhcp server ip-pool 0
[DeviceA-dhcp-pool-0] network 10.1.1.0 mask 255.255.255.0
```

3. Configure Host A (DHCP client) and Host B. (Details not shown.)
4. Configure Device B:

Enable DHCP snooping, and configure GigabitEthernet 1/0/3 as a DHCP trusted interface.

```
<DeviceB> system-view
[DeviceB] dhcp snooping enable
```

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] dhcp snooping trust
[DeviceB-GigabitEthernet1/0/3] quit
```

Enable ARP attack detection for user validity check.

```
[DeviceB] vlan 10
[DeviceB-vlan10] arp detection enable
```

Configure GigabitEthernet 1/0/3 as an ARP trusted interface.

```
[DeviceB-vlan10] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] arp detection trust
[DeviceB-GigabitEthernet1/0/3] quit
```

Configure a static IP source guard entry on interface GigabitEthernet 1/0/2.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] ip source binding ip-address 10.1.1.6 mac-address
0001-0203-0607 vlan 10
[DeviceB-GigabitEthernet1/0/2] quit
```

Enable ARP packet validity check by checking the MAC addresses and IP addresses of ARP packets.

```
[DeviceB] arp detection validate dst-mac ip src-mac
```

Configure port isolation.

```
[DeviceB] port-isolate group 1
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port-isolate enable group 1
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port-isolate enable group 1
[DeviceB-GigabitEthernet1/0/2] quit
```

After the configurations are completed, Device B first checks the validity of ARP packets received on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2. If the ARP packets are confirmed valid, Device B performs user validity check by using the static IP source guard bindings and finally DHCP snooping entries. However, ARP broadcast requests sent from Host A can pass the check on Device B and reach Host B. Port isolation fails.

Enable ARP restricted forwarding.

```
[DeviceB] vlan 10
[DeviceB-vlan10] arp restricted-forwarding enable
[DeviceB-vlan10] quit
```

Verifying the configuration

Verify that Device B forwards ARP broadcast requests from Host A to Device A through the trusted interface GigabitEthernet 1/0/3. Host B cannot receive such packets. Port isolation operates correctly.

Configuring ARP scanning and fixed ARP

About this task

ARP scanning is typically used together with the fixed ARP feature in small-scale and stable networks.

ARP scanning automatically creates ARP entries for devices in an address range. The device performs ARP scanning in the following steps:

1. Sends ARP requests for each IP address in the address range.
2. Obtains their MAC addresses through received ARP replies.
3. Creates dynamic ARP entries.

You can manually trigger ARP scanning or enable automatic ARP scanning. Automatic ARP scanning periodically sends ARP requests for all IP addresses in the range at the specified rate set by using the **arp scan auto send-rate** command.

Fixed ARP converts existing dynamic ARP entries (including those generated through ARP scanning) to static ARP entries. These static ARP entries are of the same attributes as the ARP entries that are manually configured. This feature prevents ARP entries from being modified by attackers.

You can set the ARP packet sending rate if the scanning range has a large number of IP addresses. This setting can avoid high CPU usage and heavy network load caused by a burst of ARP traffic.

Restrictions and guidelines

IP addresses in existing ARP entries are not scanned.

If you trigger ARP scanning and enable automatic ARP scanning, both of them take effect. As a best practice, use automatic ARP scanning only on networks where users come online and go offline frequently.

Due to the limit on the total number of static ARP entries, some dynamic ARP entries might fail the conversion.

The **arp fixup** command is a one-time operation. You can use this command again to convert the dynamic ARP entries learned later to static.

To delete a static ARP entry converted from a dynamic one, use the **undo arp** *ip-address* [*vpn-instance-name*] command. You can also use the **reset arp all** command to delete all ARP entries or the **reset arp static** command to delete all static ARP entries.

Triggering ARP scanning

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Trigger ARP scanning.

   arp scan [*start-ip-address* **to** *end-ip-address*] [**send-rate** { **ppm** *ppm* | *pps* }]

CAUTION:

ARP scanning will take some time. To stop an ongoing scan, press **Ctrl** + **C**. Dynamic ARP entries are created based on ARP replies received before the scan is terminated.

Configuring automatic ARP scanning

1. Enter system view.

   system-view
2. Set the ARP packet sending rate for automatic ARP scanning.

   arp scan auto send-rate { **ppm** *ppm* | **pps** *pps* }

   By default, the device sends ARP packets at the rate of 48 pps during automatic ARP scanning.

3. Enter interface view.
   interface *interface-type interface-number*
4. Enable automatic ARP scanning.
   arp scan auto enable [*start-ip-address* **to** *end-ip-address*]
   By default, automatic ARP scanning is disabled.

Configuring fixed ARP

1. Enter system view.
   system-view
2. Convert existing dynamic ARP entries to static ARP entries.
   arp fixup

Configuring ARP gateway protection

About ARP gateway protection

Configure this feature on interfaces not connected with a gateway to prevent gateway spoofing attacks.

When such an interface receives an ARP packet, it checks whether the sender IP address in the packet is consistent with that of any protected gateway. If yes, it discards the packet. If not, it handles the packet correctly.

Restrictions and guidelines

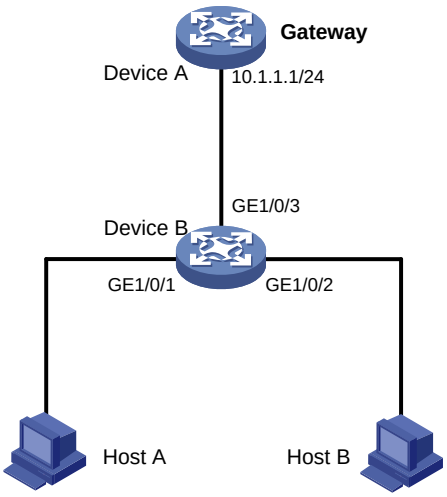
You can enable ARP gateway protection for a maximum of eight gateways on an interface.

Do not configure both the **arp filter source** and **arp filter binding** commands on an interface.

If ARP gateway protection works with ARP attack detection and ARP snooping, ARP gateway protection applies first.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
   Supported interface types include Layer 2 Ethernet interface and Layer 2 aggregate interface.
3. Enable ARP gateway protection for the specified gateway.
   arp filter source *ip-address*
   By default, ARP gateway protection is disabled.



Example: Configuring ARP gateway protection

Network configuration

As shown in Figure 6, Host B launches gateway spoofing attacks to Device B. As a result, traffic that Device B intends to send to Device A is sent to Host B.

Configure Device B to block such attacks.

Figure 6 Network diagram

Procedure

Configure ARP gateway protection on Device B.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] arp filter source 10.1.1.1
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] arp filter source 10.1.1.1
```

Verifying the configuration

Verify that GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 discard the incoming ARP packets whose sender IP address is the IP address of the gateway.

Configuring ARP filtering

ARP filtering

The ARP filtering feature can prevent gateway spoofing and user spoofing attacks.

An interface enabled with this feature checks the sender IP and MAC addresses in a received ARP packet against permitted entries. If a match is found, the packet is handled correctly. If not, the packet is discarded.

Restrictions and guidelines

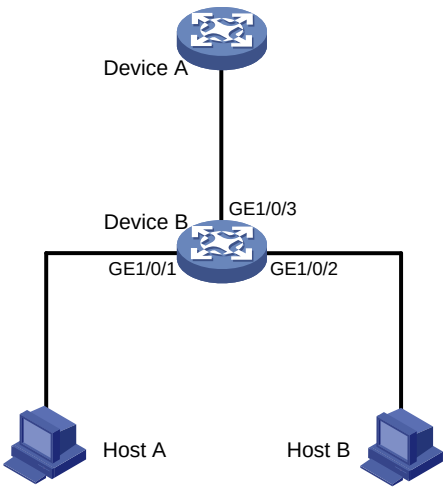
You can configure a maximum of eight permitted entries on an interface.

Do not configure both the **arp filter source** and **arp filter binding** commands on an interface.

If ARP filtering works with ARP attack detection and ARP snooping, ARP filtering applies first.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
   Supported interface types include Ethernet interface and Layer 2 aggregate interface.
3. Enable ARP filtering and configure a permitted entry.
   arp filter binding *ip-address mac-address*
   By default, ARP filtering is disabled.



Example: Configuring ARP filtering

Network configuration

As shown in Figure 7, the IP and MAC addresses of Host A are 10.1.1.2 and 000f-e349-1233, respectively. The IP and MAC addresses of Host B are 10.1.1.3 and 000f-e349-1234, respectively.

Configure ARP filtering on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 of Device B to permit ARP packets from only Host A and Host B.

Figure 7 Network diagram

Procedure

Configure ARP filtering on Device B.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] arp filter binding 10.1.1.2 000f-e349-1233
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] arp filter binding 10.1.1.3 000f-e349-1234
```

Verifying the configuration

Verify that GigabitEthernet 1/0/1 permits ARP packets from Host A and discards other ARP packets.

Verify that GigabitEthernet 1/0/2 permits ARP packets from Host B and discards other ARP packets.

Configuring ARP sender IP address checking

About ARP sender IP address checking

This feature allows a gateway to check the sender IP address of an ARP packet in a VLAN before ARP learning. If the sender IP address is within the allowed IP address range, the gateway continues ARP learning. If the sender IP address is out of the range, the gateway determines the ARP packet as an attack packet and discards it.

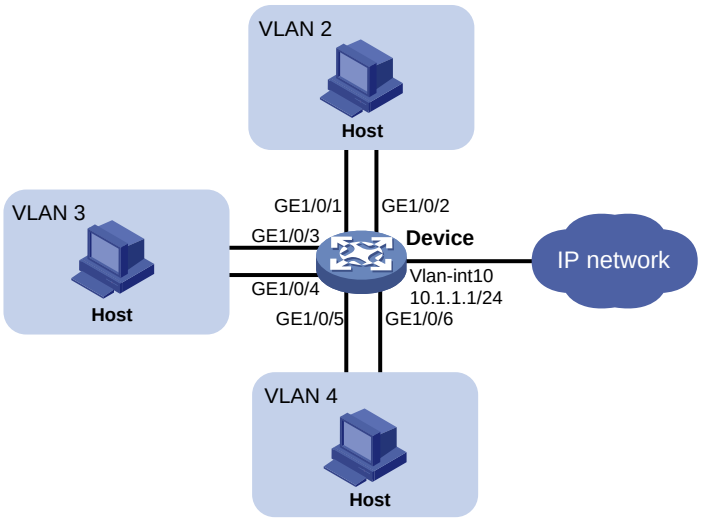
Restrictions and guidelines

If the VLAN is a sub-VLAN and is associated with a super VLAN, configure this checking feature only in the sub-VLAN.

If Layer 3 communication is configured between the secondary VLANs associated with a primary VLAN, configure this feature in the primary VLAN. If Layer 3 communication is not configured between the secondary VLANs associated with a primary VLAN, configure this feature in the intended VLAN.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable the ARP sender IP address checking feature and specify the IP address range.
   arp sender-ip-range *start-ip-address end-ip-address*
   By default, the ARP sender IP address checking feature is disabled.



Example: Configuring ARP sender IP address checking

Network configuration

As shown in Figure 8, perform the following tasks:

- Create a super VLAN and associate it with VLANs 2, 3, and 4. VLANs 2, 3, and 4 are isolated at Layer 2 but interoperable at Layer 3. All hosts in VLANs 2, 3, and 4 use the gateway IP address 10.1.1.1/24 for Layer 3 communication.
- Configure the ARP sender IP address checking feature in VLAN 2 and specify the sender IP address range 10.1.1.1 to 10.1.1.10.

Figure 8 Network diagram

Procedure

Create VLAN 10.

```
<Device> system-view
[Device] vlan 10
[Device-vlan10] quit
```

Create VLAN-interface 10, and assign IP address 10.1.1.1/24 to it.

```
[Device] interface vlan-interface 10
[Device-Vlan-interface10] ip address 10.1.1.1 255.255.255.0
[Device] quit
```

Create VLAN 2, and assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to the VLAN.

```
[Device] vlan 2
[Device-vlan2] port gigabitethernet 1/0/1 gigabitethernet 1/0/2
[Device-vlan2] quit
```

Create VLAN 3, and assign GigabitEthernet 1/0/3 and GigabitEthernet 1/0/4 to the VLAN.

```
[Device] vlan 3
[Device-vlan3] port gigabitethernet 1/0/3 gigabitethernet 1/0/4
[Device-vlan3] quit
```

Create VLAN 4, and assign GigabitEthernet 1/0/5 and GigabitEthernet 1/0/6 to the VLAN.

```
[Device] vlan 4
[Device-vlan4] port gigabitethernet 1/0/5 gigabitethernet 1/0/6
[Device-vlan4] quit
```

Configure VLAN 10 as a super VLAN, and associate sub-VLANs 2, 3, and 4 with the super VLAN.

```
[Device] vlan 10
[Device-vlan10] supervlan
[Device-vlan10] subvlan 2 3 4
[Device-vlan10] quit
```

Enable the ARP sender IP address checking feature in VLAN 2 and specify the IP address range 10.1.1.1 to 10.1.1.10.

```
[Device] vlan 2
[Device-vlan2] arp sender-ip-range 10.1.1.1 10.1.1.10
```

Verifying the configuration

Verify that the device accepts only ARP packets whose sender IP addresses are within the specified address range 10.1.1.1 to 10.1.1.10. The device discards the ARP packets with the sender IP addresses that are out of the range.

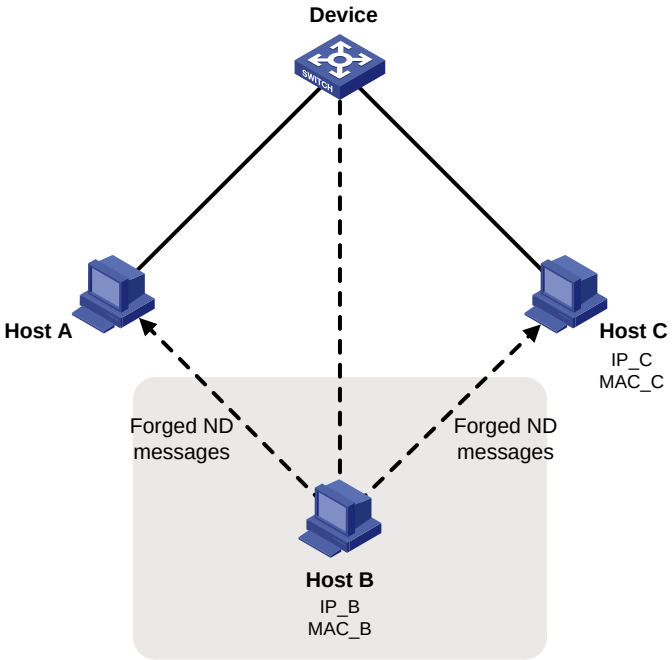
Configuring ND attack defense



About ND attack defense

IPv6 Neighbor Discovery (ND) attack defense is able to identify forged ND messages to prevent ND attacks.

The IPv6 ND protocol does not provide any security mechanisms and is vulnerable to network attacks. As shown in Figure 1, an attacker can send the following forged ICMPv6 messages to perform ND attacks:

- Forged NS/NA/RS messages with an IPv6 address of a victim host. The gateway and other hosts update the ND entry for the victim with incorrect address information. As a result, all packets intended for the victim are sent to the attacking terminal.
- Forged RA messages with the IPv6 address of a victim gateway. As a result, all hosts attached to the victim gateway maintain incorrect IPv6 configuration parameters and ND entries.

Figure 1 ND attack diagram

ND attack defense tasks at a glance

All ND attack defense tasks are optional.

- Enabling source MAC consistency check for ND messages
- Configuring ND attack detection
- Configuring RA guard

Enabling source MAC consistency check for ND messages

About this task

The source MAC consistency check feature is typically configured on gateways to prevent ND attacks.

This feature checks the source MAC address and the source link-layer address for consistency for each arriving ND message.

- If the source MAC address and the source link-layer address are not the same, the device drops the packet.
- If the addresses are the same, the device continues learning ND entries.

The ND logging feature logs source MAC inconsistency events, and it sends the log messages to the information center. The information center can then output log messages from different source modules to different destinations. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   `system-view`
2. Enable source MAC consistency check for ND messages.
   `ipv6 nd mac-check enable`
   By default, source MAC consistency check is disabled for ND messages.
3. (Optional.) Enable the ND logging feature.
   `ipv6 nd check log enable`
   By default, the ND logging feature is disabled.
   As a best practice, disable the ND logging feature to avoid excessive ND logs.

Configuring ND attack detection

About ND attack detection

ND attack detection checks incoming ND messages for user validity to prevent spoofing attacks. It is typically configured on access devices.

ND attack detection defines the following types of interfaces on a VLAN network:

- **ND trusted interface**—Performs no user validity check on the received ND messages.
- **ND untrusted interface**—Discards incoming RA and redirect messages, and performs the user validity check on other types of incoming ND messages.

ND attack detection compares the source IPv6 address and the source MAC address in an incoming ND message against security entries from other modules.

- If a match is found, the device verifies the user as legal, and it forwards the packet.
- If no match is found, the device verifies the user as illegal, and it discards the ND message.

ND attack detection uses static IPv6 source guard binding entries, ND snooping entries, and DHCPv6 snooping entries for user validity check.

- Static IPv6 source guard binding entries are created by using the **`ipv6 source binding`** command. For information about IPv6 source guard, see "Configuring IP source guard."

- ND snooping entries are automatically generated by the ND snooping feature. For information about ND snooping, see IPv6 neighbor discovery configuration in *Layer 3–IP Services Configuration Guide*.
- DHCPv6 snooping entries are automatically generated by the DHCPv6 snooping feature. For information about DHCPv6 snooping, see *Layer 3–IP Services Configuration Guide*.

Restrictions and guidelines for ND attack detection configuration

When you configure ND attack detection, follow these restrictions and guidelines:

- To prevent ND untrusted interfaces from dropping all received ND messages, make sure one or more of the these features are configured: IPv6 source guard static bindings, DHCPv6 snooping, and ND snooping.
- To make the IPv6 source guard static bindings effective for ND attack detection, you must perform the following operations:
  - Specify the **vlan** *vlan-id* option in the **ipv6 source binding** command.
  - Enable ND attack detection for the same VLAN.

Configuring ND attack detection for a VLAN

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable ND attack detection.
   ipv6 nd detection enable
   By default, ND attack detection is disabled.
4. (Optional.) Configure the interface as ND trusted interface:
   a. Return to system view.
      quit
   b. Enter Layer 2 Ethernet or aggregate interface view.
      interface *interface-type interface-number*
   c. Configure the interface as ND trusted interface.
      ipv6 nd detection trust
      By default, all interfaces are ND untrusted interfaces.

Ignoring ingress ports of ND packets

About this task

With ND attack detection enabled, the device can perform security check on received packets based on the local and remote IPSG bindings. Remote IPSG bindings do not contain port information. The device drops ND packets that match remote IPSG bindings because it does not find matching ingress ports for these packets. To prevent the device from dropping these packets, you can configure the device to ignore ingress ports of ND packets. This feature does not examine the ingress ports of ND packets, so that ND packets that match remote IPSG bindings will not be dropped.

Procedure

1. Enter system view.
   system-view
2. Ignore ingress ports of ND packets in ND attack detection.
   ipv6 nd detection port-match-ignore
   By default, ingress ports of ND packets are examined in ND attack detection.

Enabling ND attack detection logging

About this task

This feature allows a device to generate logs when it detects invalid ND packets. The log information helps administrators locate and solve problems. Each log records the following information:

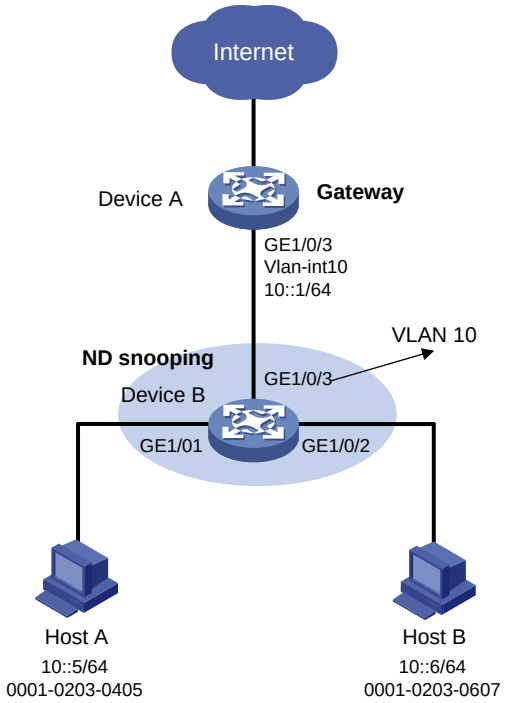
- Victim port numbers in a VLAN.
- Source IP address of the invalid ND packets.
- Source MAC address of the invalid ND packets.
- VLAN ID of the invalid ND packets.
- Total number of dropped ND packets.

Procedure

1. Enter system view.
   system-view
2. Enable ND attack detection logging.
   ipv6 nd detection log enable
   By default, ND attack detection logging is disabled.

Display and maintenance commands for ND attack detection

Execute **display** commands in any view and **reset** commands in user view.



Task	Command
Display statistics for ND messages dropped by ND attack detection.	**display ipv6 nd detection statistics** [**interface** *interface-type interface-number* [**service-instance** *instance-id*]]
Clear ND attack detection statistics.	**reset ipv6 nd detection statistics** [**interface** *interface-type interface-number* [**service-instance** *instance-id*]]

Example: Configuring ND attack detection

Network configuration

As shown in Figure 2, configure ND attack detection on Device B to check user validity for ND messages from Host A and Host B.

Figure 2 Network diagram

Procedure

1. Configure Device A:

   # Create VLAN 10.

   ```
   <DeviceA> system-view
   [DeviceA] vlan 10
   [DeviceA-vlan10] quit
   ```

   # Configure GigabitEthernet 1/0/3 to trunk VLAN 10.

   ```
   [DeviceA] interface gigabitethernet 1/0/3
   [DeviceA-GigabitEthernet1/0/3] port link-type trunk
   [DeviceA-GigabitEthernet1/0/3] port trunk permit vlan 10
   [DeviceA-GigabitEthernet1/0/3] quit
   ```

   # Assign IPv6 address 10::1/64 to VLAN-interface 10.

   ```
   [DeviceA] interface vlan-interface 10
   [DeviceA-Vlan-interface10] ipv6 address 10::1/64
   [DeviceA-Vlan-interface10] quit
   ```

2. Configure Device B:

   # Create VLAN 10.

   ```
   <DeviceB> system-view
   [DeviceB] vlan 10
   [DeviceB-vlan10] quit
   ```

   # Configure GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 to trunk VLAN 10.

   ```
   [DeviceB] interface gigabitethernet 1/0/1
   [DeviceB-GigabitEthernet1/0/1] port link-type access
   [DeviceB-GigabitEthernet1/0/1] port access vlan 10
   [DeviceB-GigabitEthernet1/0/1] quit
   ```

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type access
[DeviceB-GigabitEthernet1/0/2] port access vlan 10
[DeviceB-GigabitEthernet1/0/2] quit
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan 10
[DeviceB-GigabitEthernet1/0/3] quit
```

Enable ND attack detection for VLAN 10.

```
[DeviceB] vlan 10
[DeviceB-vlan10] ipv6 nd detection enable
```

Enable ND snooping for IPv6 global unicast addresses and ND snooping for IPv6 link-local addresses in VLAN 10.

```
[DeviceB-vlan10] ipv6 nd snooping enable global
[DeviceB-vlan10] ipv6 nd snooping enable link-local
[DeviceB-vlan10] quit
```

Configure GigabitEthernet 1/0/3 as ND trusted interface.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] ipv6 nd detection trust
```

Verifying the configuration

Verify that Device B inspects all ND messages received by GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 based on the ND snooping entries. (Details not shown.)

Configuring RA guard

About RA guard

RA guard allows Layer 2 access devices to analyze and block unwanted and forged RA messages.

Upon receiving an RA message, the device makes the forwarding or dropping decision based on the role of the attached device or the RA guard policy.

1. If the role of the device attached to the receiving interface is **router**, the device forwards the RA message. If the role is **host**, the device drops the RA message.
2. If no attached device role is set, the device uses the RA guard policy applied to the VLAN of the receiving interface to match the RA message.
   - If the policy does not contain match criteria, the policy will not take effect and the device forwards the RA message.
   - If the RA message content matches every criterion in the policy, the device forwards the message. Otherwise, the device drops the message.

Specifying the role of the attached device

Restrictions and guidelines

Make sure your setting is consistent with the type of the attached device. If you are not aware of the device type, do not specify a role for the device.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.
   - Enter Layer 2 Ethernet interface view.
     interface *interface-type interface-number*
   - Enter aggregate interface view.
     interface bridge-aggregation *interface-number*
3. Specify the role of the device attached to the interface.
   ipv6 nd raguard role { **host** | **router** }
   By default, the role of the device attached to the interface is not specified.

Configuring and applying an RA guard policy

About this task

Configure an RA guard policy if you do not specify a role for the attached device or if you want to filter the RA messages sent by a router.

Procedure

1. Enter system view.
   system-view
2. Create an RA guard policy and enter its view.
   ipv6 nd raguard policy *policy-name*
3. Configure the RA guard policy.
   Choose the following tasks as needed:
   - Specify an ACL match criterion.
     if-match acl { *ipv6-acl-number* | **name** *ipv6-acl-name* }
   - Specify a prefix match criterion.
     if-match prefix acl { *ipv6-acl-number* | **name** *ipv6-acl-name* }
   - Specify a router preference match criterion.
     if-match router-preference maximum { **high** | **low** | **medium** }
   - Specify an M flag match criterion.
     if-match autoconfig managed-address-flag { **off** | **on** }
   - Specify an O flag match criterion.
     if-match autoconfig other-flag { **off** | **on** }
   - Specify a maximum or minimum hop limit match criterion.
     if-match hop-limit { **maximum** | **minimum** } *limit*

   By default, the RA guard policy is not configured.
4. Quit RA guard policy view.
   quit
5. Enter VLAN view.
   vlan *vlan-number*
6. Apply an RA guard policy to the VLAN.
   ipv6 nd raguard apply policy [*policy-name*]
   By default, no RA guard policy is applied to the VLAN.

Enabling the RA guard logging feature

About this task

This feature allows a device to generate logs when it detects forged RA messages. The log information helps administrators locate and solve problems. Each log records the following information:

- Name of the interface that received the forged RA message.
- Source IP address of the forged RA message.
- Number of RA messages dropped on the interface.

The RA guard logging feature sends the log messages to the information center. The information center can then output log messages from different source modules to different destinations. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.
   `system-view`
2. Enable the RA guard logging feature.
   `ipv6 nd raguard log enable`
   By default, the RA guard logging feature is disabled.

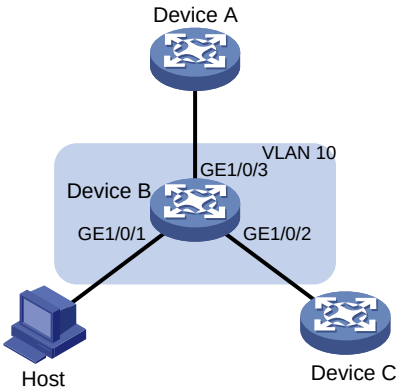
Display and maintenance commands for RA guard

Execute **`display`** commands in any view.

Task	Command
Display the RA guard policy configuration.	**`display ipv6 nd raguard policy`** [*`policy-name`*]
Display RA guard statistics.	**`display ipv6 nd raguard statistics`** [**`interface`** *`interface-type interface-number`*]
Clear RA guard statistics.	**`reset ipv6 nd raguard statistics`** [**`interface`** *`interface-type interface-number`*]

Example: Configuring RA guard

Network configuration



As shown in Figure 3, GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3 of Device B are in VLAN 10.

Configure RA guard on Device B to filter forged and unwanted RA messages.

- Configure an RA policy in VLAN 10 for GigabitEthernet 1/0/2 to filter all RA messages received from the unknown device.
- Specify **host** as the role of the host. All RA messages received on GigabitEthernet 1/0/1 are dropped.

- Specify **router** as the role of the Device A. All RA messages received on GigabitEthernet 1/0/3 are forwarded.

Figure 3 Network diagram

Procedure

Create an RA guard policy named **policy1**.

```
<DeviceB> system-view
[DeviceB] ipv6 nd raguard policy policy1
```

Set the maximum router preference to **high** for the RA guard policy.

```
[DeviceB-raguard-policy-policy1] if-match router-preference maximum high
```

Specify **on** as the M flag match criterion for the RA guard policy.

```
[DeviceB-raguard-policy-policy1] if-match autoconfig managed-address-flag on
```

Specify **on** as the O flag match criterion for the RA guard policy.

```
[DeviceB-raguard-policy-policy1] if-match autoconfig other-flag on
```

Set the maximum advertised hop limit to 120 for the RA guard policy.

```
[DeviceB-raguard-policy-policy1] if-match hop-limit maximum 120
```

Set the minimum advertised hop limit to 100 for the RA guard policy.

```
[DeviceB-raguard-policy-policy1] if-match hop-limit minimum 100
[DeviceB-raguard-policy-policy1] quit
```

Assign GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 to VLAN 10.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type access
[DeviceB-GigabitEthernet1/0/1] port access vlan 10
[DeviceB-GigabitEthernet1/0/1] quit
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type access
[DeviceB-GigabitEthernet1/0/2] port access vlan 10
[DeviceB-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 to trunk VLAN 10.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan 10
[DeviceB-GigabitEthernet1/0/3] quit
```

Apply the RA guard policy **policy1** to VLAN 10.

```
[DeviceB] vlan 10
```

```
[DeviceB-vlan10] ipv6 nd raguard apply policy policy1
[DeviceB-vlan10] quit
```

Specify **host** as the role of the device attached to GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] ipv6 nd raguard role host
[DeviceB-GigabitEthernet1/0/1] quit
```

Specify **router** as the role of the device attached to GigabitEthernet 1/0/3.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] ipv6 nd raguard role router
[DeviceB-GigabitEthernet1/0/3] quit
```

Verifying the configuration

Verify that the device forwards or drops RA messages received on GigabitEthernet 1/0/2 based on the RA guard policy. (Details not shown.)

Verify that the device drops RA messages received on GigabitEthernet 1/0/1. (Details not shown.)

Verify that the device forwards RA messages received on GigabitEthernet 1/0/3 to other interfaces in VLAN 10. (Details not shown.)

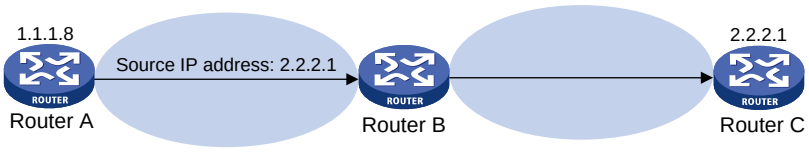
uRPF check modes 1
uRPF extended functions 2
Network application 2
Restrictions and guidelines: uRPF configuration 2
Enabling uRPF globally 2
Display and maintenance commands for uRPF 3

Configuring uRPF



About uRPF

Unicast Reverse Path Forwarding (uRPF) protects a network against source address spoofing attacks, such as DoS and DDoS attacks.

uRPF application scenario

Attackers send packets with a forged source address to access a system that uses IPv4-based authentication, in the name of authorized users or even the administrator. Even if the attackers or other hosts cannot receive any response packets, the attacks are still disruptive to the attacked target.

Figure 1 Source address spoofing attack

As shown in Figure 1, an attacker on Router A sends the server (Router B) requests with a forged source IP address 2.2.2.1 at a high rate. Router B sends response packets to IP address 2.2.2.1 (Router C). Consequently, both Router B and Router C are attacked. If the administrator disconnects Router C by mistake, the network service is interrupted.

Attackers can also send packets with different forged source addresses or attack multiple servers simultaneously to block connections or even break down the network.

uRPF can prevent these source address spoofing attacks. It checks whether an interface that receives a packet is the output interface of the FIB entry that matches the source address of the packet. If not, uRPF considers it a spoofing attack and discards the packet.

uRPF check modes

uRPF supports strict and loose modes.

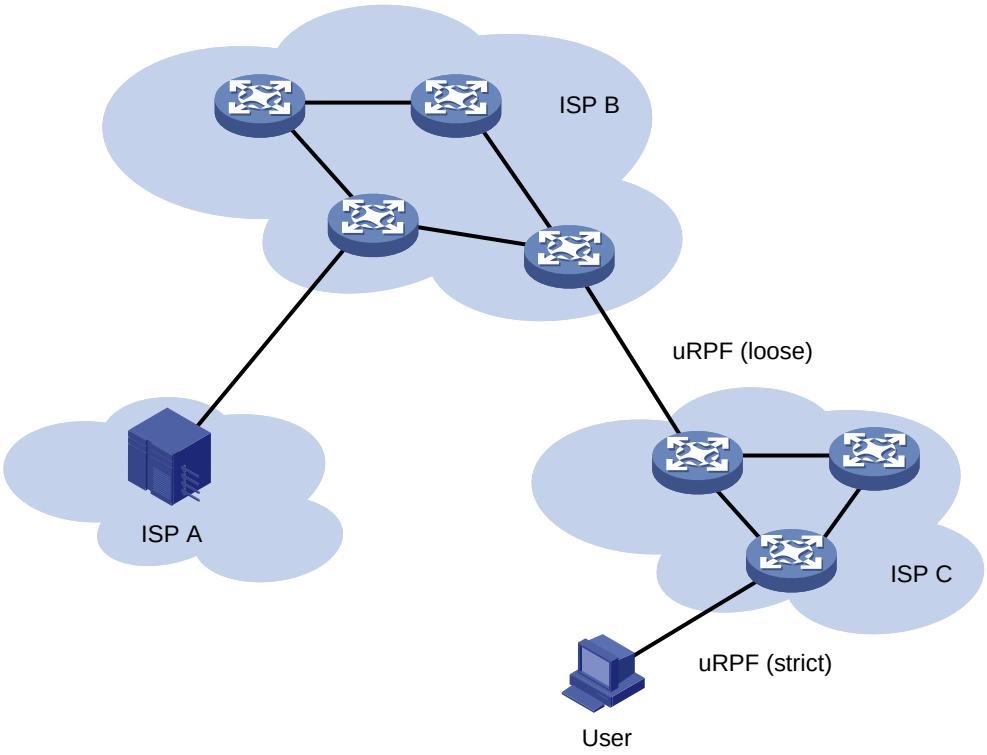
Strict uRPF check

To pass strict uRPF check, the source address of a packet and the receiving interface must match the destination address and output interface of a FIB entry. In some scenarios (for example, asymmetrical routing), strict uRPF might discard valid packets.

Strict uRPF is often deployed between a PE and a CE.

Loose uRPF check

To pass loose uRPF check, the source address of a packet must match the destination address of a FIB entry. Loose uRPF can avoid discarding valid packets, but might let go attack packets.



Loose uRPF is often deployed between ISPs, especially in asymmetrical routing.

uRPF extended functions

Network application

As shown in Figure 2, strict uRPF check is configured between an ISP network and a customer network. Loose uRPF check is configured between ISPs.

Figure 2 Network diagram

Restrictions and guidelines: uRPF configuration

If you enable uRPF on an interface, you can use the **`display ip interface`** command to display statistics about packets discarded by uRPF (displayed as "Drops" and "Suppressed drops"). If you enable uRPF globally, the system does not provide statistics about packets discarded by uRPF.

If you configure uRPF globally and on an interface, the interface preferentially uses the interface-specific settings.

Do not use strict uRPF if ECMP routing is available in the network. Service packets that travel along ECMP routes cannot pass the strict uRPF check and will be dropped.

Enabling uRPF globally

Restrictions and guidelines

Global uRPF takes effect on all interfaces of the device.

Procedure

1. Enter system view.
   `system-view`

2. Enable uRPF globally.
   ip urpf { **loose** | **strict** }
   By default, uRPF is disabled.

Display and maintenance commands for uRPF

Execute **display** commands in any view.

Task	Command
Display uRPF configuration.	**display ip urpf** [**interface** *interface-type interface-number*] [**slot** *slot-number*]

Configuring SAVI

About SAVI

Source Address Validation Improvement (SAVI) checks the validity of the source addresses of global unicast IPv6 packets. It implements the validity check by using the ND snooping, DHCPv6 snooping, ND attack detection, and IP source guard features. SAVI checks only global unicast addresses and forwards the packets that pass the validity check. Packets sourced from an invalid address are dropped.

SAVI application scenarios

DHCPv6-only

The hosts connected to the SAVI-enabled device obtain addresses only through DHCPv6. DHCPv6 messages, ND messages (RA and RR messages excluded), and IPv6 data packets are checked based on DHCPv6 snooping entries and static IPv6 source guard binding entries.

SLAAC-only

The hosts connected to the SAVI-enabled device obtain addresses only through Stateless Address Autoconfiguration (SLAAC). In this scenario, SAVI drops all DHCPv6 messages. Only ND messages and IPv6 data packets are checked based on DHCPv6 snooping entries and static IPv6 source guard binding entries.

DHCPv6+SLAAC

The hosts connected to the SAVI-enabled device obtain addresses through DHCPv6 and SLAAC. In this scenario, SAVI checks all DHCPv6 messages, ND messages, and IPv6 data packets based on DHCPv6 snooping entries, ND snooping entries, and static IPv6 source guard binding entries.

SAVI tasks at a glance

To configure SAVI, perform the following tasks:

1. Enabling SAVI
2. Configuring IPv6 source guard
3. Configuring DHCPv6 snooping
4. Configuring ND parameters
5. (Optional.) Setting the entry deletion delay
6. (Optional.) Enabling

Enabling SAVI

1. Enter system view.
   `system-view`
2. Enable SAVI.
   `ipv6 savi strict`
   By default, SAVI is disabled.

Configuring IPv6 source guard

1. Enable IPv6 source guard on an interface.
2. (Optional.) Configure static IPv6SG bindings.

For more information about IPv6 source guard configuration, see "Configuring IP source guard."

Configuring DHCPv6 snooping

Restrictions and guidelines

Enable only DHCPv6 snooping for the SLAAC-only scenario.

Procedure

1. Enable DHCPv6 snooping.
2. Specify DHCPv6 snooping trusted ports.
3. Enable recording client information in DHCPv6 snooping entries.

For more information about DHCPv6 snooping configuration, see *Layer 3—IP Services Configuration Guide*.

Configuring ND parameters

Restrictions and guidelines

Enable only ND attack detection for the DHCPv6-only scenario.

Procedure

1. Enable ND snooping for global unicast addresses.

   For more information about ND snooping, see IPv6 basics in *Layer 3—IP Services Configuration Guide*.
2. Enable ND attack detection.

   For more information about ND attack detection, see "Configuring ND attack defense."
3. Specify ND trusted ports.

   For more information about ND trusted ports, see "Configuring ND attack defense."

Setting the entry deletion delay

About this task

The entry deletion delay is the period of time that the device waits before deleting the DHCPv6 snooping entries and ND snooping entries for a down port.

Procedure

1. Enter system view.

   system-view
2. Set the entry deletion delay.

   ipv6 savi down-delay *delay-time*

   By default, the entry deletion delay is 30 seconds.

Enabling filtering entry logging

About this task

Filtering entries are effective bindings used for filtering IPv6 packets by the source IPv6 address. Filtering entry logging enables the device to generate log messages for filtering entries. A log message contains the IPv6 address, MAC address, VLAN, and interface of a filtering entry.

The device sends filtering entry log messages to the information center. With the information center, you can set log message filtering and output rules, including output destinations. For more information about using the information center, see *Network Management and Monitoring Configuration Guide*.

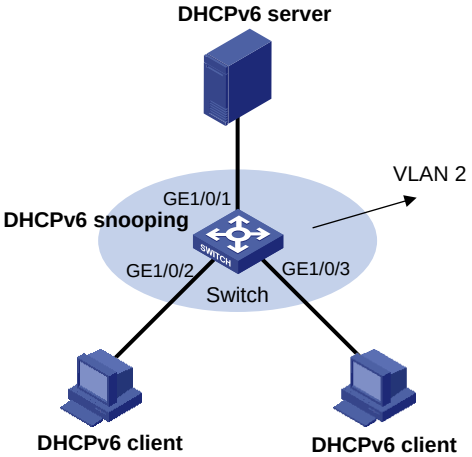
Feature and software compatiblity

This feature is available only in Release 1107 or later.

Procedure

1. Enter system view.
   `system-view`
2. Enable filtering entry logging.
   `ipv6 savi log enable filter-entry`
   By default, filtering entry logging is disabled.

SAVI configuration examples



Example: Configuring DHCPv6-only SAVI

Network configuration

As shown in Figure 1, configure SAVI on the switch to meet the following requirements:

- Clients obtain IPv6 addresses only through DHCPv6.
- SAVI checks the source addresses of DHCPv6 messages, ND messages (RA and RR messages excluded), and IPv6 data packets on GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3.

Figure 1 Network diagram

Procedure

Enable SAVI.

```
<Switch> system-view
[Switch] ipv6 savi strict
```

Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to VLAN 2.

```
[Switch] vlan 2
[Switch-vlan2] port gigabitethernet 1/0/1 gigabitethernet 1/0/2 gigabitethernet 1/0/3
[Switch-vlan2] quit
```

Enable DHCPv6 snooping.

```
[Switch] ipv6 dhcp snooping enable
```

Configure GigabitEthernet 1/0/1 as a DHCPv6 snooping trusted port.

```
[Switch] interface gigabitethernet 1/0/1
[Switch-GigabitEthernet1/0/1] ipv6 dhcp snooping trust
[Switch-GigabitEthernet1/0/1] quit
```

Enable recording DHCPv6 snooping entries on GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3.

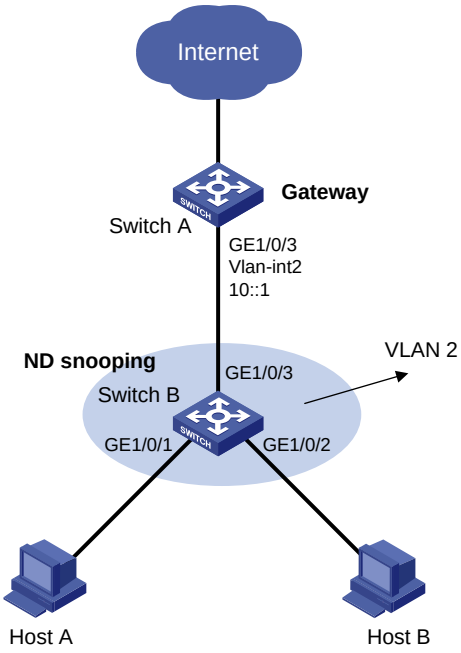
```
[Switch] interface gigabitethernet 1/0/2
[Switch-GigabitEthernet1/0/2] ipv6 dhcp snooping binding record
[Switch-GigabitEthernet1/0/2] quit
[Switch] interface gigabitethernet 1/0/3
[Switch-GigabitEthernet1/0/3] ipv6 dhcp snooping binding record
[Switch-GigabitEthernet1/0/3] quit
```

Enable ND attack detection.

```
[Switch] vlan 2
[Switch-vlan2] ipv6 nd detection enable
[Switch-vlan2] quit
```

Enable IPv6 source guard on GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3.

```
[Switch] interface gigabitethernet 1/0/2
[Switch-GigabitEthernet1/0/2] ipv6 verify source ip-address mac-address
[Switch-GigabitEthernet1/0/2] quit
[Switch] interface gigabitethernet 1/0/3
[Switch-GigabitEthernet1/0/3] ipv6 verify source ip-address mac-address
[Switch-GigabitEthernet1/0/3] quit
```



Example: Configuring SLAAC-only SAVI

Network configuration

As shown in Figure 2, configure SAVI on Switch B to meet the following requirements:

- Hosts obtain IPv6 addresses only through SLAAC.
- DHCPv6 messages are dropped on GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 in VLAN 2.
- SAVI checks the source addresses of ND messages and IPv6 data packets on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

Figure 2 Network diagram

Procedure

Enable SAVI.

```
<SwitchB> system-view
[SwitchB] ipv6 savi strict
```

Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 to VLAN 2.

```
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/1 gigabitethernet 1/0/2 gigabitethernet 1/0/3
[SwitchB-vlan2] quit
```

Enable ND snooping for global unicast addresses in VLAN 2.

```
[SwitchB] vlan 2
[SwitchB-vlan2] ipv6 nd snooping enable global
```

Enable ND attack detection for VLAN 2.

```
[SwitchB-vlan2] ipv6 nd detection enable
[SwitchB-vlan2] quit
```

Enable DHCPv6 snooping.

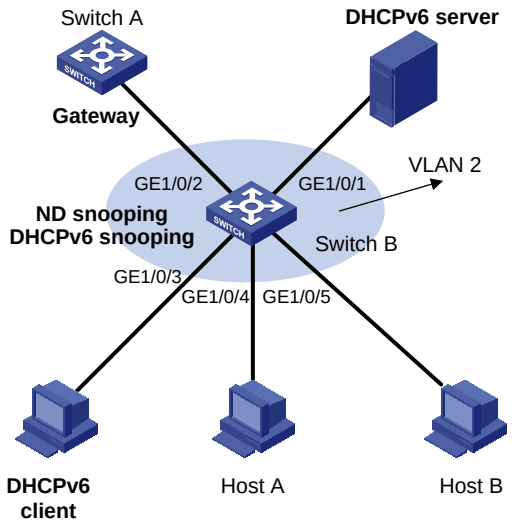
```
[SwitchB] ipv6 dhcp snooping enable
```

Configure GigabitEthernet 1/0/3 as an ND trusted port.

```
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] ipv6 nd detection trust
[SwitchB-GigabitEthernet1/0/3] quit
```

Enable IPv6 source guard on GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] ipv6 verify source ip-address mac-address
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] ipv6 verify source ip-address mac-address
[SwitchB-GigabitEthernet1/0/2] quit
```



Example: Configuring DHCPv6+SLAAC SAVI

Network configuration

As shown in Figure 3, configure SAVI on Switch B to meet the following requirements:

- Hosts obtain IP addresses through DHCPv6 or SLAAC.
- SAVI checks the source addresses of DHCPv6 messages, ND messages, and IPv6 data packets on GigabitEthernet 1/0/3 through GigabitEthernet 1/0/5.

Figure 3 Network diagram

Procedure

Enable SAVI.

```
<SwitchB> system-view
[SwitchB] ipv6 savi strict
```

Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/5 to VLAN 2.

```
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/1 gigabitethernet 1/0/2 gigabitethernet 1/0/3
gigabitethernet 1/0/4 gigabitethernet 1/0/5
```

Enable DHCPv6 snooping.

```
[SwitchB] ipv6 dhcp snooping enable
```

Enable recording DHCPv6 snooping entries on GigabitEthernet 1/0/3 through GigabitEthernet 1/0/5.

```
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] ipv6 dhcp snooping binding record
[SwitchB-GigabitEthernet1/0/3] quit
[SwitchB] interface gigabitethernet 1/0/4
[SwitchB-GigabitEthernet1/0/4] ipv6 dhcp snooping binding record
[SwitchB-GigabitEthernet1/0/4] quit
[SwitchB] interface gigabitethernet 1/0/5
[SwitchB-GigabitEthernet1/0/5] ipv6 dhcp snooping binding record
[SwitchB-GigabitEthernet1/0/5] quit
```

Configure GigabitEthernet 1/0/1 as a DHCPv6 snooping trusted port.

```
[SwitchB] interface gigabitethernet 1/0/1
```

```
[SwitchB-GigabitEthernet1/0/1] ipv6 dhcp snooping trust
[SwitchB-GigabitEthernet1/0/1] quit
```

Enable ND snooping for global unicast addresses in VLAN 2.

```
[SwitchB] vlan 2
[SwitchB-vlan2] ipv6 nd snooping enable global
```

Enable ND attack detection for VLAN 2.

```
[SwitchB-vlan2] ipv6 nd detection enable
[SwitchB-vlan2] quit
```

Configure GigabitEthernet 1/0/2 as an ND trusted port.

```
[SwitchB] interface gigabitethernet 1/0/2
[SwitchB-GigabitEthernet1/0/2] ipv6 nd detection trust
[SwitchB-GigabitEthernet1/0/2] quit
```

Enable IPv6 source guard on GigabitEthernet 1/0/3 through GigabitEthernet 1/0/5.

```
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] ipv6 verify source ip-address mac-address
[SwitchB-GigabitEthernet1/0/3] quit
[SwitchB] interface gigabitethernet 1/0/4
[SwitchB-GigabitEthernet1/0/4] ipv6 verify source ip-address mac-address
[SwitchB-GigabitEthernet1/0/4] quit
[SwitchB] interface gigabitethernet 1/0/5
[SwitchB-GigabitEthernet1/0/5] ipv6 verify source ip-address mac-address
```

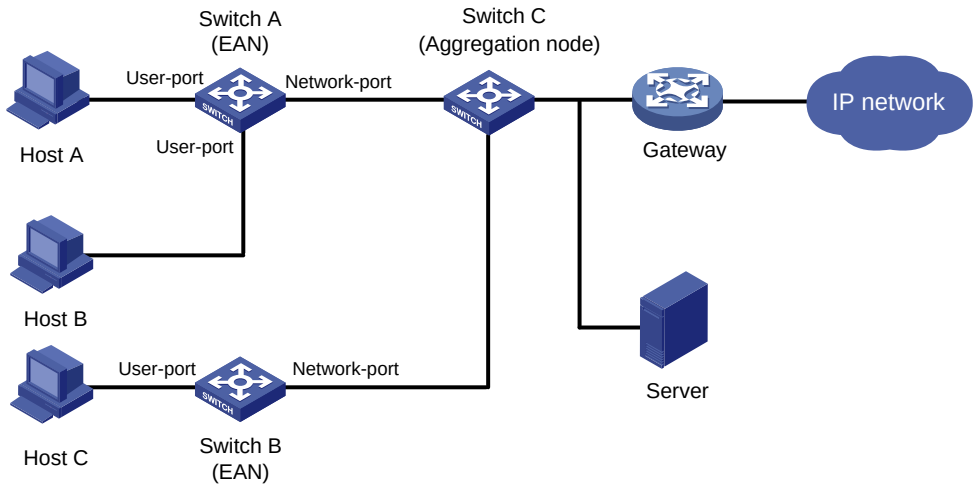
Configuring MFF

About MFF



MAC-forced forwarding (MFF) implements Layer 2 isolation and Layer 3 communication between hosts in the same broadcast domain.

An MFF-enabled device intercepts ARP requests and returns the MAC address of a gateway (or server) to the senders. In this way, the senders are forced to send packets to the gateway for traffic monitoring and attack prevention.

MFF network model

As shown in Figure 1, hosts are connected to Switch C through Switch A and Switch B, which are called Ethernet access nodes (EANs). The MFF-enabled EANs forward packets from hosts to the gateway for further forwarding. The hosts are isolated at Layer 2, but they can communicate at Layer 3.

Figure 1 Network diagram for MFF

MFF works with any of the following features to implement traffic filtering and Layer 2 isolation on the EANs:

- ARP snooping (see *Layer 3—IP Services Configuration Guide*).
- IP source guard (see "Configuring IP source guard").
- ARP detection (see "Configuring ARP attack protection").
- VLAN mapping (see *Layer 2—LAN Switching Configuration Guide*).

Port roles

Two types of ports, user port and network port, exist in an MFF-enabled VLAN.

User port

An MFF user port is directly connected to a host and processes the following packets differently:

- Allows multicast packets to pass.
- Delivers ARP packets to the CPU.

- Processes unicast packets as follows:
  - If gateways' MAC addresses have been learned, the user port allows only the unicast packets with the gateways' MAC addresses as the destination MAC addresses to pass.
  - If no gateways' MAC addresses have been learned, the user port discards all received unicast packets.

Network port

An MFF network port is connected to any of the following networking devices:

- An access switch.
- A distribution switch.
- A gateway.
- A server.

A network port processes the following packets differently:

- Allows multicast packets to pass.
- Delivers ARP packets to the CPU.
- Denies broadcast packets other than DHCP and ARP packets.

Processing of ARP packets in MFF

An MFF-enabled device implements Layer 3 communication between hosts by intercepting ARP requests from the hosts and replies with the MAC address of a gateway. This mechanism helps reduce the number of broadcast messages.

The MFF device processes ARP packets as follows:

- After receiving an ARP request from a host, the MFF device sends the MAC address of the corresponding gateway to the host. In this way, hosts in the network have to communicate at Layer 3 through a gateway.
- After receiving an ARP request from a gateway, the MFF device sends the requested host's MAC address to the gateway if the corresponding entry is available. If the entry is not available, the MFF device forwards the ARP request.
- The MFF device forwards ARP replies between hosts and gateways.
- If the source MAC addresses of ARP requests from gateways are different from those recorded, the MFF device updates and broadcasts the IP and MAC addresses of the gateways.

MFF default gateway

MFF applies to only networks where the hosts' IP addresses are manually configured. Because the hosts cannot obtain the gateway information through DHCP, the default gateway must be specified by the **`mac-forced-forwarding default-gateway`** command. MFF maintains only one default gateway for each VLAN. MFF updates the MAC address of the default gateway upon receiving an ARP packet with a different sender MAC address from the default gateway.

Protocols and standards

RFC 4562, *MAC-Forced Forwarding*

MFF tasks at a glance

To configure MFF, perform the following tasks:

1. Enabling MFF
2. Configuring a network port
3. (Optional.) Enabling periodic gateway probe
4. Specifying the IP addresses of servers

   If servers exist in the network, you must perform this task to ensure communication between the servers and hosts.

Enabling MFF

Restrictions and guidelines

- An MFF-enabled device and a host cannot ping each other.
- When MFF works with static IP source guard bindings, you must configure VLAN IDs in the static bindings. Otherwise, IP packets allowed by IP source guard are permitted even if their destination MAC addresses are not the MAC address of the gateway.
- MFF is not supported in a network where VRRP load balancing mode is configured.

Prerequisites

For MFF to take effect, make sure ARP snooping is enabled on the VLAN where MFF is enabled.

Procedure

1. Enter system view.

   system-view
2. Enter VLAN view.

   vlan *vlan-id*
3. Enable MFF.

   mac-forced-forwarding default-gateway *gateway-ip*

   By default, MFF is disabled.

Configuring a network port

Restrictions and guidelines

In a VLAN with MFF enabled, you need to configure the following ports as network ports:

- Upstream ports connected to the gateway.
- Ports connected to other MFF devices.

Link aggregation is supported by network ports in an MFF-enabled VLAN, but it is not supported by user ports in the VLAN. You can add the network ports to link aggregation groups, but cannot add the user ports to link aggregation groups. For more information about link aggregation, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Configure the port as a network port.

   mac-forced-forwarding network-port

   By default, the port is a user port.

Enabling periodic gateway probe

About this task

You can configure the MFF device to detect gateways every 30 seconds for the change of MAC addresses by sending forged ARP packets. The ARP packets use 0.0.0.0 as the sender IP address and bridge MAC address as the sender MAC address.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Enable periodic gateway probe.
   mac-forced-forwarding gateway probe
   By default, this feature is disabled.

Specifying the IP addresses of servers

About this task

Server IP addresses can be those of the interfaces on a router in a VRRP group and those of the servers collaborating with MFF, such as a RADIUS server.

When the MFF device receives an ARP request from a server, the device searches IP-to-MAC address entries it has stored. Then the device replies with the requested MAC address to the server.

As a result, packets from a host to a server are forwarded by the gateway. However, packets from a server to a host are not forwarded by the gateway.

MFF does not check whether the IP address of a server is on the same network segment as that of a gateway. Instead, it checks whether the IP address of a server is all-zero or all-one. An all-zero or all-one server IP address is invalid.

Restrictions and guidelines

If the server's interface connecting to the MFF device uses secondary IP addresses to send ARP packets, include all these IP addresses in the server IP address list.

Procedure

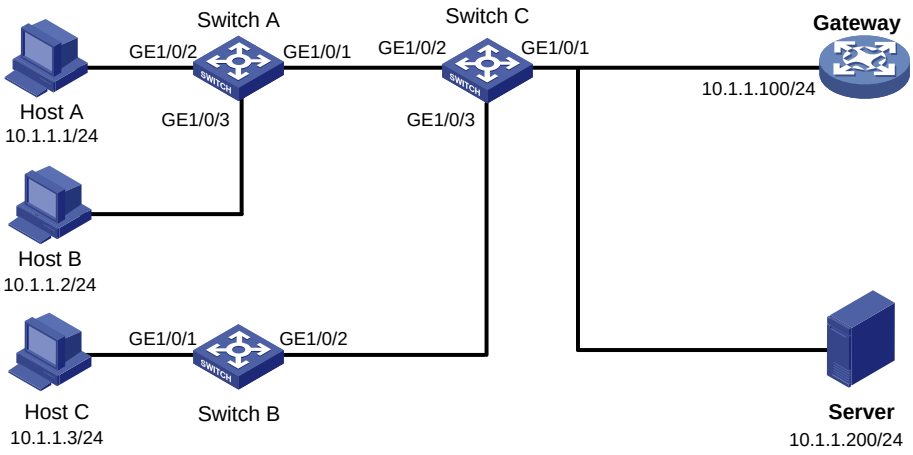
1. Enter system view.
   system-view
2. Enter VLAN view.
   vlan *vlan-id*
3. Specify the IP addresses of servers.
   mac-forced-forwarding server *server-ip*&<1-10>
   By default, no server IP address is specified.

Display and maintenance commands for MFF

Execute **display** commands in any view.

Task	Command
Display MFF port configuration.	**display mac-forced-forwarding interface**
Display the MFF configuration for a VLAN.	**display mac-forced-forwarding vlan** *vlan-id*

MFF configuration examples



Example: Configuring MFF in a tree network

Network configuration

As shown in Figure 2, all the devices are in VLAN 100. Hosts A, B, and C are assigned IP addresses manually.

Configure MFF to isolate the hosts at Layer 2 and allow them to communicate with each other through the gateway at Layer 3.

Figure 2 Network diagram

Procedure

1. Configure the IP addresses of the hosts and the gateway, as shown in Figure 2.
2. Configure Switch A:

   # Configure MFF on VLAN 100.

   ```
   [SwitchA] vlan 100
   [SwitchA-vlan100] mac-forced-forwarding default-gateway 10.1.1.100
   ```

   # Specify the IP address of the server.

   ```
   [SwitchA-vlan100] mac-forced-forwarding server 10.1.1.200
   ```

   # Enable ARP snooping on VLAN 100.

   ```
   [SwitchA-vlan100] arp snooping enable
   [SwitchA-vlan100] quit
   ```

   # Configure GigabitEthernet 1/0/1 as a network port.

   ```
   [SwitchA] interface gigabitethernet 1/0/1
   [SwitchA-GigabitEthernet1/0/1] mac-forced-forwarding network-port
   ```
3. Configure Switch B:

Configure MFF on VLAN 100.

```
[SwitchB] vlan 100
[SwitchB-vlan100] mac-forced-forwarding default-gateway 10.1.1.100
```

Specify the IP address of the server.

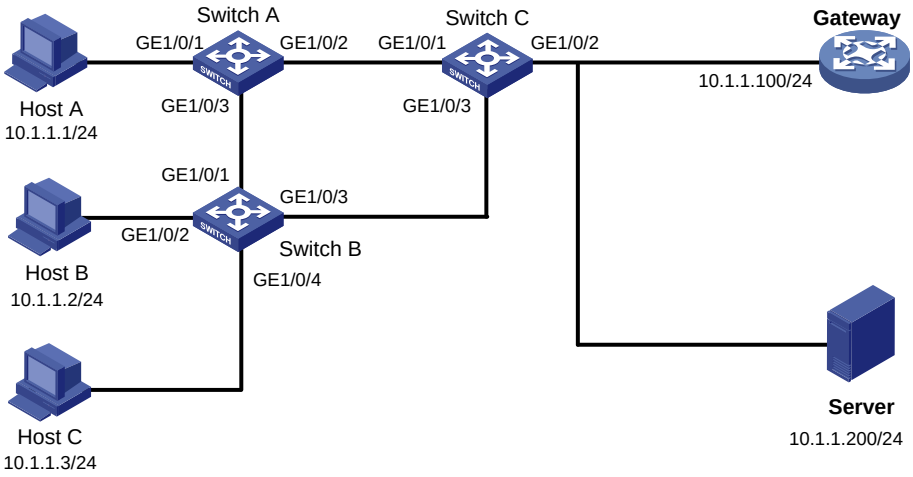
```
[SwitchB-vlan100] mac-forced-forwarding server 10.1.1.200
```

Enable ARP snooping on VLAN 100.

```
[SwitchB-vlan100] arp snooping enable
[SwitchB-vlan100] quit
```

Configure GigabitEthernet 1/0/2 as a network port.

```
[SwitchB] interface gigabitethernet 1/0/2 1/0/6
[SwitchB-GigabitEthernet1/0/2] mac-forced-forwarding network-port
```



Example: Configuring MFF in a ring network

Network configuration

As shown in Figure 3, all the devices are in VLAN 100, and the switches form a ring. Hosts A, B, and C are assigned IP addresses manually.

Configure MFF to isolate the hosts at Layer 2 and allow them to communicate with each other through the gateway at Layer 3.

Figure 3 Network diagram

Procedure

1. Configure the IP addresses of the hosts and the gateway, as in shown in Figure 3.
2. Configure Switch A:

   # Enable STP globally to make sure STP is enabled on interfaces.

   ```
   [SwitchA] stp global enable
   ```

   # Configure MFF on VLAN 100.

   ```
   [SwitchA] vlan 100
   [SwitchA-vlan100] mac-forced-forwarding default-gateway 10.1.1.100
   ```

   # Specify the IP address of the server.

   ```
   [SwitchA-vlan100] mac-forced-forwarding server 10.1.1.200
   ```

   # Enable ARP snooping on VLAN 100.

   ```
   [SwitchA-vlan100] arp snooping enable
   ```

```
[SwitchA-vlan100] quit
```

Configure GigabitEthernet 1/0/2 and GigabitEthernet 1/0/3 as network ports.

```
[SwitchA] interface gigabitethernet 1/0/2
[SwitchA-GigabitEthernet1/0/2] mac-forced-forwarding network-port
[SwitchA-GigabitEthernet1/0/2] quit
[SwitchA] interface gigabitethernet 1/0/3
[SwitchA-GigabitEthernet1/0/3] mac-forced-forwarding network-port
```

3. Configure Switch B:

Enable STP globally to make sure STP is enabled on interfaces.

```
[SwitchB] stp global enable
```

Configure MFF on VLAN 100.

```
[SwitchB] vlan 100
[SwitchB-vlan100] mac-forced-forwarding default-gateway 10.1.1.100
```

Specify the IP address of the server.

```
[SwitchB-vlan100] mac-forced-forwarding server 10.1.1.200
```

Enable ARP snooping on VLAN 100.

```
[SwitchB-vlan100] arp snooping enable
[SwitchB-vlan100] quit
```

Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/3 as network ports.

```
[SwitchB] interface gigabitethernet 1/0/1
[SwitchB-GigabitEthernet1/0/1] mac-forced-forwarding network-port
[SwitchB-GigabitEthernet1/0/1] quit
[SwitchB] interface gigabitethernet 1/0/3
[SwitchB-GigabitEthernet1/0/3] mac-forced-forwarding network-port
```

4. Enable STP on Switch C globally to make sure STP is enabled on interfaces.

```
<SwitchC> system-view
[SwitchC] stp global enable
```

Configuring crypto engines 1
About crypto engines 1
Display and maintenance commands for crypto engines 1

Configuring crypto engines

About crypto engines

Crypto engines encrypt and decrypt data for service modules.

The device supports only one software crypto engine, which is a set of software encryption algorithms. The software crypto engine is always enabled.

When a service module requires data encryption/decryption, it sends the desired data to the crypto engine. After the crypto engine completes data encryption/decryption, it sends the data back to the service module.

Display and maintenance commands for crypto engines

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display crypto engine information.	**display crypto-engine**
Display crypto engine statistics.	**display crypto-engine statistics** [**engine-id** *engine-id* **slot** *slot-number*]
Clear crypto engine statistics.	**reset crypto-engine statistics** [**engine-id** *engine-id* **slot** *slot-number*]

Configuring FIPS

About FIPS

Federal Information Processing Standards (FIPS) was developed by the National Institute of Standards and Technology (NIST) of the United States. FIPS specifies the requirements for cryptographic modules.

FIPS security levels

FIPS 140-2 defines four levels of security, named Level 1 to Level 4, from low to high. The device supports Level 2.

Unless otherwise noted, the term "FIPS" refers to Level-2 FIPS 140-2 in this document.

FIPS functionality

In FIPS mode, the device has strict security requirements. It performs self-tests on cryptography modules to verify that the modules are operating correctly.

A FIPS device also meets the functionality requirements defined in Network Device Protection Profile (NDPP) of Common Criteria (CC).

FIPS self-tests

To ensure correct operation of cryptography modules, FIPS provides self-test mechanisms, including power-up self-tests and conditional self-tests.

If a power-up self-test fails, the device where the self-test process exists reboots. If a conditional self-test fails, the system outputs a self-test failure message.

NOTE:

If a self-test fails, contact H3C Support.

Power-up self-tests

The power-up self-test examines the availability of FIPS-allowed cryptographic algorithms.

The device supports the following types of power-up self-tests:

- Known-answer test (KAT)

  A cryptographic algorithm is run on data for which the correct output is already known. The calculated output is compared with the known answer. If they are not identical, the KAT test fails.

- Pairwise conditional test (PWCT)
  - **Signature and authentication test**—The test is run when a DSA, RSA, or ECDSA asymmetrical key pair is generated. The system uses the private key to sign the specific data, and then uses the public key to authenticate the signed data. If the authentication is successful, the test succeeds.
  - **Encryption and decryption test**—The test is run when an RSA asymmetrical key pair is generated. The system uses the public key to encrypt a plain text string, and then uses the private key to decrypt the encrypted text. If the decryption result is the same as the original plain text string, the test succeeds.

The power-up self-test examines the cryptographic algorithms listed in Table 1.

Table 1 Power-up self-tests list

Type	Operations
KAT	Tests the following algorithms: • SHA1, SHA224, SHA256, SHA384, and SHA512. • HMAC-SHA1, HMAC-SHA224, HMAC-SHA256, HMAC-SHA384, and HMAC-SHA512. • AES. • RSA (signature and authentication). • ECDH. • DRBG. • GCM. • GMAC.
PWCT	Tests the following algorithms: • RSA (signature and authentication). • RSA (encryption and decryption). • DSA (signature and authentication). • ECDSA (signature and authentication).

Conditional self-tests

A conditional self-test runs when an asymmetrical cryptographic module or a random number generator module is invoked. Conditional self-tests include the following types:

- **PWCT signature and authentication**—This test is run when a DSA or RSA asymmetrical key pair is generated. The system uses the private key to sign the specific data, and then uses the public key to authenticate the signed data. If the authentication is successful, the test succeeds.
- **Continuous random number generator test**—Runs when a random number is generated. The system compares the generated random number with the previously generated random number. If the two numbers are the same, the test fails. This test also runs when a DSA or RSA asymmetrical key pair is generated.

Restrictions and guidelines: FIPS

Requirements for key pairs and passwords

Before you reboot the device to enter FIPS mode, the system automatically removes all key pairs configured in non-FIPS mode and all FIPS-incompliant digital certificates. FIPS-incompliant digital certificates are MD5-based certificates with a key modulus length less than 2048 bits. You cannot log in to the device through SSH after the device enters FIPS mode. To log in to the device in FIPS mode through SSH, log in to the device through a console port and create a key pair for the SSH server.

The password for entering the device in FIPS mode must comply with the password control policies, such as password length, complexity, and aging policy. When the aging timer for a password expires, the system prompts you to change the password. If you adjust the system time after the device enters FIPS mode, the login password might expire before the next login, because the original system time is typically much earlier than the actual time.

Configuration rollback guidelines

Configuration rollback is supported in FIPS mode and also during a switch between FIPS mode and non-FIPS mode. After a configuration rollback between FIPS mode and non-FIPS mode, perform the following tasks:

1. Delete the local user and configure a new local user. Local user attributes include password, user role, and service type.

2. Save the current configuration file.
3. Specify the current configuration file as the startup configuration file.
4. Reboot the device. The new configuration takes effect after the reboot. During this process, do not exit the system or perform other operations.

If a device enters FIPS or non-FIPS mode through automatic reboot, configuration rollback fails. To support configuration rollback, you must execute the **save** command after the device enters FIPS or non-FIPS mode.

IRF compatibility

All devices in an IRF fabric must be operating in the same mode, whether in FIPS mode or non-FIPS mode.

To enable FIPS mode for an IRF fabric, you must reboot the entire IRF fabric.

Feature changes in FIPS mode

After the system enters FIPS mode, the following feature changes occur:

- The user login authentication mode can only be scheme.
- The FTP/TFTP server and client are disabled.
- The Telnet server and client are disabled.
- The HTTP server is disabled.
- SNMPv1 and SNMPv2c are disabled. Only SNMPv3 is available.
- The SSL server supports only TLS1.0, TLS1.1, and TLS1.2.
- The SSH server does not support SSHv1 clients or DSA key pairs.
- The generated RSA and DSA key pairs must have a modulus length of 2048 bits.

  When the device acts as a server to authenticate a client through the public key, the key pair for the client must also have a modulus length of 2048 bits.
- The generated ECDSA key pairs must have a modulus length of more than 256 bits.

  When the device acts as a server to authenticate a client through the public key, the key pair for the client must also have a modulus length of more than 256 bits.
- SSH, SNMPv3, IPsec, and SSL do not support DES, 3DES, RC4, or MD5.
- The password control feature cannot be disabled globally. The **undo password-control enable** command does not take effect.
- An AAA shared key, IKE pre-shared key, or SNMPv3 authentication key must have at least 15 characters and must contain uppercase and lowercase letters, digits, and special characters.
- The password for a device management local user and password for switching user roles must comply with the password control policies. By default, the password must have at least 15 characters and must contain uppercase and lowercase letters, digits, and special characters.

Entering FIPS mode

About entering FIPS mode

For the device to enter FIPS mode, you can use one of the following methods:

- **Automatic reboot**—The system automatically performs the following operations:
  a. Prompts you to specify the username and password for the next login.
  b. Creates a default FIPS configuration file named **fips-startup.cfg**.
  c. Specifies the default FIPS configuration file as the startup configuration file.
  d. Reboots and loads the default FIPS configuration file to enter the FIPS mode.

- **Manual reboot**—You must complete the required configuration tasks and reboot the device manually.

Restrictions and guidelines

After you execute the **`fips mode enable`** command, the system prompts you to choose a reboot method.

- If you do not make a choice within 30 seconds or press **Ctrl**+**C**, the system enables FIPS mode and waits for you to manually complete the FIPS mode configuration tasks.
- If you select the automatic reboot method, you can press **Ctrl**+**C** to abort both the interactive FIPS mode configuration process and the **`fips mode enable`** command.

Using the automatic reboot method to enter FIPS mode

Prerequisites

To ensure login password effectiveness under the password control policies, set the correct system time.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enable FIPS mode.

   ```
   fips mode enable
   ```

   By default, the FIPS mode is disabled.

3. After the reboot method choice prompt appears, enter **Y** within 30 minutes.

   The system starts the interactive FIPS mode configuration process.

CAUTION:

System reboot might interrupt ongoing services. Please perform the previous operations with caution.

4. Enter the login username and password as prompted.

   The password must have a minimum of 15 characters and must contain uppercase and lowercase letters, digits, and special characters. After you enter the username and password, the device performs the following operations:

   - Creates a device management local user that uses the entered username and password.
   - Assigns the user the terminal service and the network-admin user role.
   - Saves the running configuration and specifies the configuration file as the startup configuration file.
   - Reboots, loads the startup configuration file, and enters FIPS mode.

To log in to the device, you must enter the configured username and password. After login, you are identified as the FIPS mode crypto officer.

Using the manual reboot method to enter FIPS mode

Prerequisites

1. To ensure login password effectiveness under the password control policies, set the correct system time.

2. Configure the password control feature.
   a. Enable the password control feature globally.
   b. Configure password control policies.
      - Set the number of character types a password must contain to 4.
      - Set the minimum number of characters for each type to one character.
      - Set the minimum length for a user password to 15 characters.

   For more information about the password control feature, see password control in *Security Configuration Guide*.
3. Configure a local user.
   - Create a device management local user.
   - Specify a password that complies with the password control policies.
   - Assign the terminal service to the user.
   - Assign the network-admin user role to the user.

Procedure

1. Enter system view.

   `system-view`
2. Enable FIPS mode.

   `fips mode enable`

   By default, the FIPS mode is disabled.
3. After the reboot method choice prompt appears, enter **N**.

   The system enables FIPS mode and waits for you to complete the FIPS mode configuration tasks. Before rebooting the device to enter FIPS mode, do not execute any commands except for **`save`** and commands used to prepare for entering FIPS mode. If you execute any other commands, the commands might not take effect.

   CAUTION:
   - System reboot might interrupt ongoing services. Perform this operation with caution.
   - After you select the manual reboot method to enable FIPS mode, you must manually complete the configurations for entering FIPS mode. Otherwise, you cannot log in to the system correctly.
4. Save the running configuration and specify the configuration file as the startup configuration file.
5. Delete the .mdb startup configuration file.

   When loading a .mdb configuration file, the device loads all settings in the file. The settings that are not supported in FIPS mode might affect device operation.
6. Reboot the device.

   The device reboots, loads the startup configuration file, and enters FIPS mode. To log in to the device, you must enter the configured username and password. After login, you are identified as the FIPS mode crypto officer.

Manually triggering self-tests

About this task

You can manually trigger FIPS self-tests to verify operation of cryptography modules anytime as required. The triggered self-tests are the same as the power-up self-tests.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Trigger self-tests.
   ```
   fips self-test
   ```

CAUTION:

A successful self-test requires that all cryptographic algorithms pass the self-test. If the self-test fails, the device where the self-test process exists reboots.

Exiting FIPS mode

About this task

After you disable FIPS mode and reboot the device, the device operates in non-FIPS mode.

For the device to exit FIPS mode, you can use one of the following reboot methods:

- **Automatic reboot**—The system automatically creates a default non-FIPS configuration file named **non-fips-startup.cfg**, specifies the file as the startup configuration file, and reboots to enter non-FIPS mode. You can log in to the device without providing username or password.
- **Manual reboot**—You must manually complete the configuration tasks for entering non-FIPS mode, and then reboot the device. To log in to the device after the reboot, you must enter user information as required by the authentication mode settings.

  The following are the default authentication mode settings:
  - **VTY line**—Password authentication.
  - **AUX line**—Authentication is disabled. (Devices that have only the console or AUX port.)

  You can modify the authentication settings as needed.

Using the automatic reboot method to exit FIPS mode

1. Enter system view.
   ```
   system-view
   ```
2. Disable FIPS mode.
   ```
   undo fips mode enable
   ```
   By default, the FIPS mode is disabled.
3. Select the automatic reboot method.

CAUTION:

System reboot might interrupt ongoing services. Please perform the previous operations with caution.

Using the manual reboot method to exit FIPS mode

1. Enter system view.
   ```
   system-view
   ```
2. Disable FIPS mode.
   ```
   undo fips mode enable
   ```
   By default, the FIPS mode is disabled.
3. Select the manual reboot method.

CAUTION:

System reboot might interrupt ongoing services. Please perform the previous operations with caution.

4. Configure login authentication settings.
   - If you logged in to the device through SSH, perform the following tasks without disconnecting the current user line:
     - Set the authentication mode to **scheme** for VTY lines.
     - Specify the username and password. If you do not specify the username or password, the device uses the current username and password.
   - If you logged in to the device through a console port, configure login authentication settings for the current type of user lines as described in the following table:

Current login method	Login authentication requirements
Scheme	Set the authentication to scheme and specify the username and password. If you do not specify the username or password, the device uses the current username and password.
Password	Set the authentication to password and specify the password. If you do not specify the password, the device uses the current password.
None	Set the authentication to none.

5. Save the running configuration and specify the file as the startup configuration file.
6. Delete the .mdb startup configuration file.
7. Reboot the device.

Display and maintenance commands for FIPS

Execute **display** commands in any view.

Task	Command
Display the version number of the device algorithm base.	**display crypto version**
Display the FIPS mode state.	**display fips status**

FIPS configuration examples

Example: Entering FIPS mode through automatic reboot

Network configuration

Use the automatic reboot method to enter FIPS mode, and use a console port to log in to the device in FIPS mode.

Procedure

If you want to save the current configuration, execute the **save** command before you enable FIPS mode.

Enable FIPS mode and choose the automatic reboot method to enter FIPS mode. Set the username to **root** and the password to **12345zxcvb!@#$%ZXCVB**.

```
<Sysname> system-view
[Sysname] fips mode enable
FIPS mode change requires a device reboot. Continue? [Y/N]:y
Reboot the device automatically? [Y/N]:y
The system will create a new startup configuration file for FIPS mode. After you set the login username and password for FIPS mode, the device will reboot automatically.
Enter username(1-55 characters):root
Enter password(15-63 characters):
Confirm password:
Waiting for reboot... After reboot, the device will enter FIPS mode.
```

Verifying the configuration

After the device reboots, enter a username of **root** and a password of **12345zxcvb!@#$%ZXCVB**. The system prompts you to configure a new password. After you configure the new password, the device enters FIPS mode. The new password must be different from the previous password. It must include at least 15 characters, and contain uppercase and lowercase letters, digits, and special characters. For more information about the requirements for the password, see the system output.

```
Press ENTER to get started.
login: root
Password:
First login or password reset. For security reason, you need to change your password. Please enter your password.
old password:
new password:
confirm:
Updating user information. Please wait ... ...
…
<Sysname>
```

Display the FIPS mode state.

```
<Sysname> display fips status
FIPS mode is enabled.
```

Display the default configuration file.

```
<Sysname> more fips-startup.cfg
#
 password-control enable
#
local-user root class manage
 service-type terminal
 authorization-attribute user-role network-admin
#
 fips mode enable
#
return

<Sysname>
```

Example: Entering FIPS mode through manual reboot

Network configuration

Use the manual reboot method to enter FIPS mode, and use a console port to log in to the device in FIPS mode.

Procedure

Enable the password control feature globally.

```
<Sysname> system-view
[Sysname] password-control enable
```

Set the number of character types a password must contain to 4, and set the minimum number of characters for each type to one character.

```
[Sysname] password-control composition type-number 4 type-length 1
```

Set the minimum length of user passwords to 15 characters.

```
[Sysname] password-control length 15
```

Add a local user account for device management, including a username of **test**, a password of **12345zxcvb!@#$%ZXCVB**, a user role of **network-admin**, and a service type of **terminal**.

```
[Sysname] local-user test class manage
[Sysname-luser-manage-test] password simple 12345zxcvb!@#$%ZXCVB
[Sysname-luser-manage-test] authorization-attribute user-role network-admin
[Sysname-luser-manage-test] service-type terminal
[Sysname-luser-manage-test] quit
```

Enable FIPS mode, and choose the manual reboot method to enter FIPS mode.

```
[Sysname] fips mode enable
FIPS mode change requires a device reboot. Continue? [Y/N]:y
Reboot the device automatically? [Y/N]:n
Change the configuration to meet FIPS mode requirements, save the configuration to the
next-startup configuration file, and then reboot to enter FIPS mode.
```

Save the current configuration to the root directory of the storage medium, and specify it as the startup configuration file.

```
[Sysname] save
The current configuration will be written to the device. Are you sure? [Y/N]:y
Please input the file name(*.cfg)[flash:/startup.cfg]
(To leave the existing filename unchanged, press the enter key):
flash:/startup.cfg exists, overwrite? [Y/N]:y
Validating file. Please wait...
Saved the current configuration to mainboard device successfully.
[Sysname] quit
```

Delete the startup configuration file in binary format.

```
<Sysname> delete flash:/startup.mdb
Delete flash:/startup.mdb?[Y/N]:y
Deleting file flash:/startup.mdb...Done.
```

Reboot the device.

```
<Sysname> reboot
```

Verifying the configuration

After the device reboots, enter a username of **test** and a password of **12345zxcvb!@#$%ZXCVB**. The system prompts you to configure a new password. After you configure the new password, the

device enters FIPS mode. The new password must be different from the previous password. It must include at least 15 characters, and contain uppercase and lowercase letters, digits, and special characters. For more information about the requirements for the password, see the system output.

```
Press ENTER to get started.
login: test
Password:
First login or password reset. For security reason, you need to change your pass
word. Please enter your password.
old password:

Example: Exiting FIPS mode through automatic reboot

Network configuration

After logging in to the device in FIPS mode through a console port, use the automatic reboot method to exit FIPS mode.

Procedure

Disable FIPS mode.

```
[Sysname] undo fips mode enable
FIPS mode change requires a device reboot. Continue? [Y/N]:y
The system will create a new startup configuration file for non-FIPS mode and then reboot
automatically. Continue? [Y/N]:y
Waiting for reboot... After reboot, the device will enter non-FIPS mode.
```

Verifying the configuration

After the device reboots, you can enter the system.

```
<Sysname>
```

Display the FIPS mode state.

```
<Sysname> display fips status
FIPS mode is disabled.
```

Example: Exiting FIPS mode through manual reboot

Network configuration

After logging in to the device in FIPS mode through the console port with username **test** and password **12345zxcvb!@#$%ZXCVB**, use the manual reboot method to exit FIPS mode.

Procedure

Disable FIPS mode.

```
[Sysname] undo fips mode enable
FIPS mode change requires a device reboot. Continue? [Y/N]:y
```

```
The system will create a new startup configuration file for non-FIPS mode, and then reboot automatically. Continue? [Y/N]:n
Change the configuration to meet non-FIPS mode requirements, save the configuration to the next-startup configuration file, and then reboot to enter non-FIPS mode.
```

Save the current configuration to the root directory of the storage medium, and specify it as the startup configuration file.

```
[Sysname] save
The current configuration will be written to the device. Are you sure? [Y/N]:y
Please input the file name(*.cfg)[flash:/startup.cfg]
(To leave the existing filename unchanged, press the enter key):
flash:/startup.cfg exists, overwrite? [Y/N]:y
Validating file. Please wait...
Saved the current configuration to mainboard device successfully.
[Sysname] quit
```

Delete the startup configuration file in binary format.

```
<Sysname> delete flash:/startup.mdb
Delete flash:/startup.mdb?[Y/N]:y
Deleting file flash:/startup.mdb...Done.
```

Reboot the device.

```
<Sysname> reboot
```

Verifying the configuration

After the device reboots, authentication is disabled for console login by default. You can press **Enter** to enter non-FIPS mode without authentication.

```
Press ENTER to get started.
login: test
Password:
Last successfully login time:…
…
<Sysname>
```

Display the FIPS mode state.

```
<Sysname> display fips status
FIPS mode is disabled.
```

Configuring an 802.1X client

About 802.1X clients

As shown in Figure 1, the 802.1X client feature allows the access device to act as the supplicant in the 802.1X architecture. For information about the 802.1X architecture, see "802.1X overview."

Figure 1 802.1X client network diagram

802.1X client tasks at a glance

To configure an 802.1X client, perform the following tasks:

1. Enabling the 802.1X client feature
2. Configuring an 802.1X client username and password
3. Specifying an 802.1X client EAP authentication method
4. (Optional.) Configuring an 802.1X client MAC address
5. (Optional.) Specifying an 802.1X client mode for sending EAP-Response and EAPOL-Logoff packets
6. (Optional.) Configuring an 802.1X client anonymous identifier
7. Specifying an SSL client policy

   This task is required when you specify PEAP-MSCHAPv2, PEAP-GTC, TTLS-MSCHAPv2, or TTLS-GTC authentication as the 802.1X client EAP authentication method.

Enabling the 802.1X client feature

1. Enter system view.

   `system-view`
2. Enter Ethernet interface view.

   `interface` *`interface-type interface-number`*
3. Enable the 802.1X client feature.

   `dot1x supplicant enable`

   By default, the 802.1X client feature is disabled.

Configuring an 802.1X client username and password

Restrictions and guidelines

To ensure successful authentication, make sure the username and password configured on the 802.1X client is consistent with the username and password configured on the authentication server.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Configure an 802.1X client username.
   dot1x supplicant username *username*
   By default, no 802.1X client username is configured.
4. Set an 802.1X client password.
   dot1x supplicant password { **cipher** | **simple** } *string*
   By default, no 802.1X client password is configured.

Specifying an 802.1X client EAP authentication method

About this task

The following EAP authentication methods are available for the 802.1X client feature:

- MD5-Challenge.
- PEAP-MSCHAPv2.
- PEAP-GTC.
- TTLS-MSCHAPv2.
- TTLS-GTC.

Restrictions and guidelines

The following matrix shows the restrictions for the selection of authentication methods on the 802.1X client and the authenticator:

Authentication method specified on the 802.1X client	Packet exchange method specified on the authenticator
MD5-Challenge	• CHAP • EAP
• PEAP-MSCHAPv2 • PEAP-GTC • TTLS-MSCHAPv2 • TTLS-GTC	EAP

For information about 802.1X packet exchange methods, see "Configuring 802.1X."

Make sure the specified 802.1X client EAP authentication method is supported by the authentication server.

Procedure

1. Enter system view.

   system-view

2. Enter Ethernet interface view.

   interface *interface-type interface-number*

3. Specify an 802.1X client EAP authentication method.

   dot1x supplicant eap-method { **md5** | **peap-gtc** | **peap-mschapv2** | **ttls-gtc** | **ttls-mschapv2** }

   By default, the EAP authentication method is MD5-Challenge.

Configuring an 802.1X client MAC address

About this task

The authenticator adds the MAC address of an authenticated 802.1X client to the MAC address table and then assigns access rights to the client.

If the device has multiple Ethernet interfaces that act as 802.1X clients to seek MACsec protection, configure a unique MAC address for each interface to ensure successful 802.1X client authentication. For information about MACsec, see "Configuring MACsec."

You can use either of the following methods to configure a unique MAC address for each interface:

- Execute the **mac-address** command in Ethernet interface view. For information about this command, see *Layer 2—LAN Switching Command Reference*.
- Configure an 802.1X client MAC address.

Procedure

1. Enter system view.

   system-view

2. Enter Ethernet interface view.

   interface *interface-type interface-number*

3. Configure an 802.1X client MAC address.

   dot1x supplicant mac-address *mac-address*

   By default, an Ethernet interface uses the interface's MAC address for 802.1X client authentication. If the interface's MAC address is unavailable, the interface uses the device's MAC address for 802.1X client authentication.

Specifying an 802.1X client mode for sending EAP-Response and EAPOL-Logoff packets

About this task

802.1X client authentication supports unicast and multicast modes to send EAP-Response and EAPOL-Logoff packets. As a best practice, use multicast mode to avoid 802.1X client authentication failures if the NAS device in the network does not support receiving unicast EAP-Response or EAPOL-Logoff packets.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Specify a mode for 802.1X client authentication to send EAP-Response and EAPOL-Logoff packets.
   dot1x supplicant transmit-mode { **multicast** | **unicast** }
   By default, 802.1X client authentication uses unicast mode to send EAP-Response and EAPOL-Logoff packets.

Configuring an 802.1X client anonymous identifier

About this task

At the first authentication phase, packets sent to the authenticator are not encrypted. The use of an 802.1X client anonymous identifier prevents the 802.1X client username from being disclosed at the first phase. The 802.1X client sends the anonymous identifier to the authenticator instead of the 802.1X client username. The 802.1X client username will be sent to the authenticator in encrypted packets at the second phase.

If no 802.1X client anonymous identifier is configured, the 802.1X client sends the 802.1X client username at the first authentication phase.

The configured 802.1X client anonymous identifier takes effect only if one of the following EAP authentication methods is used:

- PEAP-MSCHAPv2.
- PEAP-GTC.
- TTLS-MSCHAPv2.
- TTLS-GTC.

If the MD5-Challenge EAP authentication is used, the configured 802.1X client anonymous identifier does not take effect. The 802.1X client uses the 802.1X client username at the first authentication phase.

Restrictions and guidelines

Do not configure the 802.1X client anonymous identifier if the vendor-specific authentication server cannot identify anonymous identifiers.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Configure an 802.1X client anonymous identifier.
   dot1x supplicant anonymous identify *identifier*
   By default, no 802.1X client anonymous identifier is configured.

Specifying an SSL client policy

About this task

If the PEAP-MSCHAPv2, PEAP-GTC, TTLS-MSCHAPv2, or TTLS-GTC authentication is used, the 802.1X client authentication process is as follows:

- **The first phase**—The 802.1X client acts as an SSL client to negotiate with the SSL server.

  The SSL client uses the SSL parameters defined in the specified SSL client policy to establish a connection with the SSL server for negotiation. The SSL parameters include a PKI domain, supported cipher suites, and the SSL version. For information about SSL client policy configuration, see "Configuring SSL."
- **The second phase**—The 802.1X client uses the negotiated result to encrypt and transmit the interchanged authentication packets.

If the MD5-Challenge authentication is used, the 802.1X client does not use an SSL client policy during the authentication process.

Procedure

1. Enter system view.

   system-view
2. Enter Ethernet interface view.

   interface *interface-type interface-number*
3. Specify an SSL client policy.

   dot1x supplicant ssl-client-policy *policy-name*

   By default, the default SSL client policy is used.

Display and maintenance commands for 802.1X client

Execute **display** commands in any view.

Task	Command
Display 802.1X client information.	**display dot1x supplicant** [**interface** *interface-type interface-number*]

Configuring attack detection and prevention

Overview

Attack detection and prevention enables a device to detect attacks by inspecting arriving packets, and to take prevention actions (such as packet dropping) to protect a private network.

Attacks that the device can prevent

This section describes the attacks that the device can detect and prevent.

UDP flood attack

A UDP flood attacker sends UDP packets to a host at a fast rate. These packets consume a large amount of the target host's bandwidth, so the host cannot provide other services.

TCP fragment attack

An attacker launches TCP fragment attacks by sending attack TCP fragments defined in RFC 1858:

- First fragments in which the TCP header is smaller than 20 bytes.
- Non-first fragments with a fragment offset of 8 bytes (FO=1).

Typically, packet filter detects the source and destination IP addresses, source and destination ports, and transport layer protocol of the first fragment of a TCP packet. If the first fragment passes the detection, all subsequent fragments of the TCP packet are allowed to pass through.

Because the first fragment of attack TCP packets does not hit any match in the packet filter, the subsequent fragments can all pass through. After the receiving host reassembles the fragments, a TCP fragment attack occurs.

To prevent TCP fragment attacks, enable TCP fragment attack prevention to drop attack TCP fragments.

Login dictionary attack

The login dictionary attack is an automated process to attempt to log in by trying all possible passwords from a pre-arranged list of values (the dictionary). Multiple login attempts can occur in a short period of time.

You can configure the login delay feature to slow down the login dictionary attacks. This feature enables the device to delay accepting another login request after detecting a failed login attempt for a user.

Configuring and applying an attack defense policy

Creating an attack defense policy

About this task

An attack defense policy contains a set of attack detection and prevention configuration.

To configure attack defense configuration such as detection signatures and protection actions, you must first create an attack defense policy and enter its view.

Restrictions and guidelines

CAUTION:

The default thresholds for triggering attack prevention might not be appropriate for your network. Set appropriate according to the actual application scenarios. Small thresholds might affect the Internet or webpage access speed. Large thresholds might make your network vulnerable to attacks.

Software and feature compatibility

This feature is supported only in R1129 and later versions.

Procedure

1. Enter system view.
   system-view
2. Create an attack defense policy and enter its view.
   attack-defense policy *policy-name*

Configuring a single-packet attack defense policy

About this task

Apply the single-packet attack defense policy to the interface or security zone that is connected to the external network.

Single-packet attack detection inspects incoming packets based on the packet signature. If an attack packet is detected, the device can take the following actions:

- Output logs (the default action).
- Drop attack packets.

You can also configure the device to not take any actions.

Software and feature compatibility

This feature is supported only in R1129 and later versions.

Procedure

1. Enter system view.
   system-view
2. Enter attack defense policy view.
   attack-defense policy *policy-name*
3. Configure signature detection for specific single-packet attack types, and specify the actions against the attacks.
   signature detect { **land** | **smurf** } [**action** { { **drop** | **logging** }* | **none** }]
   signature detect { **ping-of-death** | **teardrop** } **action** { **drop** | **logging** }*

Configuring a UDP flood attack defense policy

Software and feature compatibility

This feature is supported only in R1129 and later versions.

Procedure

1. Enter system view.
   system-view
2. Enter attack defense policy view.
   attack-defense policy *policy-name*
3. Enable global UDP flood attack detection.
   udp-flood detect non-specific
   By default, global UDP flood attack detection is disabled.
4. Set the global trigger threshold for UDP flood attack prevention.
   udp-flood threshold *threshold-value*
   The default setting is 1000.
5. Specify global actions against UDP flood attacks.
   udp-flood action { **drop** | **logging** } *
   By default, no global action is specified for UDP flood attacks.
6. Configure IP address-specific UDP flood attack detection.
   udp-flood detect { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**threshold** *threshold-value*] [**action** { { **drop** | **logging** } * | **none** }]
   By default, IP address-specific UDP flood attack detection is not configured

Configuring TCP fragment attack prevention

About this task

The TCP fragment attack prevention feature detects the length and fragment offset of received TCP fragments and drops attack TCP fragments.

Restrictions and guidelines

TCP fragment attack prevention takes precedence over single-packet attack prevention. When both are used, incoming TCP packets are processed first by TCP fragment attack prevention and then by the single-packet attack defense policy.

Procedure

1. Enter system view.
   system-view
2. Enable TCP fragment attack prevention.
   attack-defense tcp fragment enable
   By default, TCP fragment attack prevention is enabled.

Enabling the login delay

About this task

The login delay feature delays the device from accepting a login request from a user after the user fails a login attempt. This feature can slow down login dictionary attacks.

The login delay feature is independent of the login attack prevention feature.

Procedure

1. Enter system view.

   `system-view`

2. Enable the login delay feature.

   `attack-defense login reauthentication-delay` *`seconds`*

   By default, the login delay feature is disabled. The device does not delay accepting a login request from a user who has failed a login attempt.

Display and maintenance commands for attack detection and prevention

Use the **`display`** commands in any view.

Task	Command
Display attack defense policy configuration.	**`display attack-defense policy`** [*`policy-name`*]

Notice

The information in this document is subject to change without notice. All contents in this document, including statements, information, and recommendations, are believed to be accurate, but they are presented without warranty of any kind, express or implied. H3C shall not be liable for technical or editorial errors or omissions contained herein.

Preface

This configuration guide describes the high availability fundamentals and configuration procedures. The high availability technologies include fault detection and fault failover. Failure detection technologies focus on fault detection and isolation. Failover technologies focus on network recovery.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators working with the S5570S-EI and S5500V3-SI switch series.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** >

	Folder.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

Configuring Ethernet OAM

About Ethernet OAM

Ethernet Operation, Administration, and Maintenance (OAM) is a tool that monitors Layer 2 link status and addresses common link-related issues on the "last mile." Ethernet OAM improves Ethernet management and maintainability. You can use it to monitor the status of the point-to-point link between two directly connected devices.

Major functions of Ethernet OAM

Ethernet OAM provides the following functions:

- **Link performance monitoring**—Monitors the performance indices of a link, including packet loss, delay, and jitter, and collects traffic statistics of various types.
- **Fault detection and alarm**—Checks the connectivity of a link by sending OAM protocol data units (OAMPDUs) and reports to the network administrators when a link error occurs.
- **Remote loopback**—Checks link quality and locates link errors by looping back OAMPDUs.

Ethernet OAMPDUs

Ethernet OAM operates on the data link layer. Ethernet OAM reports the link status by periodically exchanging OAMPDUs between devices, so that the administrator can effectively manage the network.

Ethernet OAMPDUs include the following types shown in Table 1.

Table 1 Functions of different types of OAMPDUs

OAMPDU type	Function
Information OAMPDU	Used for transmitting state information of an Ethernet OAM entity, including the information about the local device and remote devices, and customized information, to the remote Ethernet OAM entity, and maintaining OAM connections.
Event Notification OAMPDU	Used by link monitoring to notify the remote OAM entity when it detects problems on the link in between.
Loopback Control OAMPDU	Used for remote loopback control. By inserting the information used to enable/disable loopback to a loopback control OAMPDU, you can enable/disable loopback on a remote OAM entity.

NOTE:

Throughout this document, an Ethernet OAM-enabled port is called an Ethernet OAM entity or an OAM entity.

How Ethernet OAM works

This section describes the working procedures of Ethernet OAM.

Ethernet OAM connection establishment

OAM connection establishment is also known as the Discovery phase, where an Ethernet OAM entity discovers the remote OAM entity to establish a session.

In this phase, two connected OAM entities exchange Information OAMPDUs to advertise their OAM configuration and capabilities to each other for a comparison. If their Loopback, link detection, and link event settings match, the OAM entities establish an OAM connection.

An OAM entity operates in active mode or passive mode. OAM entities in active mode initiate OAM connections, and OAM entities in passive mode wait and respond to the OAM connection requests. To set up an OAM connection between two OAM entities, you must set at least one entity to operate in active mode.

Table 2 shows the actions that a device can perform in different modes.

Table 2 Active Ethernet OAM mode and passive Ethernet OAM mode

Item	Active Ethernet OAM mode	Passive Ethernet OAM mode
Initiating OAM Discovery	Available	Unavailable
Responding to OAM Discovery	Available	Available
Transmitting Information OAMPDUs	Available	Available
Transmitting Event Notification OAMPDUs	Available	Available
Transmitting Information OAMPDUs without any TLV	Available	Available
Transmitting Loopback Control OAMPDUs	Available	Unavailable
Responding to Loopback Control OAMPDUs	Available	Available

After an Ethernet OAM connection is established, the Ethernet OAM entities exchange Information OAMPDUs at the handshake packet transmission interval to detect the availability of the Ethernet OAM connection. If an Ethernet OAM entity receives no Information OAMPDU within the Ethernet OAM connection timeout time, the Ethernet OAM connection is considered disconnected.

Link monitoring

Error detection in an Ethernet is difficult, especially when the physical connection in the network is not disconnected, but network performance is degrading gradually.

Link monitoring detects link faults in various environments. Ethernet OAM entities monitor link status by exchanging Event Notification OAMPDUs. When detecting one of the link error events listed in Table 3, an OAM entity sends an Event Notification OAMPDU to its peer OAM entity. The network administrator can keep track of network status changes by retrieving the log.

Table 3 Ethernet OAM link error events

Ethernet OAM link events	Description
Errored symbol event	An errored symbol event occurs when the number of detected symbol errors in the detection window (specified number of received symbols) exceeds the predefined threshold.
Errored frame event	An errored frame event occurs when the number of detected error frames in the detection window (specified detection interval) exceeds the predefined threshold.
Errored frame period event	An errored frame period event occurs when the number of frame errors in the detection window (specified number of received frames) exceeds the predefined threshold.
Errored frame seconds event	An errored frame seconds event occurs when the number of errored frame seconds (the second in which an errored frame appears is called an

Ethernet OAM link events	Description
	errored frame second) detected on a port in the detection window (specified detection interval) reaches the predefined threshold.

Remote fault detection

Information OAMPDUs are exchanged periodically among Ethernet OAM entities across established OAM connections. When traffic is interrupted due to device failure or unavailability, the Ethernet OAM entity at the faulty end sends error information to its peer. The Ethernet OAM entity uses the flag field in Information OAMPDUs to indicate the error information (any critical link event type as shown in Table 4). You can use the log information to track ongoing link status and troubleshoot problems promptly.

Table 4 Critical link events

Type	Description	OAMPDU transmission frequencies
Link Fault	Peer link signal is lost.	Once per second.
Dying Gasp	An unexpected fault, such as power failure, occurred.	Non-stop.
Critical Event	An undetermined critical event happened.	Non-stop.

Remote loopback

Remote loopback is available only after the Ethernet OAM connection is established. With remote loopback enabled, the Ethernet OAM entity in active mode sends non-OAMPDUs to its peer. After receiving these frames, the peer does not forward them according to their destination addresses. Instead, it returns them to the sender along the original path.

Remote loopback enables you to check the link status and locate link failures. Performing remote loopback periodically helps to detect network faults promptly. Furthermore, performing remote loopback by network segments helps to locate network faults.

Protocols and standards

IEEE 802.3ah, *Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications*

Restrictions and guidelines: Ethernet OAM configuration

The device's support for sending and receiving Information OAMPDUs carrying critical link events is as follows:

- Can receive Information OAMPDUs carrying the critical link events listed in Table 4.
- Cannot send Information OAMPDUs carrying Link Fault events.
- Can send Information OAMPDUs carrying Dying Gasp events when the device is rebooted or relevant ports are manually shut down. Physical IRF ports, however, are unable to send this type of OAMPDUs.
- Cannot send Information OAMPDUs carrying Critical Events.

Ethernet OAM tasks at a glance

To configure Ethernet OAM, perform the following tasks:

1. Configuring basic Ethernet OAM functions
2. (Optional.) Configuring the Ethernet OAM connection detection timers
3. (Optional.) Configuring link event detection

Configuring basic Ethernet OAM functions

About this task

To set up an Ethernet OAM connection between two Ethernet OAM entities, you must set at least one entity to operate in active mode. An Ethernet OAM entity can initiate OAM connection only in active mode.

Restrictions and guidelines

To change the Ethernet OAM mode on an Ethernet OAM-enabled port, first disable Ethernet OAM on the port.

Procedure

1. Enter system view.

   System-view

2. Enter Layer 2/Layer 3 Ethernet port view.

   interface *interface-type interface-number*

3. Set the Ethernet OAM mode.

   oam mode { **active** | **passive** }

   The default is active Ethernet OAM mode.

4. Enable Ethernet OAM.

   oam enable

   Ethernet OAM is disabled by default.

Configuring the Ethernet OAM connection detection timers

About the Ethernet OAM connection detection timers

After an Ethernet OAM connection is established, the Ethernet OAM entities exchange Information OAMPDUs at the handshake packet transmission interval to detect the availability of the Ethernet OAM connection. If an Ethernet OAM entity receives no Information OAMPDU within the Ethernet OAM connection timeout time, the Ethernet OAM connection is considered disconnected.

By adjusting the handshake packet transmission interval and the connection timeout timer, you can change the detection time resolution for Ethernet OAM connections.

Restrictions and guidelines for configuring Ethernet OAM connection detection timers

When you configure Ethernet OAM, follow these restrictions and guidelines:

- You can configure this command in system view or port view. The configuration in system view takes effect on all ports, and the configuration in port view takes effect on the specified port. For a port, the configuration in port view takes precedence.
- After the timeout timer of an Ethernet OAM connection expires, the local OAM entity ages out and terminates its connection with the peer OAM entity. To keep the Ethernet OAM connections stable, set the connection timeout timer to be at least five times the handshake packet transmission interval.

Configuring the Ethernet OAM connection detection timers globally

1. Enter system view.
   System-view
2. Configure the Ethernet OAM handshake packet transmission interval.
   oam global timer hello *interval*
   The default is 1000 milliseconds.
3. Configure the Ethernet OAM connection timeout timer.
   oam global timer keepalive *interval*
   The default is 5000 milliseconds.

Configuring the Ethernet OAM connection detection timers on a port

1. Enter system view.
   System-view
2. Enter Layer 2/Layer 3 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the Ethernet OAM handshake packet transmission interval.
   oam timer hello *interval*

By default, an interface uses the value configured globally.

4. Configure the Ethernet OAM connection timeout timer.
   oam timer keepalive *interval*
   By default, an interface uses the value configured globally.

Configuring errored symbol event detection

Restrictions and guidelines for configuring errored symbol event detection

You can configure this function in system view or port view. The configuration in system view takes effect on all ports, and the configuration in port view takes effect on the specified port. For a port, the configuration in port view takes precedence.

Configuring errored symbol event detection globally

1. Enter system view.
   system-view
2. Configure the errored symbol event detection window.
   oam global errored-symbol-period window *window-value*
   By default, the errored symbol event detection window is 100000000.
3. Configure the errored symbol event triggering threshold.
   oam global errored-symbol-period threshold *threshold-value*
   By default, the errored symbol event triggering threshold is 1.

Configuring errored symbol event detection on a port

1. Enter system view.
   system-view
2. Enter Layer 2/Layer 3 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the errored symbol event detection window.
   oam errored-symbol-period window *window-value*
   By default, an interface uses the value configured globally.
4. Configure the errored symbol event triggering threshold.
   oam errored-symbol-period threshold *threshold-value*
   By default, an interface uses the value configured globally.

Configuring errored frame event detection

Restrictions and guidelines for configuring errored frame event detection

You can configure this function in system view or port view. The configuration in system view takes effect on all ports, and the configuration in port view takes effect on the specified port. For a port, the configuration in port view takes precedence.

Configuring errored frame event detection globally

1. Enter system view.
   system-view
2. Configure the errored frame event detection window.
   oam global errored-frame window *window-value*
   By default, the errored frame event detection window is 1000 milliseconds.
3. Configure the errored frame event triggering threshold.
   oam global errored-frame threshold *threshold-value*
   By default, the errored frame event triggering threshold is 1.

Configuring errored frame event detection on a port

1. Enter system view.
   system-view
2. Enter Layer 2/Layer 3 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the errored frame event detection window.
   oam errored-frame window *window-value*
   By default, an interface uses the value configured globally.
4. Configure the errored frame event triggering threshold.
   oam errored-frame threshold *threshold-value*
   By default, an interface uses the value configured globally.

Configuring errored frame period event detection

Restrictions and guidelines for configuring errored frame period event detection

You can configure this function in system view or port view. The configuration in system view takes effect on all ports, and the configuration in port view takes effect on the specified port. For a port, the configuration in port view takes precedence.

Configuring errored frame period event detection globally

1. Enter system view.

system-view

2. Configure the errored frame period event detection window.
   oam global errored-frame-period window *window-value*
   By default, the errored frame period event detection window is 10000000.
3. Configure the errored frame period event triggering threshold.
   oam global errored-frame-period threshold *threshold-value*
   By default, the errored frame period event triggering threshold is 1.

Configuring errored frame period event detection on a port

1. Enter system view.
   system-view
2. Enter Layer 2/Layer 3 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the errored frame period event detection window.
   oam errored-frame-period window *window-value*
   By default, an interface uses the value configured globally.
4. Configure the errored frame period event triggering threshold.
   oam errored-frame-period threshold *threshold-value*
   By default, an interface uses the value configured globally.

Configuring errored frame seconds event detection

Restrictions and guidelines for configuring errored frame seconds event detection

- You can configure this function in system view or port view. The configuration in system view takes effect on all ports, and the configuration in port view takes effect on the specified port. For a port, the configuration in port view takes precedence.
- Make sure the errored frame seconds triggering threshold is less than the errored frame seconds detection window. Otherwise, no errored frame seconds event can be generated.

Configuring errored frame seconds event detection globally

1. Enter system view.
   system-view
2. Configure the errored frame seconds event detection window.
   oam global errored-frame-seconds window *window-value*
   By default, the errored frame seconds event detection window is 60000 milliseconds.
3. Configure the errored frame seconds event triggering threshold.
   oam global errored-frame-seconds threshold *threshold-value*
   By default, the errored frame seconds event triggering threshold is 1.

Configuring errored frame seconds event detection on a port

1. Enter system view.
   system-view
2. Enter Layer 2/Layer 3 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the errored frame seconds event detection window.
   oam errored-frame-seconds window *window-value*
   By default, an interface uses the value configured globally.
4. Configure the errored frame seconds event triggering threshold.
   oam errored-frame-seconds threshold *threshold-value*
   By default, an interface uses the value configured globally.

Configuring the action a port takes after it receives an Ethernet OAM event from the remote end

About this task

This feature enables a port to log events and automatically terminate the OAM connection and set the link state to down.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2/Layer 3 Ethernet port view.
   interface *interface-type interface-number*
3. Configure the action the port takes after it receives an Ethernet OAM event from the remote end.
   oam remote-failure { **connection-expired** | **critical-event** | **dying-gasp** | **link-fault** } **action error-link-down**
   By default, the port only logs the Ethernet OAM event it receives from the remote end.

Enabling Ethernet OAM remote loopback for a port

△ **CAUTION:**
Use this feature with caution, because enabling Ethernet OAM remote loopback impacts other services.

About Ethernet OAM remote loopback

When you enable Ethernet OAM remote loopback on a port, the port sends Loopback Control OAMPDUs to a remote port. After receiving the Loopback Control OAMPDUs, the remote port enters the loopback state. The remote port then returns any packets sent from the local port except

OAMPDUs. By observing how many of these packets return, you can calculate the packet loss ratio on the link and evaluate the link performance.

Restrictions and guidelines for enabling Ethernet OAM remote loopback

- Ethernet OAM remote loopback is available only after the Ethernet OAM connection is established. It can be performed only by Ethernet OAM entities operating in active Ethernet OAM mode.
- Remote loopback is available only on full-duplex links that support remote loopback at both ends.
- Ethernet OAM remote loopback must be supported by both the remote port and the sending port.
- Enabling Ethernet OAM remote loopback interrupts data communications. After Ethernet OAM remote loopback is disabled, all the ports involved will go down and then come up. Ethernet OAM remote loopback can be disabled by any of the following events:
  - Disabling Ethernet OAM.
  - Disabling Ethernet OAM remote loopback.
  - Timeout of the Ethernet OAM connection.
- Enabling internal loopback test on a port in remote loopback test can terminate the remote loopback test. For more information about loopback test, see *Interface Configuration Guide*.
- You can enable Ethernet OAM remote loopback on a specific port in user view, system view, or Ethernet port view. The configuration effects are the same.

Enabling Ethernet OAM remote loopback for a port in system view

1. (Optional.) Enter system view.
   `system-view`
   You can also perform this task in user view.
2. Enable Ethernet OAM remote loopback for a port.
   `oam remote-loopback start interface` *`interface-type interface-number`*
   By default, Ethernet OAM remote loopback is disabled.

Enabling Ethernet OAM remote loopback for a port in interface view

1. Enter system view.
   `system-view`
2. Enter Layer 2/Layer 3 Ethernet port view.
   `interface` *`interface-type interface-number`*
3. Enable Ethernet OAM remote loopback on the port.
   `oam remote-loopback start`
   By default, Ethernet OAM remote loopback is disabled.

Rejecting the Ethernet OAM remote loopback request from a remote port

About this task

The Ethernet OAM remote loopback feature impacts other services. To solve this problem, you can disable a port from being controlled by the Loopback Control OAMPDUs sent by a remote port. The local port then rejects the Ethernet OAM remote loopback request from the remote port.

Restrictions and guidelines

This feature does not affect the ongoing remote loopback test on the port. It takes effect when the next remote loopback starts on the port.

Procedure

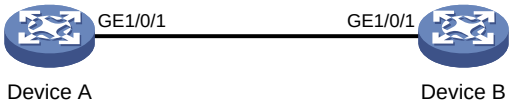
1. Enter system view.
   system-view
2. Enter Layer 2/Layer 3 Ethernet port view.
   interface *interface-type interface-number*
3. Reject the Ethernet OAM remote loopback request from a remote port.
   oam remote-loopback reject-request
   By default, a port does not reject the Ethernet OAM remote loopback request from a remote port.

Display and maintenance commands for Ethernet OAM

Execute **display** commands in any view and **reset** commands in user view:

Task	Command
Display information about an Ethernet OAM connection.	**display oam** { **local** | **remote** } [**interface** *interface-type interface-number*]
Display Ethernet OAM configuration.	**display oam configuration** [**interface** *interface-type interface-number*]
Display the statistics on critical events after an Ethernet OAM connection is established.	**display oam critical-event** [**interface** *interface-type interface-number*]
Display the statistics on Ethernet OAM link error events after an Ethernet OAM connection is established.	**display oam link-event** { **local** | **remote** } [**interface** *interface-type interface-number*]
Clear statistics on Ethernet OAM packets and Ethernet OAM link error events.	**reset oam** [**interface** *interface-type interface-number*]

Ethernet OAM configuration examples



Example: Configuring Ethernet OAM

Network configuration

On the network shown in Figure 1, perform the following operations:

- Enable Ethernet OAM on Device A and Device B to auto-detect link errors between the two devices
- Determine the performance of the link between Device A and Device B by collecting statistics about the error frames received by Device A

Figure 1 Network diagram

Procedure

1. Configure Device A:

   # Configure GigabitEthernet 1/0/1 to operate in active Ethernet OAM mode, and enable Ethernet OAM for it.

   ```
   <DeviceA> system-view
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] oam mode active
   [DeviceA-GigabitEthernet1/0/1] oam enable
   ```

   # Set the errored frame event detection window to 20000 milliseconds, and set the errored frame event triggering threshold to 10.

   ```
   [DeviceA-GigabitEthernet1/0/1] oam errored-frame window 200
   [DeviceA-GigabitEthernet1/0/1] oam errored-frame threshold 10
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

2. Configure Device B:

   # Configure GigabitEthernet 1/0/1 to operate in passive Ethernet OAM mode (the default), and enable Ethernet OAM for it.

   ```
   <DeviceB> system-view
   [DeviceB] interface gigabitethernet 1/0/1
   [DeviceB-GigabitEthernet1/0/1] oam mode passive
   [DeviceB-GigabitEthernet1/0/1] oam enable
   [DeviceB-GigabitEthernet1/0/1] quit
   ```

Verifying the configuration

Use the **`display oam critical-event`** command to display the statistics of Ethernet OAM critical link events. For example:

Display the statistics of Ethernet OAM critical link events on all the ports of Device A.

```
[DeviceA] display oam critical-event
-----------[GigabitEthernet1/0/1] -----------
 Local link status   : UP
 Event statistics
   Link fault        : Not occurred
```

```
   Dying gasp        : Not occurred
   Critical event    : Not occurred
```

The output shows that no critical link event occurred on the link between Device A and Device B.

Use the **display oam link-event** command to display the statistics of Ethernet OAM link events. For example:

Display Ethernet OAM link event statistics of the local end of Device A.

```
[DeviceA] display oam link-event local
------------ [GigabitEthernet1/0/1] -----------
 Link status: UP
 OAM local errored frame event
   Event time stamp        : 5789 x 100 milliseconds
   Errored frame window    : 200 x 100 milliseconds
   Errored frame threshold : 10 error frames
   Errored frame           : 13 error frames
   Error running total     : 350 error frames
   Event running total     : 17 events
```

The output shows the following:

- 350 errors occurred after Ethernet OAM is enabled on Device A.
- 17 errors were caused by error frames.
- The link is unstable.

Configuring CFD

About CFD

Connectivity Fault Detection (CFD), which conforms to IEEE 802.1ag Connectivity Fault Management (CFM) and ITU-T Y.1731, is an end-to-end per-VLAN link layer OAM mechanism. CFD is used for link connectivity detection, fault verification, and fault location.

Basic CFD concepts

Maintenance domain

A maintenance domain (MD) defines the network or part of the network where CFD plays its role. An MD is identified by its MD name.

Maintenance association

A maintenance association (MA) is a part of an MD. You can configure multiple MAs in an MD as needed. An MA is identified by the MD name + MA name.

An MA serves the specified VLAN or no VLAN. An MA that serves a VLAN is considered to be carrying VLAN attribute. An MA that serves no VLAN is considered to be carrying no VLAN attribute.

Maintenance point

An MP is configured on a port and belongs to an MA. MPs include the following types: maintenance association end points (MEPs) and maintenance association intermediate points (MIPs).

MEPs define the boundary of the MA. Each MEP is identified by a MEP ID.

MEPs include inward-facing MEPs and outward-facing MEPs:

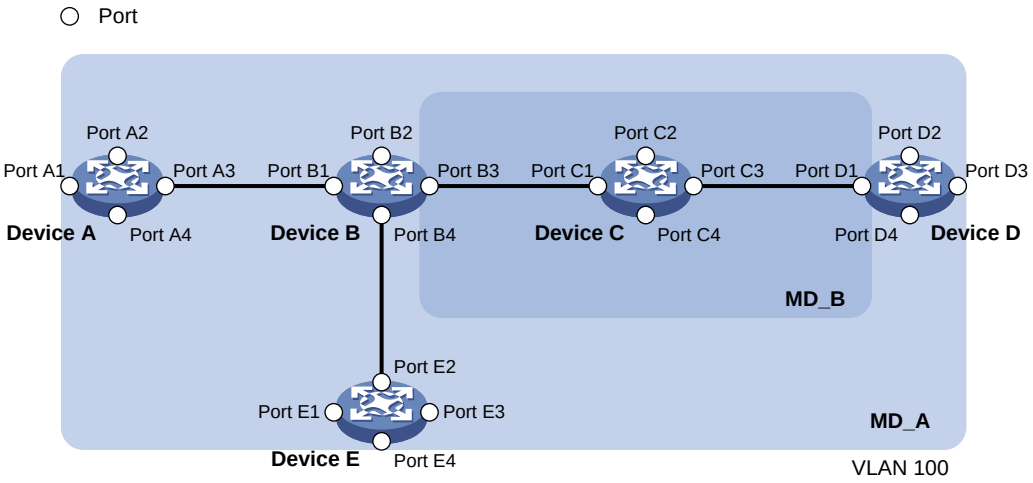
- An outward-facing MEP sends packets to its host port.
- An inward-facing MEP does not send packets to its host port. Rather, it sends packets to other ports on the device.

A MIP is internal to an MA. It cannot send CFD packets actively, but it can handle and respond to CFD packets. MIPs are automatically created by the device. By cooperating with MEPs, a MIP can perform a function similar to ping and traceroute.

MEP list

A MEP list is a collection of local MEPs allowed to be configured and the remote MEPs to be monitored in the same MA. It lists all the MEPs configured on different devices in the same MA. The MEPs all have unique MEP IDs. When a MEP receives from a remote device a continuity check message (CCM) carrying a MEP ID not in the MEP list of the MA, it drops the message.

The local device must send CCM messages carrying the Remote Defect Indication (RDI) flag bits. Otherwise, the peer device cannot sense certain failures. When a local MEP has not learned all remote MEPs in the MEP list, the MEPs in the MA might not carry the RDI flag bits in CCMs.



CFD levels

MD levels

To accurately locate faults, CFD introduces eight levels (from 0 to 7) to MDs. The bigger the number, the higher the level and the larger the area covered. Domains can touch or nest (if the outer domain has a higher level than the nested one) but cannot intersect or overlap.

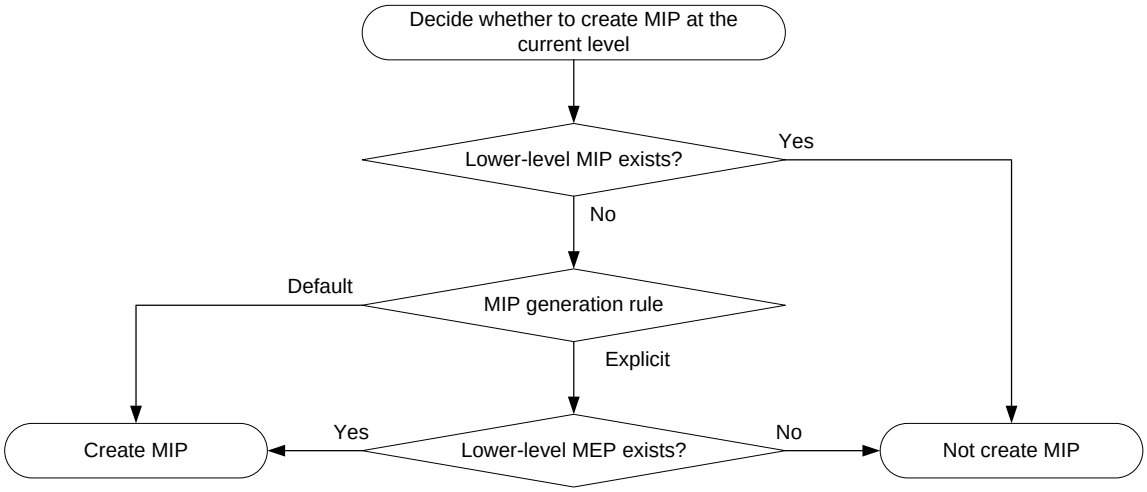
MD levels facilitate fault location and make fault location more accurate. As shown in Figure 1, MD_A in light blue nests MD_B in dark blue. If a connectivity fault is detected at the boundary of MD_A, any of the devices in MD_A, including Device A through Device E, might fail. If a connectivity fault is also detected at the boundary of MD_B, the failure points can be any of Device B through Device D. If the devices in MD_B can operate correctly, at least Device C is operational.

Figure 1 Two nested MDs

CFD exchanges messages and performs operations on a per-domain basis. By planning MDs correctly in a network, you can use CFD to rapidly locate failure points.

MA and MP levels

The level of an MA equals the level of the MD to which the MA belongs.



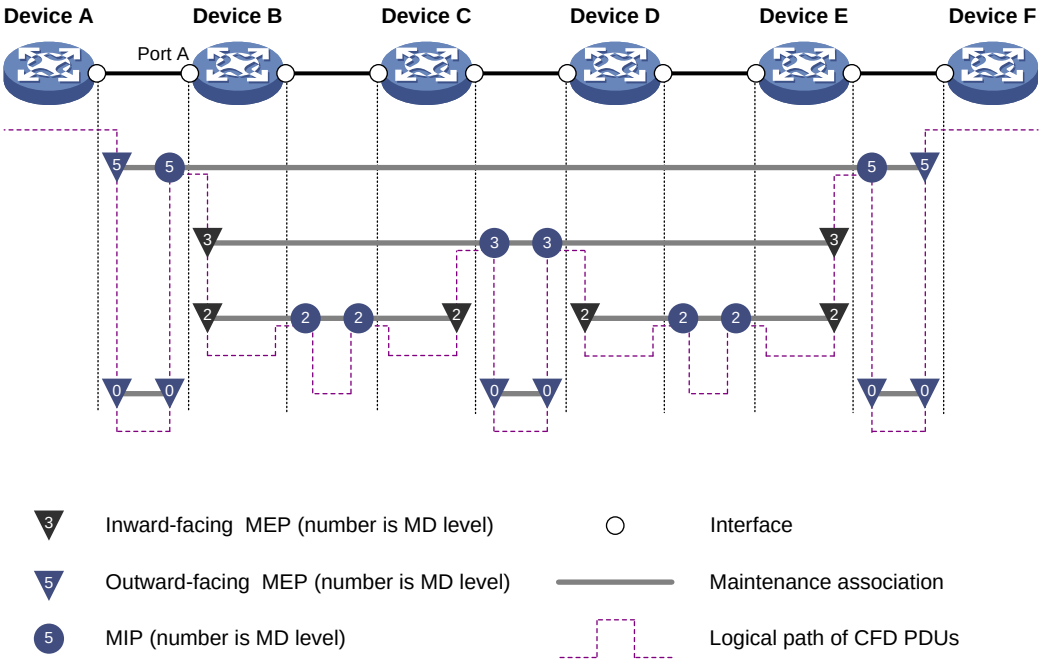
The level of a MEP equals the level of the MD to which the MEP belongs.

The level of a MIP is defined by its generation rule and the MD to which the MIP belongs. MIPs are generated on each port automatically according to the following MIP generation rules:

- **Default rule**—If no lower-level MIP exists on an interface, a MIP is created on the current level. A MIP can be created even if no MEP is configured on the interface.
- **Explicit rule**—If no lower-level MIP exists and a lower-level MEP exists on an interface, a MIP is created on the current level. A MIP can be created only when a lower-level MEP is created on the interface.

If a port has no MIP, the system will check the MAs in each MD (from low to high levels), and follow the procedure as described in Figure 2 to create or not to create MIPs at the current level.

Figure 2 Procedure of creating MIPs



CFD grading example

Figure 3 demonstrates a grading example of the CFD module. Four levels of MDs (0, 2, 3, and 5) are designed. The bigger the number, the higher the level and the larger the area covered. MPs are configured on the ports of Device A through Device F. Port A of Device B is configured with the following MPs:

- A level 5 MIP.
- A level 3 inward-facing MEP.
- A level 2 inward-facing MEP.
- A level 0 outward-facing MEP.

Figure 3 CFD grading example

Packet processing of MPs

For an MA carrying VLAN attribute, MPs of the MA send packets only in the VLAN that the MA serves. The level of packets sent by an MP equals the level of the MD to which the MP belongs.

For an MA not carrying VLAN attribute, MPs of the MA can only be outward-facing MEPs. The level of packets sent by an outward-facing MEP equals the level of the MD to which the MEP belongs.

A MEP forwards packets at a higher level without any processing and only processes packets of its level or lower.

A MIP forwards packets of a different level without any processing and only processes packets of its level.

CFD functions

CFD functions, which are implemented through the MPs, include:

- Continuity check (CC).
- Loopback (LB).
- Linktrace (LT).
- Alarm indication signal (AIS).
- Loss measurement (LM).
- Delay measurement (DM).
- Test (TST).

Continuity check

Connectivity faults are usually caused by device faults or configuration errors. Continuity check examines the connectivity between MEPs. This function is implemented through periodic sending of CCMs by the MEPs. A CCM sent by one MEP is intended to be received by all the other MEPs in the same MA. If a MEP fails to receive the CCMs within 3.5 times the sending interval, the link is considered as faulty and a log is generated. When multiple MEPs send CCMs at the same time, the multipoint-to-multipoint link check is achieved. CCM frames are multicast frames.

Loopback

Similar to ping at the IP layer, loopback verifies the connectivity between a source device and a target device. To implement this function, the source MEP sends loopback messages (LBMs) to the target MEP. Depending on whether the source MEP can receive a loopback reply message (LBR) from the target MEP, the link state between the two can be verified.

LBM frames are multicast and unicast frames. The device can send and receive unicast LBM frames, and can receive multicast LBM frames but cannot send multicast LBM frames. LBR frames are unicast frames.

Linktrace

Linktrace is similar to traceroute. It identifies the path between the source MEP and the target MP. The source MEP sends the linktrace messages (LTMs) to the target MP. After receiving the messages, the target MP and the MIPs that the LTM frames pass send back linktrace reply messages (LTRs) to the source MEP. Based on the reply messages, the source MEP can identify the path to the target MP. LTM frames are multicast frames and LTRs are unicast frames.

AIS

The AIS function suppresses the number of error alarms reported by MEPs. If a local MEP does not receive any CCM frames from its peer MEP within 3.5 times the CCM transmission interval, it immediately starts sending AIS frames. The AIS frames are sent periodically in the opposite direction of CCM frames. When the peer MEP receives the AIS frames, it suppresses the error alarms locally, and continues to send the AIS frames. If the local MEP receives CCM frames within 3.5 times the

CCM transmission interval, it stops sending AIS frames and restores the error alarm function. AIS frames are multicast frames.

LM

The LM function measures the frame loss in a certain direction between a pair of MEPs. The source MEP sends loss measurement messages (LMMs) to the target MEP. The target MEP responds with loss measurement replies (LMRs). The source MEP calculates the number of lost frames according to the counter values of the two consecutive LMRs (the current LMR and the previous LMR). LMMs and LMRs are unicast frames.

DM

The DM function measures frame delays between two MEPs, including the following types:

- One-way frame delay measurement

  The source MEP sends a one-way delay measurement (1DM) frame, which carries the transmission time, to the target MEP. When the target MEP receives the 1DM frame, it does the following:

  - Records the reception time.
  - Calculates and records the link transmission delay and jitter (delay variation) according to the transmission time and reception time.

  1DM frames are unicast frames.

- Two-way frame delay measurement

  The source MEP sends a delay measurement message (DMM), which carries the transmission time, to the target MEP. When the target MEP receives the DMM, it responds with a delay measurement reply (DMR). The DMR carries the reception time and transmission time of the DMM and the transmission time of the DMR. When the source MEP receives the DMR, it does the following:

  - Records the DMR reception time.
  - Calculates the link transmission delay and jitter according to the DMR reception time and DMM transmission time.

  DMM frames and DMR frames are unicast frames.

TST

The TST function tests the bit errors between two MEPs. The source MEP sends a TST frame, which carries the test pattern, such as pseudo random bit sequence (PRBS) or all-zero, to the target MEP. When the target MEP receives the TST frame, it determines the bit errors by calculating and comparing the content of the TST frame. TST frames are unicast frames.

EAIS

Ethernet Alarm Indication Signal (EAIS) enables collaboration between the Ethernet port status and the AIS function. When a port on the device (not necessarily an MP) goes down, it immediately starts to send EAIS frames periodically to suppress the error alarms. When the port goes up again, it immediately stops sending EAIS frames. When the MEP receives the EAIS frames, it suppresses the error alarms locally, and continues to send the EAIS frames. If a MEP receives no EAIS frames within 3.5 times the EAIS frame transmission interval, the fault is considered cleared. The port stops sending EAIS frames and restores the error alarm function. EAIS frames are multicast frames.

Collaboration between CFD and Track

CFD can collaborate with Track as follows:

- If CFD detects that the peer is reachable, it notifies the Track module. The Track module sets the state of the track entry to Positive.

- If CFD detects that the peer is unreachable, it notifies the Track module. The Track module sets the state of the track entry to Negative.

For more information about Track, see "Configuring Track."

Protocols and standards

- IEEE 802.1ag, *Virtual Bridged Local Area Networks Amendment 5: Connectivity Fault Management*
- ITU-T Y.1731, *OAM functions and mechanisms for Ethernet based networks*

Restrictions and guidelines: CFD configuration

When you configure CFD, follow these restrictions and guidelines:

- Configure CC before you use the MEP ID of the remote MEP to configure other CFD functions. This restriction does not apply when you use the MAC address of the remote MEP to configure other CFD functions.
- Typically, a port blocked by the spanning tree feature cannot receive or send CFD messages except in the following cases:
  - The port is configured as an outward-facing MEP.
  - The port is configured as a MIP or inward-facing MEP, which can still receive and send CFD messages except CCM messages.

  For more information about the spanning tree feature, see *Layer 2—LAN Switching Configuration Guide*.

CFD tasks at a glance

To configure CFD, perform the following tasks:

1. Configuring basic CFD settings
   a. Enabling CFD
   b. Configuring service instances
   c. Configuring MEPs
   d. Configuring MIP auto-generation rules
2. Configuring CFD functions
   a. Configuring CC
   b. (Optional.) Configuring LB
   c. (Optional.) Configuring LT
   d. (Optional.) Configuring AIS
   e. (Optional.) Configuring LM
   f. (Optional.) Configuring one-way DM
   g. (Optional.) Configuring two-way DM
   h. (Optional.) Configuring TST
3. (Optional.) Configuring EAIS
4. Enabling CC status change notification

Prerequisites for CFD

For CFD to work correctly, design the network by performing the following tasks:

- Grade the MDs in the entire network, and define the boundary of each MD.
- Assign a name for each MD. Make sure the devices in the same MD use the same MD name.
- Define the MA in each MD according to the VLAN you want to monitor.
- Assign a name for each MA. Make sure that the devices in the same MA in the same MD use the same MA name.
- Determine the MEP list of each MA in each MD. Make sure devices in the same MA maintain the same MEP list.
- At the edges of MD and MA, MEPs must be designed at the device port. MIPs can be designed on devices or ports that are not at the edges.

Configuring basic CFD settings

Enabling CFD

1. Enter system view.

   system-view
2. Enable CFD.

   cfd enable

   By default, CFD is disabled.

Configuring service instances

About this task

Before configuring the MEPs and MIPs, you must first configure service instances. A service instance is a set of service access points (SAPs), and belongs to an MA in an MD.

The MD and MA define the level attribute and VLAN attribute of the messages handled by the MPs in a service instance. The MPs of the MA that carries no VLAN attribute do not belong to any VLAN.

Procedure

1. Enter system view.

   system-view
2. Create an MD.

   cfd md *md-name* [**index** *index-value*] **level** *level-value* [**md-id** { **dns** *dns-name* | **mac** *mac-address subnumber* | **none** }]
3. Create a service instance.

   cfd service-instance *instance-id* **ma-id** { **icc-based** *ma-name* | **integer** *ma-num* | **string** *ma-name* | **vlan-based** [*vlan-id*] } [**ma-index** *index-value*] **md** *md-name* [**vlan** *vlan-id*]

Configuring MEPs

About this task

CFD is implemented through various operations on MEPs. As a MEP is configured on a service instance, the MD level and VLAN attribute of the service instance become the attribute of the MEP.

Restrictions and guidelines

- You can specify an interface as the MEP for only one of the non-VLAN-specific MAs at the same level. In addition, the MEP must be outward facing.
- If a MEP in a non-VLAN-specific MA does not receive a CCM message within 3.5 CCM intervals from a remote MEP, the local MEP sets its interface to link down state. This behavior of the local MEP facilitates fast switchover for RRPP or Smart Link.

Prerequisites

Before you configure MEPs, you must configure service instances.

Procedure

1. Enter system view.
   system-view
2. Configure a MEP list.
   cfd meplist *mep-list* **service-instance** *instance-id*
   The created MEP must be included in the configured MEP list.
3. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
4. Create a MEP.
   cfd mep *mep-id* **service-instance** *instance-id* { **inbound** | **outbound** }

Configuring MIP auto-generation rules

About this task

As functional entities in a service instance, MIPs respond to various CFD frames, such as LTM and LBM frames. You can configure MIP auto-generation rules for the system to automatically create MIPs.

Any of the following events can cause MIPs to be created or deleted after you have configured the **cfd mip-rule** command:

- Enabling or disabling CFD.
- Creating or deleting MEPs on a port.
- Changes occur to the VLAN attribute of a port.
- The rule specified in the **cfd mip-rule** command changes.

Restrictions and guidelines

- An MA carrying no VLAN attribute is typically used to detect direct link status. The system cannot generate MIPs for such MAs.
- For an MA carrying VLAN attribute, the system does not generate MIPs if the same or a higher level MEP exists on the interface.

Procedure

1. Enter system view.
   system-view

2. Configure MIP auto-generation rules.

   cfd mip-rule { **default** | **explicit** } **service-instance** *instance-id*

   By default, no rules for generating MIPs are configured, and the system does not automatically create any MIP.

Configuring CFD functions

Configuring CC

About this task

After the CC function is configured, MEPs in an MA can periodically send CCM frames to maintain connectivity.

You must configure CC before you use the MEP ID of the remote MEP to configure other CFD functions. This restriction does not apply when you use the MAC address of the remote MEP to configure other CFD functions.

When the lifetime of a CCM frame expires, the link to the sending MEP is considered disconnected. When setting the CCM interval, use the settings described in Table 1.

Table 1 CCM interval field encoding

CCM interval field	Transmission interval	Maximum CCM lifetime
1	10/3 milliseconds	35/3 milliseconds
2	10 milliseconds	35 milliseconds
3	100 milliseconds	350 milliseconds
4	1 second	3.5 seconds
5	10 seconds	35 seconds
6	60 seconds	210 seconds
7	600 seconds	2100 seconds

NOTE:

- The value range for the interval field is 1 to 7. If you set the value to 1 or 2, the continuity check might work incorrectly due to hardware restrictions.
- The CCM messages with an interval field value of 1 to 3 are short-interval CCM messages. The CCM messages with an interval field value of 4 to 7 are long-interval CCM messages.

Restrictions and guidelines

When you configure the CCM interval, follow these restrictions and guidelines:

- Configure the same CCM interval field value for all MEPs in the same MA.
- After the CCM interval field is modified, the MEP that does not support hardware CC must wait for another CCM interval before sending CCMs.
- If the device cannot process short-interval CCM messages, setting the CCM interval field value to smaller than 4 might cause the CC function to operate unsteadily.

Only outward-facing MEPs on a physical port support hardware CC. The hardware CC function does not take effect if the physical port is a member port of an aggregation group.

Procedure

1. Enter system view.

system-view

2. (Optional.) Set the CCM interval field.
   cfd cc interval *interval-value* **service-instance** *instance-id*
   By default, the interval field value is 4.
3. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
4. Enable CCM sending on a MEP.
   cfd cc service-instance *instance-id* **mep** *mep-id* **enable**
   By default, CCM sending is disabled on a MEP.
5. (Optional.) Enable hardware CC on a MEP.
   a. Return to system view.
      quit
   b. Enter Layer 2 Ethernet interface view.
      interface *interface-type interface-number*
   c. Enable hardware CC on a MEP.
      cfd hardware-cc service-instance *instance-id* **remote-mep** *mep-list*
      By default, hardware CC is disabled on a MEP.

Configuring LB

To verify the link state between the local MEP and the remote MEP, execute the following command in any view:

cfd loopback service-instance *instance-id* **mep** *mep-id* { **target-mac** *mac-address* | **target-mep** *target-mep-id* } [**number** *number*]

Configuring LT

About this task

LT can trace the path between source and target MEPs, and can locate link faults by automatically sending LT messages. The two functions are implemented in the following way:

- **Tracing path**—The source MEP first sends LTM messages to the target MEP. Based on the LTR messages in response to the LTM messages, the path between the two MEPs is identified.
- **LT messages automatic sending**—If the source MEP fails to receive CCM frames from the target MEP within 3.5 times the transmission interval, it considers the link faulty. The source MEP then sends LTM frames, with the TTL field set to the maximum value 255, to the target MEP. Based on the returned LTRs, the fault source is located.

Prerequisites

Before you configure LT on a MEP in an MA carrying VLAN attribute, create the VLAN to which the MA belongs.

Procedure

1. Identify the path between a source MEP and a target MEP.
   cfd linktrace service-instance *instance-id* **mep** *mep-id* { **target-mac** *mac-address* | **target-mep** *target-mep-id* } [**ttl** *ttl-value*] [**hw-only**]
   This command is available in any view.
2. Enter system view.
   system-view

3. Enable LT messages automatic sending.
   cfd linktrace auto-detection [**size** *size-value*]
   By default, LT messages automatic sending is disabled.

Configuring AIS

About this task

The AIS function suppresses the number of error alarms reported by MEPs.

Restrictions and guidelines

If you enable AIS, the MEPs in a service instance cannot send AIS frames in the following conditions:

- No AIS frame transmission level is configured.
- The AIS frame transmission level is lower than the MD level of the service instance.

If you enable AIS and configure an AIS frame transmission level equal to the MD level of a service instance, the MEPs in the service instance:

- Can suppress error alarms.
- Cannot send AIS frames to MDs with higher level.

Procedure

1. Enter system view.
   system-view
2. Enable AIS.
   cfd ais enable
   By default, AIS is disabled.
3. Configure the AIS frame transmission level.
   cfd ais level *level-value* **service-instance** *instance-id*
   By default, the AIS frame transmission level is not configured.
   The AIS frame transmission level must be higher than the MD level of the service instance.
4. Configure the AIS frame transmission interval.
   cfd ais period *period-value* **service-instance** *instance-id*
   By default, the AIS frame transmission interval is 1 second.

Configuring LM

About this task

The LM function measures frame loss between MEPs. Frame loss statistics include the number of lost frames, the frame loss ratio, and the average number of lost frames for the source and target MEPs.

Procedure

To configure LM, execute the following command in any view:

cfd slm service-instance *instance-id* **mep** *mep-id* { **target-mac** *mac-address* | **target-mep** *target-mep-id* } [**dot1p** *dot1p-value*] [**number** *number*] [**interval** *interval*]

Configuring one-way DM

About this task

The one-way DM function measures the one-way frame delay between two MEPs, and monitors and manages the link transmission performance.

Restrictions and guidelines

Follow these guidelines when you configure one-way DM on a MEP:

- One-way DM requires that the time setting at the transmitting MEP and the receiving MEP be the same. For the purpose of frame delay variation measurement, the requirement can be relaxed.
- To view the test result, use the **display cfd dm one-way history** command on the target MEP.

Procedure

To configure one-way DM, execute the following command in any view:

cfd dm one-way service-instance *instance-id* **mep** *mep-id* { **target-mac** *mac-address* | **target-mep** *target-mep-id* } [**number** *number*]

Configuring two-way DM

About this task

The two-way DM function measures the two-way frame delay, average two-way frame delay, and two-way frame delay variation between two MEPs. It also monitors and manages the link transmission performance.

Procedure

To configure two-way DM, execute the following command in any view:

cfd dm two-way service-instance *instance-id* **mep** *mep-id* { **target-mac** *mac-address* | **target-mep** *target-mep-id* } **dot1p** *dot1p-value*] [**number** *number*] [**interval** *interval*]

Configuring TST

About this task

The TST function detects bit errors on a link, and monitors and manages the link transmission performance.

Restrictions and guidelines

To view the test result, use the **display cfd tst** command on the target MEP.

Procedure

To configure TST, execute the following command in any view:

cfd tst service-instance *instance-id* **mep** *mep-id* { **target-mac** *mac-address* | **target-mep** *target-mep-id* } [**number** *number*] [**length-of-test** *length*] [**pattern-of-test** { **all-zero** | **prbs** } [**with-crc**]]

Configuring EAIS

Restrictions and guidelines

Follow these guidelines when you configure EAIS on a MEP:

- You can configure EAIS on a device that does not support or is not configured with CFD. However, EAIS must collaborate with the CFD function in the network, so you must configure CFD in the network.
- You can configure EAIS on the member port of an aggregation group, but the configuration does not take effect. If you configure EAIS on the port and then add it to an aggregation group, the EAIS configuration immediately fails to take effect. After the port leaves the aggregation group, the EAIS configuration takes effect.
- If the intersection of the configured VLANs where the EAIS frames can be transmitted and the VLANs to which the port belongs is empty, no EAIS frame is sent. If the intersection contains more than 70 VLANs and the EAIS frame transmission interval is 1 second, the CPU usage will be too high. As a best practice, set the EAIS frame transmission interval to 60 seconds in this case.

Procedure

1. Enter system view.

   system-view
2. Enable port status-AIS collaboration.

   cfd ais-track link-status global

   By default, port status-AIS collaboration is disabled.
3. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.

   interface *interface-type interface-number*
4. Configure the EAIS frame transmission level.

   cfd ais-track link-status level *level-value*

   By default, the EAIS frame transmission level is not configured.
5. Configure the EAIS frame transmission interval.

   cfd ais-track link-status period *period-value*

   By default, the EAIS frame transmission interval is not configured.
6. Specify the VLANs where the EAIS frames can be transmitted.

   cfd ais-track link-status vlan *vlan-list*

   By default, the EAIS frames can only be transmitted within the default VLAN of the port.

   The EAIS frames are transmitted within the intersection of the VLANs specified with this command and the existing VLANs on the device.

Enabling CC status change notification

About this task

In a CFD network, when the CC of a local MEP detects a link fault, this feature enables other MEPs in the service instance to notify the remote MEP that the CC status of the local MEP has changed to failed. If the port collaboration triggering event configured for the remote MEP is remote interface down status, the remote MEP will trigger port collaboration.

After you enable this feature, when the local MEP in a service instance detects a CC status change, other MEPs in the service instance will notify this status change to the remote MEP through CCMs.

Procedure

1. Enter system view.
   system-view
2. Enable CC status change notification.
   cfd mac-status-reference cc-status service-instance *instance-id*
   By default, CC status change notification is disabled.

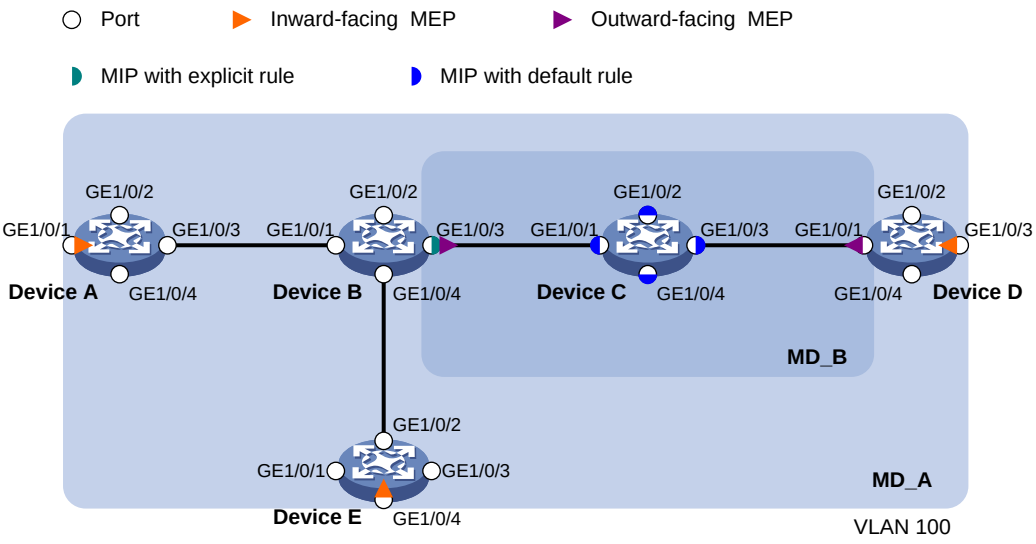
Display and maintenance commands for CFD

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the AIS configuration and information on the specified MEP.	**display cfd ais** [**service-instance** *instance-id* [**mep** *mep-id*]]
Display the AIS configuration and information associated with the status of the specified port.	**display cfd ais-track link-status** [**interface** *interface-type interface-number*]
Display the one-way DM result on the specified MEP.	**display cfd dm one-way history** [**service-instance** *instance-id* [**mep** *mep-id*]]
Display LTR information received by a MEP.	**display cfd linktrace-reply** [**service-instance** *instance-id* [**mep** *mep-id*]]
Display the content of the LTR messages received as responses to the automatically sent LTMs.	**display cfd linktrace-reply auto-detection** [**size** *size-value*]
Display MD configuration information.	**display cfd md**
Display the attribute and running information of the MEPs.	**display cfd mep** *mep-id* **service-instance** *instance-id*
Display MEP lists in a service instance.	**display cfd meplist** [**service-instance** *instance-id*]
Display MP information.	**display cfd mp** [**interface** *interface-type interface-number*]
Display information about a remote MEP.	**display cfd remote-mep service-instance** *instance-id* **mep** *mep-id*
Display service instance configuration.	**display cfd service-instance** [*instance-id*]
Display CFD status.	**display cfd status**
Display the TST result on the specified MEP.	**display cfd tst** [**service-instance** *instance-id* [**mep** *mep-id*]]
Clear the one-way DM result on the specified MEP.	**reset cfd dm one-way history** [**service-instance** *instance-id* [**mep** *mep-id*]]
Clear the TST result on the specified MEP.	**reset cfd tst** [**service-instance**

Task	Command
	instance-id [**mep** *mep-id*]]

CFD configuration examples



Example: Configuring CFD

Network configuration

As shown in Figure 4:

- The network comprises five devices and is divided into two MDs: MD_A (level 5) and MD_B (level 3). All ports belong to VLAN 100, and the MAs in the two MDs all serve VLAN 100. Assume that the MAC addresses of Device A through Device E are 0010-FC01-6511, 0010-FC02-6512, 0010-FC03-6513, 0010-FC04-6514, and 0010-FC05-6515, respectively.
- MD_A has three edge ports: GigabitEthernet 1/0/1 on Device A, GigabitEthernet 1/0/3 on Device D, and GigabitEthernet 1/0/4 on Device E. They are all inward-facing MEPs. MD_B has two edge ports: GigabitEthernet 1/0/3 on Device B and GigabitEthernet 1/0/1 on Device D. They are both outward-facing MEPs.
- In MD_A, Device B is designed to have MIPs when its port is configured with low level MEPs. Port GigabitEthernet 1/0/3 is configured with MEPs of MD_B, and the MIPs of MD_A can be configured on this port. You must configure the MIP generation rule of MD_A as explicit.
- The MIPs of MD_B are designed on Device C, and are configured on all ports. You must configure the MIP generation rule as default.
- Configure CC to monitor the connectivity among all the MEPs in MD_A and MD_B. Configure LB to locate link faults, and use the AIS and EAIS functions to suppress the error alarms that are reported.
- After the status information of the entire network is obtained, use LT, LM, one-way DM, two-way DM, and TST to detect link faults.

Figure 4 Network diagram

Procedure

1. Configure a VLAN and assign ports to it:

On each device shown in Figure 4, create VLAN 100 and assign ports GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4 to VLAN 100.

2. Enable CFD:

Enable CFD on Device A.

```
<DeviceA> system-view
[DeviceA] cfd enable
```

Configure Device B through Device E in the same way Device A is configured. (Details not shown.)

3. Configure service instances:

Create MD_A (level 5) on Device A, and create service instance 1 (in which the MA is identified by a VLAN and serves VLAN 100).

```
[DeviceA] cfd md MD_A level 5
[DeviceA] cfd service-instance 1 ma-id vlan-based md MD_A vlan 100
```

Configure Device E in the same way Device A is configured. (Details not shown.)

Create MD_A (level 5) on Device B, and create service instance 1 (in which the MA is identified by a VLAN and serves VLAN 100).

```
[DeviceB] cfd md MD_A level 5
[DeviceB] cfd service-instance 1 ma-id vlan-based md MD_A vlan 100
```

Create MD_B (level 3), and create service instance 2 (in which the MA is identified by a VLAN and serves VLAN 100).

```
[DeviceB] cfd md MD_B level 3
[DeviceB] cfd service-instance 2 ma-id vlan-based md MD_B vlan 100
```

Configure Device D in the same way Device B is configured. (Details not shown.)

Create MD_B (level 3) on Device C, and create service instance 2 (in which the MA is identified by a VLAN and serves VLAN 100).

```
[DeviceC] cfd md MD_B level 3
[DeviceC] cfd service-instance 2 ma-id vlan-based md MD_B vlan 100
```

4. Configure MEPs:

On Device A, configure a MEP list in service instance 1, and create inward-facing MEP 1001 in service instance 1 on GigabitEthernet 1/0/1.

```
[DeviceA] cfd meplist 1001 4002 5001 service-instance 1
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] cfd mep 1001 service-instance 1 inbound
[DeviceA-GigabitEthernet1/0/1] quit
```

On Device B, configure a MEP list in service instances 1 and 2.

```
[DeviceB] cfd meplist 1001 4002 5001 service-instance 1
[DeviceB] cfd meplist 2001 4001 service-instance 2
```

Create outward-facing MEP 2001 in service instance 2 on GigabitEthernet 1/0/3.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] cfd mep 2001 service-instance 2 outbound
[DeviceB-GigabitEthernet1/0/3] quit
```

On Device D, configure a MEP list in service instances 1 and 2.

```
[DeviceD] cfd meplist 1001 4002 5001 service-instance 1
[DeviceD] cfd meplist 2001 4001 service-instance 2
```

Create outward-facing MEP 4001 in service instance 2 on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] cfd mep 4001 service-instance 2 outbound
[DeviceD-GigabitEthernet1/0/1] quit
```

Create inward-facing MEP 4002 in service instance 1 on GigabitEthernet 1/0/3.

```
[DeviceD] interface gigabitethernet 1/0/3
[DeviceD-GigabitEthernet1/0/3] cfd mep 4002 service-instance 1 inbound
[DeviceD-GigabitEthernet1/0/3] quit
```

On Device E, configure a MEP list in service instance 1.

```
[DeviceE] cfd meplist 1001 4002 5001 service-instance 1
```

Create inward-facing MEP 5001 in service instance 1 on GigabitEthernet 1/0/4.

```
[DeviceE] interface gigabitethernet 1/0/4
[DeviceE-GigabitEthernet1/0/4] cfd mep 5001 service-instance 1 inbound
[DeviceE-GigabitEthernet1/0/4] quit
```

5. Configure MIPs:

Configure the MIP generation rule in service instance 1 on Device B as **explicit**.

```
[DeviceB] cfd mip-rule explicit service-instance 1
```

Configure the MIP generation rule in service instance 2 on Device C as **default**.

```
[DeviceC] cfd mip-rule default service-instance 2
```

6. Configure CC:

On Device A, enable the sending of CCM frames for MEP 1001 in service instance 1 on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] cfd cc service-instance 1 mep 1001 enable
[DeviceA-GigabitEthernet1/0/1] quit
```

On Device B, enable the sending of CCM frames for MEP 2001 in service instance 2 on GigabitEthernet 1/0/3.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] cfd cc service-instance 2 mep 2001 enable
[DeviceB-GigabitEthernet1/0/3] quit
```

On Device D, enable the sending of CCM frames for MEP 4001 in service instance 2 on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] cfd cc service-instance 2 mep 4001 enable
[DeviceD-GigabitEthernet1/0/1] quit
```

Enable the sending of CCM frames for MEP 4002 in service instance 1 on GigabitEthernet 1/0/3.

```
[DeviceD] interface gigabitethernet 1/0/3
[DeviceD-GigabitEthernet1/0/3] cfd cc service-instance 1 mep 4002 enable
[DeviceD-GigabitEthernet1/0/3] quit
```

On Device E, enable the sending of CCM frames for MEP 5001 in service instance 1 on GigabitEthernet 1/0/4.

```
[DeviceE] interface gigabitethernet 1/0/4
[DeviceE-GigabitEthernet1/0/4] cfd cc service-instance 1 mep 5001 enable
[DeviceE-GigabitEthernet1/0/4] quit
```

7. Configure hardware CC:

Configure hardware CC on GigabitEthernet 1/0/1 of Device D to enable MEP 4001 to receive CCM frames from MEP 2001.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] cfd hardware-cc service-instance 2 remote-mep 2001
[DeviceD-GigabitEthernet1/0/1] quit
```

8. Configure AIS:

Enable AIS on Device B. Configure the AIS frame transmission level as 5 and AIS frame transmission interval as 1 second in service instance 2.

```
[DeviceB] cfd ais enable
[DeviceB] cfd ais level 5 service-instance 2
[DeviceB] cfd ais period 1 service-instance 2
```

9. Configure EAIS:

Enable port status-AIS collaboration on Device B.

```
[DeviceB] cfd ais-track link-status global
```

On GigabitEthernet 1/0/3 of Device B, configure the EAIS frame transmission level as 5 and the EAIS frame transmission interval as 60 seconds. Specify the VLANs where the EAIS frames can be transmitted as VLAN 100.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] cfd ais-track link-status level 5
[DeviceB-GigabitEthernet1/0/3] cfd ais-track link-status period 60
[DeviceB-GigabitEthernet1/0/3] cfd ais-track link-status vlan 100
[DeviceB-GigabitEthernet1/0/3] quit
```

Verifying the configuration

1. Verify the LB function when the CC function detects a link fault:

Enable LB on Device A to check the status of the link between MEP 1001 and MEP 5001 in service instance 1.

```
[DeviceA] cfd loopback service-instance 1 mep 1001 target-mep 5001
Loopback to MEP 5001 with the sequence number start from 1001-43404:
Reply from 0010-fc05-6515: sequence number=1001-43404 time=5ms
Reply from 0010-fc05-6515: sequence number=1001-43405 time=5ms
Reply from 0010-fc05-6515: sequence number=1001-43406 time=5ms
Reply from 0010-fc05-6515: sequence number=1001-43407 time=5ms
Reply from 0010-fc05-6515: sequence number=1001-43408 time=5ms
Sent: 5        Received: 5        Lost: 0
```

2. Verify the LT function after the CC function obtains the status information of the entire network:

Identify the path between MEP 1001 and MEP 5001 in service instance 1 on Device A.

```
[DeviceA] cfd linktrace service-instance 1 mep 1001 target-mep 5001
Linktrace to MEP 5001 with the sequence number 1001-43462:
MAC address               TTL     Last MAC         Relay action
0010-fc05-6515            63      0010-fc02-6512   Hit
```

3. Verify the LM function after the CC function obtains the status information of the entire network:

Test the frame loss from MEP 1001 to MEP 4002 in service instance 1 on Device A.

```
[DeviceA] cfd slm service-instance 1 mep 1001 target-mep 4002
Reply from 0010-fc04-6514
Far-end frame loss: 10    Near-end frame loss: 20
Reply from 0010-fc04-6514
Far-end frame loss: 40    Near-end frame loss: 40
Reply from 0010-fc04-6514
Far-end frame loss: 0     Near-end frame loss: 10
Reply from 0010-fc04-6514
Far-end frame loss: 30    Near-end frame loss: 30

Average
Far-end frame loss: 20    Near-end frame loss: 25
```

```
Far-end frame loss rate: 25.00%    Near-end frame loss rate: 32.00%
Send LMMs: 5        Received: 5        Lost: 0
```

4. Verify the one-way DM function after the CC function obtains the status information of the entire network:

Test the one-way frame delay from MEP 1001 to MEP 4002 in service instance 1 on Device A.

```
[DeviceA] cfd dm one-way service-instance 1 mep 1001 target-mep 4002
5 1DMs have been sent. Please check the result on the remote device.
```

Display the one-way DM result on MEP 4002 in service instance 1 on Device D.

```
[DeviceD] display cfd dm one-way history service-instance 1 mep 4002
Service instance: 1
MEP ID: 4002
Sent 1DM total number: 0
Received 1DM total number: 5
Frame delay: 10ms 9ms 11ms 5ms 5ms
Delay average: 8ms
Delay variation: 5ms 4ms 6ms 0ms 0ms
Variation average: 3ms
```

5. Verify the two-way DM function after the CC function obtains the status information of the entire network:

Test the two-way frame delay from MEP 1001 to MEP 4002 in service instance 1 on Device A.

```

Configuring DLDP

About DLDP

Physical layer detection mechanisms, such as auto-negotiation, can detect physical signals and faults. However, they cannot detect communication failures for unidirectional links where the physical layer is in connected state.

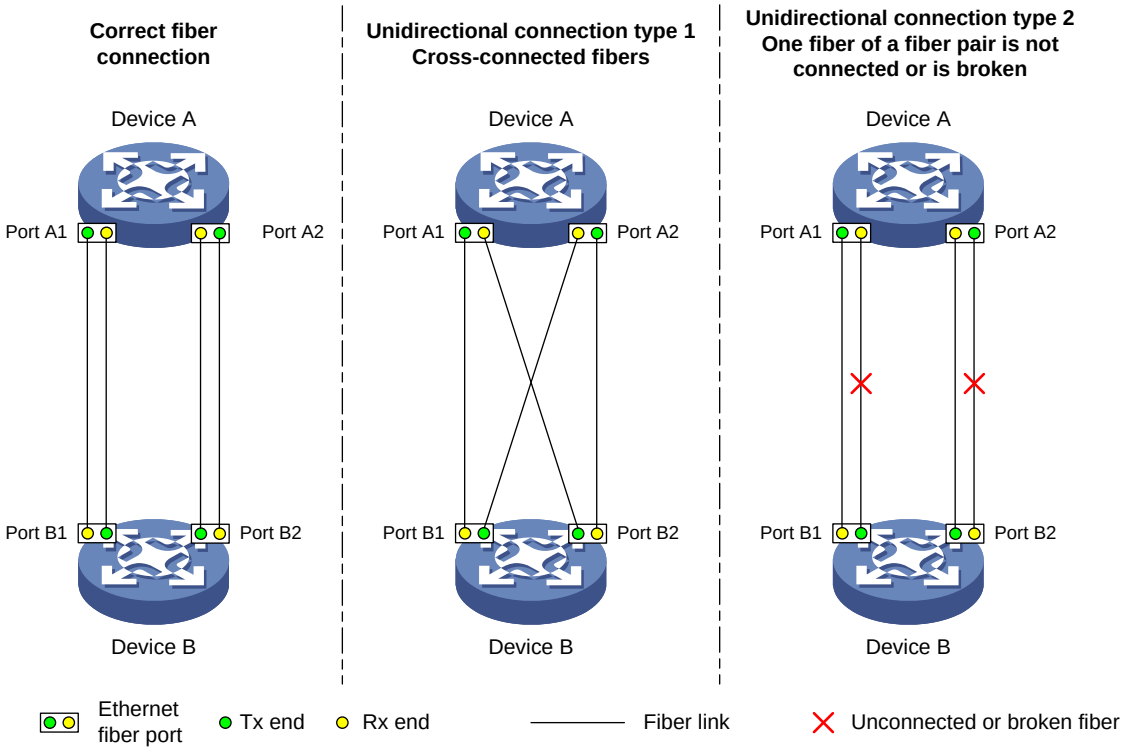
As an H3C-proprietary data link layer protocol, the Device Link Detection Protocol (DLDP) can do the following:

- Monitor status of the fiber link or twisted-pair link at the link layer.
- Cooperate with physical layer protocols to detect whether the link is correctly connected and whether the two ends of the link can exchange packets correctly.

When DLDP detects unidirectional links, it can automatically shut down the faulty port to avoid network problems. Alternatively, a user can manually shut down the faulty port.

Application scenario

A link becomes unidirectional when only one end of the link can receive packets from the other end.



Unidirectional fiber links occur in the following cases:

- Fibers are cross-connected.
- A fiber is not connected at one end or one fiber of a fiber pair is broken.

Figure 1 shows a correct fiber connection and two types of unidirectional fiber connections.

When DLDP detects unidirectional links, it can automatically shut down the faulty port to avoid network problems. Alternatively, a user can manually shut down the faulty port.

Figure 1 Correct and incorrect fiber connections

Basic concepts

DLDP neighbor states

If port A can receive link-layer packets from port B on the same link, port B is a DLDP neighbor of port A. Two ports that can exchange packets are neighbors.

Table 1 DLDP neighbor states

DLDP timer	Description
Confirmed	The link to a DLDP neighbor is bidirectional.
Unconfirmed	The state of the link to a newly discovered neighbor is not determined.

DLDP port states

A DLDP-enabled port is called a DLDP port. A DLDP port can have multiple neighbors, and its state varies by the DLDP neighbor state.

Table 2 DLDP port states

State	Description
Initial	DLDP is enabled on the port, but is disabled globally.
Inactive	DLDP is enabled on the port and globally, and the link is physically down.
Bidirectional	DLDP is enabled on the port and globally, and at least one neighbor in Confirmed state exists.
Unidirectional	DLDP is enabled on the port and globally, and no neighbor in Confirmed state exists. In this state, a port does not send or receive packets other than DLDP packets any more.

DLDP timers

Table 3 DLDP timers

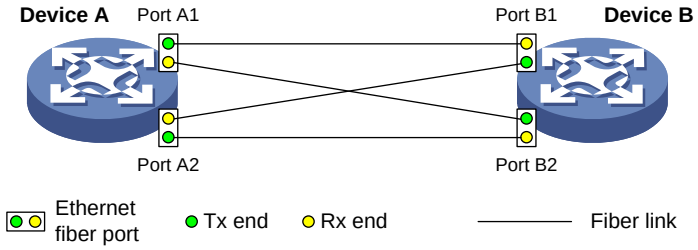
DLDP timer	Description
Advertisement timer	Advertisement packet sending interval (the default is 5 seconds and is configurable).
Probe timer	Probe packet sending interval. This timer is set to 1 second.
Echo timer	The Echo timer is triggered when a probe is launched for a new neighbor. The neighbor information is deleted when the timer expires. This timer is set to 10 seconds.
Entry timer	When a new neighbor joins, a neighbor entry is created and the corresponding Entry timer is triggered if the neighbor is in Confirmed state. When an Advertisement is received, the device updates the corresponding neighbor entry and the Entry timer. When the Entry timer expires, the Enhanced timer and Echo timer are triggered for the neighbor. The value of an Entry timer is three times that of the Advertisement timer.
Enhanced timer	Probe packet sending interval. This timer is set to 1 second. When the Entry timer expires, the Enhanced timer is triggered and probe packets are sent. At the same time, the Echo timer is triggered.
DelayDown timer	If a port is physically down, the device triggers the DelayDown timer, rather than removing the corresponding neighbor entry. The default DelayDown timer is 1 second and is configurable. When the DelayDown timer expires, the device removes the corresponding DLDP neighbor information if the port is down, and does not perform any operation if the port is up.
RecoverProbe timer	This timer is set to 2 seconds. A port in unidirectional state regularly sends RecoverProbe packets to detect whether a unidirectional link has been restored to bidirectional.

DLDP authentication mode

You can use DLDP authentication to prevent network attacks and illegal detecting.

Table 4 DLDP authentication mode

Authentication mode	Processing at the DLDP packet sending side	Processing at the DLDP packet receiving side
Non-authentication	The sending side sets the Authentication field of DLDP packets to 0.	The receiving side examines the authentication information of received DLDP packets and drops packets where the authentication information conflicts with the local configuration.
Plaintext authentication	The sending side sets the Authentication field to the password configured in plain text.	
MD5 authentication	The sending side encrypts the user configured password by using MD5 algorithm, and assigns the digest to the Authentication field.	



How DLDP works

Detecting one neighbor

When two devices are connected through an optical fiber or a network cable, enable DLDP to detect unidirectional links to the neighbor. The following illustrates the unidirectional link detection process in two cases:

- Unidirectional links occur before you enable DLDP.

  Figure 2 Cross-connected fibers

  As shown in Figure 2, before you enable DLDP, the optical fibers between Device A and Device B are cross-connected. After you enable DLDP, the four ports are all up and in unidirectional state, and they send RecoverProbe packets. Take Port A1 as an example to illustrate the unidirectional link detection process.

  a. Port A1 receives the RecoverProbe packet from Port B2, and returns a RecoverEcho packet.

  b. Port B2 cannot receive any RecoverEcho packet from Port A1, so Port B2 cannot become the neighbor of Port A1.

  c. Port B1 can receive the RecoverEcho packet from Port A1, but Port B1 is not the intended destination, so Port B1 cannot become the neighbor of Port A1.

  The same process occurs on the other three ports. The four ports are all in unidirectional state.

- Unidirectional links occur after you enable DLDP.

  Figure 3 Broken fiber

  As shown in Figure 3, Device A and Device B are connected through an optical fiber. After you enable DLDP, Port A1 and Port B1 establish the bidirectional neighborship in the following way:

  a. Port A1 that is physically up enters the unidirectional state and sends a RecoverProbe packet.

  b. After receiving the RecoverProbe packet, Port B1 returns a RecoverEcho packet.

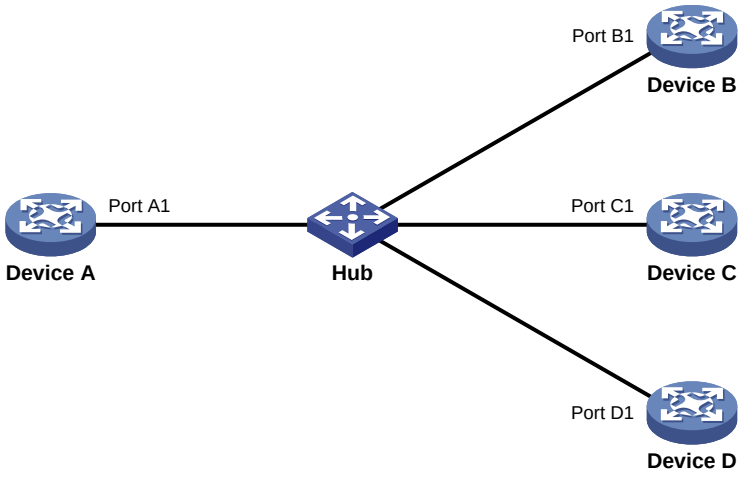
  c. After Port A1 receives the RecoverEcho packet, it examines the neighbor information in the packet. If the neighbor information matches the local information, Port A1 establishes the neighborship with Port B1 and transits to bidirectional state. Port A1 then starts the Entry timer and periodically sends Advertisement packets.

d. After Port B1 receives the Advertisement packet, it establishes the Unconfirmed neighborship with Port A1. Port B1 then starts the Echo timer and Probe timer, and periodically sends Probe packets.

e. After receiving the Probe packet, Port A1 returns an Echo packet.

f. After Port B1 receives the Echo packet, it examines the neighbor information in the packet. If the neighbor information matches the local information, the neighbor state of Port A1 becomes Confirmed. Port B1 then transits to bidirectional state, starts the Entry timer, and periodically sends Advertisement packets.

The bidirectional neighborship between Port A1 and Port B1 is now established.



After that, when Port B1's Rx end fails to receive signals, Port B1 is physically down and enters the Inactive state. Because Port B1's Tx end can still send signals to Port A1, Port A1 stays up. After the Entry timer for Port B1 expires, Port A1 starts the Enhanced timer and Echo timer, and sends a probe packet to Port B1. Because Port A1's Tx line is broken, Port A1 cannot receive the Echo packet from Port B1 after the Echo timer expires. Port A1 then enters the unidirectional state, and sends a Disable packet to Port B1. At the same time, Port A1 deletes the neighborship with Port B1, and starts the RecoverProbe timer. Port B1 stays in Inactive state during this process.

When an interface is physically down, but the Tx end of the interface is still operating, DLDP sends a LinkDown packet to inform the peer to delete the relevant neighbor entry.

Detecting multiple neighbors

When multiple devices are connected through a hub, enable DLDP on all interfaces connected to the hub to detect unidirectional links among the neighbors. When no Confirmed neighbor exists, an interface enters the unidirectional state.

Figure 4 Network diagram

As shown in Figure 4, Device A through Device D are connected through a hub, and enabled with DLDP. When Port A1, Port B1, and Port C1 detect that the link to Port D1 fails, they delete the neighborship with Port D1, but stay in bidirectional state.

Restrictions and guidelines: DLDP configuration

When you configure DLDP, follow these configuration restrictions and guidelines:

- For DLDP to operate correctly, enable DLDP on both sides and make sure the following settings are consistent:
  - Interval to send Advertisement packets.
  - DLDP authentication mode.

- Password.

- For DLDP to operate correctly, configure the full duplex mode for the ports at the two ends of the link, and configure the same speed for the two ports.

DLDP tasks at a glance

To configure DLDP, perform the following tasks:

1. Enabling DLDP
2. (Optional.) Setting the interval to send advertisement packets
3. (Optional.) Setting the DelayDown timer
4. (Optional.) Setting the port shutdown mode
5. (Optional.) Configuring DLDP authentication

Enabling DLDP

About this task

After a port is enabled with DLDP, the port enters Initial state and then transitions to Unidirectional state. By default, DLDP blocks a port immediately when the port transitions to Unidirectional state. This behavior causes a traffic disruption that lasts until the port enters Bidirectional state when establishing a Confirmed neighbor.

You can set the delay time for DLDP to block a port upon an Initial-to-Unidirectional state transition. DLDP does not block the port until the delay time expires.

Procedure

1. Enter system view.

   system-view

2. Enable DLDP globally.

   dldp global enable

   By default, DLDP is globally disabled.

3. Enter Ethernet interface view.

   interface *interface-type interface-number*

4. Enable DLDP and set the delay time for DLDP to block the port upon an Initial-to-Unidirectional state transition.

   dldp enable [**initial-unidirectional-delay** *time*]

   By default, DLDP is disabled on a port, and when DLDP is enabled, a port is blocked immediately upon an Initial-to-Unidirectional state transition.

Setting the interval to send advertisement packets

About this task

To make sure DLDP can detect unidirectional links before network performance deteriorates, set the advertisement interval appropriate for your network environment. As a best practice, use the default interval.

Procedure

1. Enter system view.

   system-view

2. Set the interval to send Advertisement packets.

   dldp interval *interval*

   By default, the interval is 5 seconds.

Setting the DelayDown timer

About this task

When the Tx line fails, some ports might go down and then come up again, causing optical signal jitters on the Rx line. To prevent the device from removing neighbor entries in such cases, set the DelayDown timer for the device. The device starts the DelayDown timer when a port goes down due to a Tx line failure. If the port remains down when the timer expires, the device removes the DLDP neighbor information. If the port comes up, the device takes no action.

Procedure

1. Enter system view.

   system-view

2. Set the DelayDown timer.

   dldp delaydown-timer *time*

   The default is 1 second.

   The DelayDown timer setting applies to all DLDP-enabled ports.

Setting the port shutdown mode

About this task

On detecting a unidirectional link, DLDP shuts down the ports in one of the following modes:

- **Auto mode**—When DLDP detects a unidirectional link, it shuts down the unidirectional port. When the link becomes bidirectional, DLDP brings up the port that was shut down.
- **Manual mode**—When DLDP detects a unidirectional link, it does not shut down the port. You need to manually shut it down. To verify the link status, use the **undo shutdown** command to bring up the port. If the link becomes bidirectional, the port becomes bidirectional. Use this mode to prevent normal links from being shut down because of false unidirectional link reports in the following cases:
  - The network performance is low.
  - The device is busy.
  - The CPU usage is high.
- **Hybrid mode**—When DLDP detects a unidirectional link, it shuts down the unidirectional port and stops link detection. To verify the link status, use the **undo shutdown** command to bring up the port. If the link becomes bidirectional, the port becomes bidirectional.

Restrictions and guidelines

You can set the port shutdown mode for all interfaces in system view or for a single interface in interface view. The setting in interface view takes precedence over the setting in system view.

To enable remote OAM loopback on a DLDP port, set the port shutdown mode to **manual**. Otherwise, DLDP automatically shuts down the port when it receives a packet sent by itself. This causes remote OAM loopback failure. For more information about Ethernet OAM, see "Configuring Ethernet OAM."

Setting the global port shutdown mode

1. Enter system view.

system-view

2. Set the global port shutdown mode.
   dldp unidirectional-shutdown { **auto** | **hybrid** | **manual** }
   The default mode is **auto**.

Setting the port shutdown mode for an interface

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Set the the port shutdown mode for the interface.
   dldp port unidirectional-shutdown { **auto** | **hybrid** | **manual** }
   By default, the global setting is used.

Configuring DLDP authentication

About this task

You can guard your network against attacks and malicious probes by configuring an appropriate DLDP authentication mode, which can be plain text authentication or MD5 authentication. If your network is safe, you can choose not to authenticate.

Procedure

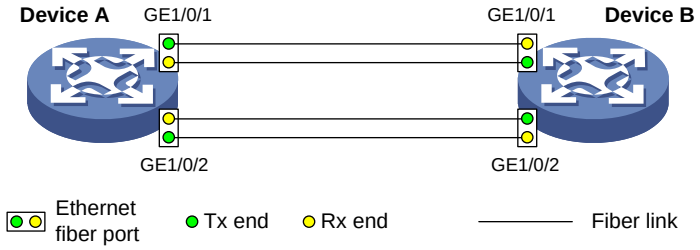
1. Enter system view.
   system-view
2. Configure a DLDP authentication mode.
   dldp authentication-mode { **md5** | **none** | **simple** }
   The default authentication mode is **none**.
3. Configure the password for DLDP authentication.
   dldp authentication-password { **cipher** | **simple** } *string*
   By default, no password is configured for DLDP authentication.
   If you do not configure the authentication password after you configure the authentication mode, the authentication mode is **none** no matter which authentication mode you configure.

Display and maintenance commands for DLDP

Execute **display** commands in any view and the **reset** command in user view.

Task	Command
Display the DLDP configuration globally and of a port.	**display dldp** [**interface** *interface-type interface-number*]
Display the statistics on DLDP packets passing through a port.	**display dldp statistics** [**interface** *interface-type interface-number*]
Clear the statistics on DLDP packets passing through a port.	**reset dldp statistics** [**interface** *interface-type interface-number*]

DLDP configuration examples



Example: Configuring the auto port shutdown mode

Network configuration

As shown in Figure 5, Device A and Device B are connected through two fiber pairs.

Configure DLDP to automatically shut down the faulty port upon detecting a unidirectional link, and automatically bring up the port after you clear the fault.

Figure 5 Network diagram

Procedure

1. Configure Device A:

   # Enable DLDP globally.

   ```
   <DeviceA> system-view
   [DeviceA] dldp global enable
   ```

   # Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] duplex full
   [DeviceA-GigabitEthernet1/0/1] speed 1000
   [DeviceA-GigabitEthernet1/0/1] dldp enable
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

   ```
   [DeviceA] interface gigabitethernet 1/0/2
   [DeviceA-GigabitEthernet1/0/2] duplex full
   [DeviceA-GigabitEthernet1/0/2] speed 1000
   [DeviceA-GigabitEthernet1/0/2] dldp enable
   [DeviceA-GigabitEthernet1/0/2] quit
   ```

   # Set the global port shutdown mode to auto.

   ```
   [DeviceA] dldp unidirectional-shutdown auto
   ```

2. Configure Device B:

   # Enable DLDP globally.

   ```
   <DeviceB> system-view
   [DeviceB] dldp global enable
   ```

   # Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

   ```
   [DeviceB] interface gigabitethernet 1/0/1
   [DeviceB-GigabitEthernet1/0/1] duplex full
   ```

```
[DeviceB-GigabitEthernet1/0/1] speed 1000
[DeviceB-GigabitEthernet1/0/1] dldp enable
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] duplex full
[DeviceB-GigabitEthernet1/0/2] speed 1000
[DeviceB-GigabitEthernet1/0/2] dldp enable
[DeviceB-GigabitEthernet1/0/2] quit
```

Set the global port shutdown mode to auto.

```
[DeviceB] dldp unidirectional-shutdown auto
```

Verifying the configuration

Display the DLDP configuration globally and on all the DLDP-enabled ports of Device A.

```
[DeviceA] display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Auto
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2

Interface GigabitEthernet1/0/1
 DLDP port state: Bidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 1
  Neighbor state: Confirmed
  Neighbor aged time: 11s
  Neighbor echo time: -

Interface GigabitEthernet1/0/2
 DLDP port state: Bidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 2
  Neighbor state: Confirmed
  Neighbor aged time: 12s
  Neighbor echo time: -
```

The output shows that both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are bidirectional.

Enable the monitoring of logs on the current terminal on Device A. Set the lowest level of the logs that can be output to the current terminal to 6.

```
[DeviceA] quit
<DeviceA> terminal monitor
```

```
The current terminal is enabled to display logs.
<DeviceA> terminal logging level 6
```

The following log information is displayed on Device A:

```
<DeviceA>%Jul 11 17:40:31:089 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the
interface Physical state on the interface GigabitEthernet1/0/1 changed to down.
%Jul 11 17:40:31:091 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/1 changed to down.
%Jul 11 17:40:31:677 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
Physical state on the interface GigabitEthernet1/0/2 changed to down.
%Jul 11 17:40:31:678 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/2 changed to down.
%Jul 11 17:40:38:544 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
Physical state on the interface GigabitEthernet1/0/1 l changed to up.
%Jul 11 17:40:38:836 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
Physical state on the interface GigabitEthernet1/0/2 changed to up.
```

The output shows the following:

- The port status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 is down and then up.
- The link status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 is always down.

Display the DLDP configuration globally and of all the DLDP-enabled ports.

```
<DeviceA> display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Auto
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2

Interface GigabitEthernet1/0/1
 DLDP port state: Unidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 0 (Maximum number ever detected: 1)

Interface GigabitEthernet1/0/2
 DLDP port state: Unidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 0 (Maximum number ever detected: 1)
```

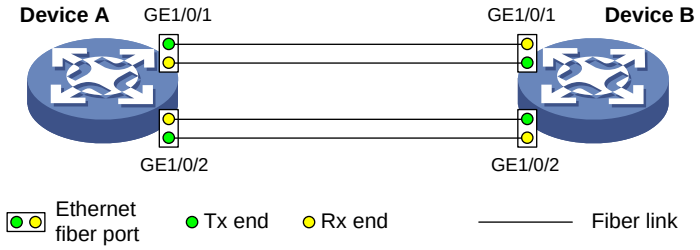
The output shows that the DLDP port status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 is unidirectional. DLDP detects unidirectional links on them and automatically shuts down the two ports.

The unidirectional links are caused by cross-connected fibers. Correct the fiber connections. As a result, the ports shut down by DLDP automatically recover, and Device A displays the following log information:

```
<DeviceA>%Jul 11 17:42:57:709 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the
interface GigabitEthernet1/0/1 changed to down.
%Jul 11 17:42:58:603 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/2 changed to down.
```

```
%Jul 11 17:43:02:342 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/1 changed to up.
%Jul 11 17:43:02:343 2012 DeviceA DLDP/6/DLDP_NEIGHBOR_CONFIRMED: A neighbor was confirmed
on interface GigabitEthernet1/0/1. The neighbor's system MAC is 0023-8956-3600, and the
port index is 1.
%Jul 11 17:43:02:344 2012 DeviceA DLDP/6/DLDP_LINK_BIDIRECTIONAL: DLDP detected a
bidirectional link on interface GigabitEthernet1/0/1.
%Jul 11 17:43:02:353 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/1 changed to up.
%Jul 11 17:43:02:357 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/2 changed to up.
%Jul 11 17:43:02:362 2012 DeviceA DLDP/6/DLDP_NEIGHBOR_CONFIRMED: A neighbor was confirmed
on interface GigabitEthernet1/0/2. The neighbor's system MAC is 0023-8956-3600, and the
port index is 2.
%Jul 11 17:43:02:362 2012 DeviceA DLDP/6/DLDP_LINK_BIDIRECTIONAL: DLDP detected a
bidirectional link on interface GigabitEthernet1/0/2.
%Jul 11 17:43:02:368 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/2 changed to up.
```

The output shows that the port status and link status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are now up and their DLDP neighbors are determined.



Example: Configuring the manual port shutdown mode

Network configuration

As shown in Figure 6, Device A and Device B are connected through two fiber pairs.

Configure DLDP to detect unidirectional links. When a unidirectional link is detected, the administrator must manually shut down the port.

Figure 6 Network diagram

Procedure

1. Configure Device A:

   # Enable DLDP globally.

   ```
   <DeviceA> system-view
   [DeviceA] dldp enable
   ```

   # Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] duplex full
   [DeviceA-GigabitEthernet1/0/1] speed 1000
   [DeviceA-GigabitEthernet1/0/1] dldp enable
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] duplex full
[DeviceA-GigabitEthernet1/0/2] speed 1000
[DeviceA-GigabitEthernet1/0/2] dldp enable
[DeviceA-GigabitEthernet1/0/2] quit
```

Set the global port shutdown mode to manual.

```
[DeviceA] dldp unidirectional-shutdown manual
```

2. Configure Device B:

Enable DLDP globally.

```
<DeviceB> system-view
[DeviceB] dldp global enable
```

Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] duplex full
[DeviceB-GigabitEthernet1/0/1] speed 1000
[DeviceB-GigabitEthernet1/0/1] dldp enable
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] duplex full
[DeviceB-GigabitEthernet1/0/2] speed 1000
[DeviceB-GigabitEthernet1/0/2] dldp enable
[DeviceB-GigabitEthernet1/0/2] quit
```

Set the global port shutdown mode to manual.

```
[DeviceB] dldp unidirectional-shutdown manual
```

Verifying the configuration

Display the DLDP configuration globally and on all the DLDP-enabled ports of Device A.

```
[DeviceA] display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Manual
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2

Interface GigabitEthernet1/0/1
 DLDP port state: Bidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port's neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 1
  Neighbor state: Confirmed
  Neighbor aged time: 11s
```

```
  Neighbor echo time: -

Interface GigabitEthernet1/0/2
 DLDP port state: Bidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port's neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 2
  Neighbor state: Confirmed
  Neighbor aged time: 12s
  Neighbor echo time: -
```

The output shows that both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are in bidirectional state, which means both links are bidirectional.

Enable the monitoring of logs on the current terminal on Device A. Set the lowest level of the logs that can be output to the current terminal to 6.

```
[DeviceA] quit
<DeviceA> terminal monitor
The current terminal is enabled to display logs.
<DeviceA> terminal logging level 6
```

The following log information is displayed on Device A:

```
<DeviceA>%Jul 12 08:29:17:786 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the
interface GigabitEthernet1/0/1 changed to down.
%Jul 12 08:29:17:787 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/1 changed to down.
%Jul 12 08:29:17:800 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/2 changed to down.
%Jul 12 08:29:17:800 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/2 changed to down.
%Jul 12 08:29:25:004 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/1 changed to up.
%Jul 12 08:29:25:005 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/1 changed to up.
%Jul 12 08:29:25:893 2012 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/2 changed to up.
%Jul 12 08:29:25:894 2012 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/2 changed to up.
```

The output shows that the port status and link status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are down and then up.

Display the DLDP configuration globally and of all the DLDP-enabled ports.

```
<DeviceA> display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Manual
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2

Interface GigabitEthernet1/0/1
```

```
 DLDP port state: Unidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 0 (Maximum number ever detected: 1)

Interface GigabitEthernet1/0/2
 DLDP port state: Unidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 0 (Maximum number ever detected: 1)
```

The output shows that the DLDP port status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 is unidirectional. DLDP detects unidirectional links on the two ports but does not shut them down.

The unidirectional links are caused by cross-connected fibers. Manually shut down the two ports:

Shut down GigabitEthernet 1/0/1.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] shutdown
```

The following log information is displayed on Device A:

```
[DeviceA-GigabitEthernet1/0/1]%Jul 12 08:34:23:717 2012 DeviceA IFNET/3/PHY_UPDOWN:
Physical state on the interface GigabitEthernet1/0/1 changed to down.

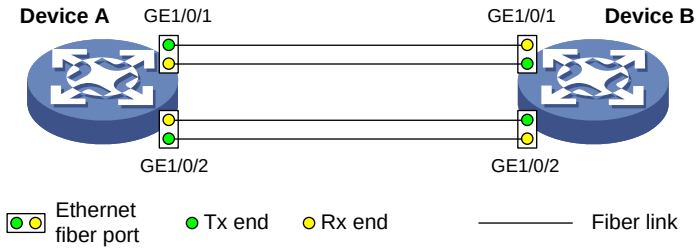
bidirectional link on interface GigabitEthernet1/0/1.
```

The output shows that the port status and link status of GigabitEthernet 1/0/1 are now up and its DLDP neighbors are determined.



Example: Configuring the hybrid port shutdown mode

Network configuration

As shown in Figure 7Figure 6, Device A and Device B are connected through two fiber pairs.

Configure DLDP to detect unidirectional links. When a unidirectional link is detected, DLDP automatically shuts down the unidirectional port. The administrator needs to bring up the port after clearing the fault.

Figure 7 Network diagram

Procedure

1. Configure Device A:

   # Enable DLDP globally.

   ```
   <DeviceA> system-view
   [DeviceA] dldp enable
   ```

   # Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] duplex full
   [DeviceA-GigabitEthernet1/0/1] speed 1000
   [DeviceA-GigabitEthernet1/0/1] dldp enable
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on the port.

   ```
   [DeviceA] interface gigabitethernet 1/0/2
   [DeviceA-GigabitEthernet1/0/2] duplex full
   ```

```
[DeviceA-GigabitEthernet1/0/2] speed 1000
[DeviceA-GigabitEthernet1/0/2] dldp enable
[DeviceA-GigabitEthernet1/0/2] quit
```

Set the global port shutdown mode to hybrid.

```
[DeviceA] dldp unidirectional-shutdown hybrid
```

2. Configure Device B:

Enable DLDP globally.

```
<DeviceB> system-view
[DeviceB] dldp global enable
```

Configure GigabitEthernet 1/0/1 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] duplex full
[DeviceB-GigabitEthernet1/0/1] speed 1000
[DeviceB-GigabitEthernet1/0/1] dldp enable
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 to operate in full duplex mode and at 1000 Mbps, and enable DLDP on it.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] duplex full
[DeviceB-GigabitEthernet1/0/2] speed 1000
[DeviceB-GigabitEthernet1/0/2] dldp enable
[DeviceB-GigabitEthernet1/0/2] quit
```

Set the global port shutdown mode to hybrid.

```
[DeviceB] dldp unidirectional-shutdown hybrid
```

Verifying the configuration

Display the DLDP configuration globally and on all the DLDP-enabled ports of Device A.

```
[DeviceA] display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Hybrid
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2

Interface GigabitEthernet1/0/1
 DLDP port state: Bidirectional
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port's neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 1
  Neighbor state: Confirmed
  Neighbor aged time: 11s
  Neighbor echo time: -

Interface GigabitEthernet1/0/2
 DLDP port state: Bidirectional
```

```
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port’s neighbors: 1
  Neighbor MAC address: 0023-8956-3600
  Neighbor port index: 2
  Neighbor state: Confirmed
  Neighbor aged time: 12s
  Neighbor echo time: -
```

The output shows that both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are in bidirectional state, which means both links are bidirectional.

Enable the monitoring of logs on the current terminal on Device A. Set the lowest level of the logs that can be output to the current terminal to 6.

```
[DeviceA] quit
<DeviceA> terminal monitor
The current terminal is enabled to display logs.
<DeviceA> terminal logging level 6
```

The following log information is displayed on Device A:

```
<DeviceA>%Jan  4 07:16:06:556 2011 DeviceA DLDP/5/DLDP_NEIGHBOR_AGED: A neighbor on
interface
GigabitEthernet1/0/1 was deleted because the neighbor was aged. The neighbor's system MAC
is 0023-8956-3600, and the port index is 162.
%Jan  4 07:16:06:560 2011 DeviceA DLDP/5/DLDP_NEIGHBOR_AGED: A neighbor on interface
GigabitEthernet1/0/2 was deleted because the neighbor was aged. The neighbor's system MAC
is 0023-8956-3600, and the port index is 165.
%Jan  4 07:16:06:724 2011 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/1 changed to down.
%Jan  4 07:16:06:730 2011 DeviceA IFNET/3/PHY_UPDOWN: Physical state on the interface
GigabitEthernet1/0/2 changed to down.
%Jan 4 07:16:06:736 2011 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/1 changed to down.
%Jan 4 07:16:06:738 2011 DeviceA IFNET/5/LINK_UPDOWN: Line protocol state on the interface
GigabitEthernet1/0/2 changed to down.
%Jan  4 07:16:07:152 2011 DeviceA DLDP/3/DLDP_LINK_UNIDIRECTIONAL: DLDP detected a
unidirectional link on interface GigabitEthernet1/0/1. DLDP automatically shut down the
interface. Please manually bring up the interface.
%Jan  4 07:16:07:156 2011 DeviceA DLDP/3/DLDP_LINK_UNIDIRECTIONAL: DLDP detected a
unidirectional link on interface GigabitEthernet1/0/2. DLDP automatically shut down the
interface. Please manually bring up the interface.
```

The output shows that the port status and link status of both GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 are down.

Display the DLDP configuration globally and of all the DLDP-enabled ports.

```
<DeviceA> display dldp
 DLDP global status: Enabled
 DLDP advertisement interval: 5s
 DLDP authentication-mode: None
 DLDP unidirectional-shutdown mode: Hybrid
 DLDP delaydown-timer value: 1s
 Number of enabled ports: 2
```

```
Interface GigabitEthernet1/0/1
 DLDP port state: Inactive
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port's neighbors: 0 (Maximum number ever detected: 1)
Interface GigabitEthernet1/0/2
 DLDP port state: Inactive
 DLDP port unidirectional-shutdown mode: None
 DLDP initial-unidirectional-delay: 0s
 Number of the port's neighbors: 0 (Maximum number ever detected: 1)
```

The output shows that DLDP detects a unidirectional link and shuts down GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

The unidirectional links are caused by cross-connected fibers. Bring up the two ports after correcting the fiber connection:

Bring up GigabitEthernet 1/0/1.

```
<DeviceA> system-view
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] undo shutdown
```

The following log information is displayed on Device A:

```
[DeviceA-GigabitEthernet1/0/1]%Jan  4 07:33:26:574 2011 DeviceA IFNET/3/PHY_UPDOWN:
Physical state on the interface GigabitEthernet1/0/1 changed to up.
%Jan 4 07:33:57:562 2011 DeviceA DLDP/6/DLDP_NEIGHBOR_CONFIRMED: A neighbor was confirmed
on interface GigabitEthernet1/0/1. The neighbor's system MAC is 0023-8956-3600, and the
port index is 162.
%Jan  4 07:33:57:563 2011 DeviceA DLDP/6/DLDP_LINK_BIDIRECTIONAL: DLDP detected a

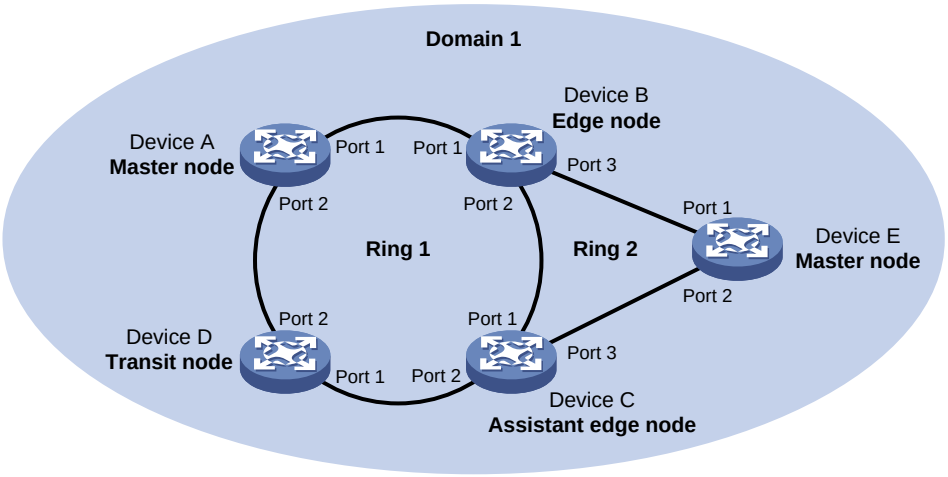
Configuring RRPP



About RRPP

The Rapid Ring Protection Protocol (RRPP) is an H3C-proprietary link layer protocol designed for Ethernet rings. RRPP can prevent broadcast storms caused by data loops when an Ethernet ring is healthy. RRPP can also rapidly restore the communication paths between the nodes when a link is disconnected on the ring. Compared with the spanning tree protocol, the convergence time of RRPP is fast and independent of the number of nodes in the Ethernet ring. RRPP is applicable to large-diameter networks.

RRPP networking

Figure 1 shows a typical RRPP network with two Ethernet rings and multiple nodes. RRPP detects ring status and sends topology change information by exchanging Rapid Ring Protection Protocol Data Units (RRPPDUs) among the nodes.

Figure 1 RRPP networking diagram

RRPP domain

An RRPP domain is uniquely identified by a domain ID. The interconnected devices with the same domain ID and control VLANs constitute an RRPP domain. An RRPP domain contains the following elements:

- Primary ring and subring.
- Control VLAN.
- Master node, transit node, edge node, and assistant edge node.
- Primary port, secondary port, common port, and edge port.

As shown in Figure 1, Domain 1 is an RRPP domain, containing two RRPP rings: Ring 1 and Ring 2. All the nodes on the two RRPP rings belong to the RRPP domain.

RRPP ring

A ring-shaped Ethernet topology is called an RRPP ring. RRPP rings include primary rings and subrings. You can configure a ring as either the primary ring or a subring by specifying its ring level. The primary ring is of level 0, and a subring is of level 1. An RRPP domain contains one or multiple

RRPP rings, one serving as the primary ring and the others serving as subrings. A ring can be in one of the following states:

- **`Health state`**—All physical links on the Ethernet ring are connected.
- **`Disconnect state`**—Some physical links on the Ethernet ring are not connected.

As shown in Figure 1, Domain 1 contains two RRPP rings: Ring 1 and Ring 2. The level is set to 0 for Ring 1 and 1 for Ring 2. Ring 1 is configured as the primary ring, and Ring 2 is configured as a subring.

Control VLAN and protected VLAN

1. Control VLAN

   In an RRPP domain, a control VLAN is dedicated to transferring RRPPDUs. On a device, the ports accessing an RRPP ring belong to the control VLANs of the ring, and only these ports can join the control VLANs.

   An RRPP domain is configured with the following control VLANs:

   - One primary control VLAN, which is the control VLAN for the primary ring.
   - One secondary control VLAN, which is the control VLAN for subrings.

   After you specify a VLAN as the primary control VLAN, the system automatically configures the secondary control VLAN. The VLAN ID is the primary control VLAN ID plus one. All subrings in the same RRPP domain share the same secondary control VLAN. IP address configuration is prohibited on the control VLAN interfaces.

2. Protected VLAN

   A protected VLAN is dedicated to transferring data packets. Both RRPP ports and non-RRPP ports can be assigned to a protected VLAN.

Node role

Each device on an RRPP ring is a node. The role of a node is configurable. RRPP has the following node roles:

- **Master node**—Each ring has only one master node. The master node initiates the polling mechanism and determines the operations to be performed after a topology change.
- **Transit node**—On the primary ring, transit nodes refer to all nodes except the master node. On the subring, transit nodes refer to all nodes except the master node and the nodes where the primary ring intersects with the subring. A transit node monitors the state of its directly connected RRPP links and notifies the master node of the link state changes, if any. Based on the link state changes, the master node determines the operations to be performed.
- **Edge node**—A special node residing on both the primary ring and a subring at the same time. An edge node acts as a master node or transit node on the primary ring and as an edge node on the subring.
- **Assistant edge node**—A special node residing on both the primary ring and a subring at the same time. An assistant edge node acts as a master node or transit node on the primary ring and as an assistant edge node on the subring. This node works in conjunction with the edge node to detect the integrity of the primary ring and to perform loop guard.

As shown in Figure 1, Ring 1 is the primary ring and Ring 2 is a subring. Device A is the master node of Ring 1. Device B, Device C, and Device D are the transit nodes of Ring 1. Device E is the master node of Ring 2, Device B is the edge node of Ring 2, and Device C is the assistant edge node of Ring 2.

Port role

1. Primary port and secondary port

   Each master node or transit node has two ports connected to an RRPP ring, a primary port and a secondary port. You can determine the role of a port.

   In terms of functionality, the primary port and the secondary port of a master node have the following differences:

- The primary port and the secondary port are designed to play the role of sending and receiving Hello packets, respectively.
- When an RRPP ring is in Health state, the secondary port logically denies protected VLANs and permits only the packets from the control VLANs.
- When an RRPP ring is in Disconnect state, the secondary port forwards packets from protected VLANs.

In terms of functionality, the primary port and the secondary port of a transit node are the same. Both are designed for transferring protocol packets and data packets over an RRPP ring.

As shown in Figure 1, Device A is the master node of Ring 1. Port 1 and Port 2 are the primary port and the secondary port of the master node on Ring 1, respectively. Device B, Device C, and Device D are the transit nodes of Ring 1. Their Port 1 and Port 2 are the primary port and the secondary port on Ring 1, respectively.

2. Common port and edge port

The ports connecting the edge node and assistant edge node to the primary ring are common ports. The ports connecting the edge node and assistant edge node only to the subrings are edge ports. You can determine the role of a port.

As shown in Figure 1, Device B and Device C reside on Ring 1 and Ring 2. Device B's Port 1 and Port 2 and Device C's Port 1 and Port 2 access the primary ring, so they are common ports. Device B's Port 3 and Device C's Port 3 access only the subring, so they are edge ports.

RRPP ring group

To reduce Edge-Hello traffic, you can configure a group of subrings on the edge node or assistant edge node. You must configure a device as the edge node of these subrings, and another device as the assistant edge node of these subrings. Additionally, the subrings of the edge node and assistant edge node must connect to the same subring packet tunnels in major ring (SRPTs). Edge-Hello packets of the edge node of these subrings travel to the assistant edge node of these subrings over the same link.

An RRPP ring group configured on the edge node is an edge node RRPP ring group. An RRPP ring group configured on an assistant edge node is an assistant edge node RRPP ring group. Only one subring in an edge node RRPP ring group is allowed to send Edge-Hello packets.

RRPPDUs

RRPPDUs of subrings are transmitted as data packets in the primary ring, and RRPPDUs of the primary ring can only be transmitted within the primary ring. In the primary ring, Common-Flush-FDB packets and Complete-Flush-FDB packets of subrings are sent to the CPU on each node for processing.

Table 1 RRPPDU types and their functions

Type	Description
Hello	The master node sends Hello packets (also known as Health packets) to detect the integrity of a ring in a network.
Fast-Hello	The master node sends Fast-Hello packets to detect the integrity of a ring in a network. Fast-Hello packets are used for the fast detection mechanism.
Link-Down	When a port on the transit node, edge node, or assistant edge node fails, the node initiates Link-Down packets to notify the master node of the disconnection of the ring.
Common-Flush-FDB	When an RRPP ring transits to Disconnect state, the master node initiates Common-Flush-FDB (FDB stands for Forwarding Database) packets. It uses the packets to instruct the transit nodes, edge nodes, and assistant edge nodes to update their own MAC address entries and ARP/ND entries.
Complete-Flush-FDB	When an RRPP ring transits to Health state, the master node sends

Type	Description
	Complete-Flush-FDB packets for the following purposes: • Instruct the transit nodes, edge nodes, and assistant edge nodes to update their MAC address entries and ARP/ND entries. • Instruct the transit nodes to unblock temporarily blocked ports.
Edge-Hello	The edge node sends Edge-Hello packets to examine the SRPTs between the edge node and the assistant edge node.
Fast-Edge-Hello	The edge node sends Fast-Edge-Hello packets to examine the SRPTs between it and the assistant edge node. Fast-Edge-Hello packets are used for the fast detection mechanism.
Major-Fault	The assistant edge node sends Major-Fault packets to notify the edge node of SRPT failure when an SRPT between assistant edge node and edge node is disconnected.

RRPP timers

When RRPP determines the link state of an Ethernet ring, it uses the following timers:

Hello timer

The Hello timer specifies the interval at which the master node sends Hello packets out of the primary port.

Fail timer

The Fail timer specifies the maximum delay of Hello packets sent from the primary port to the secondary port of the master node. If the secondary port receives the Hello packets sent by the local master node before the Fail timer expires, the ring is in Health state. If the secondary port does not receive the Hello packets before the Fail timer expires, the ring transits to Disconnect state.

In an RRPP domain, a transit node learns the Fail timer value on the master node through the received Hello packets. This ensures that all nodes in the ring network have consistent Fail timer settings.

Link-up delay timer

This feature prevents frequent switchover of RRPP traffic forwarding paths caused by unstable RRPP port states. This feature behaves differently depending on whether you specify the **`distribute`** keyword in the **`linkup-delay-timer`** command.

- If you do not specify the **`distribute`** keyword, the master node starts the link-up delay timer when a faulty port comes up and the master node receives Hello packets from the secondary port.
  - If the master node can still receive Hello packets from the secondary port after the link-up delay timer expires, the master node performs the following operations:
    - Changes the RRPP ring state from Disconnect to Health.
    - Switches the traffic from the secondary port to the primary port.
  - If the master node cannot receive Hello packets from the secondary port after the Fail timer expires and before the link-up delay timer expires, the master node performs the following operations:
    - Stops the link-up delay timer.
    - Keeps the RRPP ring in Disconnect state.
- If you specify the **`distribute`** keyword, all nodes in the RRPP domain can learn the value of the link-up delay timer through Hello packets. When the faulty port comes up, the master node performs the following operations:

- The hosting RRPP node blocks the faulty port (the faulty port cannot send or receive any packets).
- Starts the link-up delay timer.

If the port does not become faulty after the link-up delay timer expires, the hosting RRPP node sets the port state to up. The master node can receive Hello packets from its secondary port again. Then, the master node changes the RRPP ring state from Disconnect to Health and switches the traffic from the secondary port to the primary port.

If the port becomes faulty again before the link-up delay timer expires, the hosting RRPP node blocks the port and stops the link-up delay timer.

Fast-Hello timer

The Fast-Hello timer specifies the interval at which the master node sends Fast-Hello packets out of the primary port.

Fast-Fail timer

The Fast-Fail timer specifies the maximum delay of Fast-Hello packets sent from the primary port to the secondary port of the master node. If the secondary port receives the Fast-Hello packets before the Fast-Fail timer expires, the ring is in Health state. Otherwise, the ring transits to Disconnect state.

A transit node cannot learn the Fast-Fail timer value on the master node through received Fast-Hello packets.

Fast-Edge-Hello timer

The Fast-Edge-Hello timer specifies the interval at which the edge node sends Fast-Edge-Hello packets out of the common port.

Fast-Edge-Fail timer

The Fast-Edge-Fail timer specifies the maximum delay of Fast-Edge-Hello packets from the common port of the edge node to the common port of the assistant edge node. If the assistant edge node receives the Fast-Edge-Hello packets from the common port before the Fast-Edge-Fail timer expires, the ring is in Health state. Otherwise, the ring transits to Disconnect state.

How RRPP works

Polling mechanism

The polling mechanism is used by the master node of an RRPP ring to examine the Health state of the ring network.

The master node sends Hello packets out of its primary port at the Hello interval. These Hello packets travel through each transit node on the ring in turn.

- If the ring is complete, the secondary port of the master node receives Hello packets before the Fail timer expires. The master node keeps the secondary port blocked.
- If the ring is disconnected, the secondary port of the master node fails to receive Hello packets before the Fail timer expires. The master node releases the secondary port from blocking protected VLANs. It sends Common-Flush-FDB packets to instruct all transit nodes to update their own MAC address entries and ARP/ND entries.

Load balancing

In a ring network, traffic from multiple VLANs might be transmitted at the same time. RRPP can implement load balancing by transmitting traffic from different VLANs along different paths.

You can configure multiple RRPP domains for a ring network. Each RRPP domain transmits the traffic from the specified VLANs (protected VLANs). Traffic from different VLANs can be transmitted according to different topologies in the ring network for load balancing.

As shown in Figure 6, Ring 1 is configured as the primary ring of Domain 1 and Domain 2, which are configured with different protected VLANs. Device A is the master node of Ring 1 in Domain 1.

Device B is the master node of Ring 1 in Domain 2. With such configurations, traffic from different VLANs can be transmitted on different links for load balancing in the single-ring network.

Link down alarm mechanism

In an RRPP domain, when the transit node, edge node, or assistant edge node finds that any of its ports is down, it immediately sends Link-Down packets to the master node. When the master node receives a Link-Down packet, it takes the following actions:

- Releases the secondary port from blocking protected VLANs.
- Sends Common-Flush-FDB packets to instruct all the transit nodes, edge nodes, and assistant edge nodes to update their MAC address entries and ARP/ND entries.

After each node updates its own entries, traffic is switched to the normal link.

Ring recovery

When the ports in an RRPP domain on the transit nodes, edge nodes, or assistant edge nodes come up again, the ring is recovered. However, the master node might detect the ring recovery after a period of time. A temporary loop might arise in the protected VLAN during this period. As a result, a broadcast storm occurs.

To prevent such cases, non-master nodes block the ports immediately when they find the ports accessing the ring are brought up again. The nodes block only the packets from the protected VLAN, and they permit only the packets from the control VLAN to pass through. The blocked ports are activated only when the nodes determine that no loop will be generated by these ports.

Broadcast storm suppression mechanism in case of SRPT failure in a multi-homed subring

As shown in Figure 5, Ring 1 is the primary ring, and Ring 2 and Ring 3 are subrings. When the two SRPTs between the edge node and the assistant edge node are down, the master nodes of Ring 2 and Ring 3 will open their secondary ports. A loop is generated among Device B, Device C, Device E, and Device F, causing a broadcast storm.

To avoid generating a loop, the edge node will temporarily block the edge port. The blocked edge port is activated only when the edge node determines that no loop will be generated when the edge port is activated.

RRPP ring group

In an edge node RRPP ring group, only the activated subring with the smallest domain ID and ring ID can send Edge-Hello packets. In an assistant edge node RRPP ring group, any activated subring that has received Edge-Hello packets will forward these packets to the other activated subrings. When an edge node RRPP ring group and an assistant edge node RRPP ring group are configured, the CPU workload is reduced because of the following reasons:

- Only one subring sends Edge-Hello packets on the edge node.
- Only one subring receives Edge-Hello packets on the assistant edge node.

As shown in Figure 5, Device B is the edge node of Ring 2 and Ring 3. Device C is the assistant edge node of Ring 2 and Ring 3. Device B and Device C need to send or receive Edge-Hello packets frequently. If more subrings are configured or more domains are configured for load balancing, Device B and Device C will send or receive a large number of Edge-Hello packets.

To reduce Edge-Hello traffic, perform the following tasks:

- Assign Ring 2 and Ring 3 to an RRPP ring group configured on the edge node Device B.
- Assign Ring 2 and Ring 3 to an RRPP ring group configured on the assistant edge node Device C.

If all rings are activated, only Ring 2 on Device B sends Edge-Hello packets.

Fast detection mechanism

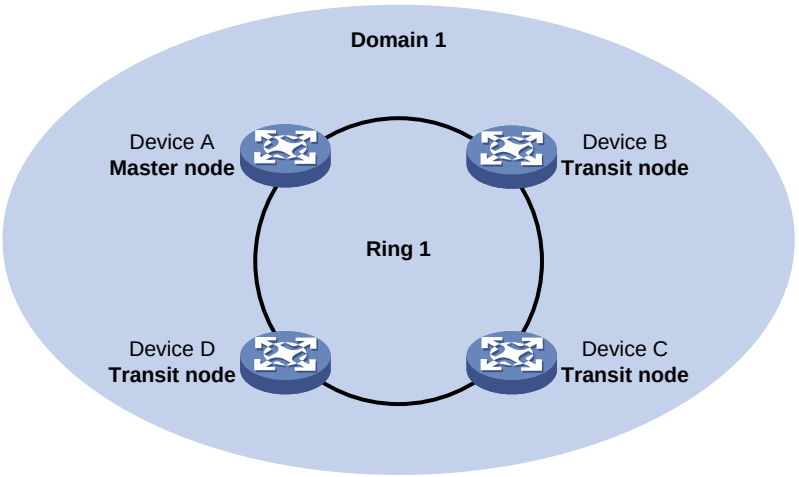
Ideally, an RRPP ring can fast converge because its transit nodes can detect link failures quickly and send out notifications immediately. In practice, some devices on an RRPP ring might not support

RRPP. RRPP can detect link failures between these devices only through the timeout mechanism. This results in long-time traffic interruption and failure to implement millisecond-level convergence.

To address this problem, a fast detection mechanism was introduced. The mechanism works as follows:

- The master node sends Fast-Hello packets out of its primary port at the interval specified by the Fast-Hello timer. If the secondary port receives the Fast-Hello packets sent by the local master node before the Fast-Fail timer expires, the entire ring is in Health state. Otherwise, the ring transits to Disconnect state.
- The edge node sends Fast-Edge-Hello packets out of its common ports at the interval specified by the timer resolution. If the assistant edge node fails to receive the Fast-Edge-Hello packets within three times the timer resolution, the SRPTs transit to Disconnect state.

As shown in Figure 2, when fast detection is enabled for RRPP domain 1, Device A (master node of Ring 1) sends Fast-Hello packets periodically. It determines the ring status according to whether Fast-Hello packets are received before the Fast-Fail timer expires, implementing link status fast detection.



To implement fast detection on an RRPP ring, enable fast detection on the master node, edge node, and assistant edge node of the RRPP ring.

Typical RRPP networking

Single ring

As shown in Figure 2, only a single ring exists in the network topology. You need only define an RRPP domain.

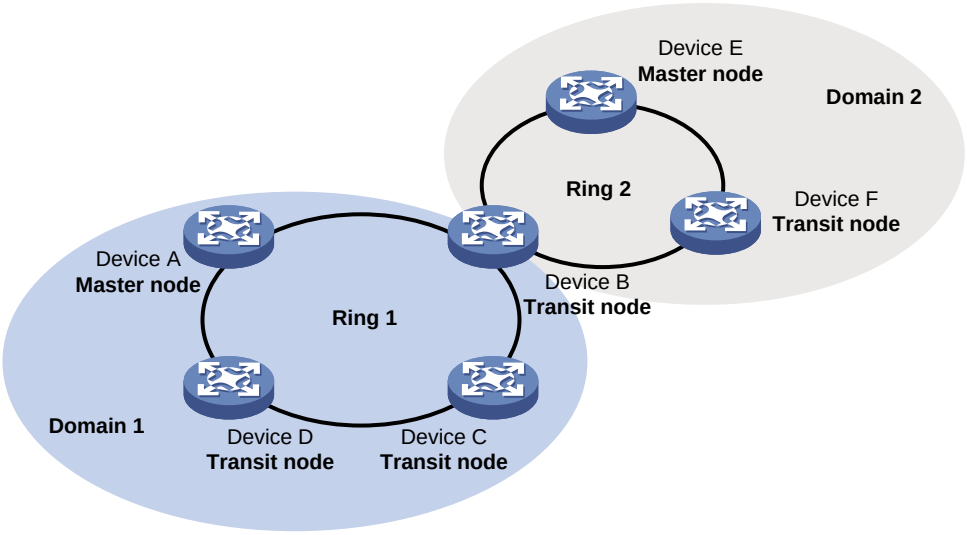


Figure 2 Schematic diagram for a single-ring network

Tangent rings

As shown in Figure 3, two or more rings exist in the network topology and only one common node exists between rings. You must define an RRPP domain for each ring.

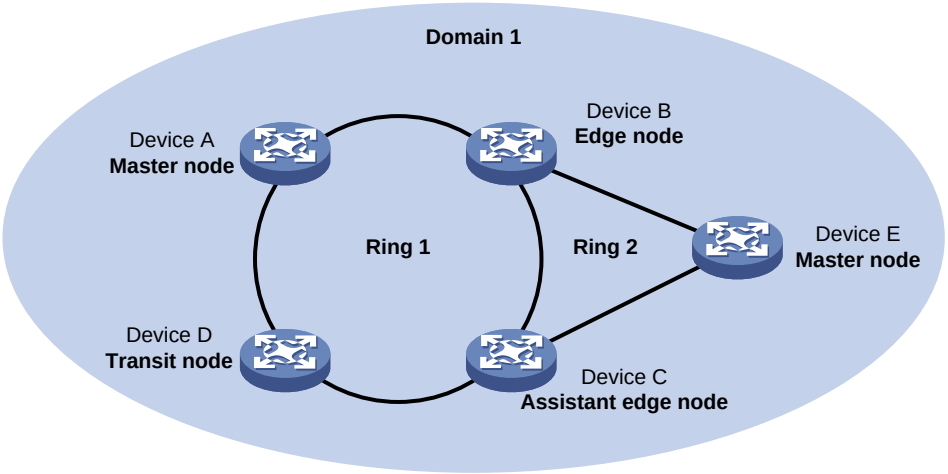

Figure 3 Schematic diagram for a tangent-ring network

Intersecting rings

As shown in Figure 4, two or more rings exist in the network topology and two common nodes exist between rings. You need only define an RRPP domain and configure one ring as the primary ring and the other rings as subrings.

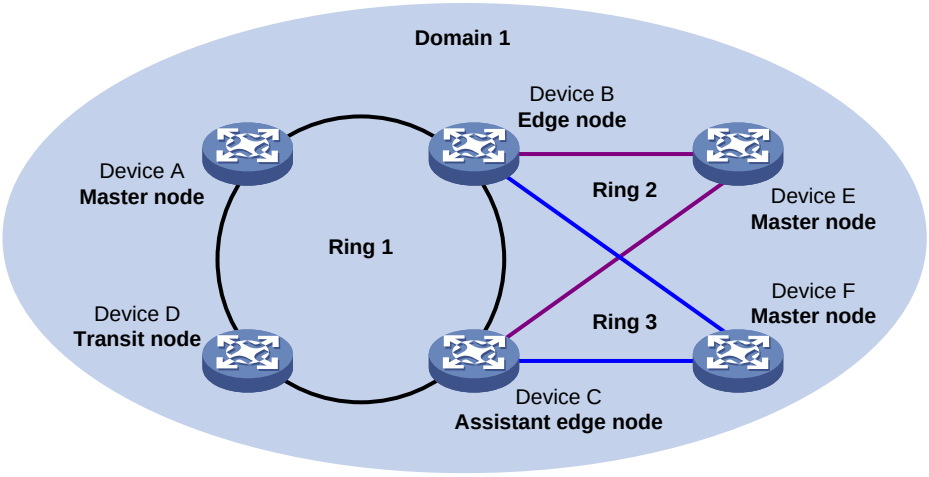

Figure 4 Schematic diagram for an intersecting-ring network

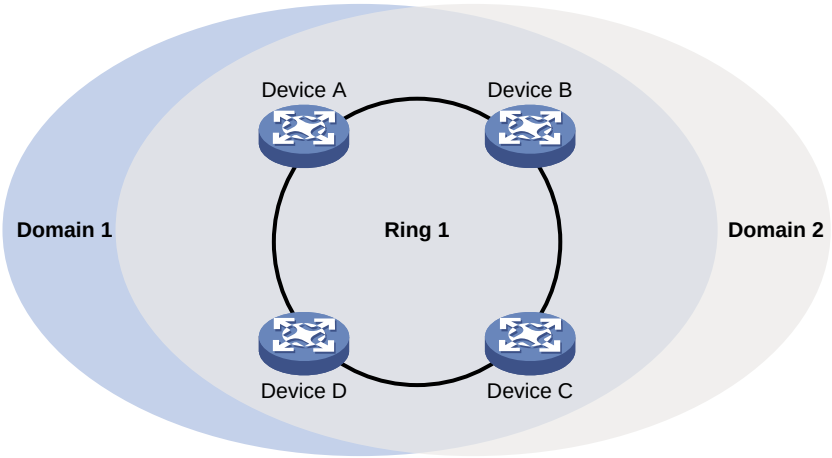
Dual-homed rings

As shown in Figure 5, two or more rings exist in the network topology and two similar common nodes exist between rings. You need only define an RRPP domain and configure one ring as the primary ring and the other rings as subrings.

Figure 5 Schematic diagram for a dual-homed-ring network

Single-ring load balancing



In a single-ring network, you can achieve load balancing by configuring multiple domains.

As shown in Figure 6:

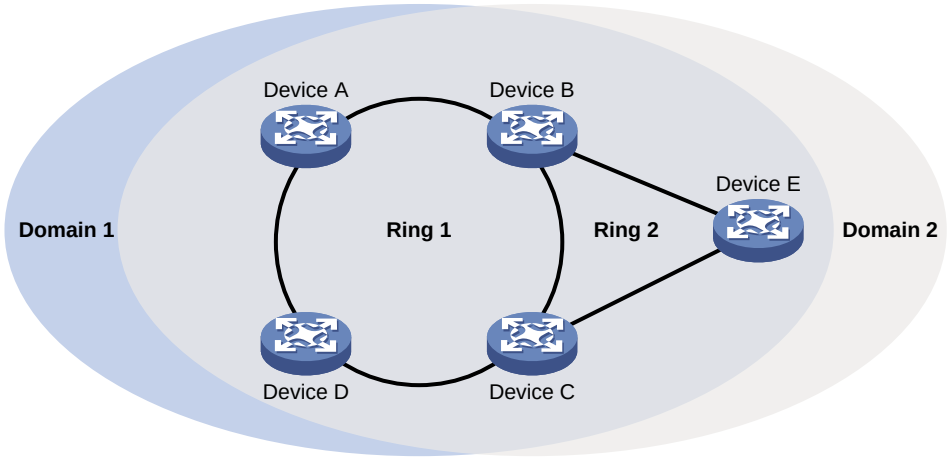
- Ring 1 is configured as the primary ring of both Domain 1 and Domain 2.
- Domain 1 and Domain 2 are configured with different protected VLANs.
- In Domain 1, Device A is configured as the master node of Ring 1.
- In Domain 2, Device B is configured as the master node of Ring 1.

Such configurations enable the ring to block different links based on VLANs and achieve single-ring load balancing.

Figure 6 Schematic diagram for a single-ring load balancing network

Intersecting-ring load balancing

In an intersecting-ring network, you can also achieve load balancing by configuring multiple domains.



As shown in Figure 7:

- Ring 1 is the primary ring and Ring 2 is the subring in both Domain 1 and Domain 2.
- Domain 1 and Domain 2 are configured with different protected VLANs.
- Device A is configured as the master node of Ring 1 in Domain 1.

- Device D is configured as the master node of Ring 1 in Domain 2.
- Device E is configured as the master node of Ring 2 in both Domain 1 and Domain 2. However, different ports on Device E are blocked in Domain 1 and Domain 2.

Traffic from different VLANs can travel over different paths in the subring and primary ring.

Figure 7 Schematic diagram for an intersecting-ring load balancing network

Protocols and standards

RFC 3619, *Extreme Networks' Ethernet Automatic Protection Switching (EAPS) Version 1*

Restrictions and guidelines: RRPP configuration

- RRPP does not have an auto election mechanism. You must configure each node in the ring network correctly for RRPP to monitor and protect the ring network.
- You can configure RRPP in the following order:
  - Create RRPP domains based on service planning.
  - Specify control VLANs and protected VLANs for each RRPP domain.
  - Determine the ring roles and node roles based on the traffic paths in each RRPP domain.

RRPP tasks at a glance

To configure RRPP, perform the following tasks:

1. Creating an RRPP domain

   Perform this task on devices you want to configure as nodes in the RRPP domain.
2. Configuring control VLANs

   Perform this task on all nodes in the RRPP domain.
3. Configuring protected VLANs

   Perform this task on all nodes in the RRPP domain.
4. Configuring RRPP rings
   a. Configuring RRPP ports

      Perform this task on each node's ports intended for accessing RRPP rings.
   b. Configuring RRPP nodes

Perform this task on all nodes in the RRPP domain.

5. Activating an RRPP domain

   Perform this task on all nodes in the RRPP domain.

6. (Optional.) Configuring RRPP timers

   Perform this task on the master node in the RRPP domain.

   - Configuring the Hello timer and Fail timer
   - Configuring the link-up delay timer

7. (Optional.) Configuring RRPP fast detection

   a. Enabling fast detection

      Perform this task on the master node, edge node, and assistant edge node in the RRPP domain.

   b. Configuring fast detection timers

      Perform this task on the master node in the RRPP domain.

8. (Optional.) Configuring an RRPP ring group

   Perform this task on the edge node and assistant edge node in the RRPP domain.

9. (Optional.) Enabling SNMP notifications for RRPP

Prerequisites for RRPP

Before you configure RRPP, you must physically construct a ring-shaped Ethernet topology.

Creating an RRPP domain

About this task

When you create an RRPP domain, specify a domain ID to uniquely identify the RRPP domain. All devices in the same RRPP domain must be configured with the same domain ID.

Restrictions and guidelines

Perform this task on devices you want to configure as nodes in the RRPP domain.

Procedure

1. Enter system view.

   `system-view`

2. Create an RRPP domain and enter RRPP domain view.

   `rrpp domain` *`domain-id`*

Configuring control VLANs

Restrictions and guidelines

- Perform this task on all nodes in the RRPP domain.
- Before you configure RRPP rings in an RRPP domain, configure the same control VLANs for all nodes in the RRPP domain first. You need only configure the primary control VLAN for an RRPP domain. The system automatically configures the secondary control VLAN. It uses the primary control VLAN ID plus 1 as the secondary control VLAN ID. For the control VLAN configuration to succeed, make sure the IDs of the two control VLANs are consecutive and have not been previously assigned.
- Do not configure the default VLAN of a port accessing an RRPP ring as the control VLAN.

- A VLAN with VLAN interface resource reservation cannot be configured as the control VLAN. For more information about VLAN interface resource reservation, see *Layer 2—LAN Switching Configuration Guide*.
- For RRPPDUs to be correctly forwarded, do not enable QinQ or VLAN mapping on control VLANs.
- After you configure RRPP rings for an RRPP domain, you cannot delete or modify the primary control VLAN of the domain. You can only use the **undo control-vlan** command to delete a primary control VLAN.
- To transparently transmit RRPPDUs on a device not configured with RRPP, make sure only the two ports accessing the RRPP ring permit packets from the control VLANs. Otherwise, the packets from other VLANs might enter the control VLANs in transparent transmission mode and strike the RRPP ring.

Procedure

1. Enter system view.
   system-view
2. Enter RRPP domain view.
   rrpp domain *domain-id*
3. Configure the primary control VLAN for the RRPP domain.
   control-vlan *vlan-id*

Configuring protected VLANs

Restrictions and guidelines

- Perform this task on all nodes in the RRPP domain.
- Before you configure RRPP rings in an RRPP domain, configure the same protected VLANs for all nodes in the RRPP domain. All VLANs to which the RRPP ports are assigned must be protected by the RRPP domains.
- When you configure load balancing, you must configure different protected VLANs for different RRPP domains.

Prerequisites

Before you configure protected VLANs, you must configure an MST region and the VLAN-to-instance mapping table. For more information about MST regions, see spanning tree configuration in *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter RRPP domain view.
   rrpp domain *domain-id*
3. Configure protected VLANs for the RRPP domain.
   protected-vlan reference-instance *instance-id-list*

Configuring RRPP rings

When you configure an RRPP ring, you must configure the ports connecting each node to the RRPP ring before configuring the nodes.

Prerequisites

Before you configure an RRPP ring, you must configure control VLANs and protected VLANs.

Configuring RRPP ports

Restrictions and guidelines

- Perform this task on each node's ports intended for accessing RRPP rings.
- Do not enable the OAM remote loopback function on an RRPP port. Otherwise, temporary broadcast storms might occur.
- To accelerate topology convergence, use the **link-delay** command to enable link status rapid report function on an RRPP port. Use this command to set the physical state change suppression interval to 0 seconds. For more information about the **link-delay** command, see *Interface Command Reference*.
- Do not assign a port to both an aggregation group and an RRPP ring. If you do so, the port does not take effect on the RRPP ring.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. Configure the link type of the interface as trunk.
   port link-type trunk
   By default, the link type of an interface is access.
   For more information about the command, see *Layer 2—LAN Switching Command Reference*.
4. Assign the trunk port to the protected VLANs of the RRPP domain.
   port trunk permit vlan { *vlan-id-list* | **all** }
   By default, a trunk port allows only packets from VLAN 1 to pass through.
   RRPP ports always allow packets from the control VLANs to pass through.
   For more information about the command, see *Layer 2—LAN Switching Command Reference*.
5. Disable the spanning tree feature.
   undo stp enable
   By default, the spanning tree feature is enabled.
   For more information about the command, see *Layer 2—LAN Switching Command Reference*.

Configuring RRPP nodes

Restrictions and guidelines

- Perform this task on all nodes in the RRPP domain.
- If a device carries multiple RRPP rings in an RRPP domain, it can only be an edge node or an assistant edge node on a subring.
- When you configure an edge node or an assistant edge node, you must configure the primary ring before configuring the subrings.

Specifying a master node

1. Enter system view.

system-view

2. Enter RRPP domain view.

   rrpp domain *domain-id*

3. Specify the current device as the master node of the ring, and specify the primary port and the secondary port.

   ring *ring-id* **node-mode master** [**primary-port** *interface-type interface-number*] [**secondary-port** *interface-type interface-number*] **level** *level-value*

Specifying a transit node

1. Enter system view.

   system-view

2. Enter RRPP domain view.

   rrpp domain *domain-id*

3. Specify the current device as a transit node of the ring, and specify the primary port and the secondary port.

   ring *ring-id* **node-mode transit** [**primary-port** *interface-type interface-number*] [**secondary-port** *interface-type interface-number*] **level** *level-value*

Specifying an edge node

1. Enter system view.

   system-view

2. Enter RRPP domain view.

   rrpp domain *domain-id*

3. Specify the current device as a master node or transit node of the primary ring, and specify the primary port and the secondary port.

   ring *ring-id* **node-mode** { **master** | **transit** } [**primary-port** *interface-type interface-number*] [**secondary-port** *interface-type interface-number*] **level** *level-value*

4. Specify the current device as the edge node of a subring, and specify the edge port.

   ring *ring-id* **node-mode edge** [**edge-port** *interface-type interface-number*]

Specifying an assistant edge node

1. Enter system view.

   system-view

2. Enter RRPP domain view.

   rrpp domain *domain-id*

3. Specify the current device as a master node or transit node of the primary ring, and specify the primary port and the secondary port.

   ring *ring-id* **node-mode** { **master** | **transit** } [**primary-port** *interface-type interface-number*] [**secondary-port** *interface-type interface-number*] **level** *level-value*

   By default, a device is not a node of the RRPP ring.

4. Specify the current device as the assistant edge node of the subring, and specify an edge port.

   ring *ring-id* **node-mode assistant-edge** [**edge-port** *interface-type interface-number*]

Activating an RRPP domain

Restrictions and guidelines

- Perform this task on all nodes in the RRPP domain.
- Before you activate an RRPP domain on the current device, enable the RRPP protocol and RRPP rings for the RRPP domain on the current device.
- Before you enable subrings on a device, you must enable the primary ring. Before you disable the primary ring on the device, you must disable all subrings. Otherwise, the system displays error prompts.
- To prevent Hello packets of subrings from being looped on the primary ring, enable the primary ring on its master node first. Then enable the subrings on their respective master nodes.

Procedure

1. Enter system view.
   `system-view`
2. Enable RRPP.
   `rrpp enable`
   By default, RRPP is disabled.
3. Enter RRPP domain view.
   `rrpp domain` *`domain-id`*
4. Enable the specified RRPP ring.
   `ring` *`ring-id`* **`enable`**
   By default, an RRPP ring is disabled.

Configuring RRPP timers

Restrictions and guidelines for RRPP timer configuration

Perform this task on the master node of an RRPP domain.

Configuring the Hello timer and Fail timer

Restrictions and guidelines

- The Fail timer must be greater than or equal to three times the Hello timer.
- In a dual-homed-ring network, to avoid temporary loops when the primary ring fails, make sure the value of *A* is greater than the value of *B*, where:
  - *A* is the difference between the Fail timer values on the master node of the subring and the master node of the primary ring.
  - *B* is twice the Hello timer value on the master node of the subring.

Procedure

1. Enter system view.
   `system-view`
2. Enter RRPP domain view.
   `rrpp domain` *`domain-id`*
3. Set the Hello timer and Fail timer for the RRPP domain.

timer hello-timer *hello-value* **fail-timer** *fail-value*

By default, the Hello timer value is 1 second and the Fail timer value is 3 seconds.

Configuring the link-up delay timer

Restrictions and guidelines

If the **distribute** keyword is not specified, the link-up delay timer value cannot be greater than the Fail timer value minus twice the Hello timer value.

If you specify the **distribute** keyword in an RRPP network implementing load balancing, you must configure the link-up delay timer for each RRPP domain for the timer to take effect. If you set different timer values for different RRPP domains, the smallest timer value takes effect.

Procedure

1. Enter system view.

   system-view
2. Enter RRPP domain view.

   rrpp domain *domain-id*
3. Set the link-up delay timer for the RRPP domain.

   linkup-delay-timer *delay-time* [**distribute**]

   By default, the link-up delay timer value is 0 seconds, and the **distribute** keyword is not specified.

Configuring RRPP fast detection

Enabling fast detection

Restrictions and guidelines

- Perform this task on the master node, edge node, and assistant edge node in the RRPP domain.
- As a best practice, configure fast detection on the master node of a subring only when the edge node and assistant edge node of the subring support fast detection.
- When you configure fast detection in an RRPP domain, enable fast detection first on the edge node, and then on the assistant edge node. Otherwise, the assistant edge node might fail to receive Fast-Edge-Hello packets and consider the master node faulty even if it is not.

Procedure

1. Enter system view.

   system-view
2. Enter RRPP domain view.

   rrpp domain *domain-id*
3. Enable fast detection.

   fast-detection enable

   By default, fast detection is disabled.

Configuring fast detection timers

Restrictions and guidelines

- Perform this task on the master node in the RRPP domain.
- The Fast-Fail timer must be equal to or greater than three times the Fast-Hello timer.
- When you configure the Fast-Hello timer, take the device capability into consideration. A small Fast-Hello timer value might cause the link to be unstable.
- In a dual-homed-ring network, to avoid temporary loops when the primary ring fails, make sure the following requirements are met:
  - The Fast-Fail timer value on the master node of the subring is equal to or greater than six times the timer resolution.
  - The difference between the Fast-Fail timer values on the master node of the subring and the master node of the primary ring is greater than twice the Fast-Hello timer value on the master node of the subring.

Procedure

1. Enter system view.

   system-view
2. Enter RRPP domain view.

   rrpp domain *domain-id*
3. Set the Fast-Hello timer and Fast-Fail timer.

   fast-timer hello-timer *hello-value* **fail-timer** *fail-value*

   By default, the Fast-Hello timer is 20 milliseconds, and the Fast-Fail timer is 60 milliseconds.
4. Set the Fast-Edge-Hello timer and Fast-Edge-Fail timer.

   fast-edge-timer hello-timer *hello-value* **fail-timer** *fail-value*

   By default, the Fast-Edge-Hello timer is 10 milliseconds, and the Fast-Edge-Fail timer is 30 milliseconds.

Configuring an RRPP ring group

About this task

To reduce Edge-Hello traffic, assign subrings with the same edge node and assistant edge node to an RRPP ring group. An RRPP ring group must be configured on both the edge node and the assistant edge node. It can only be configured on these two types of nodes.

Restrictions and guidelines

- Perform this task on the edge node and assistant edge node in the RRPP domain.
- You can assign a subring to only one RRPP ring group. The RRPP ring groups configured on the edge node and the assistant edge node must contain the same subrings. Otherwise, the RRPP ring group cannot operate correctly.
- The subrings in an RRPP ring group must share the same edge node and assistant edge node. The edge node and the assistant edge node must have the same SRPTs.
- Make sure a device is either the edge node or the assistant edge node on the subrings in an RRPP ring group.
- Make sure the RRPP ring groups on the edge node and the assistant edge node have the same configurations and activation status.
- Make sure all subrings in an RRPP ring group have the same SRPTs. If the SRPTs of these subrings are different, the RRPP ring group cannot operate correctly.

Procedure

1. Enter system view.
   system-view
2. Create an RRPP ring group and enter RRPP ring group view.
   rrpp ring-group *ring-group-id*
   By default, no RRPP ring groups exist.
3. Assign the specified subrings to the RRPP ring group.
   domain *domain-id* **ring** *ring-id-list*
   By default, no subrings are assigned to an RRPP ring group.

Enabling SNMP notifications for RRPP

About this task

To report critical RRPP events to an NMS, enable SNMP notifications for RRPP. For RRPP event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

Procedure

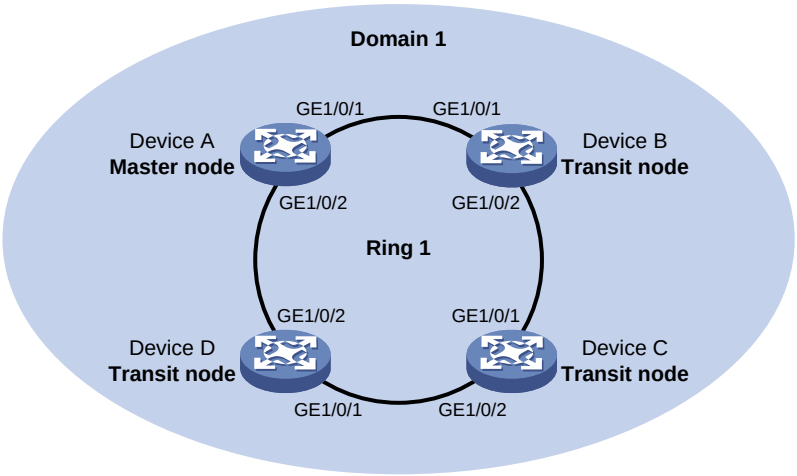
1. Enter system view.
   system-view
2. Enable SNMP notifications for RRPP.
   snmp-agent trap enable rrpp [**major-fault** | **multi-master** | **ring-fail** | **ring-recover**] *
   By default, SNMP notifications for RRPP are disabled.

Display and maintenance commands for RRPP

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display brief RRPP information.	**display rrpp brief**
Display RRPP group configuration information.	**display rrpp ring-group** [*ring-group-id*]
Display RRPPDU statistics.	**display rrpp statistics domain** *domain-id* [**ring** *ring-id*]
Display detailed RRPP information.	**display rrpp verbose domain** *domain-id* [**ring** *ring-id*]
Clear RRPPDU statistics.	**reset rrpp statistics domain** *domain-id* [**ring** *ring-id*]

RRPP configuration examples



Example: Configuring a single ring

Network configuration

As shown in Figure 8:

- Device A, Device B, Device C, and Device D form RRPP domain 1. Specify the primary control VLAN of RRPP domain 1 as VLAN 4092. Specify the protected VLANs of RRPP domain 1 as VLANs 1 through 30.
- Device A, Device B, Device C, and Device D form primary ring 1.
- Specify Device A as the master node of primary ring 1, GigabitEthernet 1/0/1 as the primary port, and GigabitEthernet 1/0/2 as the secondary port.
- Specify Device B, Device C, and Device D as the transit nodes of primary ring 1. Specify GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port on Device B, Device C, and Device D.

Figure 8 Network diagram

Procedure

1. Configure Device A:

Create VLANs 1 through 30.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceA] stp region-configuration
[DeviceA-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] link-delay up 0
[DeviceA-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceA-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] link-delay up 0
[DeviceA-GigabitEthernet1/0/2] link-delay down 0
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceA] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceA-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceA-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device A as the master node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceA-rrpp-domain1] ring 1 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceA-rrpp-domain1] ring 1 enable
[DeviceA-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceA] rrpp enable
```

2. Configure Device B:

Create VLANs 1 through 30.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] link-delay up 0
[DeviceB-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] link-delay up 0
[DeviceB-GigabitEthernet1/0/2] link-delay down 0
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceB] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceB-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceB-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device B as the transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceB-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceB-rrpp-domain1] ring 1 enable
[DeviceB-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceB] rrpp enable
```

3. Configure Device C:

   Configure Device C in the same way Device B is configured.

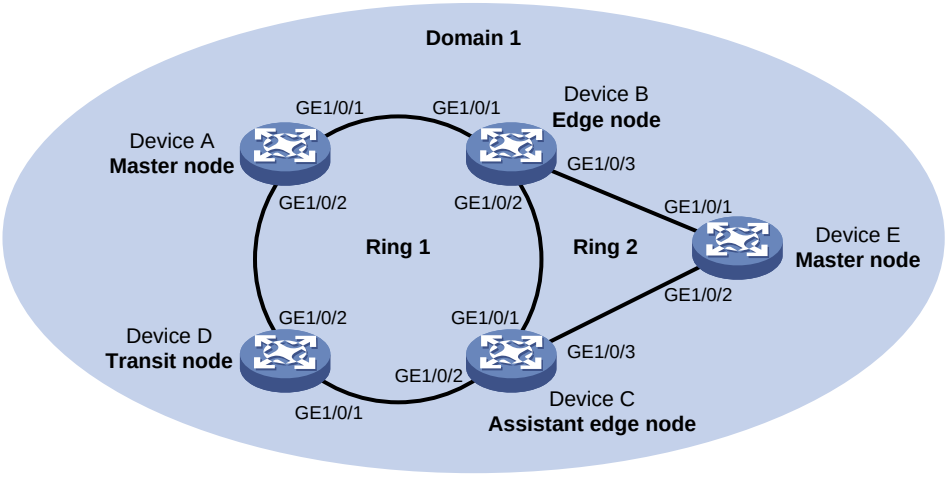
4. Configure Device D:

   Configure Device D in the same way Device B is configured.

Verifying the configuration

Use the **`display`** commands to view RRPP configuration and operational information on each device.

Example: Configuring intersecting rings



Network configuration

As shown in Figure 9:

- Device A, Device B, Device C, Device D, and Device E form RRPP domain 1. VLAN 4092 is the primary control VLAN of RRPP domain 1. RRPP domain 1 protects VLANs 1 through 30.
- Device A, Device B, Device C, and Device D form primary ring 1. Device B, Device C, and Device E form subring 2.
- Device A is the master node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 the secondary port.
- Device E is the master node of subring 2, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 the secondary port.
- Device B is the transit node of primary ring 1 and the edge node of subring 2, with GigabitEthernet 1/0/3 as the edge port.

- Device C is the transit node of primary ring 1 and the assistant edge node of subring 1, with GigabitEthernet 1/0/3 as the edge port.
- Device D is the transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 the secondary port.

Figure 9 Network diagram

Procedure

1. Configure Device A:

Create VLANs 1 through 30.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceA] stp region-configuration
[DeviceA-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] link-delay up 0
[DeviceA-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceA-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] link-delay up 0
[DeviceA-GigabitEthernet1/0/2] link-delay down 0
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
```

```
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceA] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceA-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceA-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device A as the master node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceA-rrpp-domain1] ring 1 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceA-rrpp-domain1] ring 1 enable
[DeviceA-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceA] rrpp enable
```

2. Configure Device B:

Create VLANs 1 through 30.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] link-delay up 0
[DeviceB-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] link-delay up 0
[DeviceB-GigabitEthernet1/0/2] link-delay down 0
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/3
```

```
[DeviceB-GigabitEthernet1/0/3] link-delay up 0
[DeviceB-GigabitEthernet1/0/3] undo stp enable
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/3] quit
```

Create RRPP domain 1.

```
[DeviceB] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceB-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceB-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device B as a transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceB-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceB-rrpp-domain1] ring 1 enable
```

Configure Device B as the edge node of subring 2, with GigabitEthernet 1/0/3 as the edge port. Enable ring 2.

```
[DeviceB-rrpp-domain1] ring 2 node-mode edge edge-port gigabitethernet 1/0/3
[DeviceB-rrpp-domain1] ring 2 enable
[DeviceB-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceB] rrpp enable
```

3. Configure Device C:

Create VLANs 1 through 30.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] link-delay up 0
[DeviceC-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] link-delay up 0
```

```
[DeviceC-GigabitEthernet1/0/2] link-delay down 0
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/3
[DeviceC-GigabitEthernet1/0/3] link-delay up 0
[DeviceC-GigabitEthernet1/0/3] link-delay down 0
[DeviceC-GigabitEthernet1/0/3] undo stp enable
[DeviceC-GigabitEthernet1/0/3] port link-type trunk
[DeviceC-GigabitEthernet1/0/3] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/3] quit
```

Create RRPP domain 1.

```
[DeviceC] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceC-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceC-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device C as a transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceC-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceC-rrpp-domain1] ring 1 enable
```

Configure Device C as the assistant edge node of subring 2, with GigabitEthernet 1/0/3 as the edge port. Enable ring 2.

```
[DeviceC-rrpp-domain1] ring 2 node-mode assistant-edge edge-port gigabitethernet
1/0/3
[DeviceC-rrpp-domain1] ring 2 enable
[DeviceC-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceC] rrpp enable
```

4. Configure Device D:

Create VLANs 1 through 30.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceD] stp region-configuration
[DeviceD-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] link-delay up 0
[DeviceD-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] link-delay up 0
[DeviceD-GigabitEthernet1/0/2] link-delay down 0
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceD] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceD-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceD-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device D as the transit node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceD-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceD-rrpp-domain1] ring 1 enable
[DeviceD-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceD] rrpp enable
```

5. Configure Device E:

Create VLANs 1 through 30.

```
<DeviceE> system-view
[DeviceE] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceE] stp region-configuration
[DeviceE-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceE-mst-region] active region-configuration
[DeviceE-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceE] interface gigabitethernet 1/0/1
[DeviceE-GigabitEthernet1/0/1] link-delay up 0
[DeviceE-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceE-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceE-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceE-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

```
[DeviceE-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceE] interface gigabitethernet 1/0/2
[DeviceE-GigabitEthernet1/0/2] link-delay up 0
[DeviceE-GigabitEthernet1/0/2] link-delay down 0
[DeviceE-GigabitEthernet1/0/2] undo stp enable
[DeviceE-GigabitEthernet1/0/2] port link-type trunk
[DeviceE-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceE-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceE] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceE-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceE-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device E as the master node of subring 2, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 2.

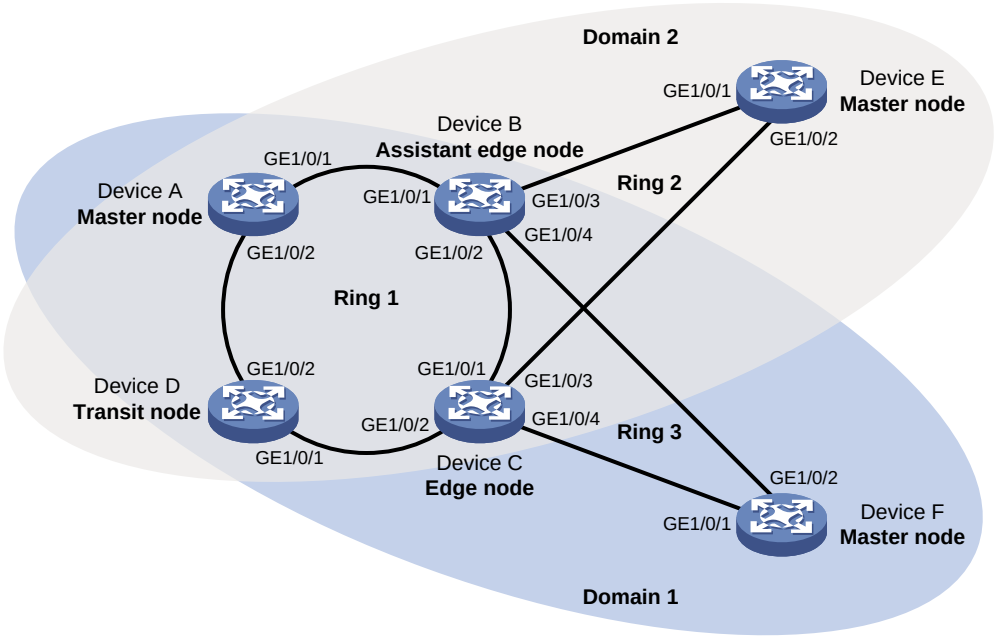
```
[DeviceE-rrpp-domain1] ring 2 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 1
[DeviceE-rrpp-domain1] ring 2 enable
[DeviceE-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceE] rrpp enable
```

Verifying the configuration

Use the **display** commands to view RRPP configuration and operational information on each device.



Example: Configuring load-balanced intersecting rings

Network configuration

As shown in Figure 10:

- Device A, Device B, Device C, Device D, and Device F form RRPP domain 1. VLAN 100 is the primary control VLAN of the RRPP domain. Device A is the master node of the primary ring, Ring 1. Device D is the transit node of Ring 1. Device F is the master node of the subring Ring 3. Device C is the edge node of the subring Ring 3. Device B is the assistant edge node of the subring Ring 3.
- Device A, Device B, Device C, Device D, and Device E form RRPP domain 2. VLAN 105 is the primary control VLAN of the RRPP domain. Device A is the master node of the primary ring, Ring 1. Device D is the transit node of Ring 1. Device E is the master node of the subring Ring 2. Device C is the edge node of the subring Ring 2. Device B is the assistant edge node of the subring Ring 2.
- Specify VLAN 11 as the protected VLAN of domain 1, and VLAN 12 the protected VLAN of domain 2. You can implement VLAN-based load balancing on Ring 1.
- Ring 2 and Ring 3 have the same edge node and assistant edge node, and the two subrings have the same SRPTs. You can add Ring 2 and Ring 3 to an RRPP ring group to reduce Edge-Hello traffic.

Figure 10 Network diagram

Procedure

1. Configure Device A:

   # Create VLANs 11 and 12.

   ```
   <DeviceA> system-view
   [DeviceA] vlan 11 to 12
   ```

   # Map VLAN 11 to MSTI 1 and VLAN 12 to MSTI 2.

   ```
   [DeviceA] stp region-configuration
   [DeviceA-mst-region] instance 1 vlan 11
   [DeviceA-mst-region] instance 2 vlan 12
   ```

   # Activate the MST region configuration.

   ```
   [DeviceA-mst-region] active region-configuration
   [DeviceA-mst-region] quit
   ```

   # Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] link-delay up 0
   [DeviceA-GigabitEthernet1/0/1] link-delay down 0
   ```

   # Disable the spanning tree feature on the port.

   ```
   [DeviceA-GigabitEthernet1/0/1] undo stp enable
   ```

   # Configure the port as a trunk port.

   ```
   [DeviceA-GigabitEthernet1/0/1] port link-type trunk
   ```

   # Remove the port from VLAN 1, and assign it to VLANs 11 and 12.

   ```
   [DeviceA-GigabitEthernet1/0/1] undo port trunk permit vlan 1
   [DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 11 12
   ```

   # Configure VLAN 11 as the default VLAN.

   ```
   [DeviceA-GigabitEthernet1/0/1] port trunk pvid vlan 11
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

   ```
   [DeviceA] interface gigabitethernet 1/0/2
   ```

```
[DeviceA-GigabitEthernet1/0/2] link-delay up 0
[DeviceA-GigabitEthernet1/0/2] link-delay down 0
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] undo port trunk permit vlan 1
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 11 12
[DeviceA-GigabitEthernet1/0/2] port trunk pvid vlan 11
[DeviceA-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceA] rrpp domain 1
```

Configure VLAN 100 as the primary control VLAN of RRPP domain 1.

```
[DeviceA-rrpp-domain1] control-vlan 100
```

Configure the VLAN mapped to MSTI 1 as the protected VLAN of RRPP domain 1.

```
[DeviceA-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device A as the master node of primary ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceA-rrpp-domain1] ring 1 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceA-rrpp-domain1] ring 1 enable
[DeviceA-rrpp-domain1] quit
```

Create RRPP domain 2.

```
[DeviceA] rrpp domain 2
```

Configure VLAN 105 as the primary control VLAN of RRPP domain 2.

```
[DeviceA-rrpp-domain2] control-vlan 105
```

Configure the VLAN mapped to MSTI 2 as the protected VLAN of RRPP domain 2.

```
[DeviceA-rrpp-domain2] protected-vlan reference-instance 2
```

Configure Device A as the master node of primary ring 1, with GigabitEthernet 1/0/2 as the master port and GigabitEthernet 1/0/1 as the secondary port. Enable ring 1.

```
[DeviceA-rrpp-domain2] ring 1 node-mode master primary-port gigabitethernet 1/0/2
secondary-port gigabitethernet 1/0/1 level 0
[DeviceA-rrpp-domain2] ring 1 enable
[DeviceA-rrpp-domain2] quit
```

Enable RRPP.

```
[DeviceA] rrpp enable
```

2. Configure Device B:

Create VLANs 11 and 12.

```
<DeviceB> system-view
[DeviceB] vlan 11 to 12
```

Map VLAN 11 to MSTI 1 and VLAN 12 to MSTI 2.

```
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 11
[DeviceB-mst-region] instance 2 vlan 12
```

Activate the MST region configuration.

```
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] link-delay up 0
```

```
[DeviceB-GigabitEthernet1/0/1] link-delay down 0
```
Disable the spanning tree feature on the port.
```
[DeviceB-GigabitEthernet1/0/1] undo stp enable
```
Configure the port as a trunk port.
```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```
Remove the port from VLAN 1, and assign it to VLANs 11 and 12.
```
[DeviceB-GigabitEthernet1/0/1] undo port trunk permit vlan 1
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 11 12
```
Configure VLAN 11 as the default VLAN.
```
[DeviceB-GigabitEthernet1/0/1] port trunk pvid vlan 11
[DeviceB-GigabitEthernet1/0/1] quit
```
Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.
```

```

Configure Device C as the transit node of primary ring 1 in RRPP domain 2, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceC-rrpp-domain2] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceC-rrpp-domain2] ring 1 enable
```

Configure Device C as the edge node of subring 2 in RRPP domain 2, with GigabitEthernet 1/0/3 as the edge port. Enable subring 2.

```
[DeviceC-rrpp-domain2] ring 2 node-mode edge edge-port gigabitethernet 1/0/3
[DeviceC-rrpp-domain2] ring 2 enable
[DeviceC-rrpp-domain2] quit
```

Enable RRPP.

```
[DeviceC] rrpp enable
```

4. Configure Device D:

Create VLANs 11 and 12.

```
<DeviceD> system-view
[DeviceD] vlan 11 to 12
```

Map VLAN 11 to MSTI 1 and VLAN 12 to MSTI 2.

```
[DeviceD] stp region-configuration
[DeviceD-mst-region] instance 1 vlan 11
[DeviceD-mst-region] instance 2 vlan 12
```

Activate the MST region configuration.

```
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] link-delay up 0
[DeviceD-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Remove the port from VLAN 1, and assign it to VLANs 11 and 12.

```
[DeviceD-GigabitEthernet1/0/1] undo port trunk permit vlan 1

[DeviceD-rrpp-domain1] quit
```

Create RRPP domain 2.

```
[DeviceD] rrpp domain 2
```

Configure VLAN 105 as the primary control VLAN of RRPP domain 2.

```
[DeviceD-rrpp-domain2] control-vlan 105
```

Configure the VLAN mapped to MSTI 2 as the protected VLAN of RRPP domain 2.

```
[DeviceD-rrpp-domain2] protected-vlan reference-instance 2
```

Configure Device D as the transit node of primary ring 1 in RRPP domain 2, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable ring 1.

```
[DeviceD-rrpp-domain2] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceD-rrpp-domain2] ring 1 enable
[DeviceD-rrpp-domain2] quit
```

Enable RRPP.

```
[DeviceD] rrpp enable
```

5. Configure Device E:

Create VLAN 12.

```
<DeviceE> system-view
[DeviceE] vlan 12
```

Map VLAN 12 to MSTI 2.

```
[DeviceE-vlan12] quit
[DeviceE] stp region-configuration
[DeviceE-mst-region] instance 2 vlan 12
```

Activate the MST region configuration.

```
[DeviceE-mst-region] active region-configuration
[DeviceE-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceE] interface gigabitethernet 1/0/1
[DeviceE-GigabitEthernet1/0/1] link-delay up 0
[DeviceE-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceE-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceE-GigabitEthernet1/0/1] port link-type trunk
```

Remove the port from VLAN 1, and assign it to VLAN 12.

```
[DeviceE-GigabitEthernet1/0/1] undo port trunk permit vlan 1
[DeviceE-GigabitEthernet1/0/1] port trunk permit vlan 12
```

Configure VLAN 12 as the default VLAN.

```
[DeviceE-GigabitEthernet1/0/1] port trunk pvid vlan 12
[DeviceE-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceE] interface gigabitethernet 1/0/2
[DeviceE-GigabitEthernet1/0/2] link-delay up 0
[DeviceE-GigabitEthernet1/0/2] link-delay down 0
[DeviceE-GigabitEthernet1/0/2] undo stp enable
[DeviceE-GigabitEthernet1/0/2] port link-type trunk
[DeviceE-GigabitEthernet1/0/2] undo port trunk permit vlan 1
[DeviceE-GigabitEthernet1/0/2] port trunk permit vlan 12
[DeviceE-GigabitEthernet1/0/2] port trunk pvid vlan 12
[DeviceE-GigabitEthernet1/0/2] quit
```

Create RRPP domain 2.

```
[DeviceE] rrpp domain 2
```

Configure VLAN 105 as the primary control VLAN of RRPP domain 2.

```
[DeviceE-rrpp-domain2] control-vlan 105
```

Configure the VLAN mapped to MSTI 2 as the protected VLAN of RRPP domain 2.

```
[DeviceE-rrpp-domain2] protected-vlan reference-instance 2
```

Configure Device E as the master mode of subring 2 in RRPP domain 2, with GigabitEthernet 1/0/2 as the primary port and GigabitEthernet 1/0/1 as the secondary port. Enable ring 2.

```
[DeviceE-rrpp-domain2] ring 2 node-mode master primary-port gigabitethernet 1/0/2
secondary-port gigabitethernet 1/0/1 level 1
[DeviceE-rrpp-domain2] ring 2 enable
[DeviceE-rrpp-domain2] quit
```

Enable RRPP.

```
[DeviceE] rrpp enable
```

6. Configure Device F:

Create VLAN 11.

```
<DeviceF> system-view
[DeviceF] vlan 11
[DeviceF-vlan11] quit
```

Map VLAN 11 to MSTI 1.

```
[DeviceF] stp region-configuration
[DeviceF-mst-region] instance 1 vlan 11
```

Activate the MST region configuration.

```
[DeviceF-mst-region] active region-configuration
[DeviceF-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceF] interface gigabitethernet 1/0/1
[DeviceF-GigabitEthernet1/0/1] link-delay up 0
[DeviceF-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceF-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceF-GigabitEthernet1/0/1] port link-type trunk
```

Remove the port from VLAN 1, and assign it to VLAN 11.

```
[DeviceF-GigabitEthernet1/0/1] undo port trunk permit vlan 1
[DeviceF-GigabitEthernet1/0/1] port trunk permit vlan 11
```

Configure VLAN 11 as the default VLAN.

```
[DeviceF-GigabitEthernet1/0/1] port trunk pvid vlan 11
[DeviceF-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceF] interface gigabitethernet 1/0/2
[DeviceF-GigabitEthernet1/0/2] link-delay up 0
[DeviceF-GigabitEthernet1/0/2] link-delay down 0
[DeviceF-GigabitEthernet1/0/2] undo stp enable
[DeviceF-GigabitEthernet1/0/2] port link-type trunk
[DeviceF-GigabitEthernet1/0/2] undo port trunk permit vlan 1
[DeviceF-GigabitEthernet1/0/2] port trunk permit vlan 11
[DeviceF-GigabitEthernet1/0/2] port trunk pvid vlan 11
[DeviceF-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceF] rrpp domain 1
```

Configure VLAN 100 as the primary control VLAN of RRPP domain 1.

```
[DeviceF-rrpp-domain1] control-vlan 100
```

Configure the VLAN mapped to MSTI 1 as the protected VLAN of RRPP domain 1.

```
[DeviceF-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device F as the master node of subring 3 in RRPP domain 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable subring 3.

```
[DeviceF-rrpp-domain1] ring 3 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 1
[DeviceF-rrpp-domain1] ring 3 enable
[DeviceF-rrpp-domain1] quit
```

Enable RRPP.

```
[DeviceF] rrpp enable
```

7. Configure RRPP ring group settings on Device B and Device C:

Create RRPP ring group 1 on Device B, and add subrings 2 and 3 to the RRPP ring group.

```
[DeviceB] rrpp ring-group 1
[DeviceB-rrpp-ring-group1] domain 2 ring 2
[DeviceB-rrpp-ring-group1] domain 1 ring 3
```

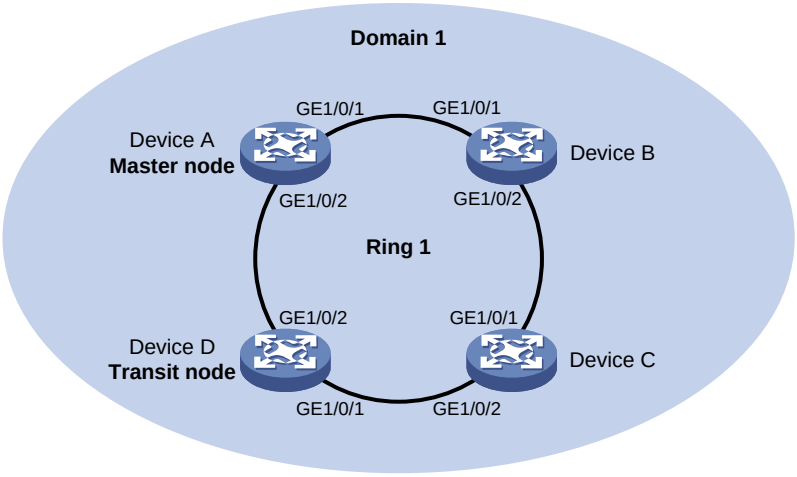
Create RRPP ring group 1 on Device C, and add subrings 2 and 3 to the RRPP ring group.

```
[DeviceC] rrpp ring-group 1
[DeviceC-rrpp-ring-group1] domain 2 ring 2
[DeviceC-rrpp-ring-group1] domain 1 ring 3
```

Verifying the configuration

Use the **display** commands to view RRPP configuration and operational information on each device.

Example: Configuring fast detection



Network configuration

As shown in Figure 11:

- Device A, Device B, Device C, and Device D form RRPP domain 1. VLAN 4092 is the primary control VLAN of RRPP domain 1. RRPP domain 1 protects VLANs 1 through 30.
- Device A is the master node and supports RRPP fast detection, providing a timer resolution of 10 milliseconds. The default Fast-Fail and Fast-Hello timers are 60 milliseconds and 20 milliseconds, respectively. Device D is a transit node. Device B and Device C do not support RRPP.

Neither Device B nor Device C supports RRPP. When the link between them fails, the link failure cannot be detected by the master node in a timely manner. Configure RRPP fast detection to implement fast link switchover even when the link between Device B and Device C fails.

Figure 11 Network diagram

Procedure

1. Configure Device A:

Create VLANs 1 through 30.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceA] stp region-configuration
[DeviceA-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] link-delay up 0
[DeviceA-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceA-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] link-delay up 0
[DeviceA-GigabitEthernet1/0/2] link-delay down 0
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceA] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceA-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceA-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device A as the master node of the primary ring Ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable Ring 1.

```
[DeviceA-rrpp-domain1] ring 1 node-mode master primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceA-rrpp-domain1] ring 1 enable
```

Enable fast detection. Set the Fast-Hello timer and Fast-Fail timer to 100 milliseconds and 300 milliseconds, respectively.

```
[DeviceA-rrpp-domain1] fast-detection enable
[DeviceA-rrpp-domain1] fast-timer hello-timer 100 fail-timer 300
[DeviceA-rrpp-domain1] quit
```

Enable the RRPP protocol.

```
[DeviceA] rrpp enable
```

2. Configure Device B:

Create VLAN 4092 and VLAN 4093.

```
<DeviceB> system-view
[DeviceB] vlan 4092 to 4093
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] link-delay up 0
[DeviceB-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30, 4092, and 4093.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30 4092 4093
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] link-delay up 0
[DeviceB-GigabitEthernet1/0/2] link-delay down 0
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30 4092 4093
```

3. Configure Device C:

Create VLAN 4092 and VLAN 4093.

```
<DeviceC> system-view
[DeviceC] vlan 4092 to 4093
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] link-delay up 0
[DeviceC-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30, 4092, and 4093.

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30 4092 4093
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] link-delay up 0
[DeviceC-GigabitEthernet1/0/2] link-delay down 0
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30 4092 4093
```

4. Configure Device D:

Create VLANs 1 through 30.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceD] stp region-configuration
[DeviceD-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

Set the physical state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] link-delay up 0
[DeviceD-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] link-delay up 0
[DeviceD-GigabitEthernet1/0/2] link-delay down 0
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/2] quit
```

Create RRPP domain 1.

```
[DeviceD] rrpp domain 1
```

Configure VLAN 4092 as the primary control VLAN of RRPP domain 1.

```
[DeviceD-rrpp-domain1] control-vlan 4092
```

Configure the VLANs mapped to MSTI 1 as the protected VLANs of RRPP domain 1.

```
[DeviceD-rrpp-domain1] protected-vlan reference-instance 1
```

Configure Device D as a transit node of the primary ring Ring 1, with GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port. Enable Ring 1.

```
[DeviceD-rrpp-domain1] ring 1 node-mode transit primary-port gigabitethernet 1/0/1
secondary-port gigabitethernet 1/0/2 level 0
[DeviceD-rrpp-domain1] ring 1 enable
[DeviceD-rrpp-domain1] quit
```

Enable the RRPP protocol.

```
[DeviceD] rrpp enable
```

Verifying the configuration

Use the **display** commands to view RRPP configuration and operational information on Device A and Device D.

Troubleshooting RRPP

The primary node cannot receive Hello packets when the link state is normal

Symptom

When the link state is normal, the master node cannot receive Hello packets, and it unblocks the secondary port.

Analysis

The following are possible causes:

- One or more nodes on the RRPP ring are not enabled with RRPP.
- The domain IDs or control VLANs are not the same for all nodes on the RRPP ring.
- The port on the RRPP ring does not work correctly.

Solution

To resolve the problem:

1. Use the **display rrpp brief** command to determine whether RRPP is enabled for all nodes. If it is not, use the **rrpp enable** command and the **ring enable** command to enable RRPP and RRPP rings for all nodes.
2. Use the **display rrpp brief** command to determine whether the domain ID and primary control VLAN ID are the same for all nodes. If they are not, set the same domain ID and primary control VLAN ID for the nodes.
3. Use the **display rrpp verbose** command to examine the link state of each port in each ring.
4. Use the **debugging rrpp** command on each node to determine whether a port receives or transmits Hello packets. If it does not, Hello packets are lost.
5. If the problem persists, contact H3C Support.

Configuring ERPS

About ERPS

Ethernet Ring Protection Switching (ERPS) is a robust link layer protocol that ensures a loop-free topology and implements quick link recovery.

ERPS structure

Figure 1 ERPS ring structure

Rings

ERPS rings can be divided into major rings and subrings. An ERPS network consists of one major ring or multiple major rings, and multiple subrings. By default, a ring is a major ring. You can configure a ring as a subring manually.

As shown in Figure 1, a major ring is a closed ring formed by Device A, Device B, Device C, and Device D. A subring is an open ring formed by the link Device C<—>Device E<—>Device F<—>Device D.

RPL

An ERPS ring is composed of many nodes. Some nodes use ring protection links (RPLs) to prevent loops on the ERPS ring. As shown in Figure 1, the link between Device A and Device B and the link between Device E and Device F are RPLs.

Nodes

ERPS nodes include owner nodes, neighbor nodes, interconnection nodes, and normal nodes.

- The owner node and neighbor node block and unblock ports on the RPL to prevent loops and switch traffic. An RPL connects an owner node and a neighbor node.
- Interconnection nodes connect different rings. Interconnection nodes reside on subrings and forward service packets but not protocol packets.
- Normal nodes forward both service packets and protocol packets.

As shown in Figure 1, on the major ring, Device A is the owner node and Device B is the neighbor node. On the subring, Device E is the owner node and Device F is the neighbor node. Devices C and D are interconnection nodes.

Ports

Each node consists of two ERPS ring member ports: Port 0 and port 1. ERPS ring member ports have the following types:

- **RPL port**—Port on an RPL link.
- **Interconnection port**—Port that connects a subring to a major ring.
- **Normal port**—Default type of a port that forwards both service packets and protocol packets.

As shown in Figure 1, ports A1, B1, E1, and F1 are RPL ports. Ports C3 and D3 are interconnection ports. Other ports are normal ports.

Instances

An ERPS ring supports multiple ERPS instances. An ERPS instance is a logical ring to process service and protocol packets. Each ERPS instance has its own owner node and maintains its own state and data. An ERPS instance is uniquely identified by the ring ID and VLAN ID of ERPS packets. The ring ID indicates the ring of ERPS packets. It can be represented by the last byte in the destination MAC address of the packets. The VLAN ID indicates the ERPS instance of the packets.

ERPS protocol packets

ERPS protocol packets are Ring Automatic Protection Switching (R-APS) packets. You can configure the R-APS packet level. A node does not process R-APS packets whose levels are greater than the level of the packets sent by the node. On a ring, the levels of R-APS packets must be the same for all nodes in an ERPS instance.

Table 1 R-APS packet types and functions

Packet type	Function
No request, RPL block (NR-RB)	When the link is stable, an owner node in idle state periodically sends NR-RB packets to inform other nodes that the RPL ports are blocked. The nodes that receive the NR-RB packets unblock available ports and update MAC address entries.
No request (NR)	After the link fault is cleared, the node that detects the recovery periodically sends NR packets. When the owner node receives the NR packets, it starts the WTR timer. The node stops sending NR packets after receiving NR-RB packets from the owner node.
Signal fail (SF)	When a link fails to send or receive signals, the node that detects the fault periodically sends SF packets. When the owner node and neighbor node receive the FS packets, they unblock the RPL ports. The node stops sending SF packets after the fault is cleared.
Manual switch (MS)	A port configured with the MS mode is blocked and periodically sends MS packets. When other nodes receive the MS packets, they unblock available ports and update MAC address entries.
Forced switch (FS)	A port configured with the FS mode is blocked and periodically sends FS packets. When other nodes receive the FS packets, they unblock all ports and update MAC address entries.
Flush	If the topology of a subring changes, the interconnection ports on the subring broadcasts flush packets. All nodes that receive the flush packets update MAC address entries.

NOTE:

- Typically R-APS packets are transmitted within a ring. The flush packets sourced from the subring can be forwarded to the major ring.
- Service packets can be transmitted between different rings.

ERPS node states

Table 2 ERPS states

State	Description
Init	State for a non-interconnection node that has less than two ERPS ring member ports or for an interconnection node that does not have ERPS ring member ports.
Idle	Stable state when all non-RPL links are available. In this state, the owner node blocks the RPL port and periodically sends NR-RB packets. The neighbor node blocks the RPL port. All nodes enter the idle state after the owner node enters the idle state.
Protection	State when a non-RPL link is faulty. In this state, the RPL link is unblocked to forward traffic. All nodes enter the protection state after a node enters the protection state.
MS	State when traffic paths are manually switched. All nodes enter the MS state after a node is configured with the MS mode.
FS	State when traffic paths are forcibly switched. All nodes enter the FS state after a node is configured with the FS mode.
Pending	Transient state between the previous states.

ERPS timers

Hold-off timer

The hold-off timer starts when the port detects a link fault. The port reports the link fault if the fault persists when the timer expires.

This timer delays the fault report time and affects the link switching performance.

Guard timer

The guard timer starts when the port detects a link recovery. The port does not process R-APS packets before the timer expires.

This timer prevents R-APS packets from impacting the network and affects the link switching performance when multiple points of failures exist.

WTR timer

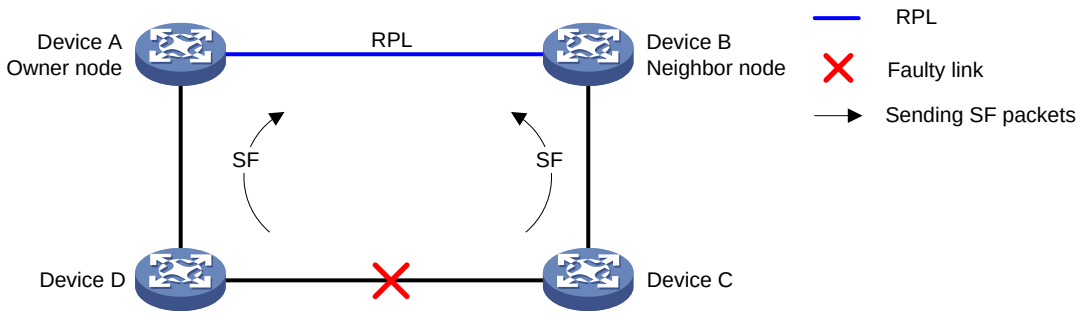
In revertive mode, the WTR timer starts when the owner node in protection state receives NR packets. The RPL is unblocked and the recovered node is blocked before the timer expires. The owner node blocks the RPL and sends NR-RB packets when the timer expires. If the port receives SF packets before the timer expires, the timer stops and the RPL remains unblocked.

This timer prevents intermittent link failures from impacting the network.

WTB timer

In revertive mode, the WTB timer starts when the owner node in MS or FS state receives NR packets. The RPL is unblocked and the recovered node sends NR packets before the timer expires. The owner node blocks the RPL and sends NR-RB packets when the timer expires. If the port receives SF packets before the timer expires, the timer stops and the RPL remains unblocked.

This timer prevents the RPL ports from being blocked and unblocked frequently.



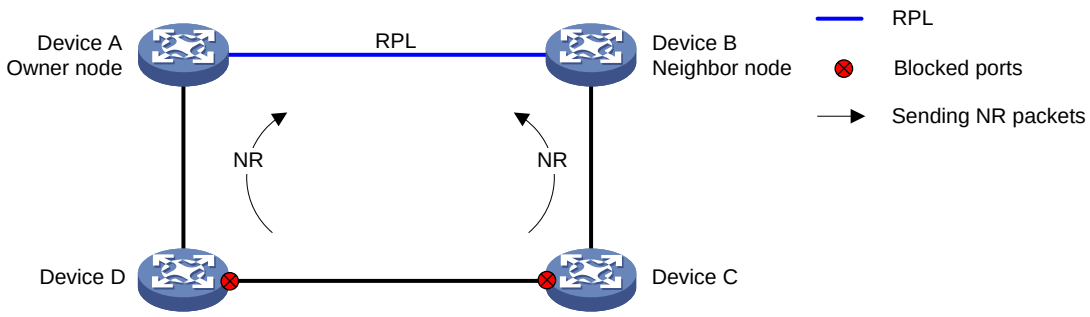
ERPS operation mechanism

ERPS uses the detection mechanism defined in ITU-T G.8032/Y.1344 to locate the point of failure and identify unidirectional or bidirectional faults.

ERPS uses the SF packets to report signal failures on a link and the NR packets to report link recovery. When a node detects a link status change, the node sends three packets first and then sends subsequent packets every five seconds.

Link-down report mechanism

Figure 2 Link-down report mechanism



As shown in Figure 2, the link-down report mechanism uses the following process:

1. Device C and Device D detect the link failure and perform the following operations:
   a. Block the ports on both side of the faulty link.
   b. Periodically send SF packets to other nodes.
2. Device A and Device B receive the SF packets and perform the following operations:
   a. Unblock RPL ports.
   b. Update the MAC address entries.

Service packets are switched to the RPL link.

Link recovery mechanism

Figure 3 Link recovery mechanism

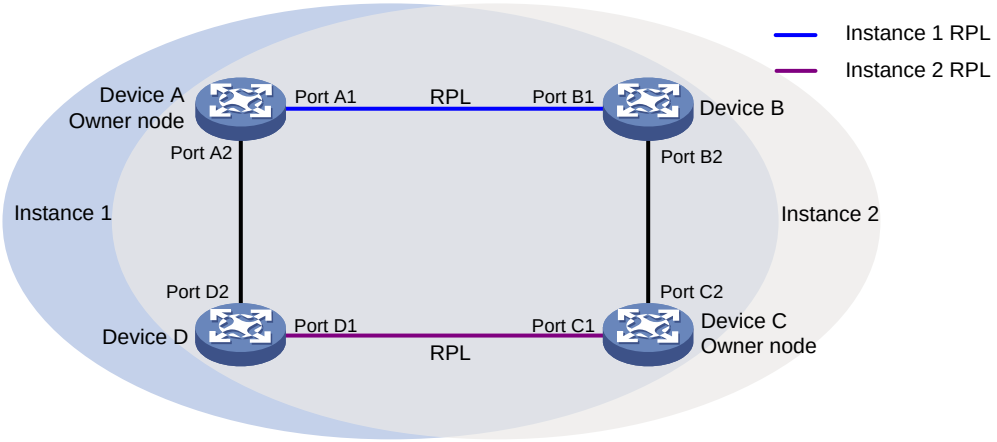
As shown in Figure 3, the link recovery mechanism uses the following process:

1. Device C and Device D detect the link recovery and perform the following operations:
   a. Block the recovered ports.
   b. Start the guard timer.
   c. Send NR packets.
2. When Device A (owner node) receives the NR packets, it does not perform any operations if it is in non-revertive mode. If Device A is in revertive mode, it performs the following operations:

a. Starts the WTR timer.

b. Blocks the RPL port and periodically sends NR-RB packets when the WTR timer expires.

3. When other nodes receive the NR-RB packets, they perform the following operations:



a. Device B (neighbor port) blocks the RPL port.

b. Device C and Device D unblock the recovered ports.

Service packets are switched to the recovered link.

Multi-instance load balancing mechanism

Figure 4 Multi-instance load balancing mechanism

An ERPS ring topology might carry traffic from multiple VLANs. Traffic from different VLANs can be load balanced among different ERPS instances.

ERPS uses the following types of VLANs:

- **Control VLAN**—Carries ERPS protocol packets. Each ERPS instance has its own control VLAN.
- **Protected VLAN**—Carries data packets. Each ERPS instance has its own protected VLAN. Protected VLANs are configured by using the mappings between VLANs and MSTIs.

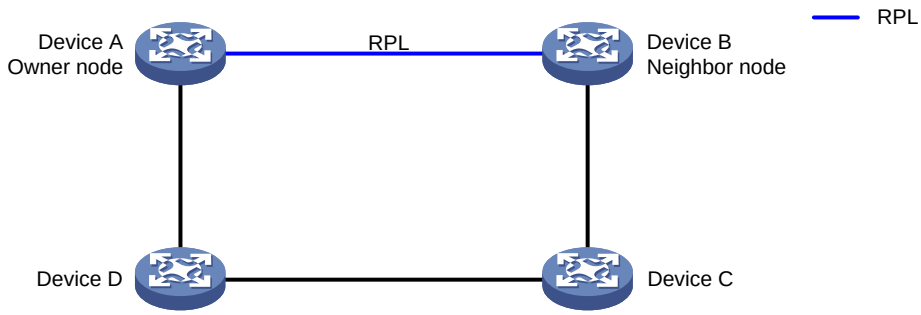
As shown in Figure 4, the ERPS ring is configured with instance 1 and instance 2. For instance 1, the owner node is Device A, and the RPL is the link between Device A and Device B. For instance 2, the owner node is Device C, and the RPL is the link between Device C and Device D. Traffic from different VLANs can be load balanced among different links.

Manual configuration mechanism

ERPS supports the following manual configuration modes:

- **MS**—Use the **`erps switch manual`** command to block an ERPS ring member port. A port in MS mode is blocked and sends MS packets. The nodes that receive the MS packets unblock available ports. If the nodes in MS mode receive an SF packet, they unblock the blocked ports.
- **FS**—Use the **`erps switch force ring`** command to block an ERPS ring member port. A port in FS mode is blocked and sends FS packets. The nodes that receive the FS packets unblock available ports. If the nodes in FS mode receive an SF packet, they do not unblock the blocked ports.

Collaboration mechanism



To detect and clear link faults typically for a fiber link, use ERPS with CFD and Track. You can associate ERPS ring member ports with the continuity check function of CFD through track entries. For more information about CFD and Track, see "Configuring CFD" and "Configuring Track."

ERPS network diagrams

One major ring

The network has one major ring.

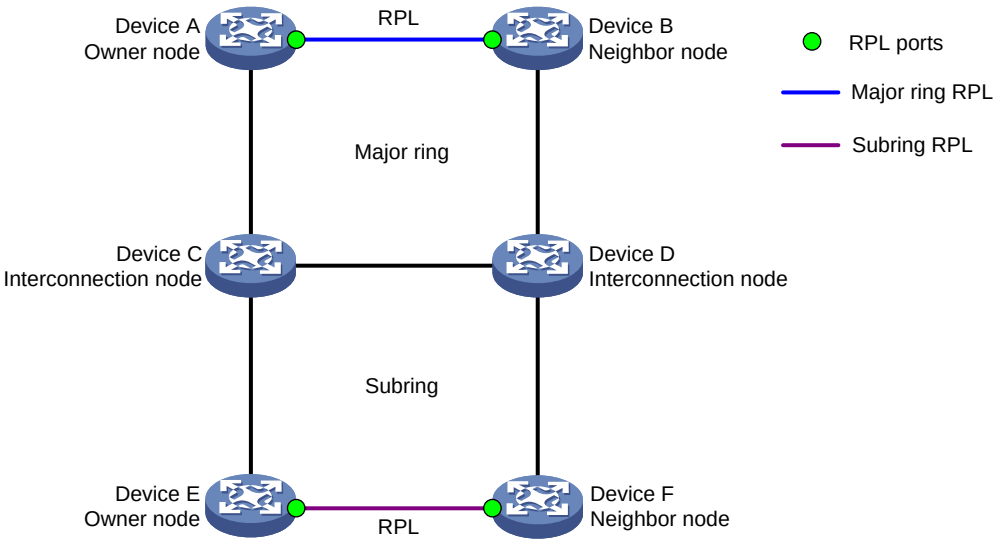


Figure 5 Network diagram

One major ring connecting one subring

The network has one major ring and one subring.

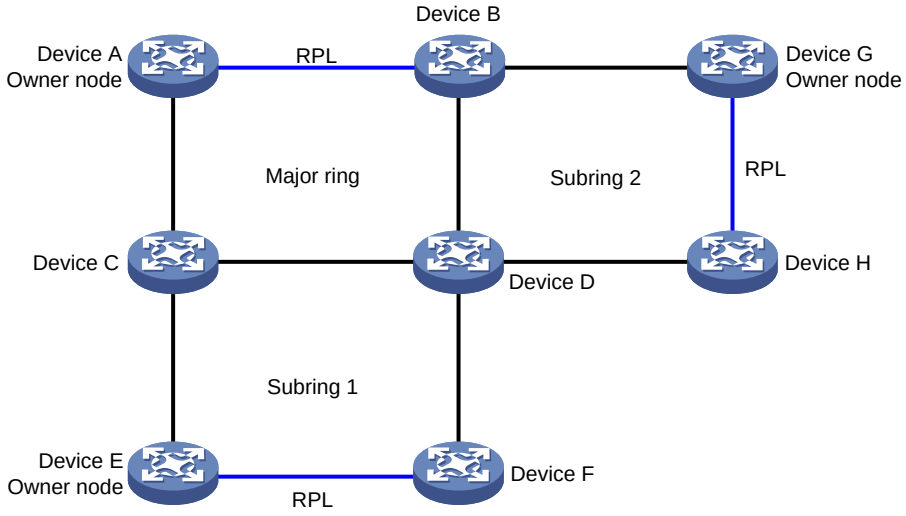

Figure 6 Network diagram

One major ring connecting multiple subrings

The network has three or more rings. Each subring is connected to the major ring by two interconnection nodes.

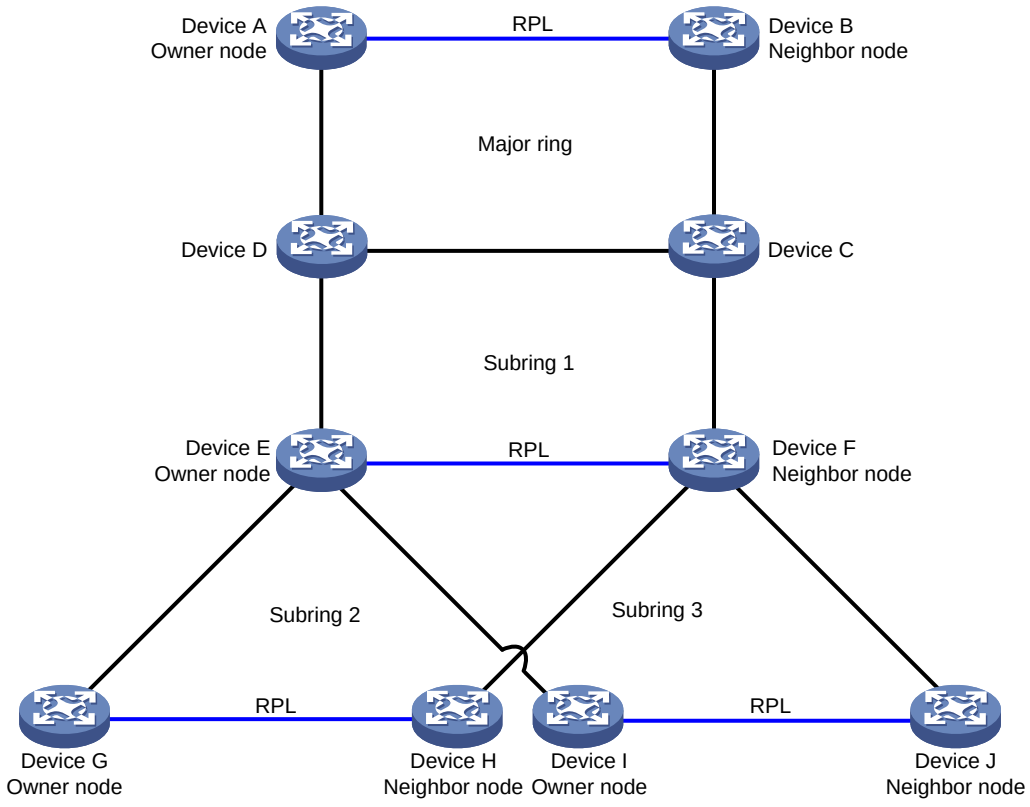

Figure 7 Network diagram

One subring connecting multiple subrings

The network has three or more rings. As shown in Figure 8, subring 1 is connected to the major ring. Other subrings are connected to subring 1 by two interconnection nodes.

Figure 8 Network diagram

One subring connecting multiple rings

The network has three or more rings. A minimum of one subring is connected to two rings. As shown in Figure 9, one interconnection node on subring 2 is connected to the major ring; and another interconnection node is connected to subring 1. As shown in Figure 10, subring 3 is connected to subring 1 and subring 2.

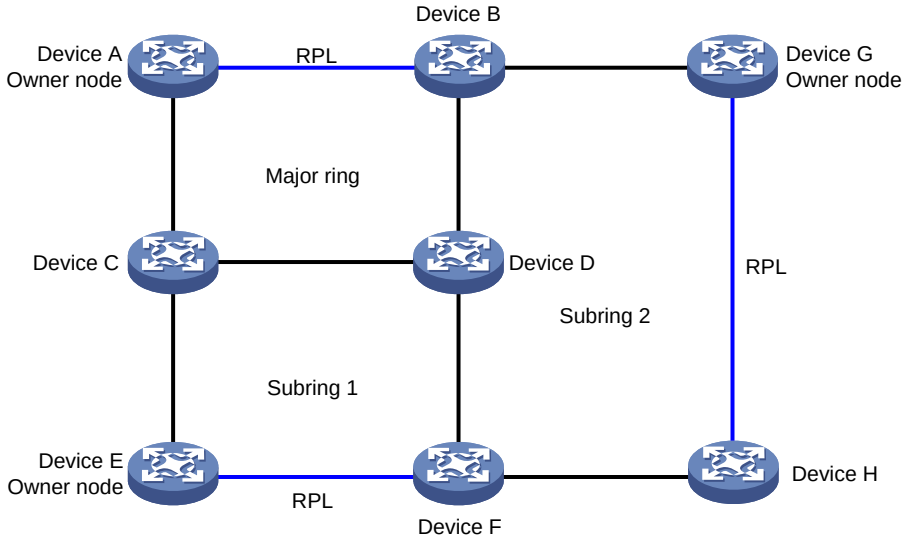

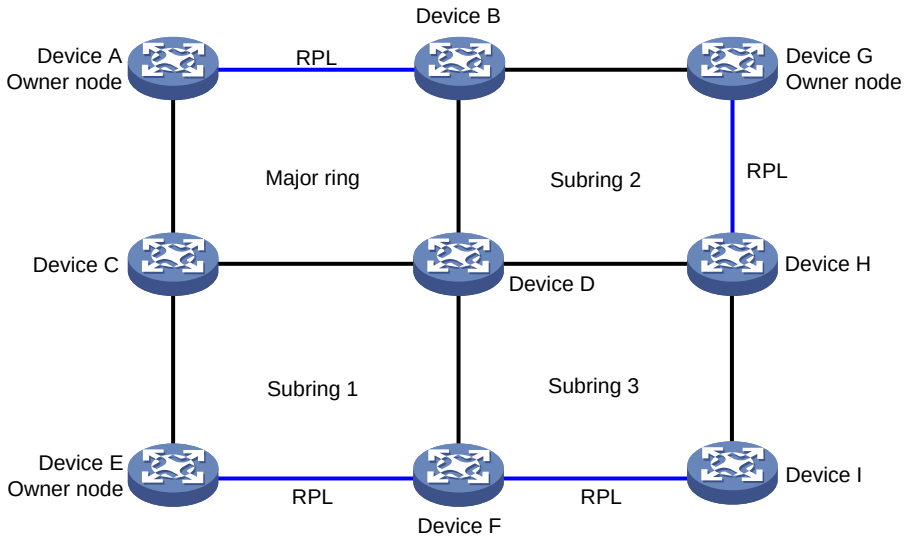

Figure 10 Network diagram 2

Protocols and standards

- ITU-T G.8032, *Recommendation ITU-T G.8032/Y.1344, Ethernet ring protection switching*
- IEEE 802.1D, *IEEE Std 802.1D™-2004, IEEE Standard for Local and Metropolitan Area Networks—Media Access Control (MAC) Bridges*
- IEEE 802.3, *IEEE Std 802.3-2008, IEEE Standard for Information technology*

Restrictions and guidelines: ERPS configuration

ERPS does not provide an election mechanism. To implement ring detection and protection, configure all nodes correctly.

ERPS tasks at a glance

To configure ERPS, perform the following tasks:

1. Enabling ERPS globally
   Perform this task on devices you want to configure as ERPS nodes.
2. Configuring an ERPS ring
   Perform this task on all nodes on an ERPS ring.
   a. Creating an ERPS ring
   b. Configuring ERPS ring member ports
   c. Configuring control VLANs
   d. Configuring protected VLANs
   e. Configuring the node role
3. Enabling ERPS for an instance
   Perform this task on all nodes on an ERPS ring.
4. (Optional.) Enabling R-APS packets to carry the ring ID in the destination MAC address
   Perform this task on all nodes on an ERPS ring.
5. (Optional.) Configuring R-APS packet levels
6. (Optional.) Setting ERPS timers
   Perform this task on the owner node on an ERPS ring.
7. (Optional.) Setting the non-revertive mode
   Perform this task on the owner node on an ERPS ring.
8. (Optional.) Setting a switchover mode
   Perform this task on the nodes that you want to block their ports.
9. (Optional.) Associating a ring with a subring
   Perform this task on the interconnection node on an ERPS ring.
10. (Optional.) Enabling flush packet transparent transmission
    Perform this task on the interconnection node on an ERPS ring.
11. (Optional.) Associating an ERPS ring member port with a track entry
12. (Optional.) Removing the MS mode and FS mode settings for an ERPS ring

Prerequisites

Before you configure ERPS, complete the following tasks:

- Establish the Ethernet ring topology.
- Determine the ERPS rings, ERPS instances, control VLANs, protected VLANs, and node roles.

Enabling ERPS globally

Restrictions and guidelines

- Perform this task on devices you want to configure as ERPS nodes.
- For ERPS to take effect for an instance, enable it globally first.

Procedure

1. Enter system view.

system-view

2. Enable ERPS globally.

   erps enable

   By default, ERPS is disabled globally.

Configuring an ERPS ring

Creating an ERPS ring

Restrictions and guidelines

- Perform this task on all nodes on an ERPS ring.
- A ring ID uniquely identifies an ERPS ring. All nodes on an ERPS ring must be configured with the same ring ID.

Procedure

1. Enter system view.

   system-view

2. Create an ERPS ring.

   erps ring *ring-id*

3. (Optional.) Configure the ring type.

   ring-type sub-ring

   By default, an ERPS ring is a major ring.

Configuring ERPS ring member ports

Restrictions and guidelines

- Perform this task on each node's ports intended for accessing ERPS rings.
- ERPS ring member ports automatically allow packets from the control VLAN to pass through.
- Do not enable Ethernet OAM remote loopback for ERPS ring member ports. This feature might cause a broadcast storm. For more information about Ethernet OAM, see "Configuring Ethernet OAM."
- For faster topology convergence, use the **link-delay** command on ERPS ring member ports to set the physical state change suppression interval to 0 seconds. For more information about the **link-delay** command, see *Interface Command Reference*.
- You must configure ERPS ring member ports as trunk ports.
- Do not assign an interface to both an aggregation group and an ERPS ring. If you do so, the interface does not take effect on the ERPS ring and cannot be displayed by using the **display erps detail** command.

Configuring ERPS ring member port attributes

1. Enter system view.

   system-view

2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.

   interface *interface-type interface-number*

3. Configure the port as a trunk port.

   port link-type trunk

By default, a port is an access port.

For more information about this command, see *Layer 2—LAN Switching Command Reference*.

4. Assign the trunk port to protected VLANs.

   port trunk permit vlan { *vlan-id-list* | **all** }

   By default, a trunk port is assigned only to VLAN 1.

   For more information about this command, see *Layer 2—LAN Switching Command Reference*.

5. Disable the spanning tree feature.

   undo stp enable

   By default, the spanning tree feature is enabled.

   For more information about this command, see *Layer 2—LAN Switching Command Reference*.

Configuring an ERPS ring member port

1. Enter system view.

   system-view

2. Enter ERPS ring view.

   erps ring *ring-id*

3. Configure an ERPS ring member port.

   { **port0** | **port1** } **interface** *interface-type interface-number*

   By default, an ERPS ring does not have ERPS ring member ports.

Configuring control VLANs

Restrictions and guidelines

- Perform this task on all nodes on an ERPS ring.
- The control VLAN must be a VLAN that has not been created on the device.
- Configure the same control VLAN for all nodes in an ERPS instance.
- Do not configure the default VLAN of an ERPS ring member port as the control VLAN.
- Do not enable QinQ or VLAN mapping on control VLANs. If you do, ERPS packets cannot be correctly forwarded and received.
- Make sure the ERPS instance has been configured. After the ERPS instance is enabled, the control VLAN cannot be changed.
- For a device not configured with ERPS to transparently transmit ERPS packets, make sure only the two ports accessing the ERPS ring permit packets from the control VLAN. If other ports on the device permit packets from the control VLAN, the packets from other VLANs might enter the control VLAN and strike the ERPS ring.

Procedure

1. Enter system view.

   system-view

2. Enter ERPS ring view.

   erps ring *ring-id*

3. Enable ERPS instance view.

   instance *instance-id*

4. Configure a control VLAN.

   control-vlan *vlan-id*

Configuring protected VLANs

Restrictions and guidelines

- Perform this task on all nodes on an ERPS ring.
- Configure the same protected VLAN for all nodes of an ERPS instance. To implement load balancing, configure different protected VLANs for different ERPS instances.

Prerequisites

Before you configure protected VLANs, you must configure an MST region and the VLAN-to-instance mapping table. For more information about MST regions, see spanning tree configuration in *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enable ERPS instance view.
   instance *instance-id*
4. Configure the protected VLANs.
   protected-vlan reference-instance *instance-id-list*

Configuring the node role

Restrictions and guidelines

- Perform this task on all nodes on an ERPS ring.
- For the owner node to work correctly, you must configure only one owner node for an ERPS ring.
- You can only configure the interconnection node for subrings.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enter ERPS instance view.
   instance *instance-id*
4. Configure the node role.
   node-role { { **owner** | **neighbor** } **rpl** | **interconnection** } { **port0** | **port1** }
   By default, a node is a normal node.

Enabling ERPS for an instance

Restrictions and guidelines

- Perform this task on all nodes on an ERPS ring.

- You can enable ERPS for an instance only when it is configured with a control VLAN and a protected VLAN.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enter ERPS instance view.
   instance *instance-id*
4. Enable ERPS for the instance.
   instance enable
   By default, ERPS is disabled for an instance.

Enabling R-APS packets to carry the ring ID in the destination MAC address

About this task

Perform this task to configure the ring ID as the last byte of the destination MAC address for R-APS packets. The ring of R-APS packets can be identified by their destination MAC addresses.

Restrictions and guidelines

Perform this task on all nodes on an ERPS ring.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enable R-APS packets to carry the ring ID in the destination MAC address.
   r-aps ring-mac
   By default, R-APS packets do not carry ring IDs in their destination MAC addresses. The last byte of the destination MAC address is 1.

Configuring R-APS packet levels

Restrictions and guidelines

Perform this task on all nodes on an ERPS ring.

On a ring, the levels of R-APS packets must be the same for all nodes in an ERPS instance.

A node does not process R-APS packets whose levels are greater than the level of R-APS packets sent by the node.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.

erps ring *ring-id*

3. Enter ERPS instance view.
   instance *instance-id*
4. Configure the R-APS packet level.
   r-aps level *level-value*
   By default, the level for R-APS packets is 7.

Setting ERPS timers

Restrictions and guidelines

Perform this task on the owner node on an ERPS ring.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enter ERPS instance view.
   instance *instance-id*
4. Set the guard timer.
   timer guard *guard-value*
   By default, the guard timer is 500 milliseconds.
5. Set the hold-off timer.
   timer hold-off *hold-off-value*
   By default, the hold-off timer is 0 milliseconds.
6. Set the WTR timer.
   timer wtr *wtr-value*
   By default, the WTR timer is 5 minutes.

Setting the non-revertive mode

About this task

Perform this task if you do not want to switch back to the recovered link after the link fault is cleared.

Restrictions and guidelines

Perform this task on the owner node on an ERPS ring.

Procedure

1. Enter system view.
   system-view
2. Enter ERPS ring view.
   erps ring *ring-id*
3. Enter ERPS instance view.
   instance *instance-id*
4. Set the non-revertive mode.

revertive-operation non-revertive

By default, revertive mode is used.

Setting a switchover mode

Restrictions and guidelines

Perform this task on the nodes that you want to block their ports.

Procedure

1. Enter system view.

   system-view

2. Set a switchover mode.

   erps switch { **force** | **manual** } **ring** *ring-id* **instance** *instance-id* { **port0** | **port1** }

   By default, no switchover mode is not set.

Associating a ring with a subring

About this task

On a multi-ring network, perform this task if you want to advertise topology changes in a subring to a ring.

Restrictions and guidelines

Perform this task on the interconnection node on an ERPS ring.

Procedure

1. Enter system view.

   system-view

2. Enter ERPS ring view.

   erps ring *ring-id*

3. Configure the ERPS ring as a subring.

   ring-type sub-ring

   By default, an ERPS ring is a major ring.

4. Enter ERPS instance view.

   instance *instance-id*

5. Associate a ring with the subring.

   sub-ring connect ring *ring-id* **instance** *instance-id*

   By default, a subring is not associated with any rings.

Enabling flush packet transparent transmission

About this task

This feature enables the interconnection nodes to forward flush packets for topology changes in the subring to the ring associated with the subring. The associated ring can flush the MAC address table quickly to speed up convergence.

Restrictions and guidelines

Perform this task on the interconnection node on an ERPS ring.

To use this feature, you must also associate a subring on the interconnection node with the ring.

Procedure

1. Enter system view.
   system-view
2. Enable flush packet transparent transmission.
   erps tcn-propagation
   By default, flush packet transparent transmission is disabled.

Associating an ERPS ring member port with a track entry

Restrictions and guidelines

Before you associate a port with a track entry, make sure the port has joined an ERPS instance.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. Associate an ERPS ring member port with a track entry.
   port erps ring *ring-id* **instance** *instance-id* **track** *track-entry-index*
   By default, an ERPS ring member port is not associated with any track entries.

Removing the MS mode and FS mode settings for an ERPS ring

About this task

After you configure this task, the owner node can ignore the WTR timer and immediately switch traffic to the recovered link upon link recovery.

This task also switches an ERPS ring in non-revertive mode to revertive mode.

Procedure

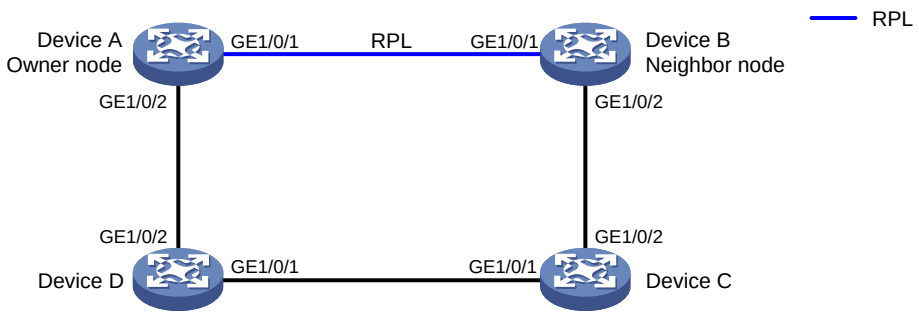
1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   erps clear ring *ring-id* **instance** *instance-id*

Displaying and maintaining ERPS

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display brief ERPS information.	**display erps**
Display detailed ERPS information.	**display erps detail ring** *ring-id* [**instance** *instance-id*]
Display ERPS packet statistics.	**display erps statistics** [**ring** *ring-id* [**instance** *instance-id*]]
Clear ERPS packet statistics.	**reset erps statistics ring** *ring-id* [**instance** *instance-id*]

ERPS configuration examples



Example: Configuring one ring

Network configuration

As shown in Figure 11, perform the following tasks to eliminate loops on the network:

- Configure the ring as ERPS ring 1.
- Configure VLAN 100 as the control VLAN for ERPS ring 1.
- Configure VLANs 1 to 30 as the protected VLANs for ERPS ring 1.
- Configure Device A as the owner node, GigabitEthernet 1/0/1 as ERPS ring member port 0 and the RPL port, and GigabitEthernet 1/0/2 as ERPS ring member port 1.
- Configure Device B as the neighbor node, GigabitEthernet 1/0/1 as ERPS ring member port 0 and the RPL port, and GigabitEthernet 1/0/2 as ERPS ring member port 1.
- Configure Device C and Device D as normal nodes, GigabitEthernet 1/0/1 as ERPS ring member port 0, and GigabitEthernet 1/0/2 as ERPS ring member port 1.

Figure 11 Network diagram

Procedure

1. Configure Device A.

   # Create VLANs 1 to 30, map these VLANs to MSTI 1, and activate the MST region configuration.

   ```
   <DeviceA> system-view
   [DeviceA] vlan 1 to 30
   [DeviceA] stp region-configuration
   [DeviceA-mst-region] instance 1 vlan 1 to 30
   [DeviceA-mst-region] active region-configuration
   ```

```
[DeviceA-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] link-delay up 0
[DeviceA-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceA-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 30.

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] link-delay up 0
[DeviceA-GigabitEthernet1/0/2] link-delay down 0
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```
[DeviceA] erps ring 1
```

Configure ERPS ring member ports.

```
[DeviceA-erps-ring1] port0 interface gigabitethernet 1/0/1
[DeviceA-erps-ring1] port1 interface gigabitethernet 1/0/2
```

Enable R-APS packets to carry ring ID in the destination MAC address.

```
[DeviceA-erps-ring1] r-aps ring-mac
```

Create ERPS instance 1.

```
[DeviceA-erps-ring1] instance 1
```

Configure the node role.

```
[DeviceA-erps-ring1-inst1] node-role owner rpl port0
```

Configure the control VLAN.

```
[DeviceA-erps-ring1-inst1] control-vlan 100
```

Configure the protected VLANs.

```
[DeviceA-erps-ring1-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceA-erps-ring1-inst1] instance enable
[DeviceA-erps-ring1-inst1] quit
[DeviceA-erps-ring1] quit
```

Enable ERPS.

```
[DeviceA] erps enable
```

2. Configure Device B.

Create VLANs 1 to 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 1 to 30
```

```
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] link-delay up 0
[DeviceB-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/1] undo stp enable
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Configure the port as a trunk port and assign it to VLANs 1 to 30.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] link-delay up 0
[DeviceB-GigabitEthernet1/0/2] link-delay down 0
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceB-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```
[DeviceB] erps ring 1
```

Configure ERPS ring member ports.

```
[DeviceB-erps-ring1] port0 interface gigabitethernet 1/0/1
[DeviceB-erps-ring1] port1 interface gigabitethernet 1/0/2
```

Enable R-APS packets to carry ring ID in the destination MAC address.

```
[DeviceB-erps-ring1] r-aps ring-mac
```

Create ERPS instance 1.

```
[DeviceB-erps-ring1] instance 1
```

Configure the node role.

```
[DeviceB-erps-ring1-inst1] node-role neighbor rpl port0
```

Configure the control VLAN.

```
[DeviceB-erps-ring1-inst1] control-vlan 100
```

Configure the protected VLANs.

```
[DeviceB-erps-ring1-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceB-erps-ring1-inst1] instance enable
[DeviceB-erps-ring1-inst1] quit
[DeviceB-erps-ring1] quit
```

Enable ERPS.

```
[DeviceB] erps enable
```

3. Configure Device C.

Create VLANs 1 to 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 30
[DeviceC] stp region-configuration
```

```
[DeviceC-mst-region] instance 1 vlan 1 to 30
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] link-delay up 0
[DeviceC-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 30.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] link-delay up 0
[DeviceC-GigabitEthernet1/0/2] link-delay down 0
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```
[DeviceC] erps ring 1
```

Configure ERPS ring member ports.

```
[DeviceC-erps-ring1] port0 interface gigabitethernet 1/0/1
[DeviceC-erps-ring1] port1 interface gigabitethernet 1/0/2
```

Enable R-APS packets to carry ring ID in the destination MAC address.

```
[DeviceC-erps-ring1] r-aps ring-mac
```

Create ERPS instance 1.

```
[DeviceC-erps-ring1] instance 1
```

Configure the control VLAN.

```
[DeviceC-erps-ring1-inst1] control-vlan 100
```

Configure the protected VLANs.

```
[DeviceC-erps-ring1-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceC-erps-ring1-inst1] instance enable
[DeviceC-erps-ring1-inst1] quit
[DeviceC-erps-ring1] quit
```

Enable ERPS.

```
[DeviceC] erps enable
```

4. Configure Device D.

Create VLANs 1 to 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 30
[DeviceD] stp region-configuration
[DeviceD-mst-region] instance 1 vlan 1 to 30
```

```
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] link-delay up 0
[DeviceD-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 30.

```
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] link-delay up 0
[DeviceD-GigabitEthernet1/0/2] link-delay down 0
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```
[DeviceD] erps ring 1
```

Configure ERPS ring member ports.

```
[DeviceD-erps-ring1] port0 interface gigabitethernet 1/0/1
[DeviceD-erps-ring1] port1 interface gigabitethernet 1/0/2
```

Enable R-APS packets to carry ring ID in the destination MAC address.

```
[DeviceD-erps-ring1] r-aps ring-mac
```

Create ERPS instance 1.

```
[DeviceD-erps-ring1] instance 1
```

Configure the control VLAN.

```
[DeviceD-erps-ring1-inst1] control-vlan 100
```

Configure the protected VLANs.

```
[DeviceD-erps-ring1-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceD-erps-ring1-inst1] instance enable
[DeviceD-erps-ring1-inst1] quit
[DeviceD-erps-ring1] quit
```

Enable ERPS.

```
[DeviceD] erps enable
```

Verifying the configuration

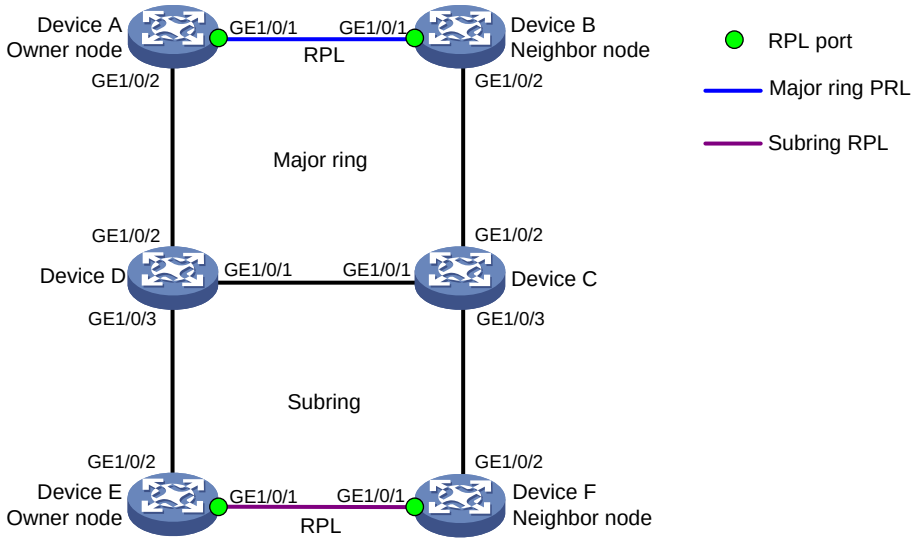
Display information about ERPS instance 1 for Device A.

```
[DeviceA] display erps detail ring 1
 Ring ID              : 1
 Port0                : GigabitEthernet1/0/1
 Port1                : GigabitEthernet1/0/2
 Subring              : No
 Default MAC          : No
```

```
Instance ID           : 1
Node role             : Owner
Node state            : Idle
Connect(ring/instance): -
Control VLAN          : 100
Protected VLAN        : Reference-instance 1
Guard timer           : 500 ms
Hold-off timer        : 0 ms
WTR timer             : 5 min
Revertive operation   : Revertive
Enable status         : Yes, Active status : Yes
R-APS level           : 7
Port                  PortRole               PortStatus
--------------------------------------------------------------------------------
Port0                 RPL                    Block
Port1                 Non-RPL                Up
```

The output shows the following information:

- Device A is the owner node.
- The ERPS ring is in idle state.
- The RPL port is blocked.
- The non-RPL port is unblocked.



Example: Configuring one subring

Network configuration

As shown in Figure 12, perform the following tasks to eliminate loops on the network:

- Configure VLAN 100 and VLAN 200 as the control VLANs for the major ring and the subring, respectively.
- Configure VLANs 1 to 30 as the protected VLANs for the major ring and subring.
- Configure Device A as the owner node for the major ring, GigabitEthernet 1/0/1 as ERPS ring member port 0 and the RPL port, and GigabitEthernet 1/0/2 as ERPS ring member port 1.
- Configure Device B as the neighbor node for the major ring, GigabitEthernet 1/0/1 as ERPS ring member port 0 and the RPL port, and GigabitEthernet 1/0/2 as ERPS ring member port 1.
- Configure Devices C and D as interconnection nodes, GigabitEthernet 1/0/1 as ERPS ring member port 0, GigabitEthernet 1/0/2 as ERPS ring member port 1, and GigabitEthernet 1/0/3 as the interconnection port.
- Configure Device E as the owner node for the subring, GigabitEthernet 1/0/1 as ERPS ring member port 0 and the RPL port, and GigabitEthernet 1/0/2 as ERPS ring member port 1.
- Configure Device F as the neighbor node for the subring, GigabitEthernet 1/0/1 as ERPS ring member port 0 and the RPL port, and GigabitEthernet 1/0/2 as ERPS ring member port 1.

Figure 12 Network diagram

Procedure

1. Configure Device A.

   # Create VLANs 1 to 30, map these VLANs to MSTI 1, and activate the MST region configuration.

   ```
   <DeviceA> system-view
   [DeviceA] vlan 1 to 30

[DeviceD-erps-ring2-inst1] quit
[DeviceD-erps-ring2] quit
```

Enable ERPS.

```
[DeviceD] erps enable
```

5. Configure Device E.

Create VLANs 1 to 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceE> system-view
[DeviceE] vlan 1 to 30
[DeviceE] stp region-configuration
[DeviceE-mst-region] instance 1 vlan 1 to 30
[DeviceE-mst-region] active region-configuration
[DeviceE-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceE] interface gigabitethernet 1/0/1
[DeviceE-GigabitEthernet1/0/1] link-delay up 0
[DeviceE-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceE-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 30.

```
[DeviceE-GigabitEthernet1/0/1] port link-type trunk
[DeviceE-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceE-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceE] interface gigabitethernet 1/0/2
[DeviceE-GigabitEthernet1/0/2] link-delay up 0
[DeviceE-GigabitEthernet1/0/2] link-delay down 0
[DeviceE-GigabitEthernet1/0/2] undo stp enable
[DeviceE-GigabitEthernet1/0/2] port link-type trunk
[DeviceE-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceE-GigabitEthernet1/0/2] quit
```

Create ERPS ring 2.

```
[DeviceE] erps ring 2
```

Configure ERPS ring member ports.

```
[DeviceE-erps-ring2] port0 interface gigabitethernet 1/0/1
[DeviceE-erps-ring2] port1 interface gigabitethernet 1/0/2
```

Configure ERPS ring 2 as the subring.

```
[DeviceE-erps-ring2] ring-type sub-ring
```

Create ERPS instance 1.

```
[DeviceE-erps-ring2] instance 1
```

Configure the node role.

```
[DeviceE-erps-ring2] node-role owner rpl port0
```

Configure the control VLAN.

```
[DeviceE-erps-ring2-inst1] control-vlan 110
```

Configure the protected VLANs.

```
[DeviceE-erps-ring2-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceE-erps-ring2-inst1] instance enable
[DeviceE-erps-ring2-inst1] quit
[DeviceE-erps-ring2] quit
```

Enable ERPS.

```
[DeviceE] erps enable
```

6. Configure Device F.

Create VLANs 1 to 30, map these VLANs to MSTI 1, and activate the MST region configuration.

```
<DeviceF> system-view
[DeviceF] vlan 1 to 30
[DeviceF] stp region-configuration
[DeviceF-mst-region] instance 1 vlan 1 to 30
[DeviceF-mst-region] active region-configuration
[DeviceF-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceF] interface gigabitethernet 1/0/1
[DeviceF-GigabitEthernet1/0/1] link-delay up 0
[DeviceF-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceF-GigabitEthernet1/0/1] undo stp enable
[DeviceF-GigabitEthernet1/0/1] port link-type trunk
```

Configure the port as a trunk port and assign it to VLANs 1 to 30.

```
[DeviceF-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceF-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceF] interface gigabitethernet 1/0/2
[DeviceF-GigabitEthernet1/0/2] link-delay up 0
[DeviceF-GigabitEthernet1/0/2] link-delay down 0
[DeviceF-GigabitEthernet1/0/2] undo stp enable
[DeviceF-GigabitEthernet1/0/2] port link-type trunk
[DeviceF-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceF-GigabitEthernet1/0/2] quit
```

Create ERPS ring 2.

```
[DeviceF] erps ring 2
```

Configure ERPS ring member ports.

```
[DeviceF-erps-ring2] port0 interface gigabitethernet 1/0/1
[DeviceF-erps-ring2] port1 interface gigabitethernet 1/0/2
```

Configure ERPS ring 2 as the subring.

```
[DeviceF-erps-ring2] ring-type sub-ring
```

Create ERPS instance 1.

```
[DeviceF-erps-ring2] instance 1
```

Configure the node role.

```
[DeviceF-erps-ring2] node-role neighbor rpl port0
```

Configure the control VLAN.

```
[DeviceF-erps-ring2-inst1] control-vlan 110
```

Configure the protected VLANs.

```
[DeviceF-erps-ring2-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceF-erps-ring2-inst1] instance enable
[DeviceF-erps-ring2-inst1] quit
[DeviceF-erps-ring2] quit
```

Enable ERPS.

```
[DeviceF] erps enable
```

Verifying the configuration

Display information about ERPS instance 1 for Device A.

```
[Device A] display erps detail ring 1
 Ring ID               : 1
 Port0                 : GigabitEthernet1/0/1
 Port1                 : GigabitEthernet1/0/2

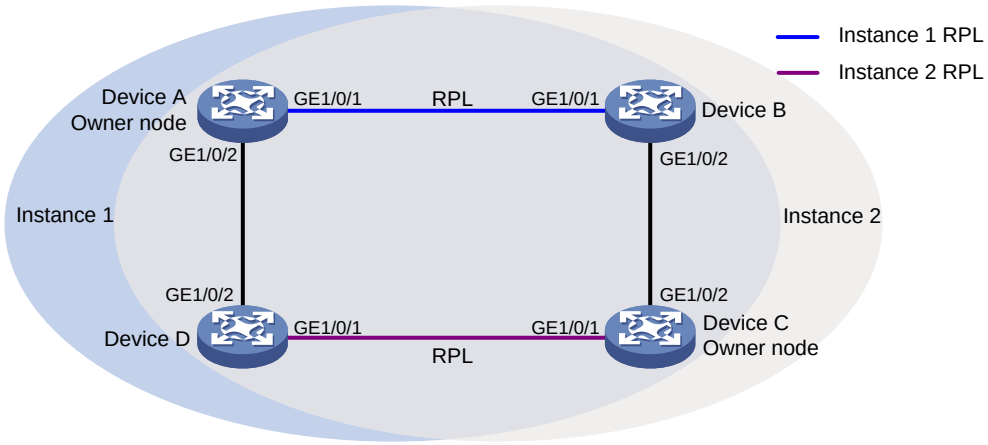
 Hold-off timer        : 0 ms
 WTR timer             : 5 min
 Revertive operation   : Revertive
 Enable status         : Yes, Active status : Yes
 R-APS level           : 7
 Port                  PortRole                PortStatus
 --------------------------------------------------------------------------------
 Port0                 RPL                     Block
 Port1                 Non-RPL                 Up
```

The output shows the following information:

- Device A is the owner node.
- The ERPS ring is in idle state.
- The RPL port is blocked.
- The non-RPL port is unblocked.



Example: Configuring one-ring multi-instance load balancing

Network configuration

As shown in Figure 13, perform the following tasks to improve network resource utilization and implement load balancing among links:

- Configure ERPS instances 1 and 2 on the ERPS ring.
- For ERPS instance 1, configure the following items:
  - Configure Device A as the owner node.
  - Configure the link between Devices A and Device B as the RPL.
  - Configure VLAN 100 as the control VLAN.
  - Configure VLANs 1 to 30 as the protected VLANs.
- For ERPS instance 2, configure the following items:
  - Configure Device A as the owner node.
  - Configure the link between Devices C and Device D as the RPL.
  - Configure VLAN 100 as the control VLAN.
  - Configure VLANs 31 to 60 as the protected VLANs.

Figure 13 Network diagram

Procedure

1. Configure Device A.

Create VLANs 1 to 60, map VLANs 1 to 30 to MSTI 1, map VLANs 31 to 60 to MSTI 2, and activate the MST region configuration.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 60
[DeviceA] stp region-configuration
[DeviceA-mst-region] instance 1 vlan 1 to 30
[DeviceA-mst-region] instance 2 vlan 31 to 60
[DeviceA-mst-region] active region-configuration
[DeviceA-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] link-delay up 0
[DeviceA-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceA-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 60.

```
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 60
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] link-delay up 0
[DeviceA-GigabitEthernet1/0/2] link-delay down 0
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 60
[DeviceA-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```
[DeviceA] erps ring 1
```

Configure ERPS ring member ports.

```
[DeviceA-erps-ring1] port0 interface gigabitethernet 1/0/1
[DeviceA-erps-ring1] port1 interface gigabitethernet 1/0/2
```

Create ERPS instance 1.

```
[DeviceA-erps-ring1] instance 1
```

Configure the node role.

```
[DeviceA-erps-ring1-inst1] node-role owner rpl port0
```

Configure the control VLAN.

```
[DeviceA-erps-ring1-inst1] control-vlan 100
```

Configure the protected VLANs.

```
[DeviceA-erps-ring1-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceA-erps-ring1-inst1] instance enable
[DeviceA-erps-ring1-inst1] quit
[DeviceA-erps-ring1] quit
```

Create ERPS instance 2.

```
[DeviceA-erps-ring1] instance 2
```

Configure the control VLAN.

```
[DeviceA-erps-ring1-inst2] control-vlan 110
```

Configure the protected VLANs.

```
[DeviceA-erps-ring1-inst2] protected-vlan reference-instance 2
```

Enable ERPS for instance 2.

```
[DeviceA-erps-ring1-inst2] instance enable
[DeviceA-erps-ring1-inst2] quit
[DeviceA-erps-ring1] quit
```

Enable ERPS.

```
[DeviceA] erps enable
```

2. Configure Device B.

Create VLANs 1 to 60, map VLANs 1 to 30 to MSTI 1, map VLANs 31 to 60 to MSTI 2, and activate the MST region configuration.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 60
```

```
[DeviceB] stp region-configuration
[DeviceB-mst-region] instance 1 vlan 1 to 30
[DeviceB-mst-region] instance 2 vlan 31 to 60
[DeviceB-mst-region] active region-configuration
[DeviceB-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] link-delay up 0
[DeviceB-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 60.

```
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 60
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] link-delay up 0
[DeviceB-GigabitEthernet1/0/2] link-delay down 0
[DeviceB-GigabitEthernet1/0/2] undo stp enable
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 60
[DeviceB-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```
[DeviceB] erps ring 1
```

Configure ERPS ring member ports.

```
[DeviceB-erps-ring1] port0 interface gigabitethernet 1/0/1
[DeviceB-erps-ring1] port1 interface gigabitethernet 1/0/2
```

Create ERPS instance 1.

```
[DeviceB-erps-ring1] instance 1
```

Configure the node role.

```
[DeviceB-erps-ring1-inst1] node-role neighbor rpl port0
```

Configure the control VLAN.

```
[DeviceB-erps-ring1-inst1] control-vlan 100
```

Configure the protected VLANs.

```
[DeviceB-erps-ring1-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceB-erps-ring1-inst1] instance enable
[DeviceB-erps-ring1-inst1] quit
[DeviceB-erps-ring1] quit
```

Create ERPS instance 2.

```
[DeviceB-erps-ring1] instance 2
```

Configure the control VLAN.

```
[DeviceB-erps-ring1-inst2] control-vlan 110
```

Configure the protected VLANs.

```
[DeviceB-erps-ring1-inst2] protected-vlan reference-instance 2
```

Enable ERPS for instance 2.

```
[DeviceB-erps-ring1-inst2] instance enable
[DeviceB-erps-ring1-inst2] quit
[DeviceB-erps-ring1] quit
```

Enable ERPS.

```
[DeviceB] erps enable
```

3. Configure Device C.

Create VLANs 1 to 60, map VLANs 1 to 30 to MSTI 1, map VLANs 31 to 60 to MSTI 2, and activate the MST region configuration.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 60
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 30
[DeviceC-mst-region] instance 2 vlan 31 to 60
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] link-delay up 0
[DeviceC-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 60.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 60
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] link-delay up 0
[DeviceC-GigabitEthernet1/0/2] link-delay down 0
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 60
[DeviceC-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```
[DeviceC] erps ring 1
```

Configure ERPS ring member ports.

```
[DeviceC-erps-ring1] port0 interface gigabitethernet 1/0/1
[DeviceC-erps-ring1] port1 interface gigabitethernet 1/0/2
```

Create ERPS instance 1.

```
[DeviceC-erps-ring1] instance 1
```

Configure the control VLAN.

```
[DeviceC-erps-ring1-inst1] control-vlan 100
```

Configure the protected VLANs.

```
[DeviceC-erps-ring1-inst1] protected-vlan reference-instance 1
```

Enable ERPS for instance 1.

```
[DeviceC-erps-ring1-inst1] instance enable
[DeviceC-erps-ring1-inst1] quit
```

```
[DeviceC-erps-ring1] quit
```

Create ERPS instance 2.

```
[DeviceC-erps-ring1] instance 2
```

Configure the node role.

```
[DeviceC-erps-ring1-inst2] node-role owner rpl port0
```

Configure the control VLAN.

```
[DeviceC-erps-ring1-inst2] control-vlan 110
```

Configure the protected VLANs.

```
[DeviceC-erps-ring1-inst2] protected-vlan reference-instance 2
```

Enable ERPS for instance 2.

```
[DeviceC-erps-ring1-inst2] instance enable
[DeviceC-erps-ring1-inst2] quit
[DeviceC-erps-ring1] quit
```

Enable ERPS.

```
[DeviceC] erps enable
```

4. Configure Device D.

Create VLANs 1 to 60, map VLANs 1 to 30 to MSTI 1, map VLANs 31 to 60 to MSTI 2, and activate the MST region configuration.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 60
[DeviceD] stp region-configuration
[DeviceD-mst-region] instance 1 vlan 1 to 30
[DeviceD-mst-region] instance 2 vlan 31 to 60
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

Set the link state change suppression interval to 0 seconds on GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] link-delay up 0
[DeviceD-GigabitEthernet1/0/1] link-delay down 0
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port and assign it to VLANs 1 to 60.

```
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 60
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] link-delay up 0
[DeviceD-GigabitEthernet1/0/2] link-delay down 0
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 60
[DeviceD-GigabitEthernet1/0/2] quit
```

Create ERPS ring 1.

```
[DeviceD] erps ring 1
```

Configure ERPS ring member ports.

```
[DeviceD-erps-ring1] port0 interface gigabitethernet 1/0/1
```

```
[DeviceD-erps-ring1] port1 interface gigabitethernet 1/0/2
```

Create ERPS instance 1.

```

```

Configure the protected VLANs.

```
[DeviceD-erps-ring1-inst2] protected-vlan reference-instance 2
```

Enable ERPS for instance 2.

```
[DeviceD-erps-ring1-inst2] instance enable
[DeviceD-erps-ring1-inst2] quit
[DeviceD-erps-ring1] quit
```

Enable ERPS.

```
[DeviceD] erps enable
```

Verifying the configuration

Display information about ERPS instance 1 for Device A.

```
[Device A] display erps detail ring 1
 Ring ID               : 1
 Port0                 : GigabitEthernet1/0/1
 Port1                 : GigabitEthernet1/0/2

```

```
Port1                   Non-RPL                 Up

 Instance ID            : 2
Node role               : Normal
Node state              : Idle
Connect(ring/instance): -
Control VLAN            : 100
Protected VLAN          : Reference-instance 2
Guard timer             : 500 ms
Hold-off timer          : 0 ms
WTR timer               : 5 min
Revertive operation     : Revertive
Enable status           : Yes, Active status : Yes
R-APS level             : 7
Port                    PortRole                PortStatus
--------------------------------------------------------------------------------
Port0                   Non-RPL                 Up
Port1                   Non-RPL                 Up
```

The output shows the following information:

- For ERPS instance 1:
  - Device A is the owner node.
  - The ERPS ring is in idle state.
  - The RPL port is blocked.
  - The non-RPL port is unblocked.
- For ERPS instance 2:
  - Device A is a normal node.
  - The ERPS ring is in idle state.
  - The non-RPL port is unblocked.

Troubleshooting ERPS

The owner node cannot receive SF packets from a faulty node when the link state is normal

Symptom

The link between the owner node and the faulty node is available, but the owner node cannot receive SF packets sent by the faulty node. The RPL port is blocked.

Analysis

Possible reasons include:

- ERPS is not enabled for some nodes on the ERPS ring.
- The ring IDs are different for the nodes on the same ERPS ring.
- The control VLAN IDs are different for the nodes in the same ERPS instance.
- A port on the ERPS ring is faulty.

Solutions

To resolve the problem:

- Use the **display erps** command to examine whether ERPS is enabled for all nodes on the ERPS ring. If ERPS is disabled for some nodes, use the **erps enable** command to enable ERPS for the nodes.
- Set the same ring ID for all nodes on a ERPS ring and configure the same control VLAN for all nodes in an ERPS instance.
- Use the **display erps detail** command to examine the port status for all nodes. Bring up the ports in down state.
- Use the **debugging erps** command on all nodes to view debugging information about packets and node status.

Configuring Smart Link

About Smart Link

Application scenario

Smart Link is an H3C-proprietary protocol that provides link redundancy and subsecond convergence time in a dual uplink network. As shown in Figure 1, Smart Link is configured on Device C and Device D. The secondary link takes over quickly when the primary link fails.

Figure 1 Dual uplink network diagram

A Smart Link network has the following devices:

- **Smart Link devices**—A Smart Link device has two uplinks. A Smart Link device must be configured with a smart link group and a transmit control VLAN to transmit flush messages. Device C and Device D in Figure 1 are Smart Link devices.
- **Associated devices**—An associated device is an uplink device to which Smart Link devices are connected. An associated device supports Smart Link, and receives flush messages sent from the specified control VLAN. When a primary/secondary link switchover occurs, the associated device updates the MAC address entries and ARP/ND entries according to received flush messages. Device A, Device B, and Device E in Figure 1 are associated devices.

Terminology

Smart link group

A smart link group consists of only two member ports: the primary and the secondary ports. Only one port is active for forwarding at a time, and the other port is blocked and in standby state. When link failure occurs on the active port due to port shutdown or the presence of unidirectional link, the standby port becomes active and takes over. The original active port transits to the blocked state.

As shown in Figure 1, Port C1 and Port C2 of Device C form a smart link group. Port C1 is active, and Port C2 is standby. Port D1 and Port D2 of Device D form another smart link group. Port D1 is active, and Port D2 is standby.

Primary/secondary port

Primary port and secondary port are two port types in a smart link group. When both ports in a smart link group are up, the primary port preferentially transits to the forwarding state. The secondary port stays in standby state. When the primary port fails, the secondary port takes over to forward traffic.

As shown in Figure 1, Port C1 of Device C and Port D1 of Device D are primary ports. Port C2 of Device C and Port D2 of Device D are secondary ports.

Primary/secondary link

The link that connects the primary port in a smart link group is the primary link. The link that connects the secondary port is the secondary link.

Flush message

When link switchover occurs, the smart link group uses flush messages to notify other devices to refresh their MAC address entries and ARP/ND entries. Flush messages are common multicast data packets, and will be dropped by a blocked receiving port.

Protected VLAN

A smart link group controls the forwarding state of protected VLANs. Each smart link group on a port controls a different protected VLAN. The state of the port in a protected VLAN is determined by the state of the port in the smart link group.

Transmit control VLAN

The transmit control VLAN is used for transmitting flush messages. When link switchover occurs, the devices (such as Device C and Device D in Figure 1) send flush messages within the transmit control VLAN.

Receive control VLAN

The receive control VLAN is used for receiving and processing flush messages. When link switchover occurs, the devices (such as Device A, Device B, and Device E in Figure 1) receive and process flush messages in the receive control VLAN. In addition, they refresh their MAC address entries and ARP/ND entries.

How Smart Link works

Link backup

As shown in Figure 1, the link on Port C1 of Device C is the primary link. The link on Port C2 of Device C is the secondary link. Port C1 is in forwarding state, and Port C2 is in standby state. When the primary link fails, Port C2 takes over to forward traffic and Port C1 is blocked and placed in standby state.

When a port switches to the forwarding state, the system outputs log information to notify the user of the port state change.

Topology change

Link switchover might outdate the MAC address entries and ARP/ND entries on all devices. A flush update mechanism is provided to ensure correct packet transmission. With this mechanism, a Smart Link-enabled device updates its information by transmitting flush messages over the backup link to its upstream devices. This mechanism requires the upstream devices to be capable of recognizing Smart Link flush messages to update their MAC address forwarding entries and ARP/ND entries.

Preemption mode

As shown in Figure 1, the link on Port C1 of Device C is the primary link. The link on Port C2 of Device C is the secondary link. When the primary link fails, Port C1 is automatically blocked and placed in standby state, and Port C2 takes over to forward traffic. When the primary link recovers, one of the following actions occurs:

- If the smart link group is not configured with a preemption mode, Port C1 stays blocked to keep traffic forwarding stable. Port C1 does not take over to forward traffic until the next link switchover.
- If the smart link group is configured with a preemption mode and the preemption conditions are met, Port C1 takes over to forward traffic as soon as its link recovers. Port C2 is automatically blocked and placed in standby state.

Load sharing

A ring network might carry traffic of multiple VLANs. Smart Link can forward traffic from different VLANs in different smart link groups for load sharing.

To implement load sharing, you can assign a port to multiple smart link groups. Configure each group with a different protected VLAN. Make sure the state of the port is different in these smart link groups, so traffic from different VLANs can be forwarded along different paths.

You can configure protected VLANs for a smart link group by referencing Multiple Spanning Tree Instances (MSTIs). For more information about MSTIs, see *Layer 2—LAN Switching Configuration Guide*.

Collaboration between Smart Link and Monitor Link for port status detection

Smart Link cannot detect when faults occur on the uplink of the upstream devices or when faults are cleared. You can configure the Monitor Link function to monitor the status of the uplink ports of the upstream devices. Monitor Link adapts the up/down state of downlink ports to uplink ports, and triggers Smart Link to perform link switchover on the downstream device. For more information about Monitor Link, see "Configuring Monitor Link."

Collaboration between Smart Link and Track for link status detection

Smart Link cannot detect unidirectional links, misconnected fibers, or packet loss on intermediate devices or network paths of the uplink. It cannot detect when faults are cleared either. To detect link status, smart link group member ports must use link detection protocols. When a fault is detected or cleared, the link detection protocols inform Smart Link to switch over the links.

Smart Link collaborates with link detection protocols through track entries. It supports only the Continuity Check (CC) function of Connectivity Fault Detection (CFD) to implement link detection. CFD notifies the smart link group member ports of fault detection events by using detection VLANs and detection ports. A port responds to a continuity check event only when the control VLAN of the smart link group to which it belongs matches the detection VLAN. For more information about track entries and the CC function of CFD, see "Configuring Track" and "Configuring CFD."

Restrictions and guidelines: Smart Link configuration

When you configure Smart Link, follow these restrictions and guidelines:

- If you configure a port as both an aggregation group member and a smart link group member, only the aggregation group configuration takes effect. The port is not shown in the output from the **display smart-link group** command. The smart link group configuration takes effect after the port leaves the aggregation group.

Smart Link tasks at a glance

To configure Smart Link, perform the following tasks:

1. Configuring a Smart Link device
   a. Configuring protected VLANs for a smart link group
   b. Configuring member ports for a smart link group
   c. (Optional.) Configuring a preemption mode for a smart link group
   d. (Optional.) Enabling the sending of flush messages
   e. (Optional.) Configuring collaboration between Smart Link and Track
2. Enabling an associated device to receive flush messages

Configuring a Smart Link device

Prerequisites for Smart Link device configuration

Before configuring a Smart Link device, complete the following tasks:

- To prevent loops, shut down a port before configuring it as a smart link group member. You can bring up the port only after completing the smart link group configuration.
- Disable the spanning tree feature, RRPP, and ERPS on the ports you want to add to the smart link group.

Configuring protected VLANs for a smart link group

Prerequisites

Before you configure protected VLANs, you must configure an MST region and the VLAN-to-instance mapping table. For more information about MST regions, see spanning tree configuration in *Layer 2—LAN Switching Configration Guide*.

Procedure

1. Enter system view.
   system-view
2. Create a smart link group and enter smart link group view.
   smart-link group *group-id*
3. Configure protected VLANs for the smart link group.
   protected-vlan reference-instance *instance-id-list*

Configuring member ports for a smart link group

Restrictions and guidelines

You can configure member ports for a smart link group either in smart link group view or in interface view. The configurations made in these two views have the same effect.

In smart link group view

1. Enter system view.
   system-view
2. Create a smart link group and enter smart link group view.
   smart-link group *group-id*
3. Configure member ports for a smart link group.
   port *interface-type interface-number* { **primary** | **secondary** }
   By default, no member port is configured for a smart link group.

In interface view

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. Configure member ports for a smart link group.
   port smart-link group *group-id* { **primary** | **secondary** }
   By default, an interface is not a smart link group member.

Configuring a preemption mode for a smart link group

1. Enter system view.
   system-view
2. Enter smart link group view.
   smart-link group *group-id*
3. Configure a preemption mode for the smart link group.
   preemption mode { **role** | **speed** [**threshold** *threshold-value*] }
   By default, preemption is disabled.
4. Configure the preemption delay.
   preemption delay *delay*
   By default, the preemption delay is 1 second.
   The preemption delay configuration takes effect only after a preemption mode is configured.

Enabling the sending of flush messages

Restrictions and guidelines

- The control VLAN configured for a smart link group must be different from the control VLAN configured for any other smart link group.
- Make sure the configured control VLAN already exists, and assign the smart link group member ports to the control VLAN.

- The control VLAN of a smart link group must also be one of its protected VLANs. Do not remove the control VLAN. Otherwise, flush messages cannot be sent correctly.

Procedure

1. Enter system view.
   system-view
2. Enter smart link group view.
   smart-link group *group-id*
3. Enable flush update.
   flush enable [**control-vlan** *vlan-id*]
   By default, flush update is enabled, and VLAN 1 is the control VLAN.

Configuring collaboration between Smart Link and Track

About this task

Smart Link collaborates with the CC function of CFD through track entries to implement link detection.

Prerequisites

Before you configure collaboration between Smart Link and Track on a port, you must assign the port to the smart link group.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. Configure collaboration between Smart Link and Track on the port.
   port smart-link group *group-id* **track** *track-entry-number*
   By default, smart link group member ports do not collaborate with track entries.

Enabling an associated device to receive flush messages

Restrictions and guidelines

- You do not need to enable all ports on the associated devices to receive flush messages. Enable the feature only on all control VLANs of ports on the primary and secondary links between the Smart Link device and the destination device.
- If no control VLAN is specified for processing flush messages, the device forwards the received flush messages without any processing.
- Make sure the receive control VLAN is the same as the transmit control VLAN configured on the Smart Link device. If they are not the same, the associated device will forward the received flush messages directly without any processing.
- Do not remove the control VLANs. Otherwise, flush messages cannot be sent correctly.
- Make sure the control VLANs are existing VLANs, and assign the ports capable of receiving flush messages to the control VLANs.

Prerequisites

Disable the spanning tree feature on the associated device's ports that connect to the member ports of the smart link group. Otherwise, the ports will discard flush messages when they are not in forwarding state if a topology change occurs.

Procedure

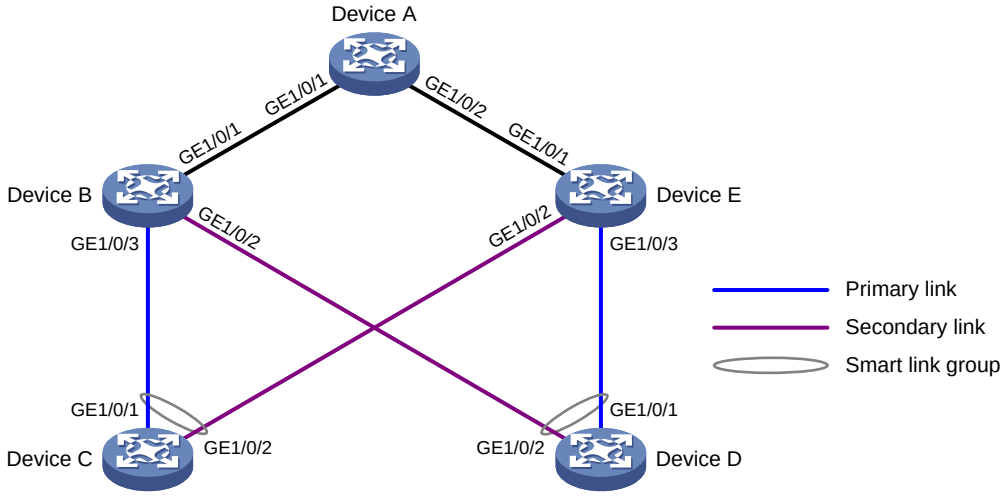
1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.
   interface *interface-type interface-number*
3. Configure the control VLANs for receiving flush messages.
   smart-link flush enable [**control-vlan** *vlan-id-list*]
   By default, no control VLAN receives flush messages.

Display and maintenance commands for Smart Link

Execute **display** commands in any view and the **reset** command in user view:

Task	Command
Display information about the received flush messages.	**display smart-link flush**
Display smart link group information.	**display smart-link group** { *group-id* | **all** }
Clear the statistics about flush messages.	**reset smart-link statistics**

Smart Link configuration examples



Example: Configuring a single smart link group

Network configuration

As shown in Figure 2:

- Device C and Device D are Smart Link devices. Device A, Device B, and Device E are associated devices. Traffic of VLANs 1 through 30 on Device C and Device D is dually uplinked to Device A.
- Configure Smart Link on Device C and Device D for dual uplink backup.

Figure 2 Network diagram

Procedure

1. Configure Device C:

Create VLANs 1 through 30.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Shut down GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] shutdown
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] shutdown
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/2] quit
```

Create smart link group 1, and configure all VLANs mapped to MSTI 1 as the protected VLANs.

```
[DeviceC] smart-link group 1
```

```
[DeviceC-smlk-group1] protected-vlan reference-instance 1
```

Configure GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port for smart link group 1.

```
[DeviceC-smlk-group1] port gigabitethernet 1/0/1 primary
[DeviceC-smlk-group1] port gigabitethernet 1/0/2 secondary
```

Enable flush message sending in smart link group 1, and configure VLAN 10 as the transmit control VLAN.

```
[DeviceC-smlk-group1] flush enable control-vlan 10
[DeviceC-smlk-group1] quit
```

Bring up GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 again.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] undo shutdown
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] undo shutdown
[DeviceC-GigabitEthernet1/0/2] quit
```

2. Configure Device D:

Create VLANs 1 through 30.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceD] stp region-configuration
[DeviceD-mst-region] instance 1 vlan 1 to 30
```

Activate the MST region configuration.

```
[DeviceD-mst-region] active region-configuration
[DeviceD-mst-region] quit
```

Shut down GigabitEthernet 1/0/1.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] shutdown
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] shutdown
[DeviceD-GigabitEthernet1/0/2] undo stp enable
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceD-GigabitEthernet1/0/2] quit
```

Create smart link group 1, and configure all VLANs mapped to MSTI 1 as the protected VLANs.

```
[DeviceD] smart-link group 1
[DeviceD-smlk-group1] protected-vlan reference-instance 1
```

Configure GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port for smart link group 1.

```
[DeviceD-smlk-group1] port gigabitethernet 1/0/1 primary
[DeviceD-smlk-group1] port gigabitethernet 1/0/2 secondary
```

Enable flush message sending in smart link group 1, and configure VLAN 20 as the transmit control VLAN.

```
[DeviceD-smlk-group1] flush enable control-vlan 20
[DeviceD-smlk-group1] quit
```

Bring up GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 again.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] undo shutdown
[DeviceD-GigabitEthernet1/0/1] quit
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] undo shutdown
[DeviceD-GigabitEthernet1/0/2] quit
```

3. Configure Device B:

Create VLANs 1 through 30.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving and configure VLAN 10 and VLAN 20 as the receive control VLANs on the port.

```
[DeviceB-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 20
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/2] undo stp enable
```

Enable flush message receiving and configure VLAN 20 as the receive control VLAN on the port.

```
[DeviceB-GigabitEthernet1/0/2] smart-link flush enable control-vlan 20
[DeviceB-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/3
[DeviceB-GigabitEthernet1/0/3] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/3] port trunk permit vlan 1 to 30
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/3] undo stp enable
```

Enable flush message receiving and configure VLAN 10 as the receive control VLAN on the port.

```
[DeviceB-GigabitEthernet1/0/3] smart-link flush enable control-vlan 10
[DeviceB-GigabitEthernet1/0/3] quit
```

4. Configure Device E:

Create VLANs 1 through 30.

```
<DeviceE> system-view
[DeviceE] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceE] interface gigabitethernet 1/0/1
[DeviceE-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceE-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving and configure VLAN 10 and VLAN 20 as the receive control VLANs on the port.

```
[DeviceE-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 20
[DeviceE-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[DeviceE] interface gigabitethernet 1/0/2
[DeviceE-GigabitEthernet1/0/2] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceE-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
```

Disable the spanning tree feature on the port.

```
[DeviceE-GigabitEthernet1/0/2] undo stp enable
```

Enable flush message receiving and configure VLAN 10 as the receive control VLAN on the port.

```
[DeviceE-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10
[DeviceE-GigabitEthernet1/0/2] quit
```

Configure GigabitEthernet 1/0/3 as a trunk port.

```
[DeviceE] interface gigabitethernet 1/0/3
[DeviceE-GigabitEthernet1/0/3] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceE-GigabitEthernet1/0/3] port trunk permit vlan 1 to 30
```

Disable the spanning tree feature on the port.

```
[DeviceE-GigabitEthernet1/0/3] undo stp enable
```

Enable flush message receiving and configure VLAN 20 as the receive control VLAN on the port.

```
[DeviceE-GigabitEthernet1/0/3] smart-link flush enable control-vlan 20
[DeviceE-GigabitEthernet1/0/3] quit
```

5. Configure Device A:

Create VLANs 1 through 30.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 30.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving and configure VLAN 10 and VLAN 20 as the receive control VLANs on the port.

```
[DeviceA-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 20
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 20
[DeviceA-GigabitEthernet1/0/2] quit
```

Verifying the configuration

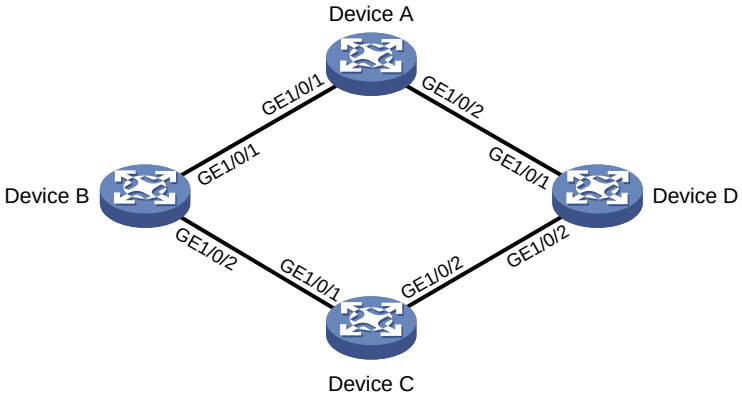
Display the smart link group configuration on Device C.

```
[DeviceC] display smart-link group 1
Smart link group 1 information:
  Device ID       : 000f-e23d-5af0
  Preemption mode : None
  Preemption delay: 1(s)
  Control VLAN    : 10
  Protected VLAN  : Reference Instance 1

  Member                  Role      State   Flush-count     Last-flush-time
  ------------------------------------------------------------------------------
  GE1/0/1                 PRIMARY   ACTIVE  5               16:45:20 2012/04/21
  GE1/0/2                 SECONDARY STANDBY 1               16:37:20 2012/04/21
```

Display the flush messages received on Device B.

```
[DeviceB] display smart-link flush
 Received flush packets                              : 5
 Receiving interface of the last flush packet        : GigabitEthernet1/0/3
 Receiving time of the last flush packet             : 16:50:21 2012/04/21
 Device ID of the last flush packet                  : 000f-e23d-5af0
 Control VLAN of the last flush packet               : 10
```



Example: Configuring multiple smart link groups load sharing

Network configuration

As shown in Figure 3:

- Device C is a Smart Link device. Device A, Device B, and Device D are associated devices. Traffic of VLANs 1 through 200 on Device C is dually uplinked to Device A by Device B and Device D.
- Implement dual uplink backup and load sharing on Device C. Traffic of VLANs 1 through 100 is uplinked to Device A by Device B. Traffic of VLANs 101 through 200 is uplinked to Device A by Device D.

Figure 3 Network diagram

Procedure

1. Configure Device C:

Create VLAN 1 through VLAN 200.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 200
```

Map VLANs 1 through 100 to MSTI 1, and VLANs 101 through 200 to MSTI 2.

```
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 100
[DeviceC-mst-region] instance 2 vlan 101 to 200
```

Activate the MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Shut down GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] shutdown
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLAN 1 through VLAN 200.

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] shutdown
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
[DeviceC-GigabitEthernet1/0/2] quit
```

Create smart link group 1, and configure all VLANs mapped to MSTI 1 as the protected VLANs for smart link group 1.

```
[DeviceC] smart-link group 1
[DeviceC-smlk-group1] protected-vlan reference-instance 1
```

Configure GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port for smart link group 1.

```
[DeviceC-smlk-group1] port gigabitethernet 1/0/1 primary
[DeviceC-smlk-group1] port gigabitethernet 1/0/2 secondary
```

Enable role preemption in smart link group 1, enable flush message sending, and configure VLAN 10 as the transmit control VLAN.

```
[DeviceC-smlk-group1] preemption mode role
[DeviceC-smlk-group1] flush enable control-vlan 10
[DeviceC-smlk-group1] quit
```

Create smart link group 2, and configure all VLANs mapped to MSTI 2 as the protected VLANs for smart link group 2.

```
[DeviceC] smart-link group 2
[DeviceC-smlk-group2] protected-vlan reference-instance 2
```

Configure GigabitEthernet 1/0/1 as the secondary port and GigabitEthernet 1/0/2 as the primary port for smart link group 2.

```
[DeviceC-smlk-group2] port gigabitethernet 1/0/2 primary
[DeviceC-smlk-group2] port gigabitethernet 1/0/1 secondary
```

Enable role preemption in smart link group 2, enable flush message sending, and configure VLAN 110 as the transmit control VLAN.

```
[DeviceC-smlk-group2] preemption mode role
[DeviceC-smlk-group2] flush enable control-vlan 110
[DeviceC-smlk-group2] quit
```

Bring up GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] undo shutdown
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] undo shutdown
[DeviceC-GigabitEthernet1/0/2] quit
```

2. Configure Device B:

Create VLAN 1 through VLAN 200.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 200
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceB-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/2] undo stp enable
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceB-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
[DeviceB-GigabitEthernet1/0/2] quit
```

3. Configure Device D:

Create VLAN 1 through VLAN 200.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 200
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceD-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/2] undo stp enable
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceD-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
[DeviceD-GigabitEthernet1/0/2] quit
```

4. Configure Device A:

Create VLAN 1 through VLAN 200.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 200
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceA-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
[DeviceA-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
```

```
[DeviceA-GigabitEthernet1/0/2] quit
```

Verifying the configuration

Display the smart link group configuration on Device C.

```
[DeviceC] display smart-link group all
Smart link group 1 information:
  Device ID       : 000f-e23d-5af0
  Preemption mode : Role
  Preemption delay: 1(s)
  Control VLAN    : 10
  Protected VLAN  : Reference Instance 1

  Member                  Role      State   Flush-count     Last-flush-time
  ------------------------------------------------------------------------------

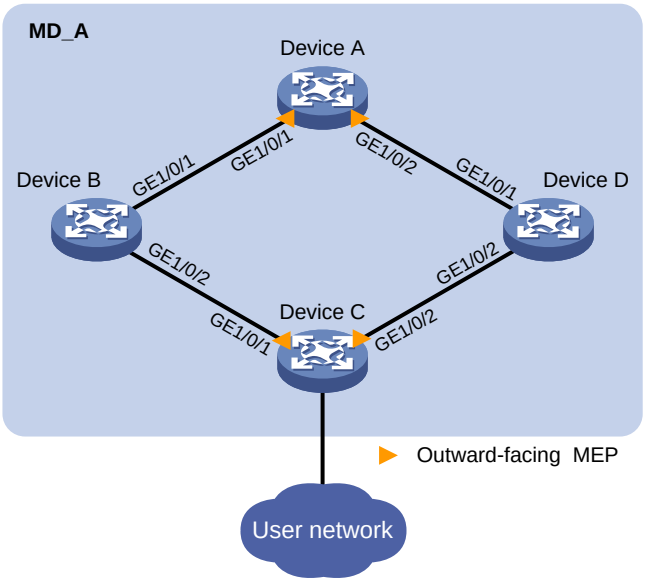
 Control VLAN of the last flush packet           : 10
```

Example: Configuring Smart Link and Track collaboration

Network configuration



As shown in Figure 4:

- Device A, Device B, Device C, and Device D form maintenance domain (MD) **MD_A** of level 5. Device C is a Smart Link device, and Device A, Device B, and Device D are associated devices. Traffic of VLANs 1 through 200 on Device C is dually uplinked to Device A by Device B and Device D.
- Configure collaboration between Smart Link and the CC function of CFD through track entries to meet the following requirements:
  - Traffic of VLANs 1 through 100 is uplinked to Device A by Device C through GigabitEthernet 1/0/1 (primary port of smart link group 1).

- Traffic of VLANs 101 through 200 is uplinked to Device A by Device C through GigabitEthernet 1/0/2 (primary port of smart link group 2).
- When the link between Device C and Device A fails, traffic is quickly switched to the secondary port of each smart link group. After the fault is cleared, traffic is switched back to the primary ports.

For more information about CFD, see "Configuring CFD."

Figure 4 Network diagram

Procedure

1. Configure Device A:

   # Create VLAN 1 through VLAN 200.

   ```
   <DeviceA> system-view
   [DeviceA] vlan 1 to 200
   ```

   # Configure GigabitEthernet 1/0/1 as a trunk port.

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] port link-type trunk
   ```

   # Assign the port to VLANs 1 through 200.

   ```
   [DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
   ```

   # Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

   ```
   [DeviceA-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
   [DeviceA-GigabitEthernet1/0/1] quit
   ```

   # Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

   ```
   [DeviceA] interface gigabitethernet 1/0/2
   [DeviceA-GigabitEthernet1/0/2] port link-type trunk
   [DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
   [DeviceA-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
   [DeviceA-GigabitEthernet1/0/2] quit
   ```

   # Enable CFD and create MD **MD_A** of level 5.

   ```
   [DeviceA] cfd enable
   [DeviceA] cfd md MD_A level 5
   ```

Create service instance 1 in which the MA name is based on the VLAN ID in **MD_A** and configure the MA to serve VLAN 10.

```
[DeviceA] cfd service-instance 1 ma-id vlan-based md MD_A vlan 10
```

Create a MEP list in service instance 1, create outward-facing MEP 1002, and enable CCM sending in service instance 1 on GigabitEthernet 1/0/1.

```
[DeviceA] cfd meplist 1001 1002 service-instance 1
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] cfd mep 1002 service-instance 1 outbound
[DeviceA-GigabitEthernet1/0/1] cfd cc service-instance 1 mep 1002 enable
[DeviceA-GigabitEthernet1/0/1] quit
```

Create service instance 2 in which the MA name is based on the VLAN ID in **MD_A** and configure the MA to serve VLAN 110.

```
[DeviceA] cfd service-instance 2 ma-id vlan-based md MD_A vlan 110
```

Create a MEP list in service instance 2, create outward-facing MEP 1002, and enable CCM sending in service instance 2 on GigabitEthernet 1/0/2.

```
[DeviceA] cfd meplist 2001 2002 service-instance 2
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] cfd mep 2002 service-instance 2 outbound
[DeviceA-GigabitEthernet1/0/2] cfd cc service-instance 2 mep 2002 enable
[DeviceA-GigabitEthernet1/0/2] quit
```

2. Configure Device B:

Create VLAN 1 through VLAN 200.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 200
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceB-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
```

Disable the spanning tree feature on the port.

```
[DeviceB-GigabitEthernet1/0/2] undo stp enable
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceB-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
[DeviceB-GigabitEthernet1/0/2] quit
```

3. Configure Device C:

Create VLAN 1 through VLAN 200.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 200
```

Map VLANs 1 through 100 to MSTI 1 and VLANs 101 through 200 to MSTI 2.

```
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 100
[DeviceC-mst-region] instance 2 vlan 101 to 200
```

Activate the MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Shut down GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] shutdown
```

Disable the spanning tree feature on the port.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the port as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] shutdown
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
[DeviceC-GigabitEthernet1/0/2] quit
```

Create smart link group 1, and configure all VLANs mapped to MSTI 1 as the protected VLANs for smart link group 1.

```
[DeviceC] smart-link group 1
[DeviceC-smlk-group1] protected-vlan reference-instance 1
```

Configure GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port for smart link group 1.

```
[DeviceC-smlk-group1] port gigabitethernet 1/0/1 primary
[DeviceC-smlk-group1] port gigabitethernet 1/0/2 secondary
```

Enable role preemption in smart link group 1, enable flush message sending, and configure VLAN 10 as the transmit control VLAN.

```
[DeviceC-smlk-group1] preemption mode role
[DeviceC-smlk-group1] flush enable control-vlan 10
[DeviceC-smlk-group1] quit
```

Create smart link group 2, and configure all VLANs mapped to MSTI 2 as the protected VLANs for smart link group 2.

```
[DeviceC] smart-link group 2
[DeviceC-smlk-group2] protected-vlan reference-instance 2
```

Configure GigabitEthernet 1/0/1 as the secondary port and GigabitEthernet 1/0/2 as the primary port for smart link group 2.

```
[DeviceC-smlk-group2] port gigabitethernet 1/0/2 primary
[DeviceC-smlk-group2] port gigabitethernet 1/0/1 secondary
```

Enable role preemption in smart link group 2, enable flush message sending, and configure VLAN 110 as the transmit control VLAN.

```
[DeviceC-smlk-group2] preemption mode role
```

```
[DeviceC-smlk-group2] flush enable control-vlan 110
[DeviceC-smlk-group2] quit
```

Enable CFD and create MD **MD_A** of level 5.

```
[DeviceC] cfd enable
[DeviceC] cfd md MD_A level 5
```

Create service instance 1 in which the MA name is based on the VLAN ID in **MD_A** and configure the MA to serve VLAN 10.

```
[DeviceC] cfd service-instance 1 ma-id vlan-based md MD_A vlan 10
```

Create a MEP list in service instance 1. Create outward-facing MEP 1001, and enable CCM sending in service instance 1 on GigabitEthernet 1/0/1.

```
[DeviceC] cfd meplist 1001 1002 service-instance 1
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] cfd mep 1001 service-instance 1 outbound
[DeviceC-GigabitEthernet1/0/1] cfd cc service-instance 1 mep 1001 enable
[DeviceC-GigabitEthernet1/0/1] quit
```

Create service instance 2 in which the MA name is based on the VLAN ID in **MD_A** and configure the MA to serve VLAN 110.

```
[DeviceC] cfd service-instance 2 ma-id vlan-based md MD_A vlan 110
```

Create a MEP list in service instance 2. Create outward-facing MEP 2001. Enable CCM sending in service instance 2 on GigabitEthernet 1/0/2.

```
[DeviceC] cfd meplist 2001 2002 service-instance 2
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] cfd mep 2001 service-instance 2 outbound
[DeviceC-GigabitEthernet1/0/2] cfd cc service-instance 2 mep 2001 enable
[DeviceC-GigabitEthernet1/0/2] quit
```

Create track entry 1 that is associated with the CFD CC function of MEP 1001 in service instance 1.

```
[DeviceC] track 1 cfd cc service-instance 1 mep 1001
```

Configure collaboration between the primary port GigabitEthernet 1/0/1 of smart link group 1 and the CC function of CFD through track entry 1, and bring up the port.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] port smart-link group 1 track 1
[DeviceC-GigabitEthernet1/0/1] undo shutdown
[DeviceC-GigabitEthernet1/0/1] quit
```

Create track entry 1 that is associated with the CFD CC function of MEP 1001 in service instance 1.

```
[DeviceC] track 2 cfd cc service-instance 2 mep 2001
```

Configure collaboration between the primary port GigabitEthernet 1/0/2 of smart link group 2 and the CC function of CFD through track entry 2, and bring up the port.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] port smart-link group 2 track 2
[DeviceC-GigabitEthernet1/0/2] undo shutdown
[DeviceC-GigabitEthernet1/0/2] quit
```

4. Configure Device D:

Create VLAN 1 through VLAN 200.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 200
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 200
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceD-GigabitEthernet1/0/1] smart-link flush enable control-vlan 10 110
[DeviceD-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
```

Assign the port to VLANs 1 through 200.

```
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 200
```

Disable the spanning tree feature on the port.

```
[DeviceD-GigabitEthernet1/0/2] undo stp enable
```

Enable flush message receiving and configure VLAN 10 and VLAN 110 as the receive control VLANs on the port.

```
[DeviceD-GigabitEthernet1/0/2] smart-link flush enable control-vlan 10 110
[DeviceD-GigabitEthernet1/0/2] quit
```

Verifying the configuration

When the optical fiber between Device A and Device B fails, display the smart link group configuration on Device C.

```
[DeviceC] display smart-link group all
Smart link group 1 information:
  Device ID       : 000f-e23d-5af0
  Preemption mode : Role
  Preemption delay: 1(s)
  Control VLAN    : 10
  Protected VLAN  : Reference Instance 1

  Member                  Role      State   Flush-count     Last-flush-time
  ------------------------------------------------------------------------------
  GE1/0/1                 PRIMARY   DOWN    5               16:45:20 2012/04/21
  GE1/0/2                 SECONDARY ACTIVE  1               16:37:20 2012/04/21

Smart link group 2 information:
  Device ID       : 000f-e23d-5af0
  Preemption mode : Role
  Preemption delay: 1(s)
  Control VLAN    : 110
  Protected VLAN  : Reference Instance 2

  Member                  Role      State   Flush-count     Last-flush-time
  ------------------------------------------------------------------------------
  GE1/0/2                 PRIMARY   ACTIVE  5               16:45:20 2012/04/21
  GE1/0/1                 SECONDARY STANDBY 1               16:37:20 2012/04/21
```

The output shows that primary port GigabitEthernet 1/0/1 of smart link group 1 fails, and secondary port GigabitEthernet 1/0/2 is in forwarding state.

Configuring Monitor Link

About Monitor Link

Monitor Link is an H3C-proprietary protocol that associates the state of downlink interfaces with the state of uplink interfaces in a monitor link group. When Monitor Link shuts down the downlink interfaces because of an uplink failure, the downstream device changes connectivity to another link.

Figure 1 Monitor Link application scenario

A monitor link group contains uplink and downlink interfaces. An interface can belong to only one monitor link group.

- Uplink interfaces are the monitored interfaces.
- Downlink interfaces are the monitoring interfaces.

As shown in Figure 1:

- Port B1 and Port B2 of Device B form a monitor link group. Port B1 is an uplink interface, and Port B2 is a downlink interface.
- Port D1 and Port D2 of Device D form another monitor link group. Port D1 is an uplink interface, and Port D2 is a downlink interface.

A monitor link group works independently of other monitor link groups. When a monitor link group does not contain any uplink interface or all its uplink interfaces are down, the monitor link group goes down. It forces all downlink interfaces down at the same time. When any uplink interface comes up, the monitor link group comes up and brings up all the downlink interfaces.

Restrictions and guidelines: Monitor Link configuration

Follow these restrictions and guidelines when you configure Monitor Link:

- Do not manually shut down or bring up the downlink interfaces in a monitor link group.
- To avoid frequent state changes of downlink interfaces in the event that uplink interfaces in the monitor link group flap, you can configure a switchover delay. The switchover delay is the time that the downlink interfaces wait before they come up following an uplink interface.

Monitor Link tasks at a glance

To configure Monitor Link, perform the following tasks:

- Enabling Monitor Link globally
- Creating a monitor link group
- Configuring monitor link group member interfaces
- (Optional.) Configuring the uplink interface threshold for triggering monitor link group state switchover
- (Optional.) Configuring the switchover delay for the downlink interfaces in a monitor link group

Enabling Monitor Link globally

About this task

All monitor link groups can operate only after you enable Monitor Link globally. When you disable Monitor Link globally, all monitor link groups cannot operate and the downlink interfaces brought down by the monitor link groups resume their original states.

Procedure

1. Enter system view.
   `system-view`
2. Enable Monitor Link globally.
   `undo monitor-link disable`
   By default, Monitor Link is enabled globally.

Creating a monitor link group

1. Enter system view.
   `system-view`
2. Create a monitor link group and enter monitor link group view.
   `monitor-link group` *`group-id`*

Configuring monitor link group member interfaces

Restrictions and guidelines

- An interface can be assigned to only one monitor link group.
- To avoid undesired down/up state changes on the downlink interfaces, configure uplink interfaces before you configure downlink interfaces.
- If you have configured a Selected port of an aggregation group as the downlink interface of a monitor link group, do not configure an Unselected port of the aggregation group as the uplink interface of the monitor link group.
- Do not add an aggregate interface and its member ports to the same monitor link group.
- You can configure member interfaces for a monitor link group in monitor link group view or interface view. Configurations made in these views have the same effect. The configuration is supported by the following interfaces:
  - Layer 2 Ethernet interfaces and Layer 2 aggregate interfaces.
  - Layer 3 Ethernet interfaces and Layer 3 aggregate interfaces.
  - Loopback interfaces.
  - VLAN interfaces.

Configuring monitor link group member interfaces in monitor link group view

1. Enter system view.
   system-view
2. Enter monitor link group view.
   monitor-link group *group-id*
3. Configure member interfaces for the monitor link group.
   port *interface-type interface-number* { **downlink** | **uplink** }
   By default, no member interfaces exist in a monitor link group.

Configuring monitor link group member interfaces in interface view

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the interface as a member of a monitor link group.
   port monitor-link group *group-id* { **downlink** | **uplink** }
   By default, the interface is not a monitor link group member.

Configuring the uplink interface threshold for triggering monitor link group state switchover

1. Enter system view.
   system-view
2. Enter monitor link group view.
   monitor-link group *group-id*
3. Configure the uplink interface threshold for triggering monitor link group state switchover.
   uplink up-port-threshold *number-of-port*
   By default, the uplink interface threshold for triggering monitor link group state switchover is 1.

Configuring the switchover delay for the downlink interfaces in a monitor link group

1. Enter system view.
   system-view
2. Enter monitor link group view.
   monitor-link group *group-id*
3. Configure the switchover delay for the downlink interfaces in the monitor link group.
   downlink up-delay *delay*
   By default, the switchover delay is 0 seconds. The downlink interfaces come up as soon as an uplink interface comes up.

Display and maintenance commands for Monitor Link

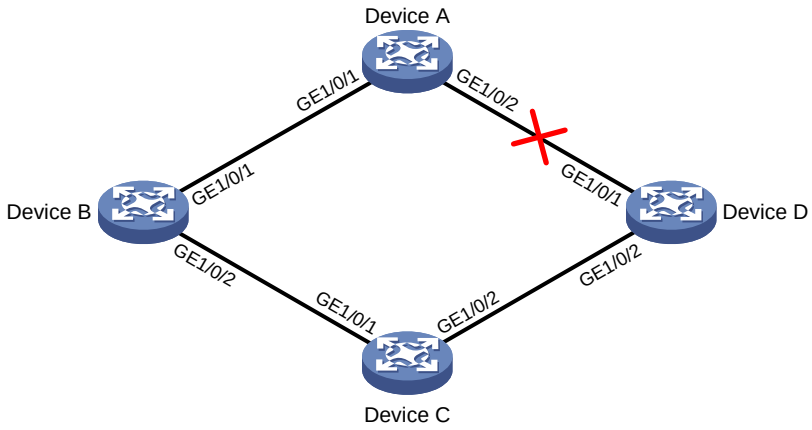
Execute the **display** command in any view:

Task	Command
Display monitor link group information.	**display monitor-link group** { *group-id* | **all** }

Monitor Link configuration examples

Example: Configuring Monitor Link

Network configuration



As shown in Figure 2:

- Device C is a Smart Link device, and Device A, Device B, and Device D are associated devices. Traffic of VLANs 1 through 30 on Device C is dual-uplinked to Device A through a smart link group.

- Implement dual uplink backup on Device C. When the link between Device A and Device B (or Device D) fails, Device C can detect the link fault. It then performs uplink switchover in the smart link group.

For more information about Smart Link, see "Configuring Smart Link."

Figure 2 Network diagram

Procedure

1. Configure Device C:

Create VLANs 1 through 30.

```
<DeviceC> system-view
[DeviceC] vlan 1 to 30
```

Map these VLANs to MSTI 1.

```
[DeviceC] stp region-configuration
[DeviceC-mst-region] instance 1 vlan 1 to 30
```

Activate MST region configuration.

```
[DeviceC-mst-region] active region-configuration
[DeviceC-mst-region] quit
```

Shut down GigabitEthernet 1/0/1.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] shutdown
```

Disable the spanning tree feature on the interface.

```
[DeviceC-GigabitEthernet1/0/1] undo stp enable
```

Configure the interface as a trunk port.

```
[DeviceC-GigabitEthernet1/0/1] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] shutdown
[DeviceC-GigabitEthernet1/0/2] undo stp enable
[DeviceC-GigabitEthernet1/0/2] port link-type trunk
[DeviceC-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceC-GigabitEthernet1/0/2] quit
```

Create smart link group 1, and configure all the VLANs mapped to MSTI 1 as the protected VLANs for smart link group 1.

```
[DeviceC] smart-link group 1
[DeviceC-smlk-group1] protected-vlan reference-instance 1
```

Configure GigabitEthernet 1/0/1 as the primary port and GigabitEthernet 1/0/2 as the secondary port for smart link group 1.

```
[DeviceC-smlk-group1] port gigabitethernet 1/0/1 primary
[DeviceC-smlk-group1] port gigabitethernet 1/0/2 secondary
```

Enable the smart link group to transmit flush messages.

```
[DeviceC-smlk-group1] flush enable
[DeviceC-smlk-group1] quit
```

Bring up GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2.

```
[DeviceC] interface gigabitethernet 1/0/1
[DeviceC-GigabitEthernet1/0/1] undo shutdown
[DeviceC-GigabitEthernet1/0/1] quit
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] undo shutdown
[DeviceC-GigabitEthernet1/0/2] quit
```

2. Configure Device A:

Create VLANs 1 through 30.

```
<DeviceA> system-view
[DeviceA] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceA] interface gigabitethernet 1/0/1
[DeviceA-GigabitEthernet1/0/1] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceA-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving on the interface.

```
[DeviceA-GigabitEthernet1/0/1] smart-link flush enable
[DeviceA-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 in the same way GigabitEthernet 1/0/1 is configured.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
[DeviceA-GigabitEthernet1/0/2] smart-link flush enable
[DeviceA-GigabitEthernet1/0/2] quit
```

3. Configure Device B:

Create VLANs 1 through 30.

```
<DeviceB> system-view
[DeviceB] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving on the interface.

```
[DeviceB-GigabitEthernet1/0/1] smart-link flush enable
```

```
[DeviceB-GigabitEthernet1/0/1] quit
```

Disable the spanning tree feature on GigabitEthernet 1/0/2.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] undo stp enable
```

Configure the interface as a trunk port.

```
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
```

Enable flush message receiving on the interface.

```
[DeviceB-GigabitEthernet1/0/2] smart-link flush enable
[DeviceB-GigabitEthernet1/0/2] quit
```

Create monitor link group 1.

```
[DeviceB] monitor-link group 1
```

Configure GigabitEthernet 1/0/1 as an uplink interface for monitor link group 1.

```
[DeviceB-mtlk-group1] port gigabitethernet 1/0/1 uplink
```

Configure GigabitEthernet 1/0/2 as a downlink interface for monitor link group 1.

```
[DeviceB-mtlk-group1] port gigabitethernet 1/0/2 downlink
[DeviceB-mtlk-group1] quit
```

4. Configure Device D:

Create VLANs 1 through 30.

```
<DeviceD> system-view
[DeviceD] vlan 1 to 30
```

Configure GigabitEthernet 1/0/1 as a trunk port.

```
[DeviceD] interface gigabitethernet 1/0/1
[DeviceD-GigabitEthernet1/0/1] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceD-GigabitEthernet1/0/1] port trunk permit vlan 1 to 30
```

Enable flush message receiving on the interface.

```
[DeviceD-GigabitEthernet1/0/1] smart-link flush enable
[DeviceD-GigabitEthernet1/0/1] quit
```

Disable the spanning tree feature on GigabitEthernet 1/0/2.

```
[DeviceD] interface gigabitethernet 1/0/2
[DeviceD-GigabitEthernet1/0/2] undo stp enable
```

Configure the interface as a trunk port.

```
[DeviceD-GigabitEthernet1/0/2] port link-type trunk
```

Assign the interface to VLANs 1 through 30.

```
[DeviceD-GigabitEthernet1/0/2] port trunk permit vlan 1 to 30
```

Enable flush message receiving on the interface.

```
[DeviceD-GigabitEthernet1/0/2] smart-link flush enable
[DeviceD-GigabitEthernet1/0/2] quit
```

Create monitor link group 1.

```
[DeviceD] monitor-link group 1
```

Configure GigabitEthernet 1/0/1 as an uplink interface for monitor link group 1.

```
[DeviceD-mtlk-group1] port gigabitethernet 1/0/1 uplink
```

Configure GigabitEthernet 1/0/2 as a downlink interface for monitor link group 1.

```
[DeviceD-mtlk-group1] port gigabitethernet 1/0/2 downlink
```

```
[DeviceD-mtlk-group1] quit
```

Verifying the configuration

When GigabitEthernet 1/0/2 on Device A goes down because of a link fault, verify information about monitor link group 1 on Device B.

```
[DeviceB] display monitor-link group 1
Monitor link group 1 information:
  Group status     : UP
  Downlink up-delay: 0(s)
  Last-up-time     : 16:38:26 2012/4/21
  Last-down-time   : 16:37:20 2012/4/21
  Up-port-threshold: 1

  Member                    Role       Status
  ----------------------------------------------
  GE1/0/1                   UPLINK     UP
  GE1/0/2                   DOWNLINK   UP
```

Verify information about monitor link group 1 on Device D.

```
[DeviceD] display monitor-link group 1
Monitor link group 1 information:
  Group status     : DOWN
  Downlink up-delay: 0(s)
  Last-up-time     : 16:37:20 2012/4/21
  Last-down-time   : 16:38:26 2012/4/21
  Up-port-threshold: 1

  Member                    Role       Status
  ----------------------------------------------
  GE1/0/1                   UPLINK     DOWN
  GE1/0/2                   DOWNLINK   DOWN (Monitor Link)
```

Configuring VRRP

About VRRP

Typically, you can configure a default gateway for every host on a LAN. All packets destined for other networks are sent through the default gateway. As shown in Figure 1, when the default gateway fails, no hosts can communicate with external networks.

Figure 1 LAN networking

Using a default gateway facilitates your configuration but requires high availability. Using more egress gateways improves link availability but introduces the problem of routing among the egresses.

Virtual Router Redundancy Protocol (VRRP) is designed to address this issue. VRRP adds a group of network gateways to a VRRP group called a virtual router. The VRRP group has one master and multiple backups, and provides a virtual IP address. The hosts on the subnet use the virtual IP address as their default network gateway to communicate with external networks.

VRRP avoids single points of failure and simplifies the configuration on hosts. When the master in the VRRP group on a multicast or broadcast LAN (for example, an Ethernet network) fails, another router in the VRRP group takes over. The switchover is complete without causing dynamic route recalculation, route re-discovery, gateway reconfiguration on the hosts, or traffic interruption.

VRRP operates in either of the following modes:

- **Standard mode**—Implemented based on RFCs. For more information, see "VRRP standard mode."
- **Load balancing mode**—Extends the VRRP standard mode to distribute load across VRRP group members. For more information, see "VRRP load balancing mode."

VRRP has two versions: VRRPv2 and VRRPv3. VRRPv2 supports IPv4 VRRP. VRRPv3 supports IPv4 VRRP and IPv6 VRRP.

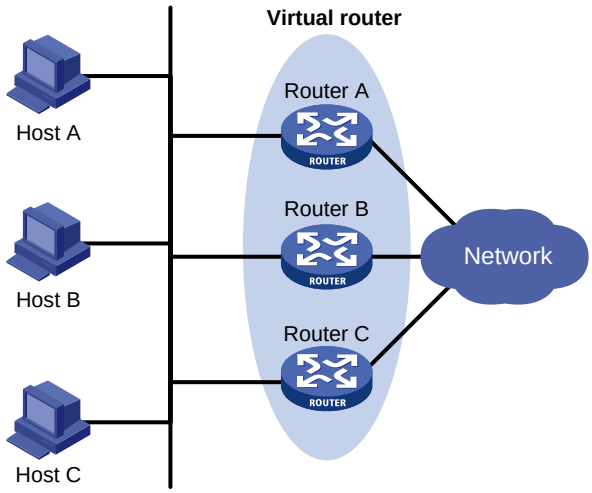
VRRP group

VRRP adds a group of network gateways to a VRRP group called a virtual router. The VRRP group has one master and multiple backups, and provides a virtual IP address. The hosts on the subnet use the virtual IP address as their default network gateway to communicate with external networks.

The administrator can add a router to a VRRP group by creating the VRRP group on a Layer 3 interface on the router.

NOTE:

On a device, the interfaces added to VRRP groups having the same VRRP group number belong to different VRRP groups.



VRRP standard mode

VRRP networking

As shown in Figure 2, Router A, Router B, and Router C form a virtual router, which has a manually configured virtual IP address. Hosts on the subnet use the virtual router as the default gateway.

The router with the highest priority among the three routers is elected as the master, and the other two are backups. Only the master in the VRRP group can provide gateway service. When the master fails, the backup routers elect a new master to take over for nonstop gateway service.

Figure 2 VRRP networking

Virtual IP address and IP address owner

The virtual IP address of the virtual router can be either of the following IP addresses:

- Unused IP address on the subnet where the VRRP group resides.
- IP address of an interface on a router in the VRRP group.

In the latter case, the router is called the IP address owner. A VRRP group can have only one IP address owner.

Router priority in a VRRP group

VRRP determines the role (master or backup) of each router in a VRRP group by priority. A router with higher priority is more likely to become the master.

A VRRP priority can be in the range of 0 to 255, and a greater number represents a higher priority. Priorities 1 to 254 are configurable. Priority 0 is reserved for special uses, and priority 255 is for the

IP address owner. The IP address owner in a VRRP group always has a running priority of 255 and acts as the master as long as it operates correctly.

Preemption

A router in a VRRP group operates in either non-preemptive mode or preemptive mode.

- **Non-preemptive mode**—The master router acts as the master as long as it operates correctly, even if a backup router is later assigned a higher priority. Non-preemptive mode helps avoid frequent switchover between the master and backup routers.
- **Preemptive mode**—A backup starts a new master election and takes over as master when it detects that it has a higher priority than the current master. Preemptive mode ensures that the router with the highest priority in a VRRP group always acts as the master.

Authentication method

To avoid attacks from unauthorized users, VRRP member routers add authentication keys in VRRP packets to authenticate one another. VRRP provides the following authentication methods:

- Simple authentication

  The sender fills an authentication key into the VRRP packet, and the receiver compares the received authentication key with its local authentication key. If the two authentication keys match, the received VRRP packet is legitimate. Otherwise, the received packet is illegitimate and gets discarded.
- MD5 authentication

  The sender computes a digest for the VRRP packet by using the authentication key and MD5 algorithm, and saves the result to the packet. The receiver performs the same operation with the authentication key and MD5 algorithm, and compares the result with the content in the authentication header. If the results match, the received VRRP packet is legitimate. Otherwise, the received packet is illegitimate and gets discarded.

On a secure network, you can choose to not authenticate VRRP packets.

NOTE:

IPv4 VRRPv3 and IPv6 VRRPv3 do not support VRRP packet authentication.

VRRP timers

Skew_Time

Skew_Time helps avoid the situation that multiple backups in a VRRP group become the master when the master in the VRRP group fails.

Skew_Time is not configurable; its value depends on the VRRP version.

- In VRRPv2 (described in RFC 3768), Skew_Time is (256 – Router priority)/256.
- In VRRPv3 (described in RFC 5798), Skew_Time is ((256 – Router priority) × VRRP advertisement interval)/256.

VRRP advertisement interval

The master in a VRRP group periodically sends VRRP advertisements to declare its presence.

You can configure the interval at which the master sends VRRP advertisements. If a backup does not receive any VRRP advertisement when the timer (3 × VRRP advertisement interval + Skew_Time) expires, it takes over as the master.

VRRP preemption delay timer

You can configure the VRRP preemption delay timer for the following purposes:

- Avoid frequent state changes among members in a VRRP group.
- Provide the backups with enough time to collect information (such as routing information).

In preempt mode, a backup does not immediately become the master after it receives an advertisement with lower priority than the local priority. Instead, it waits for a period of time (preemption delay time + Skew_Time) before taking over as the master.

Master election

Routers in a VRRP group determine their roles by priority. When a router joins a VRRP group, it has a backup role. The router role changes according to the following situations:

- If the backup does not receive any VRRP advertisement when the timer (3 × advertisement interval + Skew_Time) expires, it becomes the master.
- If the backup receives a VRRP advertisement with the same or greater priority within the timer (3 × advertisement interval + Skew_Time), it remains a backup.
- If the backup receives a VRRP advertisement with a smaller priority within the timer (3 × advertisement interval + Skew_Time), the following results apply:
  - It remains a backup when operating in non-preemptive mode.
  - It becomes the master when operating in preemptive mode.

The elected master starts a VRRP advertisement interval to periodically send VRRP advertisements to notify the backups that it is operating correctly. Each of the backups starts a timer to wait for advertisements from the master.

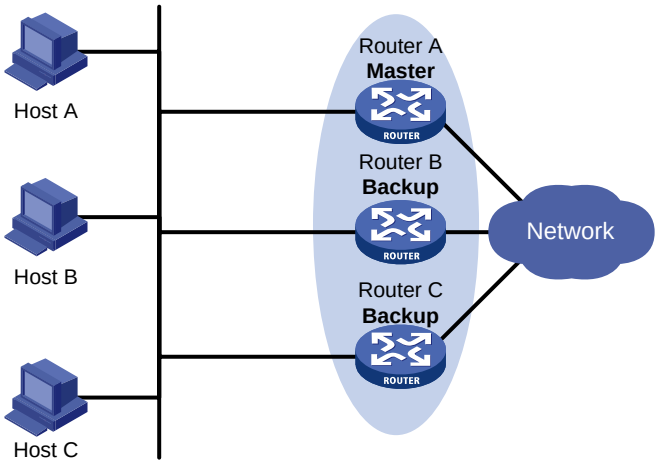
When multiple routers in a VRRP group declare that they are the master because of network problems, the one with the highest priority becomes the master. If two routers have the same priority, the one with the highest IP address becomes the master.

VRRP tracking

The VRRP tracking function uses network quality analyzer (NQA) or bidirectional forwarding detection (BFD) to monitor the state of the master or the upstream link. The collaboration between VRRP and NQA or BFD through a track entry implements the following functions:

- Monitors the upstream link and changes the priority of the router according to the state of the link. If the upstream link fails, the hosts on the subnet cannot access external networks through the router and the state of the track entry becomes Negative. The priority of the master decreases by a specified value, and a router with a higher priority in the VRRP group becomes the master. The switchover ensures uninterrupted communication between the hosts on the subnet and external networks.
- Monitors the state of the master on the backups. When the master fails, a backup immediately takes over to ensure uninterrupted communication.

When the track entry changes from Negative to Positive or Notready, the router automatically restores its priority. For more information about track entries, see "Configuring Track."



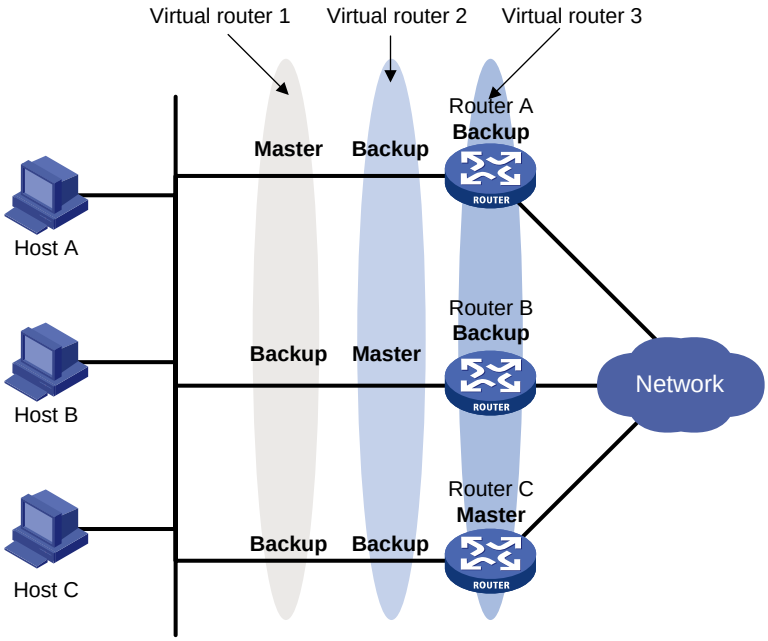
To enable VRRP tracking, configure the routers in the VRRP group to operate in preemptive mode first. This configuration ensures that only the router with the highest priority operates as the master.

VRRP application

Master/backup

In master/backup mode, only the master forwards packets, as shown in Figure 3. When the master fails, a new master is elected from among the backups. This mode requires only one VRRP group, and each router in the group has a different priority. The one with the highest priority becomes the master.

Figure 3 VRRP in master/backup mode



Assume that Router A is acting as the master to forward packets to external networks, and Router B and Router C are backups in listening state. When Router A fails, Router B and Router C elect a new master to forward packets for hosts on the subnet.

Load sharing

A router can join multiple VRRP groups. With different priorities in different VRRP groups, the router can act as the master in one VRRP group and a backup in another.

In load sharing mode, multiple VRRP groups provide gateway services. This mode requires a minimum of two VRRP groups, and each group has one master and multiple backups. The master roles in the VRRP groups are assumed by different routers, as shown in Figure 4.

Figure 4 Load sharing of VRRP

A router can be in multiple VRRP groups and have a different priority in each group.

As shown in Figure 4, the following VRRP groups exist:

- **VRRP group 1**—Router A is the master. Router B and Router C are the backups.
- **VRRP group 2**—Router B is the master. Router A and Router C are the backups.
- **VRRP group 3**—Router C is the master. Router A and Router B are the backups.

To implement load sharing among Router A, Router B, and Router C, perform the following tasks:

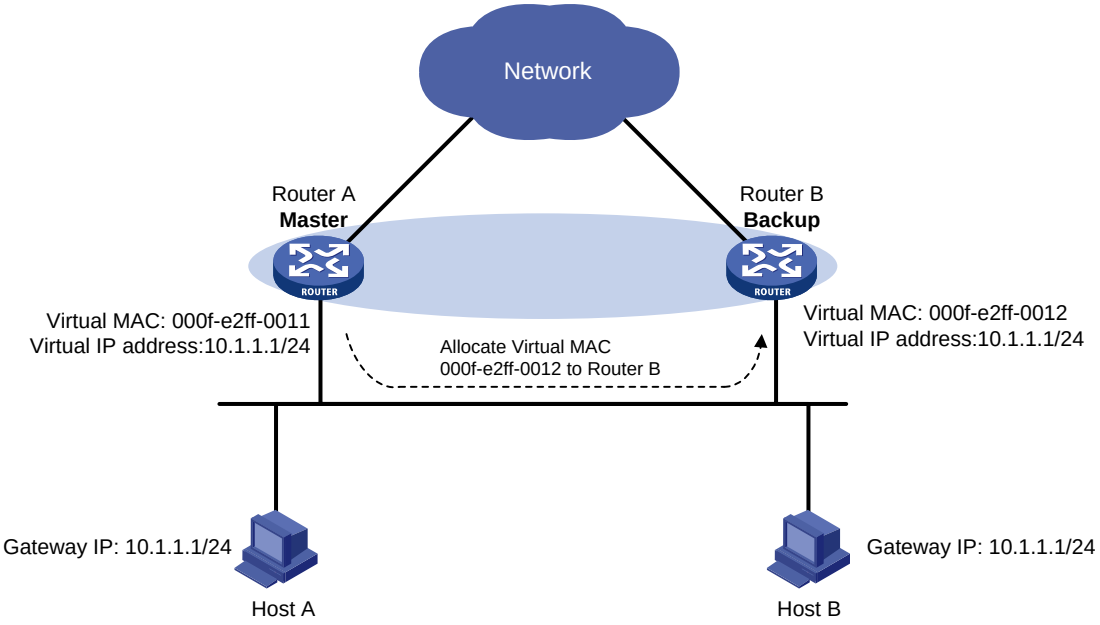
- Configure the virtual IP addresses of VRRP group 1, 2, and 3 as default gateway IP addresses for hosts on the subnet.
- Assign the highest priority to Router A, B, and C in VRRP group 1, 2, and 3, respectively.

VRRP load balancing mode

In a standard-mode VRRP group, only the master can forward packets and backups are in listening state. You can create multiple VRRP groups to share traffic, but you must configure different gateways for hosts on the subnet.

In load balancing mode, a VRRP group maps its virtual IP address to multiple virtual MAC addresses, assigning one virtual MAC address to each member router. Every router in this VRRP group can forward traffic and respond to IPv4 ARP requests or IPv6 ND requests from hosts. Because their virtual MAC addresses are different, traffic from hosts is distributed across the VRRP group members. Load balancing mode simplifies configuration and improves forwarding efficiency.

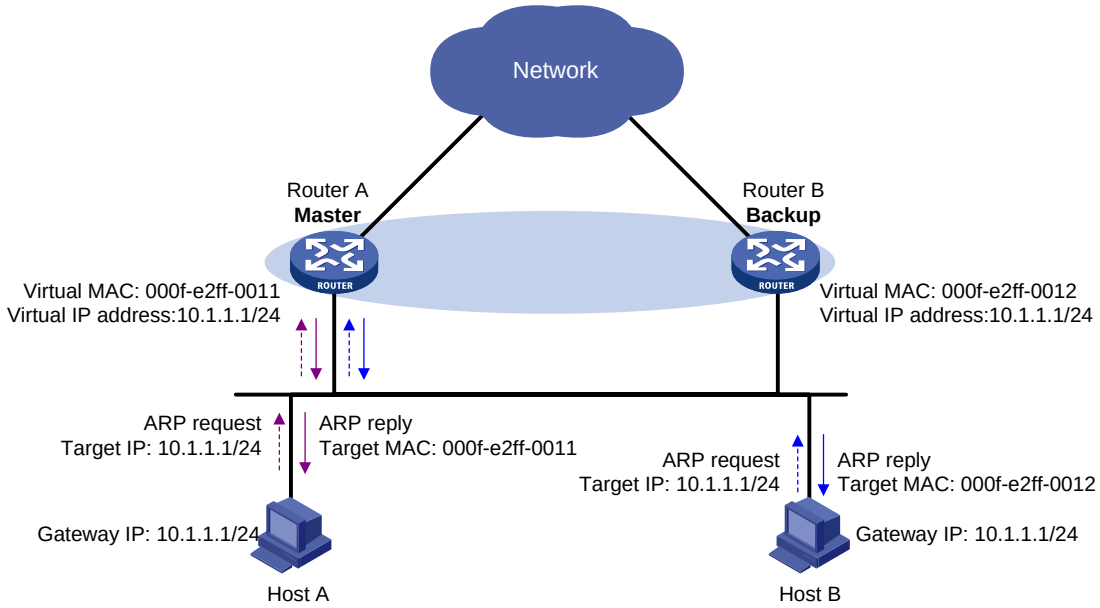
VRRP load balancing mode uses the same master election, preemption, and tracking mechanisms as the standard mode. New mechanisms have been introduced to VRRP load balancing mode, as described in the following sections.



Virtual MAC address assignment

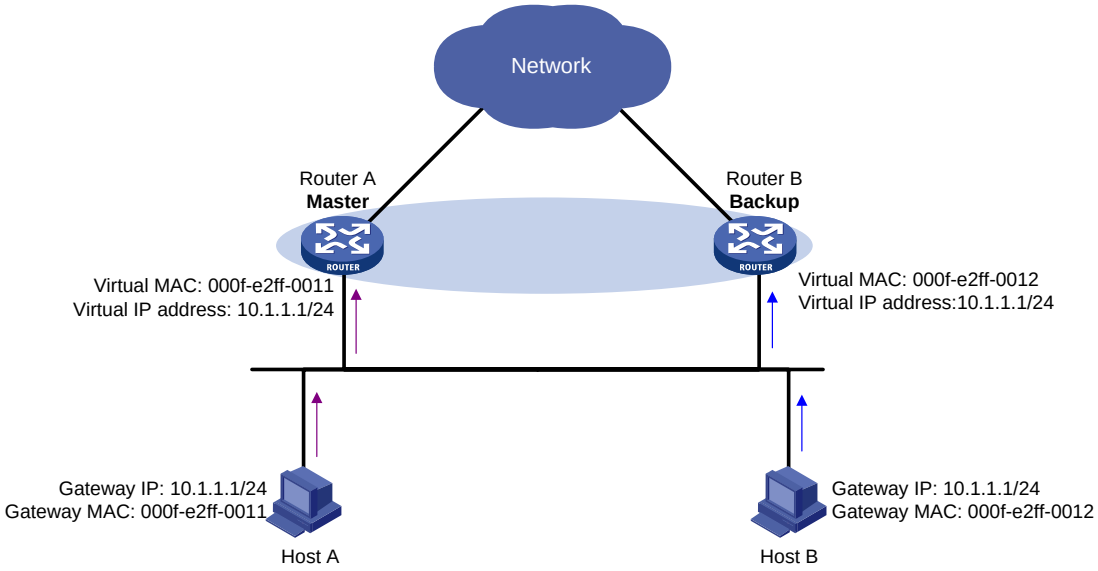
In load balancing mode, the master assigns virtual MAC addresses to routers in the VRRP group. The master uses different MAC addresses to respond to ARP requests or ND requests from different hosts. The backup routers, however, do not answer ARP requests or ND requests from hosts.

In an IPv4 network, a load balanced VRRP group works as follows:



1. The master assigns virtual MAC addresses to all member routers, including itself. This example assumes that the virtual IP address of the VRRP group is 10.1.1.1/24, Router A is the master, and Router B is the backup. Router A assigns 000f-e2ff-0011 for itself and 000f-e2ff-0012 for Router B. See Figure 5.

   Figure 5 Virtual MAC address assignment



2. When an ARP request arrives, the master (Router A) selects a virtual MAC address based on the load balancing algorithm to answer the ARP request. In this example, Router A returns the virtual MAC address of itself in response to the ARP request from Host A. Router A returns the virtual MAC address of Router B in response to the ARP request from Host B. See Figure 6.

   Figure 6 Answering ARP requests

3. Each host sends packets to the returned MAC address. As shown in Figure 7, Host A sends packets to Router A and Host B sends packets to Router B.

Figure 7 Sending packets to different routers for forwarding

In the ARP reply sent by the master, the source MAC address in the Ethernet header is different from the sender MAC address in the message body. For the Layer 2 device to forward the ARP packet, follow these configuration guidelines on the Layer 2 device:

- Do not enable ARP packet source MAC address consistency check.
- Do not specify the **src-mac** keyword when you enable ARP packet validity check for ARP detection.

For more information about ARP packet source MAC address consistency check and ARP detection, see *Security Configuration Guide*.

Virtual forwarder

Virtual forwarder creation

Virtual MAC addresses enable traffic distribution across routers in a VRRP group. To enable routers in the VRRP group to forward packets, VFs must be created on them. Each VF is associated with a virtual MAC address in the VRRP group and forwards packets that are sent to this virtual MAC address.

VFs are created on routers in a VRRP group, as follows:

1. The master assigns virtual MAC addresses to all routers in the VRRP group. Each member router creates a VF for this MAC address and becomes the owner of this VF.
2. Each VF owner advertises its VF information to the other member routers.
3. After receiving the VF advertisement, each of the other routers creates the advertised VF.

Eventually, every member router maintains one VF for each virtual MAC address in the VRRP group.

VF weight and priority

The weight of a VF indicates the forwarding capability of a VF. A higher weight means higher forwarding capability. When the weight is lower than the lower limit of failure, the VF cannot forward packets.

The priority of a VF determines the VF state. Among the VFs created on different member routers for the same virtual MAC address, the VF with the highest priority is in active state. This VF, known as the active virtual forwarder (AVF), forwards packets. All other VFs listen to the state of the AVF and are known as the listening virtual forwarders (LVFs). VF priority is in the range of 0 to 255, where 255

is reserved for the VF owner. When the weight of a VF owner is higher than or equal to the lower limit of failure, the priority of the VF owner is 255.

The priority of a VF is calculated based on its weight.

- If the VF weight is higher than or equal to the lower limit of failure, the following VF priorities apply:
  - On a VF owner, the VF priority is 255.
  - On a non-VF owner, the VF priority is calculated as weight/(number of local AVFs + 1).
- If the VF weight is lower than the lower limit of failure, the VF priority is 0.

VF backup

The VFs corresponding to a virtual MAC address on different routers in the VRRP group back up one another.

Figure 8 VF information

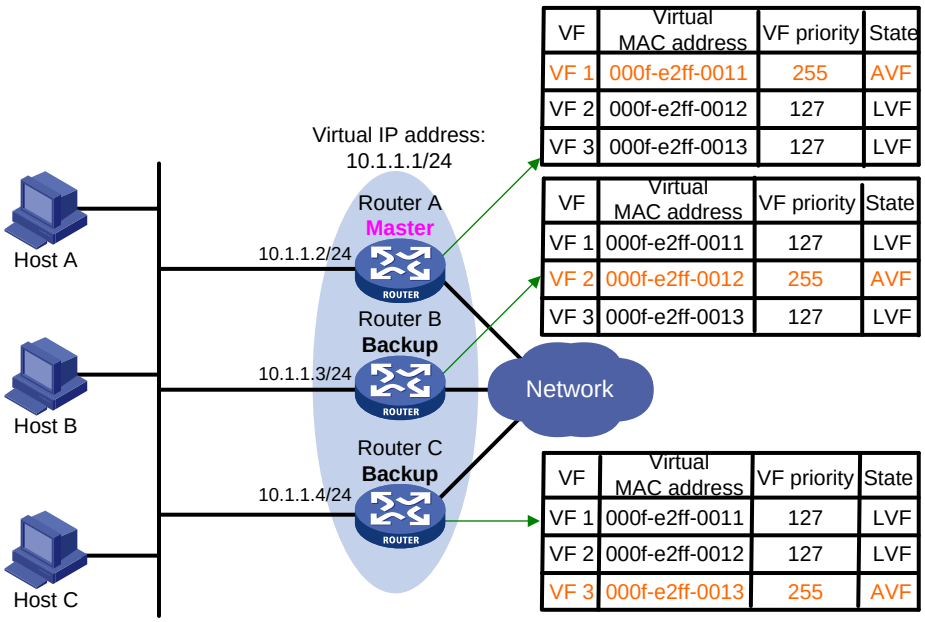


Figure 8 shows the VF table on each router in the VRRP group and how the VFs back up one another. The master, Router A, assigns virtual MAC addresses 000f-e2ff-0011, 000f-e2ff-0012, and 000f-e2ff-0013 to itself, Router B, and Router C, respectively. Each router creates VF 1, VF 2, and VF 3 for virtual MAC addresses 000f-e2ff-0011, 000f-e2ff-0012, and 000f-e2ff-0013, respectively. The VFs for the same virtual MAC address on different routers back up one another. For example, the VF 1 instances on Router A, Router B, and Router C back up one another.

- The VF 1 instance on Router A (the VF 1 owner) has priority 255. It acts as the AVF to forward packets sent to virtual MAC address 000f-e2ff-0011.
- The VF 1 instances on Router B and Router C have a priority of 255/(1 + 1), or 127. Because their priorities are lower than the priority of the VF 1 instance on Router A, they act as LVFs. These LVFs listen to the state of the VF 1 instance on Router A.
- When the VF 1 instance on Router A fails, the VF 1 instances on Router B and Router C elect the one with higher priority as the new AVF. This AVF forwards packets destined for virtual MAC address 000f-e2ff-0011. If the two LVFs' priorities are the same, the LVF with a greater device MAC address becomes the new AVF.

A VF always operates in preemptive mode. When an LVF finds its priority value higher than the one advertised by the AVF, the LVF declares itself as the AVF.

VF timers

When the AVF on a router fails, the new AVF on another router creates the following timers for the failed AVF:

- **Redirect timer**—Before this timer expires, the master still uses the virtual MAC address corresponding to the failed AVF to respond to ARP/ND requests from hosts. The VF owner can share traffic load if the VF owner resumes normal operation within this time. When this timer expires, the master stops using the virtual MAC address corresponding to the failed AVF to respond to ARP/ND requests from hosts.
- **Timeout timer**—The duration after which the new AVF takes over responsibilities of the failed VF owner. Before this timer expires, all routers in the VRRP group keep the VFs that correspond to the failed AVF. The new AVF forwards packets destined for the virtual MAC address of the failed AVF. When this timer expires, all routers in the VRRP group remove the VFs that correspond to the failed AVF, including the new AVF. Packets destined for the virtual MAC address of the failed AVF are not forwarded any longer.

VF tracking

An AVF forwards packets destined for the MAC address of the AVF. If the AVF's upstream link fails but no LVF takes over, the hosts that use the AVF's MAC address as their gateway MAC address cannot access the external network.

The VF tracking function can solve this problem. You can use NQA or BFD to monitor the upstream link state of the VF owner, and associate the VFs with NQA or BFD through the tracking function. This enables the collaboration between VRRP and NQA or BFD through the Track module. When the upstream link fails, the state of the track entry changes to Negative. The weights of the VFs (including the AVF) on the router decrease by a specific value. The corresponding LVF with a higher priority on another router becomes the AVF and forwards packets.

Protocols and standards

- RFC 3768, *Virtual Router Redundancy Protocol (VRRP)*
- RFC 5798, *Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6*

Configuring IPv4 VRRP

Restrictions and guidelines: IPv4 VRRP configuration

IPv4 VRRP does not take effect on member ports of aggregation groups.

Configuration on the routers in an IPv4 VRRP group must be consistent.

Each IPv4 VRRP group corresponds to a virtual MAC address. The maximum number of IPv4 VRRP groups supported on an interface depends on the maximum number of virtual MAC addresses supported on the interface.

IPv4 VRRP tasks at a glance

To configure IPv4 VRRP, perform the following tasks:

1. Specifying an IPv4 VRRP operating mode
2. (Optional.) Specifying the IPv4 VRRP version
3. Configuring an IPv4 VRRP group
4. (Optional.) Configuring IPv4 VRRP packet attributes
5. (Optional.) Configuring VF tracking

This configuration takes effect only in VRRP load balancing mode.

6. (Optional.) Setting the packet sending mode for IPv4 VRRPv3
7. (Optional.) Enabling periodic sending of gratuitous ARP packets for IPv4 VRRP
8. (Optional.) Configuring a subordinate IPv4 VRRP group to follow a master IPv4 VRRP group
9. (Optional.) Enabling SNMP notifications for VRRP

Specifying an IPv4 VRRP operating mode

Restrictions and guidelines

After an IPv4 VRRP operating mode is configured on a router, all IPv4 VRRP groups on the router operate in the specified operating mode.

When you change the VRRP group operating mode from standard to load balancing, follow these restrictions and guidelines:

- The VRRP virtual MAC address will also change.
- The original VRRP virtual MAC address in the ARP table of the neighbor device is not refreshed until the ARP entry ages out.

Before the VRRP virtual MAC address is refreshed, temporary service traffic interruption might occur. As a best practice, perform such operations during off-peak hours to minimize service impact.

Procedure

1. Enter system view.
   system-view
2. Specify an IPv4 VRRP operating mode.
   - Specify the standard mode.
     undo vrrp mode
   - Specify the load balancing mode.
     vrrp mode load-balance [**version-8**]

   By default, VRRP operates in standard mode.

Specifying the IPv4 VRRP version

About this task

IPv4 VRRP can use VRRPv2 and VRRPv3.

Restrictions and guidelines

For an IPv4 VRRP group to operate correctly, make sure the same VRRP version is used on all routers in the IPv4 VRRP group.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Specify the version of VRRP.
   vrrp version *version-number*

   By default, VRRPv3 is used.

Configuring an IPv4 VRRP group

About this task

A VRRP group can operate correctly after you create it and assign a minimum of one virtual IP address to it. You can configure multiple virtual IP addresses for the VRRP group on an interface that connects to multiple subnets for router backup on different subnets.

If you disable an IPv4 VRRP group, the VRRP group enters **Initialize** state, and the existing configuration on the VRRP group remains unchanged. You can modify the configuration of the VRRP group. The modification takes effect when you enable the VRRP group again.

Restrictions and guidelines

Item	Remarks
VLAN interface	Do not create a VRRP group on the VLAN interface of a super VLAN because network performance might be adversely affected. For information about the super VLAN feature, see *Layer 2—LAN Switching Configuration Guide*.
Maximum number of VRRP groups and virtual IP addresses	In VRRP load balancing mode, the device supports a maximum of *MaxVRNum/N* VRRP groups. *MaxVRNum* refers to the maximum number of VRRP groups supported by the device in VRRP standard mode. *N* refers to the number of devices in the VRRP group.
Virtual IP address	When VRRP is operating in standard mode, the virtual IP address of a VRRP group can be either of the following addresses: • Unused IP address on the subnet where the VRRP group resides. • IP address of an interface on a router in the VRRP group. In load balancing mode, the virtual IP address of a VRRP group can be any unassigned IP address of the subnet where the VRRP group resides. It cannot be the IP address of any interfaces in the VRRP group. No IP address owner can exist in a VRRP group. An IPv4 VRRP group without virtual IP addresses configured can exist on a device provided that other settings (for example, priority and preemption mode) are available. Such a VRRP group stays in inactive state and does not function. For hosts in the subnet to access external networks, as a best practice, configure the following addresses in the same subnet: • Virtual IP address of an IPv4 VRRP group. • Downlink interface IP addresses of the VRRP group members.
IP address owner	On an IP address owner, as a best practice, do not use the **network** command to enable OSPF on the interface owning the virtual IP address of the VRRP group. For more information about the **network** command, see *Layer 3—IP Routing Command Reference*. After you remove the VRRP group on an IP address owner, a backup in the VRRP group takes over as the master. The actual IP address of the interface on the IP address owner will conflict with the virtual IP address of the new master. To avoid the conflict, change the IP address of the interface on the IP address owner before you remove the VRRP group from the interface. The running priority of an IP address owner is always 255, and you do not need to configure it. An IP address owner always operates in preemptive mode. If you configure the **vrrp vrid track priority reduced** or **vrrp vrid track switchover** command on an IP address owner, the configuration does not take effect until the router becomes a non-IP address owner.

Item	Remarks
VRRP association with a track entry	When the track entry changes from Negative to Positive or Notready, the router automatically restores its priority or the failed master router becomes the master again.

Creating a VRRP group and assigning a virtual IP address

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Create a VRRP group and assign a virtual IP address.
   vrrp vrid *virtual-router-id* **virtual-ip** *virtual-address*

Configuring an IPv4 VRRP group

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the priority of the router in the VRRP group.
   vrrp vrid *virtual-router-id* **priority** *priority-value*

   The default setting is 100.
4. Enable the preemptive mode for the router in a VRRP group and set the preemption delay time.
   vrrp vrid *virtual-router-id* **preempt-mode** [**delay** *delay-value*]

   By default, the router in a VRRP group operates in preemptive mode and the preemption delay time is 0 centiseconds, which means an immediate preemption.
5. Associate a VRRP group with a track entry.
   vrrp vrid *virtual-router-id* **track** *track-entry-number*
   { **forwarder-switchover member-ip** *ip-address* | **priority reduced** [*priority-reduced*] | **switchover** | **weight reduced** [*weight-reduced*] }

   By default, a VRRP group is not associated with any track entries.

Disabling an IPv4 VRRP group

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Disable a VRRP group.
   vrrp vrid *virtual-router-id* **shutdown**

   By default, an IPv4 VRRP group is enabled.

CAUTION:

You can use this command to temporarily disable an IPv4 VRRP group. After you execute this command, packets sent to the IPv4 VRRP group might be discarded.

Configuring IPv4 VRRP packet attributes

Restrictions and guidelines

- You can configure different authentication modes and authentication keys for VRRP groups on an interface. However, members of the same VRRP group must use the same authentication mode and authentication key.
- In VRRPv2, all routers in a VRRP group must have the same VRRP advertisement interval.
- In VRRPv3, authentication mode and authentication key settings do not take effect.
- In VRRPv3, routers in an IPv4 VRRP group can have different intervals for sending VRRP advertisements. The master in the VRRP group sends VRRP advertisements at specified intervals, and carries the interval in the advertisements. After a backup receives the advertisement, it records the interval in the advertisement. If the backup does not receive a VRRP advertisement before the timer (3 x recorded interval + Skew_Time) expires, it regards the master as failed and takes over.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the authentication mode and authentication key for an IPv4 VRRP group to send and receive VRRP packets.

   vrrp vrid *virtual-router-id* **authentication-mode** { **md5** | **simple** } { **cipher** | **plain** } *string*

   By default, authentication is disabled.

4. Set the interval at which the master in an IPv4 VRRP group sends VRRP advertisements.

   vrrp vrid *virtual-router-id* **timer advertise** *adver-interval*

   The default setting is 100 centiseconds.

   As a best practice to maintain system stability, set the VRRP advertisement interval to be greater than 100 centiseconds.

5. Specify the source interface for receiving and sending VRRP packets.

   vrrp vrid *virtual-router-id* **source-interface** *interface-type interface-number*

   By default, the source interface for receiving and sending VRRP packets is not specified. The interface where the VRRP group resides sends and receives VRRP packets.

6. Enable TTL check for IPv4 VRRP packets.

   vrrp check-ttl enable

   By default, TTL check for IPv4 VRRP packets is enabled.

7. Return to system view.

   quit

8. Set a DSCP value for VRRP packets.

   vrrp dscp *dscp-value*

   By default, the DSCP value for VRRP packets is 48.

   The DSCP value identifies the packet priority during transmission.

Configuring VF tracking

About this task

You can configure VF tracking in both standard mode and load balancing mode, but the function takes effect only in load balancing mode.

In load balancing mode, you can establish the collaboration between the VFs and NQA or BFD through the tracking function. When the state of the track entry transits to Negative, the weights of all VFs in the VRRP group on the router decrease by a specific value. When the state of the track entry transits to Positive or Notready, the original weight values of the VFs restore.

Restrictions and guidelines

- By default, the weight of a VF is 255, and its lower limit of failure is 10.
- When the weight of a VF owner is higher than or equal to the lower limit of failure, its priority is always 255. The priority does not change with the weight. When the upstream link of the VF owner fails, an LVF must take over as the AVF. The switchover happens when the weight of the VF owner drops below the lower limit of failure. This requires that the reduced weight for the VF owner be higher than 245.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Configure the VFs in a VRRP group to monitor a track entry.

   vrrp vrid *virtual-router-id* **track** *track-entry-number* { **forwarder-switchover member-ip** *ip-address* | **priority reduced** [*priority-reduced*] | **switchover** | **weight reduced** [*weight-reduced*] }

   By default, no track entry is specified.

Setting the packet sending mode for IPv4 VRRPv3

About this task

A router configured with VRRPv3 can process incoming VRRPv2 packets, but a router configured with VRRPv2 cannot process incoming VRRPv3 packets. When the VRRP version of the routers in a VRRP group is changed from VRRPv2 to VRRPv3, multiple masters might be elected in the VRRP group. To resolve the problem, you can set the packet sending mode for IPv4 VRRPv3. This task enables a router configured with VRRPv3 to send VRRPv2 packets and communicate with routers configured with VRRPv2.

Restrictions and guidelines

- The packet sending mode for IPv4 VRRPv3 takes effect only on outgoing VRRP packets. A router configured with VRRPv3 can process incoming VRRPv2 and VRRPv3 packets.
- If you set the packet sending mode for IPv4 VRRPv3 and configure VRRP packet authentication, authentication information will be carried in outgoing VRRPv2 packets but not in outgoing VRRPv3 packets.
- The VRRP advertisement interval is set in centiseconds by using the **vrrp vrid timer advertise** command. The VRRP advertisement interval carried in VRRPv2 packets sent from routers configured with VRRPv3 might be different from the configured value. For information about the VRRP advertisement interval, see the **vrrp vrid timer advertise** command in *High Availability Command Reference*.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Set the packet sending mode for IPv4 VRRPv3.
   vrrp vrid *virtual-router-id* **vrrpv3-send-packet** { **v2-only** | **v2v3-both** }
   By default, a router configured with VRRPv3 sends only VRRPv3 packets.

Enabling periodic sending of gratuitous ARP packets for IPv4 VRRP

About this task

This feature enables the master router in a VRRP group to periodically send gratuitous ARP packets. Then the downstream devices can update the MAC address entry for the virtual MAC address of the VRRP group in a timely manner.

Restrictions and guidelines

- This feature takes effect only in VRRP standard mode.
- If you change the sending interval for gratuitous ARP packets, the configuration takes effect at the next sending interval.
- The master sends the first gratuitous ARP packet at a random time in the second half of the set interval after you execute the **vrrp send-gratuitous-arp** command. This prevents too many gratuitous ARP packets from being sent at the same time.
- The sending interval for gratuitous ARP packets might be much longer than the set interval when the following conditions are met:
  - Multiple VRRP groups exist on the device.
  - A short sending interval is set.

Procedure

1. Enter system view.
   system-view
2. Enable periodic sending of gratuitous ARP packets for IPv4 VRRP.
   vrrp send-gratuitous-arp [**interval** *interval*]
   By default, periodic sending of gratuitous ARP packets is disabled for IPv4 VRRP.

Configuring a subordinate IPv4 VRRP group to follow a master IPv4 VRRP group

About this task

Each VRRP group determines the device role (master or backup) by exchanging VRRP packets among member devices, which might consume excessive bandwidth and CPU resources. To reduce the number of VRRP packets in the network, you can configure a subordinate VRRP group to follow a master VRRP group.

A master VRRP group determines the device role through exchanging VRRP packets among member devices. A VRRP group that follows a master group, called a subordinate VRRP group,

does not exchange VRRP packets among its member devices. The state of the subordinate VRRP group follows the state of the master group.

Restrictions and guidelines

- To ensure the master router election, configure the settings such as the router priority, preemptive mode, and tracking function for the master IPv4 VRRP group. The settings are not required for subordinate IPv4 VRRP groups.
- You can configure a subordinate VRRP group to follow a master VRRP group in both VRRP standard and load balancing modes. The configuration takes effect only in VRRP standard mode.
- An IPv4 VRRP group cannot be both a master group and a subordinate group.
- An IPv4 VRRP group stays in **Inactive** state if it is configured to follow a nonexistent master group.
- If an IPv4 VRRP group in **Inactive** or **Initialize** state follows a master group that is not in **Inactive** state, the state of the VRRP group does not change.
- A subordinate IPv4 VRRP group does not exchange VRRP packets, which might cause the MAC address entry for its virtual MAC address not to be updated on downstream devices. As a best practice, enable periodic sending of gratuitous ARP packets for IPv4 VRRP by using the **vrrp send-gratuitous-arp** command.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure an IPv4 VRRP group as a master group and assign a name to it.
   vrrp vrid *virtual-router-id* **name** *name*
   By default, an IPv4 VRRP group does not act as a master group.
4. Return to system view.
   quit
5. Enter interface view.
   interface *interface-type interface-number*
6. Configure an IPv4 VRRP group to follow a master group.
   vrrp vrid *virtual-router-id* **follow** *name*
   By default, an IPv4 VRRP group does not follow a master VRRP group.

Enabling SNMP notifications for VRRP

About this task

To report critical VRRP events to an NMS, enable SNMP notifications for VRRP. For VRRP event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

Procedure

1. Enter system view.
   system-view
2. Enable SNMP notifications for VRRP.
   snmp-agent trap enable vrrp [**auth-failure** | **new-master**]

By default, SNMP notifications for VRRP are enabled.

Display and maintenance commands for IPv4 VRRP

Execute **display** commands in any view and the **reset** command in user view.

Task	Command
Display states of IPv4 VRRP groups.	**display vrrp** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*]] [**verbose**]
Display master-to-subordinate IPv4 VRRP group bindings.	**display vrrp binding** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*] | **name** *name*]
Display statistics for IPv4 VRRP groups.	**display vrrp statistics** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*]]
Clear statistics for IPv4 VRRP groups.	**reset vrrp statistics** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*]]

Configuring IPv6 VRRP

Restrictions and guidelines: IPv6 VRRP configuration

IPv6 VRRP does not take effect on member ports of aggregation groups.

Configuration on the routers in an IPv6 VRRP group must be consistent.

Each IPv6 VRRP group corresponds to a virtual MAC address. The maximum number of IPv6 VRRP groups supported on an interface depends on the maximum number of virtual MAC addresses supported on the interface.

IPv6 VRRP tasks at a glance

To configure IPv6 VRRP, perform the following tasks:

1. Specifying an IPv6 VRRP operating mode
2. Configuring an IPv6 VRRP group
3. (Optional.) Configuring VF tracking

   This configuration takes effect only in VRRP load balancing mode.
4. (Optional.) Configuring IPv6 VRRP packet attributes
5. (Optional.) Enabling periodic sending of ND packets for IPv6 VRRP
6. (Optional.) Configuring a subordinate IPv6 VRRP group to follow a master IPv6 VRRP group

Specifying an IPv6 VRRP operating mode

Restrictions and guidelines

After the IPv6 VRRP operating mode is specified on a router, all IPv6 VRRP groups on the router operate in the specified operating mode.

Procedure

1. Enter system view.
   system-view
2. Specify an IPv6 VRRP operating mode.
   - Specify the standard mode.
     undo vrrp ipv6 mode
   - Specify the load balancing mode.
     vrrp ipv6 mode load-balance

   By default, VRRP operates in standard mode.

Configuring an IPv6 VRRP group

About this task

A VRRP group can work correctly after you create it and assign a minimum of one virtual IPv6 address for it. You can configure multiple virtual IPv6 addresses for the VRRP group on an interface that connects to multiple subnets for router backup.

If you disable an IPv6 VRRP group, the VRRP group enters **Initialize** state, and the existing configuration on the VRRP group remains unchanged. You can modify the configuration of the VRRP group. The modification takes effect when you enable the VRRP group again.

Restrictions and guidelines

Item	Remarks
VLAN interface	Do not create VRRP groups on the VLAN interface of a super VLAN. Otherwise, network performance might be adversely affected. For information about the super VLAN feature, see *Layer 2—LAN Switching Configuration Guide*.
Maximum number of VRRP groups and virtual IPv6 addresses	In VRRP load balancing mode, the device supports a maximum of *MaxVRNum/N* VRRP groups. *MaxVRNum* refers to the maximum number of VRRP groups supported by the device in VRRP standard mode. *N* refers to the number of devices in the VRRP group.
Virtual IPv6 address	In load balancing mode, the virtual IPv6 address of a VRRP group cannot be the same as the IPv6 address of any interfaces in the VRRP group. No IP address owner can exist in a VRRP group. An IPv6 VRRP group without virtual IPv6 addresses configured can exist on a device provided that other settings (for example, priority and preemption mode) are available. Such a VRRP group stays in inactive state and does not function. For hosts in the subnet to access external networks, as a best practice, configure the following addresses in the same subnet: • Virtual IPv6 address of an IPv6 VRRP group. • Downlink interface IPv6 addresses of the VRRP group members.
IP address owner	On an IP address owner, as a best practice, do not use the **ospfv3 area** command to enable OSPF on the interface owning the virtual IPv6 address of the VRRP group. For more information about the **ospfv3 area** command, see *Layer 3—IP Routing Command Reference*. After you remove the IPv6 VRRP group on an IP address owner, a backup in the IPv6 VRRP group takes over as the master. The actual IPv6 address of the interface on the IP address owner will conflict with the virtual IPv6 address of the new master. To avoid the conflict, change the IPv6 address of the interface on the IP address owner

Item	Remarks
	before you remove the IPv6 VRRP group from the interface. The running priority of an IP address owner is always 255, and you do not need to configure it. An IP address owner always operates in preemptive mode. If you configure the **vrrp ipv6 vrid track priority reduced** or **vrrp ipv6 vrid track switchover** command on an IP address owner, the configuration does not take effect until the router becomes a non-IP address owner. On an IP address owner, disable Duplicate Address Detection (DAD) on the interface configured with VRRP. To disable DAD, set the *interval* argument to 0 for the **ipv6 nd dad attempts** command. For more information about the command, see IPv6 basics commands in *Layer 3—IP Services Command Reference*.
VRRP association with a track entry	When the track entry changes from Negative to Positive or Notready, the router automatically restores its priority or the failed master router becomes the master again.

Creating a VRRP group and assign a virtual IPv6 address

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Create a VRRP group and assign a virtual IPv6 address, which is a link-local address.
   vrrp ipv6 vrid *virtual-router-id* **virtual-ip** *virtual-address* **link-local**
   The first virtual IPv6 address that you assign to an IPv6 VRRP group must be a link-local address. It must be the last address you remove. Only one link-local address is allowed in a VRRP group.

Configuring an IPv6 VRRP group

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Assign a virtual IPv6 address, which is a global unicast address.
   vrrp ipv6 vrid *virtual-router-id* **virtual-ip** *virtual-address*
   By default, no global unicast address is assigned to an IPv6 VRRP group.
4. Set the priority of the router in the VRRP group.
   vrrp ipv6 vrid *virtual-router-id* **priority** *priority-value*
   The default setting is 100.
5. Enable the preemptive mode for the router in a VRRP group and set the preemption delay time.
   vrrp ipv6 vrid *virtual-router-id* **preempt-mode** [**delay** *delay-value*]
   By default, the router in a VRRP group operates in preemptive mode and the preemption delay time is 0 centiseconds, which means an immediate preemption.
6. Associate a VRRP group with a track entry.
   vrrp ipv6 vrid *virtual-router-id* **track** *track-entry-number* { **forwarder-switchover member-ip** *ipv6-address* | **priority reduced** [*priority-reduced*] | **switchover** | **weight reduced** [*weight-reduced*] }

By default, a VRRP group is not associated with any track entries.

Disabling an IPv6 VRRP group

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Disable an IPv6 VRRP group.
   vrrp ipv6 vrid *virtual-router-id* **shutdown**
   By default, an IPv6 VRRP group is enabled.

CAUTION:
You can use this command to temporarily disable an IPv6 VRRP group. After you execute this command, packets sent to the IPv6 VRRP group might be discarded.

Configuring VF tracking

About this task

You can configure VF tracking in both standard mode and load balancing mode, but the function takes effect only in load balancing mode.

In load balancing mode, you can configure the VFs in a VRRP group to monitor a track entry. When the state of the track entry transits to Negative, the weights of all VFs in the VRRP group on the router decrease by a specific value. When the state of the track entry transits to Positive or Notready, the original weights of the VFs restore.

Restrictions and guidelines

- By default, the weight of a VF is 255, and its lower limit of failure is 10.
- When the weight of a VF owner is higher than or equal to the lower limit of failure, its priority is always 255. The priority does not change with the weight. When the upstream link of the VF owner fails, an LVF must take over as the AVF. The switchover happens when the weight of the VF owner drops below the lower limit of failure. This requires that the reduced weight for the VF owner be higher than 245.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the VFs in a VRRP group to monitor a track entry.
   vrrp ipv6 vrid *virtual-router-id* **track** *track-entry-number*
   { **forwarder-switchover member-ip** *ipv6-address* | **priority reduced** [*priority-reduced*] | **switchover** | **weight reduced** [*weight-reduced*] }
   By default, no track entry is specified.

Configuring IPv6 VRRP packet attributes

Restrictions and guidelines

- The routers in an IPv6 VRRP group can have different intervals for sending VRRP advertisements. The master in the VRRP group sends VRRP advertisements at the specified

interval and carries the interval attribute in the advertisements. After a backup receives the advertisement, it records the interval in the advertisement. If the backup does not receive a VRRP advertisement before the timer (3 x recorded interval + Skew_Time) expires, it regards the master as failed and takes over.

- A high volume of network traffic might cause a backup to fail to receive VRRP advertisements from the master within the specified time. As a result, an unexpected master switchover occurs. To solve this problem, configure a larger interval.

Procedure

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Set the IPv6 VRRP advertisement interval.

   vrrp ipv6 vrid *virtual-router-id* **timer advertise** *adver-interval*

   The default setting is 100 centiseconds.

   As a best practice to maintain system stability, set the VRRP advertisement interval to be greater than 100 centiseconds.
4. Return to system view.

   quit
5. Set a DSCP value for IPv6 VRRP packets.

   vrrp ipv6 dscp *dscp-value*

   By default, the DSCP value for IPv6 VRRP packets is 56.

   The DSCP value identifies the packet priority during transmission.

Enabling periodic sending of ND packets for IPv6 VRRP

About this task

This feature enables the master router in an IPv6 VRRP group to periodically send ND packets. Then the downstream devices can update the MAC address entry for the virtual MAC address of the IPv6 VRRP group in a timely manner.

Restrictions and guidelines

- This feature takes effect only in VRRP standard mode.
- If you change the sending interval for ND packets, the configuration takes effect at the next sending interval.
- The master sends the first ND packet at a random time in the second half of the set interval after you execute the **vrrp ipv6 send-nd** command. This prevents too many ND packets from being sent at the same time.
- The sending interval for ND packets might be much longer than the set interval when the following conditions are met:
  - Multiple IPv6 VRRP groups exist on the device.
  - A short sending interval is set.

Procedure

1. Enter system view.

   system-view
2. Enable periodic sending of ND packets for IPv6 VRRP.

   vrrp ipv6 send-nd [**interval** *interval*]

By default, periodic sending of ND packets is disabled for IPv6 VRRP.

Configuring a subordinate IPv6 VRRP group to follow a master IPv6 VRRP group

About this task

Each IPv6 VRRP group determines the device role (master or backup) by exchanging VRRP packets among member devices, which might consume excessive bandwidth and CPU resources. To reduce the number of VRRP packets in the network, you can configure a subordinate IPv6 VRRP group to follow a master IPv6 VRRP group.

A master IPv6 VRRP group determines the device role through exchanging VRRP packets among member devices. An IPv6 VRRP group that follows a master group, called a subordinate VRRP group, does not exchange VRRP packets among its member devices. The state of the subordinate VRRP group follows the state of the master group.

Restrictions and guidelines

- To ensure the master router election, configure the settings such as the router priority, preemptive mode, and tracking function for the master IPv6 VRRP group. The settings are not required for subordinate IPv6 VRRP groups.
- You can configure a subordinate IPv6 VRRP group to follow a master IPv6 VRRP group in both VRRP standard and load balancing modes. The configuration takes effect only in VRRP standard mode.
- An IPv6 VRRP group cannot be both a master group and a subordinate group.
- An IPv6 VRRP group stays in **Inactive** state if it is configured to follow a nonexistent master IPv6 VRRP group.
- If an IPv6 VRRP group in **Inactive** or **Initialize** state follows a master group that is not in **Inactive** state, the state of the VRRP group does not change.
- A subordinate IPv6 VRRP group does not exchange VRRP packets, which might cause the MAC address entry for its virtual MAC address not to be updated on downstream devices. As a best practice, enable periodic sending of ND packets for IPv6 VRRP by using the **vrrp ipv6 send-nd** command.

Procedure

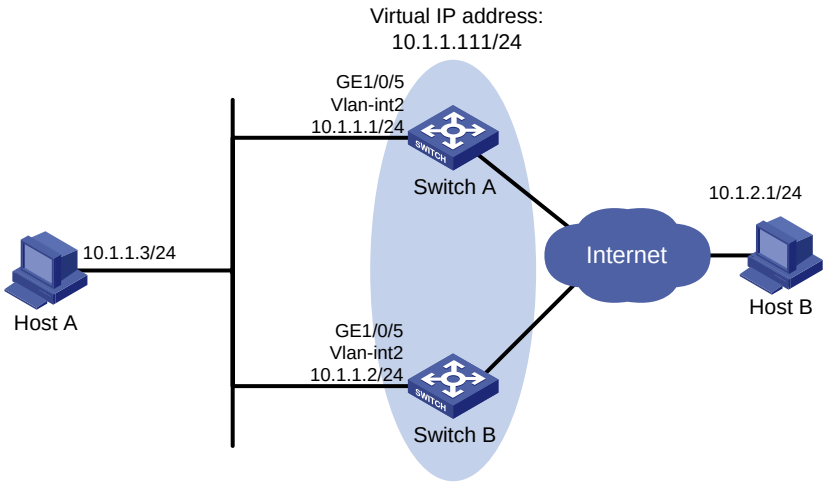
1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure an IPv6 VRRP group as a master group and assign a name to it.
   vrrp ipv6 vrid *virtual-router-id* **name** *name*
   By default, an IPv6 VRRP group does not act as a master group.
4. Return to system view.
   quit
5. Enter interface view.
   interface *interface-type interface-number*
6. Configure an IPv6 VRRP group to follow a master group.
   vrrp ipv6 vrid *virtual-router-id* **follow** *name*
   By default, an IPv6 VRRP group does not follow a master VRRP group.

Display and maintenance commands for IPv6 VRRP

Execute **display** commands in any view and the **reset** command in user view.

Task	Command
Display the states of IPv6 VRRP groups.	**display vrrp ipv6** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*]] [**verbose**]
Display master-to-subordinate IPv6 VRRP group bindings.	**display vrrp ipv6 binding** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*] | **name** *name*]
Display statistics for IPv6 VRRP groups.	**display vrrp ipv6 statistics** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*]]
Clear statistics for IPv6 VRRP groups.	**reset vrrp ipv6 statistics** [**interface** *interface-type interface-number* [**vrid** *virtual-router-id*]]

IPv4 VRRP configuration examples



Example: Configuring a single VRRP group

Network configuration

As shown in Figure 9, Switch A and Switch B form a VRRP group. They use the virtual IP address 10.1.1.111/24 to provide gateway service for the subnet where Host A resides.

Switch A operates as the master to forward packets from Host A to Host B. When Switch A fails, Switch B takes over to forward packets for Host A.

Figure 9 Network diagram

Procedure

1. Configure Switch A:

   # Configure VLAN 2.

```
<SwitchA> system-view
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/5
[SwitchA-vlan2] quit
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ip address 10.1.1.1 255.255.255.0
```

Create VRRP group 1 on VLAN-interface 2, and set its virtual IP address to 10.1.1.111.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.111
```

Assign Switch A a higher priority than Switch B in VRRP group 1, so Switch A can become the master.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
```

Configure Switch A to operate in preemptive mode, so it can become the master whenever it operates correctly. Set the preemption delay to 5000 centiseconds to avoid frequent status switchover.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 preempt-mode delay 5000
```

2. Configure Switch B:

Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB] vlan 2
[SwitchB-Vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 10.1.1.2 255.255.255.0
```

Create VRRP group 1 on VLAN-interface 2, and set its virtual IP address to 10.1.1.111.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.111
```

Set the priority of Router B to 100 in VRRP group 1.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 priority 100
```

Configure Switch B to operate in preemptive mode, and set the preemption delay to 5000 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 preempt-mode delay 5000
```

Verifying the configuration

Ping Host B from Host A. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp verbose
IPv4 Virtual Router Information:

   Interface Vlan-interface2
     VRID             : 1                  Adver Timer  : 100
     Admin Status     : Up                 State        : Master
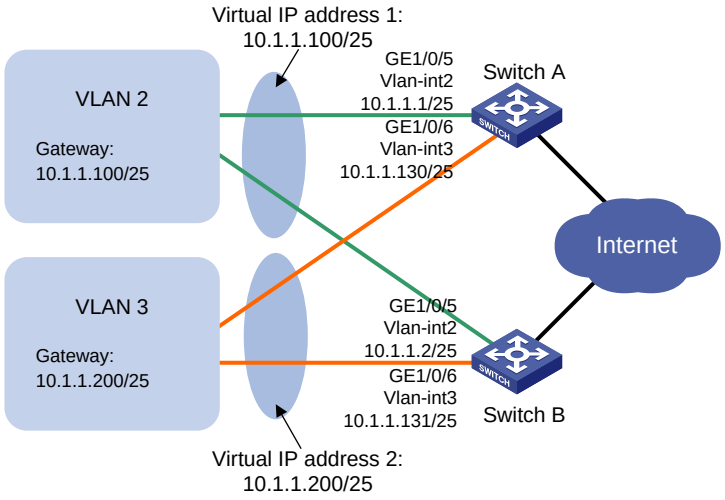
     Config Pri       : 110                Running Pri  : 110
     Preempt Mode     : Yes                Delay Time   : 5000
     Auth Type        : Not supported
```

```
Version           : 3
Virtual IP        : 10.1.1.111
Virtual MAC       : 0000-5e00-0101
Master IP         : 10.1.1.1
```

The output shows that after Switch A resumes normal operation, it becomes the master to forward packets from Host A to Host B.



Example: Configuring multiple VRRP groups

Network configuration

As shown in Figure 10, Switch A and Switch B form two VRRP groups. VRRP group 1 uses the virtual IP address 10.1.1.100/25 to provide gateway service for hosts in VLAN 2, and VRRP group 2 uses the virtual IP address 10.1.1.200/25 to provide gateway service for hosts in VLAN 3.

Assign a higher priority to Switch A than Switch B in VRRP group 1, but a lower priority in VRRP group 2. Traffic from VLAN 2 and VLAN 3 can then be distributed between the two switches. When one of the switches fails, the healthy switch provides gateway service for both VLANs.

Figure 10 Network diagram

Procedure

1. Configure Switch A:

   # Configure VLAN 2.

   ```
   <SwitchA> system-view
   [SwitchA] vlan 2
   [SwitchA-vlan2] port gigabitethernet 1/0/5
   [SwitchA-vlan2] quit
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ip address 10.1.1.1 255.255.255.128
   ```

   # Create VRRP group 1, and set its virtual IP address to 10.1.1.100.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.100
   ```

   # Assign Switch A a higher priority than Switch B in VRRP group 1, so Switch A can become the master in the group.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   [SwitchA-Vlan-interface2] quit
   ```

   # Configure VLAN 3.

```
[SwitchA] vlan 3
[SwitchA-vlan3] port gigabitethernet 1/0/6
[SwitchA-vlan3] quit
[SwitchA] interface vlan-interface 3
[SwitchA-Vlan-interface3] ip address 10.1.1.130 255.255.255.128
```

Create VRRP group 2, and set its virtual IP address to 10.1.1.200.

```
[SwitchA-Vlan-interface3] vrrp vrid 2 virtual-ip 10.1.1.200
```

2. Configure Switch B:

Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 10.1.1.2 255.255.255.128
```

Create VRRP group 1, and set its virtual IP address to 10.1.1.100.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.100
[SwitchB-Vlan-interface2] quit
```

Configure VLAN 3.

```
[SwitchB] vlan 3
[SwitchB-vlan3] port gigabitethernet 1/0/6
[SwitchB-vlan3] quit
[SwitchB] interface vlan-interface 3
[SwitchB-Vlan-interface3] ip address 10.1.1.131 255.255.255.128
```

Create VRRP group 2, and set its virtual IP address to 10.1.1.200.

```
[SwitchB-Vlan-interface3] vrrp vrid 2 virtual-ip 10.1.1.200
```

Assign Switch B a higher priority than Switch A in VRRP group 2, so Switch B can become the master in the group.

```
[SwitchB-Vlan-interface3] vrrp vrid 2 priority 110
```

Verifying the configuration

Display detailed information about the VRRP groups on Switch A.

```
[SwitchA-Vlan-interface3] display vrrp verbose

```

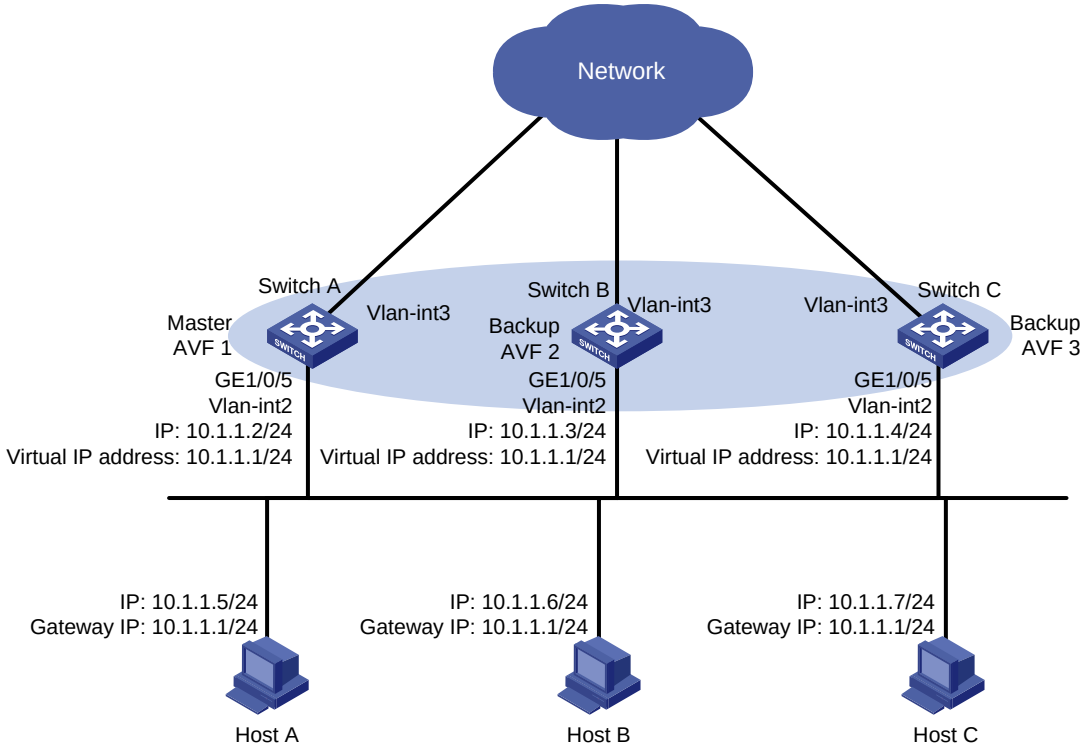
The output shows the following information:

- Switch A is operating as the master in VRRP group 1 to forward Internet traffic for hosts that use the default gateway 10.1.1.100/25.
- Switch B is operating as the master in VRRP group 2 to forward Internet traffic for hosts that use the default gateway 10.1.1.200/25.



Example: Configuring VRRP load balancing

Network configuration

As shown in Figure 11, Switch A, Switch B, and Switch C form a load-balanced VRRP group. They use the virtual IP address 10.1.1.1/24 to provide gateway service for subnet 10.1.1.0/24.

Configure VFs on Switch A, Switch B, and Switch C to monitor their respective VLAN-interface 3. When the interface on any one of them fails, the weights of the VFs on the problematic switch decrease so another AVF can take over.

Figure 11 Network diagram

Procedure

1. Configure Switch A:

   # Configure VLAN 2.

   ```
   <SwitchA> system-view
   [SwitchA] vlan 2
   [SwitchA-vlan2] port gigabitethernet 1/0/5
   [SwitchA-vlan2] quit
   ```

   # Configure VRRP to operate in load balancing mode.

   ```
   [SwitchA] vrrp mode load-balance
   ```

   # Create VRRP group 1, and set its virtual IP address to 10.1.1.1.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ip address 10.1.1.2 24
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.1
   ```

   # Assign Switch A the highest priority in VRRP group 1, so Switch A can become the master.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 120
   ```

   # Configure Switch A to operate in preemptive mode, so it can become the master whenever it operates correctly. Set the preemption delay to 5000 centiseconds to avoid frequent status switchover.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 preempt-mode delay 5000
   [SwitchA-Vlan-interface2] quit
   ```

   # Create track entry 1 to monitor the upstream link status of VLAN-interface 3. When the upstream link fails, the track entry transits to Negative.

```
[SwitchA] track 1 interface vlan-interface 3
```

Configure the VFs in VRRP group 1 to monitor track entry 1, and decrease their weights by 250 when the track entry transits to Negative.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] vrrp vrid 1 track 1 weight reduced 250
```

2. Configure Switch B:

Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
```

Configure VRRP to operate in load balancing mode.

```
[SwitchB] vrrp mode load-balance
```

Create VRRP group 1, and set its virtual IP address to 10.1.1.1.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ip address 10.1.1.3 24
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.1
```

Assign Switch B a higher priority than Switch C in VRRP group 1, so Switch B can become the master when Switch A fails.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 priority 110
```

Configure Switch B to operate in preemptive mode, and set the preemption delay to 5000 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 preempt-mode delay 5000
[SwitchB-Vlan-interface2] quit
```

Create track entry 1 to monitor the upstream link status of VLAN-interface 3. When the upstream link fails, the track entry transits to Negative.

```
[SwitchB] track 1 interface vlan-interface 3
```

Configure the VFs in VRRP group 1 to monitor track entry 1, and decrease their weights by 250 when the track entry transits to Negative.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp vrid 1 track 1 weight reduced 250
```

3. Configure Switch C:

Configure VLAN 2.

```
<SwitchC> system-view
[SwitchC] vlan 2
[SwitchC-vlan2] port gigabitethernet 1/0/5
[SwitchC-vlan2] quit
```

Configure VRRP to operate in load balancing mode.

```
[SwitchC] vrrp mode load-balance
```

Create VRRP group 1, and set its virtual IP address to 10.1.1.1.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] ip address 10.1.1.4 24
[SwitchC-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.1
```

Configure Switch C to operate in preemptive mode, and set the preemption delay to 5000 centiseconds.

```
[SwitchC-Vlan-interface2] vrrp vrid 1 preempt-mode delay 5000
[SwitchC-Vlan-interface2] quit
```

Create track entry 1 to monitor the upstream link status of VLAN-interface 3. When the upstream link fails, the track entry transits to Negative.

```
[SwitchC] track 1 interface vlan-interface 3
```

Configure the VFs in VRRP group 1 to monitor track entry 1, and decrease their weights by 250 when the track entry transits to Negative.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] vrrp vrid 1 track 1 weight reduced 250
```

Verifying the configuration

Verify that Host A can ping the external network. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp verbose

     Preempt Mode     : Yes                  Delay Time   : 5000
     Auth Type        : None
     Virtual IP       : 10.1.1.1
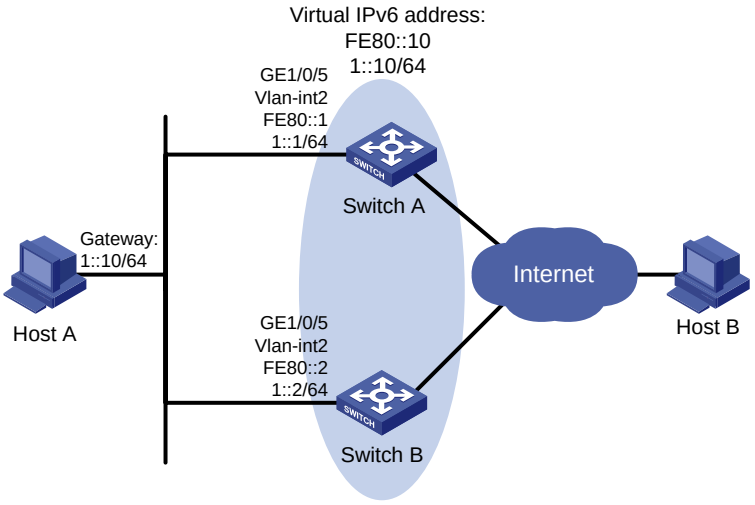
     Member IP List   : 10.1.1.3 (Local, Master)
                        10.1.1.4 (Backup)
   Forwarder Information: 2 Forwarders 1 Active
     Config Weight  : 255
     Running Weight : 255
    Forwarder 02
     State          : Active
     Virtual MAC    : 000f-e2ff-0012 (Owner)
     Owner ID       : 0000-5e01-1103
     Priority       : 255
     Active         : local
    Forwarder 03
     State          : Listening
     Virtual MAC    : 000f-e2ff-0013 (Learnt)
     Owner ID       : 0000-5e01-1105
     Priority       : 127
     Active         : 10.1.1.4
   Forwarder Weight Track Information:
     Track Object   : 1          State : Positive   Weight Reduced : 250
```

The output shows the following information:

- When Switch A fails, Switch B becomes the master because it has a higher priority than Switch C.
- The VF for virtual MAC address 000f-e2ff-0011 is removed.

IPv6 VRRP configuration examples

Example: Configuring a single VRRP group



Network configuration

As shown in Figure 12, Switch A and Switch B form a VRRP group. They use the virtual IP addresses 1::10/64 and FE80::10 to provide gateway service for the subnet where Host A resides.

Host A learns 1::10/64 as its default gateway from RA messages sent by the switches.

Switch A operates as the master to forward packets from Host A to Host B. When Switch A fails, Switch B takes over to forward packets for Host A.

Figure 12 Network diagram

Procedure

1. Configure Switch A:

   # Configure VLAN 2.

   ```
   <SwitchA> system-view
   [SwitchA] vlan 2
   [SwitchA-vlan2] port gigabitethernet 1/0/5
   [SwitchA-vlan2] quit
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ipv6 address fe80::1 link-local
   [SwitchA-Vlan-interface2] ipv6 address 1::1 64
   ```

   # Create VRRP group 1, and set its virtual IPv6 addresses to FE80::10 and 1::10.

   ```
   [SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
   [SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
   ```

   # Assign Switch A a higher priority than Switch B in VRRP group 1, so Switch A can become the master.

   ```
   [SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 priority 110
   ```

   # Configure Switch A to operate in preemptive mode, so it can become the master whenever it operates correctly. Set the preemption delay to 5000 centiseconds to avoid frequent status switchover.

   ```
   [SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode delay 5000
   ```

   # Enable Switch A to send RA messages, so Host A can learn the default gateway address.

   ```
   [SwitchA-Vlan-interface2] undo ipv6 nd ra halt
   ```

2. Configure Switch B:

   # Configure VLAN 2.

   ```
   <SwitchB> system-view
   [SwitchB] vlan 2
   [SwitchB-vlan2] port gigabitethernet 1/0/5
   [SwitchB-vlan2] quit
   ```

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ipv6 address fe80::2 link-local
[SwitchB-Vlan-interface2] ipv6 address 1::2 64
```

Create VRRP group 1 and set its virtual IPv6 addresses to FE80::10 and 1::10.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

Configure Switch B to operate in preemptive mode, and set the preemption delay to 5000 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode delay 5000
```

Enable Switch B to send RA messages, so Host A can learn the default gateway address.

```
[SwitchB-Vlan-interface2] undo ipv6 nd ra halt
```

Verifying the configuration

Ping Host B from Host A. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp ipv6 verbose

     Virtual MAC      : 0000-5e00-0201
     Master IP        : FE80::1
```

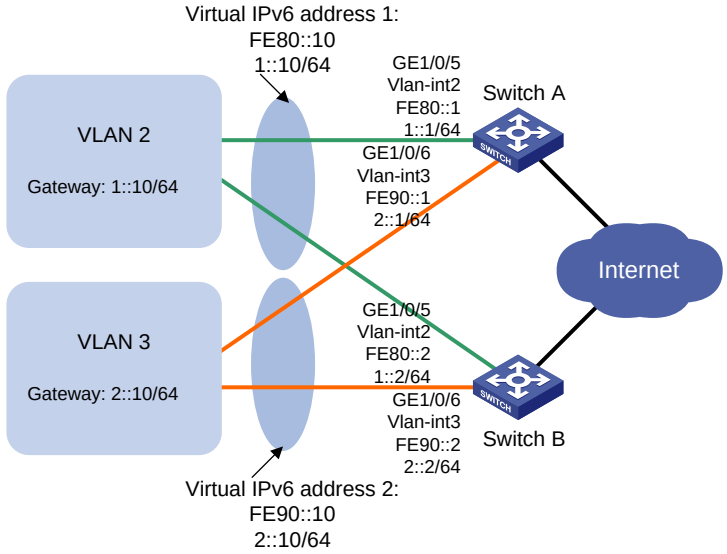
The output shows that after Switch A resumes normal operation, it becomes the master to forward packets from Host A to Host B.

Example: Configuring multiple VRRP groups



Network configuration

As shown in Figure 13, Switch A and Switch B form two VRRP groups. VRRP group 1 uses the virtual IPv6 addresses 1::10/64 and FE80::10 to provide gateway service for hosts in VLAN 2. VRRP group 2 uses the virtual IPv6 addresses 2::10/64 and FE90::10 to provide gateway service for hosts in VLAN 3.

From RA messages sent by the switches, hosts in VLAN 2 learn 1::10/64 as their default gateway. Hosts in VLAN 3 learn 2::10/64 as their default gateway.

Assign Switch A a higher priority than Switch B in VRRP group 1 but a lower priority in VRRP group 2. Traffic from VLAN 2 and VLAN 3 can then be distributed between the two switches. When one of the switches fails, the healthy switch provides gateway service for both VLANs.

Figure 13 Network diagram

Procedure

1. Configure Switch A:

Configure VLAN 2.

```
<SwitchA> system-view
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/5
[SwitchA-vlan2] quit
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ipv6 address fe80::1 link-local
[SwitchA-Vlan-interface2] ipv6 address 1::1 64
```

Create VRRP group 1, and set its virtual IPv6 addresses to FE80::10 to 1::10.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

Assign Switch A a higher priority than Switch B in VRRP group 1, so Switch A can become the master in the group.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 priority 110
```

Enable Switch A to send RA messages, so hosts in VLAN 2 can learn the default gateway address.

```
[SwitchA-Vlan-interface2] undo ipv6 nd ra halt
[SwitchA-Vlan-interface2] quit
```

Configure VLAN 3.

```
[SwitchA] vlan 3
[SwitchA-vlan3] port gigabitethernet 1/0/6
[SwitchA-vlan3] quit
[SwitchA] interface vlan-interface 3
[SwitchA-Vlan-interface3] ipv6 address fe90::1 link-local
[SwitchA-Vlan-interface3] ipv6 address 2::1 64
```

Create VRRP group 2, and set its virtual IPv6 addresses to FE90::10 and 2::10.

```
[SwitchA-Vlan-interface3] vrrp ipv6 vrid 2 virtual-ip fe90::10 link-local
[SwitchA-Vlan-interface3] vrrp ipv6 vrid 2 virtual-ip 2::10
```

Enable Switch A to send RA messages, so hosts in VLAN 3 can learn the default gateway address.

```
[SwitchA-Vlan-interface3] undo ipv6 nd ra halt
```

2. Configure Switch B:

Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ipv6 address fe80::2 link-local
[SwitchB-Vlan-interface2] ipv6 address 1::2 64
```

Create VRRP group 1, and set its virtual IPv6 addresses to FE80::10 and 1::10.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

Enable Switch B to send RA messages, so hosts in VLAN 2 can learn the default gateway address.

```
[SwitchB-Vlan-interface2] undo ipv6 nd ra halt
[SwitchB-Vlan-interface2] quit
```

Configure VLAN 3.

```
[SwitchB] vlan 3
[SwitchB-vlan3] port gigabitethernet 1/0/6
[SwitchB-vlan3] quit
[SwitchB] interface vlan-interface 3
[SwitchB-Vlan-interface3] ipv6 address fe90::2 link-local
[SwitchB-Vlan-interface3] ipv6 address 2::2 64
```

Create VRRP group 2, and set its virtual IPv6 addresses to FE90::10 and 2::10.

```
[SwitchB-Vlan-interface3] vrrp ipv6 vrid 2 virtual-ip fe90::10 link-local
[SwitchB-Vlan-interface3] vrrp ipv6 vrid 2 virtual-ip 2::10
```

Assign Switch B a higher priority than Switch A in VRRP group 2, so Switch B can become the master in the group.

```
[SwitchB-Vlan-interface3] vrrp ipv6 vrid 2 priority 110
```

Enable Switch B to send RA messages, so hosts in VLAN 3 can learn the default gateway address.

```
[SwitchB-Vlan-interface3] undo ipv6 nd ra halt
```

Verifying the configuration

Display detailed information about the VRRP groups on Switch A.

```
[SwitchA-Vlan-interface3] display vrrp ipv6 verbose

     Virtual IP       : FE90::10
                        2::10
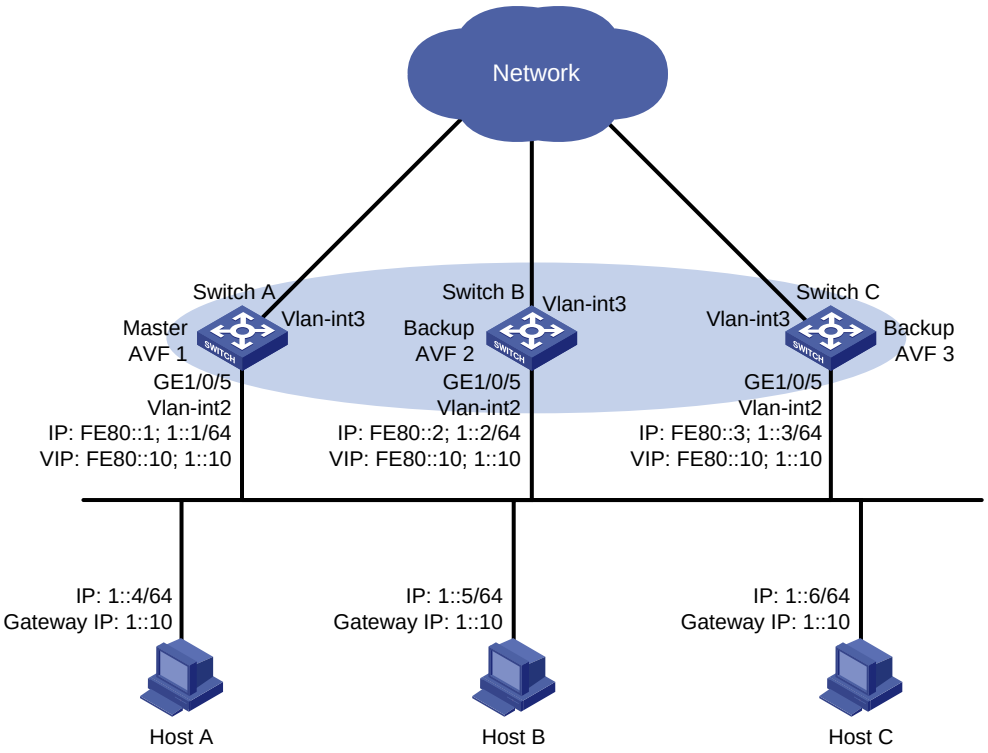
     Virtual MAC      : 0000-5e00-0202
     Master IP        : FE90::2
```

The output shows the following information:

- Switch A is operating as the master in VRRP group 1 to forward Internet traffic for hosts that use the default gateway 1::10/64.
- Switch B is operating as the master in VRRP group 2 to forward Internet traffic for hosts that use the default gateway 2::10/64.

Example: Configuring VRRP load balancing



Network configuration

As shown in Figure 14, Switch A, Switch B, and Switch C form a load balanced VRRP group. They use the virtual IPv6 addresses FE80::10 and 1::10 to provide gateway service for subnet 1::/64.

Hosts on subnet 1::/64 learn 1::10 as their default gateway from RA messages sent by the switches.

Configure VFs on Switch A, Switch B, or Switch C to monitor their respective VLAN-interface 3. When the interface on any of them fails, the weights of the VFs on the problematic switch decrease so another AVF can take over.

Figure 14 Network diagram

Procedure

1. Configure Switch A:

Configure VLAN 2.

```
<SwitchA> system-view
[SwitchA] vlan 2
[SwitchA-vlan2] port gigabitethernet 1/0/5
[SwitchA-vlan2] quit
```

Configure VRRP to operate in load balancing mode.

```
[SwitchA] vrrp ipv6 mode load-balance
```

Create VRRP group 1, and set its virtual IPv6 addresses to FE80::10 and 1::10.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] ipv6 address fe80::1 link-local
[SwitchA-Vlan-interface2] ipv6 address 1::1 64
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

Assign Switch A the highest priority in VRRP group 1, so Switch A can become the master.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 priority 120
```

Configure Switch A to operate in preemptive mode, so it can become the master whenever it operates correctly. Set the preemption delay to 5000 centiseconds to avoid frequent status switchover.

```
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode delay 5000
```

Enable Switch A to send RA messages, so hosts on subnet 1::/64 can learn the default gateway address.

```
[SwitchA-Vlan-interface2] undo ipv6 nd ra halt
[SwitchA-Vlan-interface2] quit
```

Create track entry 1 to monitor the upstream link status of VLAN-interface 3. When the upstream link fails, the track entry transits to Negative.

```
[SwitchA] track 1 interface vlan-interface 3
```

Configure the VFs in VRRP group 1 to monitor track entry 1, and decrease their weights by 250 when the track entry transits to Negative.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] vrrp ipv6 vrid 1 track 1 weight reduced 250
```

2. Configure Switch B:

Configure VLAN 2.

```
<SwitchB> system-view
[SwitchB] vlan 2
[SwitchB-vlan2] port gigabitethernet 1/0/5
[SwitchB-vlan2] quit
```

Configure VRRP to operate in load balancing mode.

```
[SwitchB] vrrp ipv6 mode load-balance
```

Create VRRP group 1, and set its virtual IPv6 addresses to FE80::10 and 1::10.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ipv6 address fe80::2 link-local
[SwitchB-Vlan-interface2] ipv6 address 1::2 64
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

Assign Switch B a higher priority than Switch C in VRRP group 1, so Switch B can become the master when Switch A fails.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 priority 110
```

Configure Switch B to operate in preemptive mode, and set the preemption delay to 5000 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode delay 5000
```

Enable Switch B to send RA messages so hosts on subnet 1::/64 can learn the default gateway address.

```
[SwitchB-Vlan-interface2] undo ipv6 nd ra halt
[SwitchB-Vlan-interface2] quit
```

Create track entry 1 to monitor the upstream link status of VLAN-interface 3. When the upstream link fails, the track entry transits to Negative.

```
[SwitchB] track 1 interface vlan-interface 3
```

Configure the VFs in VRRP group 1 to monitor track entry 1, and decrease their weights by 250 when the track entry transits to Negative.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp ipv6 vrid 1 track 1 weight reduced 250
```

3. Configure Switch C:

Configure VLAN 2.

```
<SwitchC> system-view
[SwitchC] vlan 2
[SwitchC-vlan2] port gigabitethernet 1/0/5
[SwitchC-vlan2] quit
```

Configure VRRP to operate in load balancing mode.

```
[SwitchC] vrrp ipv6 mode load-balance
```

Create VRRP group 1, and set its virtual IPv6 addresses to FE80::10 and 1::10.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] ipv6 address fe80::3 link-local
[SwitchC-Vlan-interface2] ipv6 address 1::3 64
[SwitchC-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip fe80::10 link-local
[SwitchC-Vlan-interface2] vrrp ipv6 vrid 1 virtual-ip 1::10
```

Configure Switch C to operate in preemptive mode, and set the preemption delay to 5000 centiseconds.

```
[SwitchC-Vlan-interface2] vrrp ipv6 vrid 1 preempt-mode delay 5000
```

Enable Switch C to send RA messages, so the hosts on the subnet 1::/64 can learn the default gateway address.

```
[SwitchC-Vlan-interface2] undo ipv6 nd ra halt
[SwitchC-Vlan-interface2] quit
```

Create track entry 1 to monitor the upstream link status of VLAN-interface 3. When the upstream link fails, the track entry transits to Negative.

```
[SwitchC] track 1 interface vlan-interface 3
```

Configure the VFs in VRRP group 1 to monitor track entry 1, and decrease their weights by 250 when the track entry transits to Negative.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] vrrp ipv6 vrid 1 track 1 weight reduced 250
```

Verifying the configuration

Verify that Host A can ping the external network. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp ipv6 verbose

     Priority       : 255
     Active         : local
   Forwarder Weight Track Information:
     Track Object   : 1          State : Positive   Weight Reduced : 250
```

The output shows that when VLAN-interface 3 on Switch A fails, the weights of the VFs on Switch A drop below the lower limit of failure. All VFs on Switch A transit to the **Initialize** state and cannot forward traffic. The VF for MAC address 000f-e2ff-4011 on Switch C becomes the AVF to forward traffic.

When the timeout timer (about 1800 seconds) expires, display detailed information about VRRP group 1 on Switch C.

```
[SwitchC-Vlan-interface2] display vrrp ipv6 verbose
IPv6 Virtual Router Information:
 Running Mode      : Load Balance
 Total number of virtual routers : 1
   Interface Vlan-interface2
```

```
    VRID             : 1                    Adver Timer  : 100
    Admin Status     : Up                   State        : Backup
    Config Pri       : 100                  Running Pri  : 100
    Preempt Mode     : Yes                  Delay Time   : 5000
    Become Master    : 400ms left
    Auth Type        : None
    Virtual IP       : FE80::10
                       1::10
    Member IP List   : FE80::3 (Local, Backup)
                       FE80::1 (Master)
                       FE80::2 (Backup)
  Forwarder Information: 2 Forwarders 1 Active
    Config Weight  : 255
    Running Weight : 255
   Forwarder 02
    State          : Listening
    Virtual MAC    : 000f-e2ff-4012 (Learnt)
    Owner ID       : 0000-5e01-1103
    Priority       : 127
    Active         : FE80::2
   Forwarder 03
    State          : Active
    Virtual MAC    : 000f-e2ff-4013 (Owner)
    Owner ID       : 0000-5e01-1105
    Priority       : 255
    Active         : local
  Forwarder Weight Track Information:
    Track Object   : 1          State : Positive   Weight Reduced : 250
```

The output shows that when the timeout timer expires, the VF for virtual MAC address 000f-e2ff-4011 is removed. The VF no longer forwards the packets destined for the MAC address.

When Switch A fails, display detailed information about VRRP group 1 on Switch B.

```
[SwitchB-Vlan-interface2] display vrrp ipv6 verbose
IPv6 Virtual Router Information:
 Running Mode      : Load Balance
 Total number of virtual routers : 1
   Interface Vlan-interface2
     VRID             : 1                    Adver Timer  : 100
     Admin Status     : Up                   State        : Master
     Config Pri       : 110                  Running Pri  : 110
     Preempt Mode     : Yes                  Delay Time   : 5000
     Auth Type        : None
     Virtual IP       : FE80::10
                        1::10
     Member IP List   : FE80::2 (Local, Master)
                        FE80::3 (Backup)
   Forwarder Information: 2 Forwarders 1 Active
     Config Weight  : 255
     Running Weight : 255
```

```
Forwarder 02
 State           : Active
 Virtual MAC     : 000f-e2ff-4012 (Owner)
 Owner ID        : 0000-5e01-1103
 Priority        : 255
 Active          : local
Forwarder 03
 State           : Listening
 Virtual MAC     : 000f-e2ff-4013 (Learnt)
 Owner ID        : 0000-5e01-1105
 Priority        : 127
 Active          : FE80::3
Forwarder Weight Track Information:
  Track Object   : 1          State : Positive   Weight Reduced : 250
```

The output shows the following information:

- When Switch A fails, Switch B becomes the master because it has a higher priority than Switch C.
- The VF for virtual MAC address 000f-e2ff-4011 is removed.

Troubleshooting VRRP

An error prompt is displayed

Symptom

An error prompt "The virtual router detected a VRRP configuration error." is displayed during configuration.

Analysis

This symptom is probably caused by the following reasons:

- The VRRP advertisement interval in the packet is not the same as that for the current VRRP group (in VRRPv2 only).
- The number of virtual IP addresses in the packet is not the same as that for the current VRRP group.
- The virtual IP address list is not the same as that for the current VRRP group.
- A device in the VRRP group receives illegitimate VRRP packets. For example, the IP address owner receives a VRRP packet with the priority 255.

Solution

To resolve the problem:

1. Modify the configuration on routers in VRRP groups to ensure consistent configuration.
2. Take fault location and anti-attack measures to eliminate potential threats.
3. If the problem persists, contact H3C Support.

Multiple masters appear in a VRRP group

Symptom

Multiple masters appear in a VRRP group.

Analysis

It is normal for a VRRP group to have multiple masters for a short time, and this situation requires no manual intervention.

If multiple masters coexist for a longer period, check for the following conditions:

- The masters cannot receive advertisements from each other.
- The received advertisements are illegitimate.

Solution

To resolve the problem:

1. Ping between these masters:
   - If the ping operation fails, examine network connectivity.
   - If the ping operation succeeds, check for configuration inconsistencies in the number of virtual IP addresses, virtual IP addresses, and authentication. For IPv4 VRRP, also make sure the same version of VRRP is configured on all routers in the VRRP group. For VRRPv2, make sure the same VRRP advertisement interval is configured on the routers in the VRRP group.
2. If the problem persists, contact H3C Support.

Fast VRRP state flapping

Symptom

Fast VRRP state flapping occurs.

Analysis

The VRRP advertisement interval is set too short.

Solution

To resolve the problem:

1. Increase the interval for sending VRRP advertisements or introduce a preemption delay.
2. If the problem persists, contact H3C Support.

Configuring BFD

About BFD

Bidirectional forwarding detection (BFD) provides a general-purpose, standard, medium- and protocol-independent fast failure detection mechanism. It can detect and monitor the connectivity of forwarding paths to detect communication failures quickly so that measures can be taken to ensure service continuity and enhance network availability.

BFD can uniformly and quickly detect the failures of the bidirectional forwarding paths between two devices for upper-layer protocols such as routing protocols. The hello mechanism used by upper-layer protocols needs seconds to detect a link failure, while BFD can provide detection measured in milliseconds.

Single-hop detection and multihop detection

BFD can be used for single-hop and multihop detections.

- **Single-hop detection**—Detects the IP connectivity between two directly connected systems.
- **Multihop detection**—Detects any of the paths between two systems. These paths have multiple hops, and might overlap.

BFD session modes

BFD sessions use echo packets and control packets.

Echo packet mode

Echo packets are encapsulated into UDP packets with port number 3785.

The local end of the link sends echo packets to establish BFD sessions and monitor link status. The peer end does not establish BFD sessions and only forwards the packets back to the originating end. If the local end does not receive echo packets from the peer end within the detection time, it considers the session to be down.

Control packet mode

Control packets are encapsulated into UDP packets with port number 3784 for single-hop detection or port number 4784 for multihop detection.

The two ends of the link negotiate the establishment of BFD sessions by using the session parameters carried in control packets. Session parameters include session discriminators, desired minimum packet sending and receiving intervals, and local BFD session state.

Both ends of the link exchange BFD control packets to monitor link status.

Before a BFD session is established, BFD has two operating modes—active and passive.

- **Active mode**—BFD actively sends BFD control packets regardless of whether any BFD control packet is received from the peer.
- **Passive mode**—BFD does not send control packets until a BFD control packet is received from the peer.

At least one end must operate in active mode for a BFD session to be established.

After a BFD session is established, the two ends can operate in the following BFD operating modes:

- **Asynchronous mode**—The device periodically sends BFD control packets. The device considers that the session is down if it does not receive any BFD control packets within a specific interval.

- **Demand mode**—The device periodically sends BFD control packets with the D bit set. If the peer end is operating in Asynchronous mode (default), the peer end stops sending BFD control packets after receiving control packets with the D bit set. In this case, BFD detects only the connectivity from the local end to the peer end. If the peer end does not receive control packets within the detection time, the session is declared to be down. If the peer end is operating in Demand mode, both ends stop sending BFD control packets. The system uses other mechanisms such as Hello mechanism and hardware detection to detect links. The Demand mode can be used to reduce the overhead when a large number of BFD sessions exist.

Supported features

Features	Reference
Static routing IS-IS OSPF RIP BGP IP fast reroute (FRR)	*Layer 3—IP Routing Configuration Guide*
IPv6 static routing OSPFv3	*Layer 3—IP Routing Configuration Guide*
PIM	*IP Multicast Configuration Guide*
Track	"Configuring Track"
Ethernet link aggregation	*Layer 2—LAN Switching Configuration Guide*

Protocols and standards

- RFC 5880, *Bidirectional Forwarding Detection (BFD)*
- RFC 5881, *Bidirectional Forwarding Detection (BFD) for IPv4 and IPv6 (Single Hop)*
- RFC 5882, *Generic Application of Bidirectional Forwarding Detection (BFD)*
- RFC 5883, *Bidirectional Forwarding Detection (BFD) for Multihop Paths*
- RFC 7130, *Bidirectional Forwarding Detection (BFD) on Link Aggregation Group (LAG) Interfaces*

Restrictions and guidelines: BFD configuration

- By default, the device runs BFD version 1 and is compatible with BFD version 0. You cannot change the BFD version to 0 through commands. When the peer device runs BFD version 0, the local device automatically switches to BFD version 0.
- After a BFD session is established, the two ends negotiate BFD parameters, including minimum sending interval, minimum receiving interval, initialization mode, and packet authentication, by exchanging negotiation packets. They use the negotiated parameters without affecting the session status.
- BFD session flapping might occur on an aggregate interface with member ports on different IRF member devices. When the master device, which receives and sends BFD packets, is removed or restarted, a subordinate device might not immediately take over. For example, a subordinate device will not take over when the subordinate device has a short detection time or a large number of BFD sessions.

Configuring BFD sessions in echo packet mode

Restrictions and guidelines

To avoid echo packet loss, do not configure the echo packet mode on a device with uRPF enabled. For more information about uRPF, see *Security Configuration Guide*.

When the same BFD session (with the same source IP address, destination IP address, interface, VPN, and destination port number) is associated with multiple upper layer applications, BFD selects the detection time settings for the BFD session as follows:

1. Minimum values of the following settings:
   - Settings configured in static BFD session view.
   - Settings configured in the BFD template specified by the upper layer application.
   - Settings configured by the upper layer application.
2. Settings configured in interface view or system view.
3. Default settings.

When a BFD session is associated with only one upper layer application, BFD selects the detection time settings for the BFD session as follows:

1. BFD selects the detection time settings for the BFD session based on whether the upper layer application supports using a BFD template and configuring detection time settings:
   - If a BFD template is specified and detection time settings are also configured for the upper layer application, BFD selects the settings configured in the specified BFD template.
   - If a BFD template is specified for the upper layer application that does not support configuring detection time settings, BFD selects the settings configured in the specified BFD template.
   - If detection time settings are configured for the upper layer application that does not support using a BFD template, BFD selects the configured settings.
2. Settings configured in interface view or system view.
3. Default settings.

Procedure

1. Enter system view.

   system-view
2. Configure the source IP address of echo packets.
   - Configure the source IP address of echo packets.

     bfd echo-source-ip *ip-address*

     By default, no source IPv4 address is configured for echo packets.

     As a best practice, do not configure the source IPv4 address to be on the same network segment as any local interface's IPv4 address. If you configure such a source IPv4 address, a large number of ICMP redirect packets might be sent from the peer, resulting in link congestion.
   - Configure the source IPv6 address of echo packets.

     bfd echo-source-ipv6 *ipv6-address*

     By default, no source IPv6 address is configured for echo packets.

     The source IPv6 address of echo packets can only be a global unicast address.
3. (Optional.) Set the echo packet mode parameters.
   a. Enter interface view.

      interface *interface-type interface-number*
   b. Set the minimum interval for receiving BFD echo packets.

bfd min-echo-receive-interval *interval*

The default setting is 400 milliseconds.

c. Set the detection time multiplier.

bfd detect-multiplier *value*

The default setting is 5.

Configuring BFD sessions in control packet mode

About BFD session creation methods

BFD sessions in control packet mode can be created statically or established dynamically.

BFD sessions are distinguished by the local discriminator and remote discriminator in control packets. The main difference between a statically created session and a dynamically established session is that they obtain the local discriminator and remote discriminator in different ways.

- The local discriminator and remote discriminator of a static BFD session are specified manually in the **bfd static** command or in the commands that associate specific applications with BFD.
- The local discriminator of a dynamic BFD session is assigned by the device, and the remote discriminator is obtained during BFD session negotiation. A created session without manually specified local and remote discriminators is a dynamic BFD session.

Restrictions and guidelines

After an upper-layer protocol is configured to support BFD, the device automatically creates BFD sessions in control packet mode. You do not need to perform this task.

BFD version 0 does not support the following commands:

- **bfd session init-mode**.
- **bfd authentication-mode**.
- **bfd demand enable**.
- **bfd echo enable**.

When the same BFD session (with the same source IP address, destination IP address, interface, VPN, and destination port number) is associated with multiple upper layer applications, BFD selects the detection time settings for the BFD session as follows:

1. Minimum values of the following settings:
   - Settings configured in static BFD session view.
   - Settings configured in the BFD template specified by the upper layer application.
   - Settings configured by the upper layer application.
2. Settings configured in interface view or system view.
3. Default settings.

When a BFD session is associated with only one upper layer application, BFD selects the detection time settings for the BFD session as follows:

1. BFD selects the detection time settings for the BFD session based on whether the upper layer application supports using a BFD template and configuring detection time settings:
   - If a BFD template is specified and detection time settings are also configured for the upper layer application, BFD selects the settings configured in the specified BFD template.

- If a BFD template is specified for the upper layer application that does not support configuring detection time settings, BFD selects the settings configured in the specified BFD template.
- If detection time settings are configured for the upper layer application that does not support using a BFD template, BFD selects the configured settings.

2. Settings configured in interface view or system view.
3. Default settings.

The **bfd demand enable** command cannot take effect when any of the following conditions exist:

- Echo-packet-mode BFD sessions exist on the device.
- SBFD sessions exist on the device.
- BFD sessions for detecting aggregate links exist on the device.
- After the **bfd detect-interface source-ip** command is configured, the **bfd detect-interface first-fail-timer** and **bfd detect-interface special-processing** commands are configured.

Configuring a static BFD session

About this task

A static BFD session can be used for single-hop detection and multihop detection. By working with Track, a static BFD session can provide fast failure detection. For more information about Track association with BFD, see "Configuring Track."

Restrictions and guidelines for static BFD session configuration

If a static BFD session is created on the remote end, the static BFD session must be created on the local end.

When creating a static BFD session, you must specify a peer IPv4 or IPv6 address. The system checks only the format of the IP address but not its correctness. If the peer IPv4 or IPv6 address is incorrect, the static BFD session cannot be established.

Different static BFD sessions cannot have the same local discriminator.

Creating a static BFD session for single-hop detection

1. Enter system view.

   system-view

2. Create a static BFD session and enter static BFD session view.

   IPv4:

   bfd static *session-name* **peer-ip** *ipv4-address* **interface** *interface-type interface-number* **source-ip** *ipv4-address* [**discriminator local** *local-value* **remote** *remote-value*]

   For a static BFD session to be established, specify the IPv4 address of the peer interface where the static BFD session resides for the **peer-ip** *ipv4-address* option. Specify the IPv4 address of the local interface where the static BFD session resides for the **source-ip** *ipv4-address* option.

   IPv6:

   bfd static *session-name* **peer-ipv6** *ipv6-address* **interface** *interface-type interface-number* **source-ipv6** *ipv6-address* [**discriminator local** *local-value* **remote** *remote-value*]

   For a static BFD session to be established, specify the IPv6 address of the peer interface where the static BFD session resides for the **peer-ipv6** *ipv6-address* option. Specify the IPv6

address of the local interface where the static BFD session resides for the **source-ipv6** *ipv6-address* option.

3. (Optional.) Specify the local and remote discriminators for the static BFD session.

   discriminator { **local** *local-value* | **remote** *remote-value* }

   By default, no local discriminator or remote discriminator is specified for a static BFD session.

   Use this command only if you do not specify the local or remote discriminator when creating a static BFD session.

Create a static BFD session for multihop detection

1. Enter system view.

   system-view

2. Create a static BFD session and enter static BFD session view.

   IPv4:

   bfd static *session-name* **peer-ip** *ipv4-address* [**vpn-instance** *vpn-instance-name*] **source-ip** *ipv4-address* [**discriminator local** *local-value* **remote** *remote-value* [**track-interface** *interface-type interface-number*]]

   IPv6:

   bfd static *session-name* **peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*] **source-ipv6** *ipv6-address* [**discriminator local** *local-value* **remote** *remote-value* [**track-interface** *interface-type interface-number*]]

3. (Optional.) Specify the local and remote discriminators for the static BFD session.

   discriminator { **local** *local-value* | **remote** *remote-value* }

   By default, no local discriminator or remote discriminator is specified for a static BFD session.

   Use this command only if you do not specify the local or remote discriminator when creating a static BFD session.

Configuring BFD session parameters for single-hop detection

1. Enter system view.

   system-view

2. Specify the mode for establishing a BFD session.

   bfd session init-mode { **active** | **passive** }

   By default, **active** is specified.

3. Enter interface view or static BFD session view.

   - Enter interface view.

     interface *interface-type interface-number*

   - Enter static BFD session view.

     bfd static *session-name*

     The static BFD session must already exist.

4. (Optional.) Configure the authentication mode for single-hop control packets.

   bfd authentication-mode { **hmac-md5** | **hmac-mmd5** | **hmac-msha1** | **hmac-sha1** | **m-md5** | **m-sha1** | **md5** | **sha1** | **simple** } *key-id* { **cipher** *cipher-string* | **plain** *plain-string* }

   By default, single-hop BFD packets are not authenticated.

5. Enable the Demand BFD session mode.

bfd demand enable

By default, the BFD session is in Asynchronous mode.

This command is supported only in interface view.

6. Set the minimum interval for receiving echo packets.

   bfd min-echo-receive-interval *interval*

   The default setting is 400 milliseconds.

7. Set the minimum interval for transmitting and receiving single-hop BFD control packets.
   - Set the minimum interval for transmitting single-hop BFD control packets.

     bfd min-transmit-interval *interval*

   The default setting is 400 milliseconds.
   - Set the minimum interval for receiving single-hop BFD control packets.

     bfd min-receive-interval *interval*

   The default setting is 400 milliseconds.

8. Set the single-hop detection time multiplier.

   bfd detect-multiplier *value*

   The default setting is 5.

Configuring BFD session parameters for multihop detection

1. Enter system view.

   system-view

2. Specify the mode for establishing a BFD session.

   bfd session init-mode { **active** | **passive** }

   By default, **active** is specified.

3. (Optional.) Enter static BFD session view.

   bfd static *session-name*

   The static BFD session must already exist.

4. (Optional.) Configure the authentication mode for multihop BFD control packets.

   bfd multi-hop authentication-mode { **hmac-md5** | **hmac-mmd5** | **hmac-msha1** | **hmac-sha1** | **m-md5** | **m-sha1** | **md5** | **sha1** | **simple** } *key-id* { **cipher** *cipher-string* | **plain** *plain-string* }

   By default, no authentication is performed.

5. Configure the destination port number for multihop BFD control packets.

   bfd multi-hop destination-port *port-number*

   The default setting is 4784.

   This command is supported only in system view.

6. Set the multihop detection time multiplier.

   bfd multi-hop detect-multiplier *value*

   The default setting is 5.

7. Set the minimum interval for transmitting and receiving multihop BFD control packets.
   - Set the minimum interval for transmitting multihop BFD control packets.

     bfd multi-hop min-transmit-interval *interval*

     The default setting is 400 milliseconds.
   - Set the minimum interval for receiving multihop BFD control packets.

bfd multi-hop min-receive-interval *interval*

The default setting is 400 milliseconds.

Enabling the echo function

About this task

This function enables the local system to periodically send echo packets to the remote system. The remote system loops back the echo packets to the local system without processing them. If the local system does not receive the looped-back echo packets, it declares the BFD session down.

This function is supported only for single-hop detection.

Restrictions and guidelines

This function does not take effect on BFD sessions associated with interface states.

Procedure

1. Enter system view.
   system-view
2. Enter interface view or static BFD session view.
   - Enter interface view.
     interface *interface-type interface-number*
   - Enter static BFD session view.
     bfd static *session-name*

     The static BFD session must already exist.
3. Enable the echo function.
   bfd echo [**receive** | **send**] **enable**

   By default, the echo function is disabled.

Associating the interface state with BFD

About this task

By creating a BFD session for single-hop detection through exchange of BFD control packets, this feature implements fast link detection. When BFD detects a link fault, it sets the link layer protocol state to DOWN(BFD). This behavior helps applications relying on the link layer protocol state achieve fast convergence. The source IP address of control packets is specified manually, and the destination IP address is fixed at 224.0.0.184. As a best practice, specify the IP address of the interface as the source IP address. If the interface does not have an IP address, specify a unicast IP address other than 0.0.0.0 as the source IP address.

- Layer 2 Ethernet interfaces.
- Member ports in a Layer 2 aggregation group.
- Layer 3 Ethernet interfaces.
- Member ports in a Layer 3 aggregation group.
- Layer 2 aggregate interfaces.
- Layer 3 aggregate interfaces.

Restrictions and guidelines

The echo function does not take effect on BFD sessions associated with interface states.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Associate the interface state with BFD.

   bfd detect-interface source-ip *ip-address* [**discriminator local** *local-value* **remote** *remote-value*] [**template** *template-name*]

   If the peer device does not support obtaining BFD session discriminators through autonegotiation, you must specify the discriminators on both the local and peer devices. Without the discriminators, the BFD session cannot come up.

4. (Optional.) Configure the timer that delays reporting the first BFD session establishment failure to the data link layer.

   bfd detect-interface first-fail-timer *seconds*

   By default, the first BFD session establishment failure is not reported to the data link layer.

5. (Optional.) Enable special processing for BFD sessions.

   bfd detect-interface special-processing [**admin-down** | **authentication-change** | **session-up**] *

   By default, all types of special processing are disabled for BFD sessions.

Configuring BFD session flapping suppression

About this task

When BFD detects a link failure, it tears down the BFD session and notifies the upper-layer protocol of the failure. When the upper-layer protocol re-establishes a neighbor relationship, the BFD session comes up again. BFD session flaps occur when a link fails and recovers repeatedly, which consumes significant system resources and causes network instability.

This feature allows you to suppress BFD session flapping by using the *initial-interval*, *secondary-interval*, and *maximum-interval* arguments.

- A BFD session is suppressed within the specified interval. The suppression time does not exceed the *maximum-interval*.
- After a BFD session goes down for the second time, it cannot be re-established within the *initial-interval*.
- After a BFD session goes down for the third time, it cannot be re-established within the *secondary-interval*.
- After a BFD session goes down for the fourth time and at any later time, the following rules apply:
  - If *secondary-interval* × 2^{n-3} is smaller than or equal to the *maximum-interval*, the BFD session cannot be re-established within the *secondary-interval* × 2^{n-3}.
  - If *secondary-interval* × 2^{n-3} is greater than the *maximum-interval*, the BFD session cannot be re-established within the *maximum-interval*.

  The letter n, starting from 4, is the number of times the BFD session flaps.

Procedure

1. Enter system view.

   system-view

2. Configure BFD session flapping suppression.

bfd dampening [**maximum** *maximum-interval* **initial** *initial-interval* **secondary** *secondary-interval*]

By default, BFD sessions are not suppressed.

The values for the *initial-interval* and *secondary-interval* arguments cannot be greater than or equal to the value for the *maximum-interval* argument.

Configuring a BFD template

About this task

This task can also be used to specify BFD parameters for BFD sessions that detect interface states.

Procedure

1. Enter system view.

   system-view
2. Create a BFD template and enter BFD template view.

   bfd template *template-name*
3. (Optional.) Configure the authentication mode for BFD control packets.

   bfd authentication-mode { **hmac-md5** | **hmac-mmd5** | **hmac-msha1** | **hmac-sha1** | **m-md5** | **m-sha1** | **md5** | **sha1** | **simple** } *key-id* { **cipher** *cipher-string* | **plain** *plain-string* }

   By default, no authentication is performed.
4. Set the detection time multiplier.

   bfd detect-multiplier *value*

   The default setting is 5.
5. Set the minimum interval for transmitting and receiving BFD control packets.
   - Set the minimum interval for transmitting BFD control packets.

     bfd min-transmit-interval *interval*

     The default setting is 400 milliseconds.
   - Set the minimum interval for receiving BFD control packets.

     bfd min-receive-interval *interval*

   The default setting is 400 milliseconds.

Enabling SNMP notifications for BFD

About this task

To report critical BFD events to an NMS, enable SNMP notifications for BFD. For BFD event notifications to be sent correctly, you must also configure SNMP as described in *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Enable SNMP notifications for BFD.

   snmp-agent trap enable bfd

   By default, SNMP notifications are enabled for BFD.

Display and maintenance commands for BFD

Execute the **display** command in any view and the **reset** command in user view.

Task	Command
Display BFD session information.	**display bfd session** [**discriminator local** *local-value* | **static** *session-name* | **verbose**] **display bfd session** [[**dynamic**] [**control** | **echo**] [**ip**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [**peer-ip** *ipv4-address* [**vpn-instance** *vpn-instance-name*]] [**verbose**]] **display bfd session** [[**dynamic**] [**control** | **echo**] [**ipv6**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [**peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*]] [**verbose**]] **display bfd session** [[**static**] [**ip**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [**peer-ip** *ipv4-address* [**vpn-instance** *vpn-instance-name*]] [**verbose**] **display bfd session** [[**static**] [**ipv6**] [**state** { **down** | **admin-down** | **init** | **up** }] [**discriminator remote** *remote-value*] [**peer-ipv6** *ipv6-address* [**vpn-instance** *vpn-instance-name*]] [**verbose**]
Clear BFD session statistics.	**reset bfd session statistics**

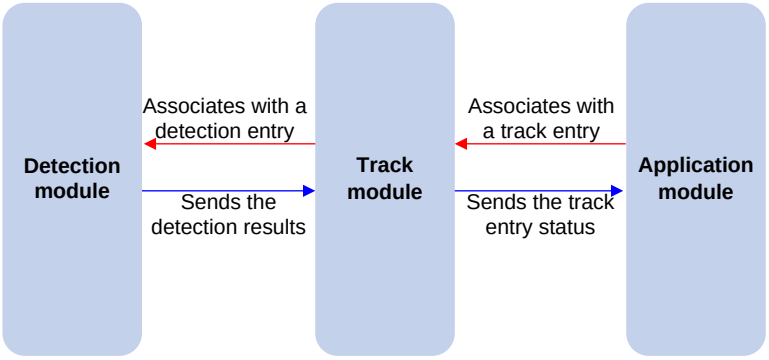
Configuring Track

About Track

The Track module works between application modules and detection modules. It shields the differences between various detection modules from application modules.



Collaboration mechanism

The Track module collaborates with detection modules and application modules.

As shown in Figure 1, collaboration is enabled when you associate the Track module with a detection module and an application module, and it operates as follows:

1. The detection module probes specific objects such as interface status, link status, network reachability, and network performance, and informs the Track module of detection results.
2. The Track module sends the detection results to the application module.
3. When notified of changes for the tracked object, the application modules can react to avoid communication interruption and network performance degradation.

Figure 1 Collaboration through the Track module

Collaboration between the Track module and a detection module

The detection module sends the detection result of the tracked object to the Track module. The Track module changes the status of the track entry as follows:

- If the tracked object operates correctly, the state of the track entry is Positive. For example, the track entry state is Positive in one of the following conditions:
  - The target interface is up.
  - The target network is reachable.
- If the tracked object does not operate correctly, the state of the track entry is Negative. For example, the track entry state is Negative in one of the following conditions:
  - The target interface is down.
  - The target network is unreachable.
- If the detection result is invalid, the state of the track entry is NotReady. For example, the track entry state is NotReady if its associated NQA operation does not exist.

Collaboration between the Track module and an application module

The track module reports the track entry status changes to the application module. The application module can then take correct actions to avoid communication interruption and network performance degradation.

Supported detection modules

The following detection modules can be associated with the Track module:

- NQA.
- BFD.
- CFD.
- Interface management.
- Route management.
- LLDP.

You can also associate a track entry with a list of objects called a tracked list. The state of a tracked list is determined by the states of all objects in the list. The following types of tracked lists are supported:

- **Boolean AND list**—The state of a Boolean AND list is determined by the states of the tracked objects using the Boolean AND operation.
- **Boolean OR list**—The state of a Boolean OR list is determined by the states of the tracked objects using the Boolean OR operation.
- **Percentage threshold list**—The state of a percentage threshold list is determined by comparing the percentage of positive objects in the list with the percentage thresholds configured for the list.
- **Weight threshold list**—The state of a weight threshold list is determined by comparing the weight of positive objects in the list with the weight thresholds configured for the list.

Supported application modules

The following application modules can be associated with the Track module:

- VRRP.
- Static routing.
- PBR
- Smart Link.
- EAA.
- ERPS.

Restrictions and guidelines: Track configuration

When configuring a track entry for an application module, you can set a notification delay to avoid immediate notification of status changes.

When the delay is not configured and the route convergence is slower than the link state change notification, communication failures occur. For example, when the master in a VRRP group detects an uplink interface failure through Track, Track immediately notifies the master to decrease its priority. A backup with a higher priority then preempts as the new master. When the failed uplink interface recovers, the Track module immediately notifies the original master to restore its priority. If the uplink route has not recovered, forwarding failure will occur.

Collaboration application example

The following is an example of collaboration between NQA, Track, and static routing.

Configure a static route with next hop 192.168.0.88 on the device. If the next hop is reachable, the static route is valid. If the next hop becomes unreachable, the static route is invalid. For this purpose, configure NQA-Track-static routing collaboration as follows:

1. Create an NQA operation to monitor the accessibility of IP address 192.168.0.88.
2. Create a track entry and associate it with the NQA operation.
   - When next hop 192.168.0.88 is reachable, NQA sends the result to the Track module. The Track module sets the track entry to Positive state.
   - When the next hop becomes unreachable, NQA sends the result to the Track module. The Track module sets the track entry to Negative state.
3. Associate the track entry with the static route.
   - When the track entry is in Positive state, the static routing module considers the static route to be valid.
   - When the track entry is in Negative state, the static routing module considers the static route to be invalid.

Track tasks at a glance

To implement the collaboration function, establish associations between the Track module and detection modules, and between the Track module and application modules.

To configure the Track module, perform the following tasks:

1. Associating the Track module with a detection module
   - Associating Track with NQA
   - Associating Track with BFD
   - Associating Track with CFD
   - Associating Track with interface management
   - Associating Track with route management
   - Associating Track with LLDP
2. Associating Track with a tracked list
   - Associating Track with a Boolean list
   - Associating Track with a percentage threshold list
   - Associating Track with a weight threshold list
3. Associating the Track module with an application module
   - Associating Track with VRRP
   - Associating Track with static routing
   - Associating Track with PBR
   - Associating Track with Smart Link
   - Associating Track with EAA
   - Associating Track with ERPS

Associating the Track module with a detection module

Associating Track with NQA

About this task

NQA supports multiple operation types to analyze network performance and service quality. For example, an NQA operation can periodically detect whether a destination is reachable, or whether a TCP connection can be established.

An NQA operation operates as follows when it is associated with a track entry:

- If the consecutive probe failures reach the specified threshold, the NQA module notifies the Track module that the tracked object has malfunctioned. The Track module then sets the track entry to Negative state.
- If the specified threshold is not reached, the NQA module notifies the Track module that the tracked object is operating correctly. The Track module then sets the track entry to Positive state.

For more information about NQA, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

If you associate a track entry with a nonexistent NQA operation or reaction entry, the state of the track entry is NotReady.

Procedure

1. Enter system view.

   system-view

2. Create a track entry, associate it with an NQA reaction entry, and enter its view.

   track *track-entry-number* **nqa entry** *admin-name operation-tag* **reaction** *item-number*

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with BFD

About this task

You can associate a track entry with an echo-mode BFD session, a control-mode BFD session, or a static BFD session. For more information about BFD, see "Configuring BFD."

The associated Track and BFD operate as follows:

- If the BFD detects that the link fails, it informs the Track module of the link failure. The Track module sets the track entry to Negative state.
- If the BFD detects that the link is operating correctly, the Track module sets the track entry to Positive state.

Restrictions and guidelines

When you associate a track entry with BFD, do not configure the virtual IP address of a VRRP group as the local or remote address of the BFD session.

For correct establishment of a control-mode BFD session, follow these guidelines when you execute the **track bfd ctrl** command:

- Execute the **track bfd ctrl** command on both the local and peer ends.
- Specify the BFD session parameters (outgoing interface, source IP address, and destination IP address of BFD control packets) correctly for the command.

Prerequisites

Before you associate Track with an echo-mode BFD session, configure the source IP address of BFD echo packets. For more information, see "Configuring BFD."

Procedure

1. Enter system view.

   system-view

2. Create a track entry, associate it with a BFD session, and enter its view. Choose the options to configure as needed:
   - Create a track entry, and associate it with an echo-mode BFD session.

     track *track-entry-number* **bfd echo interface** *interface-type interface-number* **remote** { **ip** *remote-ip-address* | **ipv6** *remote-ipv6-address* } **local** { **ip** *local-ip-address* | **ipv6** *local-ipv6-address* }
   - Create a track entry, and associate it with a control-mode BFD session.

     track *track-entry-number* **bfd ctrl** [**interface** *interface-type interface-number* | **vpn-instance** *vpn-instance-name*] **remote** { **ip** *remote-ip-address* | **ipv6** *remote-ipv6-address* } **local** { **ip** *local-ip-address* | **ipv6** *local-ipv6-address* }
   - Create a track entry, and associate it with a static BFD session.

     track *track-entry-number* **bfd static** *bfd-session-name*

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with CFD

About this task

The associated Track and CFD operate as follows:

- If the CFD detects that the link fails, it informs the Track module of the link failure. The Track module then sets the track entry to Negative state.
- If the CFD detects that the link is operating correctly, the Track module sets the track entry to Positive state.

For more information about CFD, see "Configuring CFD."

Prerequisites

Before you associate Track with CFD, enable CFD and create a MEP. For more information, see "Configuring CFD."

Procedure

1. Enter system view.

   system-view

2. Create a track entry, associate it with CFD, and enter its view.

track *track-entry-number* **cfd cc service-instance** *instance-id* **mep** *mep-id*

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with interface management

About this task

The interface management module monitors the link status or network-layer protocol status of interfaces. The associated Track and interface management operate as follows:

- When the link or network-layer protocol status of the interface changes to up, the interface management module informs the Track module of the change. The Track module sets the track entry to Positive state.
- When the link or network-layer protocol status of the interface changes to down, the interface management module informs the Track module of the change. The Track module sets the track entry to Negative state.

Procedure

1. Enter system view.

   system-view

2. Create a track entry, associate it with interface management, and enter its view.
   - Create a track entry to monitor the link status of an interface.

     track *track-entry-number* **interface** *interface-type interface-number*
   - Create a track entry to monitor the physical status of an interface.

     track *track-entry-number* **interface** *interface-type interface-number* **physical**
   - Create a track entry to monitor the network layer protocol status of an interface.

     track *track-entry-number* **interface** *interface-type interface-number* **protocol** { **ipv4** | **ipv6** }

3. Set the delay for notifying the application module of track entry state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with route management

About this task

The route management module monitors route entry changes in the routing table. The associated Track and route management operate as follows:

- When a monitored route entry is found in the routing table, the route management module informs the Track module. The Track module sets the track entry to Positive state.
- When a monitored route entry is removed from the routing table, the route management module informs the Track module of the change. The Track module sets the track entry to Negative state.

Procedure

1. Enter system view.
   system-view
2. Create a track entry, associate it with a route entry, and enter its view.
   track *track-entry-number* **ip route** [**vpn-instance** *vpn-instance-name*] **ip-address** { *mask-length* | *mask* } **reachability**
3. Set the delay for notifying the application module of track entry state changes.
   delay { **negative** *negative-time* | **positive** *positive-time* } *
   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with LLDP

About this task

The LLDP module detects neighbor availability and informs the detection result to the Track module. The associated Track and LLDP operate as follows:

- When the neighbor is available, the Track module sets the track entry to Positive state.
- When the neighbor is unavailable, the Track module sets the track entry to Negative state.

For more information about LLDP, see *Layer 2—LAN Switching Configuration Guide*.

Procedure

1. Enter system view.
   system-view
2. Create a track entry, associate it with an LLDP interface, and enter its view.
   track *track-entry-number* **lldp neighbor interface** *interface-type interface-number*
3. Set the delay for notifying the application module of track entry state changes.
   delay { **negative** *negative-time* | **positive** *positive-time* } *
   By default, the Track module notifies the application module immediately when the track entry state changes.

Associating Track with a tracked list

Associating Track with a Boolean list

About this task

A Boolean list is a list of tracked objects based on a Boolean logic. It can be further divided into the following types:

- **Boolean AND list**—A Boolean AND list is set to the Positive state only when all objects are in Positive state. If one or more objects are in Negative state, the tracked list is set to the Negative state.
- **Boolean OR list**—A Boolean OR list is set to the Positive state if any object is in Positive state. If all objects are in Negative state, the tracked list is set to the Negative state.

Procedure

1. Enter system view.
   system-view

2. Create a Boolean tracked list and enter its view.

   track *track-entry-number* **list boolean** { **and** | **or** }

3. (Optional.) Set the delay for notifying the application module of tracked list state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the tracked list state changes.

4. Add the track entry as an object to the tracked list.

   object *track-entry-number* [**not**]

   By default, a tracked list does not contain any objects.

   Repeat this step to add all interested objects to the tracked list.

Associating Track with a percentage threshold list

About this task

The state of a percentage threshold list is determined by comparing the percentage of positive objects in the list with the percentage thresholds configured for the list.

- If the percentage of positive objects is equal to or above the positive state threshold, the list is set to the Positive state.
- If the percentage of positive objects is equal to or below the negative state threshold, the list is set to the Negative state.
- The state of a percentage threshold list remains unchanged if the percentage of positive objects is below the positive state threshold and above the negative state threshold.

Procedure

1. Enter system view.

   system-view

2. Create a percentage threshold list and enter its view.

   track *track-entry-number* **list threshold percentage**

3. (Optional.) Set the delay for notifying the application module of tracked list state changes.

   delay { **negative** *negative-time* | **positive** *positive-time* } *

   By default, the Track module notifies the application module immediately when the tracked list state changes.

4. Add the track entry as an object to the tracked list.

   object *track-entry-number*

   By default, a tracked list does not contain any objects.

   Repeat this step to add all interested objects to the tracked list.

5. Configure the threshold values used to determine the state of the percentage threshold list.

   threshold percentage { **negative** *negative-threshold* | **positive** *positive-threshold* } *

   By default, the negative state threshold is 0% and the positive state threshold is 1%.

Associating Track with a weight threshold list

About this task

The state of a weight threshold list is determined by comparing the weight of positive objects in the list with the weight thresholds configured for the list.

- If the total weight of positive objects is equal to or above the positive state threshold, the list is set to the Positive state.
- If the total weight of positive objects is equal to or below the negative state threshold, the list is set to the Negative state.
- The state of a weight threshold list remains unchanged if the total weight of positive objects is below the positive state threshold and above the negative state threshold.

Procedure

1. Enter system view.
   system-view
2. Create a weight threshold list and enter its view.
   track *track-entry-number* **list threshold weight**
3. (Optional.) Set the delay for notifying the application module of tracked list state changes.
   delay { **negative** *negative-time* | **positive** *positive-time* } *
   By default, the Track module notifies the application module immediately when the tracked list state changes.
4. Add the track entry as an object to the tracked list.
   object *track-entry-number* [**weight** *weight*]
   By default, a tracked list does not contain any objects.
   Repeat this step to add all interested objects to the tracked list.
5. Configure the threshold values used to determine the state of the weight threshold list.
   threshold weight { **negative** *negative-threshold* | **positive** *positive-threshold* } *
   By default, the negative state threshold is 0 and the positive state threshold is 1.

Associating the Track module with an application module

Before you associate the Track module with an application module, make sure the associated track entry has been created.

Prerequisites for associating the Track module with an application module

Create a track entry first before you associate it with an application module.

An application module might obtain incorrect track entry status information if the associated track entry does not exist.

Associating Track with VRRP

About this task

When VRRP is operating in standard mode or load balancing mode, associate the Track module with the VRRP group to implement the following actions:

- Change the priority of a router according to the status of the uplink. If a fault occurs on the uplink of the router, the VRRP group is not aware of the uplink failure. If the router is the master, hosts in the LAN cannot access the external network. To resolve this problem, configure a detection

module-Track-VRRP collaboration. The detection module monitors the status of the uplink of the router and notifies the Track module of the detection result.

When the uplink fails, the detection module notifies the Track module to change the status of the monitored track entry to Negative. The priority of the master decreases by a user-specified value. A router with a higher priority in the VRRP group becomes the master.

- Monitor the master on a backup. If a fault occurs on the master, the backup operating in switchover mode will switch to the master immediately to maintain normal communication.

When VRRP is operating in load balancing mode, associate the Track module with the VRRP VF to implement the following functions:

- Change the priority of the AVF according to its uplink state. When the uplink of the AVF fails, the track entry changes to Negative state. The weight of the AVF decreases by a user-specified value. The VF with a higher priority becomes the new AVF to forward packets.
- Monitor the AVF status from the LVF. When the AVF fails, the LVF that is operating in switchover mode becomes the new AVF to ensure continuous forwarding.

For more information about configuring VRRP, see "Configuring VRRP."

Restrictions and guidelines for Track association with VRRP

- VRRP tracking does not take effect on an IP address owner. The configuration takes effect when the router does not act as the IP address owner.

  An IP address owner is the router with its interface IP address used as the virtual IP address of the VRRP group.
- When the status of the track entry changes from Negative to Positive or NotReady, the associated router or VF restores its priority automatically.

Associating Track with a VRRP group

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Associate a track entry with a VRRP group.

   vrrp [**ipv6**] **vrid** *virtual-router-id* **track** *track-entry-number* { **forwarder-switchover member-ip** *ip-address* | **priority reduced** [*priority-reduced*] **switchover** | **weight reduced** [*weight-reduced*] }

   By default, no track entry is associated with a VRRP group.

   This command is supported when VRRP is operating in both standard mode and load balancing mode.

Associating Track with a VRRP VF

1. Enter system view.

   system-view
2. Enter interface view.

   interface *interface-type interface-number*
3. Associate Track with a VRRP VF.

   vrrp [**ipv6**] **vrid** *virtual-router-id* **track** *track-entry-number* { **forwarder-switchover member-ip** *ip-address* | **priority reduced** [*priority-reduced*] **switchover** | **weight reduced** [*weight-reduced*] }

   By default, no track entry is associated with a VRRP VF.

   This command is configurable when VRRP is operating in standard mode or load balancing mode. However, the configuration takes effect only when VRRP is operating in load balancing mode.

Associating Track with static routing

About this task

A static route is a manually configured route to route packets. For more information about static route configuration, see *Layer 3—IP Routing Configuration Guide*.

Static routes cannot adapt to network topology changes. Link failures or network topological changes can make the routes unreachable and cause communication interruption.

To resolve this problem, configure another route to back up the static route. When the static route is reachable, packets are forwarded through the static route. When the static route is unreachable, packets are forwarded through the backup route.

To check the accessibility of a static route in real time, associate the Track module with the static route.

If you specify the next hop but not the output interface when configuring a static route, you can configure the static routing-Track-detection module collaboration. This collaboration enables you to verify the accessibility of the static route based on the track entry state.

- If the track entry is in Positive state, the following conditions exist:
  - The next hop of the static route is reachable.
  - The configured static route is valid.
- If the track entry is in Negative state, the following conditions exist:
  - The next hop of the static route is not reachable.
  - The configured static route is invalid.
- If the track entry is in NotReady state, the following conditions exist:
  - The accessibility of the next hop of the static route is unknown.
  - The static route is valid.

Restrictions and guidelines

In static routing-Track-NQA collaboration, you must configure the same VPN instance name for the NQA operation and the next hop of the static route. Otherwise, the accessibility detection cannot operate correctly.

If a static route needs route recursion, the associated track entry must monitor the next hop of the recursive route. The next hop of the static route cannot be monitored. Otherwise, a valid route might be considered invalid.

Associating Track with an IPv4 static route

1. Enter system view.

   system-view

2. Associate an IPv4 static route with a track entry to check the accessibility of the next hop.

   Public network:

   ip route-static { *dest-address* { *mask-length* | *mask* } | **group** *group-name* } { *interface-type interface-number* [*next-hop-address*] **track** *track-entry-number* | *next-hop-address* [**recursive-lookup host-route**] **track** *track-entry-number* | **vpn-instance** *d-vpn-instance-name next-hop-address* [**recursive-lookup host-route**] **track** *track-entry-number* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   VPN:

   ip route-static vpn-instance *s-vpn-instance-name* { *dest-address* { *mask-length* | *mask* } | **group** *group-name* } { *interface-type interface-number* [*next-hop-address*] **track** *track-entry-number* |

next-hop-address [**recursive-lookup host-route**] [**public**] **track** *track-entry-number* | **vpn-instance** *d-vpn-instance-name* *next-hop-address* [**recursive-lookup host-route**] **track** *track-entry-number* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

By default, an IPv4 static route is not associated with any track entries.

Associating Track with an IPv6 static route

1. Enter system view.

   system-view

2. Associate an IPv6 static route with a track entry to check the accessibility of the next hop.

   Public network:

   ipv6 route-static *ipv6-address prefix-length* { *interface-type interface-number* [*next-hop-address*] **track** *track-entry-number* | [**vpn-instance** *d-vpn-instance-name*] *next-hop-address* [**recursive-lookup host-route**] **track** *track-entry-number* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   VPN:

   ipv6 route-static vpn-instance *s-vpn-instance-name ipv6-address prefix-length* { *interface-type interface-number* [*next-hop-address*] **track** *track-entry-number* | *next-hop-address* [**public**] **track** *track-entry-number* | **vpn-instance** *d-vpn-instance-name* *next-hop-address* [**recursive-lookup host-route**] **track** *track-entry-number* } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

   By default, an IPv6 static route is not associated with any track entries.

Associating Track with PBR

About this task

PBR uses user-defined policies to route packets. You can specify parameters in a PBR policy to guide the forwarding of the packets that match specific criteria. For more information about PBR, see *Layer 3—IP Routing Configuration Guide*.

PBR cannot detect the availability of any action taken on packets. When an action is not available, packets processed by the action might be discarded. For example, if the output interface specified for PBR fails, PBR cannot detect the failure, and continues to forward matching packets out of the interface.

To enable PBR to detect topology changes and improve the flexibility of the PBR application, configure Track-PBR-detection module collaboration.

After you associate a track entry with an apply clause, the detection module associated with the track entry sends Track the detection result of the availability of the tracked object.

- The Positive state of the track entry indicates that the object is available, and the apply clause is valid.
- The Negative state of the track entry indicates that the object is not available, and the apply clause is invalid.
- The NotReady state of the track entry indicates that the apply clause is valid.

The following objects can be associated with a track entry:

- Output interface.
- Next hop.

Prerequisites for Track association with PBR

Before you associate Track with PBR, create a policy node, and set the match criteria.

Associating Track with PBR

1. Enter system view.

   system-view

2. Create a policy node and enter its view.

   policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

3. Set match criteria. Choose the options to configure as needed:

   - Set an ACL match criterion.

     if-match acl { *acl-number* | **name** *acl-name* }

     By default, no ACL match criterion is set.

     The ACL match criterion cannot match Layer 2 information.

     When using the ACL to match packets, PBR ignores the action (**permit** or **deny**) and time range settings in the ACL.

4. Set actions and associate the policy node with a track entry. Choose the options to configure as needed:

   - Set the output interface.

     apply output-interface null 0 [**track** *track-entry-number*]

     By default, no output interface is set.

   - Set the next hop.

     apply next-hop [**vpn-instance** *vpn-instance-name*] { *ip-address* [**direct**] [**track** *track-entry-number*] }&<1-6>

     By default, no next hop is set.

Associating Track with IPv6 PBR

1. Enter system view.

   system-view

2. Create an IPv6 policy node and enter its view.

   ipv6 policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

3. Set match criteria. Choose the options to configure as needed:

   - Set an ACL match criterion.

     if-match acl { *ipv6-acl-number* | **name** *ipv6-acl-name* }

     By default, no ACL match criterion is set.

     The ACL match criterion cannot match Layer 2 information.

     When using the ACL to match packets, IPv6 PBR ignores the action (**permit** or **deny**) and time range settings in the ACL.

4. Set actions and associate the policy node with a track entry. Choose the options to configure as needed:

   - Set the output interface.

     apply output-interface null 0 [**track** *track-entry-number*]

     By default, no output interface is set.

   - Set the next hop.

     apply next-hop [**vpn-instance** *vpn-instance-name*] { *ipv6-address* [**direct**] [**track** *track-entry-number*] }&<1-6>

     By default, no next hop is set.

Associating Track with Smart Link

About this task

Smart Link cannot detect unidirectional links, misconnected fibers, or packet loss on intermediate devices or network paths of the uplink. It also cannot detect when faults are cleared. To check the link status, Smart Link ports must use link detection protocols. When a fault is detected or cleared, the link detection protocols inform Smart Link to switch over the links.

You can configure the collaboration between Smart Link and Track on a smart link group member port. Smart Link collaborates with the CC feature of CFD through the track entry to detect the link status on the port.

- When the track entry is in Positive state, the link is in normal state. Smart Link does not perform link switchover for the smart link group.
- When the track entry is in Negative state, the link has failed. Smart Link determines whether to perform link switchover according to the link preemption mode and port role configured in the smart link group.
- When the track entry is in NotReady state, the port state does not change.

For more information about Smart Link, see "Configuring Smart Link."

Restrictions and guidelines

The track entry to be used for collaboration with Smart Link must have been associated with the CC feature of CFD.

Procedure

1. Enter system view.

   system-view
2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.

   interface *interface-type interface-number*
3. Configure collaboration between Smart Link and Track on the port.

   port smart-link group *group-id* **track** *track-entry-number*

   By default, the collaboration between Smart Link and Track is not configured.

Associating Track with EAA

About this task

You can configure EAA track event monitor policies to monitor the positive-to-negative or negative-to-positive state changes of track entries.

- If you specify only one track entry for a policy, EAA triggers the policy when it detects the specified state change on the track entry.
- If you specify multiple track entries for a policy, EAA triggers the policy when it detects the specified state change on the last monitored track entry. For example, if you configure a policy to monitor the positive-to-negative state change of multiple track entries, EAA triggers the policy when the last positive track entry monitored by the policy is changed to the Negative state.

You can set a suppression time for a track event monitor policy. The timer starts when the policy is triggered. The system does not process messages that report the monitored track event until the timer times out.

For more information about EAA, see *Network Management and Monitoring Configuration Guide*.

Procedure

1. Enter system view.

system-view

2. Create a CLI-defined monitor policy and enter its view, or enter the view of an existing CLI-defined monitor policy.

   rtm cli-policy *policy-name*

3. Configure a track event.

   event track *track-entry-number-list* **state** { **negative** | **positive** } [**suppress-time** *suppress-time*]

   By default, a monitor policy does not monitor any track event.

Associating Track with ERPS

About this task

To detect and clear link faults typically for a fiber link, use ERPS with CFD and Track. You can associate ERPS ring member ports with the continuity check function of CFD through track entries. CFD reports link events only when the monitored VLAN is the control VLAN of the ERPS instance for the port.

Track changes the track entry state based on the monitoring result of CFD, and notifies the track entry state change to the associated EPRS ring.

- When the track entry is in Positive state, the link of the monitored ERPS ring member port is in normal state. The ERPS ring does not switch traffic to other links.
- When the track entry is in Negative state, the link of the monitored ERPS ring member port is faulty. The ERPS ring switches traffic to other links.
- When the track entry is in NotReady state, the state of the ERPS ring member port does not change.

For more information about ERPS, see "Configuring ERPS."

Restrictions and guidelines

Before you associate a port with a track entry, make sure the port has joined an ERPS instance.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 2 Ethernet interface view or Layer 2 aggregate interface view.

   interface *interface-type interface-number*

3. Associate an ERPS ring member port with a track entry.

   port erps ring *ring-id* **instance** *instance-id* **track** *track-entry-index*

   By default, an ERPS ring member port is not associated with any track entries.

Display and maintenance commands for Track

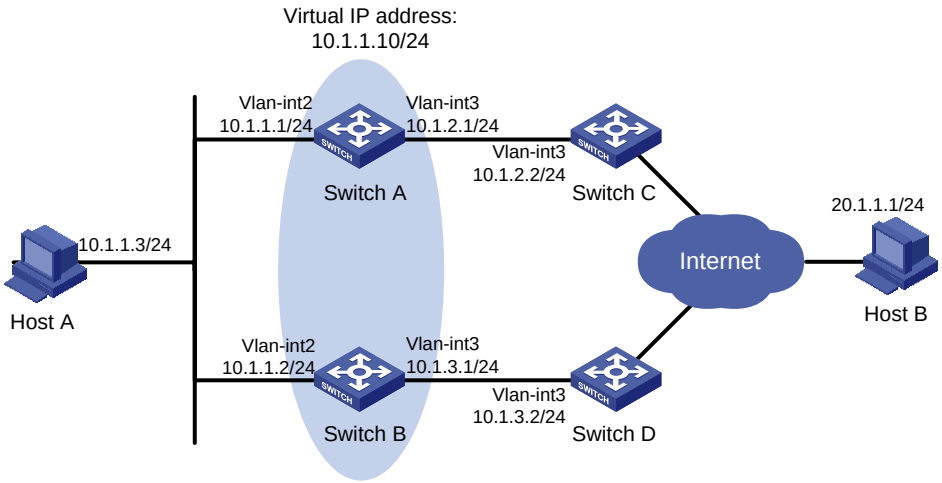
Execute **display** commands in any view.

Task	Command
Display information about track entries.	**display track** { *track-entry-number* | **all** [**negative** | **positive**] } [**brief**]

Track configuration examples

Example: Configuring VRRP-Track-NQA collaboration

Network configuration



As shown in Figure 2:

- Host A requires access to Host B. The default gateway of Host A is 10.1.1.10/24.
- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 10.1.1.10.

Configure VRRP-Track-NQA collaboration to monitor the uplink on the master and meet the following requirements:

- When Switch A operates correctly, Switch A forwards packets from Host A to Host B.
- When NQA detects a fault on the uplink of Switch A, Switch B forwards packets from Host A to Host B.

Figure 2 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 2. (Details not shown.)
2. Configure an NQA operation on Switch A:

   # Create an NQA operation with administrator name **admin** and operation tag **test**.

   ```
   <SwitchA> system-view
   [SwitchA] nqa entry admin test
   ```

   # Specify the **ICMP echo** operation type.

   ```
   [SwitchA-nqa-admin-test] type icmp-echo
   ```

   # Specify 10.1.2.2 as the destination address of ICMP echo requests.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] destination ip 10.1.2.2
   ```

   # Configure the ICMP echo operation to repeat every 100 milliseconds.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] frequency 100
   ```

   # Configure reaction entry 1, specifying that five consecutive probe failures trigger the Track module.

```
[SwitchA-nqa-admin-test-icmp-echo] reaction 1 checked-element probe-fail
threshold-type consecutive 5 action-type trigger-only
[SwitchA-nqa-admin-test-icmp-echo] quit
```

Start the NQA operation.

```
[SwitchA] nqa schedule admin test start-time now lifetime forever
```

3. On Switch A, configure track entry 1, and associate it with reaction entry 1 of the NQA operation.

```
[SwitchA] track 1 nqa entry admin test reaction 1
[SwitchA-track-1] quit
```

4. Configure VRRP on Switch A:

Specify VRRPv2 to run on VLAN-interface 2.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] vrrp version 2
```

Create VRRP group 1, and configure virtual IP address 10.1.1.10 for the group.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
```

Set the priority of Switch A to 110 in VRRP group 1.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
```

Set the authentication mode of VRRP group 1 to **simple**, and the authentication key to **hello**.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 authentication-mode simple hello
```

Configure the master to send VRRP packets every 500 centiseconds.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 timer advertise 500
```

Configure Switch A to operate in preemptive mode and set the preemption delay to 5000 centiseconds.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 preempt-mode timer delay 5000
```

Associate VRRP group 1 with track entry 1 and decrease the router priority by 30 when the state of track entry 1 changes to Negative.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 track 1 priority reduced 30
```

5. Configure VRRP on Switch B:

Specify VRRPv2 to run on VLAN-interface 2.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp version 2
```

Create VRRP group 1, and configure virtual IP address 10.1.1.10 for the group.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
```

Set the authentication mode of VRRP group 1 to **simple**, and the authentication key to **hello**.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 authentication-mode simple hello
```

Configure the master to send VRRP packets every 500 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 timer advertise 500
```

Configure Switch B to operate in preemptive mode and set the preemption delay to 5000 centiseconds.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 preempt-mode timer delay 5000
```

Verifying the configuration

Ping Host B from Host A to verify that Host B is reachable. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp verbose
IPv4 Virtual Router Information:

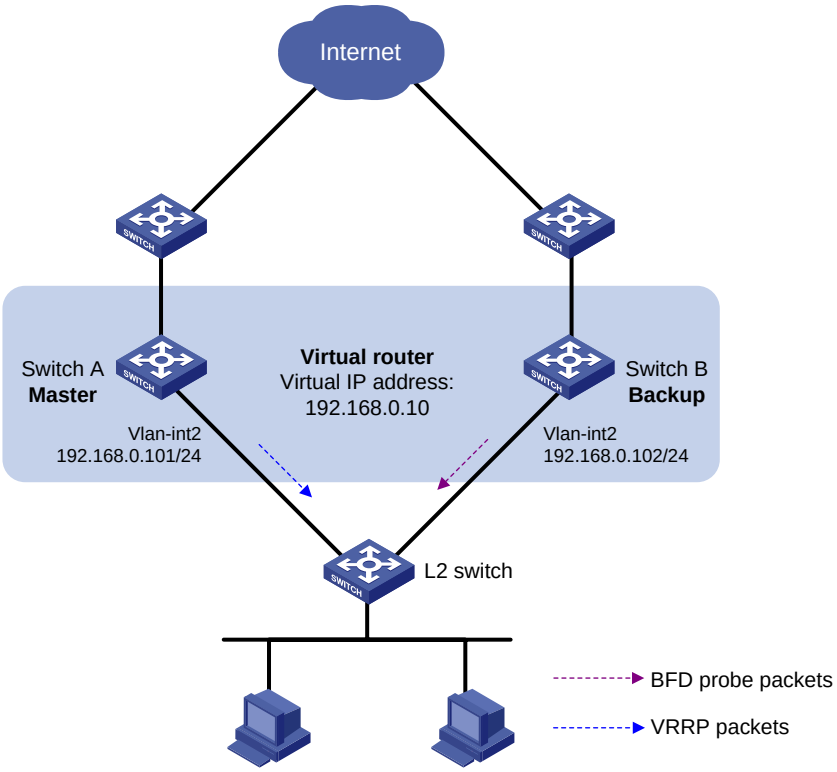
     Master IP        : 10.1.1.2
```

The output shows that Switch A becomes the backup, and Switch B becomes the master. Switch B forwards packets from Host A to Host B.

Example: Configuring an echo-mode BFD session for a VRRP backup to monitor the master

Network configuration



As shown in Figure 3:

- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 192.168.0.10.
- The default gateway of the hosts in the LAN is 192.168.0.10.

Configure VRRP-Track-BFD (echo mode) collaboration to monitor the master on the backup and meet the following requirements:

- When Switch A operates correctly, the hosts in the LAN access the Internet through Switch A.
- When Switch A fails, the backup (Switch B) can detect the state change of the master through the echo-mode BFD session and become the new master. The hosts in the LAN access the Internet through Switch B.

Figure 3 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 3. (Details not shown.)
2. Configure Switch A:

   # Create VRRP group 1, and configure virtual IP address 192.168.0.10 for the group.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 2

   VRRP Track Information:
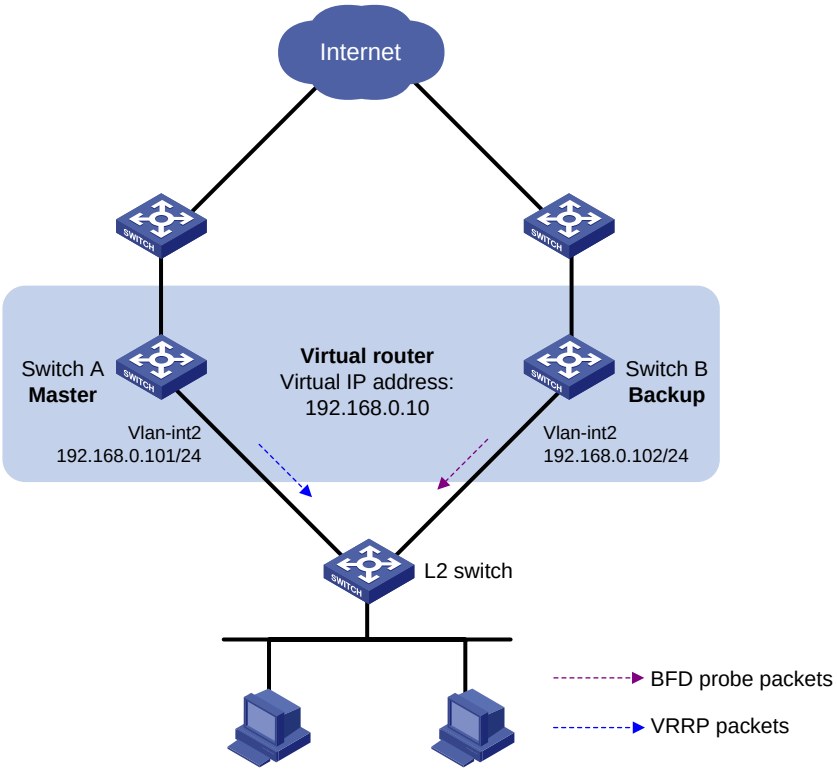
     Track Object    : 1              State : Negative          Switchover
```

The output shows that when the echo-mode BFD session detects that Switch A fails, the Track module notifies VRRP to change the status of Switch B to master. The backup can quickly preempt as the master without waiting for a period three times the advertisement interval plus the Skew_Time.

Example: Configuring a control-mode BFD session for a VRRP backup to monitor the master

Network configuration

As shown in Figure 4:



- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 192.168.0.10.
- The default gateway of the hosts in the LAN is 192.168.0.10.

Configure VRRP-Track-BFD (control mode) collaboration to monitor the master on the backup and meet the following requirements:

- When Switch A operates correctly, the hosts in the LAN access the Internet through Switch A.

- When Switch A fails, the backup (Switch B) can detect the state change of the master through the control-mode BFD session and become the new master. The hosts in the LAN access the Internet through Switch B.

Figure 4 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 4. (Details not shown.)
2. Configure Switch A:

   # Create VRRP group 1, and configure virtual IP address 192.168.0.10 for the group.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   ```

   # Set the priority of Switch A to 110 in VRRP group 1.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   [SwitchA-Vlan-interface2] return
   ```

   # Create track entry 1, and associate it with the control-mode BFD session to verify the reachability of Switch B.

   ```
   [SwitchA] track 1 bfd ctrl interface vlan-interface 2 remote ip 192.168.0.102 local
   ip 192.168.0.101
   [SwitchA-track-1] quit
   ```
3. Configure Switch B:

   # Create VRRP group 1, and configure virtual IP address 192.168.0.10 for the group.

   ```
   <SwitchB> system-view
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   ```

Configure VRRP group 1 to monitor track entry 1 so Switch B can take over as the master once the track entry changes to the Negative state.

```
[SwitchB-Vlan-interface2] vrrp vrid 1 track 1 switchover
[SwitchB-Vlan-interface2] return
```

Create track entry 1, and associate it with the control-mode BFD session to verify the reachability of Switch A.

```
[SwitchB] track 1 bfd ctrl interface vlan-interface 2 remote ip 192.168.0.101 local
ip 192.168.0.102
[SwitchB-track-1] quit
```

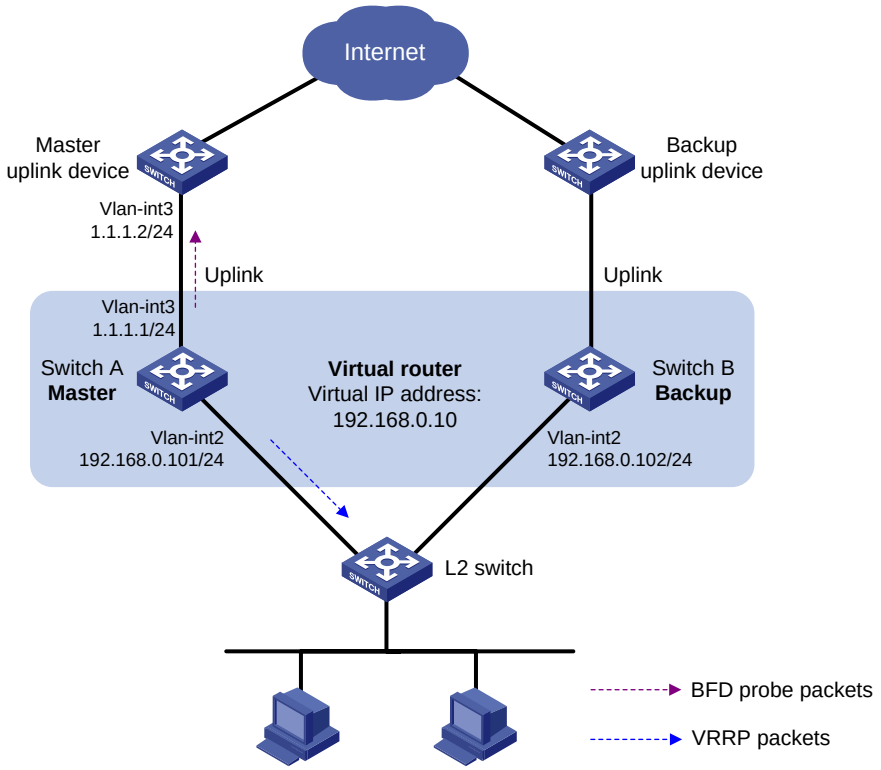
The output shows that when the control-mode BFD session detects that Switch A fails, the Track module notifies VRRP to change the status of Switch B to master. The backup can quickly preempt as the master without waiting for a period three times the advertisement interval plus the Skew_Time.

Example: Configuring an echo-mode BFD session for the VRRP master to monitor the uplink

Network configuration



As shown in Figure 5:

- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 192.168.0.10.
- The default gateway of the hosts in the LAN is 192.168.0.10.

Configure VRRP-Track-BFD (echo mode) collaboration to monitor the uplink on the master and meet the following requirements:

- When Switch A operates correctly, the hosts in the LAN access the Internet through Switch A.
- When Switch A detects that the uplink is down through the echo-mode BFD session, Switch B can preempt as the master. The hosts in the LAN can access the Internet through Switch B.

Figure 5 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 5. (Details not shown.)
2. Configure Switch A:

   # Specify 10.10.10.10 as the source address of BFD echo packets.

   ```
   <SwitchA> system-view
   [SwitchA] bfd echo-source-ip 10.10.10.10
   ```

   # Create track entry 1 for the echo-mode BFD session to verify the reachability of the uplink device (1.1.1.2).

   ```
   [SwitchA] track 1 bfd echo interface vlan-interface 3 remote ip 1.1.1.2 local ip
   1.1.1.1
   [SwitchA-track-1] quit
   ```

   # Create VRRP group 1, and specify 192.168.0.10 as the virtual IP address of the group.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   ```

   # Set the priority of Switch A to 110 in VRRP group 1.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   ```

Associate VRRP group 1 with track entry 1 and decrease the router priority by 20 when the state of track entry 1 changes to Negative.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 track 1 priority reduced 20
[SwitchA-Vlan-interface2] return
```

3. On Switch B, create VRRP group 1, and specify 192.168.0.10 as the virtual IP address of the group.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10

```

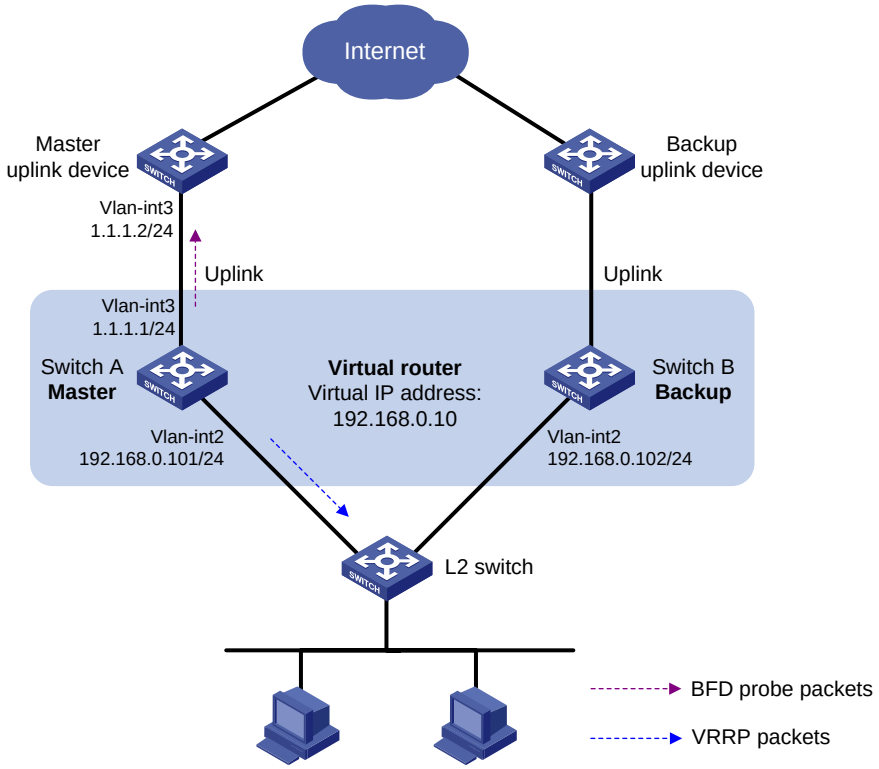
The output shows that when Switch A detects that the uplink fails through the echo-mode BFD session, it decreases its priority by 20. Switch B then preempts as the master.

Example: Configuring a control-mode BFD session for the VRRP master to monitor the uplink

Network configuration



As shown in Figure 6:

- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 192.168.0.10.
- The default gateway of the hosts in the LAN is 192.168.0.10.

Configure VRRP-Track-BFD (control mode) collaboration to monitor the uplink on the master and meet the following requirements:

- When Switch A operates correctly, the hosts in the LAN access the Internet through Switch A.
- When Switch A detects that the uplink is down through the control-mode BFD session, Switch B can preempt as the master. The hosts in the LAN can access the Internet through Switch B.

Figure 6 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 6. (Details not shown.)
2. Configure Switch A:

   # Create VRRP group 1, and specify 192.168.0.10 as the virtual IP address of the group.

   ```
   <SwitchA> system-view
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   ```

   # Set the priority of Switch A to 110 in VRRP group 1.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   ```

   # Associate VRRP group 1 with track entry 1 and decrease the router priority by 20 when the state of track entry 1 changes to Negative.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 track 1 priority reduced 20
   [SwitchA-Vlan-interface2] quit
   ```

   # Create track entry 1 for the control-mode BFD session to monitor the reachability of the uplink device (1.1.1.2).

   ```
   [SwitchA] track 1 bfd ctrl interface vlan-interface 3 remote ip 1.1.1.2 local ip
   1.1.1.1
   [SwitchA-track-1] quit
   ```

3. On the uplink device of Switch A, create track entry 1 and associate it with the control-mode BFD session to verify the reachability of the Switch A.

   ```
   <Master> system-view
   [Master] track 1 bfd ctrl interface vlan-interface 3 remote ip 1.1.1.1 local ip 1.1.1.2
   ```

4. On Switch B, create VRRP group 1, and specify 192.168.0.10 as the virtual IP address of the group.

   ```
   <SwitchB> system-view
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 192.168.0.10
   [SwitchB-Vlan-interface2] return
   ```

     Master IP        : 192.168.0.102
```

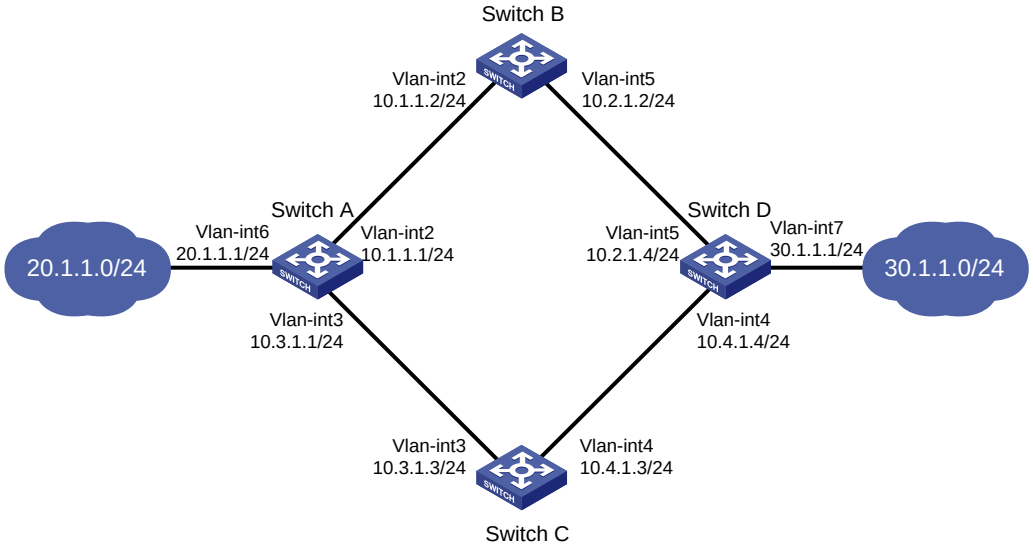
The output shows that when Switch A detects that the uplink fails through the control-mode BFD session, it decreases its priority by 20. Switch B then preempts as the master.

Example: Configuring static routing-Track-NQA collaboration

Network configuration



As shown in Figure 7:

- Switch A is the default gateway of the hosts in network 20.1.1.0/24.
- Switch D is the default gateway of the hosts in network 30.1.1.0/24.
- Hosts in the two networks communicate with each other through static routes.

To ensure network availability, configure route backup and static routing-Track-NQA collaboration on Switch A and Switch D as follows:

- On Switch A, assign a higher priority to the static route to 30.1.1.0/24 with next hop Switch B. This route is the master route. The static route to 30.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the backup route takes effect. Switch A forwards packets to 30.1.1.0/24 through Switch C.
- On Switch D, assign a higher priority to the static route to 20.1.1.0/24 with next hop Switch B. This route is the master route. The static route to 20.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the backup route takes effect. Switch D forwards packets to 20.1.1.0/24 through Switch C.

Figure 7 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 7. (Details not shown.)
2. Configure Switch A:

   # Configure a static route to 30.1.1.0/24 with next hop 10.1.1.2 and the default priority (60). Associate this static route with track entry 1.

   ```
   <SwitchA> system-view
   [SwitchA] ip route-static 30.1.1.0 24 10.1.1.2 track 1
   ```

   # Configure a static route to 30.1.1.0/24 with next hop 10.3.1.3 and priority 80.

   ```
   [SwitchA] ip route-static 30.1.1.0 24 10.3.1.3 preference 80
   ```

   # Configure a static route to 10.2.1.4 with next hop 10.1.1.2.

   ```
   [SwitchA] ip route-static 10.2.1.4 24 10.1.1.2
   ```

   # Create an NQA operation with administrator name **admin** and operation tag **test**.

   ```
   [SwitchA] nqa entry admin test
   ```

   # Specify the **ICMP echo** operation type.

   ```
   [SwitchA-nqa-admin-test] type icmp-echo
   ```

   # Specify 10.2.1.4 as the destination address of the operation.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] destination ip 10.2.1.4
   ```

   # Specify 10.1.1.2 as the next hop of the operation.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] next-hop ip 10.1.1.2
   ```

   # Configure the ICMP echo operation to repeat every 100 milliseconds.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] frequency 100
   ```

   # Configure reaction entry 1, specifying that five consecutive probe failures trigger the Track module.

   ```
   [SwitchA-nqa-admin-test-icmp-echo] reaction 1 checked-element probe-fail
   threshold-type consecutive 5 action-type trigger-only
   [SwitchA-nqa-admin-test-icmp-echo] quit
   ```

   # Start the NQA operation.

   ```
   [SwitchA] nqa schedule admin test start-time now lifetime forever
   ```

   # Configure track entry 1, and associate it with reaction entry 1 of the NQA operation.

```
[SwitchA] track 1 nqa entry admin test reaction 1
[SwitchA-track-1] quit
```

3. Configure Switch B:

Configure a static route to 30.1.1.0/24 with next hop 10.2.1.4.

```
<SwitchB> system-view
[SwitchB] ip route-static 30.1.1.0 24 10.2.1.4
```

Configure a static route to 20.1.1.0/24 with next hop 10.1.1.1.

```
[SwitchB] ip route-static 20.1.1.0 24 10.1.1.1
```

4. Configure Switch C:

Configure a static route to 30.1.1.0/24 with next hop 10.4.1.4.

```
<SwitchC> system-view
[SwitchC] ip route-static 30.1.1.0 24 10.4.1.4
```

Configure a static route to 20.1.1.0/24 with next hop 10.3.1.1.

```
[SwitchC] ip route-static 20.1.1.0 24 10.3.1.1
```

5. Configure Switch D:

Configure a static route to 20.1.1.0/24 with next hop 10.2.1.2 and the default priority (60). Associate this static route with track entry 1.

```
<SwitchD> system-view
[SwitchD] ip route-static 20.1.1.0 24 10.2.1.2 track 1
```

Configure a static route to 20.1.1.0/24 with next hop 10.4.1.3 and priority 80.

```
[SwitchD] ip route-static 20.1.1.0 24 10.4.1.3 preference 80
```

Configure a static route to 10.1.1.1 with next hop 10.2.1.2.

```
[SwitchD] ip route-static 10.1.1.1 24 10.2.1.2
```

Create an NQA operation with administrator name **admin** and operation tag **test**.

```
[SwitchD] nqa entry admin test
```

Specify the **ICMP echo** operation type.

```
[SwitchD-nqa-admin-test] type icmp-echo
```

Specify 10.1.1.1 as the destination address of the operation.

```
[SwitchD-nqa-admin-test-icmp-echo] destination ip 10.1.1.1
```

Specify 10.2.1.2 as the next hop of the operation.

```
[SwitchD-nqa-admin-test-icmp-echo] next-hop ip 10.2.1.2
```

Configure the ICMP echo operation to repeat every 100 milliseconds.

```
[SwitchD-nqa-admin-test-icmp-echo] frequency 100
```

Configure reaction entry 1, specifying that five consecutive probe failures trigger the Track module.

```
[SwitchD-nqa-admin-test-icmp-echo] reaction 1 checked-element probe-fail
threshold-type consecutive 5 action-type trigger-only
[SwitchD-nqa-admin-test-icmp-echo] quit
```

Start the NQA operation.

```
[SwitchD] nqa schedule admin test start-time now lifetime forever
```

Configure track entry 1, and associate it with reaction entry 1 of the NQA operation.

```
[SwitchD] track 1 nqa entry admin test reaction 1
[SwitchD-track-1] quit
```

Verifying the configuration

Display information about the track entry on Switch A.

```
[SwitchA] display track all
```

```
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: NQA
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    NQA entry: admin test
    Reaction: 1
    Remote IP/URL: 10.2.1.4
    Local IP:--
    Interface:--
```

The output shows that the status of the track entry is Positive, indicating that the NQA operation has succeeded and the master route is available.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 10       Routes : 10

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.1.1.0/24         Direct 0    0            10.1.1.1        Vlan2

20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
30.1.1.0/24         Static 60   0            10.1.1.2        Vlan2
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Switch A forwards packets to 30.1.1.0/24 through Switch B.

Remove the IP address of interface VLAN-interface 2 on Switch B.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] undo ip address
```

Display information about the track entry on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Negative
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: NQA
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    NQA entry: admin test
    Reaction: 1
    Remote IP/URL: 10.2.1.4
    Local IP:--
    Interface:--
```

The output shows that the status of the track entry is Negative, indicating that the NQA operation has failed and the master route is unavailable.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 10       Routes : 10

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.1.1.0/24         Direct 0    0            10.1.1.1        Vlan2

5 packet(s) transmitted, 5 packet(s) received, 0.00% packet loss
round-trip min/avg/max/std-dev = 1/1/2/1 ms
```

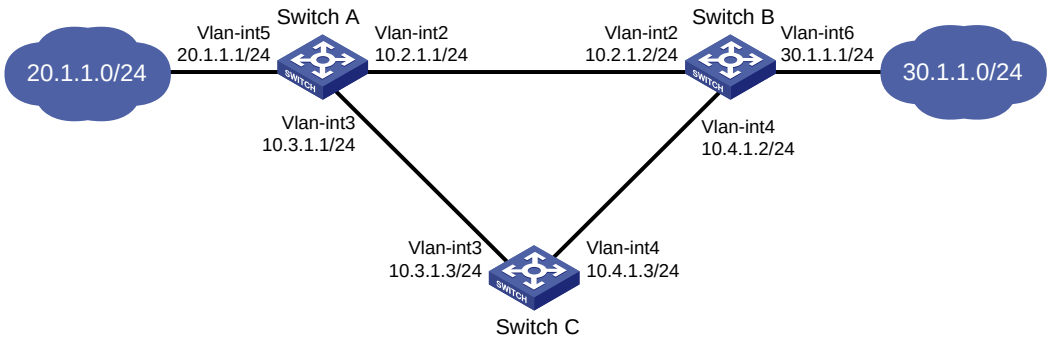
Example: Configuring static routing-Track-BFD (echo mode) collaboration

Network configuration



As shown in Figure 8:

- Switch A is the default gateway of the hosts in network 20.1.1.0/24.
- Switch B is the default gateway of the hosts in network 30.1.1.0/24.
- Hosts in the two networks communicate with each other through static routes.

To ensure network availability, configure route backup and static routing-Track-BFD (echo mode) collaboration on Switch A and Switch B as follows:

- On Switch A, assign a higher priority to the static route to 30.1.1.0/24 with next hop Switch B. This route is the master route. The static route to 30.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the echo-mode BFD session can quickly detect the route failure to make the backup route take effect.
- On Switch B, assign a higher priority to the static route to 20.1.1.0/24 with next hop Switch A. This route is the master route. The static route to 20.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the echo-mode BFD session can quickly detect the route failure to make the backup route take effect.

Figure 8 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 8. (Details not shown.)
2. Configure Switch A:

   # Configure a static route to 30.1.1.0/24 with next hop 10.2.1.2 and the default priority (60). Associate this static route with track entry 1.

   ```
   <SwitchA> system-view
   [SwitchA] ip route-static 30.1.1.0 24 10.2.1.2 track 1
   ```

   # Configure a static route to 30.1.1.0/24 with next hop 10.3.1.3 and priority 80.

   ```
   [SwitchA] ip route-static 30.1.1.0 24 10.3.1.3 preference 80
   ```

   # Specify 10.10.10.10 as the source address of BFD echo packets.

   ```
   [SwitchA] bfd echo-source-ip 10.10.10.10
   ```

   # Configure track entry 1, and associate it with the echo-mode BFD session to verify the connectivity between Switch A and Switch B.

   ```
   [SwitchA] track 1 bfd echo interface vlan-interface 2 remote ip 10.2.1.2 local ip
   10.2.1.1
   [SwitchA-track-1] quit
   ```

3. Configure Switch B:

   # Configure a static route to 20.1.1.0/24 with next hop 10.2.1.1 and the default priority (60). Associate this static route with track entry 1.

```
<SwitchB> system-view
[SwitchB] ip route-static 20.1.1.0 24 10.2.1.1 track 1
```

   # Configure a static route to 20.1.1.0/24 with next hop 10.4.1.3 and priority 80.

```
[SwitchB] ip route-static 20.1.1.0 24 10.4.1.3 preference 80
```

   # Specify 1.1.1.1 as the source address of BFD echo packets.

```
[SwitchB] bfd echo-source-ip 1.1.1.1
```

   # Configure track entry 1, and associate it with the echo-mode BFD session to verify the connectivity between Switch B and Switch A.

```
[SwitchB] track 1 bfd echo interface vlan-interface 2 remote ip 10.2.1.1 local ip
10.2.1.2
[SwitchB-track-1] quit
```

4. Configure Switch C:

   # Configure a static route to 30.1.1.0/24 with next hop 10.4.1.2.

```
<SwitchC> system-view
[SwitchC] ip route-static 30.1.1.0 24 10.4.1.2
```

   # Configure a static route to 20.1.1.0/24 with next hop 10.3.1.1.

```
[SwitchC] ip route-static 20.1.1.0 24 10.3.1.1
```

Verifying the configuration

Display information about the track entry on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: BFD echo
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    BFD session mode: Echo
    Outgoing interface: Vlan-interface2
    Remote IP: 10.2.1.2
    Local IP: 10.2.1.1
```

The output shows that the status of the track entry is Positive, indicating that next hop 10.2.1.2 is reachable.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 9        Routes : 9

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.2.1.0/24         Direct 0    0            10.2.1.1        Vlan2

10.3.1.1/32         Direct 0    0            127.0.0.1       InLoop0
20.1.1.0/24         Direct 0    0            20.1.1.1        Vlan5
20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
```

```
30.1.1.0/24         Static 60   0           10.2.1.2        Vlan2
127.0.0.0/8         Direct 0    0           127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0           127.0.0.1       InLoop0
```

The output shows that Switch A forwards packets to 30.1.1.0/24 through Switch B. The master static route has taken effect.

Remove the IP address of VLAN-interface 2 on Switch B.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] undo ip address
```

Display information about the track entry on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Negative
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: BFD echo
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    BFD session mode: Echo
    Outgoing interface: Vlan-interface2
    VPN instance name: --
    Remote IP: 10.2.1.2
    Local IP: 10.2.1.1
```

The output shows that the status of the track entry is Negative, indicating that next hop 10.2.1.2 is unreachable.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 9        Routes : 9

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.2.1.0/24         Direct 0    0           10.2.1.1        Vlan2
10.2.1.1/32         Direct 0    0           127.0.0.1       InLoop0
10.3.1.0/24         Direct 0    0           10.3.1.1        Vlan3
10.3.1.1/32         Direct 0    0           127.0.0.1       InLoop0
20.1.1.0/24         Direct 0    0           20.1.1.1        Vlan5
20.1.1.1/32         Direct 0    0           127.0.0.1       InLoop0
30.1.1.0/24         Static 80   0           10.3.1.3        Vlan3
127.0.0.0/8         Direct 0    0           127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0           127.0.0.1       InLoop0
```

The output shows that Switch A forwards packets to 30.1.1.0/24 through Switch C. The backup static route has taken effect.

Verify that the hosts in 20.1.1.0/24 can communicate with the hosts in 30.1.1.0/24 when the master route fails.

```
[SwitchA] ping -a 20.1.1.1 30.1.1.1
Ping 30.1.1.1: 56  data bytes, press CTRL_C to break
Reply from 30.1.1.1: bytes=56 Sequence=1 ttl=254 time=2 ms
Reply from 30.1.1.1: bytes=56 Sequence=2 ttl=254 time=1 ms
```

```

5 packet(s) transmitted, 5 packet(s) received, 0.00% packet loss
round-trip min/avg/max/std-dev = 1/1/2/1 ms
```

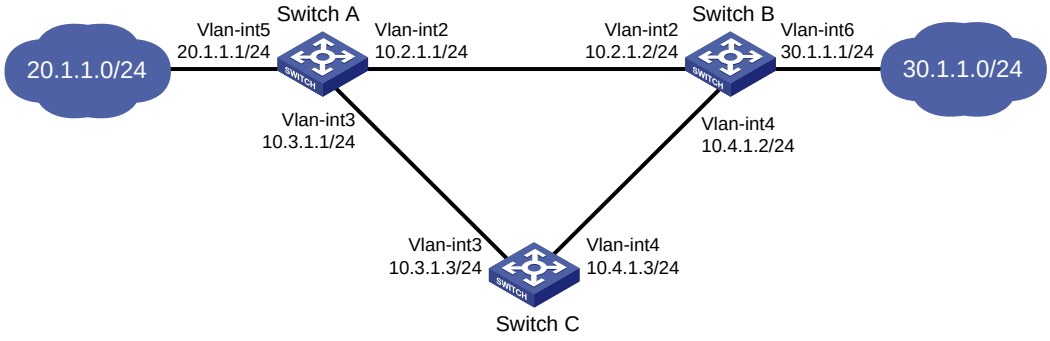
Example: Configuring static routing-Track-BFD (control mode) collaboration

Network configuration



As shown in Figure 9:

- Switch A is the default gateway of the hosts in network 20.1.1.0/24.
- Switch B is the default gateway of the hosts in network 30.1.1.0/24.
- Hosts in the two networks communicate with each other through static routes.

To ensure network availability, configure route backup and static routing-Track-BFD (control mode) collaboration on Switch A and Switch B as follows:

- On Switch A, assign a higher priority to the static route to 30.1.1.0/24 with next hop Switch B. This route is the master route. The static route to 30.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the control-mode BFD session can quickly detect the route failure to make the backup route take effect.
- On Switch B, assign a higher priority to the static route to 20.1.1.0/24 with next hop Switch A. This route is the master route. The static route to 20.1.1.0/24 with next hop Switch C acts as the backup route. When the master route is unavailable, the control-mode BFD session can quickly detect the route failure to make the backup route take effect.

Figure 9 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 9. (Details not shown.)
2. Configure Switch A:

   # Configure a static route to 30.1.1.0/24 with next hop 10.2.1.2 and the default priority (60). Associate this static route with track entry 1.

   ```
   <SwitchA> system-view
   [SwitchA] ip route-static 30.1.1.0 24 10.2.1.2 track 1
   ```

   # Configure a static route to 30.1.1.0/24 with next hop 10.3.1.3 and priority 80.

   ```
   [SwitchA] ip route-static 30.1.1.0 24 10.3.1.3 preference 80
   ```

   # Configure track entry 1, and associate it with the control-mode BFD session to verify the connectivity between Switch A and Switch B.

   ```
   [SwitchA] track 1 bfd ctrl interface vlan-interface 2 remote ip 10.2.1.2 local ip 10.2.1.1
   [SwitchA-track-1] quit
   ```

3. Configure Switch B:

   # Configure a static route to 20.1.1.0/24 with next hop 10.2.1.1 and the default priority (60). Associate this static route with track entry 1.

   ```
   <SwitchB> system-view
   [SwitchB] ip route-static 20.1.1.0 24 10.2.1.1 track 1
   ```

   # Configure a static route to 20.1.1.0/24 with next hop 10.4.1.3 and priority 80.

   ```
   [SwitchB] ip route-static 20.1.1.0 24 10.4.1.3 preference 80
   ```

   # Configure track entry 1, and associate it with the control-mode BFD session to verify the connectivity between Switch B and Switch A.

   ```
   [SwitchB] track 1 bfd ctrl interface vlan-interface 2 remote ip 10.2.1.1 local ip 10.2.1.2
   [SwitchB-track-1] quit
   ```

4. Configure Switch C:

   # Configure a static route to 30.1.1.0/24 with next hop 10.4.1.2.

   ```
   <SwitchC> system-view
   [SwitchC] ip route-static 30.1.1.0 24 10.4.1.2
   ```

   # Configure a static route to 20.1.1.0/24 with next hop 10.3.1.1.

   ```
   [SwitchC] ip route-static 20.1.1.0 24 10.3.1.1
   ```

Verifying the configuration

Display information about the track entry on Switch A.

```
[SwitchA] display track all
```

```
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: BFD ctrl
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    BFD session mode: Ctrl
    Outgoing interface: Vlan-interface2
    VPN instance name: --
    Remote IP: 10.2.1.2
    Local IP: 10.2.1.1
```

The output shows that the status of the track entry is Positive, indicating that next hop 10.2.1.2 is reachable.

Display the routing table of Switch A.

```
[SwitchA] display ip routing-table

Destinations : 9        Routes : 9

Destination/Mask    Proto  Pre  Cost         NextHop         Interface

round-trip min/avg/max/std-dev = 1/1/2/1 ms
```

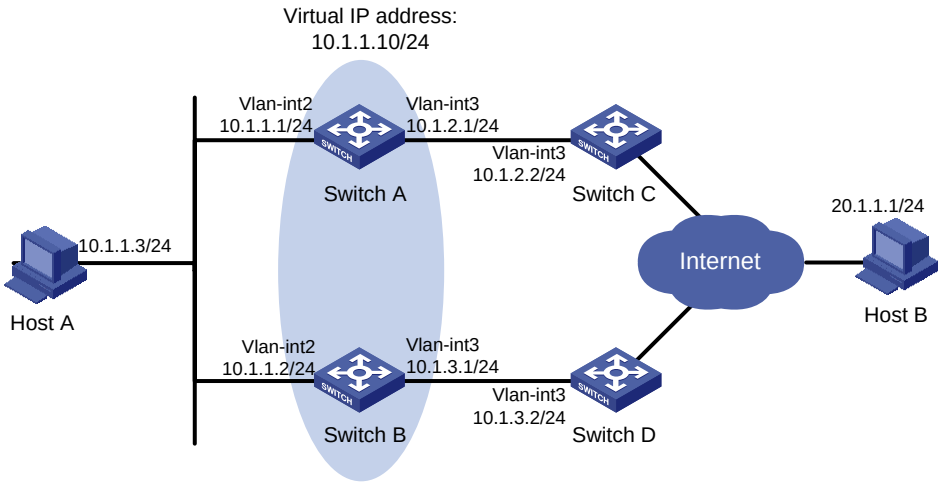
Example: Configuring VRRP-Track-interface management collaboration

Network configuration



As shown in Figure 10:

- Host A requires access to Host B. The default gateway of Host A is 10.1.1.10/24.
- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 10.1.1.10.

Configure VRRP-Track-interface management collaboration to monitor the uplink interface on the master and meet the following requirements:

- When Switch A operates correctly, Switch A forwards packets from Host A to Host B.
- When VRRP detects a fault on the uplink interface of Switch A through the interface management module, Switch B forwards packets from Host A to Host B.

Figure 10 Network diagram

Procedure

1. Create VLANs and assign ports to them. Configure the IP address of each VLAN interface, as shown in Figure 10. (Details not shown.)
2. Configure Switch A:

   # Configure track entry 1 and associate it with the link status of the uplink interface VLAN-interface 3.

   ```
   [SwitchA] track 1 interface vlan-interface 3
   [SwitchA-track-1] quit
   ```

   # Create VRRP group 1 and configure virtual IP address 10.1.1.10 for the group.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
   ```

   # Set the priority of Switch A to 110 in VRRP group 1.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
   ```

   # Associate VRRP group 1 with track entry 1 and decrease the router priority by 30 when the state of track entry 1 changes to Negative.

   ```
   [SwitchA-Vlan-interface2] vrrp vrid 1 track 1 priority reduced 30
   ```

3. On Switch B, create VRRP group 1, and configure virtual IP address 10.1.1.10 for the group.

   ```
   <SwitchB> system-view
   ```

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
```

Verifying the configuration

Ping Host B from Host A to verify that Host B is reachable. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA-Vlan-interface2] display vrrp verbose
IPv4 Virtual Router Information:

   Interface Vlan-interface2
     VRID              : 1                Adver Timer   : 100
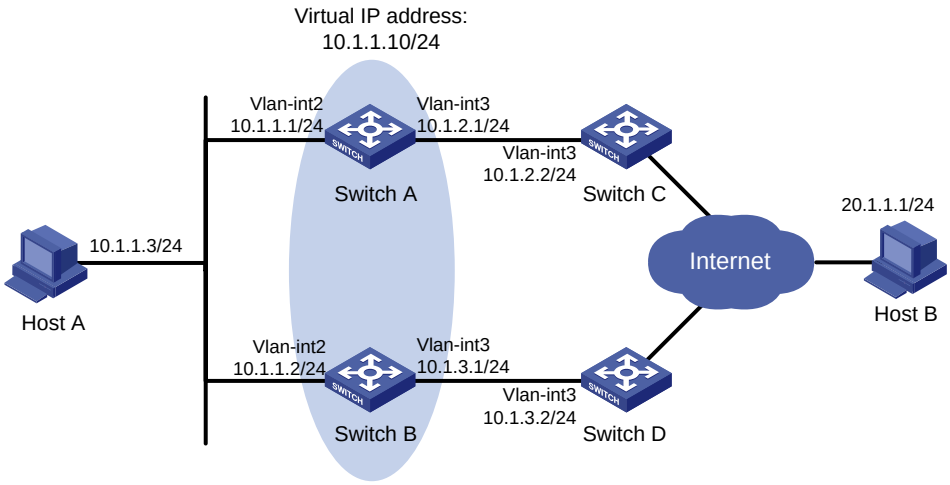
     Admin Status      : Up               State         : Master
     Config Pri        : 100              Running Pri   : 100
     Preempt Mode      : Yes              Delay Time    : 0
     Auth Type         : Not supported
     Version           : 3
     Virtual IP        : 10.1.1.10
     Virtual MAC       : 0000-5e00-0101
     Master IP         : 10.1.1.2
```

The output shows that Switch A becomes the backup, and Switch B becomes the master. Switch B forwards packets from Host A to Host B.

Example: Configuring VRRP-Track-route management collaboration

Network configuration



As shown in Figure 11:

- Host A requires access to Host B. The default gateway of Host A is 10.1.1.10/24.
- Switch A and Switch B belong to VRRP group 1. The virtual IP address of VRRP group 1 is 10.1.1.10.
- BGP peer relationships are established between Switch A and Switch C and between Switch B and Switch D. Switch C and Switch D advertise the default route 0.0.0.0/0 to Switch A and Switch B.

Configure VRRP-Track-route management collaboration to meet the following requirements:

- When Switch A operates correctly, Switch A forwards packets from Host A to Host B.
- When VRRP detects the removal of the default route from the routing table of Switch A through route management, Switch B forwards packets from Host A to Host B.

Figure 11 Network diagram

Procedure

1. Configure the IP address of each interface, as shown in Figure 11. (Details not shown.)
2. Establish an IBGP peer relationship between Switch A and Switch C, and configure Switch C to advertise the default route 0.0.0.0/0 to Switch A.

```
<SwitchA> system-view
[SwitchA] bgp 100
[SwitchA-bgp-default] peer 10.1.2.2 as-number 100
[SwitchA-bgp-default] address-family ipv4
[SwitchA-bgp-default-ipv4] peer 10.1.2.2 enable
<SwitchC> system-view
[SwitchC] bgp 100
[SwitchC-bgp-default] peer 10.1.2.1 as-number 100
[SwitchC-bgp-default] address-family ipv4
[SwitchC-bgp-default-ipv4] peer 10.1.2.1 enable
[SwitchC-bgp-default-ipv4] peer 10.1.2.1 default-route-advertise
[SwitchC-bgp-default-ipv4] quit
```

3. Configure Switch B and Switch D in the same way Switch A and Switch C are configured. (Details not shown.)
4. Configure Track and VRRP on Switch A:

   # Configure track entry 1, and associate it with the default route 0.0.0.0/0.

```
[SwitchA] track 1 ip route 0.0.0.0 0.0.0.0 reachability
[SwitchA-track-1] quit
```

   # Create VRRP group 1, and configure virtual IP address 10.1.1.10 for the group.

```
[SwitchA] interface vlan-interface 2
[SwitchA-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
```

   # Set the priority of Switch A to 110 in VRRP group 1.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 priority 110
```

   # Associate VRRP group 1 with track entry 1 and decrease the Switch priority by 30 when the state of track entry 1 changes to Negative.

```
[SwitchA-Vlan-interface2] vrrp vrid 1 track 1 priority reduced 30
[SwitchA-Vlan-interface2] quit
```

5. On Switch B, create VRRP group 1, and configure virtual IP address 10.1.1.10 for the group.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] vrrp vrid 1 virtual-ip 10.1.1.10
[SwitchB-Vlan-interface2] quit
```

Verifying the configuration

Ping Host B from Host A to verify that Host B is reachable. (Details not shown.)

Display detailed information about VRRP group 1 on Switch A.

```
[SwitchA] display vrrp verbose
IPv4 Virtual Router Information:
 Running Mode       : Standard
 Total number of virtual routers : 1
   Interface Vlan-interface2
     VRID             : 1              Adver Timer  : 100
     Admin Status     : Up             State        : Master

     Master IP         : 10.1.1.2
```

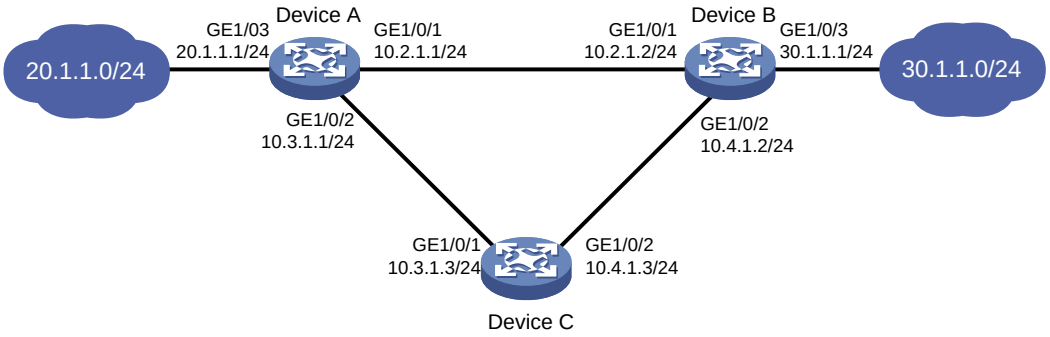
The output shows that Switch A becomes the backup, and Switch B becomes the master. Switch B forwards packets from Host A to Host B.

Example: Configuring static routing-Track-LLDP collaboration

Network requirements

As shown in Figure 12:



- Device A is the default gateway of the hosts in network 20.1.1.0/24.
- Device B is the default gateway of the hosts in network 30.1.1.0/24.
- Hosts in the two networks communicate with each other through static routes.

To ensure network availability, configure route backup and static routing-Track-LLDP collaboration on Device A and Device B as follows:

- On Device A, assign a higher priority to the static route to 30.1.1.0/24 with next hop Device B. This route is the master route. The static route to 30.1.1.0/24 with next hop Device C acts as the backup route. When the master route is unavailable, the backup route takes effect. Device A forwards packets destined for 30.1.1.0/24 to Device C.

- On Device B, assign a higher priority to the static route to 20.1.1.0/24 with next hop Device A. This route is the master route. The static route to 20.1.1.0/24 with next hop Device C acts as the backup route. When the master route is unavailable, the backup route takes effect. Device B forwards packets destined for 20.1.1.0/24 to Device C.

Figure 12 Network diagram

Procedure

1. Configure the IP address of each interface, as shown in Figure 12. (Details not shown.)
2. Configure Device A:

   # Configure a static route to 30.1.1.0/24 with next hop 10.1.1.2 and the default priority (60). Associate this static route with track entry 1.

   ```
   <DeviceA> system-view
   [DeviceA] ip route-static 30.1.1.0 24 10.2.1.2 track 1
   ```

   # Configure a static route to 30.1.1.0/24 with next hop 10.3.1.3 and priority 80.

   ```
   [DeviceA] ip route-static 30.1.1.0 24 10.3.1.3 preference 80
   ```

   # Enable LLDP globally.

   ```
   [DeviceA] lldp global enable
   ```

   # Enable LLDP on GigabitEthernet 1/0/1. (This step is optional because LLDP is enabled on the port by default.)

   ```
   [DeviceA] interface gigabitethernet 1/0/1
   [DeviceA-GigabitEthernet1/0/1] lldp enable
   ```

   # Configure track entry 1 and associate it with the availability of the neighbor for LLDP interface Gigabitethernet 1/0/1.

   ```
   [DeviceA] track 1 lldp neighbor interface gigabitethernet 1/0/1
   [DeviceA-track-1] quit
   ```

3. Configure Device B:

   # Configure a static route to 20.1.1.0/24 with next hop 10.2.1.1 and the default priority (60). Associate this static route with track entry 1.

   ```
   <DeviceB> system-view
   [DeviceB] ip route-static 20.1.1.0 24 10.2.1.1 track 1
   ```

   # Configure a static route to 20.1.1.0/24 with next hop 10.4.1.3 and priority 80.

   ```
   [DeviceB] ip route-static 20.1.1.0 24 10.4.1.3 preference 80
   ```

   # Enable LLDP globally.

   ```
   [DeviceB] lldp global enable
   ```

   # Enable LLDP on GigabitEthernet 1/0/1. (This step is optional because LLDP is enabled on the port by default.)

   ```
   [DeviceB] interface gigabitethernet 1/0/1
   [DeviceB-GigabitEthernet1/0/1] lldp enable
   ```

Configure track entry 1 and associate it with the availability of the neighbor for LLDP interface GigabitEthernet 1/0/1.

```
[DeviceB] track 1 lldp neighbor interface gigabitethernet 1/0/1
[DeviceB-track-1] quit
```

4. Configure Device C:

Configure a static route to 30.1.1.0/24 with next hop 10.4.1.2.

```
<DeviceC> system-view
[DeviceC] ip route-static 30.1.1.0 24 10.4.1.2
```

Configure a static route to 20.1.1.0/24 with next hop 10.3.1.1.

```
[DeviceC] ip route-static 20.1.1.0 24 10.3.1.1
```

Verifying the configuration

Display track entry information on Device A.

```
[DeviceA] display track all
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 32 seconds
  Tracked object type: LLDP
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    LLDP interface: GigabitEthernet1/0/1
```

The output shows that the status of track entry 1 is Positive, indicating that the neighbor of LLDP interface GigabitEthernet 1/0/1 is available. The master route takes effect.

Display the routing table of Device A.

```
[DeviceA] display ip routing-table

Destinations : 9        Routes : 9

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.2.1.0/24         Direct 0    0            10.2.1.1        GE1/0/1
10.2.1.1/32         Direct 0    0            127.0.0.1       InLoop0
10.3.1.0/24         Direct 0    0            10.3.1.1        GE1/0/2
10.3.1.1/32         Direct 0    0            127.0.0.1       InLoop0
20.1.1.0/24         Direct 0    0            20.1.1.1        GE1/0/3
20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
30.1.1.0/24         Static 60   0            10.2.1.2        GE1/0/1
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Device A forwards packets to 30.1.1.0/24 through Device B.

On Device B, disable LLDP on GigabitEthernet 1/0/1.

```
<DeviceB> system-view
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] undo lldp enable
```

Display track entry information on Device A.

```
[DeviceA] display track all
Track ID: 1
  State: Negative
  Duration: 0 days 0 hours 0 minutes 32 seconds
```

```
  Tracked object type: LLDP
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    LLDP interface: GigabitEthernet1/0/1
```

The output shows that the status of track entry 1 is Negative, indicating that the neighbor of LLDP interface GigabitEthernet 1/0/1 is unavailable. The master route fails.

Display the routing table of Device A.

```
[DeviceA] display ip routing-table

Destinations : 9        Routes : 9

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
10.2.1.0/24         Direct 0    0            10.2.1.1        GE1/0/1
10.2.1.1/32         Direct 0    0            127.0.0.1       InLoop0
10.3.1.0/24         Direct 0    0            10.3.1.1        GE1/0/2
10.3.1.1/32         Direct 0    0            127.0.0.1       InLoop0
20.1.1.0/24         Direct 0    0            20.1.1.1        GE1/0/3
20.1.1.1/32         Direct 0    0            127.0.0.1       InLoop0
30.1.1.0/24         Static 80   0            10.3.1.3        GE1/0/2
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
```

The output shows that Device A forwards packets destined for 30.1.1.0/24 to Device C. The backup static route has taken effect.

Verify that hosts in 20.1.1.0/24 can communicate with the hosts in 30.1.1.0/24 when the master route fails.

```
[DeviceA] ping -a 20.1.1.1 30.1.1.1
Ping 30.1.1.1: 56  data bytes, press CTRL_C to break
Reply from 30.1.1.1: bytes=56 Sequence=1 ttl=254 time=2 ms
Reply from 30.1.1.1: bytes=56 Sequence=2 ttl=254 time=1 ms
Reply from 30.1.1.1: bytes=56 Sequence=3 ttl=254 time=1 ms
Reply from 30.1.1.1: bytes=56 Sequence=4 ttl=254 time=2 ms
Reply from 30.1.1.1: bytes=56 Sequence=5 ttl=254 time=1 ms

--- Ping statistics for 30.1.1.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.00% packet loss
round-trip min/avg/max/std-dev = 1/1/2/1 ms
```

Verify that the hosts in 30.1.1.0/24 can communicate with the hosts in 20.1.1.0/24 when the master route fails.

```
[DeviceB] ping -a 30.1.1.1 20.1.1.1
Ping 20.1.1.1: 56  data bytes, press CTRL_C to break
Reply from 20.1.1.1: bytes=56 Sequence=1 ttl=254 time=2 ms
Reply from 20.1.1.1: bytes=56 Sequence=2 ttl=254 time=1 ms
Reply from 20.1.1.1: bytes=56 Sequence=3 ttl=254 time=1 ms
Reply from 20.1.1.1: bytes=56 Sequence=4 ttl=254 time=1 ms
Reply from 20.1.1.1: bytes=56 Sequence=5 ttl=254 time=1 ms

--- Ping statistics for 20.1.1.1 ---
5 packet(s) transmitted, 5 packet(s) received, 0.00% packet loss
```

```
round-trip min/avg/max/std-dev = 1/1/2/1 ms
```

Configuring process placement

About process placement

Process

A process contains a set of codes and provides specific functionality. For example, an AAA process provides AAA functions.

Each process runs in a protected memory space to prevent problems with one process from impacting the entire system.

Node

The term "node" in this document refers to CPUs that run the Comware system. If the IRF fabric has multiple member devices, each member device has a node.

Process redundancy

The system backs up each active process running on one node to all the other nodes. When an active process fails, one of its standby processes promptly takes over without impacting any other service.

Process redundancy provides the following benefits:

- Improves service availability.
- Enables the system to quickly regain reliability after device status changes in such conditions as insertion and removal of cards and removal of an IRF member.

Process placement

The execution of process placement policies varies by the location of active processes.

- An active process running only on the master device does not support placement optimization. If you configure a process placement policy for the process, the system displays a configuration failure message. When such an active process fails, the system automatically restarts the process. The standby processes are used for active/standby switchover.
- Some active processes can run on either the master or subordinate device. When such an active process fails, the system uses a placement policy to select a new active process among standby processes.

Default process placement policy

The system provides a default process placement policy that takes effect for all processes. By default, the default process placement policy defines the following rules:

- The active process runs on the CPU of the master, and the standby processes run on the CPU of the subordinate device.
- A process runs at the location where it ran the last time and does not move to any other location during startup or operation.

- The addition of a new node does not impact current active processes. A new active process selects one node with sufficient CPU and memory resources. (You can use the **display cpu-usage** and **display memory** commands to view CPU and memory usage information.)

You can modify the default placement policy in the view you enter by using the **placement program default** command. You can also configure a placement policy for a specific process in the view you enter by using the **placement program** *program-name* [**instance** *instance-name*] command. A placement policy for a process takes precedence over the default process placement policy.

Process placement affinities

You can configure the following settings for a process placement policy to optimize process placement:

- **affinity location-set**—Location affinity, the preference for the process to run on a specific node.
- **affinity location-type**—Location type affinity, the preference for the process to run on a particular type of node. For more information about node types, see "Configuring a location type affinity."
- **affinity program**—Process affinity, the preference for the process to run on the same node as a particular process.
- **affinity self**—Self affinity, the preference for one instance of the process to run on the same node as any other instance of the process.

Affinities include positive affinities (**attract**) and negative affinities (**repulse**), all represented by integers in the range of 1 to 100000.

- The higher the attract value, the stronger the preference.
- The higher the repulse value, the weaker the preference.

Process placement optimization

After you apply new placement policies, the system makes placement decisions based on the new policies, node resources, and topology status. If the new location for an active process is different from the current node, the system changes the state of the process to standby, and uses the standby process on the preferred location as the new active process.

Restrictions and guidelines: process placement configuration

- Configuring process placement on an IRF fabric with only one member device does not change the location of processes. All processes run on the CPU of the IRF member device.
- Configuring process placement on an IRF fabric with multiple member devices places specific active processes to specific CPUs. In case of multiple CPUs, the system performs process redundancy. The number of standby processes and their CPU locations vary by function module. The system by default automatically determines the location for each active process, and process placement optimization is not required. If optimization is required, contact H3C Support to avoid service interruption.
- For an instance of a process, the settings in placement policy view of the instance, in placement policy view of the process, and in default placement policy view are in descending order of priority. For a process, the settings in placement policy view of the process take precedence over the settings in default placement policy view.

- To view the current location of an active process and its predicted new location after optimization, use the **display placement reoptimize** command.

Process placement tasks at a glance

To configure process placement, perform the following tasks:

1. Configuring process placement policy

   Choose the following tasks as needed:

   - Configuring a location affinity
   - Configuring a location type affinity
   - Configuring a process affinity
   - Configuring a self affinity
2. Optimizing process placement

Configuring process placement policy

Configuring a location affinity

1. Enter system view.

   system-view
2. Enter placement process view.
   - Enter default placement process view.

     placement program default
   - Enter specified placement process view.

     placement program { *program-name* [**instance** *instance-name*]

   Settings in default placement process view take effect for all processes. Settings in placement process view take effect only for the specified process.
3. Set the location affinity.

   affinity location-set { **slot** *slot-number* }&<1-5> { **attract** *strength* | **default** | **none** | **repulse** *strength* }

   By default, no location affinity is set.

Configuring a location type affinity

About this task

The following location types are available:

- **current**—Current location of the active process, which can be displayed with the **display placement program** command.
- **paired**—Locations of standby processes.
- **primary**—Master device.

Procedure

1. Enter system view.

   system-view
2. Enter placement process view.

- Enter default placement process view.

  placement program default

- Enter specified placement process view.

  placement program { *program-name* [**instance** *instance-name*]

Settings in default placement process view take effect for all processes. Settings in placement process view take effect only for the specified process.

3. Set the location type affinity.

   affinity location-type { **current** | **paired** | **primary** } { **attract** *strength* | **repulse** *strength* | **default** | **none** }

   By default, no location type affinity is set.

Configuring a process affinity

1. Enter system view.

   system-view

2. Enter placement process view.
   - Enter default placement process view.

     placement program default

   - Enter specified placement process view.

     placement program { *program-name* [**instance** *instance-name*]

   Settings in default placement process view take effect for all processes. Settings in placement process view take effect only for the specified process.

3. Configure the affinity for the process to run on the same location as another process.

   affinity program *program-name* { **attract** *strength* | **default** | **none** | **repulse** *strength* }

   By default, no process affinity is set.

Configuring a self affinity

About this task

A self affinity determines the preference for one instance of a process to run on the same node as any other instance of the process. The self affinity setting does not take effect for a process that has only one instance.

Procedure

1. Enter system view.

   system-view

2. Enter placement process view.
   - Enter default placement process view.

     placement program default

   - Enter specified placement process view.

     placement program { *program-name* [**instance** *instance-name*]

   Settings in default placement process view take effect for all processes. Settings in placement process view take effect only for the specified process.

3. Configure a self affinity.

   affinity self { **attract** *strength* | **repulse** *strength* | **default** | **none** }

   By default, no self affinity is set.

Optimizing process placement

Restrictions and guidelines

CAUTION:
To avoid neighbor flapping of related protocols, make sure HA features such as NSR or GR are configured for the processes and are stable before optimizing process placement.

To keep the system stable, do not perform any tasks that require process restart when you optimize process placement.

Procedure

1. Enter system view.
   system-view
2. Optimize process placement.
   placement reoptimize

Display and maintenance commands for process placement

Execute **display** commands in any view.

Task	Command
Display service group information.	**display ha service-group** { *program-name* [**instance** *instance-name*] | **all** }
Display the running processes on a specific location.	**display placement location** { **all** | **slot** *slot-number* }
Display process placement policy information.	**display placement policy program** { program-name | **all** | **default** }
Display the location of a process.	**display placement program** { *program-name* | **all** }
Display the predicted location of a process after process placement optimization.	**display placement reoptimize program** { *program-name* [**instance** *instance-name*] | **all** }

Configuring VSRP

VSRP is available only in Release 1115 or later.

About VSRP

Virtual Service Redundancy Protocol (VSRP) backs up running services between devices to avoid service interruption.

Basic concepts

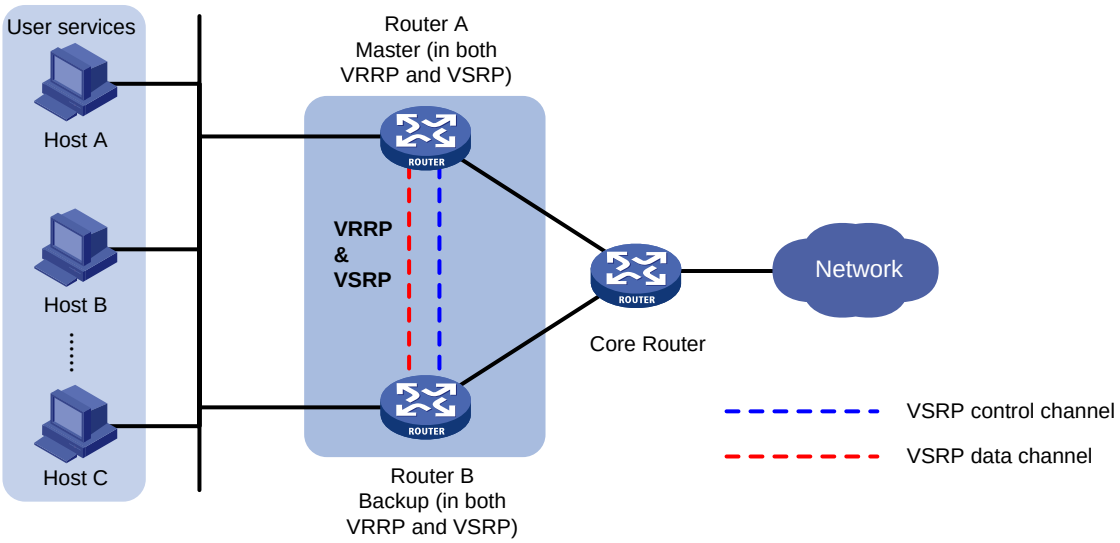
VSRP includes the following components:

- **VSRP group**—A VSRP group contains two peer devices that are enabled with VSRP.
- **VSRP peer**—The member devices in a VSRP group are the peer of each other, with one as master and the other as backup. You must configure the peer IP address on each device to create a VSRP group.
- **VSRP instance**—A VSRP instance is associated with one service to back up service data from the master to the backup for service continuity.
- **VSRP control channel and data channel**—The VSRP peers in a VSRP group synchronize VSRP instance state information and service data by establishing TCP control and data channels.
  - **Control channel**—The master backs up the status of all VSRP instances on the VSRP group to the backup in real time over the control channel.
  - **Data channel**—VSRP establishes a data channel to back up data in real time for each service associated with a VSRP instance on the VSRP group. This backup mechanism ensures that the backup device takes over the services when the master fails.

  Both the TCP control and data channels are initiated by the peer with lower IP address to the peer with higher IP address.

VSRP operating mechanism

VSRP takes advantage of VRRP to determine the role of each peer device in a VSRP group as master or backup.



As shown in Figure 1, a VSRP group contains two peer devices, which must be assigned to the same VRRP group.

VSRP determines the roles of the peer devices in the VSRP group in consistent with their roles in the VRRP group.

The master forwards traffic and backs up the services to the backup device either at a regular interval or when traffic reaches the specified threshold.

When the master in the VSRP group fails, the backup takes over to ensure service continuity. For more information about VRRP, see "Configuring VRRP."

Figure 1 VSRP networking

VSRP backup modes

A VSRP instance supports the following backup modes:

- **Hot backup mode (1:1 backup)**—The backup device issues backup data to the data plane as soon as it receives the data from the master. In this mode, the backup takes over quickly when the master fails. This mode is applicable to scenarios where a device acts as the backup in only one VSRP group.
- **Warm backup mode (N:1 backup)**—The backup device issues received backup data to the data plane when the master fails. This mode has a longer failover delay than hot backup mode. This mode is applicable to scenarios where a device acts as the backup in more than one VSRP group.

VSRP control channel fast detection

By default, a VSRP group detects the state of the failover link based only on the state of the TCP control channel. To fast detect the state of the failover link, you can perform the following tasks:

1. Use NQA or BFD to monitor the state of the failover link.
2. Establish the collaboration between the failover link state and NQA or BFD through the Track function.

A VSRP group operates differently depending on the state of the track entry associated with the VSRP group:

- When the track entry is in **Positive** or **NotReady** state, a device attempts to establish a TCP control channel with its peer.
- When the track entry changes to **Negative** state, the device terminates the TCP control channel.

Support of service modules for VSRP

VSRP can work with DHCPv4 and DHCPv6.

Restrictions and guidelines: Subinterface configuration consistency

As a best practice to maintain data consistency, make sure the peer devices in a VSRP group have consistent main interface configuration, including but not limited to the following settings:

- VLAN configuration.
- VPN configuration.

VSRP tasks at a glance

To configure VSRP, perform the following tasks:

1. Configuring a VSRP group
2. Configuring a VSRP instance
3. Specifying a virtual IPv6 address
4. Configuring VSRP for a service module
   - Configuring VSRP for DHCPv4 server
   - Configuring VSRP for DHCPv6 server

Prerequisites for VSRP

Perform the following tasks on the two peer devices in a VSRP group:

5. Configure VRRP to operate in standard mode.
6. Configure a VRRP group on the two peer devices to determine their role in the VSRP group.

NOTE:

Binding a VSRP group to an existing VRRP group does not affect the functionality of the VRRP group.

Configuring a VSRP group

7. Enter system view.

   system-view

8. Create a VSRP group and enter the VSRP peer view.

   vsrp peer *peer-name*

9. Configure TCP connection parameters for establishing VSRP channels to the peer. Choose one option as needed:
   - Configure parameters for establishing IPv4 VSRP channels to the peer.

     peer *peer-ip-address* **local** *local-ip-address* [**port** *port-id*]
   - Configure parameters for establishing IPv6 VSRP channels to the peer.

     peer ipv6 *peer-ipv6-address* **local** *local-ipv6-address* [**port** *port-id*]

   The TCP port in this command is for establishing the control channel, which cannot be a TCP port number in use. By default, TCP port 60032 is used if no TCP port is specified.

You can specify the TCP ports for establishing data channels by service type in system view when you configure VSRP for each service.

10. (Optional.) Associate a VSRP group with a track entry.

    track *track-entry-number*

Configuring a VSRP instance

About this task

A VSRP instance backs up data for its associated service.

A VSRP instance can be bound to only one VSRP group. Each VSRP instance on a VSRP group is identified by a unique backup ID.

The master forwards traffic and backs up service data to the backup device at the specified interval or when the specified traffic threshold is reached.

Restrictions and guidelines

The NAS parameters (IP address, interface, and host name) on a VSRP instance are shared by the VSRP member devices for the associated service. Configure NAS settings on a VSRP instance if its associated service requires the NAS parameters to remain unchanged after a master/backup switchover. For example, the settings are applicable to the following scenarios:

- Avoid re-authentication on master/backup switchover by maintaining the same NAS-IP-address, NAS-Port, and host name in packets sent to the RADIUS server.
- Maintain the same Option 82 values in packets sent to the DHCP server.

Procedure

1. Enter system view.

   system-view

2. Create a VSRP instance and enter VSRP instance view.

   vsrp instance *instance-name*

3. Specify a backup ID for the VSRP instance.

   backup id *backup-id* **peer** *peer-name*

   By default, a VSRP instance has no ID.

4. Bind the VSRP instance to a VRRP group. Choose one option as needed:
   - Bind the VSRP instance to an IPv4 VRRP group.

     bind vrrp vrid *virtual-router-id* **interface** *interface-type interface-number*

     By default, a VSRP instance is not bound to an IPv4 VRRP group.
   - Bind the VSRP instance to an IPv6 VRRP group.

     bind vrrp ipv6 vrid *virtual-router-id* **interface** *interface-type interface-number*

     By default, a VSRP instance is not bound to an IPv6 VRRP group.

5. Set the backup mode of the VSRP instance.

   backup mode { **hot** | **warm** }

   By default, a VSRP instance operates in hot backup mode.

6. (Optional.) Set a traffic backup interval or a traffic threshold that triggers a traffic backup.

   traffic backup { **interval** *interval-value* | **threshold** *threshold-value* } *

By default, a VSRP instance backs up traffic at 10-minute intervals or when the traffic reaches 50 MB.

7. (Optional.) Configure NAS parameters.

   nas { **id** *host-name* | **ip** *ip-address* | **port** *interface-type interface-number* }

   By default, no NAS parameters are configured.

Specifying a virtual IPv6 address

About this task

To enable VSRP for IPv6 services (such as DHCPv6), you must specify a virtual IPv6 address for the service-enabled interface. This is applicable to some special networks. In a VSRP instance, you must configure the same virtual IPv6 address on the master and the backup. Then the master advertises the virtual IPv6 address as the gateway address in RA messages to the hosts. In this way, traffic from the hosts can be directed to the master.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

   The following types of interfaces are supported:

   - Layer 3 Ethernet interface.
   - Layer 3 aggregate interface.
   - VLAN interface.

3. Specify a virtual IPv6 address for the interface that is associated with a VSRP instance.

   ipv6 virtual-address *ipv6-address* **vsrp** *vsrp-instance*

   By default, no virtual IPv6 address is specified for the interface.

Configuring VSRP for DHCPv4 server

About VSRP for DHCPv4 server

You can use VSRP to back up the address assignment data for a DHCPv4 address pool by associating that address pool with a VSRP instance.

If the peer client-side interfaces on the master and backup DHCPv4 servers have different interface names, you must also associate the interfaces with the same VSRP instance. The peer client-side interfaces are client-side interfaces that connect the master and backup DHCPv4 servers to the same subnet.

When the VSRP instance state is **Master**, the DHCPv4 server to which the DHCPv4 address pool belongs is the master device. When the VSRP instance state is **Backup**, the DHCPv4 server to which the DHCPv4 address pool belongs is the backup device.

In a VSRP group, the master DHCPv4 server assigns IP addresses together with other configuration parameters to DHCPv4 clients. The backup DHCPv4 server only receives the address pool data backed up from the master DHCPv4 server. The DHCPv4 address pool data includes lease bindings and conflicting IP addresses. For more information about DHCPv4, see *Layer 3—IP Services Configuration Guide*.

Associating a DHCPv4 address pool with a VSRP instance

1. Enter system view.
   system-view
2. Create a DHCPv4 address pool and enter its view.
   dhcp server ip-pool *pool-name*
3. Associate the address pool with a VSRP instance.
   vsrp-instance *vsrp-instance-name*
   By default, a DHCPv4 address pool is not associated with any VSRP instance.

Associating a client-side interface with a VSRP instance

About this task

If the peer client-side interfaces on the master and backup DHCPv4 servers have different interface names, you must also associate the interfaces to the same VSRP instance.

This configuration is not required if the peer client-side interfaces have the same interface name.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
   The following types of interfaces are supported:
   - Layer 3 Ethernet interface.
   - Layer 3 aggregate interface.
3. Associate the interface with a VSRP instance.
   dhcp vsrp-instance *vsrp-instance-name*
   By default, a DHCPv4 client-side interface is not associated with a VSRP instance.

Specifying the TCP port number for establishing DHCPv4 server service backup data channels

About this task

To back up address assignment data for a DHCPv4 address pool, the master DHCPv4 server must establish a data channel with the backup DHCPv4 server. You can change the port number for establishing the data channel.

Restrictions and guidelines

To establish DHCPv4 server service backup data channels successfully, you must specify the same TCP port number on the master and backup devices.

The specified port number cannot be a TCP port number in use.

Procedure

1. Enter system view.
   system-view
2. Specify a TCP port number for VSRP to establish DHCPv4 server service backup data channels.

dhcp vsrp port *port-number*

The default TCP port number is 60037.

Configuring VSRP for DHCPv6 server

About VSRP for DHCPv6 server

You can use VSRP to back up the address assignment data for a DHCPv6 address pool by associating that address pool with a VSRP instance.

If the peer client-side interfaces on the master and backup DHCPv6 servers have different interface names, you must also associate the interfaces with the same VSRP instance. The peer client-side interfaces are client-side interfaces that connect the master and backup DHCPv6 servers to the same subnet.

When the VSRP instance state is **Master**, the DHCPv6 server to which the DHCPv6 address pool belongs is the master device. When the VSRP instance state is **Backup**, the DHCPv6 server to which the DHCPv6 address pool belongs is the backup device.

In a VSRP group, the master DHCPv6 server assigns IP addresses together with other configuration parameters to DHCPv6 clients. The backup DHCPv6 server only receives the address pool data backed up from the master DHCPv6 server. The DHCPv6 address pool data includes lease bindings and conflicting IP addresses. For more information about DHCPv6, see *Layer 3—IP Services Configuration Guide*.

Restrictions and guidelines for configuring VSRP for a DHCPv6 address pool

For DHCPv6 clients to correctly renew leases or release IPv6 addresses after a switchover, use the **virtual-duid** command to generate the same virtual DUID for the master and the backup.

Associating a DHCPv6 address pool with a VSRP instance

1. Enter system view.

   system-view

2. Create a DHCPv6 address pool and enter its view.

   ipv6 dhcp pool *pool-name*

3. Associate the address pool with a VSRP instance.

   vsrp-instance *vsrp-instance-name*

   By default, a DHCPv6 address pool is not associated with a VSRP instance.

4. Specify a virtual DUID for the DHCPv6 server.

   virtual-duid { **enterprise-number** *enterprise-number* **identifier** *identifier* | **hardware-type** *hardware-type* **address** *address* }

   By default, no virtual DUID is specified for a DHCPv6 server. The DHCPv6 server uses its real DUID.

Associating a client-side interface with a VSRP instance

About this task

If the peer client-side interfaces on the master and backup DHCPv6 servers have different interface names, you must also associate the interfaces to the same VSRP instance.

This configuration is not required if the peer client-side interfaces have the same interface name.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
   The following types of interfaces are supported:
   - Layer 3 Ethernet interface.
   - Layer 3 aggregate interface.
3. Associate the interface with a VSRP instance.
   ipv6 dhcp vsrp-instance *vsrp-instance-name*
   By default, a DHCPv6 client-side interface is not associated with a VSRP instance.

Specifying the TCP port number for establishing DHCPv6 server service backup data channels

About this task

To back up address assignment data for a DHCPv6 address pool, the master DHCPv6 server must establish a data channel with the backup DHCPv6 server. You can change the port number for establishing the data channel.

Restrictions and guidelines

To establish DHCPv6 server service backup data channels successfully, you must specify the same TCP port number on the master and backup devices.

The specified port number cannot be a TCP port number in use.

Procedure

1. Enter system view.
   system-view
2. Specify a TCP port number for VSRP to establish DHCPv6 server service backup data channels.
   ipv6 dhcp vsrp port *port-number*
   The default TCP port number is 60038.

Display and maintenance commands for VSRP

Execute **display** commands in any view.

Task	Command
Display VSRP instance information.	**display vsrp instance** [*instance-name*]

Task	Command
Display VSRP group information.	**display vsrp peer** [*peer-name*]

H3C S5570S-EI&S5500V3-SI Switch Series

Network Management and Monitoring Configuration Guide

Notice

The information in this document is subject to change without notice. All contents in this document, including statements, information, and recommendations, are believed to be accurate, but they are presented without warranty of any kind, express or implied. H3C shall not be liable for technical or editorial errors or omissions contained herein.

Preface

This configuration guide describes network management and monitoring fundamentals and configuration procedures. It describes how to view system information, collect traffic statistics, assess the network performance, synchronize time for all devices with clocks in your network, and use the ping, tracert, and debug commands to check and debug the current network connectivity.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators working with the S5570S-EI and S5500V3-SI switch series.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.

>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

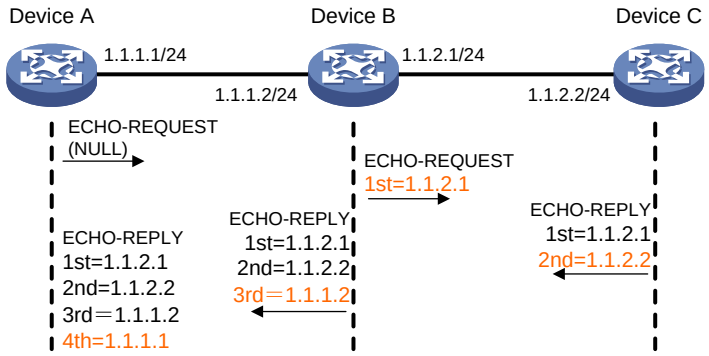
Using ping, tracert, and system debugging

This chapter covers ping, tracert, and information about debugging the system.

Ping

About ping



Use the ping utility to determine if an address is reachable.

Ping sends ICMP echo requests (ECHO-REQUEST) to the destination device. Upon receiving the requests, the destination device responds with ICMP echo replies (ECHO-REPLY) to the source device. The source device outputs statistics about the ping operation, including the number of packets sent, number of echo replies received, and the round-trip time. You can measure the network performance by analyzing these statistics.

You can use the **`ping -r`** command to display the routers through which ICMP echo requests have passed. The test procedure of **`ping -r`** is as shown in Figure 1:

1. The source device (Device A) sends an ICMP echo request to the destination device (Device C) with the RR option empty.
2. The intermediate device (Device B) adds the IP address of its outbound interface (1.1.2.1) to the RR option of the ICMP echo request, and forwards the packet.
3. Upon receiving the request, the destination device copies the RR option in the request and adds the IP address of its outbound interface (1.1.2.2) to the RR option. Then the destination device sends an ICMP echo reply.
4. The intermediate device adds the IP address of its outbound interface (1.1.1.2) to the RR option in the ICMP echo reply, and then forwards the reply.
5. Upon receiving the reply, the source device adds the IP address of its inbound interface (1.1.1.1) to the RR option. The detailed information of routes from Device A to Device C is formatted as: 1.1.1.1 <-> {1.1.1.2; 1.1.2.1} <-> 1.1.2.2.

Figure 1 Ping operation

Using a ping command to test network connectivity

Perform the following tasks in any view:

- Determine if an IPv4 address is reachable.

ping [**ip**] [**-a** *source-ip* | **-c** *count* | **-f** | **-h** *ttl* | **-i** *interface-type interface-number* | **-m** *interval* | **-n** | **-p** *pad* | **-q** | **-r** | **-s** *packet-size* | **-t** *timeout* | **-tos** *tos* | **-v** | **-vpn-instance** *vpn-instance-name*] * *host*

Increase the timeout time (indicated by the **-t** keyword) on a low-speed network.

- Determine if an IPv6 address is reachable.

  ping ipv6 [**-a** *source-ipv6* | **-c** *count* | **-i** *interface-type interface-number* | **-m** *interval* | **-q** | **-s** *packet-size* | **-t** *timeout* | **-tc** *traffic-class* | **-v** | **-vpn-instance** *vpn-instance-name*] * *host*

  Increase the timeout time (indicated by the **-t** keyword) on a low-speed network.

Example: Using the ping utility

Network configuration

As shown in Figure 2, determine if Device A and Device C can reach each other.

Figure 2 Network diagram

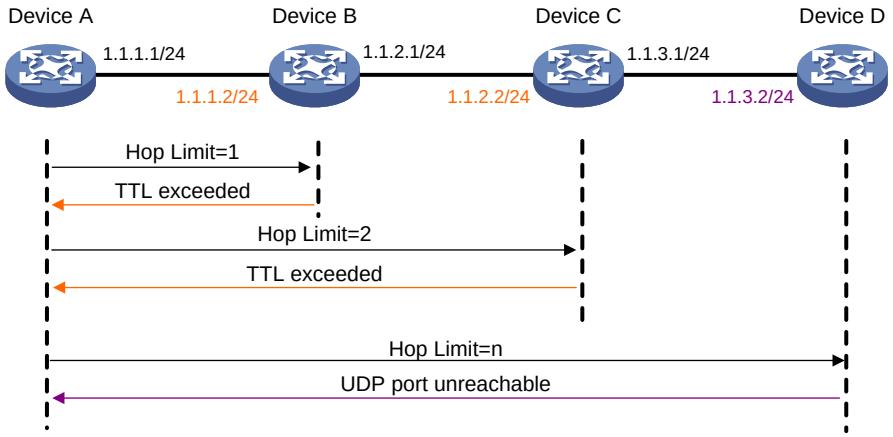
Procedure

Test the connectivity between Device A and Device C.

```
<DeviceA> ping 1.1.2.2
Ping 1.1.2.2 (1.1.2.2): 56 data bytes, press CTRL+C to break
56 bytes from 1.1.2.2: icmp_seq=0 ttl=254 time=2.137 ms
56 bytes from 1.1.2.2: icmp_seq=1 ttl=254 time=2.051 ms
56 bytes from 1.1.2.2: icmp_seq=2 ttl=254 time=1.996 ms
56 bytes from 1.1.2.2: icmp_seq=3 ttl=254 time=1.963 ms
56 bytes from 1.1.2.2: icmp_seq=4 ttl=254 time=1.991 ms

--- Ping statistics for 1.1.2.2 ---
5 packet(s) transmitted, 5 packet(s) received, 0.0% packet loss
round-trip min/avg/max/std-dev = 1.963/2.028/2.137/0.062 ms
```

The output shows the following information:



- Device A sends five ICMP packets to Device C and Device A receives five ICMP packets.
- No ICMP packet is lost.
- The route is reachable.

Tracert

About tracert

Tracert (also called Traceroute) enables retrieval of the IP addresses of Layer 3 devices in the path to a destination. In the event of network failure, use tracert to test network connectivity and identify failed nodes.

Figure 3 Tracert operation

Tracert uses received ICMP error messages to get the IP addresses of devices. Tracert works as shown in Figure 3:

1. The source device sends a UDP packet with a TTL value of 1 to the destination device. The destination UDP port is not used by any application on the destination device.
2. The first hop (Device B, the first Layer 3 device that receives the packet) responds by sending a TTL-expired ICMP error message to the source, with its IP address (1.1.1.2) encapsulated. This way, the source device can get the address of the first Layer 3 device (1.1.1.2).
3. The source device sends a packet with a TTL value of 2 to the destination device.
4. The second hop (Device C) responds with a TTL-expired ICMP error message, which gives the source device the address of the second Layer 3 device (1.1.2.2).
5. This process continues until a packet sent by the source device reaches the ultimate destination device. Because no application uses the destination port specified in the packet, the destination device responds with a port-unreachable ICMP message to the source device, with its IP address encapsulated. This way, the source device gets the IP address of the destination device (1.1.3.2).
6. The source device determines that:
   - The packet has reached the destination device after receiving the port-unreachable ICMP message.
   - The path to the destination device is 1.1.1.2 to 1.1.2.2 to 1.1.3.2.

Prerequisites

Before you use a tracert command, perform the tasks in this section.

For an IPv4 network:

- Enable sending of ICMP timeout packets on the intermediate devices (devices between the source and destination devices). If the intermediate devices are H3C devices, execute the **ip ttl-expires enable** command on the devices. For more information about this command, see *Layer 3—IP Services Command Reference*.
- Enable sending of ICMP destination unreachable packets on the destination device. If the destination device is an H3C device, execute the **ip unreachables enable** command. For more information about this command, see *Layer 3—IP Services Command Reference*.

For an IPv6 network:

- Enable sending of ICMPv6 timeout packets on the intermediate devices (devices between the source and destination devices). If the intermediate devices are H3C devices, execute the

ipv6 hoplimit-expires enable command on the devices. For more information about this command, see *Layer 3—IP Services Command Reference*.

- Enable sending of ICMPv6 destination unreachable packets on the destination device. If the destination device is an H3C device, execute the **ipv6 unreachables enable** command. For more information about this command, see *Layer 3—IP Services Command Reference*.

Using a tracert command to identify failed or all nodes in a path

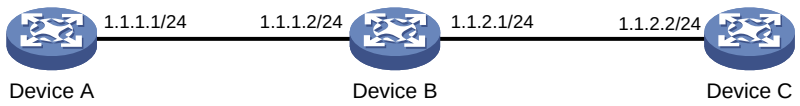
Perform the following tasks in any view:

- Trace the route to an IPv4 destination.

  tracert [**-a** *source-ip* | **-f** *first-ttl* | **-m** *max-ttl* | **-p** *port* | **-q** *packet-number* | **-t** *tos* | **-vpn-instance** *vpn-instance-name* [**-resolve-as** { **global** | **none** | **vpn** }] | **-w** *timeout*] * *host*

- Trace the route to an IPv6 destination.

  tracert ipv6 [**-a** *source-ipv6* | **-f** *first-hop* | **-m** *max-hops* | **-p** *port* | **-q** *packet-number* | **-t** *traffic-class* | **-vpn-instance** *vpn-instance-name* [**-resolve-as** { **global** | **none** | **vpn** }] | **-w** *timeout*] * *host*



Example: Using the tracert utility

Network configuration

As shown in Figure 4, Device A failed to Telnet to Device C.

Test the network connectivity between Device A and Device C. If they cannot reach each other, locate the failed nodes in the network.

Figure 4 Network diagram

Procedure

1. Configure IP addresses for the devices as shown in Figure 4.
2. Configure a static route on Device A.

```
<DeviceA> system-view
[DeviceA] ip route-static 0.0.0.0 0.0.0.0 1.1.1.2
```

3. Test connectivity between Device A and Device C.

```
[DeviceA] ping 1.1.2.2
Ping 1.1.2.2(1.1.2.2): 56 -data bytes, press CTRL+C to break
Request time out
Request time out
Request time out
Request time out
Request time out

--- Ping statistics for 1.1.2.2 ---
5 packet(s) transmitted,0 packet(s) received,100.0% packet loss
```

The output shows that Device A and Device C cannot reach each other.

4. Identify failed nodes:

   # Enable sending of ICMP timeout packets on Device B.

   ```
   <DeviceB> system-view
   [DeviceB] ip ttl-expires enable
   ```

   # Enable sending of ICMP destination unreachable packets on Device C.

   ```
   <DeviceC> system-view
   [DeviceC] ip unreachables enable
   ```

   # Identify failed nodes.

   ```
   [DeviceA] tracert 1.1.2.2
   traceroute to 1.1.2.2 (1.1.2.2) 30 hops at most,40 bytes each packet, press CTRL+C
   to break
    1  1.1.1.2 (1.1.1.2) 1 ms 2 ms 1 ms
    2  * * *
    3  * * *
    4  * * *
    5
   [DeviceA]
   ```

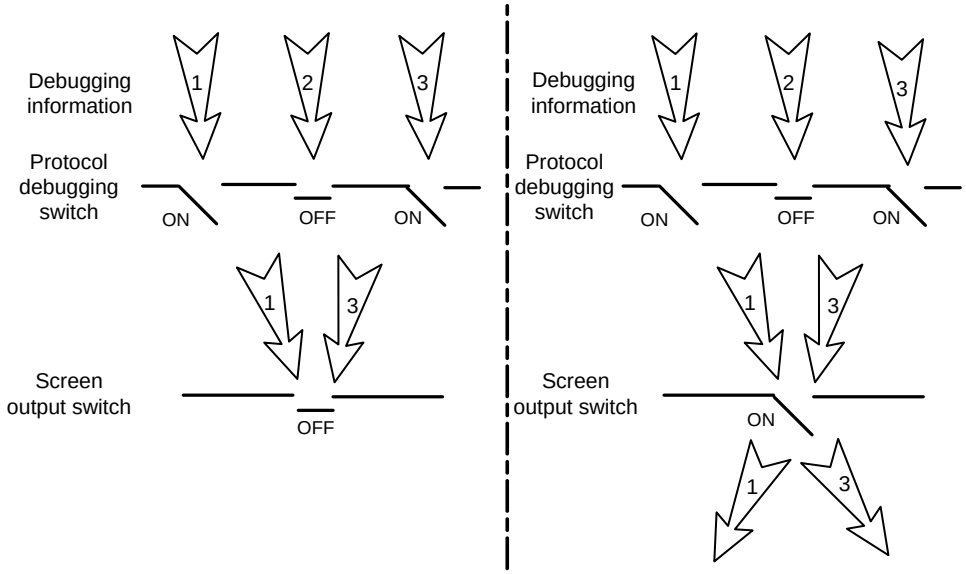
   The output shows that Device A can reach Device B but cannot reach Device C. An error has occurred on the connection between Device B and Device C.

5. To identify the cause of the issue, execute the following commands on Device A and Device C:
   - Execute the **`debugging ip icmp`** command and verify that Device A and Device C can send and receive the correct ICMP packets.
   - Execute the **`display ip routing-table`** command to verify that Device A and Device C have a route to each other.

System debugging

About system debugging

The device supports debugging for the majority of protocols and features, and provides debugging information to help users diagnose errors.



The following switches control the display of debugging information:

- **Module debugging switch**—Controls whether to generate the module-specific debugging information.
- **Screen output switch**—Controls whether to display the debugging information on a certain screen. Use **`terminal monitor`** and **`terminal logging level`** commands to turn on the screen output switch. For more information about these two commands, see *Network Management and Monitoring Command Reference*.

As shown in Figure 5, the device can provide debugging for the three modules 1, 2, and 3. The debugging information can be output on a terminal only when both the module debugging switch and the screen output switch are turned on.

Debugging information is typically displayed on a console. You can also send debugging information to other destinations. For more information, see "Configuring the information center."

Figure 5 Relationship between the module and screen output switch

Debugging a feature module

Restrictions and guidelines

CAUTION:

Output of excessive debugging messages increases the CPU usage and downgrades the system performance. To guarantee system performance, enable debugging only for modules that are in an exceptional condition.

Enable debugging for modules for troubleshooting purposes. When debugging is complete, use the **undo debugging all** command to disable all the debugging functions.

Procedure

1. Enable debugging for a module.

   debugging *module-name* [*option*]

   By default, debugging is disabled for all modules.

   This command is available in user view.

2. (Optional.) Display the enabled debugging features.

   display debugging [*module-name*]

   This command is available in any view.

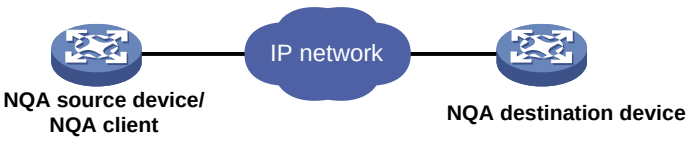
Configuring NQA

About NQA

Network quality analyzer (NQA) allows you to measure network performance, verify the service levels for IP services and applications, and troubleshoot network problems.



NQA operating mechanism

An NQA operation contains a set of parameters such as the operation type, destination IP address, and port number to define how the operation is performed. Each NQA operation is identified by the combination of the administrator name and the operation tag. You can configure the NQA client to run the operations at scheduled time periods.

As shown in Figure 1, the NQA source device (NQA client) sends data to the NQA destination device by simulating IP services and applications to measure network performance.

All types of NQA operations require the NQA client, but only the TCP, UDP echo, UDP jitter, and voice operations require the NQA server. The NQA operations for services that are already provided by the destination device such as FTP do not need the NQA server. You can configure the NQA server to listen and respond to specific IP addresses and ports to meet various test needs.

Figure 1 Network diagram

After starting an NQA operation, the NQA client periodically performs the operation at the interval specified by using the **`frequency`** command.

You can set the number of probes the NQA client performs in an operation by using the **`probe count`** command. For the voice and path jitter operations, the NQA client performs only one probe per operation and the **`probe count`** command is not available.

Collaboration with Track

NQA can collaborate with the Track module to notify application modules of state or performance changes so that the application modules can take predefined actions.

The NQA + Track collaboration is available for the following application modules:

The NQA + Track collaboration is available for the following application modules:

- VRRP.
- Static routing.
- Policy-based routing.
- Traffic redirecting.
- Smart Link.

The following describes how a static route destined for 192.168.0.88 is monitored through collaboration:

1. NQA monitors the reachability to 192.168.0.88.

2. When 192.168.0.88 becomes unreachable, NQA notifies the Track module of the change.
3. The Track module notifies the static routing module of the state change.
4. The static routing module sets the static route to invalid according to a predefined action.

For more information about collaboration, see *High Availability Configuration Guide*.

Threshold monitoring

Threshold monitoring enables the NQA client to take a predefined action when the NQA operation performance metrics violate the specified thresholds.

Table 1 describes the relationships between performance metrics and NQA operation types.

Table 1 Performance metrics and NQA operation types

Performance metric	NQA operation types that can gather the metric
Probe duration	All NQA operation types except UDP jitter, UDP tracert, path jitter, and voice
Number of probe failures	All NQA operation types except UDP jitter, UDP tracert, path jitter, and voice
Round-trip time	ICMP jitter, UDP jitter, and voice
Number of discarded packets	ICMP jitter, UDP jitter, and voice
One-way jitter (source-to-destination or destination-to-source)	ICMP jitter, UDP jitter, and voice
One-way delay (source-to-destination or destination-to-source)	ICMP jitter, UDP jitter, and voice
Calculated Planning Impairment Factor (ICPIF) (see "Configuring the voice operation")	Voice
Mean Opinion Scores (MOS) (see "Configuring the voice operation")	Voice

NQA templates

An NQA template is a set of parameters (such as destination address and port number) that defines how an NQA operation is performed. Features can use the NQA template to collect statistics.

You can create multiple NQA templates on the NQA client. Each template must be identified by a unique template name.

Restrictions and guidelines: NQA configuration

To avoid probe failures, follow these restrictions and guidelines when configuring the listening ports on the NQA client and NQA server:

- Do not specify a well-known port.
- Make sure the specified port number is not used by any services on the device.
  - To obtain the IPv4 addresses and the port numbers in use on this device, see the **Local Addr:port** field in the output from the **`display tcp`** and **`display udp`** commands.

- To obtain the IPv6 addresses and the port numbers in use on this device, see the **LAddr->port** field in the output from the **`display ipv6 tcp`** and **`display ipv6 udp`** commands.

If the source IP address of NQA probe packets has been NATed through the Easy IP feature, the local device might fail to receive NQA response packets, resulting in NQA operation failure. As a best practice, use the **`source interface`**, **`source ip`**, or **`source ipv6`** command to specify the source IP address of NQA probe packets to prevent the source IP address from being translated by NAT. In the output from the **`display nat all`** command, if the **NAT address group information** field contains the output interface IP address of NQA probe packets, or the **NAT outbound information** field contains the output interface of NQA probe packets, the source IP address of NQA probe packets will be NATed by the Easy IP feature. Avoid specifying the IP address and interface when configuring the source IP address. For more information about Easy IP, see NAT configuration in *Layer 3—IP Services Configuration Guide*.

The destination port configured for the operation (with the **`destination port`** command) on the NQA client must be the same as the listening port configured on the server.

During the initial startup phase, the device might not have generated route entries or ARP table entries to reach the destination address of the operation, or the probe packet output interface might not be up, which can result in NQA operation failure.

For latency operation results to be accurate, synchronize time between the source and the destination with an accuracy higher than or equal to the operation result calculation accuracy.

NQA tasks at a glance

To configure NQA, perform the following tasks:

1. Configuring the NQA server

   Perform this task on the destination device before you configure the TCP, UDP echo, UDP jitter, and voice operations.
2. Enabling the NQA client
3. Configuring NQA operations or NQA templates

   Choose the following tasks as needed:

   - Configuring NQA operations on the NQA client
   - Configuring NQA templates on the NQA client

   After you configure an NQA operation, you can schedule the NQA client to run the NQA operation.

   An NQA template does not run immediately after it is configured. The template creates and run the NQA operation only when it is required by the feature to which the template is applied.

Configuring the NQA server

Restrictions and guidelines

To perform TCP, UDP echo, UDP jitter, and voice operations, you must configure the NQA server on the destination device. The NQA server listens and responds to requests on the specified IP addresses and ports.

You can configure multiple TCP or UDP listening services on an NQA server, where each corresponds to a specific IP address and port number.

The IP address, port number, and VPN instance for a listening service must be unique on the NQA server and match the configuration on the NQA client.

Procedure

1. Enter system view.
   system-view
2. Enable the NQA server.
   nqa server enable
   By default, the NQA server is disabled.
3. Configure a TCP listening service.
   nqa server tcp-connect *ip-address port-number* [**vpn-instance** *vpn-instance-name*] [**tos** *tos*]
   This task is required for only TCP and DLSw operations. For the DLSw operation, the port number for the TCP listening service must be 2065.
4. Configure a UDP listening service.
   nqa server udp-echo *ip-address port-number* [**vpn-instance** *vpn-instance-name*] [**tos** *tos*]
   This task is required for only UDP echo, UDP jitter, and voice operations.

Enabling the NQA client

1. Enter system view.
   system-view
2. Enable the NQA client.
   nqa agent enable
   By default, the NQA client is enabled.
   The NQA client configuration takes effect after you enable the NQA client.

Configuring NQA operations on the NQA client

NQA operations tasks at a glance

To configure NQA operations, perform the following tasks:

1. Configuring an NQA operation
   - Configuring the ICMP echo operation
   - Configuring the ICMP jitter operation
   - Configuring the DHCP operation
   - Configuring the DNS operation
   - Configuring the FTP operation
   - Configuring the HTTP operation
   - Configuring the UDP jitter operation
   - Configuring the SNMP operation
   - Configuring the TCP operation
   - Configuring the UDP echo operation
   - Configuring the UDP tracert operation
   - Configuring the voice operation
   - Configuring the DLSw operation

- Configuring the path jitter operation

2. (Optional.) Configuring optional parameters for the NQA operation
3. (Optional.) Configuring the collaboration feature
4. (Optional.) Configuring threshold monitoring
5. (Optional.) Configuring the NQA statistics collection feature
6. (Optional.) Configuring the saving of NQA history records
7. Scheduling the NQA operation on the NQA client

Configuring the ICMP echo operation

About this task

The ICMP echo operation measures the reachability of a destination device. It has the same function as the **ping** command, but provides more output information. In addition, if multiple paths exist between the source and destination devices, you can specify the next hop for the ICMP echo operation.

The ICMP echo operation sends an ICMP echo request to the destination device per probe.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the ICMP echo type and enter its view.

   type icmp-echo

4. Specify the destination IP address for ICMP echo requests.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

5. Specify the source IP address for ICMP echo requests. Choose one option as needed:

   - Use the IP address of the specified interface as the source IP address.

     source interface *interface-type interface-number*

     By default, the source IP address of ICMP echo requests is the primary IP address of their output interface.

     The specified source interface must be up.

   - Specify the source IPv4 address.

     source ip *ip-address*

     By default, the source IPv4 address of ICMP echo requests is the primary IPv4 address of their output interface.

     The specified source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   - Specify the source IPv6 address.

     source ipv6 *ipv6-address*

     By default, the source IPv6 address of ICMP echo requests is the primary IPv6 address of their output interface.

The specified source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. Specify the output interface or the next hop IP address for ICMP echo requests. Choose one option as needed: (If you configure both the output interface and next hop IP address, only the next hop IP address takes effect. To avoid probe failure, make sure the IP address belongs to a directly connected next hop.)
   - Specify the output interface for ICMP echo requests.
     out interface *interface-type interface-number*
     By default, the output interface for ICMP echo requests is not specified. The NQA client determines the output interface based on the routing table lookup.
   - Specify the next hop IPv4 address.
     next-hop ip *ip-address*
     By default, no next hop IPv4 address is specified.
   - Specify the next hop IPv6 address.
     next-hop ipv6 *ipv6-address*
     By default, no next hop IPv6 address is specified.
7. (Optional.) Set the payload size for each ICMP echo request.
   data-size *size*
   The default payload size is 100 bytes.
8. (Optional.) Specify the payload fill string for ICMP echo requests.
   data-fill *string*
   The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring the ICMP jitter operation

About this task

The ICMP jitter operation measures unidirectional and bidirectional jitters. The operation result helps you to determine whether the network can carry jitter-sensitive services such as real-time voice and video services.

The ICMP jitter operation works as follows:

1. The NQA client sends ICMP packets to the destination device.
2. The destination device time stamps each packet it receives, and then sends the packet back to the NQA client.
3. Upon receiving the responses, the NQA client calculates the jitter according to the timestamps.

The ICMP jitter operation sends a number of ICMP packets to the destination device per probe. The number of packets to send is determined by using the **probe packet-number** command.

Restrictions and guidelines

The **display nqa history** command does not display the results or statistics of the ICMP jitter operation. To view the results or statistics of the operation, use the **display nqa result** or **display nqa statistics** command.

Before starting the operation, make sure the network devices are time synchronized by using NTP. For more information about NTP, see "Configuring NTP."

Procedure

1. Enter system view.
   system-view
2. Create an NQA operation and enter NQA operation view.

nqa entry *admin-name operation-tag*

3. Specify the ICMP jitter type and enter its view.
   type icmp-jitter
4. Specify the destination IP address for ICMP packets.
   destination ip *ip-address*
   By default, no destination IP address is specified.
5. Set the number of ICMP packets sent per probe.
   probe packet-number *number*
   The default setting is 10.
6. Set the interval for sending ICMP packets.
   probe packet-interval *interval*
   The default setting is 20 milliseconds.
7. Specify how long the NQA client waits for a response from the server before it regards the response times out.
   probe packet-timeout *timeout*
   The default setting is 3000 milliseconds.
8. Specify the source IP address for ICMP packets.
   source ip *ip-address*
   By default, the source IP address of ICMP packets is the primary IP address of their output interface.
   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no ICMP packets can be sent out.

Configuring the DHCP operation

About this task

The DHCP operation measures whether or not the DHCP server can respond to client requests. DHCP also measures the amount of time it takes the NQA client to obtain an IP address from a DHCP server.

The NQA client simulates the DHCP relay agent to forward DHCP requests for IP address acquisition from the DHCP server. The interface that performs the DHCP operation does not change its IP address. When the DHCP operation completes, the NQA client sends a packet to release the obtained IP address.

The DHCP operation acquires an IP address from the DHCP server per probe.

Procedure

1. Enter system view.
   system-view
2. Create an NQA operation and enter NQA operation view.
   nqa entry *admin-name operation-tag*
3. Specify the DHCP type and enter its view.
   type dhcp
4. Specify the IP address of the DHCP server as the destination IP address of DHCP packets.
   destination ip *ip-address*
   By default, no destination IP address is specified.
5. Specify the output interface for DHCP request packets.

out interface *interface-type interface-number*

By default, the NQA client determines the output interface based on the routing table lookup.

6. Specify the source IP address of DHCP request packets.

   source ip *ip-address*

   By default, the source IP address of DHCP request packets is the primary IP address of their output interface.

   The specified source IP address must be the IP address of a local interface, and the local interface must be up. Otherwise, no probe packets can be sent out.

Configuring the DNS operation

About this task

The DNS operation simulates domain name resolution, and it measures the time for the NQA client to resolve a domain name into an IP address through a DNS server. The obtained DNS entry is not saved.

The DNS operation resolves a domain name into an IP address per probe.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the DNS type and enter its view.

   type dns

4. Specify the IP address of the DNS server as the destination IP address of DNS packets.

   destination ip *ip-address*

   By default, no destination IP address is specified.

5. Specify the domain name to be translated.

   resolve-target *domain-name*

   By default, no domain name is specified.

Configuring the FTP operation

About this task

The FTP operation measures the time for the NQA client to transfer a file to or download a file from an FTP server.

The FTP operation uploads or downloads a file from an FTP server per probe.

Restrictions and guidelines

To upload (**put**) a file to the FTP server, use the **filename** command to specify the name of the file you want to upload. The file must exist on the NQA client.

To download (**get**) a file from the FTP server, include the name of the file you want to download in the **url** command. The file must exist on the FTP server. The NQA client does not save the file obtained from the FTP server.

Use a small file for the FTP operation. A big file might result in transfer failure because of timeout, or might affect other services because of the amount of network bandwidth it occupies.

Procedure

1. Enter system view.
   system-view
2. Create an NQA operation and enter NQA operation view.
   nqa entry *admin-name operation-tag*
3. Specify the FTP type and enter its view.
   type ftp
4. Specify an FTP login username.
   username *username*
   By default, no FTP login username is specified.
5. Specify an FTP login password.
   password { **cipher** | **simple** } *string*
   By default, no FTP login password is specified.
6. Specify the source IP address for FTP request packets.
   source ip *ip-address*
   By default, the source IP address of FTP request packets is the primary IP address of their output interface.
   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no FTP requests can be sent out.
7. Set the data transmission mode.
   mode { **active** | **passive** }
   The default mode is **active**.
8. Specify the FTP operation type.
   operation { **get** | **put** }
   The default FTP operation type is **get**.
9. Specify the destination URL for the FTP operation.
   url *url*
   By default, no destination URL is specified for an FTP operation.
   Enter the URL in one of the following formats:
   - ftp://*host*/*filename*.
   - ftp://*host:port*/*filename*.

   If the value for the *host* parameter is an IPv6 address, you must use a pair of square brackets ([]) to include the IPv6 address, for example, ftp://[2001::1]/test. The *filename* argument is required only for the **get** operation.
10. Specify the name of the file to be uploaded.
    filename *file-name*
    By default, no file is specified.
    This task is required only for the **put** operation.
    The configuration does not take effect for the **get** operation.

Configuring the HTTP operation

About this task

The HTTP operation measures the time for the NQA client to obtain responses from an HTTP server.

The HTTP operation supports the following operation types:

- **Get**—Retrieves data such as a Web page from the HTTP server.
- **Post**—Sends data to the HTTP server for processing.
- **Raw**—Sends a user-defined HTTP request to the HTTP server. You must manually configure the content of the HTTP request to be sent.

The HTTP operation completes the operation of the specified type per probe.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the HTTP type and enter its view.

   type http

4. Specify the destination URL for the HTTP operation.

   url *url*

   By default, no destination URL is specified for an HTTP operation.

   Enter the URL in one of the following formats:

   - http://*host*/*resource*
   - http://*host:port/resource*

   If the value for the *host* parameter is an IPv6 address, you must use a pair of square brackets ([]) to include the IPv6 address, for example, http://[2001::1]/test.

5. Specify an HTTP login username.

   username *username*

   By default, no HTTP login username is specified.

6. Specify an HTTP login password.

   password { **cipher** | **simple** } *string*

   By default, no HTTP login password is specified.

7. Specify the HTTP version.

   version { **v1.0** | **v1.1** }

   By default, HTTP 1.0 is used.

8. Specify the HTTP operation type.

   operation { **get** | **post** | **raw** }

   The default HTTP operation type is **get**.

   If you set the operation type to **raw**, the client pads the content configured in raw request view to the HTTP request to send to the HTTP server.

9. Configure the HTTP raw request.

   a. Enter raw request view.

   raw-request

   Every time you enter raw request view, the previously configured raw request content is cleared.

   b. Enter or paste the request content.

   By default, no request content is configured.

To ensure successful operations, make sure the request content does not contain command aliases configured by using the **alias** command. For more information about the **alias** command, see CLI commands in *Fundamentals Command Reference*.

c. Save the input and return to HTTP operation view:

quit

This step is required only when the operation type is set to **raw**.

10. Specify the source IP address for the HTTP packets.

source ip *ip-address*

By default, the source IP address of HTTP packets is the primary IP address of their output interface.

The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no request packets can be sent out.

Configuring the UDP jitter operation

About this task

The UDP jitter operation measures unidirectional and bidirectional jitters. The operation result helps you determine whether the network can carry jitter-sensitive services such as real-time voice and video services.

The UDP jitter operation works as follows:

1. The NQA client sends UDP packets to the destination port.
2. The destination device time stamps each packet it receives, and then sends the packet back to the NQA client.
3. Upon receiving the responses, the NQA client calculates the jitter according to the timestamps.

The UDP jitter operation sends a number of UDP packets to the destination device per probe. The number of packets to send is determined by using the **probe packet-number** command.

The UDP jitter operation requires both the NQA server and the NQA client. Before you perform the UDP jitter operation, configure the UDP listening service on the NQA server. For more information about UDP listening service configuration, see "Configuring the NQA server."

Restrictions and guidelines

To ensure successful UDP jitter operations and avoid affecting existing services, do not perform the operations on well-known ports from 1 to 1023.

The **display nqa history** command does not display the results or statistics of the UDP jitter operation. To view the results or statistics of the UDP jitter operation, use the **display nqa result** or **display nqa statistics** command.

Before starting the operation, make sure the network devices are time synchronized by using NTP. For more information about NTP, see "Configuring NTP."

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the UDP jitter type and enter its view.

   type udp-jitter

4. Specify the destination IP address for UDP packets.

   destination ip *ip-address*

By default, no destination IP address is specified.

The destination IP address must be the same as the IP address of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

5. Specify the destination port number for UDP packets.

   destination port *port-number*

   By default, no destination port number is specified.

   The destination port number must be the same as the port number of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

6. Specify the source IP address for UDP packets.

   source ip *ip-address*

   By default, the source IP address of UDP packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no UDP packets can be sent out.

7. Specify the source port number for UDP packets.

   source port *port-number*

   By default, the NQA client randomly picks an unused port as the source port when the operation starts.

   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.

8. Set the number of UDP packets sent per probe.

   probe packet-number *number*

   The default setting is 10.

9. Set the interval for sending UDP packets.

   probe packet-interval *interval*

   The default setting is 20 milliseconds.

10. Specify how long the NQA client waits for a response from the server before it regards the response times out.

    probe packet-timeout *timeout*

    The default setting is 3000 milliseconds.

11. (Optional.) Set the payload size for each UDP packet.

    data-size *size*

    The default payload size is 100 bytes.

12. (Optional.) Specify the payload fill string for UDP packets.

    data-fill *string*

    The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring the SNMP operation

About this task

The SNMP operation tests whether the SNMP service is available on an SNMP agent.

The SNMP operation sends one SNMPv1 packet, one SNMPv2c packet, and one SNMPv3 packet to the SNMP agent per probe.

Procedure

1. Enter system view.
   system-view
2. Create an NQA operation and enter NQA operation view.
   nqa entry *admin-name operation-tag*
3. Specify the SNMP type and enter its view.
   type snmp
4. Specify the destination address for SNMP packets.
   destination ip *ip-address*
   By default, no destination IP address is specified.
5. Specify the source IP address for SNMP packets.
   source ip *ip-address*
   By default, the source IP address of SNMP packets is the primary IP address of their output interface.
   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no SNMP packets can be sent out.
6. Specify the source port number for SNMP packets.
   source port *port-number*
   By default, the NQA client randomly picks an unused port as the source port when the operation starts.
   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.
7. Specify the community name carried in the SNMPv1 and SNMPv2c packets.
   community read { **cipher** | **simple** } *community-name*
   By default, the SNMPv1 and SNMPv2c packets carry community name **public**.
   Make sure the specified community name is the same as the community name configured on the SNMP agent.

Configuring the TCP operation

About this task

The TCP operation measures the time for the NQA client to establish a TCP connection to a port on the NQA server.

The TCP operation requires both the NQA server and the NQA client. Before you perform a TCP operation, configure a TCP listening service on the NQA server. For more information about the TCP listening service configuration, see "Configuring the NQA server."

The TCP operation sets up a TCP connection per probe.

Procedure

1. Enter system view.
   system-view
2. Create an NQA operation and enter NQA operation view.
   nqa entry *admin-name operation-tag*
3. Specify the TCP type and enter its view.
   type tcp
4. Specify the destination address for TCP packets.

destination ip *ip-address*

By default, no destination IP address is specified.

The destination address must be the same as the IP address of the TCP listening service configured on the NQA server. To configure a TCP listening service on the server, use the **nqa server tcp-connect** command.

5. Specify the destination port for TCP packets.

   destination port *port-number*

   By default, no destination port number is configured.

   The destination port number must be the same as the port number of the TCP listening service configured on the NQA server. To configure a TCP listening service on the server, use the **nqa server tcp-connect** command.

6. Specify the source IP address for TCP packets.

   source ip *ip-address*

   By default, the source IP address of TCP packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no TCP packets can be sent out.

Configuring the UDP echo operation

About this task

The UDP echo operation measures the round-trip time between the client and a UDP port on the NQA server.

The UDP echo operation requires both the NQA server and the NQA client. Before you perform a UDP echo operation, configure a UDP listening service on the NQA server. For more information about the UDP listening service configuration, see "Configuring the NQA server."

The UDP echo operation sends a UDP packet to the destination device per probe.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the UDP echo type and enter its view.

   type udp-echo

4. Specify the destination address for UDP packets.

   destination ip *ip-address*

   By default, no destination IP address is specified.

   The destination address must be the same as the IP address of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

5. Specify the destination port number for UDP packets.

   destination port *port-number*

   By default, no destination port number is specified.

   The destination port number must be the same as the port number of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

6. Specify the source IP address for UDP packets.

   source ip *ip-address*

   By default, the source IP address of UDP packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no UDP packets can be sent out.

7. Specify the source port number for UDP packets.

   source port *port-number*

   By default, the NQA client randomly picks an unused port as the source port when the operation starts.

   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.

8. (Optional.) Set the payload size for each UDP packet.

   data-size *size*

   The default setting is 100 bytes.

9. (Optional.) Specify the payload fill string for UDP packets.

   data-fill *string*

   The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring the UDP tracert operation

About this task

The UDP tracert operation determines the routing path from the source device to the destination device.

The UDP tracert operation sends a UDP packet to a hop along the path per probe.

Restrictions and guidelines

The UDP tracert operation is not supported on IPv6 networks. To determine the routing path that the IPv6 packets traverse from the source to the destination, use the **tracert ipv6** command. For more information about the command, see *Network Management and Monitoring Command Reference.*

Prerequisites

Before you configure the UDP tracert operation, you must perform the following tasks:

- Enable sending ICMP time exceeded messages on the intermediate devices between the source and destination devices. If the intermediate devices are H3C devices, use the **ip ttl-expires enable** command.
- Enable sending ICMP destination unreachable messages on the destination device. If the destination device is an H3C device, use the **ip unreachables enable** command.

  For more information about the **ip ttl-expires enable** and **ip unreachables enable** commands, see *Layer 3—IP Services Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*

3. Specify the UDP tracert operation type and enter its view.

type udp-tracert

4. Specify the destination device for the operation. Choose one option as needed:
   - Specify the destination device by its host name.

     destination host *host-name*

     By default, no destination host name is specified.
   - Specify the destination device by its IP address.

     destination ip *ip-address*

     By default, no destination IP address is specified.
5. Specify the destination port number for UDP packets.

   destination port *port-number*

   By default, the destination port number is 33434.

   This port number must be an unused number on the destination device, so that the destination device can reply with ICMP port unreachable messages.
6. Specify an output interface for UDP packets.

   out interface *interface-type interface-number*

   By default, the NQA client determines the output interface based on the routing table lookup.
7. Specify the source IP address for UDP packets.
   - Specify the IP address of the specified interface as the source IP address.

     source interface *interface-type interface-number*

     By default, the source IP address of UDP packets is the primary IP address of their output interface.
   - Specify the source IP address.

     source ip *ip-address*

     The specified source interface must be up. The source IP address must be the IP address of a local interface, and the local interface must be up. Otherwise, no probe packets can be sent out.
8. Specify the source port number for UDP packets.

   source port *port-number*

   By default, the NQA client randomly picks an unused port as the source port when the operation starts.

   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.
9. Set the maximum number of consecutive probe failures.

   max-failure *times*

   The default setting is 5.
10. Set the initial TTL value for UDP packets.

    init-ttl *value*

    The default setting is 1.
11. (Optional.) Set the payload size for each UDP packet.

    data-size *size*

    The default setting is 100 bytes.
12. (Optional.) Enable the no-fragmentation feature.

    no-fragment enable

    By default, the no-fragmentation feature is disabled.

Configuring the voice operation

About this task

The voice operation measures VoIP network performance.

The voice operation works as follows:

1. The NQA client sends voice packets at sending intervals to the destination device (NQA server).

   The voice packets are of one of the following codec types:

   - G.711 A-law.
   - G.711 μ-law.
   - G.729 A-law.
2. The destination device time stamps each voice packet it receives and sends it back to the source.
3. Upon receiving the packet, the source device calculates the jitter and one-way delay based on the timestamp.

The voice operation sends a number of voice packets to the destination device per probe. The number of packets to send per probe is determined by using the **probe packet-number** command.

The following parameters that reflect VoIP network performance can be calculated by using the metrics gathered by the voice operation:

- **Calculated Planning Impairment Factor (ICPIF)**—Measures impairment to voice quality on a VoIP network. It is decided by packet loss and delay. A higher value represents a lower service quality.
- **Mean Opinion Scores (MOS)**—A MOS value can be evaluated by using the ICPIF value, in the range of 1 to 5. A higher value represents a higher service quality.

The evaluation of voice quality depends on users' tolerance for voice quality. For users with higher tolerance for voice quality, use the **advantage-factor** command to set an advantage factor. When the system calculates the ICPIF value, it subtracts the advantage factor to modify ICPIF and MOS values for voice quality evaluation.

The voice operation requires both the NQA server and the NQA client. Before you perform a voice operation, configure a UDP listening service on the NQA server. For more information about UDP listening service configuration, see "Configuring the NQA server."

Restrictions and guidelines

To ensure successful voice operations and avoid affecting existing services, do not perform the operations on well-known ports from 1 to 1023.

The **display nqa history** command does not display the results or statistics of the voice operation. To view the results or statistics of the voice operation, use the **display nqa result** or **display nqa statistics** command.

Before starting the operation, make sure the network devices are time synchronized by using NTP. For more information about NTP, see "Configuring NTP."

Procedure

1. Enter system view.

   system-view
2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*
3. Specify the voice type and enter its view.

type voice

4. Specify the destination IP address for voice packets.

   destination ip *ip-address*

   By default, no destination IP address is configured.

   The destination IP address must be the same as the IP address of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

5. Specify the destination port number for voice packets.

   destination port *port-number*

   By default, no destination port number is configured.

   The destination port number must be the same as the port number of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

6. Specify the source IP address for voice packets.

   source ip *ip-address*

   By default, the source IP address of voice packets is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no voice packets can be sent out.

7. Specify the source port number for voice packets.

   source port *port-number*

   By default, the NQA client randomly picks an unused port as the source port when the operation starts.

   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.

8. Configure the basic voice operation parameters.
   - Specify the codec type.

     codec-type { **g711a** | **g711u** | **g729a** }

     By default, the codec type is G.711 A-law.
   - Set the advantage factor for calculating MOS and ICPIF values.

     advantage-factor *factor*

     By default, the advantage factor is 0.

9. Configure the probe parameters for the voice operation.
   - Set the number of voice packets to be sent per probe.

     probe packet-number *number*

     The default setting is 1000.
   - Set the interval for sending voice packets.

     probe packet-interval *interval*

     The default setting is 20 milliseconds.
   - Specify how long the NQA client waits for a response from the server before it regards the response times out.

     probe packet-timeout *timeout*

     The default setting is 5000 milliseconds.

10. Configure the payload parameters.

    a. Set the payload size for voice packets.

    data-size *size*

By default, the voice packet size varies by codec type. The default packet size is 172 bytes for G.711A-law and G.711 μ-law codec type, and 32 bytes for G.729 A-law codec type.

b. (Optional.) Specify the payload fill string for voice packets.

data-fill *string*

The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring the DLSw operation

About this task

The DLSw operation measures the response time of a DLSw device.

It sets up a DLSw connection to the DLSw device per probe.

Restrictions and guidelines

For the DLSw operation to succeed, configure the **nqa server tcp-connect** command on the NQA server and make sure the port number for the TCP listening service is 2065.

Procedure

1. Enter system view.

system-view

2. Create an NQA operation and enter NQA operation view.

nqa entry *admin-name operation-tag*

3. Specify the DLSw type and enter its view.

type dlsw

4. Specify the destination IP address for the probe packets.

destination ip *ip-address*

By default, no destination IP address is specified.

5. Specify the source IP address for the probe packets.

source ip *ip-address*

By default, the source IP address of the probe packets is the primary IP address of their output interface.

The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

Configuring the path jitter operation

About this task

The path jitter operation measures the jitter, negative jitters, and positive jitters from the NQA client to each hop on the path to the destination.

The path jitter operation performs the following steps per probe:

1. Obtains the path from the NQA client to the destination through tracert. A maximum of 64 hops can be detected.

2. Sends a number of ICMP echo requests to each hop along the path. The number of ICMP echo requests to send is set by using the **probe packet-number** command.

Prerequisites

Before you configure the path jitter operation, you must perform the following tasks:

- Enable sending ICMP time exceeded messages on the intermediate devices between the source and destination devices. If the intermediate devices are H3C devices, use the **ip ttl-expires enable** command.
- Enable sending ICMP destination unreachable messages on the destination device. If the destination device is an H3C device, use the **ip unreachables enable** command.

  For more information about the **ip ttl-expires enable** and **ip unreachables enable** commands, see *Layer 3—IP Services Command Reference*.

Procedure

1. Enter system view.

   system-view
2. Create an NQA operation and enter NQA operation view.

   nqa entry *admin-name operation-tag*
3. Specify the path jitter type and enter its view.

   type path-jitter
4. Specify the destination IP address for ICMP echo requests.

   destination ip *ip-address*

   By default, no destination IP address is specified.
5. Specify the source IP address for ICMP echo requests.

   source ip *ip-address*

   By default, the source IP address of ICMP echo requests is the primary IP address of their output interface.

   The source IP address must be the IP address of a local interface, and the interface must be up. Otherwise, no ICMP echo requests can be sent out.
6. Configure the probe parameters for the path jitter operation.
   a. Set the number of ICMP echo requests to be sent per probe.

      probe packet-number *number*

      The default setting is 10.
   b. Set the interval for sending ICMP echo requests.

      probe packet-interval *interval*

      The default setting is 20 milliseconds.
   c. Specify how long the NQA client waits for a response from the server before it regards the response times out.

      probe packet-timeout *timeout*

      The default setting is 3000 milliseconds.
7. (Optional.) Specify an LSR path.

   lsr-path *ip-address*&<1-8>

   By default, no LSR path is specified.

   The path jitter operation uses tracert to detect the LSR path to the destination, and sends ICMP echo requests to each hop on the LSR path.
8. Perform the path jitter operation only on the destination address.

   target-only

   By default, the path jitter operation is performed on each hop on the path to the destination.
9. (Optional.) Set the payload size for each ICMP echo request.

   data-size *size*

   The default setting is 100 bytes.

10. (Optional.) Specify the payload fill string for ICMP echo requests.

    data-fill *string*

    The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring optional parameters for the NQA operation

Restrictions and guidelines

The parameter settings take effect only on the current operation.

The supported parameters vary by NQA operation type. For information about supported parameters, see NQA commands in *Network Management and Monitoring Command Reference*.

Procedure

1. Enter system view.

   system-view

2. Enter the view of an existing NQA operation.

   nqa entry *admin-name operation-tag*

3. Specify an NQA operation type and enter its view.

   type { **dhcp** | **dlsw** | **dns** | **ftp** | **http** | **icmp-echo** | **icmp-jitter** | **path-jitter** | **snmp** | **tcp** | **udp-echo** | **udp-jitter** | **udp-tracert** | **voice** }

4. Configure a description for the operation.

   description *text*

   By default, no description is configured.

5. Set the interval at which the NQA operation repeats.

   frequency *interval*

   For a voice or path jitter operation, the default setting is 60000 milliseconds.

   For other types of operations, the default setting is 0 milliseconds, and only one operation is performed.

   When the interval expires, but the operation is not completed or is not timed out, the next operation does not start.

6. Specify the probe times.

   probe count *times*

   In an UDP tracert operation, the NQA client performs three probes to each hop to the destination by default.

   In other types of operations, the NQA client performs one probe to the destination per operation by default.

   This command is not available for the voice and path jitter operations. Each of these operations performs only one probe.

7. Set the probe timeout time.

   probe timeout *timeout*

   The default setting is 3000 milliseconds.

8. Set the maximum number of hops that the probe packets can traverse.

   ttl *value*

   The default setting is 30 for probe packets of the UDP tracert operation, and is 20 for probe packets of other types of operations.

9. Set the ToS value in the IP header of the probe packets.

   tos *value*

The default setting is 0.

10. Enable the routing table bypass feature.

    route-option bypass-route

    By default, the routing table bypass feature is disabled.

    This command does not take effect if the destination address of the NQA operation is an IPv6 address.

11. Specify the VPN instance where the operation is performed.

    vpn-instance *vpn-instance-name*

    By default, the operation is performed on the public network.

Configuring the collaboration feature

About this task

Collaboration is implemented by associating a reaction entry of an NQA operation with a track entry. The reaction entry monitors the NQA operation. If the number of operation failures reaches the specified threshold, the configured action is triggered.

Restrictions and guidelines

The collaboration feature is not available for the following types of operations:

- ICMP jitter operation.
- UDP jitter operation.
- UDP tracert operation.
- Voice operation.
- Path jitter operation.

Procedure

1. Enter system view.

   system-view

2. Enter the view of an existing NQA operation.

   nqa entry *admin-name operation-tag*

3. Configure a reaction entry.

   reaction *item-number* **checked-element probe-fail threshold-type consecutive** *consecutive-occurrences* **action-type trigger-only**

   You cannot modify the content of an existing reaction entry.

4. Return to system view.

   quit

5. Associate Track with NQA.

   For information about the configuration, see *High Availability Configuration Guide*.

6. Associate Track with an application module.

   For information about the configuration, see *High Availability Configuration Guide*.

Configuring threshold monitoring

About this task

This feature allows you to monitor the NQA operation running status.

An NQA operation supports the following threshold types:

- **average**—If the average value for the monitored performance metric either exceeds the upper threshold or goes below the lower threshold, a threshold violation occurs.
- **accumulate**—If the total number of times that the monitored performance metric is out of the specified value range reaches or exceeds the specified threshold, a threshold violation occurs.
- **consecutive**—If the number of consecutive times that the monitored performance metric is out of the specified value range reaches or exceeds the specified threshold, a threshold violation occurs.

Threshold violations for the average or accumulate threshold type are determined on a per NQA operation basis. The threshold violations for the consecutive type are determined from the time the NQA operation starts.

The following actions might be triggered:

- **none**—NQA displays results only on the terminal screen. It does not send traps to the NMS.
- **trap-only**—NQA displays results on the terminal screen, and meanwhile it sends traps to the NMS.

  To send traps to the NMS, the NMS address must be specified by using the **snmp-agent target-host** command. For more information about the command, see *Network Management and Monitoring Command Reference*.
- **trigger-only**—NQA displays results on the terminal screen, and meanwhile triggers other modules for collaboration.

In a reaction entry, configure a monitored element, a threshold type, and an action to be triggered to implement threshold monitoring.

The state of a reaction entry can be invalid, over-threshold, or below-threshold.

- Before an NQA operation starts, the reaction entry is in invalid state.
- If the threshold is violated, the state of the entry is set to over-threshold. Otherwise, the state of the entry is set to below-threshold.

Restrictions and guidelines

The threshold monitoring feature is not available for the path jitter operations.

Procedure

1. Enter system view.

   system-view
2. Enter the view of an existing NQA operation.

   nqa entry *admin-name operation-tag*
3. Enable sending traps to the NMS when specific conditions are met.

   reaction trap { **path-change** | **probe-failure** *consecutive-probe-failures* | **test-complete** | **test-failure** [*accumulate-probe-failures*] }

   By default, no traps are sent to the NMS.

   The ICMP jitter, UDP jitter, and voice operations support only the **test-complete** keyword.

   The following parameters are not available for the UDP tracert operation:

   - The **probe-failure** *consecutive-probe-failures* option.
   - The *accumulate-probe-failures* argument.
4. Configure threshold monitoring. Choose the options to configure as needed:

   - Monitor the operation duration.

     reaction *item-number* **checked-element probe-duration threshold-type** { **accumulate** *accumulate-occurrences* | **average** |

consecutive *consecutive-occurrences* } **threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

This reaction entry is not supported in the ICMP jitter, UDP jitter, UDP tracert, or voice operations

- Monitor failure times.

  reaction *item-number* **checked-element probe-fail threshold-type** { **accumulate** *accumulate-occurrences* | **consecutive** *consecutive-occurrences* } [**action-type** { **none** | **trap-only** }]

  This reaction entry is not supported in the ICMP jitter, UDP jitter, UDP tracert, or voice operations.

- Monitor the round-trip time.

  reaction *item-number* **checked-element rtt threshold-type** { **accumulate** *accumulate-occurrences* | **average** } **threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

  Only the ICMP jitter, UDP jitter, and voice operations support this reaction entry.

- Monitor packet loss.

  reaction *item-number* **checked-element packet-loss threshold-type accumulate** *accumulate-occurrences* [**action-type** { **none** | **trap-only** }]

  Only the ICMP jitter, UDP jitter, and voice operations support this reaction entry.

- Monitor the one-way jitter.

  reaction *item-number* **checked-element** { **jitter-ds** | **jitter-sd** } **threshold-type** { **accumulate** *accumulate-occurrences* | **average** } **threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

  Only the ICMP jitter, UDP jitter, and voice operations support this reaction entry.

- Monitor the one-way delay.

  reaction *item-number* **checked-element** { **owd-ds** | **owd-sd** } **threshold-value** *upper-threshold lower-threshold*

  Only the ICMP jitter, UDP jitter, and voice operations support this reaction entry.

- Monitor the ICPIF value.

  reaction *item-number* **checked-element icpif threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

  Only the voice operation supports this reaction entry.

- Monitor the MOS value.

  reaction *item-number* **checked-element mos threshold-value** *upper-threshold lower-threshold* [**action-type** { **none** | **trap-only** }]

  Only the voice operation supports this reaction entry.

The DNS operation does not support the action of sending trap messages. For the DNS operation, the action type can only be **none**.

Configuring the NQA statistics collection feature

About this task

NQA forms statistics within the same collection interval as a statistics group. To display information about the statistics groups, use the **display nqa statistics** command.

When the maximum number of statistics groups is reached, the NQA client deletes the oldest statistics group to save a new one.

A statistics group is automatically deleted when its hold time expires.

Restrictions and guidelines

The NQA statistics collection feature is not available for the UDP tracert operations.

If you use the **frequency** command to set the interval to 0 milliseconds for an NQA operation, NQA does not generate any statistics group for the operation.

Procedure

1. Enter system view.
   system-view
2. Enter the view of an existing NQA operation.
   nqa entry *admin-name operation-tag*
3. Set the statistics collection interval.
   statistics interval *interval*
   The default setting is 60 minutes.
4. Set the maximum number of statistics groups that can be saved.
   statistics max-group *number*
   By default, the NQA client can save a maximum of two statistics groups for an operation.
   To disable the NQA statistics collection feature, set the *number* argument to 0.
5. Set the hold time of statistics groups.
   statistics hold-time *hold-time*
   The default setting is 120 minutes.

Configuring the saving of NQA history records

About this task

This task enables the NQA client to save NQA history records. You can use the **display nqa history** command to display the NQA history records.

Restrictions and guidelines

The NQA history record saving feature is not available for the following types of operations:

- ICMP jitter operation.
- UDP jitter operation.
- Voice operation.
- Path jitter operation.

Procedure

1. Enter system view.
   system-view
2. Enter the view of an existing NQA operation.
   nqa entry *admin-name operation-tag*
3. Enable the saving of history records for the NQA operation.
   history-record enable
   By default, this feature is enabled only for the UDP tracert operation.
4. Set the lifetime of history records.
   history-record keep-time *keep-time*

The default setting is 120 minutes.

A record is deleted when its lifetime is reached.

5. Set the maximum number of history records that can be saved.

   history-record number *number*

   The default setting is 50.

   When the maximum number of history records is reached, the system will delete the oldest record to save a new one.

Scheduling the NQA operation on the NQA client

About this task

The NQA operation runs between the specified start time and end time (the start time plus operation duration). If the specified start time is ahead of the system time, the operation starts immediately. If both the specified start and end time are ahead of the system time, the operation does not start. To display the current system time, use the **display clock** command.

Restrictions and guidelines

You cannot enter the operation type view or the operation view of a scheduled NQA operation.

A system time adjustment does not affect started or completed NQA operations. It affects only the NQA operations that have not started.

Procedure

1. Enter system view.

   system-view

2. Specify the scheduling parameters for an NQA operation.

   nqa schedule *admin-name operation-tag* **start-time** { *hh:mm:ss* [*yyyy/mm/dd* | *mm/dd/yyyy*] | **now** } **lifetime** { *lifetime* | **forever** } [**recurring**]

Configuring NQA templates on the NQA client

Restrictions and guidelines

Some operation parameters for an NQA template can be specified by the template configuration or the feature that uses the template. When both are specified, the parameters in the template configuration take effect.

NQA template tasks at a glance

To configure NQA templates, perform the following tasks:

1. Perform at least one of the following tasks:
   - Configuring the ICMP template
   - Configuring the DNS template
   - Configuring the TCP template
   - Configuring the TCP half open template
   - Configuring the UDP template
   - Configuring the HTTP template
   - Configuring the HTTPS template

- Configuring the FTP template
- Configuring the RADIUS template
- Configuring the SSL template

2. (Optional.) Configuring optional parameters for the NQA template

Configuring the ICMP template

About this task

A feature that uses the ICMP template performs the ICMP operation to measure the reachability of a destination device. The ICMP template is supported on both IPv4 and IPv6 networks.

Procedure

1. Enter system view.

   system-view

2. Create an ICMP template and enter its view.

   nqa template icmp *name*

3. Specify the destination IP address for the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is configured.

4. Specify the source IP address for ICMP echo requests. Choose one option as needed:
   - Use the IP address of the specified interface as the source IP address.

     source interface *interface-type interface-number*

     By default, the primary IP address of the output interface is used as the source IP address of ICMP echo requests.

     The specified source interface must be up.
   - Specify the source IPv4 address.

     source ip *ip-address*

     By default, the primary IPv4 address of the output interface is used as the source IPv4 address of ICMP echo requests.

     The specified source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.
   - Specify the source IPv6 address.

     source ipv6 *ipv6-address*

     By default, the primary IPv6 address of the output interface is used as the source IPv6 address of ICMP echo requests.

     The specified source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

5. Specify the next hop IP address for ICMP echo requests.

   IPv4:

   next-hop ip *ip-address*

   IPv6:

   next-hop ipv6 *ipv6-address*

   By default, no IP address of the next hop is configured.

To avoid probe failure, make sure the IP address belongs to a directly connected next hop.

6. Configure the probe result sending on a per-probe basis.

   reaction trigger per-probe

   By default, the probe result is sent to the feature that uses the template after three consecutive failed or successful probes.

   If you execute the **reaction trigger per-probe** and **reaction trigger probe-pass** commands multiple times, the most recent configuration takes effect.

   If you execute the **reaction trigger per-probe** and **reaction trigger probe-fail** commands multiple times, the most recent configuration takes effect.

7. (Optional.) Set the payload size for each ICMP request.

   data-size *size*

   The default setting is 100 bytes.

8. (Optional.) Specify the payload fill string for ICMP echo requests.

   data-fill *string*

   The default payload fill string is the hexadecimal string 00010203040506070809.

Configuring the DNS template

About this task

A feature that uses the DNS template performs the DNS operation to determine the status of the server. The DNS template is supported on both IPv4 and IPv6 networks.

In DNS template view, you can specify the address expected to be returned. If the returned IP addresses include the expected address, the DNS server is valid and the operation succeeds. Otherwise, the operation fails.

Prerequisites

Create a mapping between the domain name and an address before you perform the DNS operation. For information about configuring the DNS server, see documents about the DNS server configuration.

Procedure

1. Enter system view.

   system-view

2. Create a DNS template and enter DNS template view.

   nqa template dns *name*

3. Specify the destination IP address for the probe packets.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination address is specified.

4. Specify the destination port number for the probe packets.

   destination port *port-number*

   By default, the destination port number is 53.

5. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

By default, the source IPv4 address of the probe packets is the primary IPv4 address of their output interface.

The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

IPv6:

source ipv6 *ipv6-address*

By default, the source IPv6 address of the probe packets is the primary IPv6 address of their output interface.

The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. Specify the source port number for the probe packets.

   source port *port-number*

   By default, the NQA client randomly picks an unused port as the source port when the operation starts.

   For the operation to succeed, make sure the specified port number is not used by any services on the device. As a best practice, use the default value.

7. Specify the domain name to be translated.

   resolve-target *domain-name*

   By default, no domain name is specified.

8. Specify the domain name resolution type.

   resolve-type { **A** | **AAAA** }

   By default, the type is type A.

   A type A query resolves a domain name to a mapped IPv4 address, and a type AAAA query to a mapped IPv6 address.

9. (Optional.) Specify the IP address that is expected to be returned.

   IPv4:

   expect ip *ip-address*

   IPv6:

   expect ipv6 *ipv6-address*

   By default, no expected IP address is specified.

Configuring the TCP template

About this task

A feature that uses the TCP template performs the TCP operation to test whether the NQA client can establish a TCP connection to a specific port on the server.

In TCP template view, you can specify the expected data to be returned. If you do not specify the expected data, the TCP operation tests only whether the client can establish a TCP connection to the server.

The TCP operation requires both the NQA server and the NQA client. Before you perform a TCP operation, configure a TCP listening service on the NQA server. For more information about the TCP listening service configuration, see "Configuring the NQA server."

Procedure

1. Enter system view.

   system-view

2. Create a TCP template and enter its view.

nqa template tcp *name*

3. Specify the destination IP address for the probe packets.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

   The destination address must be the same as the IP address of the TCP listening service configured on the NQA server. To configure a TCP listening service on the server, use the **nqa server tcp-connect** command.

4. Specify the destination port number for the operation.

   destination port *port-number*

   By default, no destination port number is specified.

   The destination port number must be the same as the port number of the TCP listening service configured on the NQA server. To configure a TCP listening service on the server, use the **nqa server tcp-connect** command.

5. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. (Optional.) Specify the payload fill string for the probe packets.

   data-fill *string*

   The default payload fill string is the hexadecimal string 00010203040506070809.

7. (Optional.) Configure the expected data.

   expect data *expression* [**offset** *number*]

   By default, no expected data is configured.

   The NQA client performs expect data check only when you configure both the **data-fill** and **expect-data** commands.

Configuring the TCP half open template

About this task

A feature that uses the TCP half open template performs the TCP half open operation to test whether the TCP service is available on the server. The TCP half open operation is used when the feature cannot get a response from the TCP server through an existing TCP connection.

In the TCP half open operation, the NQA client sends a TCP ACK packet to the server. If the client receives an RST packet, it considers that the TCP service is available on the server.

Procedure

1. Enter system view.

   system-view

2. Create a TCP half open template and enter its view.

   nqa template tcphalfopen *name*

3. Specify the destination IP address of the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

   The destination address must be the same as the IP address of the TCP listening service configured on the NQA server. To configure a TCP listening service on the server, use the **nqa server tcp-connect** command.

4. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

5. Specify the next hop IP address for the probe packets.

   IPv4:

   next-hop ip *ip-address*

   IPv6:

   next-hop ipv6 *ipv6-address*

   By default, the IP address of the next hop is configured.

   To avoid probe failure, make sure the IP address belongs to a directly connected next hop.

6. Configure the probe result sending on a per-probe basis.

   reaction trigger per-probe

   By default, the probe result is sent to the feature that uses the template after three consecutive failed or successful probes.

   If you execute the **reaction trigger per-probe** and **reaction trigger probe-pass** commands multiple times, the most recent configuration takes effect.

   If you execute the **reaction trigger per-probe** and **reaction trigger probe-fail** commands multiple times, the most recent configuration takes effect.

Configuring the UDP template

About this task

A feature that uses the UDP template performs the UDP operation to test the following items:

- Reachability of a specific port on the NQA server.
- Availability of the requested service on the NQA server.

In UDP template view, you can specify the expected data to be returned. If you do not specify the expected data, the UDP operation tests only whether the client can receive the response packet from the server.

The UDP operation requires both the NQA server and the NQA client. Before you perform a UDP operation, configure a UDP listening service on the NQA server. For more information about the UDP listening service configuration, see "Configuring the NQA server."

Procedure

1. Enter system view.

   system-view

2. Create a UDP template and enter its view.

   nqa template udp *name*

3. Specify the destination IP address of the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

   The destination address must be the same as the IP address of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

4. Specify the destination port number for the operation.

   destination port *port-number*

   By default, no destination port number is specified.

   The destination port number must be the same as the port number of the UDP listening service configured on the NQA server. To configure a UDP listening service on the server, use the **nqa server udp-echo** command.

5. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. Specify the payload fill string for the probe packets.

   data-fill *string*

   The default payload fill string is the hexadecimal string 00010203040506070809.

7. (Optional.) Set the payload size for the probe packets.

   data-size *size*

   The default setting is 100 bytes.

8. (Optional.) Configure the expected data.

   expect data *expression* [**offset** *number*]

   By default, no expected data is configured.

   Expected data check is performed only when both the **data-fill** command and the **expect data** command are configured.

Configuring the HTTP template

About this task

A feature that uses the HTTP template performs the HTTP operation to measure the time it takes the NQA client to obtain data from an HTTP server.

The expected data is checked only when the data is configured and the HTTP response contains the Content-Length field in the HTTP header.

The status code of the HTTP packet is a three-digit field in decimal notation, and it includes the status information for the HTTP server. The first digit defines the class of response.

Prerequisites

Before you perform the HTTP operation, you must configure the HTTP server.

Procedure

1. Enter system view.

   system-view

2. Create an HTTP template and enter its view.

   nqa template http *name*

3. Specify the destination URL for the HTTP template.

   url *url*

   By default, no destination URL is specified for an HTTP template.

   Enter the URL in one of the following formats:

   - http://*host*/*resource*
   - http://*host*:*port*/*resource*

   If the value for the *host* parameter is an IPv6 address, you must use a pair of square brackets ([]) to include the IPv6 address, for example, http://[2001::1]/test.

4. Specify an HTTP login username.

   username *username*

   By default, no HTTP login username is specified.

5. Specify an HTTP login password.

   password { **cipher** | **simple** } *string*

   By default, no HTTP login password is specified.

6. Specify the HTTP version.

   version { **v1.0** | **v1.1** }

By default, HTTP 1.0 is used.

7. Specify the HTTP operation type.

   operation { **get** | **post** | **raw** }

   By default, the HTTP operation type is **get**.

   If you set the operation type to raw, the client pads the content configured in raw request view to the HTTP request to send to the HTTP server.

8. Configure the content of the HTTP raw request.

   a. Enter raw request view.

      raw-request

      Every time you enter raw request view, the previously configured raw request content is cleared.

   b. Enter or paste the request content.

      By default, no request content is configured.

      To ensure successful operations, make sure the request content does not contain command aliases configured by using the **alias** command. For more information about the **alias** command, see CLI commands in *Fundamentals Command Reference*.

   c. Return to HTTP template view.

      quit

      The system automatically saves the configuration in raw request view before it returns to HTTP template view.

   This step is required only when the operation type is set to **raw**.

9. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IPv4 address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

10. (Optional.) Configure the expected status codes.

    expect status *status-list*

    By default, no expected status code is configured.

11. (Optional.) Configure the expected data.

    expect data *expression* [**offset** *number*]

    By default, no expected data is configured.

Configuring the HTTPS template

About this task

A feature that uses the HTTPS template performs the HTTPS operation to measure the time it takes for the NQA client to obtain data from an HTTPS server.

The expected data is checked only when the expected data is configured and the HTTPS response contains the Content-Length field in the HTTPS header.

The status code of the HTTPS packet is a three-digit field in decimal notation, and it includes the status information for the HTTPS server. The first digit defines the class of response.

Prerequisites

Before you perform the HTTPS operation, configure the HTTPS server and the SSL client policy for the SSL client. For information about configuring SSL client policies, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Create an HTTPS template and enter its view.

   nqa template https *name*

3. Specify the destination URL for the HTTPS template.

   url *url*

   By default, no destination URL is specified for an HTTPS template.

   Enter the URL in one of the following formats:

   - https://*host*/*resource*
   - https://*host*:*port*/*resource*

   If the value for the *host* parameter is an IPv6 address, you must use a pair of square brackets ([]) to include the IPv6 address, for example, https://[2001::1]/test.

4. Specify an HTTPS login username.

   username *username*

   By default, no HTTPS login username is specified.

5. Specify an HTTPS login password.

   password { **cipher** | **simple** } *string*

   By default, no HTTPS login password is specified.

6. Specify an SSL client policy.

   ssl-client-policy *policy-name*

   By default, no SSL client policy is specified.

7. Specify the HTTPS version.

   version { **v1.0** | **v1.1** }

   By default, HTTPS 1.0 is used.

8. Specify the HTTPS operation type.

   operation { **get** | **post** | **raw** }

   By default, the HTTPS operation type is **get**.

   If you set the operation type to raw, the client pads the content configured in raw request view to the HTTPS request to send to the HTTPS server.

9. Configure the content of the HTTPS raw request.

   a. Enter raw request view.

      raw-request

      Every time you enter raw request view, the previously configured raw request content is cleared.

   b. Enter or paste the request content.

By default, no request content is configured.

To ensure successful operations, make sure the request content does not contain command aliases configured by using the **alias** command. For more information about the **alias** command, see CLI commands in *Fundamentals Command Reference*.

c. Return to HTTPS template view.

quit

The system automatically saves the configuration in raw request view before it returns to HTTPS template view.

This step is required only when the operation type is set to **raw**.

10. Specify the source IP address for the probe packets.

IPv4:

source ip *ip-address*

By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

IPv6:

source ipv6 *ipv6-address*

By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

11. (Optional.) Configure the expected data.

expect data *expression* [**offset** *number*]

By default, no expected data is configured.

12. (Optional.) Configure the expected status codes.

expect status *status-list*

By default, no expected status code is configured.

Configuring the FTP template

About this task

A feature that uses the FTP template performs the FTP operation. The operation measures the time it takes the NQA client to transfer a file to or download a file from an FTP server.

Configure the username and password for the FTP client to log in to the FTP server before you perform an FTP operation. For information about configuring the FTP server, see *Fundamentals Configuration Guide*.

Procedure

1. Enter system view.

system-view

2. Create an FTP template and enter its view.

nqa template ftp *name*

3. Specify an FTP login username.

username *username*

By default, no FTP login username is specified.

4. Specify an FTP login password.

password { **cipher** | **simple** } *sting*

By default, no FTP login password is specified.

5. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

   The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

6. Set the data transmission mode.

   mode { **active** | **passive** }

   The default mode is **active**.

7. Specify the FTP operation type.

   operation { **get** | **put** }

   By default, the FTP operation type is **get**, which means obtaining files from the FTP server.

8. Specify the destination URL for the FTP template.

   url *url*

   By default, no destination URL is specified for an FTP template.

   Enter the URL in one of the following formats:

   - ftp://*host*/*filename*.
   - ftp://*host*:*port*/*filename*.

   If the value for the *host* parameter is an IPv6 address, you must use a pair of square brackets ([]) to include the IPv6 address, for example, ftp://[2001::1]/test.

   When you perform the **get** operation, the file name is required.

   When you perform the **put** operation, the *filename* argument does not take effect, even if it is specified. The file name for the **put** operation is determined by using the **filename** command.

9. Specify the name of a file to be transferred.

   filename *filename*

   By default, no file is specified.

   This task is required only for the **put** operation.

   The configuration does not take effect for the **get** operation.

Configuring the RADIUS template

About this task

A feature that uses the RADIUS template performs the RADIUS authentication operation to check the availability of the authentication service on the RADIUS server.

The RADIUS authentication operation workflow is as follows:

1. The NQA client sends an authentication request (Access-Request) to the RADIUS server. The request includes the username and the password. The password is encrypted by using the MD5 algorithm and the shared key.
2. The RADIUS server authenticates the username and password.
   - If the authentication succeeds, the server sends an Access-Accept packet to the NQA client.
   - If the authentication fails, the server sends an Access-Reject packet to the NQA client.
3. The NQA client determines the availability of the authentication service on the RADIUS server based on the response packet it received:
   - If an Access-Accept packet is received, the authentication service is available on the RADIUS server.
   - If an Access-Reject packet is received, the authentication service is not available on the RADIUS server.

Prerequisites

Before you configure the RADIUS template, specify a username, password, and shared key on the RADIUS server. For more information about configuring the RADIUS server, see AAA in *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view
2. Create a RADIUS template and enter its view.

   nqa template radius *name*
3. Specify the destination IP address of the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.
4. Specify the destination port number for the operation.

   destination port *port-number*

   By default, the destination port number is 1812.
5. Specify a username.

   username *username*

   By default, no username is specified.
6. Specify a password.

   password { **cipher** | **simple** } *string*

   By default, no password is specified.
7. Specify a shared key for secure RADIUS authentication.

   key { **cipher** | **simple** } *string*

   By default, no shared key is specified for RADIUS authentication.
8. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

IPv6:

source ipv6 *ipv6-address*

By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

Configuring the SSL template

About this task

A feature that uses the SSL template performs the SSL operation to measure the time required to establish an SSL connection to an SSL server.

Prerequisites

Before you configure the SSL template, you must configure the SSL client policy. For information about configuring SSL client policies, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Create an SSL template and enter its view.

   nqa template ssl *name*

3. Specify the destination IP address of the operation.

   IPv4:

   destination ip *ip-address*

   IPv6:

   destination ipv6 *ipv6-address*

   By default, no destination IP address is specified.

4. Specify the destination port number for the operation.

   destination port *port-number*

   By default, the destination port number is not specified.

5. Specify an SSL client policy.

   ssl-client-policy *policy-name*

   By default, no SSL client policy is specified.

6. Specify the source IP address for the probe packets.

   IPv4:

   source ip *ip-address*

   By default, the primary IPv4 address of the output interface is used as the source IPv4 address of the probe packets.

   The source IP address must be the IPv4 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

   IPv6:

   source ipv6 *ipv6-address*

   By default, the primary IPv6 address of the output interface is used as the source IPv6 address of the probe packets.

The source IPv6 address must be the IPv6 address of a local interface, and the interface must be up. Otherwise, no probe packets can be sent out.

Configuring optional parameters for the NQA template

Restrictions and guidelines

Unless otherwise specified, the following optional parameters apply to all types of NQA templates.

The parameter settings take effect only on the current NQA template.

Procedure

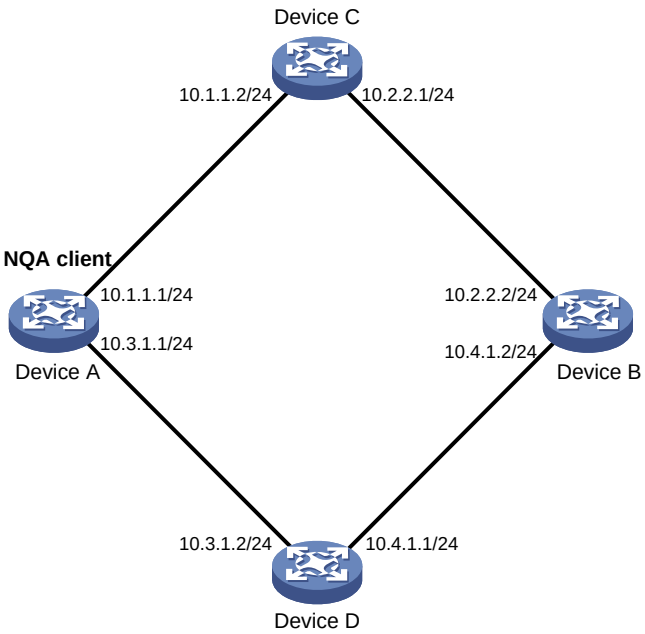
1. Enter system view.
   system-view
2. Enter the view of an existing NQA template.
   nqa template { **dns** | **ftp** | **http** | **https** | **icmp** | **radius** | **ssl** | **tcp** | **tcphalfopen** | **udp** } *name*
3. Configure a description.
   description *text*
   By default, no description is configured.
4. Set the interval at which the NQA operation repeats.
   frequency *interval*
   The default setting is 5000 milliseconds.
   If the operation is not completed when the interval expires, the next operation does not start.
5. Set the probe timeout time.
   probe timeout *timeout*
   The default setting is 3000 milliseconds.
6. Set the TTL for the probe packets.
   ttl *value*
   The default setting is 20.
   This command is not available for the ARP template.
7. Set the ToS value in the IP header of the probe packets.
   tos *value*
   The default setting is 0.
   This command is not available for the ARP template.
8. Specify the VPN instance where the operation is performed.
   vpn-instance *vpn-instance-name*
   By default, the operation is performed on the public network.
9. Set the number of consecutive successful probes to determine a successful operation event.
   reaction trigger probe-pass *count*
   The default setting is 3.
   If the number of consecutive successful probes for an NQA operation is reached, the NQA client notifies the feature that uses the template of the successful operation event.
10. Set the number of consecutive probe failures to determine an operation failure.
    reaction trigger probe-fail *count*
    The default setting is 3.

If the number of consecutive probe failures for an NQA operation is reached, the NQA client notifies the feature that uses the NQA template of the operation failure.

Display and maintenance commands for NQA

Execute **display** commands in any view.

Task	Command
Display history records of NQA operations.	**display nqa history** [*admin-name operation-tag*]
Display the current monitoring results of reaction entries.	**display nqa reaction counters** [*admin-name operation-tag* [*item-number*]]
Display the most recent result of the NQA operation.	**display nqa result** [*admin-name operation-tag*]
Display NQA server status.	**display nqa server status**
Display NQA statistics.	**display nqa statistics** [*admin-name operation-tag*]



NQA configuration examples

Example: Configuring the ICMP echo operation

Network configuration

As shown in Figure 2, configure an ICMP echo operation on the NQA client (Device A) to test the round-trip time to Device B. The next hop of Device A is Device C.

Figure 2 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 2. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create an ICMP echo operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type icmp-echo
```

Specify 10.2.2.2 as the destination IP address of ICMP echo requests.

```
[DeviceA-nqa-admin-test1-icmp-echo] destination ip 10.2.2.2
```

Specify 10.1.1.2 as the next hop. The ICMP echo requests are sent through Device C to Device B.

```
[DeviceA-nqa-admin-test1-icmp-echo] next-hop ip 10.1.1.2
```

Configure the ICMP echo operation to perform 10 probes.

```
[DeviceA-nqa-admin-test1-icmp-echo] probe count 10
```

Set the probe timeout time to 500 milliseconds for the ICMP echo operation.

```
[DeviceA-nqa-admin-test1-icmp-echo] probe timeout 500
```

Configure the ICMP echo operation to repeat every 5000 milliseconds.

```
[DeviceA-nqa-admin-test1-icmp-echo] frequency 5000
```

Enable saving history records.

```
[DeviceA-nqa-admin-test1-icmp-echo] history-record enable
```

Set the maximum number of history records to 10.

```
[DeviceA-nqa-admin-test1-icmp-echo] history-record number 10
[DeviceA-nqa-admin-test1-icmp-echo] quit
```

Start the ICMP echo operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the ICMP echo operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the ICMP echo operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 10             Receive response times: 10
    Min/Max/Average round trip time: 2/5/3
    Square-Sum of round trip time: 96
    Last succeeded probe time: 2019-08-23 15:00:01.2
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the ICMP echo operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test) history records:
  Index      Response     Status           Time
  370        3            Succeeded        2019-08-23 15:00:01.2
```

```
369         3           Succeeded       2019-08-23 15:00:01.2
368         3           Succeeded       2019-08-23 15:00:01.2
367         5           Succeeded       2019-08-23 15:00:01.2
366         3           Succeeded       2019-08-23 15:00:01.2
365         3           Succeeded       2019-08-23 15:00:01.2
364         3           Succeeded       2019-08-23 15:00:01.1
363         2           Succeeded       2019-08-23 15:00:01.1
362         3           Succeeded       2019-08-23 15:00:01.1
361         2           Succeeded       2019-08-23 15:00:01.1
```

The output shows that the packets sent by Device A can reach Device B through Device C. No packet loss occurs during the operation. The minimum, maximum, and average round-trip times are 2, 5, and 3 milliseconds, respectively.

Example: Configuring the ICMP jitter operation

Network configuration

As shown in Figure 3, configure an ICMP jitter operation to test the jitter between Device A and Device B.

Figure 3 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 3. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device A:

   # Create an ICMP jitter operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type icmp-jitter
   ```

   # Specify 10.2.2.2 as the destination address for the operation.

   ```
   [DeviceA-nqa-admin-test1-icmp-jitter] destination ip 10.2.2.2
   ```

   # Configure the operation to repeat every 1000 milliseconds.

   ```
   [DeviceA-nqa-admin-test1-icmp-jitter] frequency 1000
   [DeviceA-nqa-admin-test1-icmp-jitter] quit
   ```

   # Start the ICMP jitter operation.

   ```
   [DeviceA] nqa schedule admin test1 start-time now lifetime forever
   ```

   # After the ICMP jitter operation runs for a period of time, stop the operation.

   ```
   [DeviceA] undo nqa schedule admin test1
   ```

Verifying the configuration

Display the most recent result of the ICMP jitter operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
```

```
    Send operation times: 10             Receive response times: 10
    Min/Max/Average round trip time: 1/2/1
    Square-Sum of round trip time: 13
    Last packet received time: 2019-03-09 17:40:29.8
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
    Packets out of sequence: 0
    Packets arrived late: 0
  ICMP-jitter results:
   RTT number: 10
    Min positive SD: 0                   Min positive DS: 0

  Sum of SD delay: 4                    Sum of DS delay: 5
  Square-Sum of SD delay: 4             Square-Sum of DS delay: 7
  Lost packets for unknown reason: 0
```

Example: Configuring the DHCP operation

Network configuration

As shown in Figure 4, configure a DHCP operation to test the time required for Switch A to obtain an IP address from the DHCP server (Switch B).

Figure 4 Network diagram

Procedure

Create a DHCP operation.

```
<SwitchA> system-view
[SwitchA] nqa entry admin test1
[SwitchA-nqa-admin-test1] type dhcp
```

Specify the DHCP server address (10.1.1.2) as the destination address.

```
[SwitchA-nqa-admin-test1-dhcp] destination ip 10.1.1.2
```

Enable the saving of history records.

```
[SwitchA-nqa-admin-test1-dhcp] history-record enable
[SwitchA-nqa-admin-test1-dhcp] quit
```

Start the DHCP operation.

```
[SwitchA] nqa schedule admin test1 start-time now lifetime forever
```

After the DHCP operation runs for a period of time, stop the operation.

```
[SwitchA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the DHCP operation.

```
[SwitchA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 512/512/512
    Square-Sum of round trip time: 262144
    Last succeeded probe time: 2019-11-22 09:56:03.2
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the DHCP operation.

```
[SwitchA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          512          Succeeded        2019-11-22 09:56:03.2
```

The output shows that it took Switch A 512 milliseconds to obtain an IP address from the DHCP server.

Example: Configuring the DNS operation

Network configuration

As shown in Figure 5, configure a DNS operation to test whether Device A can perform address resolution through the DNS server and test the resolution time.

Figure 5 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 5. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create a DNS operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type dns
```

Specify the IP address of the DNS server (10.2.2.2) as the destination address.

```
[DeviceA-nqa-admin-test1-dns] destination ip 10.2.2.2
```

Specify **host.com** as the domain name to be translated.

```
[DeviceA-nqa-admin-test1-dns] resolve-target host.com
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test1-dns] history-record enable
[DeviceA-nqa-admin-test1-dns] quit
```

Start the DNS operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the DNS operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the DNS operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 62/62/62
    Square-Sum of round trip time: 3844
    Last succeeded probe time: 2019-11-10 10:49:37.3
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the DNS operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test) history records:
  Index      Response     Status           Time
  1          62           Succeeded        2019-11-10 10:49:37.3
```

The output shows that it took Device A 62 milliseconds to translate domain name **host.com** into an IP address.

Example: Configuring the FTP operation

Network configuration

As shown in Figure 6, configure an FTP operation to test the time required for Device A to upload a file to the FTP server. The login username and password are **admin** and **systemtest**, respectively. The file to be transferred to the FTP server is **config.txt**.

Figure 6 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 6. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create an FTP operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type ftp
```

Specify the URL of the FTP server.

```
[DeviceA-nqa-admin-test-ftp] url ftp://10.2.2.2
```

Specify 10.1.1.1 as the source IP address.

```
[DeviceA-nqa-admin-test1-ftp] source ip 10.1.1.1
```

Configure the device to upload file **config.txt** to the FTP server.

```
[DeviceA-nqa-admin-test1-ftp] operation put
[DeviceA-nqa-admin-test1-ftp] filename config.txt
```

Set the username to **admin** for the FTP operation.

```
[DeviceA-nqa-admin-test1-ftp] username admin
```

Set the password to **systemtest** for the FTP operation.

```
[DeviceA-nqa-admin-test1-ftp] password simple systemtest
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test1-ftp] history-record enable
[DeviceA-nqa-admin-test1-ftp] quit
```

Start the FTP operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the FTP operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the FTP operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 173/173/173
    Square-Sum of round trip time: 29929
    Last succeeded probe time: 2019-11-22 10:07:28.6
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to disconnect: 0
    Failures due to no connection: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the FTP operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          173          Succeeded        2019-11-22 10:07:28.6
```

The output shows that it took Device A 173 milliseconds to upload a file to the FTP server.

Example: Configuring the HTTP operation

Network configuration

As shown in Figure 7, configure an HTTP operation on the NQA client to test the time required to obtain data from the HTTP server.

Figure 7 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 7. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create an HTTP operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type http
```

Specify the URL of the HTTP server.

```
[DeviceA-nqa-admin-test1-http] url http://10.2.2.2/index.htm
```

Configure the HTTP operation to get data from the HTTP server.

```
[DeviceA-nqa-admin-test1-http] operation get
```

Configure the operation to use HTTP version 1.0.

```
[DeviceA-nqa-admin-test1-http] version v1.0
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test1-http] history-record enable
[DeviceA-nqa-admin-test1-http] quit
```

Start the HTTP operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the HTTP operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the HTTP operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 64/64/64
    Square-Sum of round trip time: 4096
    Last succeeded probe time: 2019-11-22 10:12:47.9
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to disconnect: 0
    Failures due to no connection: 0
```

```
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the HTTP operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          64           Succeeded        2019-11-22 10:12:47.9
```

The output shows that it took Device A 64 milliseconds to obtain data from the HTTP server.

Example: Configuring the UDP jitter operation

Network configuration

As shown in Figure 8, configure a UDP jitter operation to test the jitter, delay, and round-trip time between Device A and Device B.

Figure 8 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 8. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

   ```
   <DeviceB> system-view
   [DeviceB] nqa server enable
   ```

   # Configure a listening service to listen to UDP port 9000 on IP address 10.2.2.2.

   ```
   [DeviceB] nqa server udp-echo 10.2.2.2 9000
   ```

4. Configure Device A:

   # Create a UDP jitter operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type udp-jitter
   ```

   # Specify 10.2.2.2 as the destination address of the operation.

   ```
   [DeviceA-nqa-admin-test1-udp-jitter] destination ip 10.2.2.2
   ```

   # Set the destination port number to 9000.

   ```

Example: Configuring the SNMP operation

Network configuration

As shown in Figure 9, configure an SNMP operation to test the time the NQA client uses to get a response from the SNMP agent.

Figure 9 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 9. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure the SNMP agent (Device B):

   # Set the SNMP version to **all**.

```
<DeviceB> system-view
[DeviceB] snmp-agent sys-info version all
```

Set the read community to **public**.

```
[DeviceB] snmp-agent community read public
```

Set the write community to **private**.

```
[DeviceB] snmp-agent community write private
```

4. Configure Device A:

Create an SNMP operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type snmp
```

Specify 10.2.2.2 as the destination IP address of the SNMP operation.

```
[DeviceA-nqa-admin-test1-snmp] destination ip 10.2.2.2
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test1-snmp] history-record enable
[DeviceA-nqa-admin-test1-snmp] quit
```

Start the SNMP operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the SNMP operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the SNMP operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 50/50/50
    Square-Sum of round trip time: 2500
    Last succeeded probe time: 2019-11-22 10:24:41.1
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the SNMP operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          50           Succeeded        2019-11-22 10:24:41.1
```

The output shows that it took Device A 50 milliseconds to receive a response from the SNMP agent.

Example: Configuring the TCP operation

Network configuration

As shown in Figure 10, configure a TCP operation to test the time required for Device A to establish a TCP connection with Device B.

Figure 10 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 10. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

   ```
   <DeviceB> system-view
   [DeviceB] nqa server enable
   ```

   # Configure a listening service to listen to TCP port 9000 on IP address 10.2.2.2.

   ```
   [DeviceB] nqa server tcp-connect 10.2.2.2 9000
   ```

4. Configure Device A:

   # Create a TCP operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type tcp
   ```

   # Specify 10.2.2.2 as the destination IP address.

   ```
   [DeviceA-nqa-admin-test1-tcp] destination ip 10.2.2.2
   ```

   # Set the destination port number to 9000.

   ```
   [DeviceA-nqa-admin-test1-tcp] destination port 9000
   ```

   # Enable the saving of history records.

   ```
   [DeviceA-nqa-admin-test1-tcp] history-record enable
   [DeviceA-nqa-admin-test1-tcp] quit
   ```

   # Start the TCP operation.

   ```
   [DeviceA] nqa schedule admin test1 start-time now lifetime forever
   ```

   # After the TCP operation runs for a period of time, stop the operation.

   ```
   [DeviceA] undo nqa schedule admin test1
   ```

Verifying the configuration

Display the most recent result of the TCP operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 13/13/13
    Square-Sum of round trip time: 169
    Last succeeded probe time: 2019-11-22 10:27:25.1
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to disconnect: 0
    Failures due to no connection: 0
    Failures due to internal error: 0
```

```
    Failures due to other errors: 0
```

Display the history records of the TCP operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          13           Succeeded        2019-11-22 10:27:25.1
```

The output shows that it took Device A 13 milliseconds to establish a TCP connection to port 9000 on the NQA server.

Example: Configuring the UDP echo operation

Network configuration

As shown in Figure 11, configure a UDP echo operation on the NQA client to test the round-trip time to Device B. The destination port number is 8000.

Figure 11 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 11. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

   ```
   <DeviceB> system-view
   [DeviceB] nqa server enable
   ```

   # Configure a listening service to listen to UDP port 8000 on IP address 10.2.2.2.

   ```
   [DeviceB] nqa server udp-echo 10.2.2.2 8000
   ```

4. Configure Device A:

   # Create a UDP echo operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type udp-echo
   ```

   # Specify 10.2.2.2 as the destination IP address.

   ```
   [DeviceA-nqa-admin-test1-udp-echo] destination ip 10.2.2.2
   ```

   # Set the destination port number to 8000.

   ```
   [DeviceA-nqa-admin-test1-udp-echo] destination port 8000
   ```

   # Enable the saving of history records.

   ```
   [DeviceA-nqa-admin-test1-udp-echo] history-record enable
   [DeviceA-nqa-admin-test1-udp-echo] quit
   ```

   # Start the UDP echo operation.

   ```
   [DeviceA] nqa schedule admin test1 start-time now lifetime forever
   ```

   # After the UDP echo operation runs for a period of time, stop the operation.

   ```
   [DeviceA] undo nqa schedule admin test1
   ```

Verifying the configuration

Display the most recent result of the UDP echo operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 25/25/25
    Square-Sum of round trip time: 625
    Last succeeded probe time: 2019-11-22 10:36:17.9
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the UDP echo operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          25           Succeeded        2019-11-22 10:36:17.9
```

The output shows that the round-trip time between Device A and port 8000 on Device B is 25 milliseconds.

Example: Configuring the UDP tracert operation

Network configuration

As shown in Figure 12, configure a UDP tracert operation to determine the routing path from Device A to Device B.

Figure 12 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 12. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Execute the **ip ttl-expires enable** command on the intermediate devices and execute the **ip unreachables enable** command on Device B.
4. Configure Device A:

   # Create a UDP tracert operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type udp-tracert
   ```

   # Specify 10.2.2.2 as the destination IP address.

   ```
   [DeviceA-nqa-admin-test1-udp-tracert] destination ip 10.2.2.2
   ```

   # Set the destination port number to 33434.

   ```
   [DeviceA-nqa-admin-test1-udp-tracert] destination port 33434
   ```

Configure Device A to perform three probes to each hop.

```
[DeviceA-nqa-admin-test1-udp-tracert] probe count 3
```

Set the probe timeout time to 500 milliseconds.

```
[DeviceA-nqa-admin-test1-udp-tracert] probe timeout 500
```

Configure the UDP tracert operation to repeat every 5000 milliseconds.

```
[DeviceA-nqa-admin-test1-udp-tracert] frequency 5000
```

Specify GigabitEthernet 1/0/1 as the output interface for UDP packets.

```
[DeviceA-nqa-admin-test1-udp-tracert] out interface gigabitethernet 1/0/1
```

Enable the no-fragmentation feature.

```
[DeviceA-nqa-admin-test1-udp-tracert] no-fragment enable
```

Set the maximum number of consecutive probe failures to 6.

```
[DeviceA-nqa-admin-test1-udp-tracert] max-failure 6
```

Set the TTL value to 1 for UDP packets in the start round of the UDP tracert operation.

```
[DeviceA-nqa-admin-test1-udp-tracert] init-ttl 1
```

Start the UDP tracert operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the UDP tracert operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the UDP tracert operation.

```
[DeviceA] display nqa result admin test1

Example: Configuring the voice operation

Network configuration

As shown in Figure 13, configure a voice operation to test jitters, delay, MOS, and ICPIF between Device A and Device B.

Figure 13 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 13. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

   ```
   <DeviceB> system-view
   [DeviceB] nqa server enable
   ```

   # Configure a listening service to listen to UDP port 9000 on IP address 10.2.2.2.

   ```
   [DeviceB] nqa server udp-echo 10.2.2.2 9000
   ```

4. Configure Device A:

   # Create a voice operation.

   ```
   <DeviceA> system-view
   [DeviceA] nqa entry admin test1
   [DeviceA-nqa-admin-test1] type voice
   ```

   # Specify 10.2.2.2 as the destination IP address.

   ```
   [DeviceA-nqa-admin-test1-voice] destination ip 10.2.2.2
   ```

   # Set the destination port number to 9000.

   ```
   [DeviceA-nqa-admin-test1-voice] destination port 9000
   [DeviceA-nqa-admin-test1-voice] quit
   ```

   # Start the voice operation.

   ```
   [DeviceA] nqa schedule admin test1 start-time now lifetime forever
   ```

   # After the voice operation runs for a period of time, stop the operation.

   ```
   [DeviceA] undo nqa schedule admin test1
   ```

Verifying the configuration

```

Example: Configuring the DLSw operation

Network configuration

As shown in Figure 14, configure a DLSw operation to test the response time of the DLSw device.

Figure 14 Network diagram

Configuring Device A

Assign IP addresses to interfaces, as shown in Figure 14. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create a DLSw operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type dlsw
```

Specify 10.2.2.2 as the destination IP address.

```
[DeviceA-nqa-admin-test1-dlsw] destination ip 10.2.2.2
```

Enable the saving of history records.

```
[DeviceA-nqa-admin-test1-dlsw] history-record enable
[DeviceA-nqa-admin-test1-dlsw] quit
```

Start the DLSw operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the DLSw operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Configuring Device B

Assign IP addresses to interfaces. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can communicate with each other. (Details not shown.)

Enable the NQA server.

```
<DeviceB> system-view
[DeviceB] nqa server enable
```

Configure a listening service to listen to TCP port 2065 on IP address 10.2.2.2. (For the DLSw operation, the port number for the TCP listening service must be 2065.)

```
[DeviceB] nqa server tcp-connect 10.2.2.2 2065
```

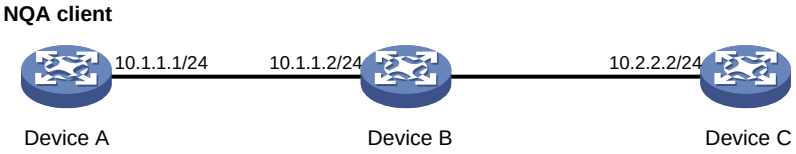
Verifying the configuration

Display the most recent result of the DLSw operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
    Send operation times: 1              Receive response times: 1
    Min/Max/Average round trip time: 19/19/19
    Square-Sum of round trip time: 361
    Last succeeded probe time: 2019-11-22 10:40:27.7
  Extended results:
    Packet loss ratio: 0%
    Failures due to timeout: 0
    Failures due to disconnect: 0
    Failures due to no connection: 0
    Failures due to internal error: 0
    Failures due to other errors: 0
```

Display the history records of the DLSw operation.

```
[DeviceA] display nqa history admin test1
NQA entry (admin admin, tag test1) history records:
  Index      Response     Status           Time
  1          19           Succeeded        2019-11-22 10:40:27.7
```



The output shows that the response time of the DLSw device is 19 milliseconds.

Example: Configuring the path jitter operation

Network configuration

As shown in Figure 15, configure a path jitter operation to test the round trip time and jitters from Device A to Device B and Device C.

Figure 15 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 15. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Execute the **ip ttl-expires enable** command on Device B and execute the **ip unreachables enable** command on Device C.

Create a path jitter operation.

```
<DeviceA> system-view
[DeviceA] nqa entry admin test1
[DeviceA-nqa-admin-test1] type path-jitter
```

Specify 10.2.2.2 as the destination IP address of ICMP echo requests.

```
[DeviceA-nqa-admin-test1-path-jitter] destination ip 10.2.2.2
```

Configure the path jitter operation to repeat every 10000 milliseconds.

```
[DeviceA-nqa-admin-test1-path-jitter] frequency 10000
[DeviceA-nqa-admin-test1-path-jitter] quit
```

Start the path jitter operation.

```
[DeviceA] nqa schedule admin test1 start-time now lifetime forever
```

After the path jitter operation runs for a period of time, stop the operation.

```
[DeviceA] undo nqa schedule admin test1
```

Verifying the configuration

Display the most recent result of the path jitter operation.

```
[DeviceA] display nqa result admin test1
NQA entry (admin admin, tag test1) test results:
  Hop IP 10.1.1.2
    Basic Results
      Send operation times: 10             Receive response times: 10
      Min/Max/Average round trip time: 9/21/14
      Square-Sum of round trip time: 2419

    Negative jitter number: 3
      Min/Max/Average negative jitter: 2/10/6
      Sum/Square-Sum positive jitter: 19/153
```

Example: Configuring NQA collaboration

Network configuration

As shown in Figure 16, configure a static route to Switch C with Switch B as the next hop on Switch A. Associate the static route, a track entry, and an ICMP echo operation to monitor the state of the static route.

Figure 16 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 16. (Details not shown.)
2. On Switch A, configure a static route, and associate the static route with track entry 1.

```
<SwitchA> system-view
```

```
[SwitchA] ip route-static 10.1.1.2 24 10.2.1.1 track 1
```

3. On Switch A, configure an ICMP echo operation:

Create an NQA operation with administrator name **admin** and operation tag **test1**.

```
[SwitchA] nqa entry admin test1
```

Configure the NQA operation type as ICMP echo.

```
[SwitchA-nqa-admin-test1] type icmp-echo
```

Specify 10.2.1.1 as the destination IP address.

```
[SwitchA-nqa-admin-test1-icmp-echo] destination ip 10.2.1.1
```

Configure the operation to repeat every 100 milliseconds.

```
[SwitchA-nqa-admin-test1-icmp-echo] frequency 100
```

Create reaction entry 1. If the number of consecutive probe failures reaches 5, collaboration is triggered.

```
[SwitchA-nqa-admin-test1-icmp-echo] reaction 1 checked-element probe-fail
threshold-type consecutive 5 action-type trigger-only
[SwitchA-nqa-admin-test1-icmp-echo] quit
```

Start the ICMP operation.

```
[SwitchA] nqa schedule admin test1 start-time now lifetime forever
```

4. On Switch A, create track entry 1, and associate it with reaction entry 1 of the NQA operation.

```
[SwitchA] track 1 nqa entry admin test1 reaction 1
```

Verifying the configuration

Display information about all the track entries on Switch A.

```
[SwitchA] display track all
Track ID: 1
  State: Positive
  Duration: 0 days 0 hours 0 minutes 0 seconds
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    NQA entry: admin test1
    Reaction: 1
```

Display brief information about active routes in the routing table on Switch A.

```
[SwitchA] display ip routing-table

Destinations : 13        Routes : 13

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
0.0.0.0/32          Direct 0    0            127.0.0.1       InLoop0
10.1.1.0/24         Static 60   0            10.2.1.1        Vlan3
10.2.1.0/24         Direct 0    0            10.2.1.2        Vlan3
10.2.1.0/32         Direct 0    0            10.2.1.2        Vlan3
10.2.1.2/32         Direct 0    0            127.0.0.1       InLoop0
10.2.1.255/32       Direct 0    0            10.2.1.2        Vlan3
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.0/32        Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
127.255.255.255/32  Direct 0    0            127.0.0.1       InLoop0
224.0.0.0/4         Direct 0    0            0.0.0.0         NULL0
224.0.0.0/24        Direct 0    0            0.0.0.0         NULL0
```

```
255.255.255.255/32  Direct 0    0           127.0.0.1       InLoop0
```

The output shows that the static route with the next hop 10.2.1.1 is active, and the status of the track entry is positive.

Remove the IP address of VLAN-interface 3 on Switch B.

```
<SwitchB> system-view
[SwitchB] interface vlan-interface 3
[SwitchB-Vlan-interface3] undo ip address
```

Display information about all the track entries on Switch A.

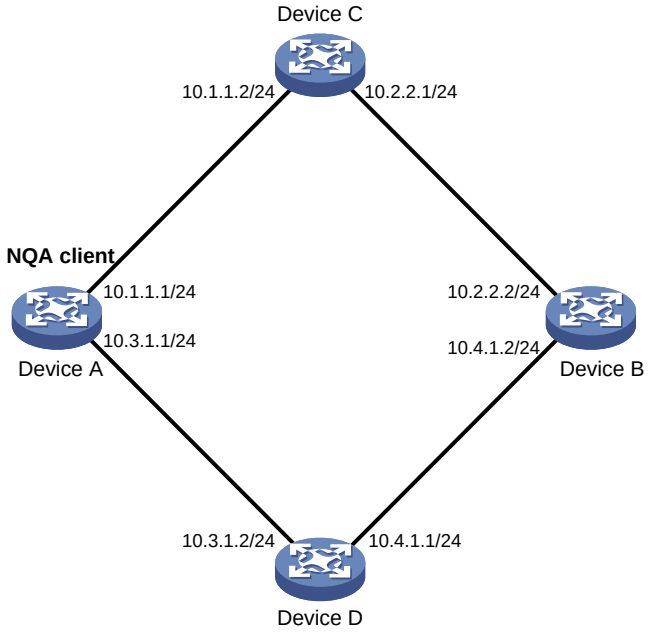
```
[SwitchA] display track all
Track ID: 1
  State: Negative
  Duration: 0 days 0 hours 0 minutes 0 seconds
  Notification delay: Positive 0, Negative 0 (in seconds)
  Tracked object:
    NQA entry: admin test1
    Reaction: 1
```

Display brief information about active routes in the routing table on Switch A.

```
[SwitchA] display ip routing-table

Destinations : 12        Routes : 12

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
0.0.0.0/32          Direct 0    0            127.0.0.1       InLoop0
10.2.1.0/24         Direct 0    0            10.2.1.2        Vlan3
10.2.1.0/32         Direct 0    0            10.2.1.2        Vlan3
10.2.1.2/32         Direct 0    0            127.0.0.1       InLoop0
10.2.1.255/32       Direct 0    0            10.2.1.2        Vlan3
127.0.0.0/8         Direct 0    0            127.0.0.1       InLoop0
127.0.0.0/32        Direct 0    0            127.0.0.1       InLoop0
127.0.0.1/32        Direct 0    0            127.0.0.1       InLoop0
127.255.255.255/32  Direct 0    0            127.0.0.1       InLoop0
224.0.0.0/4         Direct 0    0            0.0.0.0         NULL0
224.0.0.0/24        Direct 0    0            0.0.0.0         NULL0
255.255.255.255/32  Direct 0    0            127.0.0.1       InLoop0
```



The output shows that the static route does not exist, and the status of the track entry is negative.

Example: Configuring the ICMP template

Network configuration

As shown in Figure 17, configure an ICMP template for a feature to perform the ICMP echo operation from Device A to Device B.

Figure 17 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 17. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create ICMP template **icmp**.

```
<DeviceA> system-view
[DeviceA] nqa template icmp icmp
```

Specify 10.2.2.2 as the destination IP address of ICMP echo requests.

```
[DeviceA-nqatplt-icmp-icmp] destination ip 10.2.2.2
```

Set the probe timeout time to 500 milliseconds for the ICMP echo operation.

```
[DeviceA-nqatplt-icmp-icmp] probe timeout 500
```

Configure the ICMP echo operation to repeat every 3000 milliseconds.

```
[DeviceA-nqatplt-icmp-icmp] frequency 3000
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-icmp-icmp] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-icmp-icmp] reaction trigger probe-fail 2
```

Example: Configuring the DNS template

Network configuration

As shown in Figure 18, configure a DNS template for a feature to perform the DNS operation. The operation tests whether Device A can perform the address resolution through the DNS server.

Figure 18 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 18. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create DNS template **dns**.

```
<DeviceA> system-view
[DeviceA] nqa template dns dns
```

Specify the IP address of the DNS server (10.2.2.2) as the destination IP address.

```
[DeviceA-nqatplt-dns-dns] destination ip 10.2.2.2
```

Specify **host.com** as the domain name to be translated.

```
[DeviceA-nqatplt-dns-dns] resolve-target host.com
```

Set the domain name resolution type to type A.

```
[DeviceA-nqatplt-dns-dns] resolve-type A
```

Specify 3.3.3.3 as the expected IP address.

```
[DeviceA-nqatplt-dns-dns] expect ip 3.3.3.3
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-dns-dns] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-dns-dns] reaction trigger probe-fail 2
```

Example: Configuring the TCP template

Network configuration

As shown in Figure 19, configure a TCP template for a feature to perform the TCP operation. The operation tests whether Device A can establish a TCP connection to Device B.

Figure 19 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 19. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

```
<DeviceB> system-view
[DeviceB] nqa server enable
```

Configure a listening service to listen to TCP port 9000 on IP address 10.2.2.2.

```
[DeviceB] nqa server tcp-connect 10.2.2.2 9000
```

4. Configure Device A:

Create TCP template **tcp**.

```
<DeviceA> system-view
[DeviceA] nqa template tcp tcp
```

Specify 10.2.2.2 as the destination IP address.

```
[DeviceA-nqatplt-tcp-tcp] destination ip 10.2.2.2
```

Set the destination port number to 9000.

```
[DeviceA-nqatplt-tcp-tcp] destination port 9000
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-tcp-tcp] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-tcp-tcp] reaction trigger probe-fail 2
```

Example: Configuring the TCP half open template

Network configuration

As shown in Figure 20, configure a TCP half open template for a feature to test whether Device B can provide the TCP service for Device A.

Figure 20 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 20. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device A:

Create TCP half open template **test**.

```
<DeviceA> system-view
[DeviceA] nqa template tcphalfopen test
```

Specify 10.2.2.2 as the destination IP address.

```
[DeviceA-nqatplt-tcphalfopen-test] destination ip 10.2.2.2
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-tcphalfopen-test] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-tcphalfopen-test] reaction trigger probe-fail 2
```

Example: Configuring the UDP template

Network configuration

As shown in Figure 21, configure a UDP template for a feature to perform the UDP operation. The operation tests whether Device A can receive a response from Device B.

Figure 21 Network diagram

Procedure

1. Assign IP addresses to interfaces, as shown in Figure 21. (Details not shown.)
2. Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)
3. Configure Device B:

   # Enable the NQA server.

   ```
   <DeviceB> system-view
   [DeviceB] nqa server enable
   ```

   # Configure a listening service to listen to UDP port 9000 on IP address 10.2.2.2.

   ```
   [DeviceB] nqa server udp-echo 10.2.2.2 9000
   ```

4. Configure Device A:

   # Create UDP template **udp**.

   ```
   <DeviceA> system-view
   [DeviceA] nqa template udp udp
   ```

   # Specify 10.2.2.2 as the destination IP address.

   ```
   [DeviceA-nqatplt-udp-udp] destination ip 10.2.2.2
   ```

   # Set the destination port number to 9000.

   ```
   [DeviceA-nqatplt-udp-udp] destination port 9000
   ```

   # Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

   ```
   [DeviceA-nqatplt-udp-udp] reaction trigger probe-pass 2
   ```

   # Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

   ```
   [DeviceA-nqatplt-udp-udp] reaction trigger probe-fail 2
   ```

Example: Configuring the HTTP template

Network configuration

As shown in Figure 22, configure an HTTP template for a feature to perform the HTTP operation. The operation tests whether the NQA client can get data from the HTTP server.

Figure 22 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 22. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create HTTP template **http**.

```
<DeviceA> system-view
[DeviceA] nqa template http http
```

Specify **http://10.2.2.2/index.htm** as the URL of the HTTP server.

```
[DeviceA-nqatplt-http-http] url http://10.2.2.2/index.htm
```

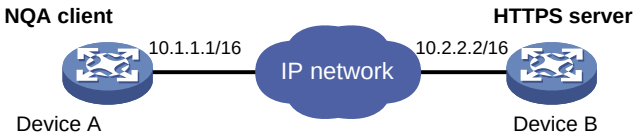
Set the HTTP operation type to **get**.

```
[DeviceA-nqatplt-http-http] operation get
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-http-http] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.



```
[DeviceA-nqatplt-http-http] reaction trigger probe-fail 2
```

Example: Configuring the HTTPS template

Network configuration

As shown in Figure 23, configure an HTTPS template for a feature to test whether the NQA client can get data from the HTTPS server (Device B).

Figure 23 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 23. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Configure an SSL client policy named **abc** on Device A, and make sure Device A can use the policy to connect to the HTTPS server. (Details not shown.)

Create HTTPS template **test**.

```
<DeviceA> system-view
[DeviceA] nqa template https https
```

Specify **http://10.2.2.2/index.htm** as the URL of the HTTPS server.

```
[DeviceA-nqatplt-https-https] url https://10.2.2.2/index.htm
```

Specify SSL client policy **abc** for the HTTPS template.

```
[DeviceA-nqatplt-https- https] ssl-client-policy abc
```

Set the HTTPS operation type to **get** (the default HTTPS operation type).

```
[DeviceA-nqatplt-https-https] operation get
```

Set the HTTPS version to 1.0 (the default HTTPS version).

```
 [DeviceA-nqatplt-https-https] version v1.0
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-https-https] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-https-https] reaction trigger probe-fail 2
```

Example: Configuring the FTP template

Network configuration

As shown in Figure 24, configure an FTP template for a feature to perform the FTP operation. The operation tests whether Device A can upload a file to the FTP server. The login username and password are **admin** and **systemtest**, respectively. The file to be transferred to the FTP server is **config.txt**.

Figure 24 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 24. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Create FTP template **ftp**.

```
<DeviceA> system-view
[DeviceA] nqa template ftp ftp
```

Specify the URL of the FTP server.

```
[DeviceA-nqatplt-ftp-ftp] url ftp://10.2.2.2
```

Specify 10.1.1.1 as the source IP address.

```
[DeviceA-nqatplt-ftp-ftp] source ip 10.1.1.1
```

Configure the device to upload file **config.txt** to the FTP server.

```
[DeviceA-nqatplt-ftp-ftp] operation put
[DeviceA-nqatplt-ftp-ftp] filename config.txt
```

Set the username to **admin** for the FTP server login.

```
[DeviceA-nqatplt-ftp-ftp] username admin
```

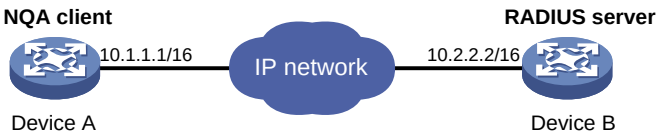
Set the password to **systemtest** for the FTP server login.

```
[DeviceA-nqatplt-ftp-ftp] password simple systemtest
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-ftp-ftp] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.



```
[DeviceA-nqatplt-ftp-ftp] reaction trigger probe-fail 2
```

Example: Configuring the RADIUS template

Network configuration

As shown in Figure 25, configure a RADIUS template for a feature to test whether the RADIUS server (Device B) can provide authentication service for Device A. The username and password are **admin** and **systemtest**, respectively. The shared key is **123456** for secure RADIUS authentication.

Figure 25 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 25. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Configure the RADIUS server. (Details not shown.)

Create RADIUS template **radius**.

```
<DeviceA> system-view
[DeviceA] nqa template radius radius
```

Specify 10.2.2.2 as the destination IP address of the operation.

```
[DeviceA-nqatplt-radius-radius] destination ip 10.2.2.2
```

Set the username to **admin**.

```
[DeviceA-nqatplt-radius-radius] username admin
```

Set the password to **systemtest**.

```
[DeviceA-nqatplt-radius-radius] password simple systemtest
```

Set the shared key to **123456** in plain text for secure RADIUS authentication.

```
[DeviceA-nqatplt-radius-radius] key simple 123456
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-radius-radius] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-radius-radius] reaction trigger probe-fail 2
```

Example: Configuring the SSL template

Network configuration

As shown in Figure 26, configure an SSL template for a feature to test whether Device A can establish an SSL connection to the SSL server on Device B.

Figure 26 Network diagram

Procedure

Assign IP addresses to interfaces, as shown in Figure 26. (Details not shown.)

Configure static routes or a routing protocol to make sure the devices can reach each other. (Details not shown.)

Configure an SSL client policy named **abc** on Device A, and make sure Device A can use the policy to connect to the SSL server on Device B. (Details not shown.)

Create SSL template **ssl**.

```
<DeviceA> system-view
[DeviceA] nqa template ssl ssl
```

Set the destination IP address and port number to **10.2.2.2** and **9000**, respectively.

```
[DeviceA-nqatplt-ssl-ssl] destination ip 10.2.2.2
[DeviceA-nqatplt-ssl-ssl] destination port 9000
```

Specify SSL client policy **abc** for the SSL template.

```
[DeviceA-nqatplt-ssl-ssl] ssl-client-policy abc
```

Configure the NQA client to notify the feature of the successful operation event if the number of consecutive successful probes reaches 2.

```
[DeviceA-nqatplt-ssl-ssl] reaction trigger probe-pass 2
```

Configure the NQA client to notify the feature of the operation failure if the number of consecutive failed probes reaches 2.

```
[DeviceA-nqatplt-ssl-ssl] reaction trigger probe-fail 2
```

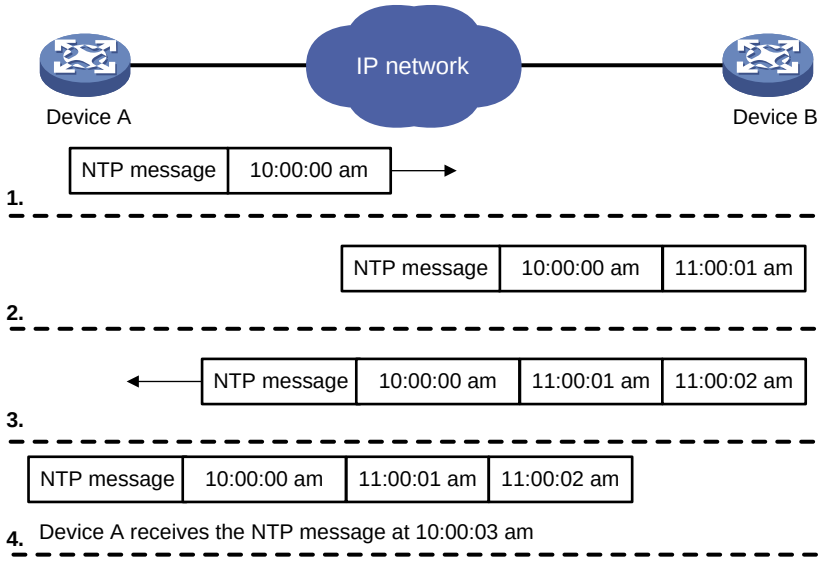
Configuring NTP

About NTP

NTP is used to synchronize system clocks among distributed time servers and clients on a network. NTP runs over UDP and uses UDP port 123.

NTP application scenarios

Various tasks, including network management, charging, auditing, and distributed computing depend on accurate and synchronized system time setting on the network devices. NTP is typically used in large networks to dynamically synchronize time among network devices.



NTP guarantees higher clock accuracy than manual system clock setting. In a small network that does not require high clock accuracy, you can keep time synchronized among devices by changing their system clocks one by one.

NTP working mechanism

Figure 1 shows how NTP synchronizes the system time between two devices (Device A and Device B, in this example). Assume that:

- Prior to the time synchronization, the time is set to 10:00:00 am for Device A and 11:00:00 am for Device B.
- Device B is used as the NTP server. Device A is to be synchronized to Device B.
- It takes 1 second for an NTP message to travel from Device A to Device B, and from Device B to Device A.
- It takes 1 second for Device B to process the NTP message.

Figure 1 Basic work flow

The synchronization process is as follows:

1. Device A sends Device B an NTP message, which is timestamped when it leaves Device A. The time stamp is 10:00:00 am (T1).

2. When this NTP message arrives at Device B, Device B adds a timestamp showing the time when the message arrived at Device B. The timestamp is 11:00:01 am (T2).
3. When the NTP message leaves Device B, Device B adds a timestamp showing the time when the message left Device B. The timestamp is 11:00:02 am (T3).
4. When Device A receives the NTP message, the local time of Device A is 10:00:03 am (T4).

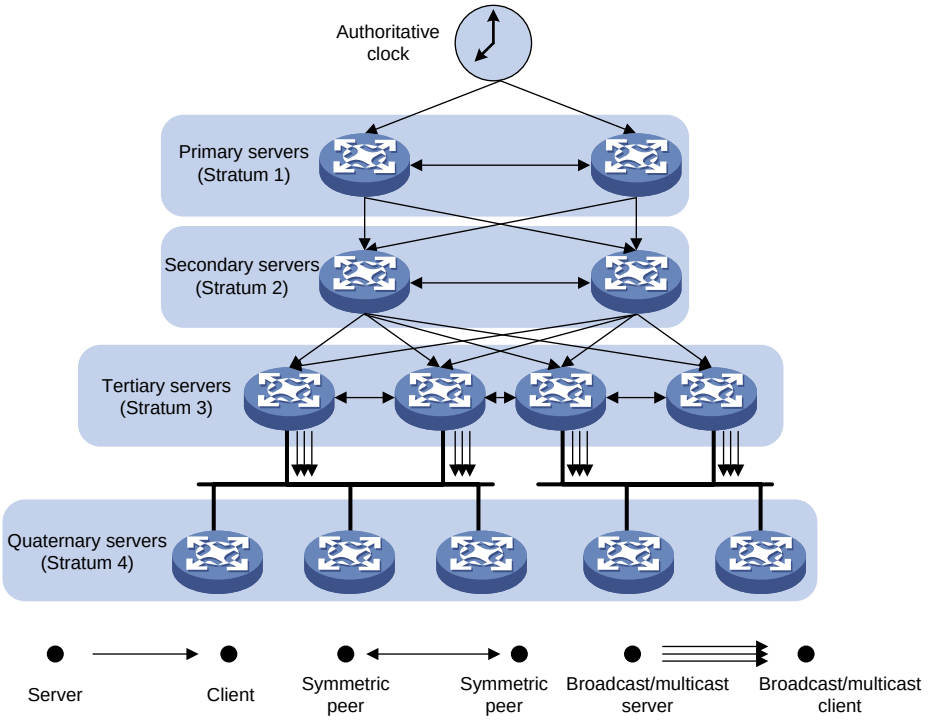
Up to now, Device A can calculate the following parameters based on the timestamps:

- The roundtrip delay of the NTP message: Delay = (T4 – T1) – (T3 – T2) = 2 seconds.
- Time difference between Device A and Device B: Offset = [(T2 – T1) + (T3 – T4)] /2 = 1 hour.

Based on these parameters, Device A can be synchronized to Device B.

This is only a rough description of the work mechanism of NTP. For more information, see the related protocols and standards.

NTP architecture



CAUTION:

When the device acts as an NTP client, the NTP server's clock stratum must be not smaller than 0 and not larger than 14. If the NTP server's clock stratum is larger than 14, the device will not synchronize with that server's clock. You can log in to the NTP server to change its clock stratum by executing the **`ntp-service refclock-master`** command.

- To check the stratum for an IPv4 NTP server, execute the **`display ntp-service sessions`** command on the device and check the **stra** field in the output.
- To check the stratum for an IPv6 NTP server, execute the **`display ntp-service ipv6 sessions`** command on the device and check the **Clock stratum** field in the output.

NTP uses stratums 0 to 16 to define clock accuracy, as shown in Figure 2. A lower stratum value represents higher accuracy.

Figure 2 NTP architecture

A stratum 1 NTP server gets its time from an authoritative time source, such as an atomic clock. It provides time for other devices as the primary NTP server. A stratum 2 time server receives its time from a stratum 1 time server, and so on.

To ensure time accuracy and availability, you can specify multiple NTP servers for a device. The device selects an optimal NTP server as the clock source based on parameters such as stratum. The clock that the device selects is called the reference source. For more information about clock selection, see the related protocols and standards.

If the devices in a network cannot synchronize to an authoritative time source, you can perform the following tasks:

- Select a device that has a relatively accurate clock from the network.
- Use the local clock of the device as the reference clock to synchronize other devices in the network.

NTP association modes

NTP supports the following association modes:

- Client/server mode
- Symmetric active/passive mode
- Broadcast mode
- Multicast mode

You can select one or more association modes for time synchronization. Table 1 provides detailed description for the four association modes.

In this document, an "NTP server" or a "server" refers to a device that operates as an NTP server in client/server mode. Time servers refer to all the devices that can provide time synchronization, including NTP servers, NTP symmetric peers, broadcast servers, and multicast servers.

Table 1 NTP association modes

Mode	Working process	Principle	Application scenario
Client/server	On the client, specify the IP address of the NTP server. A client sends a clock synchronization message to the NTP servers. Upon receiving the message, the servers automatically operate in server mode and send a reply. If the client can be synchronized to multiple time servers, it selects an optimal clock and synchronizes its local clock to the optimal reference source after receiving the replies from the servers.	A client can synchronize to a server, but a server cannot synchronize to a client.	As Figure 2 shows, this mode is intended for configurations where devices of a higher stratum synchronize to devices with a lower stratum.
Symmetric active/passive	On the symmetric active peer, specify the IP address of the symmetric passive peer. A symmetric active peer periodically sends clock synchronization messages to a symmetric passive peer. The symmetric passive peer automatically operates in symmetric passive mode and	A symmetric active peer and a symmetric passive peer can be synchronized to each other. If both of them are synchronized, the peer with a higher stratum is synchronized to the peer with a lower stratum.	As Figure 2 shows, this mode is most often used between servers with the same stratum to operate as a backup for one another. If a server fails to communicate with all the servers of a lower stratum, the server can still synchronize to the servers

Mode	Working process	Principle	Application scenario
	sends a reply. If the symmetric active peer can be synchronized to multiple time servers, it selects an optimal clock and synchronizes its local clock to the optimal reference source after receiving the replies from the servers.		of the same stratum.
Broadcast	A server periodically sends clock synchronization messages to the broadcast address 255.255.255.255. Clients listen to the broadcast messages from the servers to synchronize to the server according to the broadcast messages. When a client receives the first broadcast message, the client and the server start to exchange messages to calculate the network delay between them. Then, only the broadcast server sends clock synchronization messages.	A broadcast client can synchronize to a broadcast server, but a broadcast server cannot synchronize to a broadcast client.	A broadcast server sends clock synchronization messages to synchronize clients in the same subnet. As Figure 2 shows, broadcast mode is intended for configurations involving one or a few servers and a potentially large client population. The broadcast mode has lower time accuracy than the client/server and symmetric active/passive modes because only the broadcast servers send clock synchronization messages.
Multicast	A multicast server periodically sends clock synchronization messages to the user-configured multicast address. Clients listen to the multicast messages from servers and synchronize to the server according to the received messages.	A multicast client can synchronize to a multicast server, but a multicast server cannot synchronize to a multicast client.	A multicast server can provide time synchronization for clients in the same subnet or in different subnets. The multicast mode has lower time accuracy than the client/server and symmetric active/passive modes.

NTP security

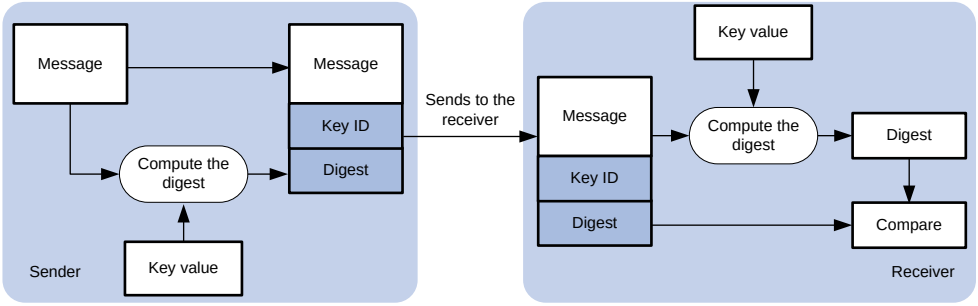
To improve time synchronization security, NTP provides the access control and authentication functions.

NTP access control

You can control NTP access by using an ACL. The access rights are in the following order, from the least restrictive to the most restrictive:

- **Peer**—Allows time requests and NTP control queries (such as alarms, authentication status, and time server information) and allows the local device to synchronize itself to a peer device.
- **Server**—Allows time requests and NTP control queries, but does not allow the local device to synchronize itself to a peer device.
- **Synchronization**—Allows only time requests from a system whose address passes the access list criteria.
- **Query**—Allows only NTP control queries from a peer device to the local device.

When the device receives an NTP request, it matches the request against the access rights in order from the least restrictive to the most restrictive: **peer**, **server**, **synchronization**, and **query**.



- If no NTP access control is configured, the **peer** access right applies.
- If the IP address of the peer device matches a **permit** statement in an ACL, the access right is granted to the peer device. If a **deny** statement or no ACL is matched, no access right is granted.
- If no ACL is specified for an access right or the ACL specified for the access right is not created, the access right is not granted.
- If none of the ACLs specified for the access rights is created, the **peer** access right applies.
- If none of the ACLs specified for the access rights contains rules, no access right is granted.

This feature provides minimal security for a system running NTP. A more secure method is NTP authentication.

NTP authentication

Use this feature to authenticate the NTP messages for security purposes. If an NTP message passes authentication, the device can receive it and get time synchronization information. If not, the device discards the message. This function makes sure the device does not synchronize to an unauthorized time server.

Figure 3 NTP authentication

As shown in Figure 3, NTP authentication is performed as follows:

1. The sender uses the key identified by the key ID to calculate a digest for the NTP message through the MD5/HMAC authentication algorithm. Then it sends the calculated digest together with the NTP message and key ID to the receiver.
2. Upon receiving the message, the receiver performs the following actions:
   a. Finds the key according to the key ID in the message.
   b. Uses the key and the MD5/HMAC authentication algorithm to calculate the digest for the message.
   c. Compares the digest with the digest contained in the NTP message.
      - If they are different, the receiver discards the message.
      - If they are the same and an NTP association is not required to be established, the receiver provides a response packet. For information about NTP associations, see "Configuring the maximum number of dynamic associations."
      - If they are the same and an NTP association is required to be established or has existed, the local device determines whether the sender is allowed to use the authentication ID. If the sender is allowed to use the authentication ID, the receiver accepts the message. If the sender is not allowed to use the authentication ID, the receiver discards the message.

Protocols and standards

- RFC 1305, *Network Time Protocol (Version 3) Specification, Implementation and Analysis*
- RFC 5905, *Network Time Protocol Version 4: Protocol and Algorithms Specification*

Restrictions and guidelines: NTP configuration

- You cannot configure both NTP and SNTP on the same device.
- NTP is supported only on the following Layer 3 interfaces:
  - Layer 3 Ethernet interfaces.
  - Layer 3 Ethernet subinterfaces.
  - Layer 3 aggregate interfaces.
  - Layer 3 aggregate subinterfaces.
  - VLAN interfaces.
  - Tunnel interfaces.
- Do not configure NTP settings on an aggregate member port.
- The NTP service and SNTP service are mutually exclusive. You can only enable either NTP service or SNTP service at a time.
- To avoid frequent time changes or even synchronization failures, do not specify more than one reference source on a network.
- For correct time synchronization, make sure the time difference between the system time and the NTP clock source is less than 68 years.

CAUTION:

When the device acts as an NTP client, the NTP server's clock stratum must be not smaller than 0 and not larger than 14. If the NTP server's clock stratum is larger than 14, the device will not synchronize with that server's clock. You can log in to the NTP server to change its clock stratum by executing the **`ntp-service refclock-master`** command.

- To check the stratum for an IPv4 NTP server, execute the **`display ntp-service sessions`** command on the device and check the **stra** field in the output.
- To check the stratum for an IPv6 NTP server, execute the **`display ntp-service ipv6 sessions`** command on the device and check the **Clock stratum** field in the output.

NTP tasks at a glance

To configure NTP, perform the following tasks:

1. Enabling the NTP service
2. Configuring NTP association mode
   - Configuring NTP in client/server mode
   - Configuring NTP in symmetric active/passive mode
   - Configuring NTP in broadcast mode
   - Configuring NTP in multicast mode
3. (Optional.) Configuring the local clock as the reference source
4. (Optional.) Configuring access control rights
5. (Optional.) Configuring NTP authentication
   - Configuring NTP authentication in client/server mode
   - Configuring NTP authentication in symmetric active/passive mode
   - Configuring NTP authentication in broadcast mode
   - Configuring NTP authentication in multicast mode
6. (Optional.) Controlling NTP message sending and receiving

- Specifying a source address for NTP messages
- Disabling an interface from receiving NTP messages
- Configuring the maximum number of dynamic associations
- Setting a DSCP value for NTP packets

7. (Optional.) Specifying the NTP time-offset thresholds for log and trap outputs

Enabling the NTP service

Restrictions and guidelines

NTP and SNTP are mutually exclusive. Before you enable NTP, make sure SNTP is disabled.

Procedure

1. Enter system view.
   system-view
2. Enable the NTP service.
   ntp-service enable
   By default, the NTP service is disabled.

Configuring NTP association mode

Configuring NTP in client/server mode

Restrictions and guidelines

To configure NTP in client/server mode, specify an NTP server for the client.

For a client to synchronize to an NTP server, make sure the server is synchronized by other devices or uses its local clock as the reference source.

If the stratum level of a server is higher than or equal to a client, the client will not synchronize to that server.

You can specify multiple servers for a client by executing the **ntp-service unicast-server** or **ntp-service ipv6 unicast-server** command multiple times.

Procedure

1. Enter system view.
   system-view
2. Specify an NTP server for the device.
   IPv4:
   ntp-service unicast-server { *server-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **maxpoll** *maxpoll-interval* | **minpoll** *minpoll-interval* | **priority** | **source** *interface-type interface-number* | **version** *number*] *
   IPv6:
   ntp-service ipv6 unicast-server { *server-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **maxpoll** *maxpoll-interval* | **minpoll** *minpoll-interval* | **priority** | **source** *interface-type interface-number*] *
   By default, no NTP server is specified.

Configuring NTP in symmetric active/passive mode

Restrictions and guidelines

To configure NTP in symmetric active/passive mode, specify a symmetric passive peer for the active peer.

For a symmetric passive peer to process NTP messages from a symmetric active peer, execute the **ntp-service enable** command on the symmetric passive peer to enable NTP.

For time synchronization between the symmetric active peer and the symmetric passive peer, make sure either or both of them are in synchronized state.

You can specify multiple symmetric passive peers by executing the **ntp-service unicast-peer** or **ntp-service ipv6 unicast-peer** command multiple times.

Procedure

1. Enter system view.

   system-view

2. Specify a symmetric passive peer for the device.

   IPv4:

   ntp-service unicast-peer { *peer-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **maxpoll** *maxpoll-interval* | **minpoll** *minpoll-interval* | **priority** | **source** *interface-type interface-number* | **version** *number*] *

   IPv6:

   ntp-service ipv6 unicast-peer { *peer-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **maxpoll** *maxpoll-interval* | **minpoll** *minpoll-interval* | **priority** | **source** *interface-type interface-number*] *

   By default, no symmetric passive peer is specified.

Configuring NTP in broadcast mode

Restrictions and guidelines

To configure NTP in broadcast mode, you must configure an NTP broadcast client and an NTP broadcast server.

For a broadcast client to synchronize to a broadcast server, make sure the broadcast server is synchronized by other devices or uses its local clock as the reference source.

Configuring the broadcast client

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the device to operate in broadcast client mode.

   ntp-service broadcast-client

   By default, the device does not operate in any NTP association mode.

   After you execute the command, the device receives NTP broadcast messages from the specified interface.

Configuring the broadcast server

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the device to operate in NTP broadcast server mode.

   ntp-service broadcast-server [**authentication-keyid** *keyid* | **version** *number*] *

   By default, the device does not operate in any NTP association mode.

   After you execute the command, the device sends NTP broadcast messages from the specified interface.

Configuring NTP in multicast mode

Restrictions and guidelines

To configure NTP in multicast mode, you must configure an NTP multicast client and an NTP multicast server.

For a multicast client to synchronize to a multicast server, make sure the multicast server is synchronized by other devices or uses its local clock as the reference source.

Configuring a multicast client

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the device to operate in multicast client mode.

   IPv4:

   ntp-service multicast-client [*ip-address*]

   IPv6:

   ntp-service ipv6 multicast-client *ipv6-address*

   By default, the device does not operate in any NTP association mode.

   After you execute the command, the device receives NTP multicast messages from the specified interface.

Configuring the multicast server

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the device to operate in multicast server mode.

   IPv4:

   ntp-service multicast-server [*ip-address*][**authentication-keyid** *keyid* | **ttl** *ttl-number* | **version** *number*]*

   IPv6:

   ntp-service ipv6 multicast-server *ipv6-address* [**authentication-keyid** *keyid* | **ttl** *ttl-number*] *

By default, the device does not operate in any NTP association mode.

After you execute the command, the device sends NTP multicast messages from the specified interface.

Configuring the local clock as the reference source

About this task

This task enables the device to use the local clock as the reference so that the device is synchronized.

Restrictions and guidelines

Make sure the local clock can provide the time accuracy required for the network. After you configure the local clock as the reference source, the local clock is synchronized, and can operate as a time server to synchronize other devices in the network. If the local clock is incorrect, timing errors occur.

The system time reverts to the initial BIOS default after a cold reboot. The system clock stops and does not record the passing of time during a warm reboot. As a best practice, do not configure the local clock as the reference source or configure the device as a time server.

Devices differ in clock precision. As a best practice to avoid network flapping and clock synchronization failure, configure only one reference clock on the same network segment and make sure the clock has high precision.

Prerequisites

Before you configure this feature, adjust the local system time to ensure that it is accurate.

Procedure

1. Enter system view.

   `system-view`

2. Configure the local clock as the reference source.

   `ntp-service refclock-master` [*`ip-address`*] [*`stratum`*]

   By default, the device does not use the local clock as the reference source.

Configuring access control rights

Prerequisites

Before you configure the right for peer devices to access the NTP services on the local device, create and configure ACLs associated with the access right. For information about configuring an ACL, see *ACL and QoS Configuration Guide*.

Restrictions and guidelines

Follow the restrictions and guidelines as described in Table 2 to configure the NTP access control rights.

Table 2 Restrictions and guidelines for configuring NTP access control rights

NTP access control right	Whether the time can be synchronized (whether configurable on a client)	Whether can synchronize the time of other devices (whether configurable on a time server)	Whether control queries are allowed
Peer	Yes	Yes	Yes
Server	No	Yes	Yes
Synchronization	No	Yes	No
Query	No	No	Yes

Procedure

1. Enter system view.

   system-view

2. Configure the right for peer devices to access the NTP services on the local device.

   IPv4:

   ntp-service access { **peer** | **query** | **server** | **synchronization** } **acl** *ipv4-acl-number*

   IPv6:

   ntp-service ipv6 { **peer** | **query** | **server** | **synchronization** } **acl** *ipv6-acl-number*

   By default, the right for peer devices to access the NTP services on the local device is **peer**.

Configuring NTP authentication

Configuring NTP authentication in client/server mode

Restrictions and guidelines

To ensure a successful NTP authentication in client/server mode, configure the same authentication key ID, algorithm, and key on the server and client. Make sure the peer device is allowed to use the key ID for authentication on the local device.

NTP authentication results differ when different configurations are performed on client and server. For more information, see Table 3. (N/A in the table means that whether the configuration is performed or not does not make any difference.)

Table 3 NTP authentication results

Client			Server	
Enable NTP authentication	**Specify the server and key**	**Trusted key**	**Enable NTP authentication**	**Trusted key**
Successful authentication				
Yes	Yes	Yes	Yes	Yes
Failed authentication				
Yes	Yes	Yes	Yes	No

Client			Server	
Yes	Yes	Yes	No	N/A
Yes	Yes	No	N/A	N/A
Authentication not performed				
Yes	No	N/A	N/A	N/A
No	N/A	N/A	N/A	N/A

Configuring NTP authentication for a client

1. Enter system view.

   system-view

2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

5. Associate the specified key with an NTP server.

   IPv4:

   ntp-service unicast-server { *server-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

   IPv6:

   ntp-service ipv6 unicast-server { *server-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

Configuring NTP authentication for a server

1. Enter system view.

   system-view

2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

Configuring NTP authentication in symmetric active/passive mode

Restrictions and guidelines

To ensure a successful NTP authentication in symmetric active/passive mode, configure the same authentication key ID, algorithm, and key on the active peer and passive peer. Make sure the peer device is allowed to use the key ID for authentication on the local device.

NTP authentication results differ when different configurations are performed on active peer and passive peer. For more information, see Table 4. (N/A in the table means that whether the configuration is performed or not does not make any difference.)

Table 4 NTP authentication results

Active peer				Passive peer	
Enable NTP authentication	**Specify the peer and key**	**Trusted key**	**Stratum level**	**Enable NTP authentication**	**Trusted key**
Successful authentication					
Yes	Yes	Yes	N/A	Yes	Yes
Failed authentication					
Yes	Yes	Yes	N/A	Yes	No
Yes	Yes	Yes	N/A	No	N/A
Yes	No	N/A	N/A	Yes	N/A
No	N/A	N/A	N/A	Yes	N/A
Yes	Yes	No	Larger than the passive peer	N/A	N/A
Yes	Yes	No	Smaller than the passive peer	Yes	N/A
Authentication not performed					
Yes	No	N/A	N/A	No	N/A
No	N/A	N/A	N/A	No	N/A
Yes	Yes	No	Smaller than the passive peer	No	N/A

Configuring NTP authentication for an active peer

1. Enter system view.

   system-view

2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

5. Associate the specified key with a passive peer.

   IPv4:

   ntp-service unicast-peer { *ip-address* | *peer-name* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

   IPv6:

   ntp-service ipv6 unicast-peer { *ipv6-address* | *peer-name* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

Configuring NTP authentication for a passive peer

1. Enter system view.

   system-view

2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

Configuring NTP authentication in broadcast mode

Restrictions and guidelines

To ensure a successful NTP authentication in broadcast mode, configure the same authentication key ID, algorithm, and key on the broadcast server and client. Make sure the peer device is allowed to use the key ID for authentication on the local device.

NTP authentication results differ when different configurations are performed on broadcast client and server. For more information, see Table 5. (N/A in the table means that whether the configuration is performed or not does not make any difference.)

Table 5 NTP authentication results

Broadcast server			**Broadcast client**	
Enable NTP authentication	**Specify the server and key**	**Trusted key**	**Enable NTP authentication**	**Trusted key**
Successful authentication				
Yes	Yes	Yes	Yes	Yes
Failed authentication				
Yes	Yes	Yes	Yes	No
Yes	Yes	Yes	No	N/A

Broadcast server			Broadcast client	
Yes	Yes	No	Yes	N/A
Yes	No	N/A	Yes	N/A
No	N/A	N/A	Yes	N/A
Authentication not performed				
Yes	Yes	No	No	N/A
Yes	No	N/A	No	N/A
No	N/A	N/A	No	N/A

Configuring NTP authentication for a broadcast client

1. Enter system view.

   system-view
2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.
3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.
4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

Configuring NTP authentication for a broadcast server

1. Enter system view.

   system-view
2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.
3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.
4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.
5. Enter interface view.

   interface *interface-type interface-number*
6. Associate the specified key with the broadcast server.

   ntp-service broadcast-server authentication-keyid *keyid*

By default, the broadcast server is not associated with a key.

Configuring NTP authentication in multicast mode

Restrictions and guidelines

To ensure a successful NTP authentication in multicast mode, configure the same authentication key ID, algorithm, and key on the multicast server and client. Make sure the peer device is allowed to use the key ID for authentication on the local device.

NTP authentication results differ when different configurations are performed on broadcast client and server. For more information, see Table 6. (N/A in the table means that whether the configuration is performed or not does not make any difference.)

Table 6 NTP authentication results

Multicast server			Multicast client	
Enable NTP authentication	**Specify the server and key**	**Trusted key**	**Enable NTP authentication**	**Trusted key**
Successful authentication				
Yes	Yes	Yes	Yes	Yes
Failed authentication				
Yes	Yes	Yes	Yes	No
Yes	Yes	Yes	No	N/A
Yes	Yes	No	Yes	N/A
Yes	No	N/A	Yes	N/A
No	N/A	N/A	Yes	N/A
Authentication not performed				
Yes	Yes	No	No	N/A
Yes	No	N/A	No	N/A
No	N/A	N/A	No	N/A

Configuring NTP authentication for a multicast client

1. Enter system view.

   system-view

2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

Configuring NTP authentication for a multicast server

1. Enter system view.

   system-view

2. Enable NTP authentication.

   ntp-service authentication enable

   By default, NTP authentication is disabled.

3. Configure an NTP authentication key.

   ntp-service authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*] *

   By default, no NTP authentication key exists.

4. Configure the key as a trusted key.

   ntp-service reliable authentication-keyid *keyid*

   By default, no authentication key is configured as a trusted key.

5. Enter interface view.

   interface *interface-type interface-number*

6. Associate the specified key with a multicast server.

   IPv4:

   ntp-service multicast-server [*ip-address*] **authentication-keyid** *keyid*

   IPv6:

   ntp-service ipv6 multicast-server *ipv6-multicast-address* **authentication-keyid** *keyid*

   By default, no multicast server is associated with the specified key.

Controlling NTP message sending and receiving

Specifying a source address for NTP messages

About this task

You can specify a source address for NTP messages directly or by specifying a source interface. If you specify a source interface for NTP messages, the device uses the IP address of the specified interface as the source address to send NTP messages.

Restrictions and guidelines

To prevent interface status changes from causing NTP communication failures, specify an interface that is always up as the source interface, a loopback interface for example.

When the device responds to an NTP request, the source IP address of the NTP response is always the IP address of the interface that has received the NTP request.

If you have specified the source interface for NTP messages in the **ntp-service unicast-server/ntp-service ipv6 unicast-server** or **ntp-service unicast-peer/ntp-service ipv6 unicast-peer** command, the IP address of the specified interface is used as the source IP address for NTP messages.

If you have configured the **ntp-service broadcast-server** or **ntp-service multicast-server/ntp-service ipv6 multicast-server** command in an interface view, the IP address of the interface is used as the source IP address for broadcast or multicast NTP messages.

Procedure

1. Enter system view.
   system-view
2. Specify the source address for NTP messages.
   IPv4:
   ntp-service source { *interface-type interface-number* | *ipv4-address* }
   IPv6:
   ntp-service ipv6 source *interface-type interface-number*
   By default, no source address is specified for NTP messages.

Disabling an interface from receiving NTP messages

About this task

When NTP is enabled, all interfaces by default can receive NTP messages. For security purposes, you can disable some of the interfaces from receiving NTP messages.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Disable the interface from receiving NTP packets.
   IPv4:
   undo ntp-service inbound enable
   IPv6:
   undo ntp-service ipv6 inbound enable
   By default, an interface receives NTP messages.

Configuring the maximum number of dynamic associations

About this task

Perform this task to restrict the number of dynamic associations to prevent dynamic associations from occupying too many system resources.

NTP has the following types of associations:

- **Static association**—A manually created association.
- **Dynamic association**—Temporary association created by the system during NTP operation. A dynamic association is removed if no messages are exchanged within about 12 minutes.

The following describes how an association is established in different association modes:

- **Client/server mode**—After you specify an NTP server, the system creates a static association on the client. The server simply responds passively upon the receipt of a message, rather than creating an association (static or dynamic).
- **Symmetric active/passive mode**—After you specify a symmetric passive peer on a symmetric active peer, static associations are created on the symmetric active peer, and dynamic associations are created on the symmetric passive peer.
- **Broadcast or multicast mode**—Static associations are created on the server, and dynamic associations are created on the client.

Restrictions and guidelines

A single device can have a maximum of 128 concurrent associations, including static associations and dynamic associations.

The **ntp-service max-dynamic-sessions** command does not affect established NTP sessions. When the number of sessions reaches or exceeds the maximum allowed limit, no new sessions can be established.

Procedure

1. Enter system view.
   system-view
2. Configure the maximum number of dynamic sessions.
   ntp-service max-dynamic-sessions *number*
   By default, the maximum number of dynamic sessions is 100.

Setting a DSCP value for NTP packets

About this task

The DSCP value determines the sending precedence of an NTP packet. Through this configuration, you can specify the DSCP value of NTP packets sent by the device when it acts as an NTP/IPv6 NTP server or client.

Procedure

1. Enter system view.
   system-view
2. Set a DSCP value for NTP packets.
   IPv4:
   ntp-service dscp *dscp-value*
   IPv6:
   ntp-service ipv6 dscp *dscp-value*
   The default DSCP value is 48 for IPv4 packets and 56 for IPv6 packets.

Specifying the NTP time-offset thresholds for log and trap outputs

About this task

By default, the system synchronizes the NTP client's time to the server and outputs a log and a trap when the time offset exceeds 128 ms for multiple times.

After you set the NTP time-offset thresholds for log and trap outputs, the system synchronizes the client's time to the server when the time offset exceeds 128 ms for multiple times, but outputs logs and traps only when the time offset exceeds the specified thresholds, respectively.

Procedure

1. Enter system view.
   system-view
2. Specify the NTP time-offset thresholds for log and trap outputs.
   ntp-service time-offset-threshold { **log** *log-threshold* | **trap** *trap-threshold* } *

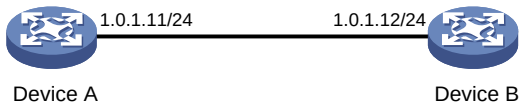
By default, no NTP time-offset thresholds are set for log and trap outputs.

Display and maintenance commands for NTP

Execute **display** commands in any view.

Task	Command
Display information about IPv6 NTP associations.	**display ntp-service ipv6 sessions** [**verbose**]
Display information about IPv4 NTP associations.	**display ntp-service sessions** [**verbose**]
Display information about NTP service status.	**display ntp-service status**
Display brief information about the NTP servers from the local device back to the primary NTP server.	**display ntp-service trace** [**source** *interface-type interface-number*]

NTP configuration examples



Example: Configuring NTP client/server association mode

Network configuration

As shown in Figure 4, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device B to operate in client mode and specify Device A as the NTP server of Device B.

Figure 4 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 4. (Details not shown.)
2. Configure Device A:

   # Enable the NTP service.

   ```
   <DeviceA> system-view
   [DeviceA] ntp-service enable
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [DeviceA] ntp-service refclock-master 2
   ```
3. Configure Device B:

   # Enable the NTP service.

   ```
   <DeviceB> system-view
   [DeviceB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceB] clock protocol ntp
   ```

Specify Device A as the NTP server of Device B.

```
[DeviceB] ntp-service unicast-server 1.0.1.11
```

Verifying the configuration

Verify that Device B has synchronized its time with Device A, and the clock stratum level of Device B is 3.

```
[DeviceB] display ntp-service status
 Clock status: synchronized
 Clock stratum: 3
 System peer: 1.0.1.11
 Local mode: client
 Reference clock ID: 1.0.1.11
 Leap indicator: 00
 Clock jitter: 0.000977 s
 Stability: 0.000 pps
 Clock precision: 2^-10
 Root delay: 0.00383 ms
 Root dispersion: 16.26572 ms
 Reference time: d0c6033f.b9923965  Wed, Dec 29 2019 18:58:07.724
 System poll interval: 64 s
```

Verify that an IPv4 NTP association has been established between Device B and Device A.

```
[DeviceB] display ntp-service sessions
       source          reference       stra reach poll  now offset  delay disper
**********************************************************************************
[12345]1.0.1.11        127.127.1.0        2     1   64   15   -4.0 0.0038 16.262
Notes: 1 source(master), 2 source(peer), 3 selected, 4 candidate, 5 configured.
 Total sessions: 1
```

Example: Configuring IPv6 NTP client/server association mode

Network configuration

As shown in Figure 5, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device B to operate in client mode and specify Device A as the IPv6 NTP server of Device B.

Figure 5 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 5. (Details not shown.)
2. Configure Device A:

Enable the NTP service.

```
<DeviceA> system-view
[DeviceA] ntp-service enable
```

Specify the local clock as the reference source, with stratum level 2.

```
[DeviceA] ntp-service refclock-master 2
```

3. Configure Device B:

Enable the NTP service.

```
<DeviceB> system-view
[DeviceB] ntp-service enable
```

Specify NTP for obtaining the time.

```
[DeviceB] clock protocol ntp
```

Specify Device A as the IPv6 NTP server of Device B.

```
[DeviceB] ntp-service ipv6 unicast-server 3000::34
```

Verifying the configuration

Verify that Device B has synchronized its time with Device A, and the clock stratum level of Device B is 3.

```
[DeviceB] display ntp-service status
 Clock status: synchronized
 Clock stratum: 3
 System peer: 3000::34
 Local mode: client
 Reference clock ID: 163.29.247.19
 Leap indicator: 00
 Clock jitter: 0.000977 s
 Stability: 0.000 pps
 Clock precision: 2^-10
 Root delay: 0.02649 ms
 Root dispersion: 12.24641 ms
 Reference time: d0c60419.9952fb3e  Wed, Dec 29 2019 19:01:45.598
 System poll interval: 64 s
```

Verify that an IPv6 NTP association has been established between Device B and Device A.

```
[DeviceB] display ntp-service ipv6 sessions
Notes: 1 source(master), 2 source(peer), 3 selected, 4 candidate, 5 configured.

 Roundtrip delay: 0.0           Dispersion: 0.0

 Total sessions: 1
```

Example: Configuring NTP symmetric active/passive association mode

Network configuration

As shown in Figure 6, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device A to operate in symmetric active mode and specify Device B as the passive peer of Device A.

Figure 6 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 6. (Details not shown.)
2. Configure Device B:

   # Enable the NTP service.

   ```
   <DeviceB> system-view
   [DeviceB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceB] clock protocol ntp
   ```

3. Configure Device A:

   # Enable the NTP service.

   ```
   <DeviceA> system-view
   [DeviceA] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceA] clock protocol ntp
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [DeviceA] ntp-service refclock-master 2
   ```

   # Configure Device B as its symmetric passive peer.

   ```
   [DeviceA] ntp-service unicast-peer 3.0.1.32
   ```

Verifying the configuration

Verify that Device B has synchronized its time with Device A.

```
[DeviceB] display ntp-service status
 Clock status: synchronized
 Clock stratum: 3
 System peer: 3.0.1.31
 Local mode: sym_passive

Example: Configuring IPv6 NTP symmetric active/passive association mode

Network configuration

As shown in Figure 7, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device A to operate in symmetric active mode and specify Device B as the IPv6 passive peer of Device A.

Figure 7 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 7. (Details not shown.)
2. Configure Device B:

   # Enable the NTP service.

   ```
   <DeviceB> system-view
   [DeviceB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceB] clock protocol ntp
   ```
3. Configure Device A:

   # Enable the NTP service.

   ```
   <DeviceA> system-view
   [DeviceA] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceA] clock protocol ntp
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [DeviceA] ntp-service refclock-master 2
   ```

   # Configure Device B as the IPv6 symmetric passive peer.

   ```
   [DeviceA] ntp-service ipv6 unicast-peer 3000::36
   ```

Verifying the configuration

Verify that Device B has synchronized its time with Device A.

```
[DeviceB] display ntp-service status
 Clock status: synchronized
```

```
Clock stratum: 3
System peer: 3000::35

```

Example: Configuring NTP broadcast association mode

Network configuration

As shown in Figure 8, configure Switch C as the NTP server for multiple devices on the same network segment so that these devices synchronize the time with Switch C.

- Configure Switch C's local clock as its reference source, with stratum level 2.
- Configure Switch C to operate in broadcast server mode and send broadcast messages from VLAN-interface 2.
- Configure Switch A and Switch B to operate in broadcast client mode, and listen to broadcast messages on VLAN-interface 2.

Figure 8 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Switch A, Switch B, and Switch C can reach each other, as shown in Figure 8. (Details not shown.)
2. Configure Switch C:

   # Enable the NTP service.

   ```
   <SwitchC> system-view
   [SwitchC] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchC] clock protocol ntp
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [SwitchC] ntp-service refclock-master 2
   ```

   # Configure Switch C to operate in broadcast server mode and send broadcast messages from VLAN-interface 2.

   ```
   [SwitchC] interface vlan-interface 2
   [SwitchC-Vlan-interface2] ntp-service broadcast-server
   ```

3. Configure Switch A:

   # Enable the NTP service.

   ```
   <SwitchA> system-view
   [SwitchA] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchA] clock protocol ntp
   ```

   # Configure Switch A to operate in broadcast client mode and receive broadcast messages on VLAN-interface 2.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ntp-service broadcast-client
   ```

4. Configure Switch B:

   # Enable the NTP service.

   ```
   <SwitchB> system-view
   [SwitchB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchB] clock protocol ntp
   ```

Configure Switch B to operate in broadcast client mode and receive broadcast messages on VLAN-interface 2.

```
[SwitchB] interface vlan-interface 2
[SwitchB-Vlan-interface2] ntp-service broadcast-client
```

Verifying the configuration

The following procedure uses Switch A as an example to verify the configuration.

Verify that Switch A has synchronized to Switch C, and the clock stratum level is 3 on Switch A and 2 on Switch C.

```
[SwitchA-Vlan-interface2] display ntp-service status
 Clock status: synchronized
 Clock stratum: 3
 System peer: 3.0.1.31
 Local mode: bclient
 Reference clock ID: 3.0.1.31
 Leap indicator: 00
 Clock jitter: 0.044281 s
 Stability: 0.000 pps
 Clock precision: 2^-10
 Root delay: 0.00229 ms
 Root dispersion: 4.12572 ms
 Reference time: d0d289fe.ec43c720  Sat, Jan  8 2019  7:00:14.922
 System poll interval: 64 s
```

Verify that an IPv4 NTP association has been established between Switch A and Switch C.

```
[SwitchA-Vlan-interface2] display ntp-service sessions
       source          reference       stra reach poll  now offset  delay disper
**********************************************************************************

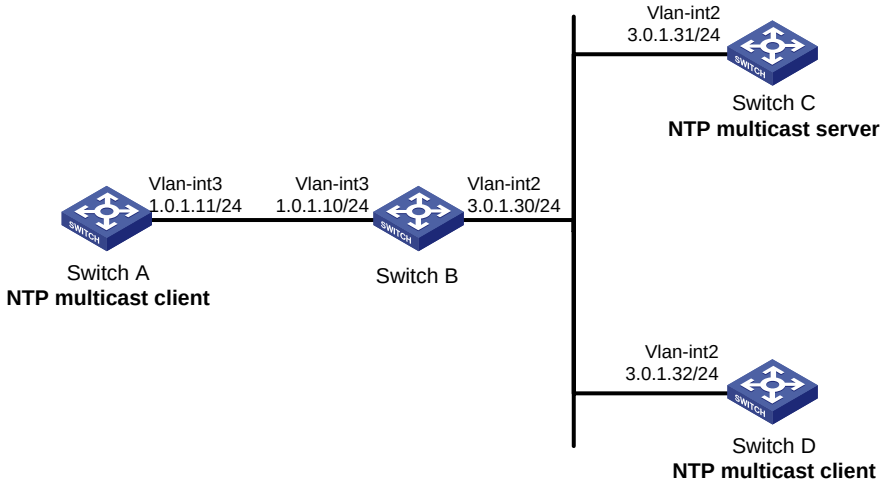
Notes: 1 source(master),2 source(peer),3 selected,4 candidate,5 configured.
 Total sessions: 1
```



Example: Configuring NTP multicast association mode

Network configuration

As shown in Figure 9, configure Switch C as the NTP server for multiple devices on different network segments so that these devices synchronize the time with Switch C.

- Configure Switch C's local clock as its reference source, with stratum level 2.
- Configure Switch C to operate in multicast server mode and send multicast messages from VLAN-interface 2.
- Configure Switch A and Switch D to operate in multicast client mode and receive multicast messages on VLAN-interface 3 and VLAN-interface 2, respectively.

Figure 9 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure the switches can reach each other, as shown in Figure 9. (Details not shown.)
2. Configure Switch C:

   # Enable the NTP service.

   ```
   <SwitchC> system-view
   [SwitchC] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchC] clock protocol ntp
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [SwitchC] ntp-service refclock-master 2
   ```

   # Configure Switch C to operate in multicast server mode and send multicast messages from VLAN-interface 2.

   ```
   [SwitchC] interface vlan-interface 2
   [SwitchC-Vlan-interface2] ntp-service multicast-server
   ```

3. Configure Switch D:

   # Enable the NTP service.

   ```
   <SwitchD> system-view
   [SwitchD] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchD] clock protocol ntp
   ```

   # Configure Switch D to operate in multicast client mode and receive multicast messages on VLAN-interface 2.

   ```
   [SwitchD] interface vlan-interface 2
   [SwitchD-Vlan-interface2] ntp-service multicast-client
   ```

4. Verify the configuration:

   # Verify that Switch D has synchronized to Switch C, and the clock stratum level is 3 on Switch D and 2 on Switch C.

   Switch D and Switch C are on the same subnet, so Switch D can receive the multicast messages from Switch C without being enabled with the multicast functions.

   ```
   [SwitchD-Vlan-interface2] display ntp-service status
    Clock status: synchronized
   ```

```
 Clock stratum: 3
 System peer: 3.0.1.31
 Local mode: bclient
 Reference clock ID: 3.0.1.31
 Leap indicator: 00
 Clock jitter: 0.044281 s
 Stability: 0.000 pps
 Clock precision: 2^-10
 Root delay: 0.00229 ms
 Root dispersion: 4.12572 ms
 Reference time: d0d289fe.ec43c720  Sat, Jan  8 2019  7:00:14.922
 System poll interval: 64 s
```

Verify that an IPv4 NTP association has been established between Switch D and Switch C.

```
[SwitchD-Vlan-interface2] display ntp-service sessions
      source          reference       stra reach poll  now offset  delay disper
********************************************************************************
 [1245]3.0.1.31        127.127.1.0        2     1   64  519   -0.0 0.0022 4.1257
Notes: 1 source(master),2 source(peer),3 selected,4 candidate,5 configured.
 Total sessions: 1
```

5. Configure Switch B:

Because Switch A and Switch C are on different subnets, you must enable the multicast functions on Switch B before Switch A can receive multicast messages from Switch C.

Enable IP multicast functions.

```
<SwitchB> system-view

Example: Configuring IPv6 NTP multicast association mode

Network configuration

As shown in Figure 10, configure Switch C as the NTP server for multiple devices on different network segments so that these devices synchronize the time with Switch C.

- Configure Switch C's local clock as its reference source, with stratum level 2.
- Configure Switch C to operate in IPv6 multicast server mode and send IPv6 multicast messages from VLAN-interface 2.
- Configure Switch A and Switch D to operate in IPv6 multicast client mode and receive IPv6 multicast messages on VLAN-interface 3 and VLAN-interface 2, respectively.

Figure 10 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure the switches can reach each other, as shown in Figure 10. (Details not shown.)
2. Configure Switch C:

   # Enable the NTP service.

   ```
   <SwitchC> system-view
   [SwitchC] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchC] clock protocol ntp
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [SwitchC] ntp-service refclock-master 2
   ```

   # Configure Switch C to operate in IPv6 multicast server mode and send multicast messages from VLAN-interface 2.

   ```
   [SwitchC] interface vlan-interface 2
   [SwitchC-Vlan-interface2] ntp-service ipv6 multicast-server ff24::1
   ```

3. Configure Switch D:

   # Enable the NTP service.

   ```
   <SwitchD> system-view
   [SwitchD] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchD] clock protocol ntp
   ```

   # Configure Switch D to operate in IPv6 multicast client mode and receive multicast messages on VLAN-interface 2.

   ```
   [SwitchD] interface vlan-interface 2

Example: Configuring NTP authentication in client/server association mode

Network configuration

As shown in Figure 11, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device B to operate in client mode and specify Device A as the NTP server of Device B.
- Configure NTP authentication on both Device A and Device B.

Figure 11 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 11. (Details not shown.)
2. Configure Device A:

   # Enable the NTP service.

   ```
   <DeviceA> system-view
   [DeviceA] ntp-service enable
   ```

   # Specify the local clock as the reference source, with stratum level 2.

   ```
   [DeviceA] ntp-service refclock-master 2
   ```
3. Configure Device B:

   # Enable the NTP service.

   ```
   <DeviceB> system-view
   [DeviceB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceB] clock protocol ntp
   ```

   # Enable NTP authentication on Device B.

   ```
   [DeviceB] ntp-service authentication enable
   ```

   # Create a plaintext authentication key, with key ID **42** and key value **aNiceKey**.

   ```
   [DeviceB] ntp-service authentication-keyid 42 authentication-mode md5 simple
   aNiceKey
   ```

   # Specify the key as a trusted key.

   ```
   [DeviceB] ntp-service reliable authentication-keyid 42
   ```

   # Specify Device A as the NTP server of Device B, and associate the server with key 42.

   ```
   [DeviceB] ntp-service unicast-server 1.0.1.11 authentication-keyid 42
   ```

   To enable Device B to synchronize its clock with Device A, enable NTP authentication on Device A.
4. Configure NTP authentication on Device A:

   # Enable NTP authentication.

   ```
   [DeviceA] ntp-service authentication enable
   ```

   # Create a plaintext authentication key, with key ID **42** and key value **aNiceKey**.

   ```
   [DeviceA] ntp-service authentication-keyid 42 authentication-mode md5 simple
   aNiceKey
   ```

   # Specify the key as a trusted key.

   ```
   [DeviceA] ntp-service reliable authentication-keyid 42
   ```

Verifying the configuration

Verify that Device B has synchronized its time with Device A, and the clock stratum level of Device B is 3.

```
[DeviceB] display ntp-service status
 Clock status: synchronized
 Clock stratum: 3
```

```
 System peer: 1.0.1.11

```

Example: Configuring NTP authentication in broadcast association mode

Network configuration

As shown in Figure 12, configure Switch C as the NTP server for multiple devices on the same network segment so that these devices synchronize the time with Switch C. Configure Switch A and Switch B to authenticate the NTP server.

- Configure Switch C's local clock as its reference source, with stratum level 3.
- Configure Switch C to operate in broadcast server mode and send broadcast messages from VLAN-interface 2.
- Configure Switch A and Switch B to operate in broadcast client mode and receive broadcast messages on VLAN-interface 2.
- Enable NTP authentication on Switch A, Switch B, and Switch C.

Figure 12 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Switch A, Switch B, and Switch C can reach each other, as shown in Figure 12. (Details not shown.)
2. Configure Switch A:

   # Enable the NTP service.

   ```
   <SwitchA> system-view
   [SwitchA] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchA] clock protocol ntp
   ```

   # Enable NTP authentication on Switch A. Create a plaintext NTP authentication key, with key ID of **88** and key value of **123456**. Specify it as a trusted key.

   ```
   [SwitchA] ntp-service authentication enable
   [SwitchA] ntp-service authentication-keyid 88 authentication-mode md5 simple 123456
   [SwitchA] ntp-service reliable authentication-keyid 88
   ```

   # Configure Switch A to operate in NTP broadcast client mode and receive NTP broadcast messages on VLAN-interface 2.

   ```
   [SwitchA] interface vlan-interface 2
   [SwitchA-Vlan-interface2] ntp-service broadcast-client
   ```

3. Configure Switch B:

   # Enable the NTP service.

   ```
   <SwitchB> system-view
   [SwitchB] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchB] clock protocol ntp
   ```

   # Enable NTP authentication on Switch B. Create a plaintext NTP authentication key, with key ID of **88** and key value of **123456**. Specify it as a trusted key.

   ```
   [SwitchB] ntp-service authentication enable
   [SwitchB] ntp-service authentication-keyid 88 authentication-mode md5 simple 123456
   [SwitchB] ntp-service reliable authentication-keyid 88
   ```

   # Configure Switch B to operate in broadcast client mode and receive NTP broadcast messages on VLAN-interface 2.

   ```
   [SwitchB] interface vlan-interface 2
   [SwitchB-Vlan-interface2] ntp-service broadcast-client
   ```

4. Configure Switch C:

   # Enable the NTP service.

   ```
   <SwitchC> system-view
   [SwitchC] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [SwitchC] clock protocol ntp
   ```

   # Specify the local clock as the reference source, with stratum level 3.

   ```
   [SwitchC] ntp-service refclock-master 3
   ```

   # Configure Switch C to operate in NTP broadcast server mode and use VLAN-interface 2 to send NTP broadcast packets.

   ```
   [SwitchC] interface vlan-interface 2
   [SwitchC-Vlan-interface2] ntp-service broadcast-server
   [SwitchC-Vlan-interface2] quit
   ```

5. Verify the configuration:

NTP authentication is enabled on Switch A and Switch B, but not on Switch C, so Switch A and Switch B cannot synchronize their local clocks to Switch C.

```
[SwitchB-Vlan-interface2] display ntp-service status
 Clock status: unsynchronized
 Clock stratum: 16
 Reference clock ID: none
```

6. Enable NTP authentication on Switch C:

Enable NTP authentication on Switch C. Create a plaintext NTP authentication key, with key ID of **88** and key value of **123456**. Specify it as a trusted key.

```
[SwitchC] ntp-service authentication enable
[SwitchC] ntp-service authentication-keyid 88 authentication-mode md5 simple 123456
[SwitchC] ntp-service reliable authentication-keyid 88
```

Specify Switch C as an NTP broadcast server, and associate key **88** with Switch C.

```
[SwitchC] interface vlan-interface 2
[SwitchC-Vlan-interface2] ntp-service broadcast-server authentication-keyid 88
```

Verifying the configuration

Verify that Switch B has synchronized its time with Switch C, and the clock stratum level of Switch B is 4.

```
[SwitchB-Vlan-interface2] display ntp-service status
 Clock status: synchronized
 Clock stratum: 4
 System peer: 3.0.1.31
 Local mode: bclient

Configuring SNTP

About SNTP

SNTP is a simplified, client-only version of NTP specified in RFC 4330. It uses the same packet format and packet exchange procedure as NTP, but provides faster synchronization at the price of time accuracy.

SNTP working mode

SNTP supports only the client/server mode. An SNTP-enabled device can receive time from NTP servers, but cannot provide time services to other devices.

If you specify multiple NTP servers for an SNTP client, the server with the best stratum is selected. If multiple servers are at the same stratum, the NTP server whose time packet is first received is selected.

Protocols and standards

RFC 4330, *Simple Network Time Protocol (SNTP) Version 4 for IPv4, IPv6 and OSI*

Restrictions and guidelines: SNTP configuration

When you configure SNTP, follow these restrictions and guidelines:

- You cannot configure both NTP and SNTP on the same device.

SNTP tasks at a glance

To configure SNTP, perform the following tasks:

1. Enabling the SNTP service
2. Specifying an NTP server for the device
3. (Optional.) Configuring SNTP authentication
4. (Optional.) Specifying the SNTP time-offset thresholds for log and trap outputs

Enabling the SNTP service

Restrictions and guidelines

The NTP service and SNTP service are mutually exclusive. Before you enable SNTP, make sure NTP is disabled.

Procedure

1. Enter system view.

   `system-view`
2. Enable the SNTP service.

   `sntp enable`

   By default, the SNTP service is disabled.

Specifying an NTP server for the device

Restrictions and guidelines

To use an NTP server as the time source, make sure its clock has been synchronized. If the stratum level of the NTP server is greater than or equal to that of the client, the client does not synchronize with the NTP server.

Procedure

1. Enter system view.

   system-view

2. Specify an NTP server for the device.

   IPv4:

   sntp unicast-server { *server-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **source** *interface-type interface-number* | **version** *number*] *

   IPv6:

   sntp ipv6 unicast-server { *server-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] [**authentication-keyid** *keyid* | **source** *interface-type interface-number*] *

   By default, no NTP server is specified for the device.

   You can specify multiple NTP servers for the client by repeating this step.

   To perform authentication, you need to specify the **authentication-keyid** *keyid* option.

Configuring SNTP authentication

About this task

SNTP authentication ensures that an SNTP client is synchronized only to an authenticated trustworthy NTP server.

Restrictions and guidelines

Enable authentication on both the NTP server and the SNTP client.

Use the same authentication key ID, algorithm, and key on the NTP server and SNTP client. Specify the key as a trusted key on both the NTP server and the SNTP client. For information about configuring NTP authentication on an NTP server, see "Configuring NTP."

On the SNTP client, associate the specified key with the NTP server. Make sure the server is allowed to use the key ID for authentication on the client.

With authentication disabled, the SNTP client can synchronize with the NTP server regardless of whether the NTP server is enabled with authentication.

Procedure

1. Enter system view.

   system-view

2. Enable SNTP authentication.

   sntp authentication enable

   By default, SNTP authentication is disabled.

3. Configure an SNTP authentication key.

sntp authentication-keyid *keyid* **authentication-mode** { **hmac-sha-1** | **hmac-sha-256** | **hmac-sha-384** | **hmac-sha-512** | **md5** } { **cipher** | **simple** } *string* [**acl** *ipv4-acl-number* | **ipv6 acl** *ipv6-acl-number*]*

By default, no SNTP authentication key exists.

4. Specify the key as a trusted key.

   sntp reliable authentication-keyid *keyid*

   By default, no trusted key is specified.

5. Associate the SNTP authentication key with an NTP server.

   IPv4:

   sntp unicast-server { *server-name* | *ip-address* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

   IPv6:

   sntp ipv6 unicast-server { *server-name* | *ipv6-address* } [**vpn-instance** *vpn-instance-name*] **authentication-keyid** *keyid*

   By default, no NTP server is specified.

Specifying the SNTP time-offset thresholds for log and trap outputs

About this task

By default, the system synchronizes the SNTP client's time to the server and outputs a log and a trap when the time offset exceeds 128 ms for multiple times.

After you set the SNTP time-offset thresholds for log and trap outputs, the system synchronizes the client's time to the server when the time offset exceeds 128 ms for multiple times, but outputs logs and traps only when the time offset exceeds the specified thresholds, respectively.

Procedure

1. Enter system view.

   system-view

2. Specify the SNTP time-offset thresholds for log and trap outputs.

   sntp time-offset-threshold { **log** *log-threshold* | **trap** *trap-threshold* } *

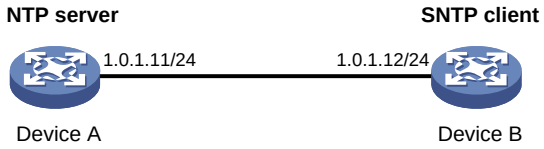
   By default, no SNTP time-offset thresholds are set for log and trap outputs.

Display and maintenance commands for SNTP

Execute **display** commands in any view.

Task	Command
Display information about all IPv6 SNTP associations.	**display sntp ipv6 sessions**
Display information about all IPv4 SNTP associations.	**display sntp sessions**

SNTP configuration examples



Example: Configuring SNTP

Network configuration

As shown in Figure 13, perform the following tasks:

- Configure Device A's local clock as its reference source, with stratum level 2.
- Configure Device B to operate in SNTP client mode, and specify Device A as the NTP server.
- Configure NTP authentication on Device A and SNTP authentication on Device B.

Figure 13 Network diagram

Procedure

1. Assign an IP address to each interface, and make sure Device A and Device B can reach each other, as shown in Figure 13. (Details not shown.)
2. Configure Device A:

   # Enable the NTP service.

   ```
   <DeviceA> system-view
   [DeviceA] ntp-service enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceA] clock protocol ntp
   ```

   # Configure the local clock as the reference source, with stratum level 2.

   ```
   [DeviceA] ntp-service refclock-master 2
   ```

   # Enable NTP authentication on Device A.

   ```
   [DeviceA] ntp-service authentication enable
   ```

   # Configure a plaintext NTP authentication key, with key ID of **10** and key value of **aNiceKey**.

   ```
   [DeviceA] ntp-service authentication-keyid 10 authentication-mode md5 simple
   aNiceKey
   ```

   # Specify the key as a trusted key.

   ```
   [DeviceA] ntp-service reliable authentication-keyid 10
   ```

3. Configure Device B:

   # Enable the SNTP service.

   ```
   <DeviceB> system-view
   [DeviceB] sntp enable
   ```

   # Specify NTP for obtaining the time.

   ```
   [DeviceB] clock protocol ntp
   ```

   # Enable SNTP authentication on Device B.

   ```
   [DeviceB] sntp authentication enable
   ```

   # Configure a plaintext authentication key, with key ID of **10** and key value of **aNiceKey**.

   ```
   [DeviceB] sntp authentication-keyid 10 authentication-mode md5 simple aNiceKey
   ```

   # Specify the key as a trusted key.

```
[DeviceB] sntp reliable authentication-keyid 10
```

Specify Device A as the NTP server of Device B, and associate the server with key 10.

```
[DeviceB] sntp unicast-server 1.0.1.11 authentication-keyid 10
```

Verifying the configuration

Verify that an SNTP association has been established between Device B and Device A, and Device B has synchronized its time with Device A.

```
[DeviceB] display sntp sessions
NTP server     Stratum   Version    Last receive time
1.0.1.11        2         4          Tue, May 17 2019  9:11:20.833 (Synced)
```

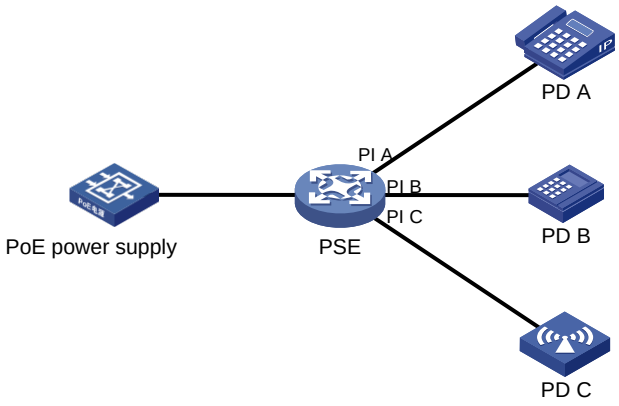
Configuring PoE

About PoE



Power over Ethernet (PoE) enables a network device to supply power to terminals over twisted pair cables.

PoE system

As shown in Figure 1, a PoE system includes the following elements:

- **PoE power supply**—A PoE power supply provides power for the entire PoE system.
- **PSE**—A power sourcing equipment (PSE) supplies power to PDs. PSE devices are classified into single-PSE devices and multiple-PSE devices.
  - A single-PSE device has only one piece of PSE firmware.
  - A multiple-PSE device has multiple PSEs. A multiple-PSE device uses PSE IDs to identify different PSEs. To view the mapping between the ID and slot number of a PSE, execute the **`display poe device`** command.
- **PI**—A power interface (PI) is a PoE-capable Ethernet interface on a PSE.
- **PD**—A powered device (PD) receives power from a PSE. PDs include IP telephones, APs, portable chargers, POS terminals, and Web cameras. You can also connect a PD to a redundant power source for reliability.

Figure 1 PoE system diagram

Protocols and standards

802.3af, 802.3at, and 802.3bt are the 3rd, 4th, and 5th editions of the PoE protocol established by the IEEE. The differences between the three PoE technologies lie in their power transmission capabilities and the number of wires used for power transmission.

- 802.3af, also known as the PoE standard, was released in 2003. It provides a maximum power output of 15.4 W and uses 2 pairs of wires for power transmission.

  The name of the 802.3af standard is *802.3af-2003, IEEE Standard for Information Technology - Telecommunications and Information Exchange Between Systems - Local and Metropolitan Area Networks - Specific Requirements - Part 3: Carrier Sense Multiple Access with Collision Detection (CSMA/CD) Access Method and Physical Layer Specifications - Data Terminal Equipment (DTE) Power Via Media Dependent Interface (MDI)*.

- 802.3at, also known as the PoE+ standard, was released in 2009. It provides a maximum power output of 30 W and uses 2 or 4 pairs of wires for power transmission. It is backward compatible with the 802.3af standard.

  The name of the *802.3at* standard is *802.3at-2009, IEEE Standard for Information technology-- Local and metropolitan area networks-- Specific requirements-- Part 3: CSMA/CD Access Method and Physical Layer Specifications Amendment 3: Data Terminal Equipment (DTE) Power via the Media Dependent Interface (MDI) Enhancements*.
- 802.3bt, also known as the PoE++ standard, was released in 2018. It provides a maximum power output of 90 W and is compatible with existing low-power PoE devices. This standard uses 4 pairs of wires for power transmission and supports PoE devices over long distances and with better performance. It is backward compatible with the 802.3af and 802.3at standards.
- The name of the 802.3bt standard is *802.3bt-2018 - IEEE Standard for Ethernet Amendment 2: Physical Layer and Management Parameters for Power over Ethernet over 4 pairs*.

Restrictions: Hardware compatibility with PoE

Only the PoE models support the PoE feature.

Restrictions and guidelines: PoE configuration

You can configure a PI through either of the following ways:

- Configure the settings directly on the PI.
- Configure a PoE profile and apply it to the PI. If you apply a PoE profile to multiple PIs, these PIs have the same PoE features. If you connect a PD to another PI, you can apply the PoE profile of the original PI to the new PI. This method relieves the task of configuring PoE on the new PI.

You can only use one way to configure a parameter for a PI. To use the other way to reconfigure a parameter, you must first remove the original configuration.

You must use the same configuration method for the **`poe max-power`** *`max-power`* and **`poe priority`** { **`critical`** | **`high`** | **`low`** } commands.

PoE configuration tasks at a glance

To configure PoE, perform the following tasks:

1. Enabling PoE
   a. Enabling PoE for a PI
2. (Optional.) Enabling AI-driven PoE
3. (Optional.) Enabling fast PoE for a PSE
4. (Optional.) Allowing inrush currents drawn by PDs
5. (Optional.) Enabling PI power cycling upon a system warm reboot
6. (Optional.) Disabling PoE on shutdown interfaces
7. (Optional.) Configuring PD detection
   - Enabling nonstandard PD detection
8. (Optional.) Configuring the PoE power
   - Configuring the maximum PI power
9. (Optional.) Configuring the PoE priority policy

- Configuring the PI priority policy

10. (Optional.) Configuring PoE monitoring
    - Monitoring PSE power
    - Monitoring PDs
11. (Optional.) Configuring a PI by using a PoE profile

    To use a PoE profile to enable PoE and configure the priority, power transmission mode, and maximum power for a PI, see "Configuring a PI by using a PoE profile."
12. (Optional.) Upgrading PSE firmware in service

Prerequisites for configuring PoE

Before you configure PoE, make sure the PoE power supply and PSEs are operating correctly.

Enabling PoE

Enabling PoE for a PI

About this task

After you enable PoE for a PI, the PI supplies power to the connected PD if the PI will not result in PSE power overload. PSE overload occurs when the sum of the power consumption of all PIs exceeds the maximum power of the PSE.

If the PI will result in PSE power overload, the following restrictions apply:

- If the PI priority policy is not enabled, the PI does not supply power to the connected PD.
- If the PI priority policy is enabled, whether the PDs can be powered depends on the priority of the PI.

For more information about the PI priority policy, see "Configuring the PI priority policy."

Power can be transmitted over a twisted pair cable in the following modes:

- **Signal pair mode**—Signal pairs (on pins 1, 2, 3, and 6) of the twisted pair cable are used for power transmission.
- **Spare pair mode**—Spare pairs (on pins 4, 5, 7, and 8) of the twisted pair cable are used for power transmission.

Restrictions and guidelines

A PI can supply power to a PD only when the PI and PD use the same power transmission mode.

When you specify a PoE standard for a PI, follow these restrictions and guidelines:

- For your configuration to take effect, restore the PI maximum power to the default before you configure this feature.
- IEEE PoE standards are not forward compatible. For a PI to supply power to PDs, make sure the PoE standard version of the PDs is the same as or earlier than the PoE standard version of the PI.
- If a PI operates in IEEE 802.3bt mode and supplies more than 30 W power, changing the PoE standard for the PI will cause the connected PDs to be power cycled. Be cautious when you modify the configuration of this feature.

Procedure

1. Enter system view.

   ```
   system-view
   ```

2. Enter PI view.
   interface *interface-type interface-number*
3. (Optional.) Configure a description for the PD connected to the PI.
   poe pd-description *text*
   By default, no description is configured for the PD connected to the PI.
4. (Optional.) Specify a PoE standard for the PI.
   poe standard { **at** | **bt** }
   By default, a PI complies with the IEEE 802.3bt PoE standard.
   Only the UPWR models support this command. For the UPWR models, see the installation guide for the switch series.
5. Enable PoE for the PI.
   poe enable
   By default, PoE is disabled on a PI.

Enabling AI-driven PoE

Restrictions and guidelines

AI-driven PoE takes effect only on PSEs that run firmware V147 or later.

- **PSEs with firmware earlier than V147**—You must use the **poe update** command to upgrade the PSE firmware and then enable AI-driven PoE on it.
- **PSEs with firmware V147 or later**—You do not need to re-enable AI-driven PoE after upgrading the firmware if you have enabled the feature before the upgrade.

Software version and feature compatibility

This feature is supported in R1122 and its later versions.

Procedure

1. Enter system view.
   system-view
2. Enable AI-driven PoE.
   poe ai enable
   By default, AI-driven PoE is disabled.
   AI-driven PoE automatically adjusts the power supply parameters to fit the power needs. If you disable AI-driven PoE, the system reverts the parameters to the settings before the adjustment.

Enabling fast PoE for a PSE

About this task

This feature enables a PI on a PSE to supply power to PDs immediately after the PSE is powered on.

Software version and feature compatibility

This feature is supported in R1122 and its later versions.

Procedure

1. Enter system view.
   system-view

2. Enable fast PoE for a PSE.

   poe fast-on enable pse *pse-id*

   By default, fast PoE is disabled on a PSE.

Allowing inrush currents drawn by PDs

About this task

Inrush current might occur at PD startup and trigger PSE self-protection, As a result, the PSE stops supplying power to the PDs. To continue power supply to the PDs, configure this feature to allow inrush current drawn by PDs.

IEEE 802.3af and IEEE 802.3at define specifications for inrush current. Support for the specifications defined by IEEE 802.3af and/or IEEE 802.3at depends on the device model.

Restrictions and guidelines

CAUTION:

Inrush current might damage device components. Use this feature with caution.

Procedure

1. Enter system view.

   system-view

2. Allow inrush current drawn by PDs.

   poe high-inrush enable pse *pse-id*

   By default, inrush current drawn by PDs is not allowed.

Enabling PI power cycling upon a system warm reboot

About this task

During the system warm reboot process (upon execution of the **reboot** command), the PIs continue supplying power to the PDs but data connections between the PDs and the device are interrupted. After the system reboots, PDs might not re-initiate data connections with the device. Power cycling PIs upon a system warm reboot allows the PDs to re-establish data connections with the device after a warm reboot.

Procedure

1. Enter system view.

   system-view

2. Enter PI power cycling upon a system warm reboot.

   poe reset enable

   By default, PI power cycling upon a system warm reboot is disabled.

Disabling PoE on shutdown interfaces

About this task

By default, the device continues supplying power to an interface after the interface is shut down by the **shutdown** command or by an upper layer module such as monitor link. As a result, the PD connected to the shutdown interface operates continuously but fails to access the network.

This task disables the PoE module from supplying power to an interface after the interface is shut down. After the interface comes up or you disable this task, the PoE module resumes power supply to the interface.

Software and feature compatibility

This feature is available only in R1132 and later versions.

Restrictions and guidelines

The task does not power off an interface that has been shut down but is supplying power to a PD.

Procedure

1. Enter system view.
   system-view
2. Disable PoE on shutdown interfaces.
   poe track-shutdown
   By default, PoE is not disabled on shutdown interfaces.

Configuring PD detection

Enabling nonstandard PD detection

About this task

PDs are classified into standard PDs and nonstandard PDs. Standard PDs are compliant with IEEE 802.3af and IEEE 802.3at. A PSE supplies power to a nonstandard PD only after nonstandard PD detection is enabled.

The device supports PSE-based and PI-based nonstandard PD detection. Enabling nonstandard PD detection for a PSE enables this feature for all PIs on the PSE. As a best practice for disabling nonstandard PD detection for all PIs successfully in one operation, disable this feature in both system view and interface view.

Procedure

1. Enter system view.
   system-view
2. Enable nonstandard PD detection. Choose one option as needed.
   - Enable nonstandard PD detection for the PSE.
     poe legacy enable pse *pse-id*
     By default, nonstandard PD detection is disabled for a PSE.
   - Execute the following commands in sequence to enable nonstandard PD detection for a PI:
     interface *interface-type interface-number*
     poe legacy enable
     By default, nonstandard PD detection is disabled for a PI.

Configuring a PD detection mode

About this task

The device detects PDs in one of the following modes:

- **None**—The device supplies power to PDs that are correctly connected to the device without causing short circuit.
- **Simple**—The device supplies power to PDs that comply with basic requirements of 802.3af or 802.3at.
- **Strict**—The device supplies power to PDs that comply with all requirements of 802.3af or 802.3at.

Restrictions and guidelines

CAUTION:

A non-PD device might be damaged when power is supplied to it. To avoid device damage, do not specify the **none** mode when the PI connects to a non-PD device.

For this feature to take effect on nonstandard PDs, you must enable detection for nonstandard PDs by using the **poe legacy enable** command.

Procedure

1. Enter system view.
   system-view
2. Enter PI view.
   interface *interface-type interface-number*
3. Configure the PD detection mode.
   poe detection-mode { **none** | **simple** | **strict** }
   By default, the PD detection mode is strict.

Configuring the PoE power

Configuring the maximum PI power

About this task

The maximum PI power is the maximum power that a PI can provide to the connected PD. If the PD requires more power than the maximum PI power, the PI does not supply power to the PD.

Procedure

1. Enter system view.
   system-view
2. Enter PI view.
   interface *interface-type interface-number*
3. Configure the maximum power for the PI.
   poe max-power *max-power*
   By default, the maximum PI power depends on the PoE standard.

Configuring the PoE priority policy

Configuring the PI priority policy

About this task

The PI priority policy enables the PSE to perform priority-based power allocation to PIs when PSE power overload occurs. The priority levels for PIs are critical, high, and low in descending order.

When PSE power overload occurs, the PSE supplies power to PDs as follows:

- If the PI priority policy is disabled, the PSE supplies power to PDs depending on whether you have configured the maximum PSE power.
  - If you have configured the maximum PSE power, the PSE does not supply power to the newly-added or existing PD that causes PSE power overload.
  - If you have not configured the maximum PSE power, the PoE self-protection mechanism is triggered. The PSE stops supplying power to all PDs.
- If the PI priority policy is enabled, the PSE supplies power to PDs as follows:
  - If a PD being powered causes PSE power overload, the PSE stops supplying power to the PD.
  - If a newly-added PD causes PSE power overload, the PSE supplies power to PDs in priority descending order of the PIs to which they are connected. If the newly-added PD and a PD being powered have the same priority, the PD being powered takes precedence. If multiple PIs being powered have the same priority, the PIs with smaller IDs takes precedence.

Restrictions and guidelines

Before you configure a PI with critical priority, make sure the remaining power from the maximum PSE power minus the maximum powers of the existing PIs with critical priority is greater than maximum power of the PI.

Configuration for a PI whose power is preempted remains unchanged.

Procedure

1. Enter system view.

   system-view

2. Enable the PI priority policy.

   poe pd-policy priority

   By default, the PI priority policy is disabled.

3. Enter PI view.

   interface *interface-type interface-number*

4. (Optional.) Configure a priority for the PI.

   poe priority { **critical** | **high** | **low** }

   By default, the priority for a PI is **low**.

Configuring PoE monitoring

Monitoring PSE power

About this task

The system monitors PSE power utilization and sends notification messages when PSE power utilization exceeds or drops below the threshold. If PSE power utilization crosses the threshold multiple times in succession, the system sends notification messages only for the first crossing. For more information about the notification message, see "Configuring SNMP."

Procedure

1. Enter system view.
   system-view
2. Configure a power alarm threshold for a PSE.
   poe utilization-threshold *value* **pse** *pse-id*
   By default, the power alarm threshold for a PSE is 80%.

Monitoring PDs

About this task

Application scenarios

Some PDs, for example, IP cameras, might become unresponsive or malfunction during operation. Due to the installation location of the cameras, restarting them might be inconvenient. With the PD monitoring feature (PoE watchdog), the device can automatically monitor the PDs around the clock to identify whether they become unresponsive or malfunction, and automatically restart them when necessary to ensure continuous operation and stability.

Operating mechanism

With PD monitoring enabled, the system automatically checks the traffic on a PI every 5 minutes. If no traffic change occurs in two consecutive checks, the system determines that one or more PDs connected to the PI are abnormal and generates a message for the administrator to check the PD status. If the traffic remains unchanged in the following 5 minutes, the system will disable and then re-enable PoE on that PI for the PDs to power cycle and recover.

Software and feature compatibility

This feature is available only in R1132 and later versions.

Procedure

1. Enter system view.
   system-view
2. Enter PI view.
   interface *interface-type interface-number*
3. Enable PD monitoring.
   poe pd-monitor enable
   By default, PD monitoring is disabled.

Configuring a PI by using a PoE profile

Restrictions and guidelines

To modify a PoE profile applied on a PI, first remove the PoE profile from the PI.

You can configure a PI either on the PI or by using a PoE profile. The **poe max-power** *max-power* and **poe priority** { **critical** | **high** | **low** } commands must be configured using the same method.

Configuring a PoE profile

1. Enter system view.
   system-view
2. Create a PoE profile and enter its view.
   poe-profile *profile-name* [*index*]
   By default, no PoE profiles exist.
3. Enable PoE.
   poe enable
   By default, PoE is disabled.
4. (Optional.) Configure the maximum PI power.
   poe max-power *max-power*
   By default, the maximum PI power is 30000 milliwatts.
5. (Optional.) Configure a PI priority.
   poe priority { **critical** | **high** | **low** }
   The default priority is **low**.
   This command takes effect only after the PI priority policy is enabled.

Applying a PoE profile

Restrictions and guidelines

You can apply a PoE profile to multiple PIs in system view or a single PI in PI view. If you perform the operation in both views for the same PI, the most recent operation takes effect.

You can apply only one PoE profile to a PI.

Applying a PoE profile in system view

1. Enter system view.
   system-view
2. Apply a PoE profile to PIs.
   apply poe-profile { **index** *index* | **name** *profile-name* } **interface** *interface-range*
   By default, a PoE profile is not applied to a PI.

Applying a PoE profile in PI view

1. Enter system view.
   system-view
2. Enter PI view.

interface *interface-type interface-number*

3. Apply the PoE profile to the interface.
   apply poe-profile { **index** *index* | **name** *profile-name* }
   By default, a PoE profile is not applied to a PI.

Upgrading PSE firmware in service

About this task

You can upgrade the PSE firmware in service in the following modes:

- **Refresh mode**—Updates the PSE firmware without deleting it. You can use the refresh mode in most cases.
- **Full mode**—Deletes the current PSE firmware and reloads a new one. Use the full mode if the PSE firmware is damaged and you cannot execute any PoE commands.

Restrictions and guidelines

If the PSE firmware upgrade fails because of interruption such as a device reboot, you can restart the device and upgrade it in full mode again. After the upgrade, restart the device manually for the new PSE firmware to take effect.

Procedure

1. Enter system view.
   system-view
2. Upgrade the PSE firmware in service.
   poe update { **full** | **refresh** } *filename* [**pse** *pse-id*]

Enabling forced PoE power supply

About this task

Before supplying power to a PD, the device performs a detection of the PD. It supplies power to the PD only after the PD passes the detection. If the PD fails the detection but the power provided by the device meets the PD specifications, you can configure this task to enable forced power supply to the PD.

When a PI is supplying power to PDs, this command triggers the device to perform the following steps:

1. Immediately stop PoE power supply on the interface.
2. Wait for the interface to switch to forced power mode.
3. Automatically re-enable PoE power supply.

Software and feature compatibility

This feature is available only in R1132 and later versions.

Restrictions and guidelines

CAUTION:

- PSE in version 2018 does not support this feature. For PSE in version 1082 to support this feature, upgrade it to version 1089 or a later version.
- This task enables the device to supply power to a PD directly without performing a detection of the PD. To avoid damaging the PD, make sure the power provided by the device meets the PD specifications before configuring this task.
- If a PI is supplying PoE power, perform this task forcibly re-enables PoE on that PI.

Procedure

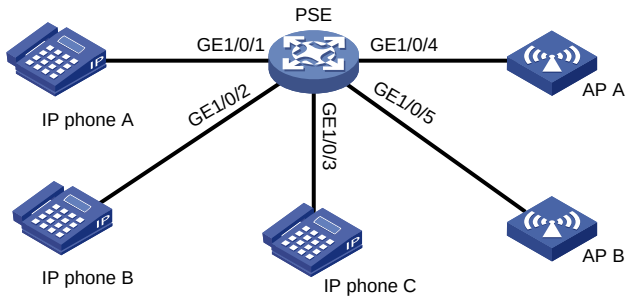
1. Enter system view.
   system-view
2. Enter PI view.
   interface *interface-type interface-number*
3. Enable forced PoE power supply.
   poe force-power
   By default, forced PoE power supply is disabled.

Display and maintenance commands for PoE

Execute **display** commands in any view.

Task	Command
Display general PSE information.	**display poe device** [**slot** *slot-number*]
Display the power supplying information for the specified PI.	**display poe interface** [*interface-type interface-number*]
Display power information for PIs.	**display poe interface power** [*interface-type interface-number*]
Display detailed PSE information.	**display poe pse** [*pse-id*]
Display the power supplying information for all PIs on a PSE.	**display poe pse** *pse-id* **interface**
Display power information for all PIs on a PSE.	**display poe pse** *pse-id* **interface power**
Display all information about the PoE profile.	**display poe-profile** [**index** *index* | **name** *profile-name*]
Display all information about the PoE profile applied to the specified PI.	**display poe-profile interface** *interface-type interface-number*

PoE configuration examples



Example: Configuring PoE

Network configuration

As shown in Figure 2, configure PoE to meet the following requirements:

- The device supplies power to IP phones and APs.
- IP phones take precedence to receive power when power overload occurs.
- Power supplied to AP B does not exceed 9000 milliwatts.

Figure 2 Network diagram

Procedure

Enable the PI priority policy.

```
<PSE> system-view
[PSE] poe pd-policy priority
```

Enable PoE on GigabitEthernet 1/0/1, GigabitEthernet 1/0/2, and GigabitEthernet 1/0/3, and configure their power supply priority as **critical**.

```
[PSE] interface gigabitethernet 1/0/1
[PSE-GigabitEthernet1/0/1] poe enable
[PSE-GigabitEthernet1/0/1] poe priority critical
[PSE-GigabitEthernet1/0/1] quit
[PSE] interface gigabitethernet 1/0/2
[PSE-GigabitEthernet1/0/2] poe enable
[PSE-GigabitEthernet1/0/2] poe priority critical
[PSE-GigabitEthernet1/0/2] quit
[PSE] interface gigabitethernet 1/0/3
[PSE-GigabitEthernet1/0/3] poe enable
[PSE-GigabitEthernet1/0/3] poe priority critical
[PSE-GigabitEthernet1/0/3] quit
```

Enable PoE on GigabitEthernet 1/0/4 and GigabitEthernet 1/0/5, and set the maximum power of GigabitEthernet 1/0/5 to 9000 milliwatts.

```
[PSE] interface gigabitethernet 1/0/4
[PSE-GigabitEthernet1/0/4] poe enable
[PSE-GigabitEthernet1/0/4] quit
[PSE] interface gigabitethernet 1/0/5
[PSE-GigabitEthernet1/0/5] poe enable
[PSE-GigabitEthernet1/0/5] poe max-power 9000
```

Verifying the configuration

Verify that the device is supplying power correctly to the IP phones and APs, and the IP phones and APs are operating correctly.

Troubleshooting PoE

Failure to set the priority of a PI to critical

Symptom

Power supply priority configuration for a PI failed.

Solution

To resolve the issue:

1. Identify whether the remaining guaranteed power of the PSE is lower than the maximum power of the PI. If it is, increase the maximum PSE power or reduce the maximum power of the PI.
2. Identify whether the priority has been configured through other methods. If the priority has been configured, remove the configuration.
3. If the issue persists, contact Technical Support.

Failure to apply a PoE profile to a PI

Symptom

PoE profile application for a PI failed.

Solution

To resolve the issue:

1. Identify whether some settings in the PoE profile have been configured. If they have been configured, remove the configuration.
2. Identify whether the settings in the PoE profile meet the requirements of the PI. If they do not, modify the settings in the PoE profile.
3. Identify whether another PoE profile is already applied to the PI. If it is, remove the application.
4. If the issue persists, contact Technical Support.

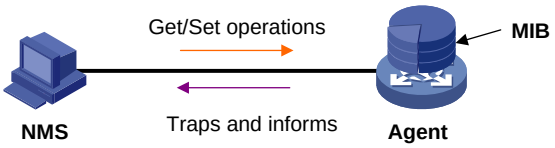
Configuring SNMP

About SNMP

Simple Network Management Protocol (SNMP) is used for a management station to access and operate the devices on a network, regardless of their vendors, physical characteristics, and interconnect technologies.



SNMP enables network administrators to read and set the variables on managed devices for state monitoring, troubleshooting, statistics collection, and other management purposes.

SNMP framework

The SNMP framework contains the following elements:

- **SNMP manager**—Works on an NMS to monitor and manage the SNMP-capable devices in the network. It can get and set values of MIB objects on an agent.
- **SNMP agent**—Works on a managed device to receive and handle requests from the NMS, and sends notifications to the NMS when events, such as an interface state change, occur.
- **Management Information Base (MIB)**—Specifies the variables (for example, interface status and CPU usage) maintained by the SNMP agent for the SNMP manager to read and set.

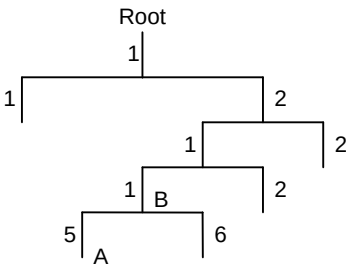


Figure 1 Relationship between NMS, agent, and MIB

MIB and view-based MIB access control

A MIB stores variables called "nodes" or "objects" in a tree hierarchy and identifies each node with a unique OID. An OID is a dotted numeric string that uniquely identifies the path from the root node to a leaf node. For example, object B in Figure 2 is uniquely identified by the OID {1.2.1.1}.

Figure 2 MIB tree

A MIB view represents a set of MIB objects (or MIB object hierarchies) with certain access privileges and is identified by a view name. The MIB objects included in the MIB view are accessible while those excluded from the MIB view are inaccessible.

A MIB view can have multiple view records each identified by a *view-name oid-tree* pair.

You control access to the MIB by assigning MIB views to SNMP groups or communities.

SNMP operations

SNMP provides the following basic operations:

- **Get**—NMS retrieves the value of an object node in an agent MIB.
- **Set**—NMS modifies the value of an object node in an agent MIB.
- **Notification**—SNMP notifications include traps and informs. The SNMP agent sends traps or informs to report events to the NMS. The difference between these two types of notification is that informs require acknowledgment but traps do not. Informs are more reliable but are also resource-consuming. Traps are available in SNMPv1, SNMPv2c, and SNMPv3. Informs are available only in SNMPv2c and SNMPv3.

Protocol versions

The device supports SNMPv1, SNMPv2c, and SNMPv3 in non-FIPS mode and supports only SNMPv3 in FIPS mode. An NMS and an SNMP agent must use the same SNMP version to communicate with each other.

- **SNMPv1**—Uses community names for authentication. To access an SNMP agent, an NMS must use the same community name as set on the SNMP agent. If the community name used by the NMS differs from the community name set on the agent, the NMS cannot establish an SNMP session to access the agent or receive traps from the agent.
- **SNMPv2c**—Uses community names for authentication. SNMPv2c is compatible with SNMPv1, but supports more operation types, data types, and error codes.
- **SNMPv3**—Uses a user-based security model (USM) to secure SNMP communication. You can configure authentication and privacy mechanisms to authenticate and encrypt SNMP packets for integrity, authenticity, and confidentiality.

Access control modes

SNMP uses the following modes to control access to MIB objects:

- **View-based Access Control Model**—VACM mode controls access to MIB objects by assigning MIB views to SNMP communities or users.
- **Role based access control**—RBAC mode controls access to MIB objects by assigning user roles to SNMP communities or users.
    - SNMP communities or users with predefined user role network-admin or level-15 have read and write access to all MIB objects.
    - SNMP communities or users with predefined user role network-operator have read-only access to all MIB objects.
    - SNMP communities or users with a user-defined user role have access rights to MIB objects as specified by the **`rule`** command.

RBAC mode controls access on a per MIB object basis, and VACM mode controls access on a MIB view basis. As a best practice to enhance MIB security, use the RBAC mode.

If you create the same SNMP community or user with both modes multiple times, the most recent configuration takes effect. For more information about RBAC, see *Fundamentals Command Reference*.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

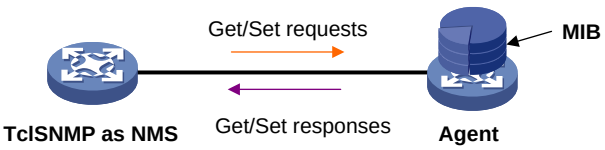
SNMP tasks at a glance

The device can act as an SNMP NMS and SNMP agent at the same time.

When the device acts as an SNMP NMS, perform the following tasks:

Configuring the device as an NMS

When the device acts as an SNMP agent, perform the following tasks:



1. Enabling the SNMP agent
2. Enabling SNMP versions
3. Configuring SNMP basic parameters
   - (Optional.) Configuring SNMP common parameters
   - Configuring an SNMPv1 or SNMPv2c community
   - Configuring an SNMPv3 group and user
4. (Optional.) Configuring SNMP notifications
5. (Optional.) Examining the system configuration for changes
6. (Optional.) Configuring SNMP logging

Configuring the device as an NMS

About this task

The device supports TclSNMP functionality based on Tcl version 8.5. Once the corresponding Lib file for TclSNMP is loaded, the device can function as an NMS. Network administrators can use standard Tcl scripts on this device to perform SNMP operations, such as get and set, on other network devices, thus checking the SNMP agent functionality on the target device or performing simple SNMP management tasks.

Figure 3 TclSNMP networking

Restrictions and guidelines

TclSNMP supports SNMP v1 and v2c.

TclSNMP does not support sending SNMP notifications.

Procedure

1. Enter Tcl configuration view from user view.

   `tclsh`

   For more information about this command, see *Fundamentals Command Reference*.
2. Load Lib file libtclsnmptools.so for the TclSNMP functionality.

   `load libtclsnmptools.so`

   The libtclsnmptools.so file is integrated in the System software package and does not require downloading.

   The `load` command is a standard Tcl command. For more information about the usage of this command, see the Tcl official documents.
3. Execute the corresponding SNMP Tcl script.

tclsnmp-command

Configuration examples

Use TclSNMP to retrieve the uptime of the target device (IP address 192.168.1.1) to verify if SNMP agent is functioning properly on the target device. The **load**, **snmpagent session**, and *xxx* **get** are standard Tcl commands, where *xxx* represents the SNMP session name.

```
<Sysname-tcl> tclsh
<Sysname-tcl> load libtclsnmptools.so
<Sysname-tcl> snmpagent session xxx -v2c -c public 192.168.1.1
<Sysname-tcl> xxx get 1.3.6.1.2.1.1.3.0
```

If information of the following format is displayed after you execute the above commands, it indicates that SNMP agent is functioning normally on the target device.

```
{.1.3.6.1.2.1.1.3.0 = Timeticks: (273076) 0:45:30.76}
```

Enabling the SNMP agent

Restrictions and guidelines

The SNMP agent is enabled when you use any command that begins with **snmp-agent** except for the **snmp-agent calculate-password** command.

The SNMP agent will fail to be enabled when the port that the agent will listen on is used by another service. You can use the **snmp-agent port** command to specify a listening port. To view the UDP port use information, execute the **display udp verbose** command. For more information about the **display udp verbose** command, see IP performance optimization commands in *Layer 3—IP Services Configuration Guide*.

If you disable the SNMP agent, the SNMP settings do not take effect. The **display current-configuration** command does not display the SNMP settings and the SNMP settings will not be saved in the configuration file. For the SNMP settings to take effect, enable the SNMP agent.

Procedure

1. Enter system view.

   system-view
2. Enable the SNMP agent.

   snmp-agent

   By default, the SNMP agent is disabled.

Enabling SNMP versions

Restrictions and guidelines

The device supports SNMPv1, SNMPv2c, and SNMPv3 in non-FIPS mode and supports only SNMPv3 in FIPS mode. An NMS and an SNMP agent must use the same SNMP version to communicate with each other.

The community name and data carried in SNMPv1 and SNMPv2c messages are in plaintext form, putting the SNMP communication at risks. As a best practice, use SNMPv3.

To use SNMP notifications in IPv6, enable SNMPv2c or SNMPv3.

Procedure

1. Enter system view.

system-view

2. Enable SNMP versions.

   In non-FIPS mode:

   snmp-agent sys-info version { **all** | { **v1** | **v2c** | **v3** } * }

   In FIPS mode:

   snmp-agent sys-info version v3

   By default, SNMPv3 is enabled.

   If you execute the command multiple times with different options, all the configurations take effect, but only one SNMP version is used by the agent and NMS for communication.

Configuring SNMP common parameters

Restrictions and guidelines

- SNMP engine ID

  An SNMP engine ID uniquely identifies a device in an SNMP managed network. Make sure the local SNMP engine ID is unique within your SNMP managed network to avoid communication problems. By default, the device is assigned a unique SNMP engine ID.

  If you have configured SNMPv3 users, change the local SNMP engine ID only when necessary. The change can void the SNMPv3 usernames and encrypted keys you have configured.

- SNMP listening port

  The SNMP agent will fail to be enabled when the port that the agent will listen on is used by another service. You can use the **snmp-agent port** command to change the SNMP listening port. As a best practice, execute the **display udp verbose** command to view the UDP port use information before specifying a new SNMP listening port. For more information about the **display udp verbose** command, see IP performance optimization commands in *Layer 3—IP Services Configuration Guide*.

- MIB view

  You can delete the default view by using the **undo snmp-agent mib-view** command. Be cautious with deleting the default MIB view. The operation blocks the access to any MIB object on the device from NMSs that use the default view. To restore the default view, restart the device.

  If you create a new MIB view, specify both permitted and excluded nodes by using the **snmp-agent mib-view** command. If the MIB view defines only excluded nodes, users bound to this view cannot access any device nodes.

  To bind MIB views, execute the **snmp-agent community** or **snmp-agent group** command.

Procedure

1. Enter system view.

   system-view

2. Specify an SNMP listening port.

   snmp-agent port *port-number*

   By default, the SNMP listening port is UDP port 161.

3. Set a local SNMP engine ID.

   snmp-agent local-engineid *engineid*

   By default, the local SNMP engine ID is the company ID plus the device ID.

4. Set an engine ID for a remote SNMP entity.

snmp-agent remote { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*] **engineid** *engineid*

By default, no remote entity engine IDs exist.

This step is required for the device to send SNMPv3 notifications to a host, typically NMS.

5. Create or update a MIB view.

   snmp-agent mib-view { **excluded** | **included** } *view-name oid-tree* [**mask** *mask-value*]

   By default, the MIB view **ViewDefault** is predefined. In this view, all the MIB objects in the **iso** subtree but the **snmpUsmMIB**, **snmpVacmMIB**, and **snmpModules.18** subtrees are accessible.

   Each *view-name oid-tree* pair represents a view record. If you specify the same record with different MIB sub-tree masks multiple times, the most recent configuration takes effect.

6. Configure the system management information.
   - Configure the system contact.

     snmp-agent sys-info contact *sys-contact*

     By default, the system contact is **New H3C Technologies Co., Ltd.**.
   - Configure the system location.

     snmp-agent sys-info location *sys-location*

     By default, the system location is **Hangzhou, China**.

7. Create an SNMP context.

   snmp-agent context *context-name*

   By default, no SNMP contexts exist.

8. Configure the maximum SNMP packet size (in bytes) that the SNMP agent can handle.

   snmp-agent packet max-size *byte-count*

   By default, an SNMP agent can process SNMP packets with a maximum size of 1500 bytes.

9. Set the DSCP value for SNMP responses.

   snmp-agent packet response dscp *dscp-value*

   By default, the DSCP value for SNMP responses is 0.

Configuring an SNMPv1 or SNMPv2c community

About configuring an SNMPv1 or SNMPv2c community

You can create an SNMPv1 or SNMPv2c community by using a community name or by creating an SNMPv1 or SNMPv2c user. After you create an SNMPv1 or SNMPv2c user, the system automatically creates a community by using the username as the community name.

Restrictions and guidelines for configuring an SNMPv1 or SNMPv2c community

SNMPv1 and SNMPv2c settings are not supported in FIPS mode.

Make sure the NMS and agent use the same SNMP community name.

Only users with the network-admin or level-15 user role can create SNMPv1 or SNMPv2c communities, users, or groups. Users with other user roles cannot create SNMPv1 or SNMPv2c communities, users, or groups even if these roles are granted access to related commands or commands of the SNMPv1 or SNMPv2c feature.

Configuring an SNMPv1/v2c community by a community name

1. Enter system view.

   system-view

2. Create an SNMPv1/v2c community. Choose one option as needed.

   - In VACM mode:

     snmp-agent community { **read** | **write** } [**simple** | **cipher**] *community-name* [**mib-view** *view-name*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   - In RBAC mode:

     snmp-agent community [**simple** | **cipher**] *community-name* **user-role** *role-name* [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

3. (Optional.) Map the SNMP community name to an SNMP context.

   snmp-agent community-map *community-name* **context** *context-name*

Configuring an SNMPv1/v2c community by creating an SNMPv1/v2c user

1. Enter system view.

   system-view

2. Create an SNMPv1/v2c group.

   snmp-agent group { **v1** | **v2c** } *group-name* [**notify-view** *view-name* | **read-view** *view-name* | **write-view** *view-name*] * [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

3. Add an SNMPv1/v2c user to the group.

   snmp-agent usm-user { **v1** | **v2c** } *user-name group-name* [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   The system automatically creates an SNMP community by using the username as the community name.

4. (Optional.) Map the SNMP community name to an SNMP context.

   snmp-agent community-map *community-name* **context** *context-name*

Configuring an SNMPv3 group and user

Restrictions and guidelines for configuring an SNMPv3 group and user

Restrictions and guidelines for privilege configuration

Only users with the network-admin or level-15 user role can create SNMPv3 users or groups.Users with other user roles cannot create SNMPv3 users or groups even if these roles are granted access to related commands or commands of the SNMPv3 feature.

Restrictions and guidelines for security level configuration

All users in an SNMP group share the security level and access rights of the group.

SNMPv3 supports the following security levels, from highest to lowest:

- **Privacy**—Authentication and encryption.
- **Authentication**—Authentication but no encryption.
- **None**—No authentication or encryption.

When you create an SNMP user group or SNMPv3 user on the device, you can specify a security level. You can also specify a security level on the NMS. The following requirements must be met when you specify a security level:

- For an SNMP connection to be established successfully, make sure the security level you specify is the same or in descending order of security for the SNMP user, on the NMS, and for the SNMP user group. If the security level is different, the security level specified on the NMS applies.
- If the security level specified on the NMS requires authentication, the security level of the SNMPv3 user must also require authentication, and the authentication password and algorithm configured on the device must match those specified on the NMS.
- If the security level specified on the NMS requires encryption, the security level of the SNMPv3 user must also require encryption, and the encryption password and algorithm configured on the device must match those specified on the NMS.

Configuring an SNMPv3 group and user in non-FIPS mode

1. Enter system view.

   system-view

2. Create an SNMPv3 group.

   snmp-agent group v3 *group-name* [**authentication** | **privacy**] [**notify-view** *view-name* | **read-view** *view-name* | **write-view** *view-name*] * [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

3. (Optional.) Calculate the encrypted form for the key in plaintext form.

   snmp-agent calculate-password *plain-password* **mode** { **3desmd5** | **3dessha** | **aes192md5** | **aes192sha** | **aes256md5** | **aes256sha** | **md5** | **sha** } { **local-engineid** | **specified-engineid** *engineid* }

4. Create an SNMPv3 user. Choose one option as needed.
   - In VACM mode:

     snmp-agent usm-user v3 *user-name group-name* [**remote** { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] [{ **cipher** | **simple** } **authentication-mode** { **md5** | **sha** } *auth-password* [**privacy-mode** { **3des** | **aes128** | **aes192** | **aes256** | **des56** } *priv-password*]] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   - In RBAC mode:

     snmp-agent usm-user v3 *user-name* **user-role** *role-name* [**remote** { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] [{ **cipher** | **simple** } **authentication-mode** { **md5** | **sha** } *auth-password* [**privacy-mode** { **3des** | **aes128** | **aes192** | **aes256** | **des56** } *priv-password*]] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

To send notifications to an SNMPv3 NMS, you must specify the **remote** keyword.

5. (Optional.) Assign a user role to the SNMPv3 user created in RBAC mode.

   snmp-agent usm-user v3 *user-name* **user-role** *role-name*

   By default, an SNMPv3 user has the user role assigned to it at its creation.

Configuring an SNMPv3 group and user in FIPS mode

1. Enter system view.

   system-view

2. Create an SNMPv3 group.

   snmp-agent group v3 *group-name* { **authentication** | **privacy** } [**notify-view** *view-name* | **read-view** *view-name* | **write-view** *view-name*] * [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

3. (Optional.) Calculate the encrypted form for the key in plaintext form.

   snmp-agent calculate-password *plain-password* **mode** { **aes192sha** | **aes256sha** | **sha** } { **local-engineid** | **specified-engineid** *engineid* }

4. Create an SNMPv3 user. Choose one option as needed.

   - In VACM mode:

     snmp-agent usm-user v3 *user-name group-name* [**remote** { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] { **cipher** | **simple** } **authentication-mode sha** *auth-password* [**privacy-mode** { **aes128** | **aes192** | **aes256** } *priv-password*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   - In RBAC mode:

     snmp-agent usm-user v3 *user-name* **user-role** *role-name* [**remote** { *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]] { **cipher** | **simple** } **authentication-mode sha** *auth-password* [**privacy-mode** { **aes128** | **aes192** | **aes256** } *priv-password*] [**acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* } | **acl ipv6** { *ipv6-acl-number* | **name** *ipv6-acl-name* }] *

   To send notifications to an SNMPv3 NMS, you must specify the **remote** keyword.

5. (Optional.) Assign a user role to the SNMPv3 user created in RBAC mode.

   snmp-agent usm-user v3 *user-name* **user-role** *role-name*

   By default, an SNMPv3 user has the user role assigned to it at its creation.

Configuring SNMP notifications

About SNMP notifications

The SNMP agent sends notifications (traps and informs) to inform the NMS of significant events, such as link state changes and user logins or logouts. After you enable notifications for a module, the module sends the generated notifications to the SNMP agent. The SNMP agent sends the received notifications as traps or informs based on the current configuration. Unless otherwise stated, the **trap** keyword in the command line includes both traps and informs.

Enabling SNMP notifications

Restrictions and guidelines

Enable an SNMP notification only if necessary. SNMP notifications are memory-intensive and might affect device performance.

To generate linkUp or linkDown notifications when the link state of an interface changes, you must perform the following tasks:

- Enable linkUp or linkDown notification globally by using the **snmp-agent trap enable standard** [**linkdown** | **linkup**] * command.
- Enable linkUp or linkDown notification on the interface by using the **enable snmp trap updown** command.

After you enable notifications for a module, whether the module generates notifications also depends on the configuration of the module. For more information, see the configuration guide for each module.

To use SNMP notifications in IPv6, enable SNMPv2c or SNMPv3.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP notifications.

   snmp-agent trap enable [**configuration** | *protocol* | **standard** [**authentication** | **coldstart** | **linkdown** | **linkup** | **warmstart**] * | **system**]

   By default, configuration change notifications, SNMP standard notifications, and system notifications are enabled. For the SNMP notifications enabling status for other modules, see the module guide.

   For the device to send SNMP notifications for a protocol, first enable the protocol.

3. Enter interface view.

   interface *interface-type interface-number*

4. Enable link state notifications.

   enable snmp trap updown

   By default, link state notifications are enabled.

Configuring parameters for sending SNMP notifications

About this task

You can configure the SNMP agent to send notifications as traps or informs to a host, typically an NMS, for analysis and management. Traps are less reliable and use fewer resources than informs, because an NMS does not send an acknowledgment when it receives a trap.

When network congestion occurs or the destination is not reachable, the SNMP agent buffers notifications in a queue. You can set the queue size and the notification lifetime (the maximum time that a notification can stay in the queue). When the queue size is reached, the system discards the new notification it receives. If modification of the queue size causes the number of notifications in the queue to exceed the queue size, the oldest notifications are dropped for new notifications. A notification is deleted when its lifetime expires.

You can extend standard linkUp/linkDown notifications to include interface description and interface type, but must make sure the NMS supports the extended SNMP messages.

Configuring the parameters for sending SNMP traps

1. Enter system view.

   system-view

2. Configure a target host.

   In non-FIPS mode:

   snmp-agent target-host trap address udp-domain { *ipv4-target-host* | **ipv6** *ipv6-target-host* } [**udp-port** *port-number*] [**dscp** *dscp-value*] [**vpn-instance** *vpn-instance-name*] **params securityname** *security-string* [**v1** | **v2c** | **v3** [**authentication** | **privacy**]]

   In FIPS mode:

   snmp-agent target-host trap address udp-domain { *ipv4-target-host* | **ipv6** *ipv6-target-host* } [**udp-port** *port-number*] [**dscp** *dscp-value*] [**vpn-instance** *vpn-instance-name*] **params securityname** *security-string* **v3** { **authentication** | **privacy** }

   By default, no target host is configured.

   SNMPv1 does not support IPv6 networks. For the configuration to take effect, avoid specifying both the **ipv6** and **v1** keywords in the same command.

3. (Optional.) Configure a source address for sending traps.

   snmp-agent trap source *interface-type interface-number*

   By default, SNMP uses the IP address of the outgoing routed interface as the source IP address.

Configuring the parameters for sending SNMP informs

1. Enter system view.

   system-view

2. Configure a target host.

   In non-FIPS mode:

   snmp-agent target-host inform address udp-domain { *ipv4-target-host* | **ipv6** *ipv6-target-host* } [**udp-port** *port-number*] [**vpn-instance** *vpn-instance-name*] **params securityname** *security-string* { **v2c** | **v3** [**authentication** | **privacy**] }

   In FIPS mode:

   snmp-agent target-host inform address udp-domain { *ipv4-target-host* | **ipv6** *ipv6-target-host* } [**udp-port** *port-number*] [**vpn-instance** *vpn-instance-name*] **params securityname** *security-string* **v3** { **authentication** | **privacy** }

   By default, no target host is configured.

   Only SNMPv2c and SNMPv3 support inform packets.

3. (Optional.) Configure a source address for sending informs.

   snmp-agent inform source *interface-type interface-number*

   By default, SNMP uses the IP address of the outgoing routed interface as the source IP address.

Configuring common parameters for sending notifications

1. Enter system view.

   system-view

2. (Optional.) Enable extended linkUp/linkDown notifications.

   snmp-agent trap if-mib link extended

By default, the SNMP agent sends standard linkUp/linkDown notifications.

If the NMS does not support extended linkUp/linkDown notifications, do not use this command.

3. (Optional.) Set the notification queue size.

   snmp-agent trap queue-size *size*

   By default, the notification queue can hold 100 notification messages.

4. (Optional.) Set the notification lifetime.

   snmp-agent trap life *seconds*

   The default notification lifetime is 120 seconds.

Examining the system configuration for changes

About this task

The SNMP module examines the system running configuration, startup configuration, and next-startup configuration file for changes periodically and generates a log if any change is found. If SNMP notifications for configuration changes has been enabled, the system generates also an SNMP notification.

Procedure

1. Enter system view.

   system-view

2. Set the interval at which the SNMP module examines the system configuration for changes.

   snmp-agent configuration-examine interval *interval*

   By default, the SNMP module examines the system configuration for changes at intervals of 600 seconds.

3. Enable SNMP notifications for system configuration changes.

   snmp-agent trap enable configuration

   By default, SNMP notifications is enabled for system configuration changes.

Configuring SNMP logging

About this task

The SNMP agent logs Get requests, Set requests, Set responses, SNMP notifications, and SNMP authentication failures, but does not log Get responses.

- **Get operation**—The agent logs the IP address of the NMS, name of the accessed node, and node OID.
- **Set operation**—The agent logs the NMS' IP address, name of accessed node, node OID, variable value, and error code and index for the Set operation.
- **Notification tracking**—The agent logs the SNMP notifications after sending them to the NMS.
- **SNMP authentication failure**—The agent logs related information when an NMS fails to be authenticated by the agent.

The SNMP module sends these logs to the information center. You can configure the information center to output these messages to certain destinations, such as the console and the log buffer. The total output size for the node field (MIB node name) and the value field (value of the MIB node) in each log entry is 1024 bytes. If this limit is exceeded, the information center truncates the data in the fields. For more information about the information center, see "Configuring the information center."

Restrictions and guidelines

Enable SNMP logging only if necessary. SNMP logging is memory-intensive and might impact device performance.

Procedure

1. Enter system view.

   system-view

2. Enable SNMP logging.

   snmp-agent log { **all** | **authfail** | **get-operation** | **set-operation** }

   By default, SNMP logging is enabled for set operations and disabled for SNMP authentication failures and get operations.

3. Enable SNMP notification logging.

   snmp-agent trap log

   By default, SNMP notification logging is disabled.

Display and maintenance commands for SNMP

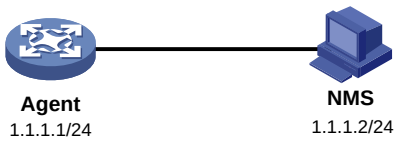
Execute **display** commands in any view.

Task	Command
Display SNMPv1 or SNMPv2c community information. (This command is not supported in FIPS mode.)	**display snmp-agent community** [**read** | **write**]
Display SNMP contexts.	**display snmp-agent context** [*context-name*]
Display SNMP group information.	**display snmp-agent group** [*group-name*]
Display the local engine ID.	**display snmp-agent local-engineid**
Display SNMP MIB node information.	**display snmp-agent mib-node** [**details** | **index-node** | **trap-node** | **verbose**]
Display MIB view information.	**display snmp-agent mib-view** [**exclude** | **include** | **viewname** *view-name*]
Display remote engine IDs.	**display snmp-agent remote** [{ *ipv4-address* | **ipv6** *ipv6-address* } [**vpn-instance** *vpn-instance-name*]]
Display SNMP agent statistics.	**display snmp-agent statistics**
Display SNMP agent system information.	**display snmp-agent sys-info** [**contact** | **location** | **version**] *
Display basic information about the notification queue.	**display snmp-agent trap queue**
Display the SNMP notifications enabling status for modules.	**display snmp-agent trap-list**
Display SNMPv3 user information.	**display snmp-agent usm-user**

Task	Command
	[**engineid** *engineid* | **username** *user-name* | **group** *group-name*] *

SNMP configuration examples

Example: Configuring SNMPv1/SNMPv2c



The device does not support this configuration example in FIPS mode.

The configuration procedure is the same for SNMPv1 and SNMPv2c. This example uses SNMPv1.

Network configuration

As shown in Figure 4, the NMS (1.1.1.2/24) uses SNMPv1 to manage the SNMP agent (1.1.1.1/24), and the agent automatically sends notifications to report events to the NMS.

Figure 4 Network diagram

Procedure

1. Configure the SNMP agent:

   # Assign IP address **1.1.1.1/24** to the agent and make sure the agent and the NMS can reach each other. (Details not shown.)

   # Specify SNMPv1, and create read-only community **public** and read and write community **private**.

   ```
   <Agent> system-view
   [Agent] snmp-agent sys-info version v1
   [Agent] snmp-agent community read public
   [Agent] snmp-agent community write private
   ```

   # Configure contact and physical location information for the agent.

   ```
   [Agent] snmp-agent sys-info contact Mr.Wang-Tel:3306
   [Agent] snmp-agent sys-info location telephone-closet,3rd-floor
   ```

   # Enable SNMP notifications, specify the NMS at 1.1.1.2 as an SNMP trap destination, and use **public** as the community name. (To make sure the NMS can receive traps, specify the same SNMP version in the **snmp-agent target-host** command as is configured on the NMS.)

   ```
   [Agent] snmp-agent trap enable
   [Agent] snmp-agent target-host trap address udp-domain 1.1.1.2 params securityname
   public v1
   ```

2. Configure the SNMP NMS:
   - Specify SNMPv1.
   - Create read-only community **public**, and create read and write community **private**.
   - Set the timeout timer and maximum number of retries as needed.

   For information about configuring the NMS, see the NMS manual.

NOTE:

The SNMP settings on the agent and the NMS must match.

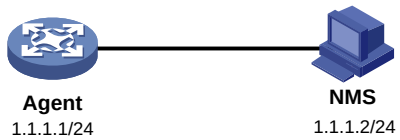
Verifying the configuration

Try to get the MTU value of the NULL0 interface from the agent. The attempt succeeds.

```
Send request to 1.1.1.1/161 ...
Protocol version: SNMPv1
Operation: Get
Request binding:
1: 1.3.6.1.2.1.2.2.1.4.135471
Response binding:
1: Oid=ifMtu.135471 Syntax=INT Value=1500
Get finished
```

Use a wrong community name to get the value of a MIB node on the agent. You can see an authentication failure trap on the NMS.

```
1.1.1.1/2934 V1 Trap = authenticationFailure
SNMP Version = V1
Community = public
Command = Trap
Enterprise = 1.3.6.1.4.1.43.1.16.4.3.50
GenericID = 4
SpecificID = 0
Time Stamp = 8:35:25.68
```



Example: Configuring SNMPv3

Network configuration

As shown in Figure 5, the NMS (1.1.1.2/24) uses SNMPv3 to monitor and manage the agent (1.1.1.1/24). The agent automatically sends notifications to report events to the NMS. The default UDP port 162 is used for SNMP notifications.

The NMS and the agent perform authentication when they establish an SNMP session. The authentication algorithm is **SHA-1** and the authentication key is **123456TESTauth&!**. The NMS and the agent also encrypt the SNMP packets between them by using the **AES** algorithm and encryption key **123456TESTencr&!**.

Figure 5 Network diagram

Configuring SNMPv3 in RBAC mode

1. Configure the agent:

   # Assign IP address **1.1.1.1/24** to the agent and make sure the agent and the NMS can reach each other. (Details not shown.)

   #Create user role **test**, and assign **test** read-only access to the objects under the **snmpMIB** node (OID:1.3.6.1.6.3.1), including the **linkUp** and **linkDown** objects.

   ```
   <Agent> system-view
   ```

```
[Agent] role name test
[Agent-role-test] rule 1 permit read oid 1.3.6.1.6.3.1
```

Assign user role **test** read-only access to the **system** node (OID:1.3.6.1.2.1.1) and read-write access to the **interfaces** node(OID:1.3.6.1.2.1.2).

```
[Agent-role-test] rule 2 permit read oid 1.3.6.1.2.1.1
[Agent-role-test] rule 3 permit read write oid 1.3.6.1.2.1.2
[Agent-role-test] quit
```

Create SNMPv3 user **RBACtest**. Assign user role **test** to **RBACtest.** Set the authentication algorithm to **SHA-1**, authentication key to **123456TESTauth&!**, encryption algorithm to **AES**, and encryption key to **123456TESTencr&!**.

```
[Agent] snmp-agent usm-user v3 RBACtest user-role test simple authentication-mode sha
123456TESTauth&! privacy-mode aes128 123456TESTencr&!
```

#Configure contact and physical location information for the agent.

```
[Agent] snmp-agent sys-info contact Mr.Wang-Tel:3306
[Agent] snmp-agent sys-info location telephone-closet,3rd-floor
```

#Enable notifications on the agent. Specify the NMS at 1.1.1.2 as the notification destination, and **RBACtest** as the username.

```
[Agent] snmp-agent trap enable
[Agent] snmp-agent target-host trap address udp-domain 1.1.1.2 params
securitynameRBACtest v3 privacy
```

2. Configure the NMS:

- Specify SNMPv3.
- Create SNMPv3 user **RBACtest**.
- Enable authentication and encryption. Set the authentication algorithm to **SHA-1**, authentication key to **123456TESTauth&!**, encryption algorithm to **AES**, and encryption key to **123456TESTencr&!**.
- Set the timeout timer and maximum number of retries.

For information about configuring the NMS, see the NMS manual.

NOTE:

The SNMP settings on the agent and the NMS must match.

Configuring SNMPv3 in VACM mode

1. Configure the agent:

Assign IP address 1.1.1.1/24 to the agent, and make sure the agent and the NMS can reach each other. (Details not shown.)

Create SNMPv3 group **managev3group** and assign **managev3group** read-only access to the objects under the **snmpMIB** node (OID: 1.3.6.1.2.1.2.2) in the **test** view, including the **linkUp** and **linkDown** objects.

```
<Agent> system-view
[Agent] undo snmp-agent mib-view ViewDefault
[Agent] snmp-agent mib-view included test snmpMIB
[Agent] snmp-agent group v3 managev3group privacy read-view test
```

#Assign SNMPv3 group **managev3group** read-write access to the objects under the **system** node (OID: 1.3.6.1.2.1.1) and **interfaces** node (OID:1.3.6.1.2.1.2) in the **test** view.

```
[Agent] snmp-agent mib-view included test 1.3.6.1.2.1.1
[Agent] snmp-agent mib-view included test 1.3.6.1.2.1.2
[Agent] snmp-agent group v3 managev3group privacy read-view test write-view test
```

Add user **VACMtest** to SNMPv3 group **managev3group**, and set the authentication algorithm to **SHA-1**, authentication key to **123456TESTauth&!**, encryption algorithm to **AES**, and encryption key to **123456TESTencr&!**.

```
[Agent] snmp-agent usm-user v3 VACMtest managev3group simple authentication-mode sha 123456TESTauth&! privacy-mode aes128 123456TESTencr&!
```

Configure contact and physical location information for the agent.

```
[Agent] snmp-agent sys-info contact Mr.Wang-Tel:3306
[Agent] snmp-agent sys-info location telephone-closet,3rd-floor
```

Enable notifications on the agent. Specify the NMS at 1.1.1.2 as the trap destination, and **VACMtest** as the username.

```
[Agent] snmp-agent trap enable
[Agent] snmp-agent target-host trap address udp-domain 1.1.1.2 params VACMtest v3 privacy
```

2. Configure the SNMP NMS:
   - Specify SNMPv3.
   - Create SNMPv3 user VACMtest.
   - Enable authentication and encryption. Set the authentication algorithm to **SHA-1**, authentication key to **123456TESTauth&!**, encryption algorithm to **AES**, and encryption key to **123456TESTencr&!**.
   - Set the timeout timer and maximum number of retries.

   For information about configuring the NMS, see the NMS manual.

NOTE:

The SNMP settings on the agent and the NMS must match.

Verifying the configuration

- Use username **RBACtest** to access the agent.

  # Retrieve the value of the **sysName** node. The value **Agent** is returned.

  # Set the value for the **sysName** node to **Sysname**. The operation fails because the NMS does not have write access to the node.

  # Shut down or bring up an interface on the agent. The NMS receives linkUP (OID: 1.3.6.1.6.3.1.1.5.4) or linkDown (OID: 1.3.6.1.6.3.1.1.5.3) notifications.

- Use username **VACMtest** to access the agent.

  # Retrieve the value of the **sysName** node. The value **Agent** is returned.

  # Set the value for the **sysName** node to **Sysname**. The operation succeeds.

  # Shut down or bring up an interface on the agent. The NMS receives **linkUP** (OID: 1.3.6.1.6.3.1.1.5.4) or **linkDown** (OID: 1.3.6.1.6.3.1.1.5.3) notifications.

Configuring RMON

About RMON

Remote Network Monitoring (RMON) is an SNMP-based network management protocol. It enables proactive remote monitoring and management of network devices.

RMON working mechanism

RMON can periodically or continuously collect traffic statistics for an Ethernet port and monitor the values of MIB objects on a device. When a value reaches the threshold, the device automatically logs the event or sends a notification to the NMS. The NMS does not need to constantly poll MIB variables and compare the results.

RMON uses SNMP notifications to notify NMSs of various alarm conditions. SNMP reports function and interface operating status changes such as link up, link down, and module failure to the NMS.

RMON groups

Among standard RMON groups, the device implements the statistics group, history group, event group, alarm group, probe configuration group, and user history group. The Comware system also implements a private alarm group, which enhances the standard alarm group. The probe configuration group and user history group are not configurable from the CLI. To configure these two groups, you must access the MIB.

Statistics group

The statistics group samples traffic statistics for monitored Ethernet interfaces and stores the statistics in the Ethernet statistics table (ethernetStatsTable). The statistics include:

- Number of collisions.
- CRC alignment errors.
- Number of undersize or oversize packets.
- Number of broadcasts.
- Number of multicasts.
- Number of bytes received.
- Number of packets received.

The statistics in the Ethernet statistics table are cumulative sums.

History group

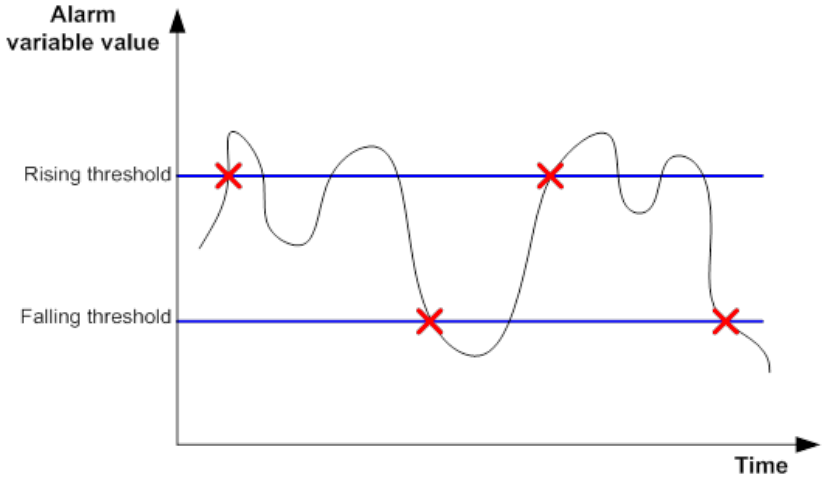
The history group periodically samples traffic statistics on interfaces and saves the history samples in the history table (etherHistoryTable). The statistics include:

- Bandwidth utilization.
- Number of error packets.
- Total number of packets.

The history table stores traffic statistics collected for each sampling interval.

Event group

The event group controls the generation and notifications of events triggered by the alarms defined in the alarm group and the private alarm group. The following are RMON alarm event handling methods:



- **Log**—Logs event information (including event time and description) in the event log table so the management device can get the logs through SNMP.
- **Trap**—Sends an SNMP notification when the event occurs.
- **Log-Trap**—Logs event information in the event log table and sends an SNMP notification when the event occurs.
- **None**—Takes no actions.

Alarm group

The RMON alarm group monitors alarm variables, such as the count of incoming packets (etherStatsPkts) on an interface. After you create an alarm entry, the RMON agent samples the value of the monitored alarm variable regularly. If the value of the monitored variable is greater than or equal to the rising threshold, a rising alarm event is triggered. If the value of the monitored variable is smaller than or equal to the falling threshold, a falling alarm event is triggered. The event group defines the action to take on the alarm event.

If an alarm entry crosses a threshold multiple times in succession, the RMON agent generates an alarm event only for the first crossing. For example, if the value of a sampled alarm variable crosses the rising threshold multiple times before it crosses the falling threshold, only the first crossing triggers a rising alarm event, as shown in Figure 1.

Figure 1 Rising and falling alarm events

Private alarm group

The private alarm group enables you to perform basic math operations on multiple variables, and compare the calculation result with the rising and falling thresholds.

The RMON agent samples variables and takes an alarm action based on a private alarm entry as follows:

1. Samples the private alarm variables in the user-defined formula.
2. Processes the sampled values with the formula.
3. Compares the calculation result with the predefined thresholds, and then takes one of the following actions:
   - Triggers the event associated with the rising alarm event if the result is equal to or greater than the rising threshold.
   - Triggers the event associated with the falling alarm event if the result is equal to or less than the falling threshold.

If a private alarm entry crosses a threshold multiple times in succession, the RMON agent generates an alarm event only for the first crossing. For example, if the value of a sampled alarm variable

crosses the rising threshold multiple times before it crosses the falling threshold, only the first crossing triggers a rising alarm event.

Sample types for the alarm group and the private alarm group

The RMON agent supports the following sample types:

- **absolute**—RMON compares the value of the monitored variable with the rising and falling thresholds at the end of the sampling interval.
- **delta**—RMON subtracts the value of the monitored variable at the previous sample from the current value, and then compares the difference with the rising and falling thresholds.

Protocols and standards

- RFC 4502, *Remote Network Monitoring Management Information Base Version 2*
- RFC 2819, *Remote Network Monitoring Management Information Base Status of this Memo*

Configuring the RMON statistics function

About the RMON statistics function

RMON implements the statistics function through the Ethernet statistics group and the history group.

The Ethernet statistics group provides the cumulative statistic for a variable from the time the statistics entry is created to the current time.

The history group provides statistics that are sampled for a variable for each sampling interval. The history group uses the history control table to control sampling, and it stores samples in the history table.

Creating an RMON Ethernet statistics entry

Restrictions and guidelines

The index of an RMON statistics entry must be globally unique. If the index has been used by another interface, the creation operation fails.

You can create only one RMON statistics entry for an Ethernet interface.

Procedure

1. Enter system view.
   system-view
2. Enter Ethernet interface view.
   interface *interface-type interface-number*
3. Create an RMON Ethernet statistics entry.
   rmon statistics *entry-number* [**owner** *text*]

Creating an RMON history control entry

Restrictions and guidelines

You can configure multiple history control entries for one interface, but you must make sure their entry numbers and sampling intervals are different.

You can create a history control entry successfully even if the specified bucket size exceeds the available history table size. RMON will set the bucket size as closely to the expected bucket size as possible.

Procedure

1. Enter system view.

   system-view
2. Enter Ethernet interface view.

   interface *interface-type interface-number*
3. Create an RMON history control entry.

   rmon history *entry-number* **buckets** *number* **interval** *interval* [**owner** *text*]

   By default, no RMON history control entries exist.

   You can create multiple RMON history control entries for an Ethernet interface.

Configuring the RMON alarm function

Restrictions and guidelines

When you create a new event, alarm, or private alarm entry, follow these restrictions and guidelines:

- The entry must not have the same set of parameters as an existing entry.
- The maximum number of entries is not reached.

Table 1 shows the parameters to be compared for duplication and the entry limits.

Table 1 RMON configuration restrictions

Entry	Parameters to be compared	Maximum number of entries
Event	• Event description (**description** *string*) • Event type (**log**, **trap**, **logtrap**, or **none**) • Community name (*security-string*)	60
Alarm	• Alarm variable (*alarm-variable*) • Sampling interval (*sampling-interval*) • Sample type (**absolute** or **delta**) • Rising threshold (*threshold-value1*) • Falling threshold (*threshold-value2*)	60
Private alarm	• Alarm variable formula (*prialarm-formula*) • Sampling interval (*sampling-interval*) • Sample type (**absolute** or **delta**) • Rising threshold (*threshold-value1*) • Falling threshold (*threshold-value2*)	50

Prerequisites

To send notifications to the NMS when an alarm is triggered, configure the SNMP agent as described in "Configuring SNMP" before configuring the RMON alarm function.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Create an RMON event entry.

   rmon event *entry-number* [**description** *string*] { **log** | **log-trap** *security-string* | **none** | **trap** *security-string* } [**owner** *text*]

   By default, no RMON event entries exist.

3. Create an RMON alarm entry.

   - Create an RMON alarm entry.

     rmon alarm *entry-number alarm-variable sampling-interval* { **absolute** | **delta** } [**startup-alarm** { **falling** | **rising** | **rising-falling** }] **rising-threshold** *threshold-value1 event-entry1* **falling-threshold** *threshold-value2 event-entry2* [**owner** *text*]

   - Create an RMON private alarm entry.

     rmon prialarm *entry-number prialarm-formula prialarm-des sampling-interval* { **absolute** | **delta** } [**startup-alarm** { **falling** | **rising** | **rising-falling** }] **rising-threshold** *threshold-value1 event-entry1* **falling-threshold** *threshold-value2 event-entry2* **entrytype** { **forever** | **cycle** *cycle-period* } [**owner** *text*]

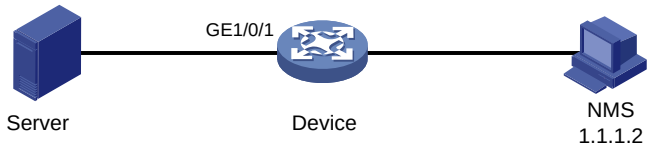
   By default, no RMON alarm entries or RMON private alarm entries exist.

   You can associate an alarm with an event that has not been created yet. The alarm will trigger the event only after the event is created.

Display and maintenance commands for RMON

Execute **display** commands in any view.

Task	Command
Display RMON alarm entries.	**display rmon alarm** [*entry-number*]
Display RMON event entries.	**display rmon event** [*entry-number*]
Display log information for event entries.	**display rmon eventlog** [*entry-number*]
Display RMON history control entries and history samples.	**display rmon history** [*interface-type interface-number*]
Display RMON private alarm entries.	**display rmon prialarm** [*entry-number*]
Display RMON statistics.	**display rmon statistics** [*interface-type interface-number*]



RMON configuration examples

Example: Configuring the Ethernet statistics function

Network configuration

As shown in Figure 2, create an RMON Ethernet statistics entry on the device to gather cumulative traffic statistics for GigabitEthernet 1/0/1.

Figure 2 Network diagram

Procedure

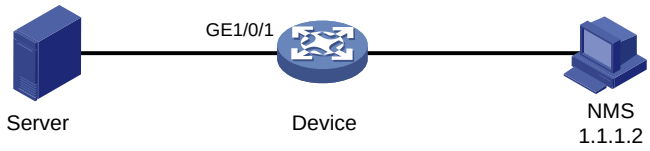
Create an RMON Ethernet statistics entry for GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rmon statistics 1 owner user1
```

Verifying the configuration

Display statistics collected for GigabitEthernet 1/0/1.

```
<Sysname> display rmon statistics gigabitethernet 1/0/1
EtherStatsEntry 1 owned by user1 is VALID.
  Interface : GigabitEthernet1/0/1<ifIndex.3>
  etherStatsOctets         : 21657     , etherStatsPkts          : 307
  etherStatsBroadcastPkts  : 56        , etherStatsMulticastPkts : 34
  etherStatsUndersizePkts  : 0         , etherStatsOversizePkts  : 0
  etherStatsFragments      : 0         , etherStatsJabbers       : 0
  etherStatsCRCAlignErrors : 0         , etherStatsCollisions    : 0
  etherStatsDropEvents (insufficient resources): 0
  Incoming packets by size:
  64     : 235       ,  65-127  : 67        ,  128-255  : 4
  256-511: 1         ,  512-1023: 0         ,  1024-1518: 0
```



Get the traffic statistics from the NMS through SNMP. (Details not shown.)

Example: Configuring the history statistics function

Network configuration

As shown in Figure 3, create an RMON history control entry on the device to sample traffic statistics for GigabitEthernet 1/0/1 every minute.

Figure 3 Network diagram

Procedure

Create an RMON history control entry to sample traffic statistics every minute for GigabitEthernet 1/0/1. Retain a maximum of eight samples for the interface in the history statistics table.

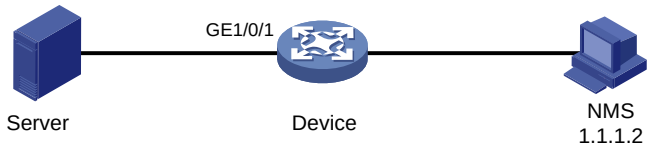
```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rmon history 1 buckets 8 interval 60 owner user1
```

Verifying the configuration

Display the history statistics collected for GigabitEthernet 1/0/1.

```
[Sysname-GigabitEthernet1/0/1] display rmon history
HistoryControlEntry 1 owned by user1 is VALID
  Sampled interface     : GigabitEthernet1/0/1<ifIndex.3>
  Sampling interval     : 60(sec) with 8 buckets max
  Sampling record 1 :
    dropevents        : 0         , octets               : 834
    packets           : 8         , broadcast packets    : 1
    multicast packets : 6         , CRC alignment errors : 0
    undersize packets : 0         , oversize packets     : 0
    fragments         : 0         , jabbers              : 0
    collisions        : 0         , utilization          : 0
  Sampling record 2 :
    dropevents        : 0         , octets               : 962
    packets           : 10        , broadcast packets    : 3
    multicast packets : 6         , CRC alignment errors : 0
    undersize packets : 0         , oversize packets     : 0
    fragments         : 0         , jabbers              : 0
    collisions        : 0         , utilization          : 0
```

Get the traffic statistics from the NMS through SNMP. (Details not shown.)



Example: Configuring the alarm function

Network configuration

As shown in Figure 4, configure the device to monitor the incoming traffic statistic on GigabitEthernet 1/0/1, and send RMON alarms when either of the following conditions is met:

- The 5-second delta sample for the traffic statistic crosses the rising threshold (100).
- The 5-second delta sample for the traffic statistic drops below the falling threshold (50).

Figure 4 Network diagram

Procedure

Configure the SNMP agent (the device) with the same SNMP settings as the NMS at 1.1.1.2. This example uses SNMPv1, read community **public**, and write community **private**.

```
<Sysname> system-view
[Sysname] snmp-agent
[Sysname] snmp-agent community read public
[Sysname] snmp-agent community write private
[Sysname] snmp-agent sys-info version v1
[Sysname] snmp-agent trap enable
[Sysname] snmp-agent trap log
[Sysname] snmp-agent target-host trap address udp-domain 1.1.1.2 params securityname
public
```

Create an RMON Ethernet statistics entry for GigabitEthernet 1/0/1.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] rmon statistics 1 owner user1
[Sysname-GigabitEthernet1/0/1] quit
```

Create an RMON event entry and an RMON alarm entry to send SNMP notifications when the delta sample for 1.3.6.1.2.1.16.1.1.1.4.1 exceeds 100 or drops below 50.

```
[Sysname] rmon event 1 trap public owner user1
[Sysname] rmon alarm 1 1.3.6.1.2.1.16.1.1.1.4.1 5 delta rising-threshold 100 1
falling-threshold 50 1 owner user1
```

NOTE:

The string 1.3.6.1.2.1.16.1.1.1.4.1 is the object instance for GigabitEthernet 1/0/1. The digits before the last digit (1.3.6.1.2.1.16.1.1.1.4) represent the object for total incoming traffic statistics. The last digit (1) is the RMON Ethernet statistics entry index for GigabitEthernet 1/0/1.

Verifying the configuration

Display the RMON alarm entry.

```
<Sysname> display rmon alarm 1
AlarmEntry 1 owned by user1 is VALID.
  Sample type                    : delta
  Sampled variable               : 1.3.6.1.2.1.16.1.1.1.4.1<etherStatsOctets.1>
  Sampling interval (in seconds) : 5
  Rising threshold               : 100(associated with event 1)
  Falling threshold              : 50(associated with event 1)
  Alarm sent upon entry startup  : risingOrFallingAlarm
  Latest value                   : 0
```

Display statistics for GigabitEthernet 1/0/1.

```
<Sysname> display rmon statistics gigabitethernet 1/0/1
EtherStatsEntry 1 owned by user1 is VALID.
```

```
Interface : GigabitEthernet1/0/1<ifIndex.3>
etherStatsOctets         : 57329     , etherStatsPkts          : 455
etherStatsBroadcastPkts  : 53        , etherStatsMulticastPkts : 353
etherStatsUndersizePkts  : 0         , etherStatsOversizePkts  : 0
etherStatsFragments      : 0         , etherStatsJabbers       : 0
etherStatsCRCAlignErrors : 0         , etherStatsCollisions    : 0
etherStatsDropEvents (insufficient resources): 0
Incoming packets by size :
64     : 7         ,  65-127  : 413       ,  128-255  : 35
256-511: 0         ,  512-1023: 0         ,  1024-1518: 0
```

The NMS receives the notification when the alarm is triggered.

Configuring the Event MIB

About the Event MIB

The Event Management Information Base (Event MIB) is an SNMPv3-based network management protocol and is an enhancement to remote network monitoring (RMON). The Event MIB uses Boolean tests, existence tests, and threshold tests to monitor MIB objects on a local or remote system. It triggers the predefined notification or set action when a monitored object meets the trigger condition.

Trigger

The Event MIB uses triggers to manage and associate the three elements of the Event MIB: monitored object, trigger condition, and action.

Monitored objects

The Event MIB can monitor the following MIB objects:

- Table node.
- Conceptual row node.
- Table column node.
- Simple leaf node.
- Parent node of a leaf node.

To monitor a single MIB object, specify it by its OID or name. To monitor a set of MIB objects, specify the common OID or name of the group and enable wildcard matching. For example, specify ifDescr.2 to monitor the description for the interface with index 2. Specify ifDescr and enable wildcard matching to monitor the descriptions for all interfaces.

Trigger test

A trigger supports Boolean, existence, and threshold tests.

Boolean test

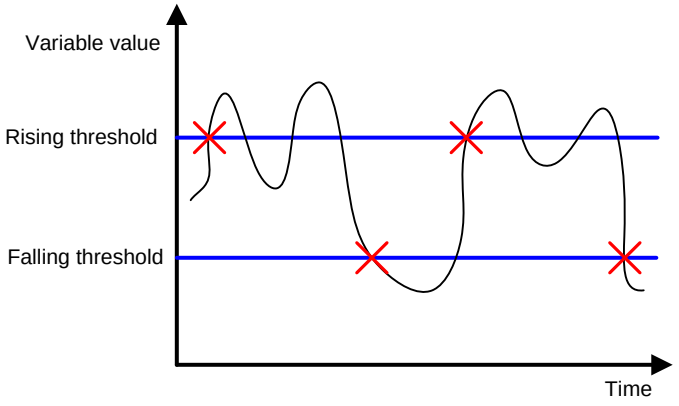
A Boolean test compares the value of the monitored object with the reference value and takes actions according to the comparison result. The comparison types include **unequal**, **equal**, **less**, **lessorequal**, **greater**, and **greaterorequal**. For example, if the comparison type is **equal**, an event is triggered when the value of the monitored object equals the reference value. The event will not be triggered again until the value becomes unequal and comes back to equal.

Existence test

An existence test monitors and manages the absence, presence, and change of a MIB object, for example, interface status. When a monitored object is specified, the system reads the value of the monitored object regularly.

- If the test type is **Absent**, the system triggers an alarm event and takes the specified action when the state of the monitored object changes to absent.
- If the test type is **Present**, the system triggers an alarm event and takes the specified action when the state of the monitored object changes to present.
- If the test type is **Changed**, the system triggers an alarm event and takes the specified action when the value of the monitored object changes.

Threshold test



A threshold test regularly compares the value of the monitored object with the threshold values.

- A rising alarm event is triggered if the value of the monitored object is greater than or equal to the rising threshold.
- A falling alarm event is triggered if the value of the monitored object is smaller than or equal to the falling threshold.
- A rising alarm event is triggered if the difference between the current sampled value and the previous sampled value is greater than or equal to the delta rising threshold.
- A falling alarm event is triggered if the difference between the current sampled value and the previous sampled value is smaller than or equal to the delta falling threshold.
- A falling alarm event is triggered if the values of the monitored object, the rising threshold, and the falling threshold are the same.
- A falling alarm event is triggered if the delta rising threshold, the delta falling threshold, and the difference between the current sampled value and the previous sampled value is the same.

The alarm management module defines the set or notification action to take on alarm events.

If the value of the monitored object crosses a threshold multiple times in succession, the managed device triggers an alarm event only for the first crossing. For example, if the value of a sampled object crosses the rising threshold multiple times before it crosses the falling threshold, only the first crossing triggers a rising alarm event, as shown in Figure 1.

Figure 1 Rising and falling alarm events

Event actions

The Event MIB triggers one or both of the following actions when the trigger condition is met:

- **Set action**—Uses SNMP to set the value of the monitored object.
- **Notification action**—Uses SNMP to send a notification to the NMS. If an object list is specified for the notification action, the notification will carry the specified objects in the object list.

Object list

An object list is a set of MIB objects. You can specify an object list in trigger view, trigger-test view (including trigger-Boolean view, trigger existence view, and trigger threshold view), and action-notification view. If a notification action is triggered, the device sends a notification carrying the object list to the NMS.

If you specify an object list respectively in any two of the views or all the three views, the object lists are added to the triggered notifications in this sequence: trigger view, trigger-test view, and action-notification view.

Object owner

Trigger, event, and object list use an owner and name for unique identification. The owner must be an SNMPv3 user that has been created on the device. If you specify a notification action for a trigger, you must establish an SNMPv3 connection between the device and NMS by using the SNMPv3 username. For more information about SNMPv3 user, see "SNMP configuration".

Restrictions and guidelines: Event MIB configuration

The Event MIB and RMON are independent of each other. You can configure one or both of the features for network management.

You must specify the same owner for a trigger, object lists of the trigger, and events of the trigger.

Event MIB tasks at a glance

To configure the Event MIB, perform the following tasks:

1. Configuring the Event MIB global sampling parameters
2. (Optional.) Configuring Event MIB object lists

   Perform this task so that the device sends a notification that carries the specified object list to the NMS when a notification action is triggered.
3. Configuring an event

   The device supports set and notification actions. Choose one or two of the following actions:
   - Creating an event
   - Configuring a set action for an event
   - Configuring a notification action for an event
   - Enabling the event
4. Configuring a trigger

   A trigger supports Boolean, existence, and threshold tests. Choose one or more of the following tests:
   - Creating a trigger and configuring its basic parameters
   - Configuring a Boolean trigger test
   - Configuring an existence trigger test
   - Configuring a threshold trigger test
   - Enabling trigger sampling
5. (Optional.) Enabling SNMP notifications for the Event MIB module

Prerequisites for configuring the Event MIB

Before you configure the Event MIB, perform the following tasks:

- Create an SNMPv3 user. Assign the user the rights to read and set the values of the specified MIB objects and object lists.

- Make sure the SNMP agent and NMS are configured correctly and the SNMP agent can send notifications to the NMS correctly.

Configuring the Event MIB global sampling parameters

Restrictions and guidelines

This tasks takes effect only on monitored instances to be created.

Procedure

1. Enter system view.
   system-view
2. Set the minimum sampling interval.
   snmp mib event sample minimum *min-number*
   By default, the minimum sampling interval is 1 second.
   The sampling interval of a trigger must be greater than the minimum sampling interval.
3. Configure the maximum number of object instances that can be concurrently sampled.
   snmp mib event sample instance maximum *max-number*
   By default, the value is 0. The maximum number of object instances that can be concurrently sampled is limited by the available resources.

Configuring Event MIB object lists

About this task

Perform this task so that the device sends a notification that carries the specified objects to the NMS when a notification action is triggered.

Procedure

1. Enter system view.
   system-view
2. Configure an Event MIB object list.
   snmp mib event object list owner *group-owner* **name** *group-name* *object-index* **oid** *object-identifier* [**wildcard**]
   The object can be a table node, conceptual row node, table column node, simple leaf node, or parent node of a leaf node.

Configuring an event

Creating an event

1. Enter system view.
   system-view
2. Create an event and enter its view.
   snmp mib event owner *event-owner* **name** *event-name*
3. (Optional.) Configure a description for the event.

description *text*

By default, an event does not have a description.

Configuring a set action for an event

1. Enter system view.

   system-view
2. Enter event view.

   snmp mib event owner *event-owner* **name** *event-name*
3. Enable the set action and enter set action view.

   action set

   By default, no action is specified for an event.
4. Specify an object by its OID for the set action.

   oid *object-identifier*

   By default, no object is specified for a set action.

   The object can be a table node, conceptual row node, table column node, simple leaf node, or parent node of a leaf node.
5. Enable OID wildcarding.

   wildcard oid

   By default, OID wildcarding is disabled.
6. Set the value for the object.

   value *integer-value*

   The default value for the object is 0.
7. (Optional.) Specify a context for the object.

   context *context-name*

   By default, no context is specified for an object.
8. (Optional.) Enable context wildcarding.

   wildcard context

   By default, context wildcarding is disabled.

   A wildcard context contains the specified context and the wildcarded part.

Configuring a notification action for an event

1. Enter system view.

   system-view
2. Enter event view

   snmp mib event owner *event-owner* **name** *event-name*
3. Enable the notification action and enter notification action view.

   action notification

   By default, no action is specified for an event.
4. Specify an object to execute the notification action by its OID.

   oid *object-identifier*

   By default, no object is specified for executing the notification action.

   The object must be a notification object.
5. Specify an object list to be added to the notification triggered by the event.

object list owner *group-owner* **name** *group-name*

By default, no object list is specified for the notification action.

If you do not specify an object list for the notification action or the specified object list does not contain variables, no variables will be carried in the notification.

Enabling the event

Restrictions and guidelines

The Boolean, existence, and threshold events can be triggered only after you perform this task.

To change an enabled event, first disable the event.

Procedure

1. Enter system view.
   system-view
2. Enter event view.
   snmp mib event owner *event-owner* **name** *event-name*
3. Enable the event.
   event enable
   By default, an event is disabled.

Configuring a trigger

Creating a trigger and configuring its basic parameters

1. Enter system view.
   system-view
2. Create a trigger and enter its view.
   snmp mib event trigger owner *trigger-owner* **name** *trigger-name*
   The trigger owner must be an existing SNMPv3 user.
3. (Optional.) Configure a description for the trigger.
   description *text*
   By default, a trigger does not have a description.
4. Set a sampling interval for the trigger.
   frequency *interval*
   By default, the sampling interval is 600 seconds.
   Make sure the sampling interval is greater than or equal to the Event MIB minimum sampling interval.
5. Specify a sampling method.
   sample { **absolute** | **delta** }
   The default sampling method is **absolute**.
6. Specify an object to be sampled by its OID.
   oid *object-identifier*
   By default, the OID is 0.0. No object is specified for a trigger.
   If you execute this command multiple times, the most recent configuration takes effect.
7. (Optional.) Enable OID wildcarding.

wildcard oid

By default, OID wildcarding is disabled.

8. (Optional.) Configure a context for the monitored object.

   context *context-name*

   By default, no context is configured for a monitored object.

9. (Optional.) Enable context wildcarding.

   wildcard context

   By default, context wildcarding is disabled.

10. (Optional.) Specify the object list to be added to the triggered notification.

    object list owner *group-owner* **name** *group-name*

    By default, no object list is specified for a trigger.

Configuring a Boolean trigger test

1. Enter system view.

   system-view

2. Enter trigger view.

   snmp mib event trigger owner *trigger-owner* **name** *trigger-name*

3. Specify a Boolean test for the trigger and enter trigger-Boolean view.

   test boolean

   By default, no test is configured for a trigger.

4. Specify a Boolean test comparison type.

   comparison { **equal** | **greater** | **greaterorequal** | **less** | **lessorequal** | **unequal** }

   The default Boolean test comparison type is **unequal**.

5. Set a reference value for the Boolean trigger test.

   value *integer-value*

   The default reference value for a Boolean trigger test is 0.

6. Specify an event for the Boolean trigger test.

   event owner *event-owner* **name** *event-name*

   By default, no event is specified for a Boolean trigger test.

7. (Optional.) Specify the object list to be added to the notification triggered by the test.

   object list owner *group-owner* **name** *group-name*

   By default, no object list is specified for a Boolean trigger test.

8. Enable the event to be triggered when the trigger condition is met at the first sampling.

   startup enable

   By default, the event is triggered when the trigger condition is met at the first sampling.

   Before the first sampling, you must enable this command to allow the event to be triggered.

Configuring an existence trigger test

1. Enter system view.

   system-view

2. Enter trigger view.

snmp mib event trigger owner *trigger-owner* **name** *trigger-name*

3. Specify an existence test for the trigger and enter trigger-existence view.
   test existence
   By default ,no test is configured for a trigger.
4. Specify an event for the existence trigger test.
   event owner *event-owner* **name** *event-name*
   By default, no event is specified for an existence trigger test.
5. (Optional.) Specify the object list to be added to the notification triggered by the test.
   object list owner *group-owner* **name** *group-name*
   By default, no object list is specified for an existence trigger test.
6. Specify an existence trigger test type.
   type { **absent** | **changed** | **present** }
   The default existence trigger test types are **present** and **absent**.
7. Specify an existence trigger test type for the first sampling.
   startup { **absent** | **present** }
   By default, both the **present** and **absent** existence trigger test types are allowed for the first sampling.

Configuring a threshold trigger test

1. Enter system view.
   system-view
2. Enter trigger view.
   snmp mib event trigger owner *trigger-owner* **name** *trigger-name*
3. Specify a threshold test for the trigger and enter trigger-threshold view.
   test boolean
   By default ,no test is configured for a trigger.
4. Specify the object list to be added to the notification triggered by the test.
   object list owner *group-owner* **name** *group-name*
   By default, no object list is specified for a threshold trigger test.
5. (Optional.) Specify the type of the threshold trigger test for the first sampling.
   startup { **falling** | **rising** | **rising-or-falling** }
   The default threshold trigger test type for the first sampling is **rising-or-falling**.
6. Specify the delta falling threshold and the falling alarm event triggered when the delta value (difference between the current sampled value and the previous sampled value) is smaller than or equal to the delta falling threshold.
   delta falling { **event owner** *event-owner* **name** *event-name* | **value** *integer-value* }
   By default, the delta falling threshold is 0, and no falling alarm event is specified.
7. Specify the delta rising threshold and the rising alarm event triggered when the delta value is greater than or equal to the delta rising threshold.
   delta rising { **event owner** *event-owner* **name** *event-name* | **value** *integer-value* }
   By default, the delta rising threshold is 0, and no rising alarm event is specified.

8. Specify the falling threshold and the falling alarm event triggered when the sampled value is smaller than or equal to the threshold.

   falling { **event owner** *event-owner* **name** *event-name* | **value** *integer-value* }

   By default, the falling threshold is 0, and no falling alarm event is specified.

9. Specify the rising threshold and the ring alarm event triggered when the sampled value is greater than or equal to the threshold.

   rising { **event owner** *event-owner* **name** *event-name* | **value** *integer-value* }

   By default, the rising threshold is 0, and no rising alarm event is specified.

Enabling trigger sampling

Restrictions and guidelines

Enable trigger sampling after you complete trigger parameters configuration. You cannot modify trigger parameters after trigger sampling is enabled. To modify trigger parameters, first disable trigger sampling.

Procedure

1. Enter system view.

   system-view

2. Enter trigger view.

   snmp mib event trigger owner *trigger-owner* **name** *trigger-name*

3. Enable trigger sampling.

   trigger enable

   By default, trigger sampling is disabled.

Enabling SNMP notifications for the Event MIB module

About this task

To report critical Event MIB events to an NMS, enable SNMP notifications for the Event MIB module. For Event MIB event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see the network management and monitoring configuration guide for the device.

Procedure

1. Enter system view.

   system-view

2. Enable snmp notifications for the Event MIB module.

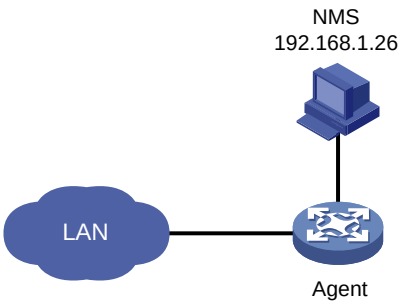
   snmp-agent trap enable event-mib

   By default, SNMP notifications are enabled for the Event MIB module.

Display and maintenance commands for Event MIB

Execute **display** commands in any view.

Task	Command
Display Event MIB configuration and statistics.	**display snmp mib event**
Display event information.	**display snmp mib event event** [**owner** *event-owner* **name** *event-name*]
Display object list information.	**display snmp mib event object list** [**owner** *group-owner* **name** *group-name*]
Display global Event MIB configuration and statistics.	**display snmp mib event summary**
Display trigger information.	**display snmp mib event trigger** [**owner** *trigger-owner* **name** *trigger-name*]



Event MIB configuration examples

Example: Configuring an existence trigger test

Network configuration

As shown in Figure 2, the device acts as the agent. Use the Event MIB to monitor the device. When interface hot-swap or virtual interface creation or deletion occurs on the device, the agent sends an mteTriggerFired notification to the NMS.

Figure 2 Network diagram

Procedure

1. Enable and configure the SNMP agent on the device:

   # Create SNMPv3 group **g3** and add SNMPv3 user **owner1** to **g3**.

   ```
   <Sysname> system-view
   [Sysname] snmp-agent usm-user v3 owner1 g3
   [Sysname] snmp-agent group v3 g3 read-view a write-view a notify-view a
   [Sysname] snmp-agent mib-view included a iso
   ```

   # Configure context **contextnameA** for the agent.

```
[Sysname] snmp-agent context contextnameA
```

Enable SNMP notifications for the Event MIB module. Specify the NMS at **192.168.1.26** as the target host for the notifications.

```
[Sysname] snmp-agent trap enable event-mib
[Sysname] snmp-agent target-host trap address udp-domain 192.168.1.26 params securityname owner1 v3
```

2. Configure the Event MIB global sampling parameters.

Set the Event MIB minimum sampling interval to 50 seconds.

```
[Sysname] snmp mib event sample minimum 50
```

Set the maximum number to 100 for object instances that can be concurrently sampled.

```
[Sysname] snmp mib event sample instance maximum 100
```

3. Create and configure a trigger:

Create a trigger and enter its view. Specify its owner as **owner1** and its name as **triggerA**.

```
[Sysname] snmp mib event trigger owner owner1 name triggerA
```

Set the sampling interval to 60 seconds. Make sure the sampling interval is greater than or equal to the Event MIB minimum sampling interval.

```
[Sysname-trigger-owner1-triggerA] frequency 60
```

Specify object OID **1.3.6.1.2.1.2.2.1.1** as the monitored object. Enable OID wildcarding.

```
[Sysname-trigger-owner1-triggerA] oid 1.3.6.1.2.1.2.2.1.1
[Sysname-trigger-owner1-triggerA] wildcard oid
```

Configure context **contextnameA** for the monitored object and enable context wildcarding.

```
[Sysname-trigger-owner1-triggerA] context contextnameA
[Sysname-trigger-owner1-triggerA] wildcard context
```

Specify the existence trigger test for the trigger.

```
[Sysname-trigger-owner1-triggerA] test existence
[Sysname-trigger-owner1-triggerA-existence] quit
```

Enable trigger sampling.

```
[Sysname-trigger-owner1-triggerA] trigger enable
[Sysname-trigger-owner1-triggerA] quit
```

Verifying the configuration

Display Event MIB brief information.

```
[Sysname] display snmp mib event summary
TriggerFailures               : 0
EventFailures                 : 0
SampleMinimum                 : 50
SampleInstanceMaximum         : 100
SampleInstance                : 20
SampleInstancesHigh           : 20
SampleInstanceLacks           : 0
```

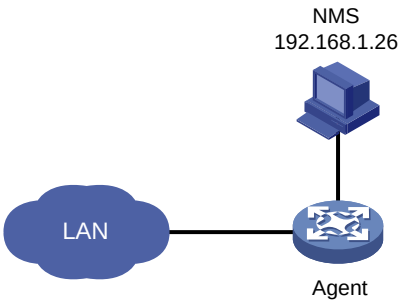
Display information about the trigger with owner **owner1** and name **trigger A**.

```
[Sysname] display snmp mib event trigger owner owner1 name triggerA
Trigger entry triggerA owned by owner1:
  TriggerComment              : N/A
  TriggerTest                 : existence
  TriggerSampleType           : absoluteValue
  TriggerValueID              : 1.3.6.1.2.1.2.2.1.1<ifIndex>
  TriggerValueIDWildcard      : true
```

```
  TriggerTargetTag            : N/A
  TriggerContextName          : contextnameA
  TriggerContextNameWildcard  : true
  TriggerFrequency(in seconds): 60
  TriggerObjOwner             : N/A
  TriggerObjName              : N/A
  TriggerEnabled              : true
  Existence entry:
   ExiTest                    : present | absent
   ExiStartUp                 : present | absent
   ExiObjOwner                : N/A
   ExiObjName                 : N/A
   ExiEvtOwner                : N/A
   ExiEvtName                 : N/A
```

Create VLAN-interface 2 on the device.

```
[Sysname] vlan 2
[Sysname-vlan2] quit
[Sysname] interface vlan 2
```



The NMS receives an mteTriggerFired notification from the device.

Example: Configuring a Boolean trigger test

Network configuration

As shown in Figure 2, the device acts as the agent. The NMS uses SNMPv3 to monitor and manage the device. Configure a trigger and configure a Boolean trigger test for the trigger. When the trigger condition is met, the agent sends an mteTriggerFired notification to the NMS.

Figure 3 Network diagram

Procedure

1. Enable and configure the SNMP agent on the device:

   # Create SNMPv3 group **g3** and add SNNPv3 user **owner1** to **g3**.

   ```
   <Sysname> system-view
   [Sysname] snmp-agent usm-user v3 owner1 g3
   [Sysname] snmp-agent group v3 g3 read-view a write-view a notify-view a
   [Sysname] snmp-agent mib-view included a iso
   ```

   # Enable SNMP notifications for the Event MIB module. Specify the NMS at **192.168.1.26** as the target host for the notifications.

   ```
   [Sysname] snmp-agent trap enable event-mib
   ```

```
[Sysname] snmp-agent target-host trap address udp-domain 192.168.1.26 params
securityname owner1 v3
```

2. Configure the Event MIB global sampling parameters.

Set the Event MIB minimum sampling interval to 50 seconds.

```
[Sysname] snmp mib event sample minimum 50
```

Set the maximum number to 100 for object instances that can be concurrently sampled.

```
[Sysname] snmp mib event sample instance maximum 100
```

3. Configure Event MIB object lists **objectA**, **objectB**, and **objectC**.

```
[Sysname] snmp mib event object list owner owner1 name objectA 1 oid
1.3.6.1.4.1.25506.2.6.1.1.1.1.6.11
[Sysname] snmp mib event object list owner owner1 name objectB 1 oid
1.3.6.1.4.1.25506.2.6.1.1.1.1.7.11
[Sysname] snmp mib event object list owner owner1 name objectC 1 oid
1.3.6.1.4.1.25506.2.6.1.1.1.1.8.11
```

4. Configure an event:

Create an event and enter its view. Specify its owner as **owner1** and its name as **EventA**.

```
[Sysname] snmp mib event owner owner1 name EventA
```

Specify the notification action for the event. Specify object OID **1.3.6.1.4.1.25506.2.6.2.0.5 (hh3cEntityExtMemUsageThresholdNotification)** to execute the notification.

```
[Sysname-event-owner1-EventA] action notification
[Sysname-event-owner1-EventA-notification] oid 1.3.6.1.4.1.25506.2.6.2.0.5
```

Specify the object list with owner **owner 1** and name **objectC** to be added to the notification when the notification action is triggered

```
[Sysname-event-owner1-EventA-notification] object list owner owner1 name objectC
[Sysname-event-owner1-EventA-notification] quit
```

Enable the event.

```
[Sysname-event-owner1-EventA] event enable
[Sysname-event-owner1-EventA] quit
```

5. Configure a trigger:

Create a trigger and enter its view. Specify its owner as **owner1** and its name as **triggerA**.

```
[Sysname] snmp mib event trigger owner owner1 name triggerA
```

Set the sampling interval to 60 seconds. Make sure the interval is greater than or equal to the global minimum sampling interval.

```
[Sysname-trigger-owner1-triggerA] frequency 60
```

Specify object OID **1.3.6.1.4.1.25506.2.6.1.1.1.1.9.11** as the monitored object.

```
[Sysname-trigger-owner1-triggerA] oid 1.3.6.1.4.1.25506.2.6.1.1.1.1.9.11
```

Specify the object list with owner **owner1** and name **objectA** to be added to the notification when the notification action is triggered.

```
[Sysname-trigger-owner1-triggerA] object list owner owner1 name objectA
```

Configure a Boolean trigger test. Set its comparison type to greater, reference value to 10, and specify the event with owner **owner1** and name **EventA**, object list with owner **owner1** and name **objectB** for the test.

```
[Sysname-trigger-owner1-triggerA] test boolean
[Sysname-trigger-owner1-triggerA-boolean] comparison greater
[Sysname-trigger-owner1-triggerA-boolean] value 10
[Sysname-trigger-owner1-triggerA-boolean] event owner owner1 name EventA
[Sysname-trigger-owner1-triggerA-boolean] object list owner owner1 name objectB
[Sysname-trigger-owner1-triggerA-boolean] quit
```

Enable trigger sampling.

```
[Sysname-trigger-owner1-triggerA] trigger enable
[Sysname-trigger-owner1-triggerA] quit
```

Verifying the configuration

Display Event MIB configuration and statistics.

```
[Sysname] display snmp mib event summary
TriggerFailures              : 0
EventFailures                : 0
SampleMinimum                : 50
SampleInstanceMaximum        : 10
SampleInstance               : 1
SampleInstancesHigh          : 1
SampleInstanceLacks          : 0
```

Display information about the Event MIB object lists.

```
[Sysname] display snmp mib event object list
Object list objectA owned by owner1:
  ObjIndex                   : 1
  ObjID                      : 1.3.6.1.4.1.25506.2.6.1.1.1.1.6.11<hh3cEntityExt
CpuUsage.11>
  ObjIDWildcard              : false
Object list objectB owned by owner1:
  ObjIndex                   : 1
  ObjID                      : 1.3.6.1.4.1.25506.2.6.1.1.1.1.7.11<hh3cEntityExt
CpuUsageThreshold.11>
  ObjIDWildcard              : false
Object list objectC owned by owner1:
  ObjIndex                   : 1

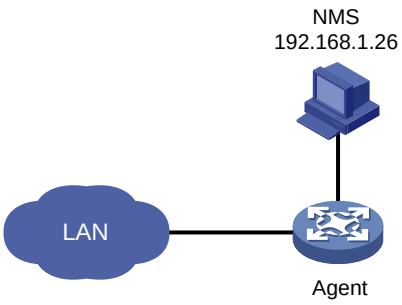
eThresholdNotification>
NotifyObjOwner             : owner1
NotifyObjName              : objectC
```

Display information about the trigger.

```
[Sysname] display snmp mib event trigger owner owner1 name triggerA
Trigger entry triggerA owned by owner1:
  TriggerComment             : N/A
  TriggerTest                : boolean
  TriggerSampleType          : absoluteValue
```

```
  TriggerValueID              : 1.3.6.1.4.1.25506.2.6.1.1.1.1.9.11<hh3cEntityExt
MemUsageThreshold.11>
  TriggerValueIDWildcard      : false
  TriggerTargetTag            : N/A
  TriggerContextName          : N/A
  TriggerContextNameWildcard  : false
  TriggerFrequency(in seconds): 60
  TriggerObjOwner             : owner1
  TriggerObjName              : objectA
  TriggerEnabled              : true
  Boolean entry:
   BoolCmp                    : greater
   BoolValue                  : 10
   BoolStartUp                : true
   BoolObjOwner               : owner1
   BoolObjName                : objectB
   BoolEvtOwner               : owner1
   BoolEvtName                : EventA
```



When the value of the monitored object 1.3.6.1.4.1.25506.2.6.1.1.1.1.9.11 becomes greater than 10, the NMS receives an mteTriggerFired notification.

Example: Configuring a threshold trigger test

Network configuration

As shown in Figure 2, the device acts as the agent. The NMS uses SNMPv3 to monitor and manage the device. Configure a trigger and configure a threshold trigger test for the trigger. When the trigger conditions are met, the agent sent an mteTriggerFired notification to the NMS.

Figure 4 Network diagram

Procedure

1. Enable and configure the SNMP agent on the device:

   # Create SNMPv3 group **g3** and add SNMPv3 user **owner1** to **g3**.

   ```
   <Sysname> system-view
   [Sysname] snmp-agent usm-user v3 owner1 g3
   [Sysname] snmp-agent group v3 g3 read-view a write-view a notify-view a
   [Sysname] snmp-agent mib-view included a iso
   ```

   # Enable SNMP notifications for the Event MIB module. Specify the NMS at **192.168.1.26** as the target host for the notifications.

   ```
   [Sysname] snmp-agent trap enable event-mib
   ```

```
[Sysname] snmp-agent target-host trap address udp-domain 192.168.1.26 params
securityname owner1 v3
[Sysname] snmp-agent trap enable
```

2. Configure the Event MIB global sampling parameters.

   # Set the Event MIB minimum sampling interval to 50 seconds.

   ```
   [Sysname] snmp mib event sample minimum 50
   ```

   # Set the maximum number to 10 for object instances that can be concurrently sampled.

   ```
   [Sysname] snmp mib event sample instance maximum 10
   ```

3. Create and configure a trigger:

   # Create a trigger and enter its view. Specify its owner as **owner1** and its name as **triggerA**.

   ```
   [Sysname] snmp mib event trigger owner owner1 name triggerA
   ```

   # Set the sampling interval to 60 seconds. Make sure the interval is greater than or equal to the Event MIB minimum sampling interval.

   ```
   [Sysname-trigger-owner1-triggerA] frequency 60
   ```

   # Specify object OID **1.3.6.1.4.1.25506.2.6.1.1.1.1.7.11** as the monitored object.

   ```
   [Sysname-trigger-owner1-triggerA] oid 1.3.6.1.4.1.25506.2.6.1.1.1.1.7.11
   ```

   # Configure a threshold trigger test. Specify the rising threshold to 80 and the falling threshold to 10 for the test.

   ```
   [Sysname-trigger-owner1-triggerA] test threshold
   [Sysname-trigger-owner1-triggerA-threshold] rising value 80
   [Sysname-trigger-owner1-triggerA-threshold] falling value 10
   [Sysname-trigger-owner1-triggerA-threshold] quit
   ```

   # Enable trigger sampling.

   ```
   [Sysname-trigger-owner1-triggerA] trigger enable
   [Sysname-trigger-owner1-triggerA] quit
   ```

Verifying the configuration

Display Event MIB configuration and statistics.

```
[Sysname] display snmp mib event summary
TriggerFailures               : 0
EventFailures                 : 0
SampleMinimum                 : 50
SampleInstanceMaximum         : 10
SampleInstance                : 1
SampleInstancesHigh           : 1
SampleInstanceLacks           : 0
```

Display information about the trigger.

```
[Sysname] display snmp mib event trigger owner owner1 name triggerA
Trigger entry triggerA owned by owner1:
  TriggerComment              : N/A
  TriggerTest                 : threshold
  TriggerSampleType           : absoluteValue
  TriggerValueID              : 1.3.6.1.4.1.25506.2.6.1.1.1.1.7.11<hh3cEntityExt
CpuUsageThreshold.11>
  TriggerValueIDWildcard      : false
  TriggerTargetTag            : N/A
  TriggerContextName          : N/A
  TriggercontextNameWildcard  : false
```

```
  TriggerFrequency(in seconds): 60
  TriggerObjOwner             : N/A
  TriggerObjName              : N/A
  TriggerEnabled              : true
Threshold entry:
   ThresStartUp               : risingOrFalling
   ThresRising                : 80
   ThresFalling               : 10
   ThresDeltaRising           : 0
   ThresDeltaFalling          : 0
   ThresObjOwner              : N/A
   ThresObjName               : N/A
   ThresRisEvtOwner           : N/A
   ThresRisEvtName            : N/A
   ThresFalEvtOwner           : N/A
   ThresFalEvtName            : N/A
   ThresDeltaRisEvtOwner      : N/A
   ThresDeltaRisEvtName       : N/A
   ThresDeltaFalEvtOwner      : N/A
   ThresDeltaFalEvtName       : N/A
```

When the rising threshold of the monitored object 1.3.6.1.4.1.25506.2.6.1.1.1.1.7.11 is greater than 80, the NMS receives an mteTriggerFired notification.

Configuring NETCONF

About NETCONF

Network Configuration Protocol (NETCONF) is an XML-based network management protocol. It provides programmable mechanisms to manage and configure network devices. Through NETCONF, you can configure device parameters, retrieve parameter values, and collect statistics. For a network that has devices from vendors, you can develop a NETCONF-based NMS system to configure and manage devices in a simple and effective way.

NETCONF structure

NETCONF has the following layers: content layer, operations layer, RPC layer, and transport protocol layer.

Table 1 NETCONF layers and XML layers

NETCONF layer	XML layer	Description
Content	Configuration data, status data, and statistics	Contains a set of managed objects, which can be configuration data, status data, and statistics. For information about the operable data, see the NETCONF XML API reference for the device.
Operations	<get>, <get-config>, <edit-config>…	Defines a set of base operations invoked as RPC methods with XML-encoded parameters. NETCONF base operations include data retrieval operations, configuration operations, lock operations, and session operations. For information about operations supported on the device, see "Supported NETCONF operations."
RPC	<rpc> and <rpc-reply>	Provides a simple, transport-independent framing mechanism for encoding RPCs. The <rpc> and <rpc-reply> elements are used to enclose NETCONF requests and responses (data at the operations layer and the content layer).
Transport protocol	In non-FIPS mode: Console, Telnet, SSH, HTTP, HTTPS, and TLS In FIPS mode: Console, SSH, HTTPS, and TLS	Provides reliable, connection-oriented, serial data links. The following transport layer sessions are available in non-FIPS mode: • CLI sessions, including NETCONF over Telnet sessions, NETCONF over SSH sessions, and NETCONF over console sessions. • NETCONF over SOAP sessions, including NETCONF over SOAP over HTTP sessions and NETCONF over SOAP over HTTPS sessions. The following transport layer sessions are available in FIPS mode: • CLI sessions, including NETCONF over SSH sessions and NETCONF over console sessions. • NETCONF over SOAP over HTTPS sessions.

Basic NETCONF concepts

XML

eXtensible Markup Language (XML) is a simple, text-based data storage language. It describes the content and structure of data exchanged between entities on the Internet.

XML is case sensitive.

NETCONF uses XML-based data encoding for the configuration data and protocol messages. NETCONF messages are XML-based and comply with RFC 4741.

Element

Elements are the basic building blocks in an XML document. They act as containers to store various types of content, including text, child elements, and attributes.

An element encloses content in a pair of start and end tags, in <*element-name*>*content*</*element-name*> format. For example, the **capability** element is `<capability>`*content*`</capability>`.

If an element does not have content, that element is called an empty element. You can present an empty element in a self-closing empty tag in <*element-name*/> format, for example, `<ok/>`.

Attribute

Attributes provide meta-level information about an element. They are added in *name*=*value* format after the element name, within the start tag. For examples, the `xmlns` and `operation` attributes in the following element specify the namespace and operation type, respectively.

```
<Syslog xmlns="http://www.h3c.com/netconf/config:1.0-Syslog"
xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0"   xc:operation="create">
```

Namespace

A namespace is an abstract container or environment created to hold a logical group of unique identifiers or names. An identifier defined in a namespace is associated only with that namespace. Each data module must have a world-unique namespace to avoid element and attribute naming conflicts.

The device supports the following types of namespaces:

- **urn:ietf:params:xml:ns:netconf:base:1.0 namespace**—This namespace defines all NETCONF elements. All NETCONF messages must declare this namespace in the RPC layer.
- **ietf-netconf namespace**—The **urn:ietf:params:xml:ns:yang:ietf-netconf-monitoring** namespace defined in a NETCONF protocol. NETCONF messages for the <get-schema> and <get><netconf-state/></get> operations must declare this namespace.
- **Common namespace**—A namespace that defines elements across service modules. In a packet that uses a common namespace, the namespace is indicated in the <top> element, and the modules are listed under the <top> element.
- **H3C common namespaces**—The http://www.h3c.com/netconf/*ns*:1.0 namespaces. The *ns* argument represents data, config, and action, which represent the data, configuration, and action namespaces, respectively. The common namespaces are shared by all modules. If used, a common namespace is typically specified for the xmlns attribute in the <top> element, and the modules are listed under the <top> element.

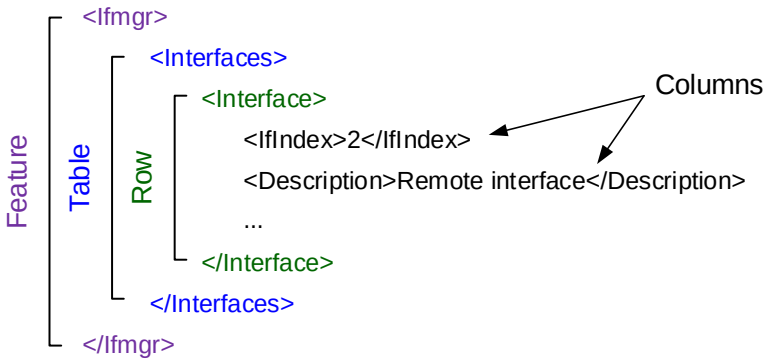
  Example:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <get-bulk>
      <filter type="subtree">
         <top xmlns="http://www.h3c.com/netconf/data:1.0">
            <Ifmgr>
               <Interfaces>
               </Interfaces>
            </Ifmgr>
         </top>
      </filter>
   </get-bulk>
```

```
</rpc>
```

- **Module-specific namespaces**—A module has its own namespace to define module-specific elements. A packet that uses a module-specific namespace does not have the <top> element. The namespace follows the module name.

  Example:



```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <get-bulk>
      <filter type="subtree">
            <Ifmgr xmlns="http://www.h3c.com/netconf/data:1.0-Ifmgr">
               <Interfaces>
               </Interfaces>
            </Ifmgr>
      </filter>
   </get-bulk>
</rpc>
```

Node, module, table, row, and column

In H3C NETCONF XML AI references, elements are also called nodes. An element might be a module (or feature), table, row, or column node, as shown in Figure 1.

- **Module**—A feature module defines a hierarchy of related nodes. The element name for a module node is the module name.
- **Table**—A table contains rows and columns, with each row representing an object instance and each column containing a parameter for the instance. A table might also contains subtables.
- **Row**—Each row represents an object instance in the table.
- **Column**—Each column contains a parameter for the instance.

Figure 1 Node, module, table, row, and column in NETCONF messages

In Figure 1, the `Ifmgr` element represents the interface management module (Ifmgr). The `Interfaces` element is a table node in the Ifmgr module and it contains a table of interfaces. The `Interface` element is a row node and it contains data about an interface in the interface table. The `IfIndex` and `Description` elements are column nodes that contain the interface index and description of the interface.

NETCONF message format

NETCONF

All NETCONF messages are XML-based and comply with RFC 4741. An incoming NETCONF message must pass XML schema check before it can be processed. If a NETCONF message fails XML schema check, the device sends an error message to the client.

For information about the NETCONF operations supported by the device and the operable data, see the NETCONF XML API reference for the device.

The following example shows a NETCONF message for getting all parameters of all interfaces on the device:

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-bulk>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
                 <Interface/>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-bulk>
</rpc>
```

NETCONF over SOAP

All NETCONF over SOAP messages are XML-based and comply with RFC 4741. NETCONF messages are contained in the <Body> element of SOAP messages. NETCONF over SOAP messages also comply with the following rules:

- SOAP messages must use the SOAP Envelope namespaces.
- SOAP messages must use the SOAP Encoding namespaces.
- SOAP messages cannot contain the following information:
  - DTD reference.
  - XML processing instructions.

The following example shows a NETCONF over SOAP message for getting all parameters of all interfaces on the device:

```
<env:Envelope xmlns:env="http://www.w3.org/2003/05/soap-envelope">
  <env:Header>
    <auth:Authentication env:mustUnderstand="1"
xmlns:auth="http://www.h3c.com/netconf/base:1.0">
      <auth:AuthInfo>800207F0120020C</auth:AuthInfo>
    </auth:Authentication>
  </env:Header>
  <env:Body>
    <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <get-bulk>
        <filter type="subtree">
          <top xmlns="http://www.h3c.com/netconf/data:1.0">
            <Ifmgr>
              <Interfaces>
                <Interface/>
              </Interfaces>
            </Ifmgr>
          </top>
        </filter>
```

```
      </get-bulk>
    </rpc>
  </env:Body>
</env:Envelope>
```

How to use NETCONF

You can use NETCONF to manage and configure the device by using the methods in Table 2.

Table 2 NETCONF methods for configuring the device

Configuration tool	Login method	Remarks
CLI	• Console port • SSH • Telnet	To perform NETCONF operations, copy valid NETCONF messages to the CLI in XML view.
Custom user interface	N/A	This method requires a NETCONF over SOAP session or NETCONF over SSH session with the device. To use a NETCONF over SOAP session, you must enable NETCONF over SOAP. Then, NETCONF messages will be encapsulated in SOAP messages for transmission.

Protocols and standards

- RFC 3339, *Date and Time on the Internet: Timestamps*
- RFC 4741, *NETCONF Configuration Protocol*
- RFC 4742, *Using the NETCONF Configuration Protocol over Secure SHell (SSH)*
- RFC 4743, *Using NETCONF over the Simple Object Access Protocol (SOAP)*
- RFC 5277, *NETCONF Event Notifications*
- RFC 5381, *Experience of Implementing NETCONF over SOAP*
- RFC 5539, *NETCONF over Transport Layer Security (TLS)*
- RFC 6241, *Network Configuration Protocol*

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode (see *Security Configuration Guide*) and non-FIPS mode.

NETCONF tasks at a glance

To configure NETCONF, perform the following tasks:

1. Establishing a NETCONF session
   a. (Optional.) Setting NETCONF session attributes
   b. Establishing NETCONF over SOAP sessions
   c. Establishing NETCONF over SSH sessions
   d. Establishing NETCONF over Telnet or NETCONF over console sessions
   e. Exchanging capabilities

2. (Optional.) Retrieving device configuration information
   - Retrieving device configuration and state information
   - Retrieving non-default settings
   - Retrieving NETCONF information
   - Retrieving YANG file content
   - Retrieving NETCONF session information
3. (Optional.) Filtering data
   - Table-based filtering
   - Column-based filtering
4. (Optional.) Locking or unlocking the running configuration
   a. Locking the running configuration
   b. Unlocking the running configuration
5. (Optional.) Modifying the configuration
6. (Optional.) Managing configuration files
   - Saving the running configuration
   - Loading the configuration
   - Rolling back the configuration
7. (Optional.) Performing CLI operations through NETCONF
8. (Optional.) Subscribing to events
   - Subscribing to syslog events
   - Subscribing to events monitored by NETCONF
   - Subscribing to events reported by modules
   - Canceling an event subscription
9. (Optional.) Terminating NETCONF sessions
10. (Optional.) Returning to the CLI

Establishing a NETCONF session

Restrictions and guidelines for NETCONF session establishment

After a NETCONF session is established, the device automatically sends its capabilities to the client. You must send the capabilities of the client to the device before you can perform any other NETCONF operations.

Before performing a NETCONF operation, make sure no other users are configuring or managing the device. If multiple users simultaneously configure or manage the device, the result might be different from what you expect.

You can use the **`aaa session-limit`** command to set the maximum number of NETCONF sessions that the device can support. If the upper limit is reached, new NETCONF users cannot access the device. For information about this command, see AAA in *Security Configuration Guide*.

Setting NETCONF session attributes

About this task

NETCONF supports the following types of namespaces:

- **Common namespace**—The common namespace is shared by all modules. In a packet that uses the common namespace, the namespace is indicated in the <top> element, and the modules are listed under the <top> element.

  Example:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <get-bulk>
      <filter type="subtree">
         <top xmlns="http://www.h3c.com/netconf/data:1.0">
            <Ifmgr>
               <Interfaces>
               </Interfaces>
            </Ifmgr>
         </top>
      </filter>
   </get-bulk>
</rpc>
```

- **Module-specific namespace**—Each module has its own namespace. A packet that uses a module-specific namespace does not have the <top> element. The namespace follows the module name.

  Example:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <get-bulk>
      <filter type="subtree">
            <Ifmgr xmlns="http://www.h3c.com/netconf/data:1.0-Ifmgr">
               <Interfaces>
               </Interfaces>
            </Ifmgr>
      </filter>
   </get-bulk>
</rpc>
```

The common namespace is incompatible with module-specific namespaces. To set up a NETCONF session, the device and the client must use the same type of namespaces. By default, the common namespace is used. If the client does not support the common namespace, use this feature to configure the device to use module-specific namespaces.

Procedure

1. Enter system view.

   system-view

2. Set the NETCONF session idle timeout time.

   netconf { **agent** | **soap** } **idle-timeout** *minute*

Keyword	Description
agent	Specifies the following sessions: • NETCONF over SSH sessions. • NETCONF over Telnet sessions. • NETCONF over console sessions. By default, the idle timeout time is 0, and the sessions never time out.
soap	Specifies the following sessions:

Keyword	Description
	• NETCONF over SOAP over HTTP sessions. • NETCONF over SOAP over HTTPS sessions. The default setting is 10 minutes.

3. Enable NETCONF logging.

   netconf log source { **all** | { **agent** | **soap** | **web** } * } { **protocol-operation** { **all** | { **action** | **config** | **get** | **set** | **session** | **syntax** | **others** } * } | **row-operation** | **verbose** }

   By default, the device logs only row operations for <action> and <edit-config> operations. NETCONF logging is disabled for all the other types of operations.

   The **web** keyword is not supported in the current software version.

4. Configure NETCONF to use module-specific namespaces.

   netconf capability specific-namespace

   By default, the common namespace is used.

   For the setting to take effect, you must reestablish the NETCONF session.

Establishing NETCONF over SOAP sessions

About this task

You can use a custom user interface to establish a NETCONF over SOAP session to the device and perform NETCONF operations. NETCONF over SOAP encapsulates NETCONF messages into SOAP messages and transmits the SOAP messages over HTTP or HTTPS.

Restrictions and guidelines

You can add an authentication domain to the <UserName> parameter of a SOAP request. The authentication domain takes effect only on the current request.

The mandatory authentication domain configured by using the **netconf soap domain** command takes precedence over the authentication domain specified in the <UserName> parameter of a SOAP request.

Procedure

1. Enter system view.

   system-view

2. Enable NETCONF over SOAP.

   In non-FIPS mode:

   netconf soap { **http** | **https** } **enable**

   In FIPS mode:

   netconf soap https enable

   By default, the NETCONF over SOAP feature is disabled if the device starts up with the initial configuration.

   If the device starts up with the factory defaults, the enabling state of NETCONF over SOAP varies depending on the hardware platform and software version, as shown in Table 3.

Table 3 Factory defaults for NETCONF over SOAP

Hardware platform	Feature	Factory default	Applicable software versions
S5570S-EI	NETCONF over SOAP over	Disabled	All versions

Hardware platform	Feature	Factory default	Applicable software versions
series	HTTP/HTTPS		
S5500V3-SI series	NETCONF over SOAP over HTTPS	Disabled	All versions
	NETCONF over SOAP over HTTP	Disabled	Versions earlier than Release 1115
		Enabled	Release 1115 or later

For more information about initial configuration, factory defaults, and startup configuration, see configuration file management in *Fundamentals Configuration Guide*.

3. Set the DSCP value for NETCONF over SOAP packets.

   In non-FIPS mode:

   netconf soap { **http** | **https** } **dscp** *dscp-value*

   In FIPS mode:

   netconf soap https dscp *dscp-value*

   By default, the DSCP value is 0 for NETCONF over SOAP packets.

4. Use an IPv4 ACL to control NETCONF over SOAP access.

   In non-FIPS mode:

   netconf soap { **http** | **https** } **acl** { *ipv4-acl-number* | **name** *ipv4-acl-name* }

   In FIPS mode:

   netconf soap https acl { *ipv4-acl-number* | **name** *ipv4-acl-name* }

   By default, no IPv4 ACL is applied to control NETCONF over SOAP access.

   Only clients permitted by the IPv4 ACL can establish NETCONF over SOAP sessions.

5. Specify a mandatory authentication domain for NETCONF users.

   netconf soap domain *domain-name*

   By default, no mandatory authentication domain is specified for NETCONF users. For information about authentication domains, see *Security Configuration Guide*.

6. Use the custom user interface to establish a NETCONF over SOAP session with the device.

   For information about the custom user interface, see the user guide for the interface.

Establishing NETCONF over SSH sessions

Prerequisites

Before establishing a NETCONF over SSH session, make sure the custom user interface can access the device through SSH.

Procedure

1. Enter system view.

   system-view

2. Enable NETCONF over SSH.

   netconf ssh server enable

   By default, NETCONF over SSH is disabled.

3. Specify the listening port for NETCONF over SSH packets.

   netconf ssh server port *port-number*

By default, the listening port number is 830.

4. Use the custom user interface to establish a NETCONF over SSH session with the device. For information about the custom user interface, see the user guide for the interface.

Establishing NETCONF over Telnet or NETCONF over console sessions

Restrictions and guidelines

To ensure the format correctness of a NETCONF message, do not enter the message manually. Copy and paste the message.

While the device is performing a NETCONF operation, do not perform any other operations, such as pasting a NETCONF message or pressing **Enter**.

For the device to identify NETCONF messages, you must add end mark **]]>]]>** at the end of each NETCONF message. Examples in this document do not necessarily have this end mark. Do add the end mark in actual operations.

Prerequisites

To establish a NETCONF over Telnet session or a NETCONF over console session, first log in to the device through Telnet or the console port.

Procedure

To enter XML view, execute the following command in user view:

`xml`

If the XML view prompt appears, the NETCONF over Telnet session or NETCONF over console session is established successfully.

Exchanging capabilities

About this task

After a NETCONF session is established, the device sends its capabilities to the client. You must use a hello message to send the capabilities of the client to the device before you can perform any other NETCONF operations.

Hello message from the device to the client

```
<?xml version="1.0" encoding="UTF-8"?><hello
xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"><capabilities>...</capabilities><sess
ion-id>1</session-id></hello>]]>]]>
```

The <capabilities> element carries the capabilities supported by the device. The supported capabilities vary by device model.

The <session-id> element carries the unique ID assigned to the NETCONF session.

Hello message from the client to the device

After receiving the hello message from the device, copy the following hello message to notify the device of the capabilities supported by the client:

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
     capability-set
   </capability>
 </capabilities>
```

```
</hello>
```

Item	Description
capability-set	Specifies a set of capabilities supported by the client. Use the <capability> and </capability> tags to enclose each user-defined capability set.

Retrieving device configuration information

Restrictions and guidelines for device configuration retrieval

During a <get>, <get-bulk>, <get-config>, or <get-bulk-config> operation, NETCONF replaces unidentifiable characters in the retrieved data with question marks (?) before sending the data to the client. If the process for a relevant module is not started yet, the operation returns the following message:

```
<?xml version="1.0"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data/>
</rpc-reply>
```

The <get><netconf-state/></get> operation does not support data filtering.

For more information about the NETCONF operations, see the NETCONF XML API references for the device.

Retrieving device configuration and state information

You can use the following NETCONF operations to retrieve device configuration and state information:

- **<get> operation**—Retrieves all device configuration and state information that matches the specified conditions.
- **<get-bulk> operation**—Retrieves data entries starting from the data entry next to the one with the specified index. One data entry contains a device configuration entry and a state information entry. The returned output does not include the index information.

The <get> message and <get-bulk> message share the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <getoperation>
    <filter>
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
          Specify the module, submodule, table name, and column name
      </top>
    </filter>
  </getoperation>
</rpc>
```

Item	Description
getoperation	Operation name, **get** or **get-bulk**.

Item	Description
filter	Specifies the filtering conditions, such as the module name, submodule name, table name, and column name. • If you specify a module name, the operation retrieves the data for the specified module. If you do not specify a module name, the operation retrieves the data for all modules. • If you specify a submodule name, the operation retrieves the data for the specified submodule. If you do not specify a submodule name, the operation retrieves the data for all submodules. • If you specify a table name, the operation retrieves the data for the specified table. If you do not specify a table name, the operation retrieves the data for all tables. • If you specify only the index column, the operation retrieves the data for all columns. If you specify the index column and any other columns, the operation retrieves the data for the index column and the specified columns.

A <get-bulk> message can carry the **count** and **index** attributes.

Item	Description
index	Specifies the index. If you do not specify this item, the index value starts with 1 by default.
count	Specifies the data entry quantity. The **count** attribute complies with the following rules: • The **count** attribute can be placed in the module node and table node. In other nodes, it cannot be resolved. • When the **count** attribute is placed in the module node, a descendant node inherits this count attribute if the descendant node does not contain the count attribute. • The <get-bulk> operation retrieves all the rest data entries starting from the data entry next to the one with the specified index if either of the following conditions occurs: ○ You do not specify the **count** attribute. ○ The number of matching data entries is less than the value of the **count** attribute.

The following <get-bulk> message example specifies the **count** and **index** attributes:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xc="http://www.h3c.com/netconf/base:1.0">
  <get-bulk>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0"
xmlns:base="http://www.h3c.com/netconf/base:1.0">
        <Syslog>
          <Logs xc:count="5">
            <Log>
              <Index>10</Index>
            </Log>
            </Logs>
        </Syslog>
      </top>
    </filter>
```

```
  </get-bulk>
</rpc>
```

When retrieving interface information, the device cannot identify whether an integer value for the <IfIndex> element represents an interface name or index. When retrieving VPN instance information, the device cannot identify whether an integer value for the <vrfindex> element represents a VPN name or index. To resolve the issue, you can use the **valuetype** attribute to specify the value type.

The **valuetype** attribute has the following values:

Value	Description
name	The element is carrying a name.
index	The element is carrying an index.
auto	Default value. The device uses the value of the element as a name for information matching. If no match is found, the device uses the value as an index for interface or information matching.

The following example specifies an index-type value for the <IfIndex> element:

```
<rpc xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <getoperation>
    <filter>
      <top xmlns="http://www.h3c.com/netconf/config:1.0"
xmlns:base="http://www.h3c.com/netconf/base:1.0">
       <VLAN>
        <TrunkInterfaces>
          <Interface>
            <IfIndex base:valuetype="index">1</IfIndex>
          </Interface>
        </TrunkInterfaces>
       </VLAN>
      </top>
    </filter >
  </getoperation>
</rpc>
```

If the <get> or < get-bulk> operation succeeds, the device returns the retrieved data in the following format:

```
<?xml version="1.0"?>
 <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
     Device state and configuration data
  </data>
</rpc-reply>
```

Retrieving non-default settings

The <get-config> and <get-bulk-config> operations are used to retrieve all non-default settings. The <get-config> and <get-bulk-config> messages can contain the <filter> element for filtering data.

The <get-config> and <get-bulk-config> messages are similar. The following is a <get-config> message example:

```
<?xml version="1.0"?>
```

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter>
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
          Specify the module name, submodule name, table name, and column name
      </top>
    </filter>
  </get-config>
</rpc>
```

If the <get-config> or <get-bulk-config> operation succeeds, the device returns the retrieved data in the following format:

```
<?xml version="1.0"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    Data matching the specified filter
  </data>
</rpc-reply>
```

Retrieving NETCONF information

Use the <get><netconf-state/></get> message to retrieve NETCONF information.

Copy the following text to the client to retrieve NETCONF information:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="m-641" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type='subtree'>
      <netconf-state xmlns='urn:ietf:params:xml:ns:yang:ietf-netconf-monitoring'>
        <getType/>
      </netconf-state>
    </filter>
  </get>
</rpc>
```

If you do not specify a value for *getType*, the retrieval operation retrieves all NETCONF information.

The value for *getType* can be one of the following operations:

Operation	Description
capabilities	Retrieves device capabilities.
datastores	Retrieves databases from the device.
schemas	Retrieves the list of the YANG file names from the device.
sessions	Retrieves session information from the device.
statistics	Retrieves NETCONF statistics.

If the <get><netconf-state/></get> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0"?>
 <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
     Retrieved NETCONF information
  </data>
</rpc-reply>
```

Retrieving YANG file content

YANG files save the NETCONF operations supported by the device. You can identify the supported operations by retrieving and analyzing the content of YANG files.

YANG files are integrated in the device software and are named in the format of *yang_identifier@yang_version.yang*. You cannot view the YANG file names by executing the **dir** command. For information about retrieving the YANG file names, see "Retrieving NETCONF information."

Copy the following text to the client to retrieve the YANG file named **H3C-syslog-data@2019-01-01.yang**:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-schema xmlns='urn:ietf:params:xml:ns:yang:ietf-netconf-monitoring'>
    <identifier>H3C-syslog-data</identifier>
    <version>2019-01-01</version>
    <format>yang</format>
  </get-schema>
</rpc>
```

If the <get-schema> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
     Content of the specified YANG file
  </data>
</rpc-reply>
```

Retrieving NETCONF session information

Use the <get-sessions> operation to retrieve NETCONF session information of the device.

Copy the following message to the client to retrieve NETCONF session information from the device:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-sessions/>
</rpc>
```

If the <get-sessions> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-sessions>
    <Session>
```

```
      <SessionID>Configuration session ID</SessionID>
      <Line>Line information</Line>
      <UserName>Name of the user creating the session</UserName>
      <Since>Time when the session was created</Since>
      <LockHeld>Whether the session holds a lock</LockHeld>
    </Session>
  </get-sessions>
</rpc-reply>
```

Example: Retrieving a data entry for the interface table

Network configuration

Retrieve a data entry for the interface table.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>urn:ietf:params:netconf:base:1.0</capability>
  </capabilities>
</hello>
```

Retrieve a data entry for the interface table.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:web="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-bulk>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0"
xmlns:web="http://www.h3c.com/netconf/base:1.0">
        <Ifmgr>
          <Interfaces web:count="1">
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-bulk>
</rpc>
```

Verifying the configuration

If the client receives the following text, the <get-bulk> operation is successful:

```
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:web="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
  <data>
    <top xmlns="http://www.h3c.com/netconf/data:1.0">
      <Ifmgr>
        <Interfaces>
          <Interface>
            <IfIndex>3</IfIndex>
```

```
            <Name>GigabitEthernet1/0/2</Name>
            <AbbreviatedName>GE1/0/2</AbbreviatedName>
            <PortIndex>3</PortIndex>
            <ifTypeExt>22</ifTypeExt>
            <ifType>6</ifType>
            <Description>GigabitEthernet1/0/2 Interface</Description>
            <AdminStatus>2</AdminStatus>
            <OperStatus>2</OperStatus>
            <ConfigSpeed>0</ConfigSpeed>
            <ActualSpeed>100000</ActualSpeed>
            <ConfigDuplex>3</ConfigDuplex>
            <ActualDuplex>1</ActualDuplex>
          </Interface>
        </Interfaces>
      </Ifmgr>
    </top>
  </data>
</rpc-reply>
```

Example: Retrieving non-default configuration data

Network configuration

Retrieve all non-default configuration data.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Retrieve all non-default configuration data.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
  </get-config>
</rpc>
```

Verifying the configuration

If the client receives the following text, the <get-config> operation is successful:

```
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:web="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <data>
```

```
        <top xmlns="http://www.h3c.com/netconf/config:1.0">
            <Ifmgr>
                <Interfaces>
                    <Interface>
                        <IfIndex>1307</IfIndex>
                        <Shutdown>1</Shutdown>
                    </Interface>
                    <Interface>
                        <IfIndex>1308</IfIndex>
                        <Shutdown>1</Shutdown>
                    </Interface>
                    <Interface>
                        <IfIndex>1309</IfIndex>
                        <Shutdown>1</Shutdown>
                    </Interface>
                    <Interface>
                        <IfIndex>1311</IfIndex>
                            <VlanType>2</VlanType>
                    </Interface>
                    <Interface>
                        <IfIndex>1313</IfIndex>
                            <VlanType>2</VlanType>
                    </Interface>
                </Interfaces>
            </Ifmgr>
            <Syslog>
                <LogBuffer>
                    <BufferSize>120</BufferSize>
                </LogBuffer>
            </Syslog>
            <System>
                <Device>
                    <SysName>Sysname</SysName>
                    <TimeZone>
                        <Zone>+11:44</Zone>
                        <ZoneName>beijing</ZoneName>
                    </TimeZone>
                </Device>
            </System>
        </top>
    </data>
</rpc-reply>
```

Example: Retrieving syslog configuration data

Network configuration

Retrieve configuration data for the Syslog module.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Retrieve configuration data for the Syslog module.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Syslog/>
      </top>
    </filter>
  </get-config>
</rpc>
```

Verifying the configuration

If the client receives the following text, the <get-config> operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <data>
        <top xmlns="http://www.h3c.com/netconf/config:1.0">
            <Syslog>
                    <LogBuffer>
                        <BufferSize>120</BufferSize>
                    </LogBuffer>
            </Syslog>
        </top>
    </data>
</rpc-reply>
```

Example: Retrieving NETCONF session information

Network configuration

Get NETCONF session information.

Procedure

Enter XML view.

```
<Sysname> xml
```

Copy the following message to the client to exchange capabilities with the device:

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
           urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Copy the following message to the client to get the current NETCONF session information on the device:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-sessions/>
</rpc>
```

Verifying the configuration

If the client receives a message as follows, the operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <get-sessions>
        <Session>
            <SessionID>1</SessionID>
            <Line>vty0</Line>
            <UserName></UserName>
            <Since>2019-01-07T00:24:57</Since>
            <LockHeld>false</LockHeld>
        </Session>
    </get-sessions>
</rpc-reply>
```

The output shows the following information:

- The session ID of an existing NETCONF session is 1.
- The login user type is vty0.
- The login time is 2019-01-07T00:24:57.
- The user does not hold the lock of the configuration.

Filtering data

About data filtering

You can define a filter to filter information when you perform a <get>, <get-bulk>, <get-config>, or <get-bulk-config> operation. Data filtering includes the following types:

- **Table-based filtering**—Filters table information.
- **Column-based filtering**—Filters information for a single column.

Restrictions and guidelines for data filtering

For table-based filtering to take effect, you must configure table-based filtering before column-based filtering.

Table-based filtering

About this task

The namespace is **http://www.h3c.com/netconf/base:1.0**. The attribute name is **filter**. For information about the support for table-based match, see the NETCONF XML API references.

Copy the following text to the client to retrieve the longest data with IP address **1.1.1.0** and mask length **24** from the IPv4 routing table:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Route>
         <Ipv4Routes>
           <RouteEntry h3c:filter="IP 1.1.1.0 MaskLen 24 longer"/>
         </Ipv4Routes>
        </Route>
      </top>
    </filter>
  </get>
</rpc>
```

Restrictions and guidelines

To use table-based filtering, specify a match criterion for the **filter** row attribute.

Column-based filtering

About this task

Column-based filtering includes full match filtering, regular expression match filtering, and conditional match filtering. Full match filtering has the highest priority and conditional match filtering has the lowest priority. When more than one filtering criterion is specified, the one with the highest priority takes effect.

Full match filtering

You can specify an element value in an XML message to implement full match filtering. If multiple element values are provided, the system returns the data that matches all the specified values.

Copy the following text to the client to retrieve configuration data of all interfaces in UP state:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
```

```
            <AdminStatus>1</AdminStatus>
          </Interface>
        </Interfaces>
      </Ifmgr>
    </top>
  </filter>
 </get>
</rpc>
```

You can also specify an attribute name that is the same as a column name of the current table at the row to implement full match filtering. The system returns only configuration data that matches this attribute name. The XML message equivalent to the above element-value-based full match filtering is as follows:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get>
    <filter type="subtree">
      <top
xmlns="http://www.h3c.com/netconf/data:1.0"xmlns:data="http://www.h3c.com/netconf/dat
a:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface data:AdminStatus="1"/>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get>
</rpc>
```

The above examples show that both element-value-based full match filtering and attribute-name-based full match filtering can retrieve the same index and column information for all interfaces in up state.

Regular expression match filtering

To implement a complex data filtering with characters, you can add a **regExp** attribute for a specific element.

The supported data types include integer, date and time, character string, IPv4 address, IPv4 mask, IPv6 address, MAC address, OID, and time zone.

Copy the following text to the client to retrieve the descriptions of interfaces, of which all the characters must be upper-case letters from A to Z:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <Description h3c:regExp="^[A-Z]*$"/>
```

```
          </Interface>
        </Interfaces>
      </Ifmgr>
    </top>
  </filter>
 </get-config>
</rpc>
```

Conditional match filtering

To implement a complex data filtering with digits and character strings, you can add a **match** attribute for a specific element. Table 4 lists the conditional match operators.

Table 4 Conditional match operators

Operation	Operator	Remarks
More than	match="more:*value*"	More than the specified value. The supported data types include date, digit, and character string.
Less than	match="less:*value*"	Less than the specified value. The supported data types include date, digit, and character string.
Not less than	match="notLess:*value*"	Not less than the specified value. The supported data types include date, digit, and character string.
Not more than	match="notMore:*value*"	Not more than the specified value. The supported data types include date, digit, and character string.
Equal	match="equal:*value*"	Equal to the specified value. The supported data types include date, digit, character string, OID, and BOOL.
Not equal	match="notEqual:*value*"	Not equal to the specified value. The supported data types include date, digit, character string, OID, and BOOL.
Include	match="include:*string*"	Includes the specified string. The supported data types include only character string.
Not include	match="exclude:*string*"	Excludes the specified string. The supported data types include only character string.
Start with	match="startWith:*string*"	Starts with the specified string. The supported data types include character string and OID.
End with	match="endWith:*string*"	Ends with the specified string. The supported data types include only character string.

Copy the following text to the client to retrieve extension information about the entity whose CPU usage is more than 50%:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Device>
          <ExtPhysicalEntities>
            <Entity>
              <CpuUsage h3c:match="more:50"></CpuUsage>
            </Entity>
          </ExtPhysicalEntities>
        </Device>
```

```
      </top>
    </filter>
  </get>
</rpc>
```

Example: Filtering data with regular expression match

Network configuration

Retrieve all data including **Gig** in the **Description** column of the Interfaces table under the Ifmgr module.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
           urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Retrieve all data including **Gig** in the **Description** column of the Interfaces table under the Ifmgr module.

```
<?xml version="1.0"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <Description h3c:regExp="(Gig)+"/>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get>
</rpc>
```

Verifying the configuration

If the client receives the following text, the operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0" message-id="100">
    <data>
        <top xmlns="http://www.h3c.com/netconf/data:1.0">
```

```
            <Ifmgr>
                <Interfaces>
                    <Interface>
                        <IfIndex>2681</IfIndex>
                        <Description>GigabitEthernet1/0/1 Interface</Description>
                    </Interface>
                    <Interface>
                        <IfIndex>2685</IfIndex>
                        <Description>GigabitEthernet1/0/2 Interface</Description>
                    </Interface>
                    <Interface>
                        <IfIndex>2689</IfIndex>
                        <Description>GigabitEthernet1/0/3 Interface</Description>
                    </Interface>
                 <Interface>
            </Ifmgr>
        </top>
    </data>
</rpc-reply>
```

Example: Filtering data by conditional match

Network configuration

Retrieve data in the **Name** column with the ifindex value not less than 5000 in the Interfaces table under the Ifmgr module.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Retrieve data in the **Name** column with the ifindex value not less than 5000 in the Interfaces table under the Ifmgr module.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
              <IfIndex h3c:match="notLess:5000"/>
              <Name/>
```

```
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get>
</rpc>
```

Verifying the configuration

If the client receives the following text, the operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0" message-id="100">
    <data>
        <top xmlns="http://www.h3c.com/netconf/data:1.0">
            <Ifmgr>
                <Interfaces>
                    <Interface>
                        <IfIndex>7241</IfIndex>
                        <Name>NULL0</Name>
                    </Interface>
                </Interfaces>
            </Ifmgr>
        </top>
    </data>
</rpc-reply>
```

Locking or unlocking the running configuration

About configuration locking and unlocking

Multiple methods are available for configuring the device, such as CLI, NETCONF, and SNMP. Before configuring, managing, or troubleshooting the device, you can lock the configuration to prevent other users from changing the device configuration. After you lock the configuration, only you can perform <edit-config> operations to change the configuration or unlock the configuration. Other users can only read the configuration.

If you close your NETCONF session, the system unlocks the configuration. You can also manually unlock the configuration.

Restrictions and guidelines for configuration locking and unlocking

The <lock> operation locks the running configuration of the device. You cannot use it to lock the configuration for a specific module.

Locking the running configuration

Copy the following text to the client to lock the running configuration:

```
<?xml version="1.0" encoding="UTF-8"?>
```

```
  <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <lock>
      <target>
        <running/>
      </target>
    </lock>
  </rpc>
```

If the <lock> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
     <ok/>
</rpc-reply>
```

Unlocking the running configuration

Copy the following text to the client to unlock the running configuration:

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <unlock>
      <target>
        <running/>
      </target>
    </unlock>
  </rpc>
```

If the <unlock> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Example: Locking the running configuration

Network configuration

Lock the device configuration so other users cannot change the device configuration.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <capabilities>
        <capability>
            urn:ietf:params:netconf:base:1.0
        </capability>
    </capabilities>
</hello>
```

Lock the configuration.

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <lock>
      <target>
        <running/>
      </target>
    </lock>
  </rpc>
```

Verifying the configuration

If the client receives the following response, the <lock> operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

If another client sends a lock request, the device returns the following response:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<rpc-error>
  <error-type>protocol</error-type>
  <error-tag>lock-denied</error-tag>
  <error-severity>error</error-severity>
  <error-message xml:lang="en"> Lock failed because the NETCONF lock is held by another
session.</error-message>
  <error-info>
    <session-id>1</session-id>
  </error-info>
  </rpc-error>
</rpc-reply>
```

The output shows that the <lock> operation failed. The client with session ID 1 is holding the lock,

Modifying the configuration

About the <edit-config> operation

The <edit-config> operation includes the following operations: merge, create, replace, remove, delete, default-operation, error-option, test-option, and incremental. For more information about the operations, see "Supported NETCONF operations."

Procedure

Copy the following text to perform the <edit-config> operation:

```
<?xml version="1.0"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target><running></running></target>
    <error-option>
       error-option
```

```
    </error-option>
    <config>
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        Specify the module name, submodule name, table name, and column name
      </top>
    </config>
  </edit-config>
</rpc>
```

The <error-option> element indicates the action to be taken in response to an error that occurs during the operation. It has the following values:

Value	Description
stop-on-error	Stops the <edit-config> operation.
continue-on-error	Continues the <edit-config> operation.
rollback-on-error	Rolls back the configuration to the configuration before the <edit-config> operation was performed. By default, an <edit-config> operation cannot be performed while the device is rolling back the configuration. If the rollback time exceeds the maximum time that the client can wait, the client determines that the <edit-config> operation has failed and performs the operation again. Because the previous rollback is not completed, the operation triggers another rollback. If this process repeats itself, CPU and memory resources will be exhausted and the device will reboot. To allow an <edit-config> operation to be performed during a configuration rollback, perform an <action> operation to change the value of the **DisableEditConfigWhenRollback** attribute to **false**.

If the <edit-config> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0">
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

You can also perform the <get> operation to verify that the current element value is the same as the value specified through the <edit-config> operation.

Example: Modifying the configuration

Network configuration

Change the log buffer size for the Syslog module to 512.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>urn:ietf:params:netconf:base:1.0</capability>
  </capabilities>
</hello>
```

Change the log buffer size for the Syslog module to 512.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:web="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config>
      <top xmlns="http://www.h3c.com/netconf/config:1.0" web:operation="merge">
        <Syslog>
          <LogBuffer>
            <BufferSize>512</BufferSize>
          </LogBuffer>
        </Syslog>
      </top>
    </config>
  </edit-config>
</rpc>
```

Verifying the configuration

If the client receives the following text, the <edit-config> operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

Saving the running configuration

About the <save> operation

A <save> operation saves the running configuration to a configuration file and specifies the file as the main next-startup configuration file.

Restrictions and guidelines

The <save> operation is resource intensive. Do not perform this operation when system resources are heavily occupied.

Procedure

Copy the following text to the client:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save OverWrite="false" Binary-only="false" Safely="false">
    <file>Configuration file name</file>
  </save>
</rpc>
```

Item	Description
file	Specifies a .cfg configuration file by its name. The name must start with the storage medium name. If you specify the file column, a file name is required. If the **Binary-only** attribute is **false**, the device saves the running configuration to both the text and binary configuration files. • If the specified .cfg file does not exist, the device creates the binary and text configuration files to save the running configuration. • If you do not specify the file column, the device saves the running configuration to the text and binary next-startup configuration files.
OverWrite	Determines whether to overwrite the specified file if the file already exists. The following values are available: • **true**—Overwrite the file. • **false**—Do not overwrite the file. The running configuration cannot be saved, and the system displays an error message. The default value is **true**.
Binary-only	Determines whether to save the running configuration only to the binary configuration file. The following values are available: • **true**—Save the running configuration only to the binary configuration file. ○ If **file** specifies a nonexistent file, the <save> operation fails. ○ If you do not specify the file column, the device identifies whether the main next-startup configuration file is specified. If yes, the device saves the running configuration to the corresponding binary file. If not, the <save> operation fails. • **false**—Save the running configuration to both the text and binary configuration files. For more information, see the description for the file column in this table. Saving the running configuration to both the text and binary configuration files requires more time. The default value is **false**.
Safely	Determines whether to save the configuration file in safe mode or fast mode. Available values: • **true**—Saves the configuration in safe mode. In this mode, the system saves the configuration in a temporary file and starts overwriting the target next-startup configuration file after the save operation is complete. If a disruptive event such as a reboot or power failure occurs during the save operation, the device can still start up with the original next-startup configuration file. • **false**—Saves the configuration in fast mode. In this mode, the system directly overwrites the target next-startup configuration file. If a disruptive event such as a reboot, power failure, out-of-memory, out-of-storage event occurs during this process, the next-startup configuration file is lost. You must specify a new startup configuration file after the device reboots. By default, the Safely attribute is set to **false** if you do not specify a value for it. Safe mode is slower than fast mode, but more secure. As a best practice, use the safe mode if the power source is not reliable or you are remotely configuring the device.

If the <save> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Example: Saving the running configuration

Network configuration

Save the running configuration to the **config.cfg** file.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Save the running configuration of the device to the **config.cfg** file.

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save>
    <file>config.cfg</file>
  </save>
</rpc>
```

Verifying the configuration

If the client receives the following response, the <save> operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Loading the configuration

About the <load> operation

The <load> operation merges the configuration from a configuration file into the running configuration as follows:

- Loads settings that do not exist in the running configuration.
- Overwrites settings that already exist in the running configuration.

Restrictions and guidelines

When you perform a <load> operation, follow these restrictions and guidelines:

- The <load> operation is resource intensive. Do not perform this operation when the system resources are heavily occupied.
- Some settings in a configuration file might conflict with the existing settings. For the settings in the file to take effect, delete the existing conflicting settings, and then load the configuration file.

Procedure

Copy the following text to the client to load a configuration file for the device:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <load>
   <file>Configuration file name</file>
  </load>
</rpc>
```

The configuration file name must start with the storage media name and end with the **.cfg** extension.

If the <load> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Rolling back the configuration

Restrictions and guidelines

The <rollback> operation is resource intensive. Do not perform this operation when the system resources are heavily occupied.

By default, an <edit-config> operation cannot be performed while the device is rolling back the configuration. To allow an <edit-config> operation to be performed during a configuration rollback, perform an <action> operation to change the value of the **DisableEditConfigWhenRollback** attribute to **false**.

Rolling back the configuration based on a configuration file

Copy the following text to the client to roll back the running configuration to the configuration in a configuration file:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <rollback>
    <file>Specify the configuration file name</file>
  </rollback>
</rpc>
```

If the <rollback> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Rolling back the configuration based on a rollback point

About this task

You can roll back the running configuration based on a rollback point when one of the following situations occurs:

- A NETCONF client sends a rollback request.
- The NETCONF session idle time is longer than the rollback idle timeout time.
- A NETCONF client is unexpectedly disconnected from the device.

Restrictions and guidelines

Multiple users might simultaneously configure the device. As a best practice, lock the system before rolling back the configuration to prevent other users from modifying the running configuration.

Procedure

1. Lock the running configuration. For more information, see "Locking or unlocking the running configuration."
2. Enable configuration rollback based on a rollback point.

   # Copy the following text to the client to perform a <save-point>/<begin> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <save-point>
        <begin>
          <confirm-timeout>100</confirm-timeout>
       </begin>
      </save-point>
</rpc>
```

Item	Description
confirm-timeout	Specifies the rollback idle timeout time in the range of 1 to 65535 seconds. The default is 600 seconds. This item is optional.

   If the <save-point/begin> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <save-point>
       <commit>
          <commit-id>1</commit-id>
       </commit>
    </save-point>
  </data>
</rpc-reply>
```

3. Modify the running configuration. For more information, see "Modifying the configuration."
4. Mark the rollback point.

   The system supports a maximum of 50 rollback points. If the limit is reached, specify the **force** attribute for the <save-point>/<commit> operation to overwrite the earliest rollback point.

   # Copy the following text to the client to perform a <save-point>/<commit> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <commit>
      <label>SUPPORT VLAN<label>
```

```
      <comment>vlan 1 to 100 and interfaces.</comment>
     </commit>
  </save-point>
</rpc>
```

The <label> and <comment> elements are optional.

If the <save-point>/<commit> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data>
    <save-point>
       <commit>
          <commit-id>2</commit-id>
       </commit>
    </save-point>
  </data>
</rpc-reply>
```

5. Retrieve the rollback point configuration records.

The following text shows the message format for a <save-point/get-commits> request:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <get-commits>
      <commit-id/>
      <commit-index/>
      <commit-label/>
    </get-commits>
  </save-point>
</rpc>
```

Specify the <commit-id/>, <commit-index/>, or <commit-label/> element to retrieve the specified rollback point configuration records. If no element is specified, the operation retrieves records for all rollback point settings.

Copy the following text to the client to perform a <save-point>/<get-commits> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <get-commits>
      <commit-label>SUPPORT VLAN</commit-label>
    </get-commits>
  </save-point>
</rpc>
```

If the <save-point/get-commits> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <data>
      <save-point>
         <commit-information>
           <CommitID>2</CommitID>
           <TimeStamp>Sun Jan 1 11:30:28 2019</TimeStamp>
           <UserName>test</UserName>
           <Label>SUPPORT VLAN</Label>
         </commit-information>
    </save-point>
```

```
  </data>
</rpc-reply>
```

6. Retrieve the configuration data corresponding to a rollback point.

   The following text shows the message format for a <save-point>/<get-commit-information> request:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <get-commit-information>
       <commit-information>
         <commit-id/>
         <commit-index/>
         <commit-label/>
       </commit-information>
       <compare-information>
         <commit-id/>
         <commit-index/>
         <commit-label/>
       </compare-information>
    </get-commit-information>
  </save-point>
</rpc>
```

   Specify one of the following elements: <commit-id/>, <commit-index/>, and <commit-label/>. The <compare-information> element is optional.

Item	Description
commit-id	Uniquely identifies a rollback point.
commit-index	Specifies 50 most recently configured rollback points. The value of 0 indicates the most recently configured one and 49 indicates the earliest configured one.
commit-label	Specifies a unique label for a rollback point.
get-commit-information	Retrieves the configuration data corresponding to the most recently configured rollback point.

   # Copy the following text to the client to perform a <save-point>/<get-commit-information> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <get-commit-information>
              <commit-information>
                 <commit-label>SUPPORT VLAN</commit-label>
              </commit-information>
    </get-commit-information>
  </save-point>
</rpc>
```

   If the <save-point/get-commit-information> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <data>
     <save-point>
        <commit-information>
```

```
            <content>
               …
               interface vlan 1
               …
            </content>
         </commit-information>
      </save-point>
   </data>
</rpc-reply>
```

7. Roll back the configuration based on a rollback point.

The configuration can also be automatically rolled back based on the most recently configured rollback point when the NETCONF session idle timer expires.

Copy the following text to the client to perform a <save-point>/<rollback> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <rollback>
      <commit-id/>
      <commit-index/>
      <commit-label/>
    </rollback>
  </save-point>
</rpc>
```

Specify one of the following elements: <commit-id/>, <commit-index/>, and <commit-label/>. If no element is specified, the operation rolls back configuration based on the most recently configured rollback point.

Item	Description
commit-id	Uniquely identifies a rollback point.
commit-index	Specifies 50 most recently configured rollback points. The value of 0 indicates the most recently configured one and 49 indicates the earliest configured one.
commit-label	Specifies the unique label of a rollback point.

If the <save-point/rollback> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok></ok>
</rpc-reply>
```

8. End the rollback configuration.

Copy the following text to the client to perform a <save-point>/<end> operation:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save-point>
    <end/>
  </save-point>
</rpc>
```

If the <save-point/end> operation succeeds, the device returns a response in the following format:

```
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <ok/>
```

```
</rpc-reply>
```

9. Unlock the configuration. For more information, see "Locking or unlocking the running configuration."

Performing CLI operations through NETCONF

About CLI operations through NETCONF

You can enclose command lines in XML messages to configure the device.

Restrictions and guidelines

Performing CLI operations through NETCONF is resource intensive. As a best practice, do not perform the following tasks:

- Enclose multiple command lines in one XML message.
- Use NETCONF to perform a CLI operation when other users are performing NETCONF CLI operations.

Procedure

Copy the following text to the client to execute the commands:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
    <Execution>
      Commands
    </Execution>
  </CLI>
</rpc>
```

The <Execution> element can contain multiple commands, with one command on one line.

If the CLI operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
    <Execution>
      <![CDATA[Responses to the commands]]>
    </Execution>
  </CLI>
</rpc-reply>
```

Example: Performing CLI operations

Network configuration

Send the **`display vlan`** command to the device.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Copy the following text to the client to execute the **`display vlan`** command:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
    <Execution>
          display vlan
    </Execution>
  </CLI>
</rpc>
```

Verifying the configuration

If the client receives the following text, the operation is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
    <Execution><![CDATA[
<Sysname>display vlan
 Total VLANs: 1
 The VLANs include:
 1(default)
   ]]>
   </Execution>
  </CLI>
</rpc-reply>
```

Subscribing to events

About event subscription

When an event takes place on the device, the device sends information about the event to NETCONF clients that have subscribed to the event.

Restrictions and guidelines

Event subscription is not supported for NETCONF over SOAP sessions.

A subscription takes effect only on the current session. It is canceled when the session is terminated.

If you do not specify the event stream to be subscribed to, the device sends syslog event notifications to the NETCONF client.

Subscribing to syslog events

Copy the following message to the client to complete the subscription:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <create-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <stream>NETCONF</stream>
      <filter>
        <event xmlns="http://www.h3c.com/netconf/event:1.0">
          <Code>code</Code>
            <Group>group</Group>
              <Severity>severity</Severity>
        </event>
      </filter>
      <startTime>start-time</startTime>
      <stopTime>stop-time</stopTime>
   </create-subscription>
</rpc>
```

Item	Description
stream	Specifies the event stream. The name for the syslog event stream is **NETCONF**.
event	Specifies the event. For information about the events to which you can subscribe, see the system log message references for the device.
code	Specifies the mnemonic symbol of the log message.
group	Specifies the module name of the log message.
severity	Specifies the severity level of the log message.
start-time	Specifies the start time of the subscription.
stop-time	Specifies the end time of the subscription.

If the subscription succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns:netconf="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

If the subscription fails, the device returns an error message in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<rpc-error>
   <error-type>error-type</error-type>
   <error-tag>error-tag</error-tag>
   <error-severity>error-severity</error-severity>
   <error-message xml:lang="en">error-message</error-message>
</rpc-error>
</rpc-reply>
```

For more information about error messages, see RFC 4741.

Subscribing to events monitored by NETCONF

After you subscribe to events as described in this section, NETCONF regularly polls the subscribed events and sends the events that match the subscription condition to the NETCONF client.

Copy the following message to the client to complete the subscription:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<create-subscription xmlns='urn:ietf:params:xml:ns:netconf:notification:1.0'>
  <stream>NETCONF_MONITOR_EXTENSION</stream>
  <filter>
    <NetconfMonitor xmlns='http://www.h3c.com/netconf/monitor:1.0'>
      <XPath>XPath</XPath>
      <Interval>interval</Interval>
      <ColumnConditions>
        <ColumnCondition>
          <ColumnName>ColumnName</ColumnName>
          <ColumnValue>ColumnValue</ColumnValue>
          <ColumnCondition>ColumnCondition</ColumnCondition>
        </ColumnCondition>
      </ColumnConditions>
      <MustIncludeResultColumns>
        <ColumnName>columnName</ColumnName>
      </MustIncludeResultColumns>
    </NetconfMonitor>
  </filter>
<startTime>start-time</startTime>
<stopTime>stop-time</stopTime>
</create-subscription>
</rpc>
```

Item	Description
stream	Specifies the event stream. The name for the event stream is **NETCONF_MONITOR_EXTENSION**.
NetconfMonitor	Specifies the filtering information for the event.
XPath	Specifies the path of the event in the format of *ModuleName*[/*SubmoduleName*]/*TableName*.
interval	Specifies the interval for NETCONF to obtain events that matches the subscription condition. The value range is 1 to 4294967 seconds. The default value is 300 seconds.
ColumnName	Specifies the name of a column in the format of [*GroupName*.]*ColumnName*.
ColumnValue	Specifies the baseline value.
ColumnCondition	Specifies the operator: • **more**. • **less**. • **notLess**. • **notMore**. • **equal**.

Item	Description
	• **notEqual**. • **include**. • **exclude**. • **startWith**. • **endWith**. Choose an operator according to the type of the baseline value.
start-time	Specifies the start time of the subscription.
stop-time	Specifies the end time of the subscription.

If the subscription succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns:netconf="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

Subscribing to events reported by modules

After you subscribe to events as described in this section, the specified modules report subscribed events to NETCONF. NETCONF sends the events to the NETCONF client.

Copy the following message to the client to complete the subscription:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xs="http://www.h3c.com/netconf/base:1.0">
<create-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
<stream>XXX_STREAM</stream>
   <filter type="subtree">
<event xmlns="http://www.h3c.com/netconf/event:1.0/xxx-features-list-name:1.0">
       <ColumnName xs:condition="Condition">value</ColumnName>
</event>
</filter>
<startTime>start-time</startTime>
<stopTime>stop-time</stopTime>
</create-subscription>
</rpc>
```

Item	Description
stream	Specifies the event stream. Supported event streams vary by device model.
event	Specifies the event name. An event stream includes multiple events. The events use the same namespaces as the event stream.
ColumnName	Specifies the name of a column.
Condition	Specifies the operator: • **more**. • **less**. • **notLess**. • **notMore**.

Item	Description
	• **equal**. • **notEqual**. • **include**. • **exclude**. • **startWith**. • **endWith**. Choose an operator according to the type of the baseline value.
value	Specifies the baseline value for the column.
start-time	Specifies the start time of the subscription.
stop-time	Specifies the end time of the subscription.

If the subscription succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns:netconf="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

Canceling an event subscription

Copy the following message to the client to cancel a subscription:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <cancel-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <stream>XXX_STREAM</stream>
  </cancel-subscription>
</rpc>
```

Item	Description
stream	Specifies the event stream.

If the cancelation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <ok/>
</rpc-reply>
```

If the subscription to be canceled does not exist, the device returns an error message in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<rpc-error>
   <error-type>error-type</error-type>
   <error-tag>error-tag</error-tag>
   <error-severity>error-severity</error-severity>
<error-message xml:lang="en">The subscription stream to be canceled doesn't exist: Stream name=XXX_STREAM.</error-message>
</rpc-error>
</rpc-reply>
```

Example: Subscribing to syslog events

Network configuration

Configure a client to subscribe to syslog events with no time limitation. After the subscription, all events on the device are sent to the client before the session between the device and client is terminated.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Subscribe to syslog events with no time limitation.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <create-subscription xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <stream>NETCONF</stream>
  </create-subscription>
</rpc>
```

Verifying the configuration

If the client receives the following response, the subscription is successful:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply xmlns="urn:ietf:params:xml:ns:netconf:base:1.0" message-id="100">
    <ok/>
</rpc-reply>
```

When another client (192.168.100.130) logs in to the device, the device sends a notification to the client that has subscribed to all events:

```
<?xml version="1.0" encoding="UTF-8"?>
<notification xmlns="urn:ietf:params:xml:ns:netconf:notification:1.0">
    <eventTime>2019-01-04T12:30:52</eventTime>
    <event xmlns="http://www.h3c.com/netconf/event:1.0">
        <Group>SHELL</Group>
        <Code>SHELL_LOGIN</Code>
        <Slot>1</Slot>
        <Severity>Notification</Severity>
        <context>VTY logged in from 192.168.100.130.</context>
    </event>
</notification>
```

Terminating NETCONF sessions

About NETCONF session termination

NETCONF allows one client to terminate the NETCONF sessions of other clients. A client whose session is terminated returns to user view.

Procedure

Copy the following message to the client to terminate a NETCONF session:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <kill-session>
    <session-id>
      Specified session-ID
    </session-id>
  </kill-session>
</rpc>
```

If the <kill-session> operation succeeds, the device returns a response in the following format:

```
<?xml version="1.0" encoding="UTF-8"?>
    <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      <ok/>
</rpc-reply>
```

Example: Terminating another NETCONF session

Network configuration

The user whose session's ID is 1 terminates the session with session ID 2.

Procedure

Enter XML view.

```
<Sysname> xml
```

Notify the device of the NETCONF capabilities supported on the client.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
            urn:ietf:params:netconf:base:1.0
    </capability>
  </capabilities>
</hello>
```

Terminate the session with session ID 2.

```
<rpc message-id="100"xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <kill-session>
    <session-id>2</session-id>
  </kill-session>
</rpc>
```

Verifying the configuration

If the client receives the following text, the NETCONF session with session ID 2 has been terminated, and the client with session ID 2 has returned from XML view to user view:

```
<?xml version="1.0" encoding="UTF-8"?>
  <rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <ok/>
</rpc-reply>
```

Returning to the CLI

Restrictions and guidelines

Before returning from XML view to the CLI, you must first complete capability exchange between the device and the client.

Procedure

Copy the following text to the client to return from XML view to the CLI:

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <close-session/>
</rpc>
```

When the device receives the close-session request, it sends the following response and returns to CLI's user view:

```
<?xml version="1.0" encoding="UTF-8"?>
<rpc-reply message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <ok/>
</rpc-reply>
```

Supported NETCONF operations

This chapter describes NETCONF operations available with Comware 7.

action

Usage guidelines

This operation sends a non-configuration operation instruction to the device, for example, a reset instruction.

XML example

Clear statistics information for all interfaces.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <action>
    <top xmlns="http://www.h3c.com/netconf/action:1.0">
      <Ifmgr>
            <ClearAllIfStatistics>
                <Clear>
                </Clear>
        </ClearAllIfStatistics>
      </Ifmgr>
    </top>
  </action>
</rpc>
```

CLI

Usage guidelines

This operation executes CLI commands.

A request message encloses commands in the <CLI> element. A response message encloses the command output in the <CLI> element.

You can use the following elements to execute commands:

- **Execution**—Executes commands in user view.
- **Configuration**—Executes commands in system view. To execute commands in a lower-level view of the system view, use the <Configuration> element to enter the view first.

  To use this element, include the **exec-use-channel** attribute and specify a value for the attribute:

  - **false**—Executes commands without using a channel.
  - **true**—Executes commands by using a temporary channel. The channel is automatically closed after the execution.
  - **persist**—Executes commands by using the persistent channel for the session.

    To use the persistent channel, first perform an <Open-channel> operation to open the persistent channel. If you do not do so, the system will automatically open the persistent channel.

    After using the persistent channel, perform a <Close-channel> operation to close the channel and return to system view. If you do not perform an <Open-channel> operation, the system stays in the view and will execute subsequent commands in the view.

You can also specify the **error-when-rollback** attribute in the <Configuration> element to indicate whether CLI operations are allowed during a configuration error-triggered configuration rollback. This attribute takes effect only if the value of the <error-option> element in <edit-config> operations is set to **rollback-on-error**. It has the following values:

- **true**—Rejects CLI operation requests and returns error messages.
- **false (the default)**—Allows CLI operations.

For CLI operations to be correctly performed, set the value of the **error-when-rollback** attribute to **true**.

A NETCONF session supports only one persistent channel and but supports multiple temporary channels.

This operation does not support executing interactive CLI commands.

You cannot execute the **quit** command by using a channel to exit user view.

XML example

Execute the **vlan 3** command in system view without using a channel.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <CLI>
     <Configuration exec-use-channel="false" error-when-rollback="true">vlan
3</Configuration>
  </CLI>
</rpc>
```

close-session

Usage guidelines

This operation terminates the current NETCONF session, unlocks the configuration, and releases the resources (for example, memory) used by the session. After this operation, you exit the XML view.

XML example

Terminate the current NETCONF session.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<close-session/>
</rpc>
```

edit-config: create

Usage guidelines

This operation creates target configuration items.

To use the **create** attribute in an <edit-config> operation, you must specify the target configuration item.

- If the table supports creating a target configuration item and the item does not exist, the operation creates the item and configures the item.
- If the specified item already exists, a data-exist error message is returned.

XML example

Set the buffer size to 120.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
```

```
  <edit-config>
    <target>
      <running/>
    </target>
    <config>
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Syslog xmlns="http://www.h3c.com/netconf/config:1.0-Syslog"
xc:operation="create">
           <LogBuffer>
             <BufferSize>120</BufferSize>
          </LogBuffer>
        </Syslog>
      </top>
    </config>
  </edit-config>
</rpc>
```

edit-config: delete

Usage guidelines

This operation deletes the specified configuration.

- If the specified target has only the table index, the operation removes all configuration of the specified target, and the target itself.
- If the specified target has the table index and configuration data, the operation removes the specified configuration data of this target.
- If the specified target does not exist, an error message is returned, showing that the target does not exist.

XML example

The syntax is the same as the edit-config message with the **create** attribute. Change the operation attribute from **create** to **delete**.

edit-config: merge

Usage guidelines

This operation commits target configuration items to the running configuration.

To use the **merge** attribute in an <edit-config> operation, you must specify the target configuration item (on a specific level):

- If the specified item exists, the operation directly updates the setting for the item.
- If the specified item does not exist, the operation creates the item and configures the item.
- If the specified item does not exist and it cannot be created, an error message is returned.

XML example

The XML data format is the same as the edit-config message with the **create** attribute. Change the operation attribute from **create** to **merge**.

edit-config: remove

Usage guidelines

This operation removes the specified configuration.

- If the specified target has only the table index, the operation removes all configuration of the specified target, and the target itself.
- If the specified target has the table index and configuration data, the operation removes the specified configuration data of this target.
- If the specified target does not exist, or the XML message does not specify any targets, a success message is returned.

XML example

The syntax is the same as the edit-config message with the **create** attribute. Change the operation attribute from **create** to **remove**.

edit-config: replace

Usage guidelines

This operation replaces the specified configuration.

- If the specified target exists, the operation replaces the configuration of the target with the configuration carried in the message.
- If the specified target does not exist but is allowed to be created, the operation creates the target and then applies the configuration.
- If the specified target does not exist and is not allowed to be created, the operation is not conducted and an invalid-value error message is returned.

XML example

The syntax is the same as the edit-config message with the **create** attribute. Change the operation attribute from **create** to **replace**.

edit-config: test-option

Usage guidelines

This operation determines whether to commit a configuration item in an <edit-configure> operation. The <test-option> element has one of the following values:

- **test-then-set**—Performs a syntax check, and commits an item if the item passes the check. If the item fails the check, the item is not committed. This is the default test-option value.
- **set**—Commits the item without performing a syntax check.
- **test-only**—Performs only a syntax check. If the item passes the check, a success message is returned. Otherwise, an error message is returned.

XML example

Test the configuration for an interface.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <test-option>test-only</test-option>
```

```
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr xc:operation="merge">
          <Interfaces>
            <Interface>
              <IfIndex>262</IfIndex>
              <Description>222</Description>
                <ConfigSpeed>2</ConfigSpeed>
                <ConfigDuplex>1</ConfigDuplex>
               </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </config>
  </edit-config>
</rpc>
```

edit-config: default-operation

Usage guidelines

This operation modifies the running configuration of the device by using the default operation method.

NETCONF uses one of the following operation attributes to modify configuration: **merge**, **create**, **delete**, and **replace**. If you do not specify an operation attribute for an edit-config message, NETCONF uses the default operation method. The value specified for the <default-operation> element takes effect only once. If you do not specify an operation attribute or the default operation method for an <edit-config> message, **merge** always applies.

The <default-operation> element has the following values:

- **merge**—Default value for the <default-operation> element.
- **replace**—Value used when the operation attribute is not specified and the default operation method is specified as **replace**.
- **none**—Value used when the operation attribute is not specified and the default operation method is specified as **none**. If this value is specified, the <edit-config> operation is used only for schema verification rather than issuing a configuration. If the schema verification is passed, a successful message is returned. Otherwise, an error message is returned.

XML example

Issue an empty operation for schema verification purposes.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <default-operation>none</default-operation>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr>
          <Interfaces>
            <Interface>
```

```
            <IfIndex>262</IfIndex>
            <Description>222222</Description>
          </Interface>
        </Interfaces>
      </Ifmgr>
    </top>
  </config>
</edit-config>
</rpc>
```

edit-config: error-option

Usage guidelines

This operation determines the action to take in case of a configuration error.

The <error-option> element has the following values:

- **stop-on-error**—Stops the operation and returns an error message. This is the default error-option value.
- **continue-on-error**—Continues the operation and returns an error message.
- **rollback-on-error**—Rolls back the configuration.

XML example

Issue the configuration for two interfaces, setting the <error-option> element to **continue-on-error**.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <error-option>continue-on-error</error-option>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr xc:operation="merge">
          <Interfaces>
            <Interface>
              <IfIndex>262</IfIndex>
              <Description>222</Description>
                <ConfigSpeed>1024</ConfigSpeed>
                <ConfigDuplex>1</ConfigDuplex>
            </Interface>
            <Interface>
              <IfIndex>263</IfIndex>
              <Description>333</Description>
                <ConfigSpeed>1024</ConfigSpeed>
                <ConfigDuplex>1</ConfigDuplex>
            </Interface>
          </Interfaces>
        </Ifmgr>
      </top>
    </config>
```

```
  </edit-config>
</rpc>
```

edit-config: incremental

Usage guidelines

This operation adds configuration data to a column without affecting the original data.

The **incremental** attribute applies to a list column such as the vlan permitlist column.

You can use the **incremental** attribute for <edit-config> operations with an attribute other than **replace**.

Support for the **incremental** attribute varies by module. For more information, see NETCONF XML API references.

XML example

Add VLANs 1 through 10 to an untagged VLAN list that has untagged VLANs 12 through 15.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:h3c="http://www.h3c.com/netconf/base:1.0">
  <edit-config>
    <target>
      <running/>
    </target>
    <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <VLAN xc:operation="merge">
          <HybridInterfaces>
            <Interface>
              <IfIndex>262</IfIndex>
              <UntaggedVlanList  h3c:incremental="true">1-10</UntaggedVlanList>
               </Interface>
          </HybridInterfaces>
        </VLAN>
      </top>
    </config>
  </edit-config>
</rpc>
```

get

Usage guidelines

This operation retrieves device configuration and state information.

XML example

Retrieve device configuration and state information for the Syslog module.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xc="http://www.h3c.com/netconf/base:1.0">
  <get>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Syslog>
```

```
        </Syslog>
      </top>
    </filter>
  </get>
</rpc>
```

get-bulk

Usage guidelines

This operation retrieves a number of data entries (including device configuration and state information) starting from the data entry next to the one with the specified index.

XML example

Retrieve device configuration and state information for all interfaces.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-bulk>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/data:1.0">
        <Ifmgr>
          <Interfaces xc:count="5" xmlns:xc="http://www.h3c.com/netconf/base:1.0">
            <Interface/>
          </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-bulk>
</rpc>
```

get-bulk-config

Usage guidelines

This operation retrieves a number of non-default configuration data entries starting from the data entry next to the one with the specified index.

XML example

Retrieve non-default configuration for all interfaces.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-bulk-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr>
        </Ifmgr>
      </top>
    </filter>
  </get-bulk-config>
</rpc>
```

get-config

Usage guidelines

This operation retrieves non-default configuration data. If no non-default configuration data exists, the device returns a response with empty data.

XML example

Retrieve non-default configuration data for the interface table.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"
xmlns:xc="http://www.h3c.com/netconf/base:1.0">
  <get-config>
    <source>
      <running/>
    </source>
    <filter type="subtree">
      <top xmlns="http://www.h3c.com/netconf/config:1.0">
        <Ifmgr>
           <Interfaces>
              <Interface/>
            </Interfaces>
        </Ifmgr>
      </top>
    </filter>
  </get-config>
</rpc>
```

get-sessions

Usage guidelines

This operation retrieves information about all NETCONF sessions in the system. You cannot specify a session ID to retrieve information about a specific NETCONF session.

XML example

Retrieve information about all NETCONF sessions in the system.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<get-sessions/>
</rpc>
```

kill-session

Usage guidelines

This operation terminates the NETCONF session for another user. This operation cannot terminate the NETCONF session for the current user.

XML example

Terminate the NETCONF session with session ID 1.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <kill-session>
    <session-id>1</session-id>
```

```
  </kill-session>
</rpc>
```

load

Usage guidelines

This operation loads the configuration. After the device finishes a <load> operation, the configuration in the specified file is merged into the running configuration of the device.

XML example

Merge the configuration in file **a1.cfg** to the running configuration of the device.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <load>
    <file>a1.cfg</file>
  </load>
</rpc>
```

lock

Usage guidelines

This operation locks the configuration. After you lock the configuration, other users cannot perform <edit-config> operations. Other NETCONF operations are allowed.

After a user locks the configuration, other users cannot use NETCONF or any other configuration methods such as CLI and SNMP to configure the device.

XML example

Lock the configuration.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
 <lock>
    <target>
        <running/>
    </target>
</lock>
</rpc>
```

rollback

Usage guidelines

This operation rolls back the configuration. To do so, you must specify the configuration file in the <file> element. After the device finishes the <rollback> operation, the current device configuration is totally replaced with the configuration in the specified configuration file.

XML example

Roll back the running configuration to the configuration in file **1A.cfg**.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <rollback>
    <file>1A.cfg</file>
  </rollback>
</rpc>
```

save

Usage guidelines

This operation saves the running configuration. You can use the <file> element to specify a file for saving the configuration. If the text does not include the file column, the running configuration is automatically saved to the main next-startup configuration file.

The **OverWrite** attribute determines whether the running configuration overwrites the original configuration file when the specified file already exists.

The **Binary-only** attribute determines whether to save the running configuration only to the binary configuration file.

The **Safely** attribute determines whether to save the configuration file in safe mode or fast mode.

XML example

Save the running configuration to file **test.cfg**.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <save OverWrite="false" Binary-only="true">
    <file>test.cfg</file>
  </save>
</rpc>
```

unlock

Usage guidelines

This operation unlocks the configuration, so other users can configure the device.

Terminating a NETCONF session automatically unlocks the configuration.

XML example

Unlock the configuration.

```
<rpc message-id="100" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<unlock>
    <target>
        <running/>
    </target>
</unlock>
</rpc>
```

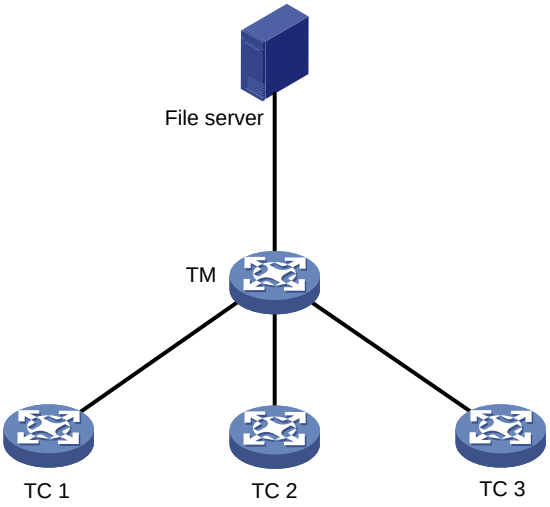
Configuring SmartMC

About SmartMC



Smart Management Center (SmartMC) centrally manages and maintains dispersed network devices at network edges. In a SmartMC network, only one device acts as the commander and the remaining devices all act as members. SmartMC provides the following features for you to manage the members from the commander:

- Configuration file backup and download.
- Software upgrade.
- Configuration deployment.
- Faulty member replacement.

SmartMC network framework

Figure 1 shows the basic framework of a SmartMC network.

Figure 1 SmartMC network framework

The SmartMC network contains the following elements:

- **Commander**—Also called topology master (TM), which manages all members in the SmartMC network.
- **Member**—Also called topology client (TC), which is managed by the commander.
- **File server**—Stores startup software images and configuration files for the commander and members.

SmartMC network establishment

A SmartMC network can be established automatically or manually. In an automatically established SmartMC network, the commander obtains member information through NETCONF sessions to form the network topology. The member information includes port information, LLDP neighbor information, STP information, device type, and software version. In a manually established SmartMC network, the commander obtains member's LLDP neighbor information through NETCONF sessions and member's hardware information through SNMP Get operations.

Automatic SmartMC network establishment

The commander and members use the following procedure to establish a SmartMC network:

1. After SmartMC is enabled, the commander broadcasts a SmartMC packet at an interval of 15 seconds to detect members in the network. The SmartMC packet contains information of the commander, such as its bridge MAC address and the IP address of VLAN-interface 1.
2. When a member receives the packet, it records the commander information, and returns a response packet to the commander. The response packet contains information of the member, such as its bridge MAC address and the IP address of VLAN-interface 1.
3. When the commander receives the response packet, it initiates a NETCONF session to the member with the default username **admin** and the default password **admin**. The commander then obtains detailed information about the member through the session, including port information, LLDP neighbor information, STP information, device type, and software version.
4. The commander establishes a connection to the member for tracking the liveliness of the member, and adds the member to the SmartMC network.
5. Based on the LLDP neighbor information obtained from all members, the commander forms a SmartMC topology.

After the SmartMC network is established, the commander and members check for the existence of each other by exchanging SmartMC packets.

- When a member receives a SmartMC broadcast packet from the commander, it compares the bridge MAC address in the packet with the recorded bridge MAC address. If the two bridge MAC addresses are the same, the member returns a response packet to the commander. If the member does not receive a broadcast packet from the commander within the time limit, the member determines that the commander does not exist in the network anymore. Then, the member clears the commander information. The time limit is a random value in the range of 60 to 120 seconds.
- When the commander receives a response packet from a member, it compares the bridge MAC address in the packet with the recorded bridge MAC address. If the two bridge MAC addresses are the same, the commander determines that the member still exists in the network. If the commander does not receive a response packet from a member within 150 seconds, the commander determines that the member is offline. Then, the commander sets the status of the member to offline.

Manual SmartMC network establishment

You can log in to the Web interface of the commander, and enter the IP address, username, and password of the members to manually add them to the network. The members can join the network without exchanging SmartMC packets with the commander. For more information, see *Comware 7 Web-Based Products User Guide*.

After you specify the information of a member on the commander, the commander performs the following operations to add the member to the network:

- Verify that the member can be accessed through Telnet.
- Obtain basic member information, including LLDP neighbor information through NETCONF.
- Obtain hardware information through SNMP Get operations.

SmartMC features

Bulk configuration deployment for members

This feature allows you to deploy multiple command lines to members from the commander, eliminating the need to log in to members and configure the command one by one.

The procedure for bulk configuration deployment is as follows:

1. The commander acts as a Telnet client and establishes Telnet connections to the members.

2. The commander deploys a batch file to the members through Telnet connections. The batch file is created on the commander and contains command lines to be deployed.
3. The members run the command lines in the file.

Bulk configuration deployment for ports connecting APs and IP phones

This feature is designed to automatically detect the connection of APs and IP phones, and to automatically distribute configurations in bulk to the access ports. This simplifies and accelerates the process of configuring network devices, providing network administrators with an efficient management method.

The working mechanism of the bulk configuration deployment function is as follows:

1. Create batch files: The network administrator creates and binds command line batch files for APs and IP phones through the Web interface.
2. Device access: APs or IP phones connect to the SmartMC network through a TC.
3. Configuration deployment: Once the TM detects the connection of an AP or IP phone using the LLDP protocol, it sends the configurations from the corresponding command line batch file to the access port of the AP or IP phone, thus achieving automated configuration for the APs and IP phones.

Configuration file backup

You can use the following methods to back up the next-startup configuration file on the commander and members:

- **Automatic backup**—Enable this feature for the commander and all members in the network to immediately perform a backup. After that, the commander and members back up the configuration file at a user-specified interval.
- **Manual backup**—Manually trigger a backup on the commander or the specified members or SmartMC groups.

To back up the configuration file on a member, the commander instructs the member by unicasting a SmartMC packet. When a member receives the packet, it saves the running configuration to the next-startup configuration file and uploads the file to the file server.

Startup software and configuration file upgrade

This feature enables users to upgrade startup software and the configuration file of member devices from the commander.

Before upgrade, you must upload the upgrade files from the commander to the file server and specify the upgrade files on the file server for the members to download.

The procedure for startup software and configuration file upgrade is as follows:

1. The commander instructs the members (or SmartMC group) to download the upgrade files from the file server.
2. The members download the upgrade files from the file server.
3. The members upgrade the startup software and configuration file as follows:
    - **Startup software upgrade**—Uses the boot loader method to perform an upgrade. The members might be restarted during the upgrade process.
    - **Configuration file upgrade**—Replaces the current configuration file with the upgrade configuration file. The members will not be restarted during the upgrade process.

Faulty member replacement

You can use the following methods to replace a faulty member:

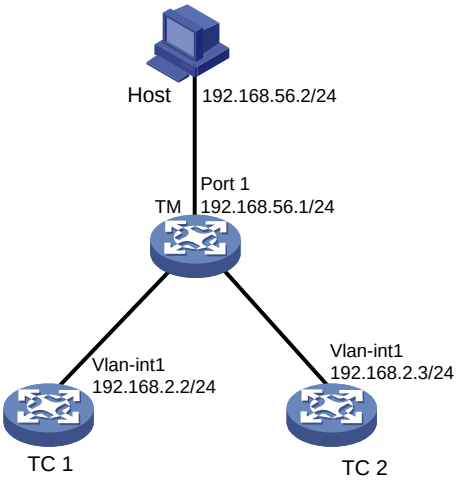
- **Automatic replacement**—Enables the commander to record the positions of all members in the topology for replacement. When the commander discovers that the new member has physically replaced the faulty member, it compares the new member with the faulty one. The commander performs a replacement if the following requirements are met:
    - The new member is deployed at the same topological position as the faulty one.

- The models of the new member and faulty member are the same.

  The commander then instructs the new member to download the configuration file of the faulty member from the file server. After downloading the configuration file, the new member runs the configuration file to complete the replacement.

- **Manual replacement**—After the faulty member is physically replaced, you manually trigger a configuration replacement. The new member will download the configuration file of the faulty member from the file server and run the file to complete the replacement.

Outgoing interface for a SmartMC network



The outgoing interface feature allows hosts connecting to an outgoing interface to access all the members in a SmartMC network. You can configure multiple outgoing interfaces for a SmartMC network.

As shown in Figure 2, the host is connected to port 1 on the TM and TC 1 and TC 2 are in a different network segment than the host. The host can access the Web interface of the TM but cannot access the Web interface of any member.

If port 1 on the TM is configured as the outgoing interface, the system mirrors the IP address of each member to a new address. The new address contains the IP address of the outgoing interface and the port number assigned by the commander to the member in the format of *IP address*:*Port number*. This enables the host to access the Web interfaces of members from the Web interface of the TM.

To access the Web interface of a member, enter the Web interface of the commander, and click **Visibility** from the navigation pane. Then, click the **Topology** tab, select the target member, and click **Login to Web interface**.

Figure 2 SmartMC network

Automatic link aggregation

Automatic link aggregation automatically bundles multiple physical Ethernet links between two members into one logical link, called an aggregate link. This feature provides increased link bandwidth and improved link reliability.

NOTE:

- Automatic link aggregation cannot be performed between the commander and a member, or between a member and a device outside the SmartMC network. You can aggregate the links between the commander and a member manually. For more information about manual link aggregation, see Ethernet link aggregation in *Layer 2—LAN Switching Configuration Guide*.
- If a member enabled with automatic link aggregation joins a SmartMC network whose commander is disabled with the aggregation feature, the feature will be disabled for the member as well. This might affect service traffic forwarding on the member.

VLAN creation for members

To simplify configuration and management, you can create a VLAN for members. Then, all access ports on a member that are not connected to other members or the commander are assigned to the VLAN.

If a member has access ports that are connected to offline devices, you must remove the offline devices before creating a VLAN for the member.

The VLAN creation fails for a member if one or more access ports cannot be assigned to the VLAN. If the VLAN creation fails, the VLAN memberships for the access ports are restored to the state before the VLAN was created.

The failure to create a VLAN for a member does not affect the VLAN creation for other members.

Resource monitoring

Resource monitoring allows you to view CPU usage, memory usage, temperature information,

You can view the usage and temperature information on the commander

Restrictions and guidelines: SmartMC configuration

Only users with the network-admin role can configure SmartMC. For more information about user roles, see RBAC in *Fundamentals Configuration Guide*.

A SmartMC network is established in VLAN 1. For the network to work correctly, do not configure security settings in VLAN 1.

You need to enable SmartMC on both the commander and members and perform all the other SmartMC tasks only on the commander.

SmartMC tasks at a glance

To configure SmartMC, perform the following tasks:

1. Enabling SmartMC
2. Specifying a file server

   This task is required for configuring automatic configuration file backup, replacing faulty members, and upgrading the startup software and configuration file on members.
3. (Optional.) Configuring an outgoing interface for the SmartMC network
4. (Optional.) Enabling automatic Ethernet link aggregation
5. (Optional.) Modifying the password of the default user for members
6. Creating a SmartMC group

   This task is required for upgrading the startup software and configuration file on members and deploying a batch file to a SmartMC group.
7. (Optional.) Deploying and managing configuration
   - Creating a VLAN for members
   - Deploying a batch file to members
   - Configuring a batch file for ports connecting APs or IP phones
   - Backing up configuration files
8. (Optional.) Monitoring and maintaining the SmartMC network
   - Configuring resource monitoring
   - Upgrading the startup software and configuration file on members

- Managing the network topology
- Replacing faulty members

Prerequisites for SmartMC

Before you configure SmartMC, perform the following tasks on the commander and members:

- Enable the Telnet service, and configure scheme authentication for VTY user lines. For information about Telnet service and VTY user lines, see CLI login configuration in *Fundamentals Configuration Guide*.
- Configure a local user.
  - Specify the username and password.
    - On the commander, make sure the username and password are the same as the username and password configured by using the **smartmc tm username** *username* **password** { **cipher** | **simple** } *string* **enable** command.
    - On a member, set both the username and password to **admin**, and execute the **password-control length 4**, **password-control composition type-number 1 type-length 1**, and **undo password-control complexity user-name check** commands to lower the password complexity requirements.

      This is because SmartMC requires that the commander use username **admin** and password **admin** to communicate with members, which does not meet the default password complexity requirements. For more information about these commands, see password control commands in *Security Command Reference*.

      After the SmartMC network is established, you can increase the password complexity requirements and use the **smartmc tc password** command to modify the username and password.
  - Specify the Telnet, HTTP, and HTTPS services for the user.
  - Set the RBAC role of the local user to network-admin.

  For information about local users, see AAA configuration in *Security Configuration Guide*. For information about user roles, see RBAC configuration in *Fundamentals Configuration Guide*.
- Enable NETCONF over SOAP over HTTP. For information about NETCONF over SOAP, see NETCONF configuration in *Network Management and Monitoring Configuration Guide*.
- Enable LLDP globally. For information about LLDP, see *Layer 2—LAN Switching Configuration Guide*.
- To manage the commander and members through a Web interface, you must enable the HTTP and HTTPS services, and set the service type to HTTP and HTTPS for the local user. For information about Web login, HTTP, and HTTPS, see *Fundamentals Configuration Guide*.
- To manually establish a SmartMC network, you must configure the **snmp-agent community read public** and **snmp-agent sys-info version v2c** commands on the members. For information about SNMP, see *Network Management and Monitoring Configuration Guide*.

Enabling SmartMC

About this task

Enable this feature on both the commander and members to enable management of members from the commander.

Restrictions and guidelines

A SmartMC network must have one and only one commander.

If you change the role of the commander to member or disable SmartMC on the commander, all SmartMC settings in its running configuration will be cleared.

SmartMC fails to be enabled if ACL resources are insufficient. If ACL resources are insufficient, use the **undo acl** command to delete unnecessary ACLs and then enable SmartMC. You can execute the **display acl** command to view ACL configuration and match statistics. For more information about ACLs, see *ACL and QoS Configuration Guide*.

SmartMC fails to be enabled if ports 80 and 443 have been used.

If you execute the **smartmc enable** command multiple times, the most recent configuration takes effect. You can execute the command to change the device role or the password.

Procedure

1. Enter system view.

   system-view

2. Enable SmartMC and set the device role.

   smartmc { **tc** | **tm username** *username* **password** { **cipher** | **simple** } *string* } **enable**

   By default, SmartMC is disabled.

Specifying a file server

About this task

In a SmartMC network, a file server is used to store the following files:

- Upgrade startup software files and upgrade configuration file for members.
- Backup configuration files of the commander and members.

The system supports using an FTP or SFTP server as the file server. For information about FTP servers, see configuring FTP in *Fundamentals Configuration Guide*. For information about SFTP servers, see configuring SSH in *Security Configuration Guide*.

Restrictions and guidelines

You can use the following methods to specify a file server:

- Specify the IP address of a file server.
- Specify the IP address of the commander. The commander will act as a file server.

To configure the commander to act as a file server, make sure the commander has enough storage space for storing the files required by members.

To use an independent file server, connect the file server to the commander instead of the members as a best practice. The file server uses VLAN 1 to communicate with the SmartMC network. If you connect the file server to members, creating a VLAN for members will assign member interfaces connecting to the file server to the created VLAN, causing file server disconnection. For more information about member VLAN creation, see "Creating a VLAN for members."

Procedure

1. Enter system view.

   system-view

2. Specify a file server.

   smartmc { **ftp-server** | **sftp-server** } { *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port*] [**vpn-instance** *vpn-instance-name*] [**directory** *directory*] **username** *username* **password** { **cipher** | **simple** } *string*

   By default, no file server is specified.

Configuring an outgoing interface for the SmartMC network

Restrictions and guidelines

VLAN-interface 1 cannot be used as an outgoing interface, because the SmartMC network is established in VLAN 1.

A member port of a Layer 3 aggregation group cannot be used as an outgoing interface for SmartMC, and vice versa. If a configured outgoing interface is a member port of a Layer 3 aggregation group, the outgoing interface does not take effect. For more information about Layer 3 aggregation groups, see Ethernet link aggregation in *Layer 2—LAN Switching Configuration Guide*.

If you specify a VLAN interface as the outgoing interface, the system issues the **service slot** *slot-number* command to the outgoing interface and VLAN-interface 1. The *slot-number* argument represents the member ID of the master device. If you specify a Layer 3 Ethernet interface as the outgoing interface, the system issues the command only to VLAN-interface 1. If you remove the outgoing interface configuration, the **service slot** *slot-number* configuration remains, and you can modify the configuration manually as needed.

For more information about the **service** command, see VLAN commands in *Layer 2—LAN Switching Command Reference*.

Procedure

1. Enter system view.
   system-view
2. Enter VLAN interface view or Layer 3 Ethernet interface view.
   - **Enter VLAN interface view.**
     interface vlan *interface-number*
   - **Enter Layer 3 Ethernet interface view.**
     interface *interface-type interface-number*
3. Configure the interface as an outgoing interface.
   smartmc outbound
   By default, no interface is used as an outgoing interface.

Enabling automatic Ethernet link aggregation

Restrictions and guidelines

Enabling or disabling automatic link aggregation might cause network flapping, and the members might go offline for a short period of time.

Procedure

1. Enter system view.
   system-view
2. Enable automatic Ethernet link aggregation.
   smartmc auto-link-aggregation enable
   By default, automatic Ethernet link aggregation is disabled.

Modifying the password of the default user for members

About this task

During SmartMC network establishment, the commander uses the default username and password to establish NETCONF sessions to members automatically added to the network. The default username and password of the members for NETCONF session establishment are **admin** and **admin**.

To enhance security, you can perform this task to change the password for the default user **admin** of the members after the commander adds the members to the network.

Restrictions and guidelines

Do not modify the password for members that are manually added to the SmartMC network. If you modify the password for a manually added member, you will not be able to manage that member from the commander.

You can use the **display smartmc tc verbose** command to identify the method used to add the members.

Procedure

1. Enter system view.

   system-view
2. Modify the password of the default user for members.

   smartmc tc password [**cipher**] *string*

Creating a SmartMC group

About this task

This feature allows you to create a SmartMC group on the commander and add members to the group. When you perform the following operations, you can specify a SmartMC group to apply the operations to all members in the group:

- Startup software upgrade.
- Configuration file upgrade.
- Configuration deployment.

Procedure

1. Enter system view.

   system-view
2. Create a SmartMC group and enter its view.

   smartmc group *group-name*
3. (Optional.) Display predefined device types.

   match device-type ?
4. Set a match criterion.

   match { **device-type** *device-type* | **ip-address** *ip-address* { *ip-mask-length* | *ip-mask* } | **mac-address** *mac-address mac-mask-length* }

   By default, no match criterion is set.
5. If the device type of the members is not predefined on the commander, perform the following tasks to manually define the device type on the commander:

a. Return to system view.

quit

b. Define a device type on the commander.

smartmc tc sysoid *sysoid* **device-type** *device-type*

To obtain the SYSOID of a member, execute the **display smartmc tc verbose** command.

You cannot define a predefined member type as another type.

Creating a VLAN for members

Restrictions and guidelines

If you perform this task multiple times to create a VLAN for members, the most recent configuration takes effect.

Procedure

1. Enter system view.

system-view

2. Creating a VLAN for members and assign access ports on the members to the VLAN.

smartmc vlan *vlan-id* { **group** *group-name-list* | **tc** *tc-id-list* }

Deploying a batch file to members

1. Execute the following command in user view to create a batch file and edit the command lines to be deployed to members.

create batch-file *cmd-filename*

Each command occupies a line in the batch file. When you finish editing, enter a percent sign (%) to return to user view.

Make sure the command lines that you enter are correct because the system does not verify whether the command lines are correct.

2. Enter system view.

system-view

3. Deploy the batch file to a list of members or SmartMC groups.

smartmc batch-file *cmd-filename* **deploy** { **group** *group-name-list* | **tc** *tc-id-list* }

Configuring a batch file for ports connecting APs or IP phones

Restrictions and guidelines

All commands in the batch file must be commands used in interface view.

The size of the batch file cannot exceed 8190 characters.

Make sure the file name is correct when specifying the batch file because the system does not verify whether the file name is correct. After specifying the batch file, do not delete the file or rename the file.

Content changes of a batch file and binding of a different batch file on the device affect only APs and IP phones that come online afterwards. The APs and IP phones that are already connected are not affected.

Procedure

1. (Optional.) Execute the following command in user view to create a batch file and edit the command lines to be deployed to members.

   create batch-file *cmd-filename*

   Each command occupies a line in the batch file. When you finish editing, enter a percent sign (%) to return to user view.

   Make sure the command lines that you enter are correct because the system does not verify whether the command lines are correct.
2. Enter system view.

   system-view
3. Enable batch file deployment.

   smartmc batch-file-apply enable

   By default, batch file deployment is enabled.
4. Specify the batch file for ports connecting APs or IP phones.

   smartmc batch-file *batch-file-name* **apply** { **ap** | **phone** }

   To disable the commander from deploying batch files to ports, execute the **undo smartmc batch-file-apply enable** command to disable batch file deployment.

Backing up configuration files

About this task

Perform this task to back up the configuration file of the commander or the specified members. Configuration files automatically backed up to the file server are named in the format of *device_bridge_MAC_address*_**backup.cfg**.

Restrictions and guidelines

When you change the commander in the SmartMC network, make sure the backup configuration file of the original commander on the file server is deleted. If the file still exists, the new commander might download the file and run the settings. This will cause a conflict in the network.

The maximum number of members that can perform automatic configuration at the same time is limited by the performance of the file server. If automatic configuration backup fails, set the maximum number of members to a smaller value.

Prerequisites

Before performing this task, you must specify a file server (see "Specifying a file server").

Procedure

1. Enter system view.

   system-view
2. Set the maximum number of members that can perform configuration file backup at the same time.

   smartmc backup configuration max-number *max-number*

   By default, a maximum of five members can perform automatic configuration backup at the same time.
3. Back up configuration files.

   Choose one option as needed:

- Enable automatic configuration file backup and set the backup interval.
  smartmc backup startup-configuration interval *interval-time*
  By default, automatic configuration file backup is disabled.
- Manually back up the configuration file on the commander or the specified members.
  smartmc backup configuration { **group** *group-name-list* | **tc** [*tc-id-list*] }
  TC ID 0 represents the commander.

Configuring resource monitoring

1. Enter system view.
   system-view
2. Set the interval for the commander to obtain resource monitoring information.
   smartmc resource-monitor interval *interval*
   The default setting is 1 minute.
3. Set the aging time for resource monitoring information.
   smartmc resource-monitor max-age *max-age*
   The default setting is 24 hours.
4. Enable resource monitoring.
   smartmc resource-monitor [**cpu** | **memory** | **temperature**]* [**group** *group-name-list* | **tc** { *tc-id-list* | **mac-address** *mac-address* } | **tm**]
   By default, resource monitoring is disabled.
   If you do not specify a resource type, this command enables resource monitoring for all resource types.
   If you do not specify a device to monitor (member or commander), this command enables resource monitoring on the commander and all members.

Upgrading the startup software and configuration file on members

About upgrading the startup software and configuration file on members

You can use the following methods to upgrade the startup software and configuration file on members:

- Schedule an upgrade by specifying an upgrade time or upgrade delay.
- Upgrade immediately by not specifying an upgrade time or upgrade delay.

Restrictions and guidelines for startup software and configuration file upgrade

A member can perform only one upgrade task at a time.

An immediate upgrade cannot be cancelled. If you specify a delay time or upgrade time to perform a scheduled upgrade, the upgrade operation can be cancelled by using the **undo smartmc upgrade** command before it starts.

Prerequisites

Before performing this task, you must specify a file server (see "Specifying a file server").

Upgrading the startup software and configuration file on members

Upgrading the startup software and configuration file in one step

1. Enter system view.

   system-view

2. Upgrade the startup software on members in one step.

   smartmc upgrade boot-loader tc { *tc-id-list* { **boot** *boot-filename* **system** *system-filename* | **file** *ipe-filename* } }&<1-40> [**delay** *delay-time* | **time** *in-time*]

   CAUTION:

   Upgrading the startup software might interrupt services. Before the upgrade, make sure service operation will not be affected.

3. Upgrade the configuration file on members in one step.

   smartmc upgrade startup-configuration tc { *tc-id-list cfg-filename* }&<1-40> [**delay** *delay-time* | **time** *in-time*]

   CAUTION:

   To ensure correct device operation, make sure the contents of the configuration file are correct. After the upgrade, the configuration in the new file will become the running configuration.

Configuring startup software and configuration file upgrade step by step

1. Enter system view.

   system-view

2. Configure startup software upgrade for members step by step:

   a. Specify the upgrade startup software files.

      smartmc tc *tc-id* **boot-loader** { *ipe-filename* | **boot** *boot-filename* **system** *system-filename* }

   b. Upgrade the startup software on members.

      smartmc upgrade boot-loader tc *tc-id-list*

   CAUTION:

   Upgrading the startup software might interrupt services. Before the upgrade, make sure service operation will not be affected.

3. Configure configuration file upgrade for members step by step:

   a. Specify the upgrade configuration file.

      smartmc tc *tc-id* **startup-configuration** *cfg-filename*

   b. Upgrade the configuration file on members.

      smartmc upgrade startup-configuration tc *tc-id-list*

CAUTION:

To ensure correct device operation, make sure the contents of the configuration file are correct. After the upgrade, the configuration in the new file will become the running configuration.

Upgrading the startup software and configuration file on all members in SmartMC groups

Upgrading the startup software and configuration file in one step

1. Enter system view.

   system-view

2. Upgrade the startup software on all members in SmartMC groups in one step.

   smartmc upgrade boot-loader group { *group-name-list* [**boot** *boot-filename* **system** *system-filename* | **file** *ipe-filename*] }&<1-40> [**delay** *minutes* | **time** *in-time*]

CAUTION:

Upgrading the startup software might interrupt services. Before the upgrade, make sure service operation will not be affected.

3. Upgrade the configuration file on all members in SmartMC groups in one step.

   smartmc upgrade startup-configuration group { *group-name-list* **file** *cfg-filename* }&<1-40> [**delay** *minutes* | **time** *in-time*]

CAUTION:

To ensure correct device operation, make sure the contents of the configuration file are correct. After the upgrade, the configuration in the new file will become the running configuration.

Configuring startup software and configuration file upgrade step by step

1. Enter system view.

   system-view

2. Enter SmartMC group view.

   smartmc group *group-name*

3. Specify the upgrade startup software files for the SmartMC group.

   boot-loader file { *ipe-filename* | **boot** *boot-filename* **system** *system-filename* }

   By default, no upgrade startup software files are specified for a SmartMC group.

4. Specify the upgrade configuration file for the SmartMC group.

   startup-configuration *cfgfile*

   By default, no upgrade configuration file is specified for a SmartMC group.

5. Return to system view.

   quit

6. Upgrade the startup software and configuration file on all members in the SmartMC group.

   Choose one option as needed:

   - Upgrade the startup software.

     smartmc upgrade boot-loader group *group-name-list* [**delay** *minutes* | **time** *in-time*]

CAUTION:

Upgrading the startup software might interrupt services. Before the upgrade, make sure service operation will not be affected.

- Upgrade the configuration file.

  smartmc upgrade startup-configuration group *group-name-list* [**delay** *minutes* | **time** *in-time*]

CAUTION:

To ensure correct device operation, make sure the contents of the configuration file are correct. After the upgrade, the configuration in the new file will become the running configuration.

Managing the network topology

Refreshing the network topology

About this task

You can use the following methods to refresh the network topology:

- **Automatic topology refresh**—Specify the refresh interval to allow the commander to refresh the network topology periodically.
- **Manual topology refresh**—Execute the **smartmc topology-refresh** command to manually refresh the network topology.

Restrictions and guidelines

The topology refresh time depends on the number of members in the network.

Procedure

Choose one option as needed:

- Manually refresh the network topology in any view.

  smartmc topology-refresh
- Configure automatic network topology refresh.
  1. Enter system view.

     system-view
  2. Set the automatic topology refresh interval.

     smartmc topology-refresh interval *interval*

     By default, the automatic topology refresh interval is 60 seconds.

Saving the network topology

About this task

This task allows you to save the current network topology to the **topology.dba** file in the flash memory. After the commander reboots, it uses the **topology.dba** file to restore the network topology.

Procedure

1. Enter system view.

system-view

2. Save the network topology.
   smartmc topology-save

Replacing faulty members

Restrictions and guidelines

Make sure the new member for replacement and the faulty member have the same neighbor relationship and device model.

Make sure the new member has a different member ID than all the members in the SmartMC network, including offline members. Faulty members are considered offline.

To automatically replace a faulty member, first enable automatic replacement, and then install the new member at the location where the faulty member was installed and connect all cables.

To manually replace a faulty member, first install the new member at the location where the faulty member was installed, connect all cables, and then execute the manual replacement command.

Prerequisites

Before you replace a faulty member, specify a file server (see "Specifying a file server").

Procedure

1. Enter system view.
   system-view
2. Replace faulty members.
   Choose one option as needed:
   - Enable automatic faulty member replacement.
     smartmc auto-replace enable
     By default, automatic faulty member replacement is disabled.
   - Manually replace a faulty member.
     smartmc replace tc *tc-id1* **faulty-tc** *tc-id2*

Display and maintenance commands for SmartMC

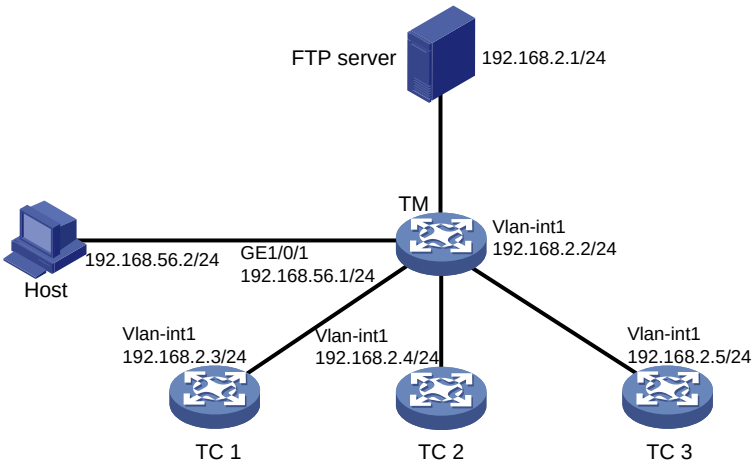
Execute **display** commands in any view.

Task	Command
Display the backup status on members.	**display smartmc backup configuration status**
Display the batch file execution results.	**display smartmc batch-file status** [**ap** | **last** *number* | **phone**]
Display SmartMC configuration.	**display smartmc configuration**
Display connections between the devices in the SmartMC network.	**display smartmc device-link**
Display SmartMC group information.	**display smartmc group** [*group-name*] [**verbose**]
Display the faulty member replacement status.	**display smartmc replace status**

Task	Command
Display resource monitoring information.	**display smartmc resource-monitor** [**cpu** | **memory** | **temperature**] * [**tc** *tc-id* | **tm**]
Display resource monitoring configuration.	**display smartmc resource-monitor configuration**
Display member information.	**display smartmc tc** [*tc-id*][**verbose**]
Display log information in the log buffer on a member.	**display smartmc tc** *tc-id* **log buffer** [**module** *module-name* [**mnemonic** *mnemonic-value*]]
Display restart log information for a member.	**display smartmc tc** *tc-id* **log restart**
Display VLAN creation results for members.	**display smartmc vlan**
Display member upgrade status.	**display smartmc upgrade status**

SmartMC configuration examples

Example: Configuring SmartMC



Network configuration

As shown in Figure 3, member 1, member 2, and member 3 belong to the same device type: S5570S-EI series. The IP address of the file server is 192.168.2.1. The username and password for accessing the file server are **admin** and **hello12345**, respectively.

Perform the following tasks to establish a SmartMC network and upgrade the configuration file on the members:

1. Configure the commander and members to automatically establish a SmartMC network.
2. Configure interface GigabitEthernet 1/0/1 as the outgoing interface for the SmartMC network.
3. Create a SmartMC group and add the members to the group.
4. Upgrade the configuration file on all members in the SmartMC group.
5. Save configuration file **startup.cfg** on the file server.

Figure 3 Network diagram

Procedure

1. Configure TC 1:

Configure VLAN-interface 1.

```
<TC1> system-view
[TC1] interface vlan-interface 1
[TC1-Vlan-interface1] ip address 192.168.2.3 24
[TC1-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TC1] ip http enable
[TC1] ip https enable
```

Enable the Telnet service.

```
[TC1] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TC1] netconf soap http enable
```

Enable LLDP globally.

```
[TC1] lldp global enable
```

Create a user.

```
[TC1] local-user admin
```

Lower password complexity requirements. For more information about these commands, see password control commands in *Security Command Reference*.

```
[TC1-luser-manage-admin] password-control length 4
[TC1-luser-manage-admin] password-control composition type-number 1 type-length 1
[TC1-luser-manage-admin] undo password-control complexity user-name check
```

Set the username and password to **admin**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TC1-luser-manage-admin] password simple admin
[TC1-luser-manage-admin] service-type telnet http https
[TC1-luser-manage-admin] authorization-attribute user-role network-admin
[TC1-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TC1] line vty 0 63
[TC1-line-vty0-63] authentication-mode scheme
[TC1-line-vty0-63] quit
```

Enable SmartMC and set the device role to **tc**.

```
[TC1] smartmc tc enable
```

2. Configure TC 2 and TC 3 in the same way TC 1 is configured. (Details not shown.)

3. Configure the TM:

Configure GigabitEthernet 1/0/1.

```
<TM> system-view
[TM] interface gigabitethernet 1/0/1
[TM-GigabitEthernet1/0/1] port link-mode route
[TM-GigabitEthernet1/0/1] ip address 192.168.52.2 24
[TM-GigabitEthernet1/0/1] quit
```

Configure VLAN-interface 1.

```
[TM] interface vlan-interface 1
[TM-Vlan-interface1] ip address 192.168.2.2 24
[TM-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TM] ip http enable
```

```
[TM] ip https enable
```

Enable the Telnet service.

```
[TM] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TM] netconf soap http enable
```

Enable LLDP globally.

```
[TM] lldp global enable
```

Create a user. Set the username to **admin** and the password to **hello12345**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TM] local-user admin
[TM-luser-manage-admin] password simple hello12345
[TM-luser-manage-admin] service-type telnet http https
[TM-luser-manage-admin] authorization-attribute user-role network-admin
[TM-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TM] line vty 0 63
[TM-line-vty0-63] authentication-mode scheme
[TM-line-vty0-63] quit
```

Enable SmartMC, set the device role to commander, and set the username to **admin** and the password (plaintext) to **hello12345**.

```
[TM] smartmc tm username admin password simple hello12345 enable
```

Specify GigabitEthernet 1/0/1 as the outgoing interface.

```
[TM] interface gigabitethernet 1/0/1
[TM-GigabitEthernet1/0/1] smartmc outbound
[TM-GigabitEthernet1/0/1] quit
```

Set the file server IP address, username, and plaintext password to 192.168.2.1, **admin**, and **hello12345**, respectively.

```
[TM] smartmc ftp-server 192.168.2.1 username admin password simple hello12345
```

Create SmartMC group **S1** and enter its view.

```
[TM] smartmc group S1
```

Create an IP address match criterion to add all members in the specified network segment to SmartMC group **S1**.

```
[TM-smartmc-group-S1] match ip-address 192.168.2.0 24
```

Specify the upgrade configuration file **startup.cfg** for SmartMC group **S1**.

```
[TM-smartmc-group-S1] startup-configuration startup.cfg
[TM-smartmc-group-S1] quit
```

Upgrade the configuration file on all members in SmartMC group **S1**.

```
[TM] smartmc upgrade startup-configuration group S1 file startup.cfg
```

Verifying the configuration

Display brief information about all members after the SmartMC network is established.

```
[TM] display smartmc tc
    TCID DeviceType Sysname  IpAddress       MacAddress     Status   Version
    1    S5570S-EI  TC1      192.168.2.3     201c-e7c3-0300 Normal   7.1.070 ESS 1103
    2    S5570S-EI  TC2      192.168.2.4     201c-e7c3-0301 Normal   7.1.070 ESS 1103
    3    S5570S-EI  TC3      192.168.2.5     201c-e7c3-0302 Normal   7.1.070 ESS 1103
```

Display the configuration file upgrade status on the members.

```
<TM> display smartmc upgrade status
```

```
ID    IpAddress        MacAddress      Status      UpdateTime        UpdateFile
1     192.168.2.3      201c-e7c3-0300  Finished    Immediately       startup.cfg
2     192.168.2.4      201c-e7c3-0301  Finished    Immediately       startup.cfg
3     192.168.2.5      201c-e7c3-0302  Finished    Immediately       startup.cfg
```

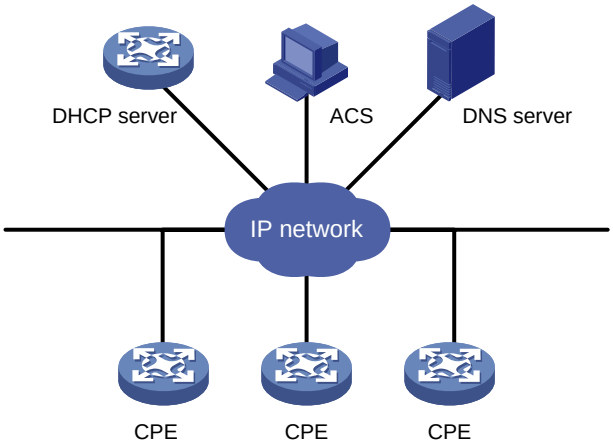
Configuring CWMP

About CWMP



CPE WAN Management Protocol (CWMP), also called "TR-069," is a DSL Forum technical specification for remote management of network devices.

The protocol was initially designed to provide remote autoconfiguration through a server for large numbers of dispersed end-user devices in a network. CWMP can be used on different types of networks, including Ethernet.

CWMP network framework

Figure 1 shows a basic CWMP network framework.

Figure 1 CWMP network framework

A basic CWMP network includes the following network elements:

- **ACS**—Autoconfiguration server, the management device in the network.
- **CPE**—Customer premises equipment, the managed device in the network.
- **DNS server**—Domain name system server. CWMP defines that the ACS and the CPE use URLs to identify and access each other. DNS is used to resolve the URLs.
- **DHCP server**—Assigns ACS attributes along with IP addresses to CPEs when the CPEs are powered on. DHCP server is optional in CWMP. With a DHCP server, you do not need to configure ACS attributes manually on each CPE. The CPEs can contact the ACS automatically when they are powered on for the first time.

The device is operating as a CPE in the CWMP framework.

Basic CWMP functions

You can autoconfigure and upgrade CPEs in bulk from the ACS.

Autoconfiguration

You can create configuration files for different categories of CPEs on the ACS. Based on the device models and serial numbers of the CPEs, the ACS verifies the categories of the CPEs and issues the associated configuration to them.

The following are methods available for the ACS to issue configuration to the CPE:

- Transfers the configuration file to the CPE, and specifies the file as the next-startup configuration file. At a reboot, the CPE starts up with the ACS-specified configuration file.
- Runs the configuration in the CPE's RAM. The configuration takes effect immediately on the CPE. For the running configuration to survive a reboot, you must save the configuration on the CPE.

CPE software management

The ACS can manage CPE software upgrade.

When the ACS finds a software version update, the ACS notifies the CPE to download the software image file from a specific location. The location can be the URL of the ACS or an independent file server.

If the CPE successfully downloads the software image file and the file is validated, the CPE notifies the ACS of a successful download. If the CPE fails to download the software image file or the file is invalidated, the CPE notifies the ACS of an unsuccessful download.

Data backup

The ACS can require the CPE to upload a configuration file or log file to a specific location. The destination location can be the ACS or a file server.

CPE status and performance monitoring

The ACS can monitor the status and performance of CPEs. Table 1 shows the available CPE status and performance objects for the ACS to monitor.

Table 1 CPE status and performance objects available for the ACS to monitor

Category	Objects	Remarks
Device information	Manufacturer ManufacturerOUI SerialNumber HardwareVersion SoftwareVersion	N/A
Operating status and information	DeviceStatus UpTime	N/A
Configuration file	ConfigFile	Local configuration file stored on CPE for upgrade. The ACS can issue configuration to the CPE by transferring a configuration file to the CPE or running the configuration in CPE's RAM.
CWMP settings	ACS URL	URL address of the ACS to which the CPE initiates a CWMP connection. This object is also used for main/backup ACS switchover.
	ACS username ACS password	When the username and password of the ACS are changed, the ACS changes the ACS username and password on the CPE to the new username and password. When a main/backup ACS switchover occurs, the main ACS also changes the ACS username and password to the backup ACS username and password.
	PeriodicInformEnable	Whether to enable or disable the periodic Inform feature.
	PeriodicInformInterval	Interval for periodic connection from the CPE

Category	Objects	Remarks
		to the ACS for configuration and software update.
	PeriodicInformTime	Scheduled time for connection from the CPE to the ACS for configuration and software update.
	ConnectionRequestURL (CPE URL)	N/A
	ConnectionRequestUsername (CPE username) ConnectionRequestPassword (CPE password)	CPE username and password for authentication from the ACS to the CPE.

How CWMP works

RPC methods

CWMP uses remote procedure call (RPC) methods for bidirectional communication between CPE and ACS. The RPC methods are encapsulated in HTTP or HTTPS.

Table 2 shows the primary RPC methods used in CWMP.

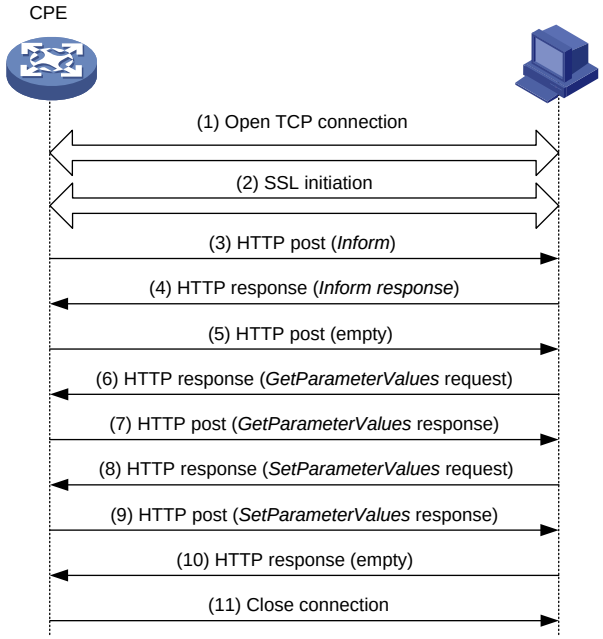
Table 2 RPC methods

RPC method	Description
Get	The ACS obtains the values of parameters on the CPE.
Set	The ACS modifies the values of parameters on the CPE.
Inform	The CPE sends an Inform message to the ACS for the following purposes: • Initiates a connection to the ACS. • Reports configuration changes to the ACS. • Periodically updates CPE settings to the ACS.
Download	The ACS requires the CPE to download a configuration or software image file from a specific URL for software or configuration update.
Upload	The ACS requires the CPE to upload a file to a specific URL.
Reboot	The ACS reboots the CPE remotely for the CPE to complete an upgrade or recover from an error condition.

Autoconnect between ACS and CPE

The CPE automatically initiates a connection to the ACS when one of the following events occurs:

- ACS URL change. The CPE initiates a connection request to the new ACS URL.
- CPE startup. The CPE initiates a connection to the ACS after the startup.
- Timeout of the periodic Inform interval. The CPE re-initiates a connection to the ACS at the Inform interval.
- Expiration of the scheduled connection initiation time. The CPE initiates a connection to the ACS at the scheduled time.



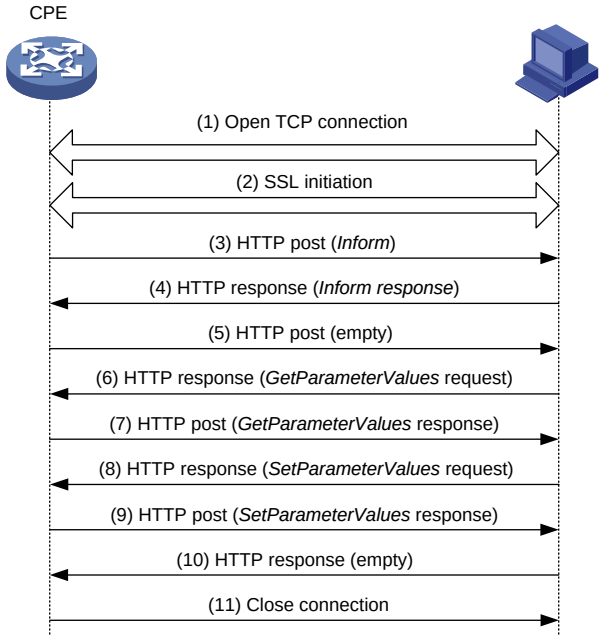
CWMP connection establishment

Step 1 through step 5 in Figure 2 show the procedure of establishing a connection between the CPE and the ACS.

1. After obtaining the basic ACS parameters, the CPE initiates a TCP connection to the ACS.

2. If HTTPS is used, the CPE and the ACS initialize SSL for a secure HTTP connection.
3. The CPE sends an Inform message in HTTPS to initiate a CWMP session.
4. After the CPE passes authentication, the ACS returns an Inform response to establish the session.
5. After sending all requests, the CPE sends an empty HTTP post message.

Figure 2 CWMP connection establishment



Main/backup ACS switchover

Typically, two ACSs are used in a CWMP network for consecutive monitoring on CPEs. When the main ACS needs to reboot, it points the CPE to the backup ACS. Step 6 through step 11 in Figure 3 show the procedure of a main/backup ACS switchover.

1. Before the main ACS reboots, it queries the ACS URL set on the CPE.
2. The CPE replies with its ACS URL setting.
3. The main ACS sends a Set request to change the ACS URL on the CPE to the backup ACS URL.
4. After the ACS URL is modified, the CPE sends a response.
5. The main ACS sends an empty HTTP message to notify the CPE that it has no other requests.
6. The CPE closes the connection, and then initiates a new connection to the backup ACS URL.

Figure 3 Main and backup ACS switchover

Restrictions and guidelines: CWMP configuration

CWMP is available only in IPv4 networks. If you configure CWMP in an IPv6 network, the feature does not take effect.

You can configure ACS and CPE attributes from the CPE's CLI, the DHCP server, or the ACS. For an attribute, the CLI- and ACS-assigned values have higher priority than the DHCP-assigned value. The CLI- and ACS-assigned values overwrite each other, whichever is assigned later.

This document only describes configuring ACS and CPE attributes from the CLI and DHCP server. For more information about configuring and using the ACS, see ACS documentation.

CWMP tasks at a glance

To configure CWMP, perform the following tasks:

1. Enabling CWMP from the CLI

   You can also enable CWMP from a DHCP server.
2. Configuring ACS attributes
   a. Configuring the preferred ACS attributes
   b. (Optional.) Configuring the default ACS attributes from the CLI
3. Configuring CPE attributes
   a. Specifying an SSL client policy for HTTPS connection to ACS

      This task is required when the ACS uses HTTPS for secure access.
   b. (Optional.) Configuring ACS authentication parameters
   c. (Optional.) Configuring the provision code
   d. (Optional.) Configuring the CWMP connection interface
   e. (Optional.) Configuring autoconnect parameters
   f. (Optional.) Setting the close-wait timer

g. (Optional.) Enabling NAT traversal for the CPE

Enabling CWMP from the CLI

1. Enter system view.
   system-view
2. Enter CWMP view.
   cwmp
3. Enable CWMP.
   cwmp enable
   By default, CWMP is disabled.

Configuring ACS attributes

About ACS attributes

You can configure two sets of ACS attributes for the CPE: preferred and default.

- The preferred ACS attributes are configurable from the CPE's CLI, the DHCP server, and ACS.
- The default ACS attributes are configurable only from the CLI.

If the preferred ACS attributes are not configured, the CPE uses the default ACS attributes for connection establishment.

Configuring the preferred ACS attributes

Assigning ACS attributes from the DHCP server

The DHCP server in a CWMP network assigns the following information to CPEs:

- IP addresses for the CPEs.
- DNS server address.
- ACS URL and ACS login authentication information.

This section introduces how to use DHCP option 43 to assign the ACS URL and ACS login authentication username and password. For more information about DHCP and DNS, see *Layer 3—IP Services Configuration Guide*.

If the DHCP server is an H3C device, you can configure DHCP option 43 by using the **option 43 hex 01***length URL username password* command.

- *length*—A hexadecimal number that indicates the total length of the *length*, *URL*, *username*, and *password* arguments, including the spaces between these arguments. No space is allowed between the **01** keyword and the length value.
- *URL*—ACS URL.
- *username*—Username for the CPE to authenticate to the ACS.
- *password*—Password for the CPE to authenticate to the ACS.

NOTE:

The ACS URL, username and password must use the hexadecimal format and be space separated.

The following example configures the ACS address as **http://169.254.76.31:7547/acs**, username as **1234**, and password as **5678**:

```
<Sysname> system-view
[Sysname] dhcp server ip-pool 0
[Sysname-dhcp-pool-0] option 43 hex
0127687474703A2F2F3136392E3235342E37362E33313A373534372F6163732031323334203536373 8
```

Table 3 Hexadecimal forms of the ACS attributes

Attribute	Attribute value	Hexadecimal form
Length	39 characters	27
ACS URL	http://169.254.76.31:7547/acs	687474703A2F2F3136392E3235342E37362E33313A373534372F61637320 **NOTE:** The two ending digits (20) represent the space.
ACS connect username	1234	3132333420 **NOTE:** The two ending digits (20) represent the space.
ACS connect password	5678	35363738

Configuring the preferred ACS attributes from the CLI

1. Enter system view.
   system-view
2. Enter CWMP view.
   cwmp
3. Configure the preferred ACS URL.
   cwmp acs url *url*
   By default, no preferred ACS URL has been configured.
4. Configure the username for authentication to the preferred ACS URL.
   cwmp acs username *username*
   By default, no username has been configured for authentication to the preferred ACS URL.
5. (Optional.) Configure the password for authentication to the preferred ACS URL.
   cwmp acs password { **cipher** | **simple** } *string*
   By default, no password has been configured for authentication to the preferred ACS URL.

Configuring the default ACS attributes from the CLI

1. Enter system view.
   system-view
2. Enter CWMP view.
   cwmp
3. Configure the default ACS URL.
   cwmp acs default url *url*
   By default, no default ACS URL has been configured.
4. Configure the username for authentication to the default ACS URL.
   cwmp acs default username *username*
   By default, no username has been configured for authentication to the default ACS URL.

5. (Optional.) Configure the password for authentication to the default ACS URL.

   cwmp acs default password { **cipher** | **simple** } *string*

   By default, no password has been configured for authentication to the default ACS URL.

Configuring CPE attributes

About CPE attributes

You can configure the following CPE attributes only from the CPE's CLI.

- CWMP connection interface.
- NAT traversal.
- Maximum number of connection retries.
- SSL client policy for HTTPS connection to ACS.

For other CPE attribute values, you can assign them to the CPE from the CPE's CLI or the ACS. The CLI- and ACS-assigned values overwrite each other, whichever is assigned later.

Specifying an SSL client policy for HTTPS connection to ACS

About this task

This task is required when the ACS uses HTTPS for secure access. CWMP uses HTTP or HTTPS for data transmission. When HTTPS is used, the ACS URL begins with **https://**. You must specify an SSL client policy for the CPE to authenticate the ACS for HTTPS connection establishment.

Prerequisites

Before you perform this task, first create an SSL client policy. For more information about configuring SSL client policies, see *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Enter CWMP view.

   cwmp

3. Specify an SSL client policy.

   ssl client-policy *policy-name*

   By default, no SSL client policy is specified.

Configuring ACS authentication parameters

About this task

To protect the CPE against unauthorized access, configure a CPE username and password for ACS authentication. When an ACS initiates a connection to the CPE, the ACS must provide the correct username and password.

Procedure

1. Enter system view.

   system-view

2. Enter CWMP view.

cwmp

3. Configure the username for authentication to the CPE.

   cwmp cpe username *username*

   By default, no username has been configured for authentication to the CPE.

4. (Optional.) Configure the password for authentication to the CPE.

   cwmp cpe password { **cipher** | **simple** } *string*

   By default, no password has been configured for authentication to the CPE.

   The password setting is optional. You can specify only a username for authentication.

Configuring the provision code

About this task

The ACS can use the provision code to identify services assigned to each CPE. For correct configuration deployment, make sure the same provision code is configured on the CPE and the ACS. For information about the support of your ACS for provision codes, see the ACS documentation.

Procedure

1. Enter system view.

   system-view

2. Enter CWMP view.

   cwmp

3. Configure the provision code.

   cwmp cpe provision-code *provision-code*

   The default provision code is **PROVISIONINGCODE**.

Configuring the CWMP connection interface

About this task

The CWMP connection interface is the interface that the CPE uses to communicate with the ACS. To establish a CWMP connection, the CPE sends the IP address of this interface in the Inform messages, and the ACS replies to this IP address.

Typically, the CPE selects the CWMP connection interface automatically. If the CWMP connection interface is not the interface that connects the CPE to the ACS, the CPE fails to establish a CWMP connection with the ACS. In this case, you need to manually set the CWMP connection interface.

Procedure

1. Enter system view.

   system-view

2. Enter CWMP view.

   cwmp

3. Specify the interface that connects to the ACS as the CWMP connection interface.

   cwmp cpe connect interface *interface-type interface-number*

   By default, no CWMP connection interface is specified.

Configuring autoconnect parameters

About this task

You can configure the CPE to connect to the ACS periodically, or at a scheduled time for configuration or software update.

The CPE retries a connection automatically when one of the following events occurs:

- The CPE fails to connect to the ACS. The CPE considers a connection attempt as having failed when the close-wait timer expires. This timer starts when the CPE sends an Inform request. If the CPE fails to receive a response before the timer expires, the CPE resends the Inform request.
- The connection is disconnected before the session on the connection is completed.

To protect system resources, limit the number of retries that the CPE can make to connect to the ACS.

Configuring the periodic Inform feature

1. Enter system view.
   `system-view`
2. Enter CWMP view.
   `cwmp`
3. Enable the periodic Inform feature.
   `cwmp cpe inform interval enable`
   By default, this function is disabled.
4. Set the Inform interval.
   `cwmp cpe inform interval` *`interval`*
   By default, the CPE sends an Inform message to start a session every 600 seconds.

Scheduling a connection initiation

1. Enter system view.
   `system-view`
2. Enter CWMP view.
   `cwmp`
3. Schedule a connection initiation.
   `cwmp cpe inform time` *`time`*
   By default, no connection initiation has been scheduled.

Setting the maximum number of connection retries

1. Enter system view.
   `system-view`
2. Enter CWMP view.
   `cwmp`
3. Set the maximum number of connection retries.
   `cwmp cpe connect retry` *`retries`*
   By default, the CPE retries a failed connection until the connection is established.

Setting the close-wait timer

About this task

The close-wait timer specifies the following:

- The maximum amount of time the CPE waits for the response to a session request. The CPE determines that its session attempt has failed when the timer expires.
- The amount of time the connection to the ACS can be idle before it is terminated. The CPE terminates the connection to the ACS if no traffic is sent or received before the timer expires.

Procedure

1. Enter system view.
   `system-view`
2. Enter CWMP view.
   `cwmp`
3. Set the close-wait timer.
   `cwmp cpe wait timeout` *`seconds`*
   By default, the close-wait timer is 30 seconds.

Enabling NAT traversal for the CPE

About this task

For the connection request initiated from the ACS to reach the CPE, you must enable NAT traversal on the CPE when a NAT gateway resides between the CPE and the ACS.

The NAT traversal feature complies with RFC 3489 Simple Traversal of UDP Through NATs (STUN). The feature enables the CPE to discover the NAT gateway, and obtain an open NAT binding (a public IP address and port binding) through which the ACS can send unsolicited packets. The CPE sends the binding to the ACS when it initiates a connection to the ACS. For the connection requests sent by the ACS at any time to reach the CPE, the CPE maintains the open NAT binding. For more information about NAT, see *Layer 3—IP Services Configuration Guide*.

Procedure

1. Enter system view.
   `system-view`
2. Enter CWMP view.
   `cwmp`
3. Enable NAT traversal.
   `cwmp cpe stun enable`
   By default, NAT traversal is disabled on the CPE.

Display and maintenance commands for CWMP

Execute **`display`** commands in any view.

Task	Command
Display CWMP configuration.	**`display cwmp configuration`**
Display the current status of CWMP.	**`display cwmp status`**

CWMP configuration examples

Example: Configuring CWMP

Network configuration

As shown in Figure 4, use H3C IMC BIMS as the ACS to bulk-configure the devices (CPEs), and assign ACS attributes to the CPEs from the DHCP server.

The configuration files for the CPEs in equipment rooms A and B are **configure1.cfg** and **configure2.cfg**, respectively.

Figure 4 Network diagram

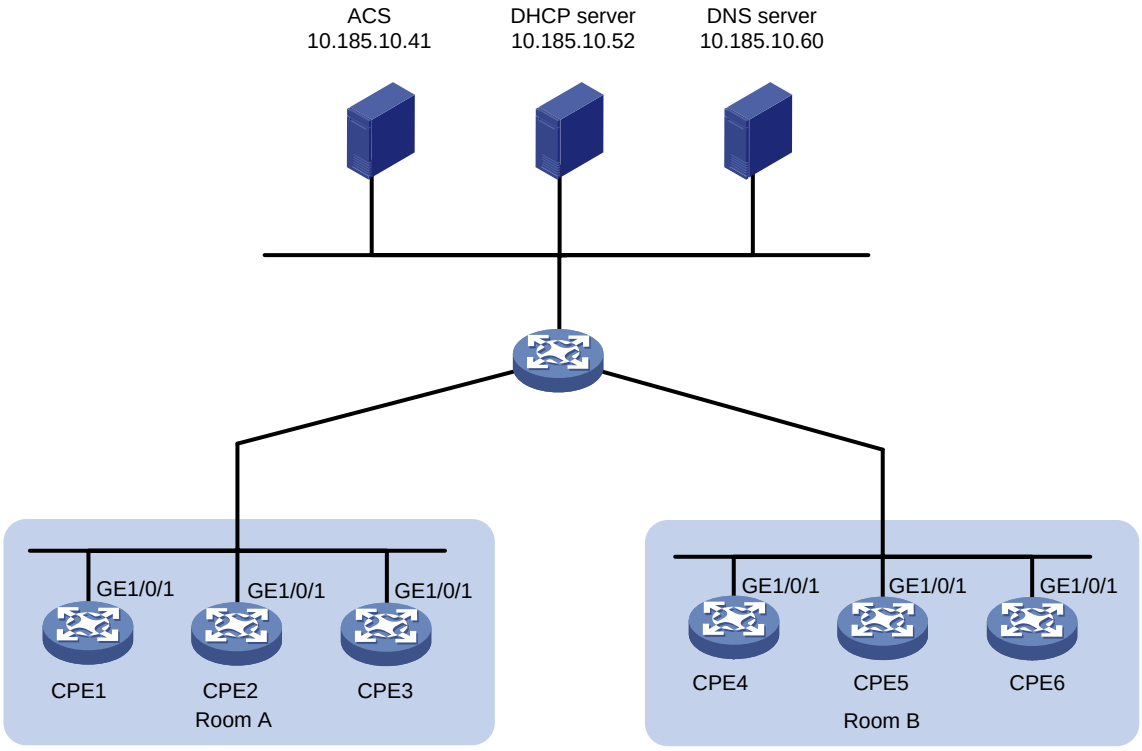


Table 4 shows the ACS attributes for the CPEs to connect to the ACS.

Table 4 ACS attributes

Item	Setting
Preferred ACS URL	http://10.185.10.41:9090
ACS username	admin
ACS password	12345

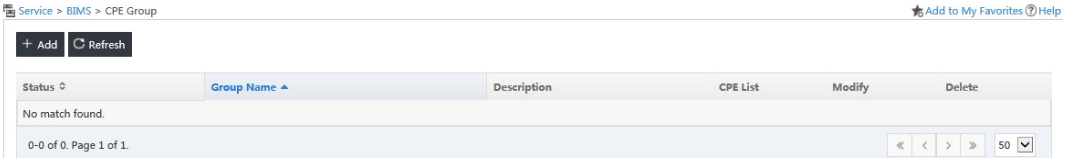
Table 5 lists serial numbers of the CPEs.

Table 5 CPE list

Room	Device	Serial number
A	CPE 1	210231A95YH10C000045
	CPE 2	210235AOLNH12000010

Room	Device	Serial number
	CPE 3	210235AOLNH12000015
B	CPE 4	210235AOLNH12000017
	CPE 5	210235AOLNH12000020
	CPE 6	210235AOLNH12000022

Configuring the ACS



Figures in this section are for illustration only.

To configure the ACS:

1. Log in to the ACS:
   a. Launch a Web browser on the ACS configuration terminal.
   b. In the address bar of the Web browser, enter the ACS URL and port number. This example uses **http://10.185.10.41:8080/imc**.
   c. On the login page, enter the ACS login username and password, and then click **Login**.
2. Create a CPE group for each equipment room:
   a. Select **Service** > **BIMS** > **CPE Group** from the top navigation bar.

      The **CPE Group** page appears.

      Figure 5 CPE Group page

   b. Click **Add**.
   c. Enter a username, and then click **OK**.

      Figure 6 Adding a CPE group

   d. Repeat the previous two steps to create a CPE group for CPEs in Room B.
3. Add CPEs to the CPE group for each equipment room:
   a. Select **Service** > **BIMS** > **Resource Management** > **Add CPE** from the top navigation bar.
   b. On the **Add CPE** page, configure the following parameters:
      - **Authentication Type**—Select **ACS UserName**.
      - **CPE Name**—Enter a CPE name.
      - **ACS Username**—Enter **admin**.
      - **ACS Password Generated**—Select **Manual Input**.
      - **ACS Password**—Enter a password for ACS authentication.

- **ACS Confirm Password**—Re-enter the password.
- **CPE Model**—Select the CPE model.
- **CPE Group**—Select the CPE group.

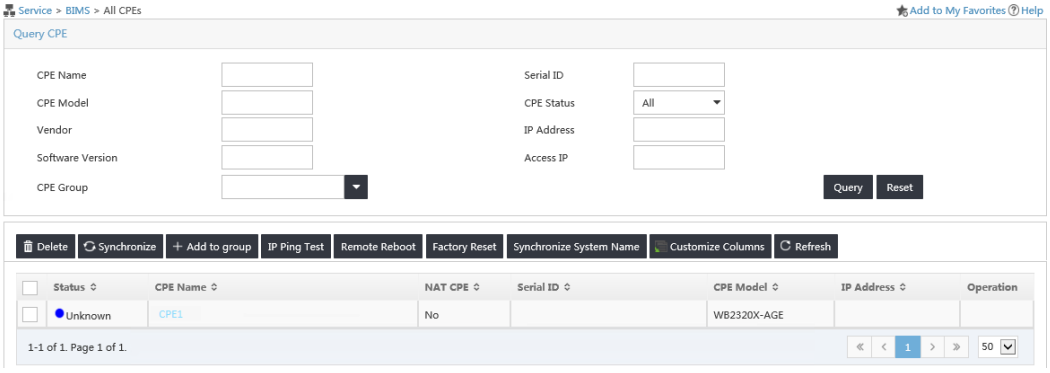


Figure 7 Adding a CPE

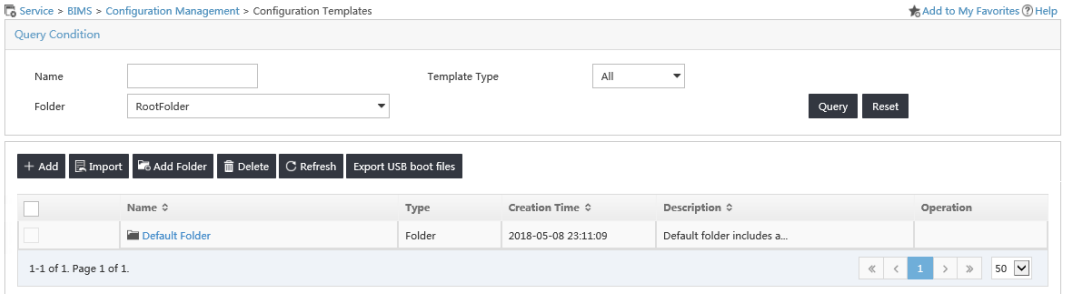
c. Click **OK**.

d. Verify that the CPE has been added successfully from the **All CPEs** page.

Figure 8 Viewing CPEs



e. Repeat the previous steps to add CPE 2 and CPE 3 to the CPE group for Room A, and add CPEs in Room B to the CPE group for Room B.

4. Configure a configuration template for each equipment room:

a. Select **Service** > **BIMS** > **Configuration Management** > **Configuration Templates** from the top navigation bar.

Figure 9 Configuration Templates page

b. Click **Import**.

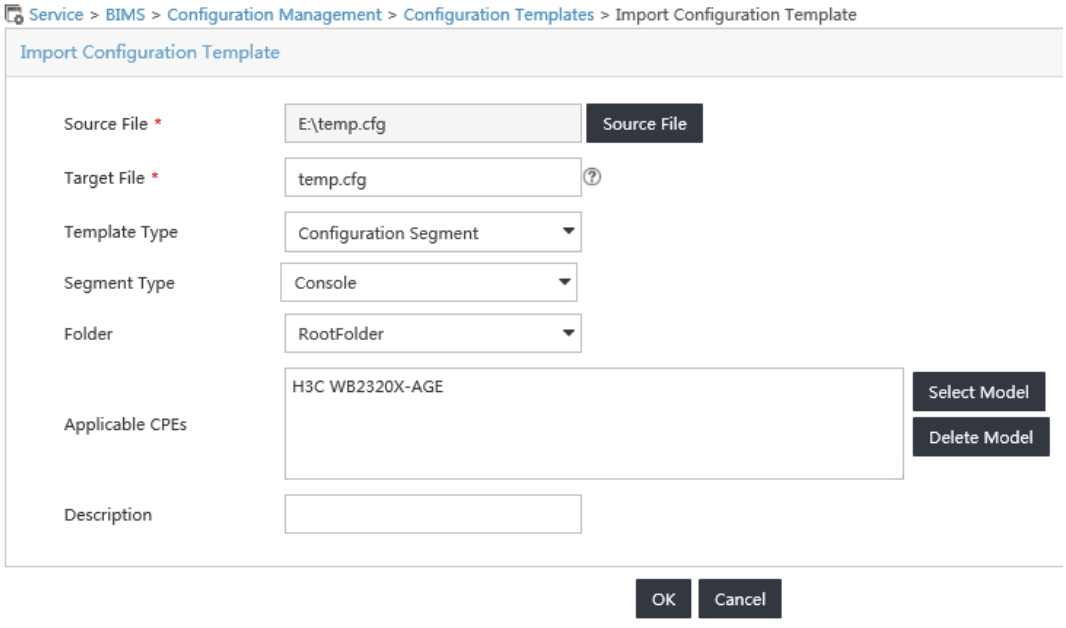
c. Select a source configuration file, select **Configuration Segment** as the template type, and then click **OK**.

The created configuration template will be displayed in the **Configuration Template** list after a successful file import.

IMPORTANT:

If the first command in the configuration template file is **`system-view`**, make sure no characters exist in front of the command.

Figure 10 Importing a configuration template



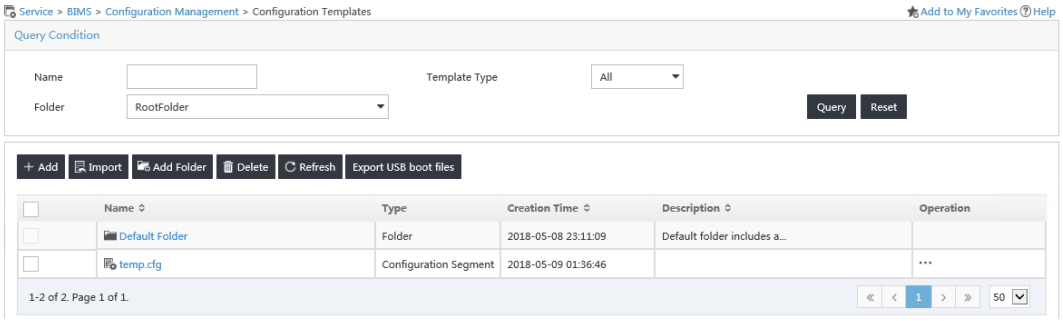


Figure 11 Configuration Template list

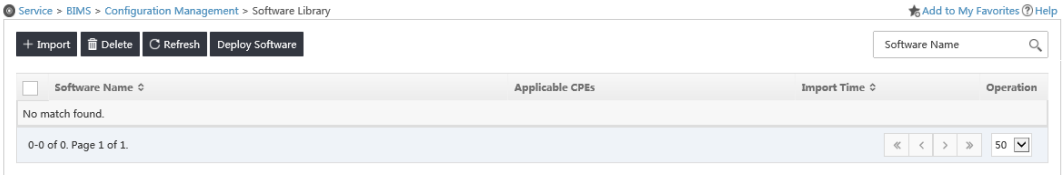

d. Repeat the previous steps to configure a configuration template for Room B.

5. Add software library entries:

a. Select **Service** > **BIMS** > **Configuration Management** > **Software Library** from the top navigation bar.

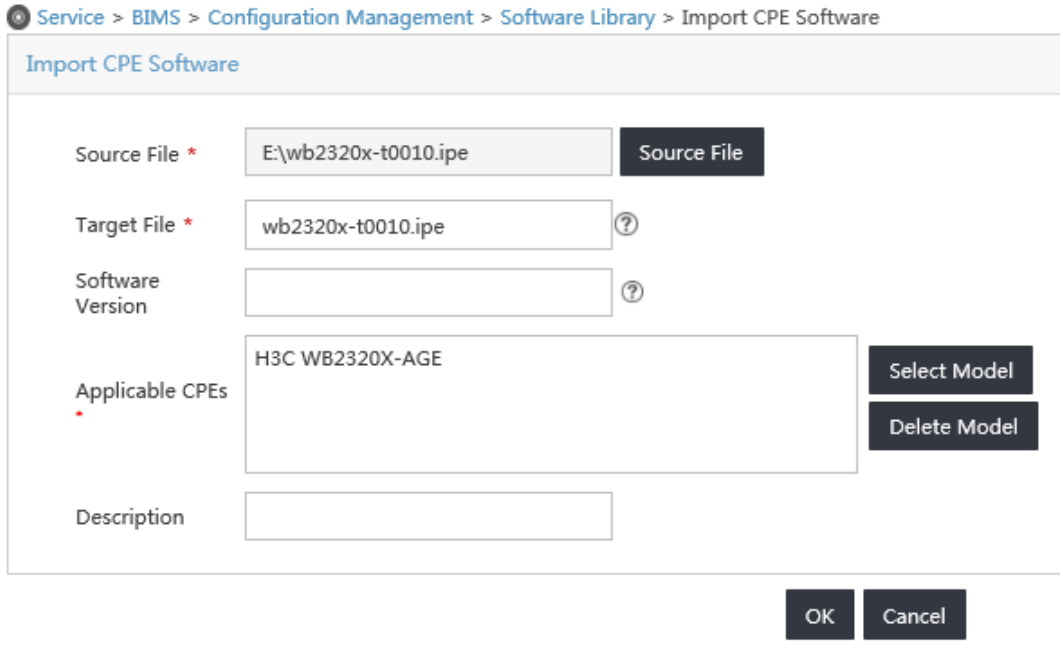

Figure 12 Software Library page

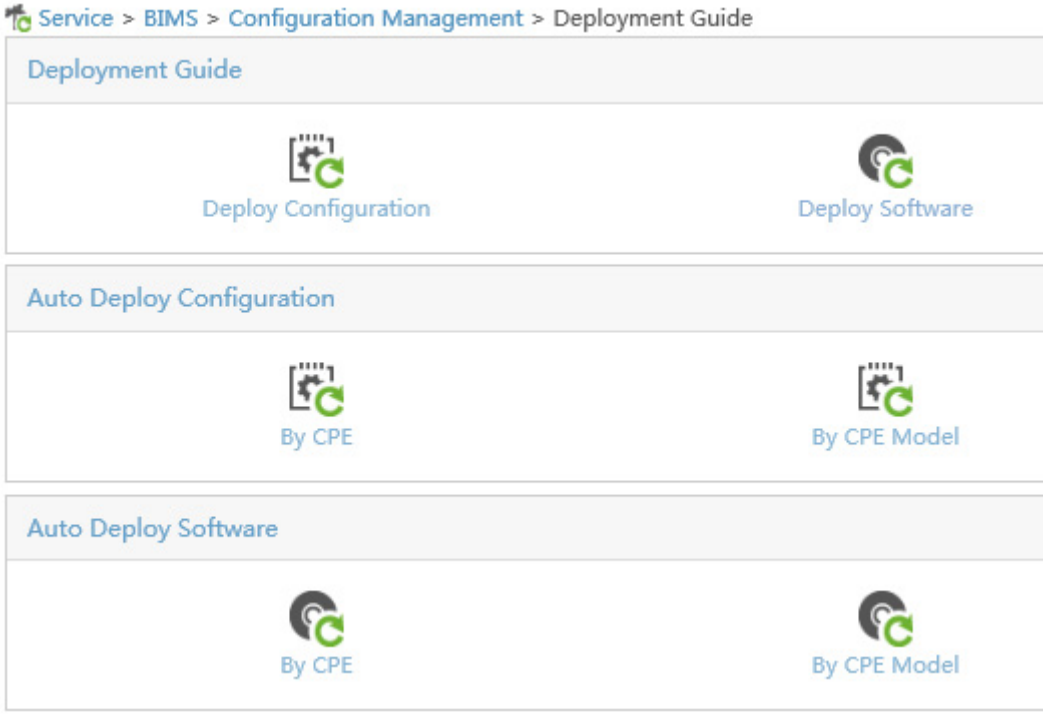
b. Click **Import**.

c. Select a source file, and then click **OK**.

Figure 13 Importing CPE software

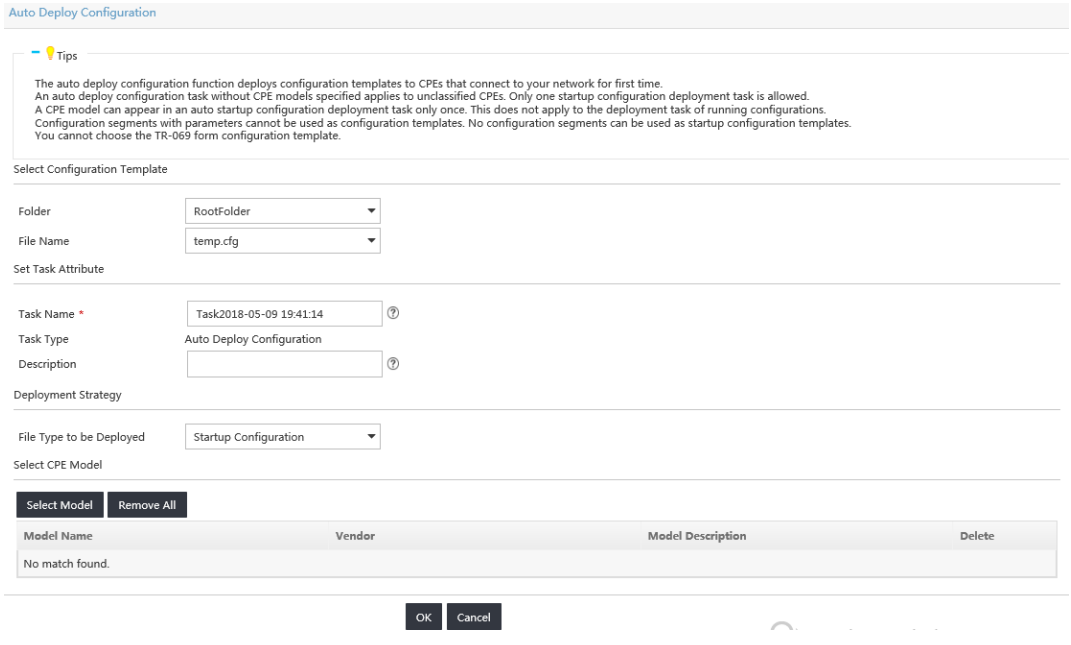


d. Repeat the previous steps to add software library entries for CPEs of different models.

6. Create an auto-deployment task for each equipment room:

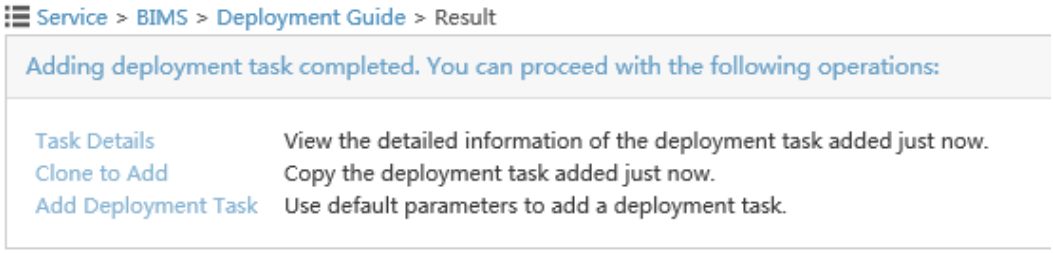
a. Select **Service** > **BIMS** > **Configuration Management** > **Deployment Guide** from the top navigation bar.

Figure 14 Deployment Guide



b. Click **By CPE Model** from the **Auto Deployment Configuration** field.

c. Select a configuration template, select **Startup Configuration** from the **File Type to be Deployed** list, and click **Select Model** to select CPEs in Room A. Then, click **OK**.



You can search for CPEs by CPE group.

Figure 15 Auto deployment configuration

d. Click **OK** on the **Auto Deploy Configuration** page.

Figure 16 Operation result

e. Repeat the previous steps to add a deployment task for CPEs in Room B.

Configuring the DHCP server

In this example, an H3C device is operating as the DHCP server.

1. Configure an IP address pool to assign IP addresses and DNS server address to the CPEs. This example uses subnet 10.185.10.0/24 for IP address assignment.

Enable DHCP.

```
<DHCP_server> system-view
[DHCP_server] dhcp enable
```

Enable DHCP server on VLAN-interface 1.

```
[DHCP_server] interface vlan-interface 1
[DHCP_server-Vlan-interface1] dhcp select server
[DHCP_server-Vlan-interface1] quit
```

Exclude the DNS server address 10.185.10.60 and the ACS IP address 10.185.10.41 from dynamic allocation.

```
[DHCP_server] dhcp server forbidden-ip 10.185.10.41
[DHCP_server] dhcp server forbidden-ip 10.185.10.60
```

Create DHCP address pool 0.

```
[DHCP_server] dhcp server ip-pool 0
```

Assign subnet 10.185.10.0/24 to the address pool, and specify the DNS server address 10.185.10.60 in the address pool.

```
[DHCP_server-dhcp-pool-0] network 10.185.10.0 mask 255.255.255.0
[DHCP_server-dhcp-pool-0] dns-list 10.185.10.60
```

2. Configure DHCP Option 43 to contain the ACS URL, username, and password in hexadecimal format.

```
[DHCP_server-dhcp-pool-0] option 43 hex
013B687474703A2F2F6163732E6461746161626173653A393039302F616373207669636B79203132333
435
```

Configuring the DNS server

Map http://acs.database:9090 to http://10.185.1.41:9090 on the DNS server. For more information about DNS configuration, see DNS server documentation.

Connecting the CPEs to the network

Connect CPE 1 to the network, and then power on the CPE. (Details not shown.)

Log in to CPE 1 and configure its VLAN-interface 2 to use DHCP for IP address acquisition and assign interface GigabitEthernet 1/0/1 to VLAN 2.

```
<CPE1> system-view
[CPE1] vlan 2
[CPE1-vlan2] quit
```

```
[CPE1] interface gigabitethernet 1/0/1
[CPE1-GigabitEthernet1/0/1] port access vlan 2
[CPE1-GigabitEthernet1/0/1] quit
[CPE1] interface vlan-interface 2
[CPE1-Vlan-interface2] ip address dhcp-alloc
```

Repeat the previous steps to configure the other CPEs.

Verifying the configuration

Execute the **display current-configuration** command to verify that the running configurations on CPEs are the same as the configurations issued by the ACS.

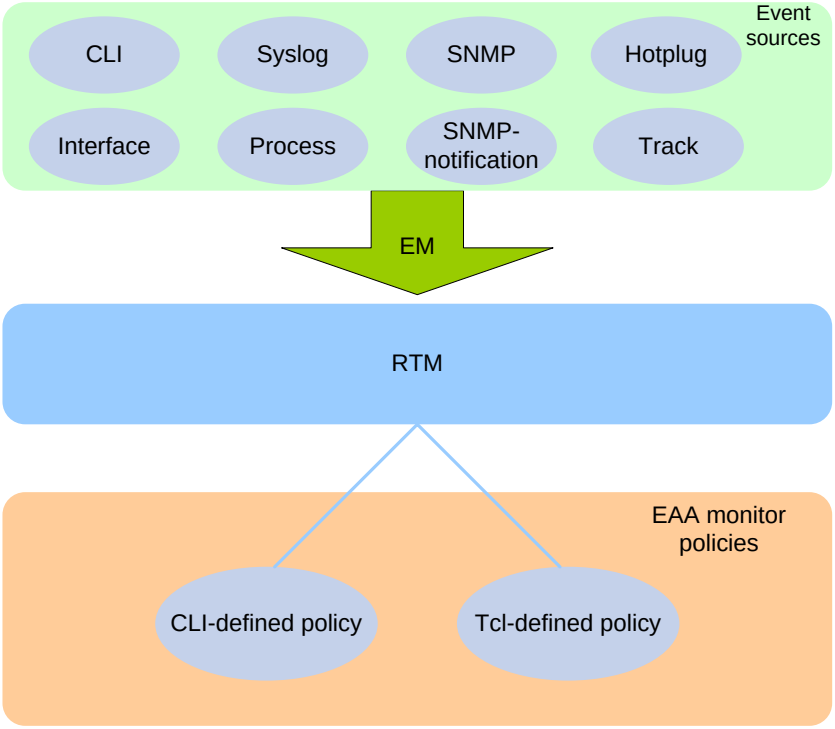
Configuring EAA



About EAA

Embedded Automation Architecture (EAA) is a monitoring framework that enables you to self-define monitored events and actions to take in response to an event. It allows you to create monitor policies by using the CLI or Tcl scripts.

EAA framework

EAA framework includes a set of event sources, a set of event monitors, a real-time event manager (RTM), and a set of user-defined monitor policies, as shown in Figure 1.

Figure 1 EAA framework

Event sources

Event sources are software or hardware modules that trigger events (see Figure 1).

For example, the CLI module triggers an event when you enter a command. The Syslog module (the information center) triggers an event when it receives a log message.

Event monitors

EAA creates one event monitor to monitor the system for the event specified in each monitor policy. An event monitor notifies the RTM to run the monitor policy when the monitored event occurs.

RTM

RTM manages the creation, state machine, and execution of monitor policies.

EAA monitor policies

A monitor policy specifies the event to monitor and actions to take when the event occurs.

You can configure EAA monitor policies by using the CLI or Tcl.

A monitor policy contains the following elements:

- One event.
- A minimum of one action.
- A minimum of one user role.
- One running time setting.

For more information about these elements, see "Elements in a monitor policy."

Elements in a monitor policy

Elements in an EAA monitor policy include event, action, user role, and runtime.

Event

Table 1 shows types of events that EAA can monitor.

Table 1 Monitored events

Event type	Description
CLI	CLI event occurs in response to monitored operations performed at the CLI. For example, a command is entered, a question mark (?) is entered, or the **Tab** key is pressed to complete a command.
Hotplug	Hot-swapping event occurs when the monitored member device joins or leaves the IRF fabric.
Interface	Each interface event is associated with two user-defined thresholds: start and restart. An interface event occurs when the monitored interface traffic statistic crosses the start threshold in the following situations: • The statistic crosses the start threshold for the first time. • The statistic crosses the start threshold each time after it crosses the restart threshold.
process	Process event occurs in response to a state change of the monitored process (such as an exception, shutdown, start, or restart). Both manual and automatic state changes can cause the event to occur.
SNMP	Each SNMP event is associated with two user-defined thresholds: start and restart. SNMP event occurs when the monitored MIB variable's value crosses the start threshold in the following situations: • The monitored variable's value crosses the start threshold for the first time. • The monitored variable's value crosses the start threshold each time after it crosses the restart threshold.
SNMP-Notification	SNMP-Notification event occurs when the monitored MIB variable's value in an SNMP notification matches the specified condition. For example, the broadcast traffic rate on an Ethernet interface reaches or exceeds 30%.
Syslog	Syslog event occurs when the information center receives the monitored log within a specific period. NOTE: The log that is generated by the EAA RTM does not trigger the monitor policy to run.
Track	Track event occurs when the state of the track entry changes from Positive to Negative or from Negative to Positive. If you specify multiple track entries for a policy, EAA triggers the policy only when the state of all the track entries changes from Positive

Event type	Description
	(Negative) to Negative (Positive). If you set a suppress time for a policy, the timer starts when the policy is triggered. The system does not process the messages that report the track entry state change from Positive (Negative) to Negative (Positive) until the timer times out.

Action

You can create a series of order-dependent actions to take in response to the event specified in the monitor policy.

The following are available actions:

- Executing a command.
- Executing a reboot without saving the running configuration.
- Enabling an active/standby switchover.
- Sending a log.

User role

For EAA to execute an action in a monitor policy, you must assign the policy the user role that has access to the action-specific commands and resources. If EAA lacks access to an action-specific command or resource, EAA does not perform the action and all the subsequent actions.

For example, a monitor policy has four actions numbered from 1 to 4. The policy has user roles that are required for performing actions 1, 3, and 4. However, it does not have the user role required for performing action 2. When the policy is triggered, EAA executes only action 1.

For more information about user roles, see RBAC in *Fundamentals Configuration Guide*.

Runtime

The runtime limits the amount of time that the monitor policy runs its actions from the time it is triggered. This setting prevents a policy from running its actions permanently to occupy resources.

EAA environment variables

EAA environment variables decouple the configuration of action arguments from the monitor policy so you can modify a policy easily.

An EAA environment variable is defined as a <*variable_name variable_value*> pair and can be used in different policies. When you define an action, you can enter a variable name with a leading dollar sign (**$***variable_name*). EAA will replace the variable name with the variable value when it performs the action.

To change the value for an action argument, modify the value specified in the variable pair instead of editing each affected monitor policy.

EAA environment variables include system-defined variables and user-defined variables.

System-defined variables

System-defined variables are provided by default, and they cannot be created, deleted, or modified by users. System-defined variable names start with an underscore (_) sign. The variable values are set automatically depending on the event setting in the policy that uses the variables.

System-defined variables include the following types:

- **Public variable**—Available for any events.
- **Event-specific variable**—Available only for the specific event type. For example, the CLI event-specific variable is _cmd. When an CLI event is triggered, the value of _cmd is the command line matching the monitor policy.

Table 2 shows all system-defined variables.

Table 2 System-defined EAA environment variables by event type

Event	Variable name and description
Any event	_event_id: Event ID. _event_type: Event type. _event_type_string: Event type description. _event_time: Time when the event occurs. _event_severity: Severity level of an event.
CLI	_cmd: Commands that are matched.
Hotplug	_slot: ID of the member device that joins or leaves the IRF fabric
Interface	_ifname: Interface name.
Process	_process_name: Process name.
SNMP	_oid: OID of the MIB variable where an SNMP operation is performed. _oid_value: Value of the MIB variable.
SNMP-Notification	_oid: OID that is included in the SNMP notification.
Syslog	_syslog_pattern: Log message content.

User-defined variables

You can use user-defined variables for all types of events.

User-defined variable names can contain digits, characters, and the underscore sign (_), except that the underscore sign cannot be the leading character.

Restrictions and guidelines

Make sure the actions in different policies do not conflict. Policy execution result will be unpredictable if policies that conflict in actions are running concurrently.

You can assign the same policy name to a CLI-defined policy and a Tcl-defined policy. However, you cannot assign the same name to policies that are the same type.

A monitor policy supports only one event and runtime. If you configure multiple events for a policy, the most recent one takes effect.

A monitor policy supports a maximum of 64 valid user roles. User roles added after this limit is reached do not take effect.

Configuring a user-defined EAA environment variable

About this task

Configure user-defined EAA environment variables so that you can use them when creating EAA monitor policies.

Procedure

1. Enter system view.
   ```
   system-view
   ```
2. Configure a user-defined EAA environment variable.

rtm environment *var-name var-value*

For the system-defined variables, see Table 2.

Configuring a monitor policy from the CLI

Tasks at a glance

1. Creating a CLI-defined policy
2. (Optional.) Setting the size for the EAA-monitored log buffer
3. Configuring an event
4. Configuring an action
5. Assigning a user role to a CLI-defined policy
6. Configuring the policy action runtime
7. Enabling the CLI-defined monitor policy

Creating a CLI-defined policy

1. Enter system view.

   system-view
2. Create a CLI-defined policy and enter its view.

   rtm cli-policy *policy-name*

Setting the size for the EAA-monitored log buffer

About this task

This task is required only when a syslog event is specified for a CLI-defined policy.

After you specify and enable a syslog event EAA monitor policy, the system copies a log to the EAA-monitored log buffer upon generation of the log. The EAA module compares the log in the buffer with the log event. If they match, the monitor policy is triggered.

Under normal circumstances, you can use the default size setting for the EAA-monitored log buffer. However, when a feature is abnormal or multiple debugging functions are enabled, a large number of logs might be generated in a short time, causing some logs to be discarded before they are matched. In this case, you can increase the size of the EAA-monitored log buffer according to the device memory usage.

Procedure

1. Enter system view.

   system-view
2. Set the size for the EAA-monitored log buffer.

   rtm event syslog buffer-size *buffer-size*

   By default, the EAA-monitored log buffer can store a maximum of 50000 logs.

Configuring an event

Restrictions and guidelines

A monitor policy supports only one event. If you configure multiple events for a policy, the most recent one takes effect.

Procedure

1. Enter system view.

   system-view

2. Create a CLI-defined policy and enter its view.

   rtm cli-policy *policy-name*

3. Configure an event for the policy. Choose one option as needed:

   - Configure a CLI event.

     event cli { **async** [**skip**] | **sync** } **mode** { **execute** | **help** | **tab** } **pattern** *regular-exp*

   - Configure a hotplug event.

     event hotplug [**insert** | **remove**] **slot** *slot-number*

   - Configure an interface event.

     event interface *interface-list* **monitor-obj** *monitor-obj* **start-op** *start-op* **start-val** *start-val* **restart-op** *restart-op* **restart-val** *restart-val* [**interval** *interval*]

   - Configure a process event.

     event process { **exception** | **restart** | **shutdown** | **start** } [**name** *process-name* [**instance** *instance-id*]] [**slot** *slot-number*]

   - Configure an SNMP event.

     event snmp oid *oid* **monitor-obj** { **get** | **next** } **start-op** *start-op* **start-val** *start-val* **restart-op** *restart-op* **restart-val** *restart-val* [**interval** *interval*]

   - Configure an SNMP-Notification event.

     event snmp-notification oid *oid* **oid-val** *oid-val* **op** *op* [**drop**]

   - Configure a Syslog event.

     event syslog priority { *priority* | **all** } **msg** *msg* **occurs** *times* **period** *period*

   - Configure a track event.

     event track *track-list* **state { negative** | **positive** } [**suppress-time** *suppress-time*]

   By default, a monitor policy does not contain an event.

Configuring an action

Restrictions and guidelines

You can configure a series of actions to be executed in response to the event specified in a monitor policy. EAA executes the actions in ascending order of action IDs. When you add actions to a policy, you must make sure the execution order is correct. If two actions have the same ID, the most recent one takes effect.

Procedure

1. Enter system view.

   system-view

2. Create a CLI-defined policy and enter its view.

   rtm cli-policy *policy-name*

3. Configure the actions to take when the event occurs. Choose the options to configure as needed:

- Configure a CLI action.
  action *number* **cli** *command-line*
- Configure a reboot action.
  action *number* **reboot** [**slot** *slot-number*]
- Configure an active/standby switchover action.
  action *number* **switchover**
- Configure a logging action.
  action *number* **syslog priority** *priority* **facility** *local-number* **msg** *msg-body*

By default, a monitor policy does not contain any actions.

Assigning a user role to a CLI-defined policy

Restrictions and guidelines

An EAA policy cannot have both the **security-audit** user role and any other user roles. Any previously assigned user roles are automatically removed when you assign the **security-audit** user role to the policy. The previously assigned **security-audit** user role is automatically removed when you assign any other user roles to the policy.

Procedure

1. Enter system view.
   system-view
2. Create a CLI-defined policy and enter its view.
   rtm cli-policy *policy-name*
3. (Optional.) Assign a user role to the policy.
   user-role *role-name*
   By default, a monitor policy contains user roles that its creator had at the time of policy creation.

Configuring the policy action runtime

1. Enter system view.
   system-view
2. Create a CLI-defined policy and enter its view.
   rtm cli-policy *policy-name*
3. (Optional.) Configure the policy action runtime.
   running-time *time*
   The default policy action runtime is 20 seconds.
   If you configure multiple action runtimes for a policy, the most recent one takes effect.

Enabling the CLI-defined monitor policy

About this task

A CLI-defined monitor policy takes effect only after you enable it.

Procedure

1. Enter system view.
   system-view

2. Create a CLI-defined policy and enter its view.
   rtm cli-policy *policy-name*
3. Enable the CLI-defined policy.
   commit

Configuring a monitor policy by using Tcl

About this task

A Tcl script contains two parts: Line 1 and the other lines.

- Line 1

  Line 1 defines the event, user roles, and policy action runtime. After you create and enable a Tcl monitor policy, the device immediately parses, delivers, and executes Line 1.

  Line 1 must use the following format:

  ::platformtools::rtm::event_register *event-type arg1 arg2 arg3* … **user-role** *role-name1* | [**user-role** *role-name2* | […]] [**running-time** *running-time*]

  - The *arg1 arg2 arg3* … arguments represent event matching rules. If an argument value contains spaces, use double quotation marks ("") to enclose the value. For example, "a b c."
  - The configuration requirements for the *event-type*, *user-role*, and *running-time* arguments are the same as those for a CLI-defined monitor policy.

- The other lines

  From the second line, the Tcl script defines the actions to be executed when the monitor policy is triggered. You can use multiple lines to define multiple actions. The system executes these actions in sequence. The following actions are available:

  - Standard Tcl commands.
  - EAA-specific Tcl actions:
    - switchover (**::platformtools::rtm::action switchover**)
    - syslog (**::platformtools::rtm::action syslog priority** *priority* **facility** *local-number* **msg** *msg-body*). For more information about these arguments, see EAA commands in *Network Management and Monitoring Command Reference*.
  - Commands supported by the device.

Restrictions and guidelines

To revise the Tcl script of a policy, you must suspend all monitor policies first, and then resume the policies after you finish revising the script. The system cannot execute a Tcl-defined policy if you edit its Tcl script without first suspending these policies.

Procedure

1. Download the Tcl script file to the device by using FTP or TFTP.

   For more information about using FTP and TFTP, see *Fundamentals Configuration Guide*.
2. Create and enable a Tcl monitor policy.
   a. Enter system view.
      system-view
   b. Create a Tcl-defined policy and bind it to the Tcl script file.
      rtm tcl-policy *policy-name tcl-filename*

   By default, no Tcl policies exist.

Make sure the script file is saved on all IRF member devices. This practice ensures that the policy can run correctly after a master/subordinate switchover occurs or the member device where the script file resides leaves the IRF.

Suspending monitor policies

About this task

This task suspends all CLI-defined and Tcl-defined monitor policies. If a policy is running when you perform this task, the system suspends the policy after it executes all the actions.

Restrictions and guidelines

To restore the operation of the suspended policies, execute the **undo rtm scheduler suspend** command.

Procedure

1. Enter system view.
   system-view
2. Suspend monitor policies.
   rtm scheduler suspend

Display and maintenance commands for EAA

Execute **display** commands except for the **display this** command in any view.

Task	Command
Display the running configuration of all CLI-defined monitor policies.	**display current-configuration**
Display user-defined EAA environment variables.	**display rtm environment** [*var-name*]
Display EAA monitor policies.	**display rtm policy** { **active** | **registered** [**verbose**] } [*policy-name*]
Display the running configuration of a CLI-defined monitor policy in CLI-defined monitor policy view.	**display this**

EAA configuration examples

Example: Configuring a CLI event monitor policy by using Tcl

Network configuration

As shown in Figure 2, use Tcl to create a monitor policy on the Device. This policy must meet the following requirements:

- EAA sends the log message "rtm_tcl_test is running" when a command that contains the **display this** string is entered.
- The system executes the command only after it executes the policy successfully.

Figure 2 Network diagram

Procedure

Edit a Tcl script file (rtm_tcl_test.tcl, in this example) for EAA to send the message "rtm_tcl_test is running" when a command that contains the **display this** string is executed.

```
::platformtools::rtm::event_register cli sync mode execute pattern display this
user-role network-admin
::platformtools::rtm::action syslog priority 1 facility local4 msg rtm_tcl_test is
running
```

Download the Tcl script file from the TFTP server at **1.2.1.1**.

```
<Sysname> tftp 1.2.1.1 get rtm_tcl_test.tcl
```

Create Tcl-defined policy **test** and bind it to the Tcl script file.

```
<Sysname> system-view
[Sysname] rtm tcl-policy test rtm_tcl_test.tcl
[Sysname] quit
```

Verifying the configuration

Execute the **display rtm policy registered** command to verify that a Tcl-defined policy named **test** is displayed in the command output.

```
<Sysname> display rtm policy registered
Total number: 1
Type  Event             TimeRegistered       PolicyName
TCL   CLI               Aug 01 09:47:12 2019 test
```

Enable the information center to output log messages to the current monitoring terminal.

```
<Sysname> terminal monitor
The current terminal is enabled to display logs.
<Sysname> system-view
[Sysname] info-center enable
Information center is enabled.
[Sysname] quit
```

Execute the **display this** command. Verify that the system displays an "rtm_tcl_test is running" message and a message that the policy is being executed successfully.

```
[Sysname] display this
%Aug  1 09:50:04:634 2019 Sysname RTM/1/RTM_ACTION: rtm_tcl_test is running
%Aug  1 09:50:04:636 2019 Sysname RTM/6/RTM_POLICY: TCL policy test is running
successfully.
#
return
```

Example: Configuring a CLI event monitor policy from the CLI

Network configuration

Configure a policy from the CLI to monitor the event that occurs when a question mark (?) is entered at the command line that contains letters and digits.

When the event occurs, the system executes the command and sends the log message "hello world" to the information center.

Procedure

Create CLI-defined policy **test** and enter its view.

```
<Sysname> system-view
[Sysname] rtm cli-policy test
```

Add a CLI event that occurs when a question mark (?) is entered at any command line that contains letters and digits.

```
[Sysname-rtm-test] event cli async mode help pattern [a-zA-Z0-9]
```

Add an action that sends the message "hello world" with a priority of 4 from the logging facility **local3** when the event occurs.

```
[Sysname-rtm-test] action 0 syslog priority 4 facility local3 msg "hello world"
```

Add an action that enters system view when the event occurs.

```
[Sysname-rtm-test] action 2 cli system-view
```

Add an action that creates VLAN 2 when the event occurs.

```
[Sysname-rtm-test] action 3 cli vlan 2
```

Set the policy action runtime to 2000 seconds.

```
[Sysname-rtm-test] running-time 2000
```

Specify the **network-admin** user role for executing the policy.

```
[Sysname-rtm-test] user-role network-admin
```

Enable the policy.

```
[Sysname-rtm-test] commit
```

Verifying the configuration

Execute the **display rtm policy registered** command to verify that a CLI-defined policy named **test** is displayed in the command output.

```
[Sysname-rtm-test] display rtm policy registered
Total number: 1
Type  Event      TimeRegistered       PolicyName
CLI   CLI        Aug  1 14:56:50 2019 test
```

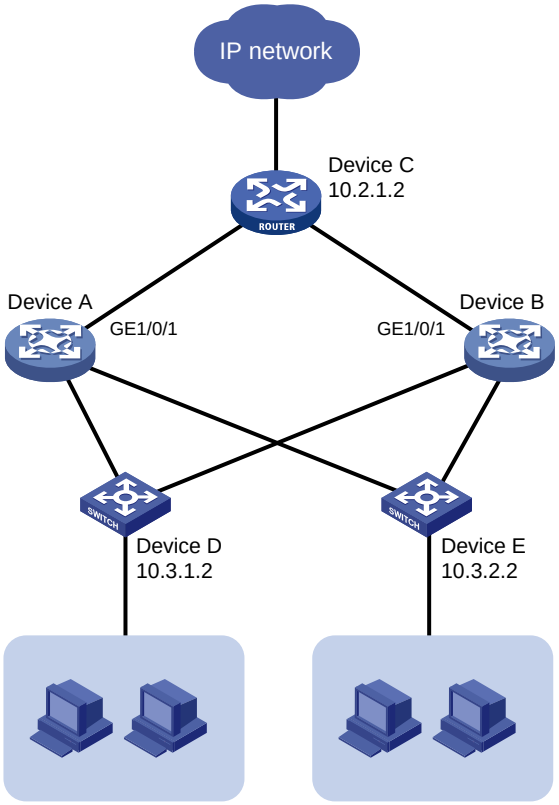
Enable the information center to output log messages to the current monitoring terminal.

```
[Sysname-rtm-test] return
<Sysname> terminal monitor
The current terminal is enabled to display logs.
<Sysname> system-view
[Sysname] info-center enable
Information center is enabled.
[Sysname] quit
```

Enter a question mark (?) at a command line that contains a letter **d**. Verify that the system displays a "hello world" message and a message that the policy is being executed successfully on the terminal screen.

```
<Sysname> d?
  debugging
  delete
  diagnostic-logfile
  dir
  display
```

```
<Sysname>d%Aug  1 14:57:20:218 2019 Sysname RTM/4/RTM_ACTION: "hello world"
%Aug  1 14:58:11:170 2019 Sysname RTM/6/RTM_POLICY: CLI policy test is running
successfully.
```



Example: Configuring a track event monitor policy from the CLI

Network configuration

As shown in Figure 3, Device A has established BGP sessions with Device D and Device E. Traffic from Device D and Device E to the Internet is forwarded through Device A.

Configure a CLI-defined EAA monitor policy on Device A to disconnect the sessions with Device D and Device E when GigabitEthernet 1/0/1 connected to Device C is down. In this way, traffic from Device D and Device E to the Internet can be forwarded through Device B.

Figure 3 Network diagram

Procedure

Display BGP peer information for Device A.

```
<DeviceA> display bgp peer ipv4

 BGP local router ID: 1.1.1.1
 Local AS number: 100
 Total number of peers: 3                 Peers in established state: 3
```

```
* - Dynamically created peer
Peer                    AS  MsgRcvd  MsgSent OutQ PrefRcv Up/Down  State

10.2.1.2                200       13       16    0       0 00:16:12 Established
10.3.1.2                300       13       16    0       0 00:10:34 Established
10.3.2.2                300       13       16    0       0 00:10:38 Established
```

Create track entry **1** and associate it with the link state of GigabitEthernet 1/0/1.

```
<Device A> system-view
[Device A] track 1 interface gigabitethernet 1/0/1
```

Configure a CLI-defined EAA monitor policy so that the system automatically disables session establishment with Device D and Device E when GigabitEthernet 1/0/1 is down.

```
[Device A] rtm cli-policy test
[Device A-rtm-test] event track 1 state negative
[Device A-rtm-test] action 0 cli system-view
[Device A-rtm-test] action 1 cli bgp 100
[Device A-rtm-test] action 2 cli peer 10.3.1.2 ignore
[Device A-rtm-test] action 3 cli peer 10.3.2.2 ignore
[Device A-rtm-test] user-role network-admin
[Device A-rtm-test] commit
[Device A-rtm-test] quit
```

Verifying the configuration

Shut down GigabitEthernet 1/0/1.

```
[Device A] interface gigabitethernet 1/0/1
[Device A-GigabitEthernet1/0/1] shutdown
```

Execute the **display bgp peer ipv4** command on Device A to display BGP peer information. Verify that no BGP peer is in established state.

Example: Configuring a CLI event monitor policy with EAA environment variables from the CLI

Network configuration

Define an environment variable to match the IP address 1.1.1.1.

Configure a policy from the CLI to monitor the event that occurs when a command line that contains **loopback0** is executed. In the policy, use the environment variable for IP address assignment.

When the event occurs, the system performs the following tasks:

- Creates the Loopback 0 interface.
- Assigns 1.1.1.1/24 to the interface.
- Sends the matching command line to the information center.

Procedure

Configure an EAA environment variable for IP address assignment. The variable name is **loopback0IP**, and the variable value is **1.1.1.1**.

```
<Sysname> system-view
[Sysname] rtm environment loopback0IP 1.1.1.1
```

Create the CLI-defined policy **test** and enter its view.

```
[Sysname] rtm cli-policy test
```

Add a CLI event that occurs when a command line that contains **loopback0** is executed.

```
[Sysname-rtm-test] event cli async mode execute pattern loopback0
```

Add an action that enters system view when the event occurs.

```
[Sysname-rtm-test] action 0 cli system-view
```

Add an action that creates the interface Loopback 0 and enters loopback interface view.

```
[Sysname-rtm-test] action 1 cli interface loopback 0
```

Add an action that assigns the IP address 1.1.1.1 to Loopback 0. The **loopback0IP** variable is used in the action for IP address assignment.

```
[Sysname-rtm-test] action 2 cli ip address $loopback0IP 24
```

Add an action that sends the matching **loopback0** command with a priority of 0 from the logging facility **local7** when the event occurs.

```
[Sysname-rtm-test] action 3 syslog priority 0 facility local7 msg $_cmd
```

Specify the **network-admin** user role for executing the policy.

```
[Sysname-rtm-test] user-role network-admin
```

Enable the policy.

```
[Sysname-rtm-test] commit
[Sysname-rtm-test] return
<Sysname>
```

Verifying the configuration

Enable the information center to output log messages to the current monitoring terminal.

```
<Sysname> terminal monitor
The current terminal is enabled to display logs.
<Sysname> terminal log level debugging
<Sysname> system-view
[Sysname] info-center enable
Information center is enabled.
```

Execute the **loopback0** command. Verify that the system displays a "loopback0" message and a message that the policy is being executed successfully on the terminal screen.

```
[Sysname] interface loopback0
[Sysname-LoopBack0]%Aug  1 09:46:10:592 2019 Sysname RTM/7/RTM_ACTION: interface
loopback0
%Aug  1 09:46:10:613 2019 Sysname RTM/6/RTM_POLICY: CLI policy test is running
successfully.
```

Verify that Loopback 0 has been created and its IP address is 1.1.1.1.

```
<Sysname-LoopBack0> display interface loopback brief
Brief information on interfaces in route mode:
Link: ADM - administratively down; Stby - standby
Protocol: (s) - spoofing
Interface            Link Protocol Primary IP         Description
Loop0                UP   UP(s)    1.1.1.1

<Sysname-LoopBack0>
```

Monitoring and maintaining processes

About monitoring and maintaining processes

The system software of the device is a full-featured, modular, and scalable network operating system based on the Linux kernel. The system software features run the following types of independent processes:

- **User process**—Runs in user space. Most system software features run user processes. Each process runs in an independent space so the failure of a process does not affect other processes. The system automatically monitors user processes. The system supports preemptive multithreading. A process can run multiple threads to support multiple activities. Whether a process supports multithreading depends on the software implementation.
- **Kernel thread**—Runs in kernel space. A kernel thread executes kernel code. It has a higher security level than a user process. If a kernel thread fails, the system breaks down. You can monitor the running status of kernel threads.

Process monitoring and maintenance tasks at a glance

To monitor and maintain processes, perform the following tasks:

- Monitoring and maintaining user processes
  - Monitoring and maintaining processes

    The commands in this section apply to both user processes and kernel threads.
  - Monitoring and maintaining user processes

    The commands in this section apply only to user processes.
- Monitoring and maintaining kernel threads
  - Monitoring and maintaining processes

    The commands in this section apply to both user processes and kernel threads.
  - Monitoring and maintaining kernel threads

    The commands in this section apply only to kernel threads.

Monitoring and maintaining processes

About this task

The commands in this section apply to both user processes and kernel threads. You can use the commands for the following purposes:

- Display the overall memory usage.
- Display the running processes and their memory and CPU usage.
- Locate abnormal processes.

If a process consumes excessive memory or CPU resources, the system identifies the process as an abnormal process.

- If an abnormal process is a user process, troubleshoot the process as described in "Monitoring and maintaining user processes."

- If an abnormal process is a kernel thread, troubleshoot the process as described in "Monitoring and maintaining kernel threads."

Procedure

Execute the following commands in any view.

Task	Command
Display memory usage.	**display memory** [**summary**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display process state information.	**display process** [**all** | **job** *job-id* | **name** *process-name*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display CPU usage for all processes.	**display process cpu** [**slot** *slot-number* [**cpu** *cpu-number*]]
Monitor process running state.	**monitor process** [**dumbtty**] [**iteration** *number*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Monitor thread running state.	**monitor thread** [**dumbtty**] [**iteration** *number*] [**slot** *slot-number* [**cpu** *cpu-number*]]

For more information about the **display memory** command, see *Fundamentals Command Reference*.

Monitoring and maintaining user processes

About monitoring and maintaining user processes

Use this feature to monitor abnormal user processes and locate problems.

Configuring core dump

About this task

The core dump feature enables the system to generate a core dump file each time a process crashes until the maximum number of core dump files is reached. A core dump file stores information about the process. You can send the core dump files to H3C Support to troubleshoot the problems.

Restrictions and guidelines

Core dump files consume storage resources. Enable core dump only for processes that might have problems.

Procedure

Execute the following commands in user view:

1. (Optional.) Specify the directory for saving core dump files.

   exception filepath *directory*

   By default, the directory for saving core dump files is the root directory of the default file system. For more information about the default file system, see file system management in *Fundamentals Configuration Guide*.

2. Enable core dump for a process and specify the maximum number of core dump files, or disable core dump for a process.

   process core { **maxcore** *value* | **off** } { **job** *job-id* | **name** *process-name* }

By default, a process generates a core dump file for the first exception and does not generate any core dump files for subsequent exceptions.

Display and maintenance commands for user processes

Execute **display** commands in any view and other commands in user view.

Task	Command
Display context information for process exceptions.	**display exception context** [**count** *value*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display the core dump file directory.	**display exception filepath** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display log information for all user processes.	**display process log** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display memory usage for all user processes.	**display process memory** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display heap memory usage for a user process.	**display process memory heap job** *job-id* [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display memory content starting from a specified memory block for a user process.	**display process memory heap job** *job-id* **address** *starting-address* **length** *memory-length* [**slot** *slot-number* [**cpu** *cpu-number*]]
Display the addresses of memory blocks with a specified size used by a user process.	**display process memory heap job** *job-id* **size** *memory-size* [**offset** *offset-size*] [**slot** *slot-number* [**cpu** *cpu-number*]]
Clear context information for process exceptions.	**reset exception context** [**slot** *slot-number* [**cpu** *cpu-number*]]

Monitoring and maintaining kernel threads

Configuring kernel thread deadloop detection

About this task

Kernel threads share resources. If a kernel thread monopolizes the CPU, other threads cannot run, resulting in a deadloop.

This feature enables the device to detect deadloops. If a thread occupies the CPU for a specific interval, the device determines that a deadloop has occurred and generates a deadloop message.

Restrictions and guidelines

CAUTION:

Change kernel thread deadloop detection settings only under the guidance of H3C Support. Inappropriate configuration can cause system breakdown.

Procedure

1. Enter system view.

   system-view

2. Enable kernel thread deadloop detection.

   monitor kernel deadloop enable [**slot** *slot-number* [**cpu** *cpu-number* [**core** *core-number*&<1-64>]]]

   By default, kernel thread deadloop detection is enabled.

3. (Optional.) Set the threshold for identifying a kernel thread deadloop.

   monitor kernel deadloop time *time* [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, the threshold for identifying a kernel thread deadloop is 20 seconds.

4. (Optional.) Exclude a kernel thread from kernel thread deadloop detection.

   monitor kernel deadloop exclude-thread *tid* [**slot** *slot-number* [**cpu** *cpu-number*]]

   When enabled, kernel thread deadloop detection monitors all kernel threads by default.

5. (Optional.) Specify the action to be taken in response to a kernel thread deadloop.

   monitor kernel deadloop action { **reboot** | **record-only** } [**slot** *slot-number* [**cpu** *cpu-number*]]

   The default action is **reboot**.

Configuring kernel thread starvation detection

About this task

Starvation occurs when a thread is unable to access shared resources.

Kernel thread starvation detection enables the system to detect and report thread starvation. If a thread is not executed within a specific interval, the system determines that a starvation has occurred and generates a starvation message.

Thread starvation does not impact system operation. A starved thread can automatically run when certain conditions are met.

Restrictions and guidelines

CAUTION:

Configure kernel thread starvation detection only under the guidance of H3C Support. Inappropriate configuration can cause system breakdown.

Procedure

1. Enter system view.

   system-view

2. Enable kernel thread starvation detection.

   monitor kernel starvation enable [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, kernel thread starvation detection is disabled.

3. (Optional.) Set the threshold for identifying a kernel thread starvation.

   monitor kernel starvation time *time* [**slot** *slot-number* [**cpu** *cpu-number*]]

   By default, the threshold for identifying a kernel thread starvation is 120 seconds.

4. (Optional.) Exclude a kernel thread from kernel thread starvation detection.

monitor kernel starvation exclude-thread *tid* [**slot** *slot-number* [**cpu** *cpu-number*]]

When enabled, kernel thread starvation detection monitors all kernel threads by default.

Display and maintenance commands for kernel threads

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display kernel thread deadloop detection configuration.	**display kernel deadloop configuration** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread deadloop information.	**display kernel deadloop** *show-number* [*offset*] [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread exception information.	**display kernel exception** *show-number* [*offset*] [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread reboot information.	**display kernel reboot** *show-number* [*offset*] [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread starvation detection configuration.	**display kernel starvation configuration** [**slot** *slot-number* [**cpu** *cpu-number*]]
Display kernel thread starvation information.	**display kernel starvation** *show-number* [*offset*] [**verbose**] [**slot** *slot-number* [**cpu** *cpu-number*]]
Clear kernel thread deadloop information.	**reset kernel deadloop** [**slot** *slot-number* [**cpu** *cpu-number*]]
Clear kernel thread exception information.	**reset kernel exception** [**slot** *slot-number* [**cpu** *cpu-number*]]
Clear kernel thread reboot information.	**reset kernel reboot** [**slot** *slot-number* [**cpu** *cpu-number*]]
Clear kernel thread starvation information.	**reset kernel starvation** [**slot** *slot-number* [**cpu** *cpu-number*]]

Configuring port mirroring

About port mirroring

Port mirroring copies the packets passing through a port to a port that connects to a data monitoring device for packet analysis.

Terminology

The following terms are used in port mirroring configuration.

Mirroring source

The mirroring sources can be one or more monitored ports called source ports.

Packets passing through mirroring sources are copied to a port connecting to a data monitoring device for packet analysis. The copies are called mirrored packets.

Source device

The device where the mirroring sources reside is called a source device.

Mirroring destination

The mirroring destination connects to a data monitoring device and is the destination port (also known as the monitor port) of mirrored packets. Mirrored packets are sent out of the monitor port to the data monitoring device.

A monitor port might receive multiple copies of a packet when it monitors multiple mirroring sources. For example, two copies of a packet are received on Port A when the following conditions exist:

- Port A is monitoring bidirectional traffic of Port B and Port C on the same device.
- The packet travels from Port B to Port C.

Destination device

The device where the monitor port resides is called the destination device.

Mirroring direction

The mirroring direction specifies the direction of the traffic that is copied on a mirroring source.

- **Inbound**—Copies packets received.
- **Outbound**—Copies packets sent.
- **Bidirectional**—Copies packets received and sent.

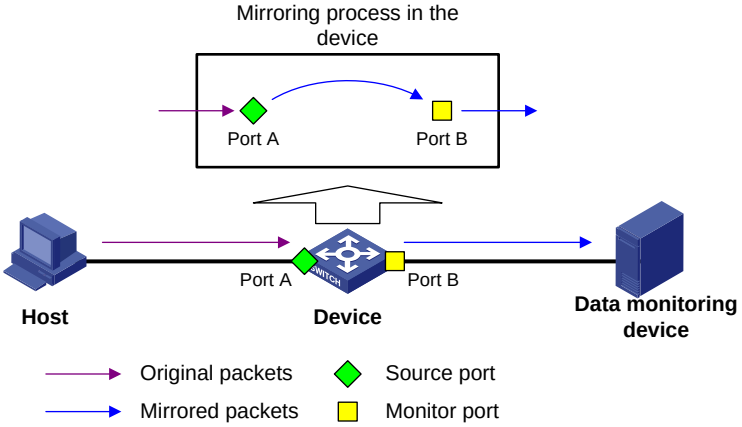
Mirroring group

Port mirroring is implemented through mirroring groups. Mirroring groups can be classified into local mirroring groups, remote source groups, and remote destination groups.

Reflector port, egress port, and remote probe VLAN

Reflector ports, remote probe VLANs, and egress ports are used for Layer 2 remote port mirroring. The remote probe VLAN is a dedicated VLAN for transmitting mirrored packets to the destination device. Both the reflector port and egress port reside on a source device and send mirrored packets to the remote probe VLAN.

On port mirroring devices, all ports except source, destination, reflector, and egress ports are called common ports.



Port mirroring classification

Port mirroring can be classified into local port mirroring and remote port mirroring.

- **Local port mirroring**—The source device is directly connected to a data monitoring device. The source device also acts as the destination device and forwards mirrored packets directly to the data monitoring device.
- **Remote port mirroring**—The source device is not directly connected to a data monitoring device. The source device sends mirrored packets to the destination device, which forwards the packets to the data monitoring device. Because the source device and destination device are on the same Layer 2 network, remote port mirroring is also called Layer 2 remote port mirroring or remote SPAN (RSPAN).

Local port mirroring

Figure 1 Local port mirroring implementation

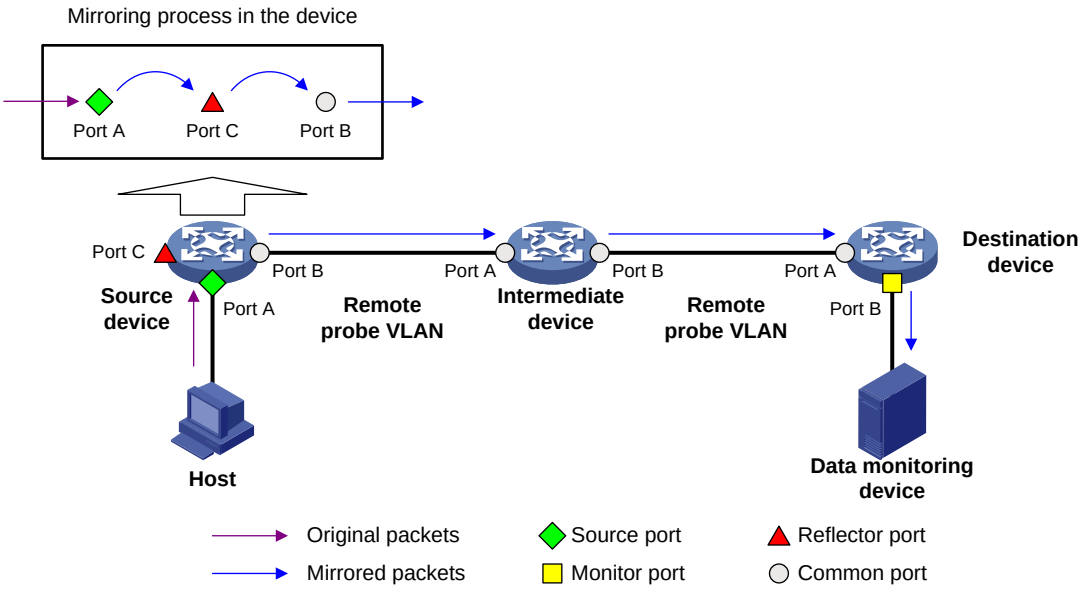
As shown in Figure 1, the source port (Port A) and the monitor port (Port B) reside on the same device. Packets received on Port A are copied to Port B. Port B then forwards the packets to the data monitoring device for analysis.

Layer 2 remote port mirroring

In Layer 2 remote port mirroring, the mirroring sources and destination reside on different devices and are in different mirroring groups.

A remote source group is a mirroring group that contains the mirroring sources. A remote destination group is a mirroring group that contains the mirroring destination. Intermediate devices are the devices between the source device and the destination device.

Layer 2 remote port mirroring can be implemented through the reflector port method or the egress port method.



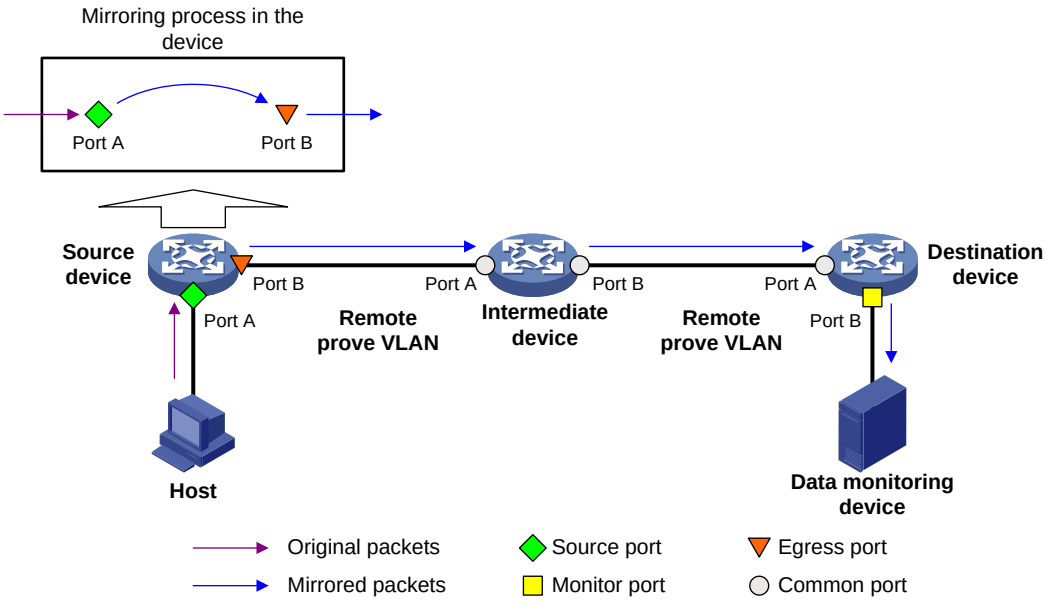
Reflector port method

In Layer 2 remote port mirroring that uses the reflector port method, packets are mirrored as follows:

1. The source device copies packets received on the mirroring sources to the reflector port.
2. The reflector port broadcasts the mirrored packets in the remote probe VLAN.
3. The intermediate devices transmit the mirrored packets to the destination device through the remote probe VLAN.
4. Upon receiving the mirrored packets, the destination device determines whether the ID of the mirrored packets is the same as the remote probe VLAN ID. If the two VLAN IDs match, the

destination device forwards the mirrored packets to the data monitoring device through the monitor port.

Figure 2 Layer 2 remote port mirroring implementation through the reflector port method



Egress port method

In Layer 2 remote port mirroring that uses the egress port method, packets are mirrored as follows:

1. The source device copies packets received on the mirroring sources to the egress port.
2. The egress port forwards the mirrored packets to the intermediate devices.
3. The intermediate devices flood the mirrored packets in the remote probe VLAN and transmit the mirrored packets to the destination device.
4. Upon receiving the mirrored packets, the destination device determines whether the ID of the mirrored packets is the same as the remote probe VLAN ID. If the two VLAN IDs match, the destination device forwards the mirrored packets to the data monitoring device through the monitor port.

Figure 3 Layer 2 remote port mirroring implementation through the egress port method

Restrictions and guidelines: Port mirroring configuration

The reflector port method for Layer 2 remote port mirroring can be used to implement local port mirroring with multiple data monitoring devices.

In the reflector port method, the reflector port broadcasts mirrored packets in the remote probe VLAN. By assigning the ports that connect to data monitoring devices to the remote probe VLAN, you can implement local port mirroring to mirror packets to multiple data monitoring devices. The egress port method cannot implement local port mirroring in this way.

Configuring local port mirroring

Restrictions and guidelines for local port mirroring configuration

A local mirroring group takes effect only after it is configured with the monitor port and mirroring sources.

Local port mirroring tasks at a glance

To configure local port mirroring, perform the following tasks:

1. Configuring mirroring sources
2. Configuring the monitor port

Creating a local mirroring group

1. Enter system view.

system-view

2. Create a local mirroring group.
   mirroring-group *group-id* **local**

Configuring mirroring sources

Restrictions and guidelines for mirroring source configuration

When you configure source ports for a local mirroring group, follow these restrictions and guidelines:

- A mirroring group can contain multiple source ports.
- A port can act as a source port for multiple mirroring groups.
- A source port cannot be configured as a reflector port, egress port, or monitor port.

Configuring source ports

- Configure source ports in system view:
  a. Enter system view.
     system-view
  b. Configure source ports for a local mirroring group.
     mirroring-group *group-id* **mirroring-port** *interface-list* { **both** | **inbound** | **outbound** }
     By default, no source port is configured for a local mirroring group.
- Configure source ports in interface view:
  a. Enter system view.
     system-view
  b. Enter interface view.
     interface *interface-type interface-number*
  c. Configure the port as a source port for a local mirroring group.
     mirroring-group *group-id* **mirroring-port** { **both** | **inbound** | **outbound** }
     By default, a port does not act as a source port for any local mirroring groups.

Configuring the monitor port

Restrictions and guidelines

Do not enable the spanning tree feature on the monitor port.

Only one monitor port can be specified for a local mirroring group.

For a Layer 2 aggregate interface configured as the monitor port of a mirroring group, do not configure its member ports as source ports of the mirroring group.

Use a monitor port only for port mirroring, so the data monitoring device receives only the mirrored traffic.

Procedure

- Configure the monitor port in system view:
  a. Enter system view.
     system-view
  b. Configure the monitor port for a local mirroring group.

mirroring-group *group-id* **monitor-port** *interface-type interface-number*

By default, no monitor port is configured for a local mirroring group.

- Configure the monitor port in interface view:
  a. Enter system view.
     system-view
  b. Enter interface view.
     interface *interface-type interface-number*
  c. Configure the port as the monitor port for a mirroring group.
     mirroring-group *group-id* **monitor-port**
     By default, a port does not act as the monitor port for any local mirroring groups.

Configuring local port mirroring group with multiple monitoring devices

About local port mirroring with multiple monitoring devices

To monitor interesting traffic passing through a device on multiple directly connected data monitoring devices, configure local port mirroring with a remote probe VLAN as follows:

1. Configure a remote source group on the device.
2. Configure mirroring sources and a reflector port for the remote source group.
3. Specify a VLAN as the remote probe VLAN and assign the ports connecting to the data monitoring devices to the VLAN.

This configuration enables the device to copy packets received on the mirroring sources to the reflector port, which broadcasts the packets in the remote probe VLAN. The packets are then sent out of the member ports of the remote probe VLAN to the data monitoring devices.

Restrictions and guidelines

The reflector port must be a port not in use. Do not connect a network cable to the reflector port.

When a port is configured as a reflector port, the port restores to the factory default settings. You cannot configure other features on the reflector port.

Do not assign a source port of a mirroring group to the remote probe VLAN of the mirroring group.

A VLAN can act as the remote probe VLAN for only one remote source group. As a best practice, use the VLAN for port mirroring exclusively. Do not create a VLAN interface for the VLAN or configure other features for the VLAN.

The remote probe VLAN must be a static VLAN.

To delete a VLAN that has been configured as the remote probe VLAN for a mirroring group, remove the remote probe VLAN from the mirroring group first.

Procedure

1. Enter system view.
   system-view
2. Create a remote source group.
   mirroring-group *group-id* **remote-source**
3. Configure mirroring sources for the remote source group. Choose one option as needed:
   - Configure mirroring ports in system view.

mirroring-group *group-id* **mirroring-port** *interface-list* { **both** | **inbound** | **outbound** }

- Execute the following commands in sequence to enter interface view and then configure the interface as a source port.

  interface *interface-type interface-number*

  mirroring-group *group-id* **mirroring-port** { **both** | **inbound** | **outbound** }

  quit

4. Configure the reflector port for the remote source group.

   mirroring-group *group-id* **reflector-port** *reflector-port*

   By default, no reflector port is configured for a remote source group.
5. Create a VLAN and enter its view.

   vlan *vlan-id*
6. Assign the ports that connect to the data monitoring devices to the VLAN.

   port *interface-list*

   By default, a VLAN does not contain any ports.
7. Return to system view.

   quit
8. Specify the VLAN as the remote probe VLAN for the remote source group.

   mirroring-group *group-id* **remote-probe vlan** *vlan-id*

   By default, no remote probe VLAN is configured for a remote source group.

Configuring Layer 2 remote port mirroring

Restrictions and guidelines for Layer 2 remote port mirroring configuration

To ensure successful traffic mirroring, configure devices in the order of the destination device, the intermediate devices, and the source device.

If intermediate devices exist, configure the intermediate devices to allow the remote probe VLAN to pass through.

For a mirrored packet to successfully arrive at the remote destination device, make sure its VLAN ID is not removed or changed.

Do not configure both MVRP and Layer 2 remote port mirroring. Otherwise, MVRP might register the remote probe VLAN with incorrect ports, which would cause the monitor port to receive undesired copies. For more information about MVRP, see *Layer 2—LAN Switching Configuration Guide*.

To monitor the bidirectional traffic of a source port, disable MAC address learning for the remote probe VLAN on the source, intermediate, and destination devices. For more information about MAC address learning, see *Layer 2—LAN Switching Configuration Guide*.

Layer 2 remote port mirroring with reflector port configuration task list

Configuring the destination device

1. Creating a remote destination group

2. Configuring the monitor port
3. Configuring the remote probe VLAN
4. Assigning the monitor port to the remote probe VLAN

Configuring the source device

1. Creating a remote source group
2. Configuring mirroring sources
3. Configuring the reflector port
4. Configuring the remote probe VLAN

Layer 2 remote port mirroring with egress port configuration task list

Configuring the destination device

1. Creating a remote destination group
2. Configuring the monitor port
3. Configuring the remote probe VLAN
4. Assigning the monitor port to the remote probe VLAN

Configuring the source device

1. Creating a remote source group
2. Configuring mirroring sources
3. Configuring the egress port
4. Configuring the remote probe VLAN

Creating a remote destination group

Restrictions and guidelines

Perform this task on the destination device only.

Procedure

1. Enter system view.
   `system-view`
2. Create a remote destination group.
   `mirroring-group` *`group-id`* **`remote-destination`**

Configuring the monitor port

Restrictions and guidelines for monitor port configuration

Perform this task on the destination device only.

Do not enable the spanning tree feature on the monitor port.

For a Layer 2 aggregate interface configured as the monitor port of a mirroring group, do not configure its member ports as source ports of the mirroring group.

Use a monitor port only for port mirroring, so the data monitoring device receives only the mirrored traffic.

A monitor port can belong to only one mirroring group.

Only one monitor port can be specified for a remote destination group.

Configuring the monitor port in system view

1. Enter system view.
   system-view
2. Configure the monitor port for a remote destination group.
   mirroring-group *group-id* **monitor-port** *interface-type interface-number*
   By default, no monitor port is configured for a remote destination group.

Configuring the monitor port in interface view

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the port as the monitor port for a remote destination group.
   mirroring-group *group-id* **monitor-port**
   By default, a port does not act as the monitor port for any remote destination groups.

Configuring the remote probe VLAN

Restrictions and guidelines

This task is required on the both the source and destination devices.

Only an existing static VLAN can be configured as a remote probe VLAN.

When a VLAN is configured as a remote probe VLAN, use the remote probe VLAN for port mirroring exclusively.

Configure the same remote probe VLAN for the remote source group and the remote destination group.

Procedure

1. Enter system view.
   system-view
2. Configure the remote probe VLAN for the remote source or destination group.
   mirroring-group *group-id* **remote-probe vlan** *vlan-id*
   By default, no remote probe VLAN is configured for a remote source or destination group.

Assigning the monitor port to the remote probe VLAN

Restrictions and guidelines

Perform this task on the destination device only.

Procedure

1. Enter system view.
   system-view
2. Enter the interface view of the monitor port.
   interface *interface-type interface-number*
3. Assign the port to the remote probe VLAN.

- Assign an access port to the remote probe VLAN.
  port access vlan *vlan-id*
- Assign a trunk port to the remote probe VLAN.
  port trunk permit vlan *vlan-id*
- Assign a hybrid port to the remote probe VLAN.
  port hybrid vlan *vlan-id* { **tagged** | **untagged** }

For more information about the **port access vlan**, **port trunk permit vlan**, and **port hybrid vlan** commands, see *Layer 2—LAN Switching Command Reference*.

Creating a remote source group

Restrictions and guidelines

Perform this task on the source device only.

Procedure

1. Enter system view.
   system-view
2. Create a remote source group.
   mirroring-group *group-id* **remote-source**

Configuring mirroring sources

Restrictions and guidelines for mirroring source configuration

Perform this task on the source device only.

When you configure source ports for a remote source group, follow these restrictions and guidelines:

- Do not assign a source port of a mirroring group to the remote probe VLAN of the mirroring group.
- A mirroring group can contain multiple source ports.
- A port can act as a source port for multiple mirroring groups.
- A source port cannot be configured as a reflector port, monitor port, or egress port.

Configuring source ports

- Configure source ports in system view:
  a. Enter system view.
     system-view
  b. Configure source ports for a remote source group.
     mirroring-group *group-id* **mirroring-port** *interface-list* { **both** | **inbound** | **outbound** }
     By default, no source port is configured for a remote source group.
- Configure source ports in interface view:
  a. Enter system view.
     system-view
  b. Enter interface view.
     interface *interface-type interface-number*
  c. Configure the port as a source port for a remote source group.

mirroring-group *group-id* **mirroring-port** { **both** | **inbound** | **outbound** }

By default, a port does not act as a source port for any remote source groups.

Configuring the reflector port

Restrictions and guidelines for reflector port configuration

Perform this task on the source device only.

A remote source group supports only one reflector port.

Configuring the reflector port in system view

1. Enter system view.

   system-view

2. Configure the reflector port for a remote source group.

   mirroring-group *group-id* **reflector-port** *interface-type interface-number*

CAUTION:

- The port to be configured as a reflector port must be a port not in use. Do not connect a network cable to a reflector port.
- When a port is configured as a reflector port, the default settings of the port are automatically restored. You cannot configure other features on the reflector port.
- If an IRF port is bound to only one physical interface, do not configure the physical interface as a reflector port. Otherwise, the IRF might split.

By default, no reflector port is configured for a remote source group.

Configuring the reflector port in interface view

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Configure the port as the reflector port for a remote source group.

   mirroring-group *group-id* **reflector-port**

CAUTION:

- The port to be configured as a reflector port must be a port not in use. Do not connect a network cable to a reflector port.
- When a port is configured as a reflector port, the default settings of the port are automatically restored. You cannot configure other features on the reflector port.
- If an IRF port is bound to only one physical interface, do not configure the physical interface as a reflector port. Otherwise, the IRF might split.

By default, a port does not act as the reflector port for any remote source groups.

Configuring the egress port

Restrictions and guidelines for egress port configuration

Perform this task on the source device only.

Disable the following features on the egress port:

- Spanning tree.
- 802.1X.
- IGMP snooping.
- Static ARP.
- MAC address learning.

A port of an existing mirroring group cannot be configured as an egress port.

A mirroring group supports only one egress port.

Configuring the egress port in system view

1. Enter system view.
   system-view
2. Configure the egress port for a remote source group.
   mirroring-group *group-id* **monitor-egress** *interface-type interface-number*
   By default, no egress port is configured for a remote source group.
3. Enter the egress port view.
   interface *interface-type interface-number*
4. Assign the egress port to the remote probe VLAN.
   - Assign a trunk port to the remote probe VLAN.
     port trunk permit vlan *vlan-id*
   - Assign a hybrid port to the remote probe VLAN.
     port hybrid vlan *vlan-id* { **tagged** | **untagged** }

   For more information about the **port trunk permit vlan** and **port hybrid vlan** commands, see *Layer 2—LAN Switching Command Reference*.

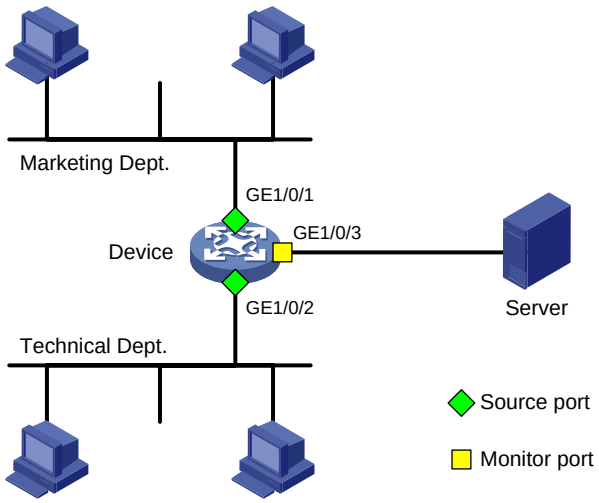
Configuring the egress port in interface view

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Configure the port as the egress port for a remote source group.
   mirroring-group *group-id* **monitor-egress**
   By default, a port does not act as the egress port for any remote source groups.

Display and maintenance commands for port mirroring

Execute **display** commands in any view.

Task	Command
Display mirroring group information.	**display mirroring-group** { *group-id* | **all** | **local** | **remote-destination** | **remote-source** }



Port mirroring configuration examples

Example: Configuring local port mirroring (in source port mode)

Network configuration

As shown in Figure 4, configure local port mirroring in source port mode to enable the server to monitor the bidirectional traffic of the two departments.

Figure 4 Network diagram

Procedure

Create local mirroring group 1.

```
<Device> system-view
[Device] mirroring-group 1 local
```

Configure GigabitEthernet 1/0/1 and GigabitEthernet 1/0/2 as source ports for local mirroring group 1.

```
[Device] mirroring-group 1 mirroring-port gigabitethernet 1/0/1 gigabitethernet 1/0/2
both
```

Configure GigabitEthernet 1/0/3 as the monitor port for local mirroring group 1.

```
[Device] mirroring-group 1 monitor-port gigabitethernet 1/0/3
```

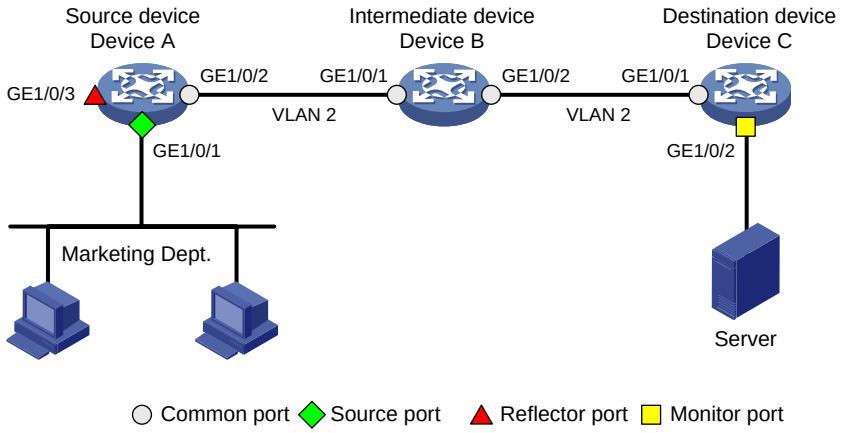
Disable the spanning tree feature on the monitor port (GigabitEthernet 1/0/3).

```
[Device] interface gigabitethernet 1/0/3
[Device-GigabitEthernet1/0/3] undo stp enable
[Device-GigabitEthernet1/0/3] quit
```

Verifying the configuration

Verify the mirroring group configuration.

```
[Device] display mirroring-group all
Mirroring group 1:
    Type: Local
    Status: Active
    Mirroring port:
```



```
    GigabitEthernet1/0/1   Both
    GigabitEthernet1/0/2   Both
Monitor port: GigabitEthernet1/0/3
```

Example: Configuring Layer 2 remote port mirroring (with reflector port)

Network configuration

As shown in Figure 5, configure Layer 2 remote port mirroring to enable the server to monitor the bidirectional traffic of the Marketing Department.

Figure 5 Network diagram

Procedure

1. Configure Device C (the destination device):

   # Configure GigabitEthernet 1/0/1 as a trunk port, and assign the port to VLAN 2.

   ```
   <DeviceC> system-view
   [DeviceC] interface gigabitethernet 1/0/1
   [DeviceC-GigabitEthernet1/0/1] port link-type trunk
   [DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 2
   [DeviceC-GigabitEthernet1/0/1] quit
   ```

   # Create a remote destination group.

   ```
   [DeviceC] mirroring-group 2 remote-destination
   ```

   # Create VLAN 2.

   ```
   [DeviceC] vlan 2
   ```

   # Disable MAC address learning for VLAN 2.

   ```
   [DeviceC-vlan2] undo mac-address mac-learning enable
   [DeviceC-vlan2] quit
   ```

   # Configure VLAN 2 as the remote probe VLAN for the mirroring group.

   ```
   [DeviceC] mirroring-group 2 remote-probe vlan 2
   ```

   # Configure GigabitEthernet 1/0/2 as the monitor port for the mirroring group.

   ```
   [DeviceC] interface gigabitethernet 1/0/2
   [DeviceC-GigabitEthernet1/0/2] mirroring-group 2 monitor-port
   ```

   # Disable the spanning tree feature on GigabitEthernet 1/0/2.

   ```
   [DeviceC-GigabitEthernet1/0/2] undo stp enable
   ```

Assign GigabitEthernet 1/0/2 to VLAN 2.

```
[DeviceC-GigabitEthernet1/0/2] port access vlan 2
[DeviceC-GigabitEthernet1/0/2] quit
```

2. Configure Device B (the intermediate device):

Create VLAN 2.

```
<DeviceB> system-view
[DeviceB] vlan 2
```

Disable MAC address learning for VLAN 2.

```
[DeviceB-vlan2] undo mac-address mac-learning enable
[DeviceB-vlan2] quit
```

Configure GigabitEthernet 1/0/1 as a trunk port, and assign the port to VLAN 2.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 2
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port, and assign the port to VLAN 2.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 2
[DeviceB-GigabitEthernet1/0/2] quit
```

3. Configure Device A (the source device):

Create a remote source group.

```
<DeviceA> system-view
[DeviceA] mirroring-group 1 remote-source
```

Create VLAN 2.

```
[DeviceA] vlan 2
```

Disable MAC address learning for VLAN 2.

```
[DeviceA-vlan2] undo mac-address mac-learning enable
[DeviceA-vlan2] quit
```

Configure VLAN 2 as the remote probe VLAN for the mirroring group.

```
[DeviceA] mirroring-group 1 remote-probe vlan 2
```

Configure GigabitEthernet 1/0/1 as a source port for the mirroring group.

```
[DeviceA] mirroring-group 1 mirroring-port gigabitethernet 1/0/1 both
```

Configure GigabitEthernet 1/0/3 as the reflector port for the mirroring group.

```
[DeviceA] mirroring-group 1 reflector-port gigabitethernet 1/0/3
This operation may delete all settings made on the interface. Continue? [Y/N]: y
```

Configure GigabitEthernet 1/0/2 as a trunk port, and assign the port to VLAN 2.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 2
[DeviceA-GigabitEthernet1/0/2] quit
```

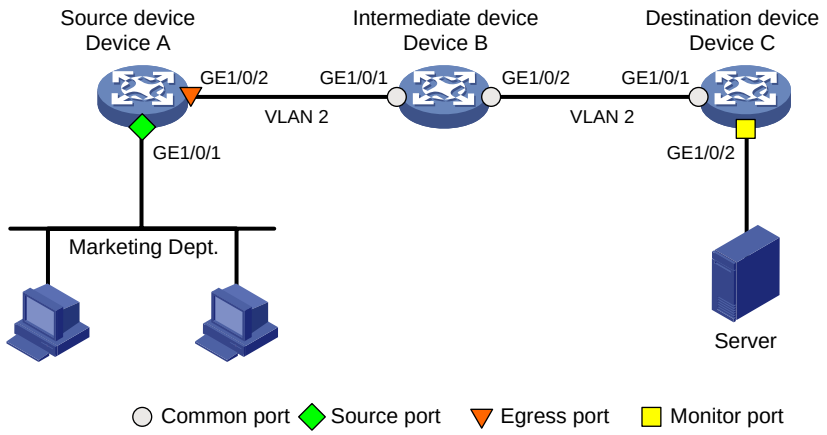
Verifying the configuration

Verify the mirroring group configuration on Device C.

```
[DeviceC] display mirroring-group all
Mirroring group 2:
    Type: Remote destination
    Status: Active
```

```
    Monitor port: GigabitEthernet1/0/2
    Remote probe VLAN: 2
```

Verify the mirroring group configuration on Device A.



```
[DeviceA] display mirroring-group all
Mirroring group 1:
    Type: Remote source
    Status: Active
    Mirroring port:
        GigabitEthernet1/0/1  Both
    Reflector port: GigabitEthernet1/0/3
    Remote probe VLAN: 2
```

Example: Configuring Layer 2 remote port mirroring (with egress port)

Network configuration

On the Layer 2 network shown in Figure 6, configure Layer 2 remote port mirroring to enable the server to monitor the bidirectional traffic of the Marketing Department.

Figure 6 Network diagram

Procedure

1. Configure Device C (the destination device):

   # Configure GigabitEthernet 1/0/1 as a trunk port, and assign the port to VLAN 2.

   ```
   <DeviceC> system-view
   [DeviceC] interface gigabitethernet 1/0/1
   [DeviceC-GigabitEthernet1/0/1] port link-type trunk
   [DeviceC-GigabitEthernet1/0/1] port trunk permit vlan 2
   [DeviceC-GigabitEthernet1/0/1] quit
   ```

   # Create a remote destination group.

   ```
   [DeviceC] mirroring-group 2 remote-destination
   ```

   # Create VLAN 2.

   ```
   [DeviceC] vlan 2
   ```

   # Disable MAC address learning for VLAN 2.

   ```
   [DeviceC-vlan2] undo mac-address mac-learning enable
   ```

```
[DeviceC-vlan2] quit
```

Configure VLAN 2 as the remote probe VLAN for the mirroring group.

```
[DeviceC] mirroring-group 2 remote-probe vlan 2
```

Configure GigabitEthernet 1/0/2 as the monitor port for the mirroring group.

```
[DeviceC] interface gigabitethernet 1/0/2
[DeviceC-GigabitEthernet1/0/2] mirroring-group 2 monitor-port
```

Disable the spanning tree feature on GigabitEthernet 1/0/2.

```
[DeviceC-GigabitEthernet1/0/2] undo stp enable
```

Assign GigabitEthernet 1/0/2 to VLAN 2 as an access port.

```
[DeviceC-GigabitEthernet1/0/2] port access vlan 2
[DeviceC-GigabitEthernet1/0/2] quit
```

2. Configure Device B (the intermediate device):

Create VLAN 2.

```
<DeviceB> system-view
[DeviceB] vlan 2
```

Disable MAC address learning for VLAN 2.

```
[DeviceB-vlan2] undo mac-address mac-learning enable
[DeviceB-vlan2] quit
```

Configure GigabitEthernet 1/0/1 as a trunk port, and assign the port to VLAN 2.

```
[DeviceB] interface gigabitethernet 1/0/1
[DeviceB-GigabitEthernet1/0/1] port link-type trunk
[DeviceB-GigabitEthernet1/0/1] port trunk permit vlan 2
[DeviceB-GigabitEthernet1/0/1] quit
```

Configure GigabitEthernet 1/0/2 as a trunk port, and assign the port to VLAN 2.

```
[DeviceB] interface gigabitethernet 1/0/2
[DeviceB-GigabitEthernet1/0/2] port link-type trunk
[DeviceB-GigabitEthernet1/0/2] port trunk permit vlan 2
[DeviceB-GigabitEthernet1/0/2] quit
```

3. Configure Device A (the source device):

Create a remote source group.

```
<DeviceA> system-view
[DeviceA] mirroring-group 1 remote-source
```

Create VLAN 2.

```
[DeviceA] vlan 2
```

Disable MAC address learning for VLAN 2.

```
[DeviceA-vlan2] undo mac-address mac-learning enable
[DeviceA-vlan2] quit
```

Configure VLAN 2 as the remote probe VLAN of the mirroring group.

```
[DeviceA] mirroring-group 1 remote-probe vlan 2
```

Configure GigabitEthernet 1/0/1 as a source port for the mirroring group.

```
[DeviceA] mirroring-group 1 mirroring-port gigabitethernet 1/0/1 both
```

Configure GigabitEthernet 1/0/2 as the egress port for the mirroring group.

```
[DeviceA] mirroring-group 1 monitor-egress gigabitethernet 1/0/2
```

Configure GigabitEthernet 1/0/2 as a trunk port, and assign the port to VLAN 2.

```
[DeviceA] interface gigabitethernet 1/0/2
[DeviceA-GigabitEthernet1/0/2] port link-type trunk
[DeviceA-GigabitEthernet1/0/2] port trunk permit vlan 2
```

Disable the spanning tree feature on the port.

```
[DeviceA-GigabitEthernet1/0/2] undo stp enable
[DeviceA-GigabitEthernet1/0/2] quit
```

Verifying the configuration

Verify the mirroring group configuration on Device C.

```
[DeviceC] display mirroring-group all
Mirroring group 2:
    Type: Remote destination
    Status: Active
    Monitor port: GigabitEthernet1/0/2
    Remote probe VLAN: 2
```

Verify the mirroring group configuration on Device A.

```
[DeviceA] display mirroring-group all
Mirroring group 1:
    Type: Remote source
    Status: Active
    Mirroring port:
        GigabitEthernet1/0/1  Both
    Monitor egress port: GigabitEthernet1/0/2
    Remote probe VLAN: 2
```

Configuring flow mirroring

About flow mirroring

Flow mirroring copies packets matching a class to a destination for packet analyzing and monitoring. It is implemented through QoS.

To implement flow mirroring through QoS, perform the following tasks:

- Define traffic classes and configure match criteria to classify packets to be mirrored. Flow mirroring allows you to flexibly classify packets to be analyzed by defining match criteria.
- Configure traffic behaviors to mirror the matching packets to the specified destination.

You can configure an action to mirror the matching packets to one of the following destinations:

- **Interface**—The matching packets are copied to an interface and then forwarded to a data monitoring device for analysis.
- **CPU**—The matching packets are copied to the CPU of an IRF member device. The CPU analyzes the packets or delivers them to upper layers.

For more information about QoS policies, traffic classes, and traffic behaviors, see *ACL and QoS Configuration Guide*.

Restrictions and guidelines: Flow mirroring configuration

For information about the configuration commands except the **`mirror-to`** command, see *ACL and QoS Command Reference*.

Flow mirroring tasks at a glance

To configure flow mirroring, perform the following tasks:

1. Configuring a traffic class

   A traffic class defines the criteria that filters the traffic to be mirrored.
2. Configuring a traffic behavior

   A traffic behavior specifies mirroring destinations.
3. Configuring a QoS policy
4. Applying a QoS policy

   Choose one of the following tasks:
   - Applying a QoS policy to an interface
   - Applying a QoS policy to a VLAN
   - Applying a QoS policy globally

Configuring a traffic class

1. Enter system view.

   `system-view`
2. Create a class and enter class view.

traffic classifier *classifier-name* [**operator** { **and** | **or** }]

3. Configure match criteria.
   if-match *match-criteria*
   By default, no match criterion is configured in a traffic class.
4. (Optional.) Display traffic class information.
   display traffic classifier
   This command is available in any view.

Configuring a traffic behavior

Procedure

1. Enter system view.
   system-view
2. Create a traffic behavior and enter traffic behavior view.
   traffic behavior *behavior-name*
3. Configure mirroring destinations for the traffic behavior. Choose one option as needed:
   - Mirror traffic to interfaces.
     mirror-to interface *interface-type interface-number*
     By default, no mirroring actions exist to mirror traffic to interfaces.
   - Mirror traffic to the CPU.
     mirror-to cpu
     By default, no mirroring actions exist to mirror traffic to the CPU.
4. (Optional.) Display traffic behavior configuration.
   display traffic behavior
   This command is available in any view.

Configuring a QoS policy

1. Enter system view.
   system-view
2. Create a QoS policy and enter QoS policy view.
   qos policy *policy-name*
3. Associate a class with a traffic behavior in the QoS policy.
   classifier *classifier-name* **behavior** *behavior-name*
   By default, no traffic behavior is associated with a class.
4. (Optional.) Display QoS policy configuration.
   display qos policy
   This command is available in any view.

Applying a QoS policy

Applying a QoS policy to an interface

Restrictions and guidelines

You can apply a QoS policy to an interface to mirror the traffic of the interface.

A policy can be applied to multiple interfaces.

A QoS policy cannot be applied in the outbound direction of an interface. In the inbound direction of an interface, only one QoS policy can be applied.

Procedure

1. Enter system view.
   system-view
2. Enter interface view.
   interface *interface-type interface-number*
3. Apply a policy to the interface.
   qos apply policy *policy-name* **inbound**
4. (Optional.) Display the QoS policy applied to the interface.
   display qos policy interface
   This command is available in any view.

Applying a QoS policy to a VLAN

Restrictions and guidelines

You can apply a QoS policy to a VLAN to mirror the traffic on all ports in the VLAN.

Procedure

1. Enter system view.
   system-view
2. Apply a QoS policy to a VLAN.
   qos vlan-policy *policy-name* **vlan** *vlan-id-list* **inbound**
3. (Optional.) Display the QoS policy applied to the VLAN.
   display qos vlan-policy
   This command is available in any view.

Applying a QoS policy globally

Restrictions and guidelines

You can apply a QoS policy globally to mirror the traffic on all ports.

Procedure

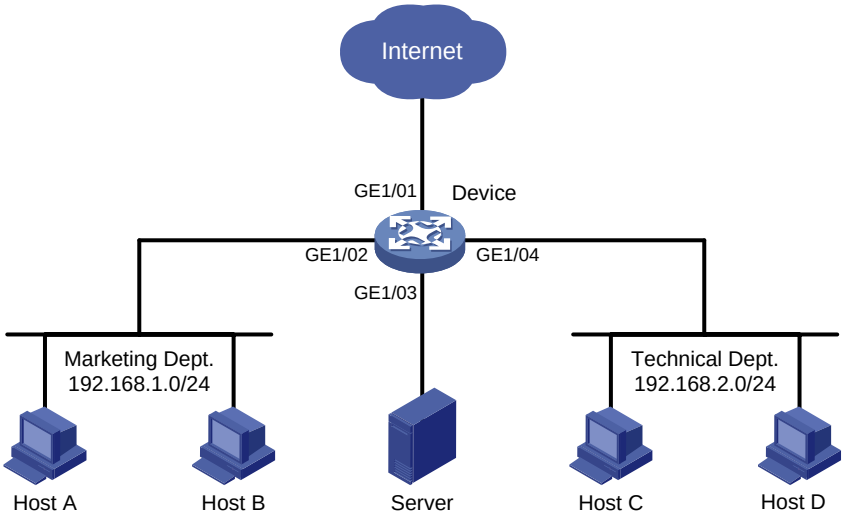
1. Enter system view.
   system-view
2. Apply a QoS policy globally.
   qos apply policy *policy-name* **global inbound**

3. (Optional.) Display global QoS policies.

   display qos policy global

   This command is available in any view.

Flow mirroring configuration examples



Example: Configuring flow mirroring

Network configuration

As shown in Figure 7, configure flow mirroring so that the server can monitor the following traffic:

- All traffic that the Technical Department sends to access the Internet.
- IP traffic that the Technical Department sends to the Marketing Department during working hours (8:00 to 18:00) on weekdays.

Figure 7 Network diagram

Procedure

Create working hour range **work**, in which working hours are from 8:00 to 18:00 on weekdays.

```
<Device> system-view
[Device] time-range work 8:00 to 18:00 working-day
```

Create IPv4 advanced ACL 3000 to allow packets from the Technical Department to access the Internet and the Marketing Department during working hours.

```
[Device] acl advanced 3000
[Device-acl-ipv4-adv-3000] rule permit tcp source 192.168.2.0 0.0.0.255 destination-port eq www
[Device-acl-ipv4-adv-3000] rule permit ip source 192.168.2.0 0.0.0.255 destination 192.168.1.0 0.0.0.255 time-range work
[Device-acl-ipv4-adv-3000] quit
```

Create traffic class **tech_c**, and configure the match criterion as ACL 3000.

```
[Device] traffic classifier tech_c
[Device-classifier-tech_c] if-match acl 3000
[Device-classifier-tech_c] quit
```

Create traffic behavior **tech_b**, configure the action of mirroring traffic to GigabitEthernet 1/0/3.

```
[Device] traffic behavior tech_b
[Device-behavior-tech_b] mirror-to interface gigabitethernet 1/0/3
[Device-behavior-tech_b] quit
```

Create QoS policy **tech_p**, and associate traffic class **tech_c** with traffic behavior **tech_b** in the QoS policy.

```
[Device] qos policy tech_p
[Device-qospolicy-tech_p] classifier tech_c behavior tech_b
[Device-qospolicy-tech_p] quit
```

Apply QoS policy **tech_p** to the incoming packets of GigabitEthernet 1/0/4.

```
[Device] interface gigabitethernet 1/0/4
[Device-GigabitEthernet1/0/4] qos apply policy tech_p inbound
[Device-GigabitEthernet1/0/4] quit
```

Verifying the configuration

Verify that the server can monitor the following traffic:

- All traffic sent by the Technical Department to access the Internet.
- IP traffic that the Technical Department sends to the Marketing Department during working hours on weekdays.

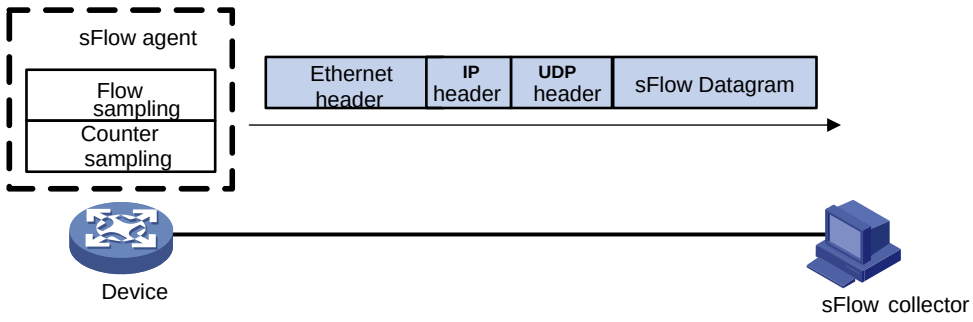
Configuring sFlow

About sFlow

sFlow is a traffic monitoring technology.

As shown in Figure 1, the sFlow system involves an sFlow agent embedded in a device and a remote sFlow collector. The sFlow agent collects interface counter information and packet information and encapsulates the sampled information in sFlow packets. When the sFlow packet buffer is full, or the aging timer (fixed to 1 second) expires, the sFlow agent performs the following actions:

- Encapsulates the sFlow packets in the UDP datagrams.
- Sends the UDP datagrams to the specified sFlow collector.



The sFlow collector analyzes the information and displays the results. One sFlow collector can monitor multiple sFlow agents.

sFlow provides the following sampling mechanisms:

- **Flow sampling**—Obtains packet information.
- **Counter sampling**—Obtains interface counter information.

sFlow can use flow sampling and counter sampling at the same time.

Figure 1 sFlow system

Protocols and standards

- RFC 3176, *InMon Corporation's sFlow: A Method for Monitoring Traffic in Switched and Routed Networks*
- sFlow.org, *sFlow Version 5*

Configuring basic sFlow information

Restrictions and guidelines

As a best practice, manually configure an IP address for the sFlow agent. The device periodically checks whether the sFlow agent has an IP address. If the sFlow agent does not have an IP address, the device automatically selects an IPv4 address for the sFlow agent but does not save the IPv4 address in the configuration file.

Only one IP address can be configured for the sFlow agent on the device, and a newly configured IP address overwrites the existing one.

Procedure

1. Enter system view.
   system-view
2. Configure an IP address for the sFlow agent.
   sflow agent { **ip** *ipv4-address* | **ipv6** *ipv6-address* }
   By default, no IP address is configured for the sFlow agent.
3. Configure the sFlow collector information.
   sflow collector *collector-id* [**vpn-instance** *vpn-instance-name*] { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port-number* | **datagram-size** *size* | **time-out** *seconds* | **description** *string*] *
   By default, no sFlow collector information is configured.
4. Specify the source IP address of sFlow packets.
   sflow source { **ip** *ipv4-address* | **ipv6** *ipv6-address* } *
   By default, the source IP address is determined by routing.

Configuring flow sampling

About this task

Perform this task to configure flow sampling on an Ethernet interface. The sFlow agent performs the following tasks:

1. Samples packets on that interface according to the configured parameters.
2. Encapsulates the packets into sFlow packets.
3. Encapsulates the sFlow packets in the UDP packets and sends the UDP packets to the specified sFlow collector.

Restrictions and guidelines

The sFlow sampling function shares the CPU's buffer resources with other protocols. A high sampling rate might cause traffic to preempt the buffer, causing critical protocol packets such as BFD, LACP, and LLDP packets to be lost. As a best practice, disable the sFlow function when you enable protocols like BFD, LACP, or LLDP, because these protocols require high packet precision.

Procedure

1. Enter system view.
   system-view
2. Enter Layer 2 Ethernet interface view or Layer 3 Ethernet interface view.
   interface *interface-type interface-number*
3. (Optional.) Set the flow sampling mode.
   sflow sampling-mode determine | **random**
   By default, random sampling is used.
4. Enable flow sampling and specify the number of packets out of which flow sampling samples a packet on the interface.
   sflow sampling-rate *rate*
   By default, flow sampling is disabled.
   As a best practice, set the sampling interval to 2^n that is greater than or equal to 8192, for example, 32768.
5. (Optional.) Set the maximum number of bytes (starting from the packet header) that flow sampling can copy per packet.

sflow flow max-header *length*

The default setting is 128 bytes.

As a best practice, use the default setting.

6. Specify the sFlow instance and sFlow collector for flow sampling.

   sflow flow [**instance** *instance-id*] **collector** *collector-id*

   By default, no sFlow instance or sFlow collector is specified for flow sampling.

Configuring counter sampling

About this task

Perform this task to configure counter sampling on an Ethernet interface. The sFlow agent performs the following tasks:

1. Periodically collects the counter information on that interface.
2. Encapsulates the counter information into sFlow packets.
3. Encapsulates the sFlow packets in the UDP packets and sends the UDP packets to the specified sFlow collector.

Procedure

1. Enter system view.

   system-view

2. Enter Layer 2 Ethernet interface view or Layer 3 Ethernet interface view.

   interface *interface-type interface-number*

3. Enable counter sampling and set the counter sampling interval.

   sflow counter interval *interval*

   By default, counter sampling is disabled.

4. Specify the sFlow instance and sFlow collector for counter sampling.

   sflow counter [**instance** *instance-id*] **collector** *collector-id*

   By default, no sFlow instance or sFlow collector is specified for counter sampling.

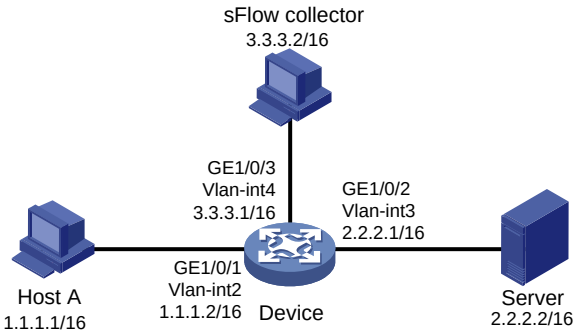
Display and maintenance commands for sFlow

Execute **display** commands in any view.

Task	Command
Display sFlow configuration.	**display sflow**

sFlow configuration examples

Example: Configuring sFlow



Network configuration

As shown in Figure 2, perform the following tasks:

- Configure flow sampling in random mode and counter sampling on GigabitEthernet 1/0/1 of the device to monitor traffic on the port.

- Configure the device to send sampled information in sFlow packets through GigabitEthernet 1/0/3 to the sFlow collector.

Figure 2 Network diagram

Procedure

1. Configure VLANs, assign Ethernet interfaces to VLANs, and configure IP addresses and subnet masks for VLAN interfaces, as shown in Figure 2. (Details not shown.)
2. Configure the sFlow agent and configure information about the sFlow collector:

   # Configure the IP address for the sFlow agent.

   ```
   <Device> system-view
   [Device] sflow agent ip 3.3.3.1
   ```

   # Configure information about the sFlow collector. Specify the sFlow collector ID as 1, IP address as 3.3.3.2, port number as 6343 (default), and description as **netserver**.

   ```
   [Device] sflow collector 1 ip 3.3.3.2 description netserver
   ```

3. Configure counter sampling:

   # Enable counter sampling and set the counter sampling interval to 120 seconds on GigabitEthernet 1/0/1.

   ```
   [Device] interface gigabitethernet 1/0/1
   [Device-GigabitEthernet1/0/1] sflow counter interval 120
   ```

   # Specify sFlow collector 1 for counter sampling.

   ```
   [Device-GigabitEthernet1/0/1] sflow counter collector 1
   ```

4. Configure flow sampling:

   # Enable flow sampling and set the flow sampling mode to random and sampling interval to 32767.

   ```
   [Device-GigabitEthernet1/0/1] sflow sampling-mode random
   [Device-GigabitEthernet1/0/1] sflow sampling-rate 32767
   ```

   # Specify sFlow collector 1 for flow sampling.

   ```
   [Device-GigabitEthernet1/0/1] sflow flow collector 1
   ```

Verifying the configuration

Verify the following items:

- GigabitEthernet 1/0/1 enabled with sFlow is active.
- The counter sampling interval is 120 seconds.
- The flow sampling interval is 32767 (one packet is sampled from every 32767 packets).

```
[Device-GigabitEthernet1/0/1] display sflow
sFlow datagram version: 5
Global information:
Agent IP: 3.3.3.1(CLI)
```

```
Source address:
Collector information:
ID    IP              Port  Aging      Size VPN-instance Description
1     3.3.3.2         6343  N/A        1400              netserver
Port counter sampling information:
Interface   Instance   CID   Interval(s)
GE1/0/1     1          1     120
Port flow sampling information:
Interface   Instance   FID   MaxHLen Rate       Mode      Status
GE1/0/1        1          1     128     32767      Random    Active
```

Troubleshooting sFlow

The remote sFlow collector cannot receive sFlow packets

Symptom

The remote sFlow collector cannot receive sFlow packets.

Analysis

The possible reasons include:

- The sFlow collector is not specified.
- sFlow is not configured on the interface.
- The IP address of the sFlow collector specified on the sFlow agent is different from that of the remote sFlow collector.
- No IP address is configured for the Layer 3 interface that sends sFlow packets.
- An IP address is configured for the Layer 3 interface that sends sFlow packets. However, the UDP datagrams with this source IP address cannot reach the sFlow collector.
- The physical link between the device and the sFlow collector fails.
- The sFlow collector is bound to a non-existent VPN.
- The length of an sFlow packet is less than the sum of the following two values:
  - The length of the sFlow packet header.
  - The number of bytes that flow sampling can copy per packet.

Solution

To resolve the problem:

1. Use the **`display sflow`** command to verify that sFlow is correctly configured.
2. Verify that a correct IP address is configured for the device to communicate with the sFlow collector.
3. Verify that the physical link between the device and the sFlow collector is up.
4. Verify that the VPN bound to the sFlow collector already exists.
5. Verify that the length of an sFlow packet is greater than the sum of the following two values:
   - The length of the sFlow packet header.
   - The number of bytes (as a best practice, use the default setting) that flow sampling can copy per packet.

Configuring the information center

About the information center

The information center on the device receives logs generated by source modules and outputs logs to different destinations according to log output rules. Based on the logs, you can monitor device performance and troubleshoot network problems.

Figure 1 Information center diagram

Log types

Logs are classified into the following types:

- **Standard system logs**—Record common system information. Unless otherwise specified, the term "logs" in this document refers to standard system logs.
- **Diagnostic logs**—Record debugging messages.
- **Security logs**—Record security information, such as authentication and authorization information.
- **Hidden logs**—Record log information not displayed on the terminal, such as input commands.
- **Trace logs**—Record system tracing and debugging messages, which can be viewed only after the devkit package is installed.

Log levels

Logs are classified into eight severity levels from 0 through 7 in descending order. The information center outputs logs with a severity level that is higher than or equal to the specified level. For example, if you specify a severity level of 6 (informational), logs that have a severity level from 0 to 6 are output.

Table 1 Log levels

Severity value	Level	Description
0	Emergency	The system is unusable. For example, the system authorization has expired.
1	Alert	Action must be taken immediately. For example, traffic on an interface exceeds the upper limit.
2	Critical	Critical condition. For example, the device temperature exceeds the upper limit, the power module fails, or the fan tray fails.
3	Error	Error condition. For example, the link state changes.
4	Warning	Warning condition. For example, an interface is disconnected, or the memory resources are used up.
5	Notification	Normal but significant condition. For example, a terminal logs in to the device, or the device reboots.

Severity value	Level	Description
6	Informational	Informational message. For example, a command or a ping operation is executed.
7	Debugging	Debugging message.

Log destinations

The system outputs logs to the following destinations: console, monitor terminal, log buffer, log host, and log file. Log output destinations are independent and you can configure them after enabling the information center. One log can be sent to multiple destinations.

Default output rules for logs

A log output rule specifies the source modules and severity level of logs that can be output to a destination. Logs matching the output rule are output to the destination. Table 2 shows the default log output rules.

Table 2 Default output rules

Destination	Log source modules	Output switch	Severity
Console	All supported modules	Enabled	Debugging
Monitor terminal	All supported modules	Disabled	Debugging
Log host	All supported modules	Enabled	Informational
Log buffer	All supported modules	Enabled	Informational
Log file	All supported modules	Enabled	Informational

Default output rules for diagnostic logs

Diagnostic logs can only be output to the diagnostic log file, and cannot be filtered by source modules and severity levels. Table 3 shows the default output rule for diagnostic logs.

Table 3 Default output rule for diagnostic logs

Destination	Log source modules	Output switch	Severity
Diagnostic log file	All supported modules	Enabled	Debugging

Default output rules for security logs

Security logs can only be output to the security log file, and cannot be filtered by source modules and severity levels. Table 4 shows the default output rule for security logs.

Table 4 Default output rule for security logs

Destination	Log source modules	Output switch	Severity
Security log file	All supported modules	Disabled	Debugging

Default output rules for hidden logs

Hidden logs can be output to the log host, the log buffer, and the log file. Table 5 shows the default output rules for hidden logs.

Table 5 Default output rules for hidden logs

Destination	Log source modules	Output switch	Severity
Log host	All supported modules	Enabled	Informational
Log buffer	All supported modules	Enabled	Informational
Log file	All supported modules	Enabled	Informational

Default output rules for trace logs

Trace logs can only be output to the trace log file, and cannot be filtered by source modules and severity levels. Table 6 shows the default output rules for trace logs.

Table 6 Default output rules for trace logs

Destination	Log source modules	Output switch	Severity
Trace log file	All supported modules	Enabled	Debugging

Log formats and field descriptions

Log formats

The format of logs varies by output destinations. Table 7 shows the original format of log information, which might be different from what you see. The actual format varies by the log resolution tool used.

Table 7 Log formats

Output destination	Format
Console, monitor terminal, log buffer, or log file	Prefix Timestamp Sysname Module/Level/Mnemonic: Content Example: `%Nov 24 14:21:43:502 2019 Sysname SHELL/5/SHELL_LOGIN: VTY logged in from 192.168.1.26`

Log host	**Non-customized format**:
	<PRI>Timestamp Sysname %%vvModule/Level/Mnemonic: Location; Content
	Example:
	`<190>Nov 24 16:22:21 2019 Sysname %%10SHELL/5/SHELL_LOGIN: -DevIP=1.1.1.1; VTY logged in from 192.168.1.26<190>Nov 24 16:22:21 2016 Sysname %%10 SHELL/5/SHELL_LOGIN: -DevIP=1.1.1.1; VTY logged in from 192.168.1.26`
	CMCC format:
	<PRI>Timestamp Sysname %vvModule/Level/Mnemonic: Location; Content
	`<189>Oct 9 14:59:04 2019 Sysname %10SHELL/5/SHELL_LOGIN: VTY logged in from 192.168.1.21`
	SGCC format:
	<PRI> Timestamp Sysname Devtype Content
	`<189> 2019-03-18 15:39:45 Sysname FW 0 2 admin 10.1.1.1`
	Unicom format:

Output destination	Format
	<PRI>Timestamp Hostip vvModule/Level/Serial_number: Content Example: `<189>Oct 13 16:48:08 2019 10.1.1.1 10SHELL/5/210231a64jx073000020: VTY logged in from 192.168.1.21`

Log field description

Table 8 Log field description

Field	Description
Prefix (information type)	A log to a destination other than the log host has an identifier in front of the timestamp: • An identifier of percent sign (%) indicates a log with a level equal to or higher than informational. • An identifier of asterisk (*) indicates a debugging log or a trace log. • An identifier of caret (^) indicates a diagnostic log.
PRI (priority)	A log destined for the log host has a priority identifier in front of the timestamp. The priority is calculated by using this formula: facility*8+level, where: • **facility** is the facility name. Facility names local0 through local7 correspond to values 16 through 23. The facility name can be configured using the **`info-center loghost`** command. It is used to identify log sources on the log host, and to query and filter the logs from specific log sources. • **level** is in the range of 0 to 7. See Table 1 for more information about severity levels.
Timestamp	Records the time when the log was generated. Logs sent to the log host and those sent to the other destinations have different timestamp precisions, and their timestamp formats are configured with different commands. For more information, see Table 9 and Table 10.
Hostip	Source IP address of the log. If the **`info-center loghost source`** command is configured, this field displays the IP address of the specified source interface. Otherwise, this field displays the sysname. This field exists only in logs that are sent to the log host in unicom format.
Serial number	Serial number of the device that generated the log. This field exists only in logs that are sent to the log host in unicom format.
Sysname (host name or host IP address)	The sysname is the host name or IP address of the device that generated the log. You can use the **`sysname`** command to modify the name of the device.
%% (vendor ID)	Indicates that the information was generated by an H3C device. This field exists only in logs sent to the log host.
vv (version information)	Identifies the version of the log, and has a value of 10. This field exists only in logs that are sent to the log host.
Module	Specifies the name of the module that generated the log. You can enter the **`info-center source ?`** command in system view to view the module list.
Level	Identifies the level of the log. See Table 1 for more information about severity levels.
Mnemonic	Describes the content of the log. It contains a string of up to 32 characters.
Location	Optional field that identifies the log sender. This field exists only in logs that are sent to the log host in non-customized or CMCC format. The field contains the following information:

Field	Description
	• **DevIp**—IP address of the log sender. • **Slot**—Member ID of the IRF member device that sent the log.
Devtype	Device type. This field exists only in logs that are sent to the log host in SGCC format.
Content	Provides the content of the log.

Table 9 Timestamp precisions and configuration commands

Item	Destined for the log host	Destined for the console, monitor terminal, log buffer, and log file
Precision	Seconds (default) or milliseconds	Milliseconds
Command used to set the timestamp format	**info-center timestamp loghost**	**info-center timestamp**

Table 10 Description of the timestamp parameters

Timestamp parameters	Description
boot	Time that has elapsed since system startup, in the format of xxx.yyy. xxx represents the higher 32 bits, and yyy represents the lower 32 bits, of milliseconds elapsed. Logs that are sent to all destinations other than a log host support this parameter. **Example**: `%0.109391473 Sysname FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` 0.109391473 is a timestamp in the **boot** format.
date	Current date and time. • For logs output to a log host, the timestamp can be in the format of MMM DD hh:mm:ss YYYY (accurate to seconds) or MMM DD hh:mm:ss.ms YYYY (accurate to milliseconds). • For logs output to other destinations, the timestamp is in the format of MMM DD hh:mm:ss:ms YYYY. All logs support this parameter. **Example**: `%May 30 05:36:29:579 2019 Sysname FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` May 30 05:36:29:579 2019 is a timestamp in the **date** format in logs sent to the console.
iso	Timestamp format stipulated in ISO 8601, accurate to seconds (default) or milliseconds. Only logs that are sent to a log host support this parameter. **Example**: `<189>2019-05-30T06:42:44 Sysname %%10FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` 2019-05-30T06:42:44 is a timestamp in the **iso** format accurate to seconds. A timestamp accurate to milliseconds is like 2019-05-30T06:42:44.708.
none	No timestamp is included. All logs support this parameter.

Timestamp parameters	Description
	Example: `% Sysname FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` No timestamp is included.
`no-year-date`	Current date and time without year or millisecond information, in the format of MMM DD hh:mm:ss. Only logs that are sent to a log host support this parameter. **Example**: `<189>May 30 06:44:22 Sysname %%10FTPD/5/FTPD_LOGIN: User ftp (192.168.1.23) has logged in successfully.` May 30 06:44:22 is a timestamp in the **`no-year-date`** format.

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

Information center tasks at a glance

Managing standard system logs

1. Enabling the information center
2. Outputting logs to various destinations

   Choose the following tasks as needed:
   - Outputting logs to the console
   - Outputting logs to the monitor terminal
   - Outputting logs to log hosts
   - Outputting logs to the log buffer
   - Saving logs to the log file
3. (Optional.) Setting the minimum storage period
4. (Optional.) Enabling synchronous information output
5. (Optional.) Configuring log suppression

   Choose the following tasks as needed:
   - Enabling duplicate log suppression
   - Configuring log suppression for a module
   - Disabling an interface from generating link up or link down logs
6. (Optional.) Enabling SNMP notifications for system logs

Managing hidden logs

1. Enabling the information center
2. Outputting logs to various destinations

   Choose the following tasks as needed:

- Outputting logs to log hosts
- Outputting logs to the log buffer
- Saving logs to the log file

3. (Optional.) Setting the minimum storage period
4. (Optional.) Configuring log suppression

   Choose the following tasks as needed:
   - Enabling duplicate log suppression
   - Configuring log suppression for a module

Managing security logs

1. Enabling the information center
2. (Optional.) Configuring log suppression

   Choose the following tasks as needed:
   - Enabling duplicate log suppression
   - Configuring log suppression for a module
3. Managing security logs
   - Saving security logs to the security log file
   - Managing the security log file

Managing diagnostic logs

1. Enabling the information center
2. (Optional.) Configuring log suppression

   Choose the following tasks as needed:
   - Enabling duplicate log suppression
   - Configuring log suppression for a module
3. Saving diagnostic logs to the diagnostic log file

Managing trace logs

1. Enabling the information center
2. (Optional.) Configuring log suppression

   Choose the following tasks as needed:
   - Enabling duplicate log suppression
   - Configuring log suppression for a module
3. Setting the maximum size of the trace log file

Enabling the information center

About this task

The information center can output logs only after it is enabled.

Procedure

1. Enter system view.

   `system-view`

2. Enable the information center.
   info-center enable
   The information center is enabled by default.

Outputting logs to various destinations

Outputting logs to the console

Restrictions and guidelines

The **terminal monitor**, **terminal debugging**, and **terminal logging** commands take effect only for the current connection between the terminal and the device. If a new connection is established, the default is restored.

Procedure

1. Enter system view.
   system-view
2. (Optional.) Configure an output rule for sending logs to the console.
   info-center source { *module-name* | **default** } **console** { **deny** | **level** *severity* }
   For information about the default output rules, see "Default output rules for logs."
3. (Optional.) Configure the timestamp format.
   info-center timestamp { **boot** | **date** | **none** }
   The default timestamp format is **date**.
4. Return to user view.
   quit
5. Enable log output to the console.
   terminal monitor
   By default, log output to the console is enabled.
6. Enable output of debugging messages to the console.
   terminal debugging
   By default, output of debugging messages to the console is disabled.
   This command enables output of debugging-level log messages to the console.
7. Set the lowest severity level of logs that can be output to the console.
   terminal logging level *severity*
   The default setting is 6 (informational).

Outputting logs to the monitor terminal

About this task

Monitor terminals refer to terminals that log in to the device through the AUX or VTY line.

Restrictions and guidelines

The **terminal monitor**, **terminal debugging**, and **terminal logging** commands take effect only for the current connection between the terminal and the device. If a new connection is established, the default is restored.

Procedure

1. Enter system view.
   system-view
2. (Optional.) Configure an output rule for sending logs to the monitor terminal.
   info-center source { *module-name* | **default** } **monitor** { **deny** | **level** *severity* }
   For information about the default output rules, see "Default output rules for logs."
3. (Optional.) Configure the timestamp format.
   info-center timestamp { **boot** | **date** | **none** }
   The default timestamp format is **date**.
4. Return to user view.
   quit
5. Enable log output to the monitor terminal.
   terminal monitor
   By default, log output to the monitor terminal is disabled.
6. Enable output of debugging messages to the monitor terminal.
   terminal debugging
   By default, output of debugging messages to the monitor terminal is disabled.
   This command enables output of debugging-level log messages to the monitor terminal.
7. Set the lowest level of logs that can be output to the monitor terminal.
   terminal logging level *severity*
   The default setting is 6 (informational).

Outputting logs to log hosts

Restrictions and guidelines

The device supports the following methods (in descending order of priority) for outputting logs of a module to designated log hosts:

- Fast log output.
  For information about the modules that support fast log output and how to configure fast log output, see "Configuring fast log output."
- Flow log.
  For information about the modules that support flow log output and how to configure flow log output, see "Configuring flow log."
- Information center.

If you configure multiple log output methods for a module, only the method with the highest priority takes effect.

Procedure

1. Enter system view.
   system-view
2. (Optional.) Configure a log output filter or a log output rule. Choose one option as needed:
   - Configure a log output filter.
     info-center filter *filter-name* { *module-name* | **default** } { **deny** | **level** *severity* }

You can create multiple log output filters. When specifying a log host, you can apply a log output filter to the log host to control log output.

- Configure a log output rule for the log host output destination.

  info-center source { *module-name* | **default** } **loghost** { **deny** | **level** *severity* }

  For information about the default log output rules for the log host output destination, see "Default output rules for logs."

The system chooses the settings to control log output to a log host in the following order:

a. Log output filter applied to the log host.

b. Log output rules configured for the log host output destination by using the **info-center source** command.

c. Default log output rules (see "Default output rules for logs").

3. (Optional.) Specify a source IP address for logs sent to log hosts.

info-center loghost source *interface-type interface-number*

By default, the source IP address of logs sent to log hosts is the primary IP address of their outgoing interfaces.

4. (Optional.) Specify the format in which logs are output to log hosts.

info-center format { **cmcc** | **unicom** }

By default, logs are output to log hosts in non-customized format.

5. (Optional.) Configure the timestamp format.

info-center timestamp loghost { **date** [**with-milliseconds**] | **iso** [**with-milliseconds** | **with-timezone**] * | **no-year-date** | **none** }

The default timestamp format is **date**.

6. Specify a log host and configure related parameters.

info-center loghost [**vpn-instance** *vpn-instance-name*] { *hostname* | *ipv4-address* | **ipv6** *ipv6-address* } [**port** *port-number*] [**dscp** *dscp-value*] [**facility** *local-number*] [**filter** *filter-name*]

By default, no log hosts or related parameters are specified.

The value for the *port-number* argument must be the same as the value configured on the log host. Otherwise, the log host cannot receive logs.

Outputting logs to the log buffer

About this task

This feature enables log output to the log buffer. You can use the **display logbuffer** command to display the log buffer information and the buffered logs.

Procedure

1. Enter system view.

system-view

2. (Optional.) Configure an output rule for sending logs to the log buffer.

info-center source { *module-name* | **default** } **logbuffer** { **deny** | **level** *severity* }

For information about the default output rules, see "Default output rules for logs."

3. (Optional.) Configure the timestamp format.

info-center timestamp { **boot** | **date** | **none** }

The default timestamp format is **date**.

4. Enable log output to the log buffer.

   info-center logbuffer

   By default, log output to the log buffer is enabled.

5. (Optional.) Set the maximum log buffer size.

   info-center logbuffer size *buffersize*

   By default, a maximum of 512 logs can be buffered.

Saving logs to the log file

About this task

The log file feature enables log output to the log file. The system saves logs from the log file buffer to the log file. After saving logs to the log file, the system clears the log file buffer.

Log saving from the log file buffer to the log file is triggered by the following situations:

- Periodic saving.
- A manual immediate saving of buffered logs to the log file.
- The log file buffer is full.

A log file is automatically created when needed and has a maximum capacity. The log file capacity restrictions are as follows:

- When log file overwrite-protection is enabled and no log file space is available, the device stops saving new logs.

  When log file overwrite-protection is disabled and no log file space or storage device space is available, the system will replace the oldest logs with new logs.

TIP:

- Clean up the storage space of the device regularly to ensure sufficient storage space for the log file feature.
- As a best practice, back up the log files regularly to avoid loss of important logs.

Procedure

1. Enter system view.

   system-view

2. (Optional.) Configure an output rule for sending logs to the log file.

   info-center source { *module-name* | **default** } **logfile** { **deny** | **level** *severity* }

   For information about the default output rules, see "Default output rules for logs."

3. Enable the log file feature.

   info-center logfile enable

   By default, the log file feature is enabled.

4. (Optional.) Enable log file overwrite-protection.

   info-center logfile overwrite-protection [**all-port-powerdown**]

   By default, log file overwrite-protection is disabled.

   Log file overwrite-protection is supported only in FIPS mode.

5. (Optional.) Set the maximum log file size.

   info-center logfile size-quota *size*

   By default, the maximum log file size is 10 MB.

6. (Optional.) Specify the log file directory.

info-center logfile directory *dir-name*

The default log file directory is **flash:/logfile**.

This command cannot survive an IRF reboot or a master/subordinate switchover.

7. Save logs in the log file buffer to the log file. Choose one or both options as needed:
   - Configure the automatic log file saving interval.
     info-center logfile frequency *freq-sec*
     The default log file saving interval is 86400 seconds.
   - Immediately save logs from the log file buffer to the log file.
     logfile save
     This command is available in any view.

Setting the minimum storage period

About this task

Use this feature to set the minimum storage period for logs in the log buffer and log file. This feature ensures that logs will not be overwritten by new logs during a set period of time.

By default, when the log buffer or log file is full, new logs will automatically overwrite the oldest logs. After the minimum storage period is set, the system identifies the storage period of a log to determine whether to delete the log. The system current time minus a log's generation time is the log's storage period.

- If the storage period of a log is shorter than or equal to the minimum storage period, the system does not delete the log. The new log will not be saved.
- If the storage period of a log is longer than the minimum storage period, the system deletes the log to save the new log.

Procedure

1. Enter system view.
   system-view
2. Set the log minimum storage period for logs.
   info-center syslog min-age *min-age*
   By default, the log minimum storage period is not set.

Enabling synchronous information output

About this task

System log output interrupts ongoing configuration operations, obscuring previously entered commands. Synchronous information output shows the obscured commands. It also provides a command prompt in command editing mode, or a [Y/N] string in interaction mode so you can continue your operation from where you were stopped.

Procedure

1. Enter system view.
   system-view
2. Enable synchronous information output.
   info-center synchronous
   By default, synchronous information output is disabled.

Configuring log suppression

Enabling duplicate log suppression

About this task

The information center on the device outputs logs generated by service modules. The device identifies logs that have the same module name, level, mnemonic, location, and text as duplicate logs.

In some scenarios, for example, ARP attack or link failure, the service modules will generate a large volume of duplicate logs during a short period of time. Recording and output of consecutive duplicate logs wastes system and network resources. To resolve this issue, you can enable duplicate log suppression.

With this feature enabled, when a service module generates a log, the information center outputs the log and starts the duplicate log suppression timer. The suppression period of the duplicate log suppression timer varies by phase. The suppression periods in phase 1, 2, and later phases are 30 seconds, 2 minutes, and 10 minutes, respectively.

After you enable duplicate log suppression, the system starts suppression upon outputting a log:

- If only duplicate logs of the log are received during the suppression period of a phase, the information center does not output the duplicate logs. When the suppression period of the phase expires, the information center outputs the suppressed log and the number of times the log is suppressed, and starts the next suppression phase.
- If a different log is received during the suppression period of a phase, the information center performs the following operations:
  - Stops suppression on the log, and outputs the suppressed log and the number of times the log is suppressed.
  - Outputs the different log and starts phase-1 suppression for that log.
- If no log is received within the suppression period of any phase, the information center deletes the duplicate log suppression timer, stops suppression on the log, and does not output any log.

Procedure

1. Enter system view.

   `system-view`

2. Enable duplicate log suppression.

   `info-center logging suppress duplicates`

   By default, duplicate log suppression is disabled.

Examples

The following example uses SHELL_CMD logs to verify the duplicate log suppression feature. After the user executes a command on the device, the information center receives a SHELL_CMD log generated by the shell module, encapsulates the log, and then outputs the log to the log buffer.

1. Verify the suppression effect in phases 1, 2, 3, and 4 of a log (with suppression period of 30 seconds, 2 minutes, 10 minutes, and 10 minutes):

   # In a lab environment, continuously execute the **`display logbuffer`** command for 25 minutes.

   # View the output logs in the log buffer.

   ```
   <Sysname> display logbuffer
   Log buffer: Enabled
   Max buffer size: 1024
   Actual buffer size: 512
   ```

```
Dropped messages: 0
Overwritten messages: 0
Current messages: 5
%Jul 20 13:01:20:615 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer
%Jul 20 13:01:50:718 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 2 times in last 30 seconds.
%Jul 20 13:03:50:732 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 5 times in last 2 minutes.
%Jul 20 13:13:50:830 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 10 times in last 10 minutes.
%Jul 20 13:23:50:211 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 6 times in last 10 minutes.
```

The output shows the following information:

- The information center received the log **SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**; Command is display logbuffer**.
- In phase 1, the log was suppressed twice by the information center.
- In phase 2, the log was suppressed five times by the information center.
- In phase 3, the log was suppressed 10 times by the information center.
- In phase 4, the log was suppressed six times by the information center.

2. Continue to verify how duplicate log suppression works when a different log is received during the suppression period of a log:

Execute the **`display logbuffer`** command three times, and then execute the **`display interface brief`** command.

View the output logs in the log buffer.

```
<Sysname> display logbuffer
Log buffer: Enabled
Max buffer size: 1024
Actual buffer size: 512
Dropped messages: 0
Overwritten messages: 0
Current messages: 5
%Jul 20 13:01:20:615 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer
%Jul 20 13:01:50:718 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 2 times in last 30 seconds.
%Jul 20 13:03:50:732 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 5 times in last 2 minutes.
%Jul 20 13:13:50:830 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 10 times in last 10 minutes.
%Jul 20 13:23:50:211 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 6 times in last 10 minutes.
%Jul 20 13:24:56:205 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display logbuffer This message repeated 3 times in last 1 minute 6 seconds.
%Jul 20 13:25:41:205 2022 Sysname SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**;
Command is display interface brief.
<Sysname>
```

The output shows the following information:

- The information center stopped suppression for the log **SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**; Command is display logbuffer**.

- The information center output the log **SHELL/6/SHELL_CMD: -Line=con0-IPAddr=**-User=**; Command is display interface brief**, and started suppression for it.

Configuring log suppression for a module

About this task

This feature suppresses output of logs. You can use this feature to filter out the logs that you are not concerned with.

Perform this task to configure a log suppression rule to suppress output of all logs or logs with a specific mnemonic value for a module.

Procedure

1. Enter system view.

   system-view

2. Configure a log suppression rule for a module.

   info-center logging suppress module *module-name* **mnemonic** { **all** | *mnemonic-value* }

   By default, the device does not suppress output of any logs from any modules.

Disabling an interface from generating link up or link down logs

About this task

By default, an interface generates link up or link down log information when the interface state changes. In some cases, you might want to disable certain interfaces from generating this information. For example:

- You are concerned about the states of only some interfaces. In this case, you can use this function to disable other interfaces from generating link up and link down log information.
- An interface is unstable and continuously outputs log information. In this case, you can disable the interface from generating link up and link down log information.

Use the default setting in normal cases to avoid affecting interface status monitoring.

Procedure

1. Enter system view.

   system-view

2. Enter interface view.

   interface *interface-type interface-number*

3. Disable the interface from generating link up or link down logs.

   undo enable log updown

   By default, an interface generates link up and link down logs when the interface state changes.

Enabling SNMP notifications for system logs

About this task

This feature enables the device to send an SNMP notification for each log message it outputs. The device encapsulates the logs in SNMP notifications and then sends them to the SNMP module and the log trap buffer.

You can configure the SNMP module to send received SNMP notifications in SNMP traps or informs to remote hosts. For more information, see "Configuring SNMP."

To view the traps in the log trap buffer, access the MIB corresponding to the log trap buffer.

Procedure

1. Enter system view.
   system-view
2. Enable SNMP notifications for system logs.
   snmp-agent trap enable syslog
   By default, the device does not send SNMP notifications for system logs.
3. Set the maximum number of traps that can be stored in the log trap buffer.
   info-center syslog trap buffersize *buffersize*
   By default, the log trap buffer can store a maximum of 1024 traps.

Managing security logs

Saving security logs to the security log file

About this task

Security logs are very important for locating and troubleshooting network problems. Generally, security logs are output together with other logs. It is difficult to identify security logs among all logs.

To solve this problem, you can save security logs to the security log file without affecting the current log output rules.

After you enable the security log file feature, the system processes security logs as follows:

1. Outputs security logs to the security log file buffer.
2. Saves logs from the security log file buffer to the security log file at the specified interval.
   If you have the security-audit role, you can also manually save security logs to the security log file.
3. Clears the security log file buffer immediately after the security logs are saved to the security log file.

Restrictions and guidelines

The device supports only one security log file. The system will overwrite old logs with new logs when the security log file is full. To avoid security log loss, you can set an alarm threshold for the security log file usage ratio. When the alarm threshold is reached, the system outputs a message to inform you of the alarm. You can log in to the device with the security-audit user role and back up the security log file to prevent the loss of important data.

Procedure

1. Enter system view.
   system-view
2. Enable the security log file feature.
   info-center security-logfile enable
   By default, the security log file feature is disabled.
3. Set the interval at which the system saves security logs.
   info-center security-logfile frequency *freq-sec*
   The default security log file saving interval is 86400 seconds.
4. (Optional.) Set the maximum size for the security log file.

info-center security-logfile size-quota *size*

By default, the maximum security log file size is 10 MB.

5. (Optional.) Set the alarm threshold of the security log file usage.

   info-center security-logfile alarm-threshold *usage*

   By default, the alarm threshold of the security log file usage ratio is 80. When the usage of the security log file reaches 80%, the system will send a message.

Managing the security log file

Restrictions and guidelines

To use the security log file management commands, you must have the security-audit user role. For information about configuring the security-audit user role, see AAA in *Security Configuration Guide*.

Procedure

1. Enter system view.

   system-view

2. Change the directory of the security log file.

   info-center security-logfile directory *dir-name*

   By default, the security log file is saved in the **seclog** directory in the root directory of the storage device.

   The device uses the default security log file directory after an IRF reboot or a master/subordinate switchover.

3. Manually save all logs in the security log file buffer to the security log file.

   security-logfile save

   This command is available in any view.

4. (Optional.) Display the summary of the security log file.

   display security-logfile summary

   This command is available in any view.

Saving diagnostic logs to the diagnostic log file

About this task

By default, the diagnostic log file feature saves diagnostic logs from the diagnostic log file buffer to the diagnostic log file at the specified saving interval. You can also manually trigger an immediate saving of diagnostic logs to the diagnostic log file. After saving diagnostic logs to the diagnostic log file, the system clears the diagnostic log file buffer.

The device supports only one diagnostic log file. The diagnostic log file has a maximum capacity. When the capacity is reached, the system replaces the oldest diagnostic logs with new logs.

Procedure

1. Enter system view.

   system-view

2. Enable the diagnostic log file feature.

   info-center diagnostic-logfile enable

   By default, the diagnostic log file feature is enabled.

3. (Optional.) Set the maximum diagnostic log file size.

   info-center diagnostic-logfile quota *size*

By default, the maximum diagnostic log file size is 10 MB.

4. (Optional.) Specify the diagnostic log file directory.

   info-center diagnostic-logfile directory *dir-name*

   The default diagnostic log file directory is **flash:/diagfile**.

   The device uses the default diagnostic log file directory after an IRF reboot or a master/subordinate switchover.

5. Save diagnostic logs in the diagnostic log file buffer to the diagnostic log file. Choose one option as needed:
   - Configure the automatic diagnostic log file saving interval.

     info-center diagnostic-logfile frequency *freq-sec*

     The default saving interval is 86400 seconds.
   - Manually save diagnostic logs to the diagnostic log file.

     diagnostic-logfile save

     This command is available in any view.

Setting the maximum size of the trace log file

About this task

The device has only one trace log file. When the trace log file is full, the device overwrites the oldest trace logs with new ones.

Procedure

1. Enter system view.

   system-view

2. Set the maximum size for the trace log file.

   info-center trace-logfile quota *size*

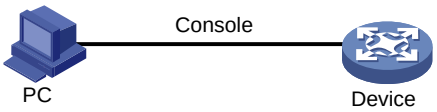
   The default maximum size of the trace log file is 1 MB.

Display and maintenance commands for information center

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display the diagnostic log file configuration.	**display diagnostic-logfile summary**
Display the information center configuration.	**display info-center**
Display information about log output filters.	**display info-center filter** [*filter-name*]
Display log buffer information and buffered logs.	**display logbuffer** [**reverse**] [**level** *severity* | **size** *buffersize* | **slot** *slot-number*] * [**last-mins** *mins*]
Display the log buffer summary.	**display logbuffer summary** [**level** *severity* | **slot** *slot-number*] *
Display the content of the log file	**display logfile buffer**

Task	Command
buffer.	
Display the log file configuration.	**display logfile summary**
Display the content of the security log file buffer. (To execute this command, you must have the security-audit user role.)	**display security-logfile buffer**
Display summary information of the security log file.	**display security-logfile summary**
Clear the log buffer.	**reset logbuffer**



Information center configuration examples

Example: Outputting logs to the console

Network configuration

Configure the device to output to the console FTP logs that have a minimum severity level of **warning**.

Figure 2 Network diagram

Procedure

Enable the information center.

```
<Device> system-view
[Device] info-center enable
```

Disable log output to the console.

```
[Device] info-center source default console deny
```

To avoid output of unnecessary information, disable all modules from outputting log information to the specified destination (**console** in this example) before you configure the output rule.

Configure an output rule to output to the console FTP logs that have a minimum severity level of **warning**.

```
[Device] info-center source ftp console level warning
[Device] quit
```

Enable log output to the console.

```
<Device> terminal logging level 6
<Device> terminal monitor
The current terminal is enabled to display logs.
```

Now, if the FTP module generates logs, the information center automatically sends the logs to the console, and the console displays the logs.

Example: Outputting logs to a UNIX log host

Network configuration

Configure the device to output to the UNIX log host FTP logs that have a minimum severity level of **informational**.

Figure 3 Network diagram

Procedure

1. Make sure the device and the log host can reach each other. (Details not shown.)
2. Configure the device:

   # Enable the information center.

   ```
   <Device> system-view
   [Device] info-center enable
   ```

   # Specify log host 1.2.0.1/16 with **local4** as the logging facility.

   ```
   [Device] info-center loghost 1.2.0.1 facility local4
   ```

   # Disable log output to the log host.

   ```
   [Device] info-center source default loghost deny
   ```

   To avoid output of unnecessary information, disable all modules from outputting logs to the specified destination (**loghost** in this example) before you configure an output rule.

   # Configure an output rule to output to the log host FTP logs that have a minimum severity level of **informational**.

   ```
   [Device] info-center source ftp loghost level informational
   ```

3. Configure the log host:

   The log host configuration procedure varies by the vendor of the UNIX operating system. The following shows an example:

   a. Log in to the log host as a root user.

   b. Create a subdirectory named **Device** in directory **/var/log/**, and then create file **info.log** in the **Device** directory to save logs from the device.

      ```
      # mkdir /var/log/Device
      # touch /var/log/Device/info.log
      ```

   c. Edit file **syslog.conf** in directory **/etc/** and add the following contents:

      ```
      # Device configuration messages
      local4.info /var/log/Device/info.log
      ```

      In this configuration, **local4** is the name of the logging facility that the log host uses to receive logs. The value **info** indicates the **informational** severity level. The UNIX system records the log information that has a minimum severity level of **informational** to file **/var/log/Device/info.log**.

NOTE:

Follow these guidelines while editing file **/etc/syslog.conf**:

- Comments must be on a separate line and must begin with a pound sign (#).
- No redundant spaces are allowed after the file name.
- The logging facility name and the severity level specified in the **/etc/syslog.conf** file must be identical to those configured on the device by using the **info-center loghost** and **info-center source** commands. Otherwise, the log information might not be output to the log host correctly.

d. Display the process ID of **syslogd**, kill the **syslogd** process, and then restart **syslogd** by using the **–r** option to validate the configuration.

```
# ps -ae | grep syslogd
147
# kill -HUP 147
# syslogd -r &
```

Now, the device can output FTP logs to the log host, which stores the logs to the specified file.

Example: Outputting logs to a Linux log host

Network configuration

Configure the device to output to the Linux log host 1.2.0.1/16 FTP logs that have a minimum severity level of **informational**.

Figure 4 Network diagram

Procedure

1. Make sure the device and the log host can reach each other. (Details not shown.)
2. Configure the device:

   # Enable the information center.

   ```
   <Device> system-view
   [Device] info-center enable
   ```

   # Specify log host 1.2.0.1/16 with **local5** as the logging facility.

   ```
   [Device] info-center loghost 1.2.0.1 facility local5
   ```

   # Disable log output to the log host.

   ```
   [Device] info-center source default loghost deny
   ```

   To avoid outputting unnecessary information, disable all modules from outputting log information to the specified destination (**loghost** in this example) before you configure an output rule.

   # Configure an output rule to enable output to the log host FTP logs that have a minimum severity level of **informational**.

   ```
   [Device] info-center source ftp loghost level informational
   ```

3. Configure the log host:

   The log host configuration procedure varies by the vendor of the Linux operating system. The following shows an example:

   a. Log in to the log host as a root user.

b. Create a subdirectory named **Device** in directory **/var/log/**, and create file **info.log** in the **Device** directory to save logs from the device.

```
# mkdir /var/log/Device
# touch /var/log/Device/info.log
```

c. Edit file **syslog.conf** in directory **/etc/** and add the following contents:

```
# Device configuration messages
local5.info /var/log/Device/info.log
```

In this configuration, **local5** is the name of the logging facility that the log host uses to receive logs. The value **info** indicates the **informational** severity level. The Linux system will store the log information with a severity level equal to or higher than **informational** to file **/var/log/Device/info.log**.

NOTE:

Follow these guidelines while editing file **/etc/syslog.conf**:

- Comments must be on a separate line and must begin with a pound sign (#).
- No redundant spaces are allowed after the file name.
- The logging facility name and the severity level specified in the **/etc/syslog.conf** file must be identical to those configured on the device by using the **info-center loghost** and **info-center source** commands. Otherwise, the log information might not be output to the log host correctly.

d. Display the process ID of **syslogd**, kill the **syslogd** process, and then restart **syslogd** by using the **-r** option to validate the configuration.

Make sure the **syslogd** process is started with the **-r** option on the Linux log host.

```
# ps -ae | grep syslogd
147
# kill -9 147
# syslogd -r &
```

Now, the device can output FTP logs to the log host, which stores the logs to the specified file.

Configuring cloud connections

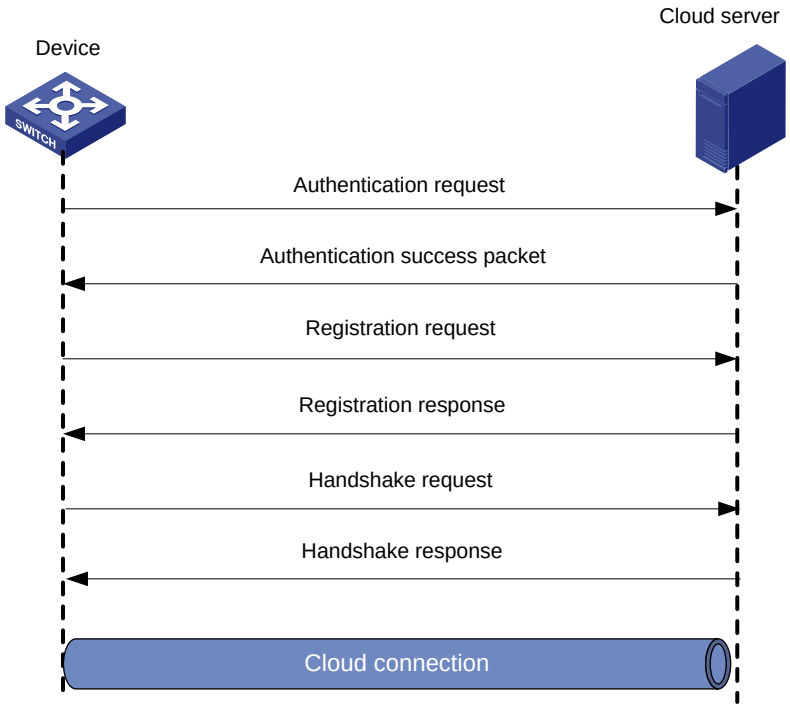
About cloud connections

A cloud connection is a management tunnel established between a local device and the H3C cloud server. It enables you to manage the local device from the cloud server without accessing the network where the device resides.

Multiple subconnections

After a local device establishes a connection with the cloud server, service modules on the local device can establish multiple subconnections with the microservices on the cloud server. These subconnections are independent from each other and provide separate communication channels for different services. This mechanism avoids interference among different services.

Cloud connection establishment



The cloud connection is established as follows:

1. The device sends an authentication request to the cloud server.
2. The cloud server sends an authentication success packet to the device.

   The device passes the authentication only if the serial number of the device has been added to the cloud server. If the authentication fails, the cloud server sends an authentication failure packet to the device.
3. The device sends a registration request to the cloud server.
4. The cloud server sends a registration response to the device.

   The registration response contains the uniform resource locator (URL) used to establish a cloud connection.
5. The device uses the URL to send a handshake request (changing the protocol from HTTP to WebSocket) to the cloud server.
6. The cloud server sends a handshake response to the device to finish establishing the cloud connection.
7. The device sends a subconnection URL request to the cloud server.
8. The cloud server sends a response that contains the microservice list and all subconnection URLs to the device.
9. The service module registers on the cloud connection management module.
10. The cloud connection management module sends the corresponding URLs to the service module.
11. The service module establishes subconnections with the cloud server.

Figure 1 Establishing a cloud connection

Configuring a cloud connection

About this task

For a device to establish a cloud connection to the cloud server, specify the domain name of the cloud server on the device.

For a device to establish a cloud connection to the cloud server, perform either of the following tasks:

- Specify the domain name of the cloud server on the device through CLI.
- Configure an interface of the device as a DHCP client and the cloud server as the DHCP server. The device obtains the IP address of the DHCP server and parses the option 253 field in the DHCP packets to obtain the IPv4 domain name of the cloud server. It parses the option 65253 field in the DHCPv6 packets to obtain the IPv6 domain name of the cloud server. For more information about the option 253 field and the option 65253 field, see DHCP configuration and DHCPv6 configuration in *Layer 3—IP Services Configuration Guide*.

After establishing the cloud connection, the local device sends keepalive packets to the cloud server periodically. If the device does not receive a response from the cloud server within three keepalive intervals, the device sends a registration request to re-establish the cloud connection.

Prerequisites

Add the serial number of the device to be managed to the cloud server.

Configure DNS to ensure that the domain name of the cloud server can be translated into an IP address.

Restrictions and guidelines

The domain name obtained through DHCP has a higher priority than the domain name configured manually.

If a device obtains the domain name of the cloud server through DHCP after establishing a cloud connection to the cloud server with the manually configured domain name, the device performs the following tasks:

- If the automatically obtained and manually configured domain names are identical, the device retains the cloud connection.
- If the automatically obtained and manually configured domain names are different, the device tears down the cloud connection and then establishes a cloud connection to the cloud server with the automatically obtained domain name.

Procedure

1. Enter system view.

   system-view

2. Configure the domain name of the cloud server.
   - Configure the IPv4 domain name of the cloud server.

     cloud-management server { **domain** *domain-name* [**vpn-instance** *vpn-instance-name*] [**source-ip** *ip-address*] | **port** *port-number* }
   - Configure the IPv6 domain name of the cloud server.

     cloud-management server ipv6 domain *domain-name* [**vpn-instance** *vpn-instance-name*] [**source-ip** *ip-address*]

   For S5570S-EI device, by default:
   - In a version earlier than F1127, the domain name of the cloud server is not configured.
   - In F1127 or a later version, when the device starts up without loading any configuration, the domain name of the cloud server is not configured. If the device starts up with the factory settings, the domain name of the cloud server is cloudnet.h3c.com.

   For S5500V3-SI device, the domain name of the cloud server is oasis.h3c.com for versions earlier than R1115. The domain name of the cloud server is cloudnet.h3c.com for R1115 and later.

   Only the R1122 and later versions support configuring the IPv6 domain name of the cloud server.
3. (Optional) Set the keepalive interval.

   cloud-management keepalive *interval*

   By default, the keepalive interval is 180 seconds.
4. (Optional) Specify the TCP port number used to establish cloud connections.

   cloud-management server port *port-number*

   By default, the TCP port number used to establish cloud connections is 443.
5. (Optional.) Set the password for establishing cloud connections to the cloud server.

   cloud-management server password { **cipher** | **simple** } *string*

   By default, no password is set for establishing cloud connections to the cloud server.

   The feature is supported only in R1107 and later.

Unbinding the device from the Oasis server

About this task

A device can be registered on the Oasis server by only one user.

To register a device that has been registered by another user, you need to take the following steps:

1. Obtain a verification code for device unbinding from the Oasis server.
2. Execute the command on the device for sending the verification code to the Oasis server.

3. Register the device on the Oasis server.

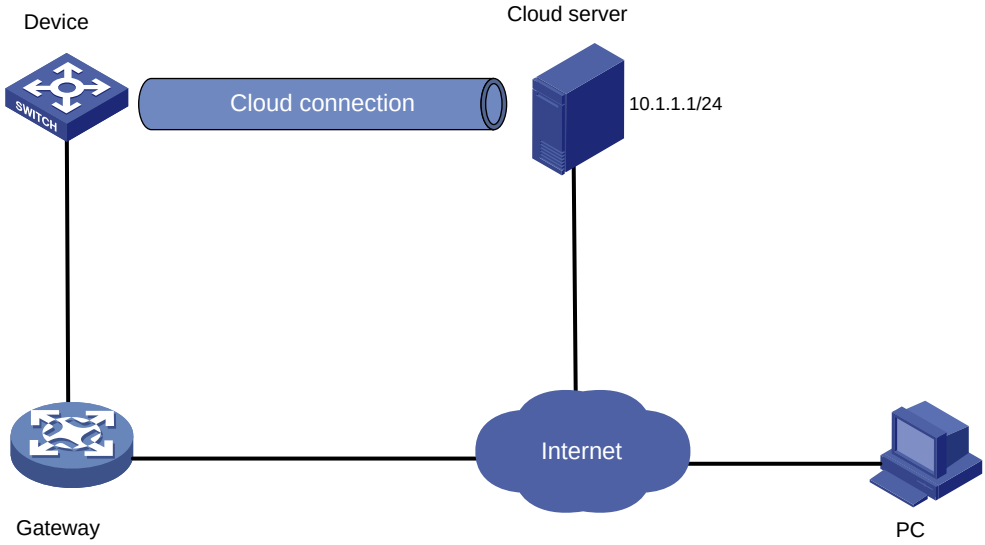
Procedure

1. Enter system view.
   system-view
2. Send the verification code for device unbinding to the Oasis server.
   cloud-management unbinding-code *code*

Display and maintenance commands for cloud connections

Execute **display** commands in any view and **reset** commands in user view.

Task	Command
Display cloud connection state information.	**display cloud-management state**
Re-establish the cloud connection to the cloud server.	**reset cloud-management tunnel**



Cloud connection configuration examples

Example: Configuring a cloud connection

Network configuration

As shown in Figure 2, configure the device to establish a cloud connection with the cloud server.

Figure 2 Network diagram

Procedure

1. Configure IP addresses for interfaces, and configure a routing protocol to ensure that the devices can reach each other. (Details not shown.)

2. Log in to the cloud server to add the serial number of the device to the server. (Details not shown.)

   The IP address of the cloud server is 10.1.1.1/24 and the domain name is **cloud.com**.

3. Configure the domain name of the cloud server as **cloud.com**.

```
<Device> system-view
[Device] cloud-management server domain cloud.com
```

   # Map IP address 10.1.1.1 to host name **cloud.com**.

```
[Device] ip host cloud.com 10.1.1.1
```

Verifying the configuration

Verify that the device and the cloud server have established a cloud connection.

```
[Device] display cloud-management state
Cloud connection state   : Established
Device state             : Request_success
Cloud server address     : 10.1.1.1
Cloud server domain name : cloud.com
Cloud server port        : 443
Connected at             : Wed Jan  27 14:18:40 2019
Duration                 : 00d 00h 02m 01s
```

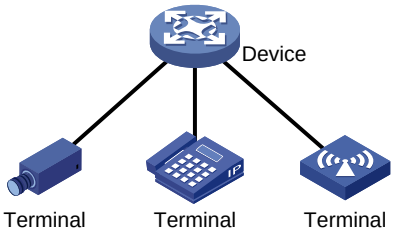
Configuring EPA

About EPA



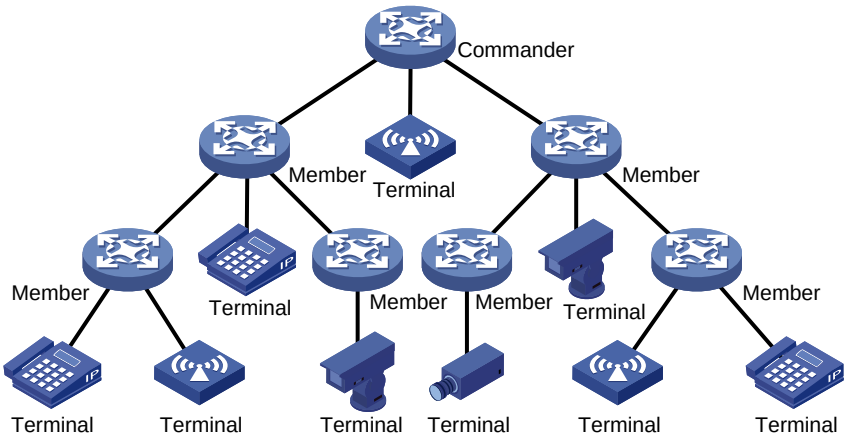
Endpoint Analysis (EPA) allows you to monitor associations and disassociations of endpoints (for example, cameras and IP phones) connecting to an H3C device.

Application scenarios

Non-SmartMC networking

As shown in Figure 1, the device configured with EPA monitors associations and disassociations of endpoints connecting to it. The device can be a standalone device or an IRF fabric. For an IRF fabric, EPA monitors endpoints connecting to all members. The collected association and disassociation information will be reported to the master device for processing.

Figure 1 Non-SmartMC networking



SmartMC networking

In a SmartMC network as shown in Figure 2, EPA settings are configured only on the commander. The members report association and disassociation information about their associated endpoints to the commander. The commander records such information about all associated endpoints in the network, and deploys EPA settings to the members.

You can view EPA information in the entire network on the commander.

Figure 2 SmartMC networking

Endpoint identification methods

EPA supports the following endpoint identification methods:

- **Static identification**—Identifies associations and disassociations of endpoints by matching MAC addresses of the endpoints. This method requires manual configuration of endpoint MAC addresses on the device and is applicable to networks with a small number of endpoints. This method can only identify cameras and cannot identify the vendor and operating system of cameras.
- **Automatic identification**—Identifies associations and disassociations of endpoints through the fields in packets. This method is applicable to networks with a large number of endpoints. This method can identify the endpoint category, vendor and operating system of endpoints. This method needs to work with BYOD.

Static endpoint identification

EPA monitors endpoint associations and disassociations by monitoring the generation and aging of MAC address entries learned by devices. A device configured with EPA can monitor only endpoints in the same subnet as the endpoint access port on the device.

For more information about MAC address entries, see *Layer 2—LAN Switching Configuration Guide*.

Collecting endpoint association information

If a device configured with EPA learns a new MAC address entry, it compares the MAC address and VLAN ID with the configured EPA monitor rules.

- If a match is found, the device determines that a monitored endpoint came online.
  - In a non-SmartMC network, the device records the endpoint association event locally.
  - In a SmartMC network, if the device is the commander, it records the endpoint association event locally. If the device is a member, it reports the event to the commander.
- If no match is found, the device determines that the endpoint is not a monitored endpoint and does not record the endpoint association event.

Collecting endpoint disassociation information

When the MAC address entry of an endpoint ages out, the device determines that the endpoint went offline.

- In a non-SmartMC network, the device records the endpoint disassociation event locally for 7 days.
- In a SmartMC network, the commander records the endpoint disassociation event for 7 days.

Synchronizing information in a SmartMC network

In a SmartMC network, endpoint monitor rules are configured on the commander and deployed to all members by the commander. The rules take effect on both the commander and members. If a member detects an association or disassociation event of a monitored endpoint, it reports the event to the commander for statistics collection and analysis.

You can view endpoint associations and disassociations that occurred in the entire network from the commander. For more information about SmartMC, see "Configuring SmartMC."

Automatic endpoint identification

As Internet technologies develop, many enterprises allow employees to use their own mobile devices (for example, mobile phones, tablets, and laptops) to access internal networks. This might create security risks. To ensure security by managing endpoints, administrators must know what endpoints are in the network, including endpoint category and endpoint operating system.

EPA can automatically identify endpoints by working with BYOD. When an endpoint accesses the network, EPA obtains fingerprint information from the authentication request of an endpoint and matches the fingerprint with the BYOD endpoint identification rules. If a match is found, EPA considers that the endpoint is online and records the MAC address, endpoint category, and vendor of the endpoint.

A BYOD endpoint identification rule is a fingerprint entry, which includes the fingerprint type, fingerprint value, endpoint category, and endpoint vendor, and endpoint OS.

BYOD supports the following endpoint fingerprints:

- **DHCP Option 55 fingerprint**—Parameter request list option. The option is used by an endpoint to request specified configuration parameters. To use this fingerprint, enable recording of client information in DHCP snooping entries on the access interface of endpoints. For more information about DHCP Option55 and DHCP snooping, see DHCP in *Layer 3—IP Services Configuration Guide*.
- **HTTP user agent fingerprint**—Located in the header of HTTP requests to carry information about the endpoint operating system, Web browser, and versions. To use this fingerprint, enable portal authentication on the access interface of endpoints. For more information about portal authentication, see DHCP in *Security Configuration Guide*.
- **MAC address fingerprint**—MAC address of the endpoint or MAC address range to which the endpoint belongs.

Static endpoint identification has higher priority than dynamic endpoint identification. The device matches fingerprint information for an endpoint in the following order:

1. DHCP Option 55 fingerprint.
2. HTTP user agent fingerprint.
3. MAC address fingerprint.

The system has predefined BYOD endpoint identification rules. You can also configure BYOD endpoint identification rules depending on the network requirements.

For more information about BYOD, see AAA in Security Configuration Guide.

Restrictions: Software version compatibility with EPA

EPA is supported only in Release 1112 and later.

Restrictions and guidelines: EPA configuration

Do not use the **mac-address dynamic** command to configure dynamic MAC address entries for monitored endpoints. If you do so, the system might fail to identify endpoint association events.

When you configure EPA in a SmartMC network, follow these restrictions and guidelines:

- Make sure all devices in the network support EPA.
- You can configure endpoint monitor rules only on the commander.
- Configure the same aging time for MAC address entries on all devices in the SmartMC network. Otherwise, endpoint association and disassociation analysis on the commander might be inaccurate. For more information about MAC address entries, see *Layer 2—LAN Switching Configuration Guide*.
- To view endpoint association and disassociation events in a SmartMC network, execute the **display epa monitor-information** command on the commander instead of a member. If you execute the command on a member, the command displays only association events of endpoints connecting to the member.

Configuring static endpoint identification

Restrictions and guidelines

When you configure static endpoint identification rules, follow these restrictions and guidelines:

- To configure multiple rules to monitor an endpoint in different VLANs, make sure the specified VLAN ranges in these rules do not overlap with each other.
- As a best practice to ensure the optimal EPA performance, specify the VLANs in which an endpoint will be monitored.
- If you configure a rule to monitor an endpoint in all VLANs, make sure the endpoint will not come online from over 10 VLANs.
- You can configure a maximum of 1024 monitor rules. As a best practice to ensure the optimal EPA performance, do not configure over 512 monitor rules.
- You can specify a rule ID when creating a monitor rule. If you do not specify the ID, the system assigns the smallest available ID to the rule.
- You cannot execute the **epa monitor-rule** command multiple times to edit an existing rule. To edit an existing rule, use the **undo epa monitor-rule** command to delete the rule and then create the rule again.

Procedure

1. Enter system view.

   system-view

2. Create a static endpoint identification rule.

   epa monitor-rule [*monitor-rule-id*] **mac** *mac-address* [**mask** *mac-mask*] [**vlan** *vlan-id*]

   By default, no static endpoint identification rules exist.

Configuring dynamic endpoint identification

Prerequisites

The system has predefined BYOD endpoint identification rules. You can also configure BYOD endpoint identification rules depending on the network requirements (see AAA in *Security Configuration Guide*).

Restrictions and guidelines

After you modify a fingerprint entry, the modified parameters are reflected for matching online endpoints only if they log out and log in again.

Procedure

1. Enter system view.

   system-view

2. Enable automatic endpoint identification.

   epa auto-identify enable

   By default, automatic endpoint identification is disabled.

Disabling EPA logging

About this task

By default, the EPA module logs endpoint associations and disassociations. If a monitored endpoint comes online or goes offline frequently, the device will generate a large number of log entries. In this case, to avoid affecting device performance, disable EPA logging as a best practice.

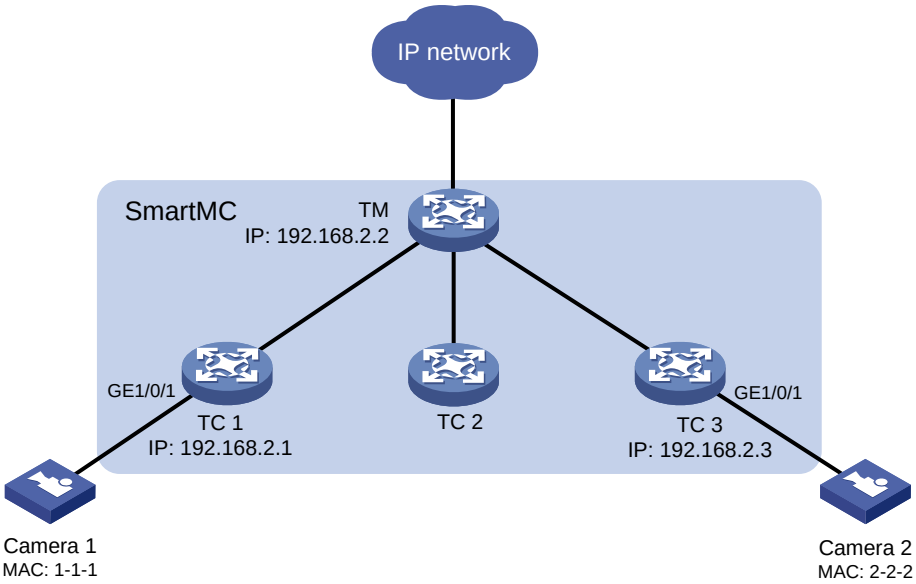
Procedure

1. Enter system view.
   `system-view`
2. Disable EPA logging.
   `epa online-offline-log disable`
   By default, EPA logging is enabled.

Display and maintenance commands for EPA

Execute **`display`** commands in any view.

Task	Command
Display endpoint association and disassociation information detected by EPA.	**`display epa monitor-information`** [**`online`** | **`offline`**] [**`device`** *`device-id`* | **`mac`** *`mac-address`* [**`vlan`** *`vlan-id`*]] [**`verbose`**]



EPA configuration examples

Example: Configuring EPA

Network configuration

As shown in Figure 3, the SmartMC network is established manually. Configure the devices in SmartMC network so EPA can automatically identify camera 1 and camera 2 when they access the SmartMC network.

Figure 3 Network diagram

Configuring the TM

1. Configure SmartMC:

   # Configure VLAN-interface 1.

   ```
   [TM] interface vlan-interface 1
   [TM-Vlan-interface1] ip address 192.168.2.2 24
   [TM-Vlan-interface1] quit
   ```

   # Enable HTTP and HTTPS.

   ```
   [TM] ip http enable
   [TM] ip https enable
   ```

   # Enable the Telnet service.

   ```
   [TM] telnet server enable
   ```

   # Enable NETCONF over SOAP over HTTP.

   ```
   [TM] netconf soap http enable
   ```

   # Enable LLDP globally.

   ```
   [TM] lldp global enable
   ```

   # Create a user. Set the username to **admin** and password to **hello12345**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

   ```
   [TM] local-user admin
   [TM-luser-manage-admin] password simple hello12345
   [TM-luser-manage-admin] service-type telnet http https
   [TM-luser-manage-admin] authorization-attribute user-role network-admin
   [TM-luser-manage-admin] quit
   ```

   # Set scheme authentication for VTY user lines 0 to 63.

   ```
   [TM] line vty 0 63
   [TM-line-vty0-63] authentication-mode scheme
   [TM-line-vty0-63] quit
   ```

   # Enable SmartMC, set the device role to commander, and set the username to **admin** and the password (plaintext) to **hello12345**.

   ```
   [TM] smartmc tm username admin password simple hello12345 enable
   ```

2. Configure static endpoint identification rules on the commander.

```
[TM] epa monitor-rule mac 1-1-1
[TM] epa monitor-rule mac 2-2-2
```

Configuring TC 1

1. Configure SmartMC:

Configure VLAN-interface 1.

```
<TC1> system-view
[TC1] interface vlan-interface 1
[TC1-Vlan-interface1] ip address 192.168.2.1 24
[TC1-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TC1] ip http enable
[TC1] ip https enable
```

Enable the Telnet service.

```
[TC1] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TC1] netconf soap http enable
```

Enable LLDP globally.

```
[TC1] lldp global enable
```

Create a user named **admin**.

```
[TC1] local-user admin
```

Lower password complexity requirements. For more information about these commands, see password control commands in *Security Command Reference*.

```
[TC1-luser-manage-admin] password-control length 4
[TC1-luser-manage-admin] password-control composition type-number 1 type-length 1
[TC1-luser-manage-admin] undo password-control complexity user-name check
```

Set the username and password to **admin**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TC1-luser-manage-admin] password simple admin
[TC1-luser-manage-admin] service-type telnet http https
[TC1-luser-manage-admin] authorization-attribute user-role network-admin
[TC1-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TC1] line vty 0 63
[TC1-line-vty0-63] authentication-mode scheme
[TC1-line-vty0-63] quit
```

Enable SmartMC and set the device role to member.

```
[TC1] smartmc tc enable
```

Configuring TC 3

Configure TC 3 in the same way TC 1 is configured. (Details not shown.)

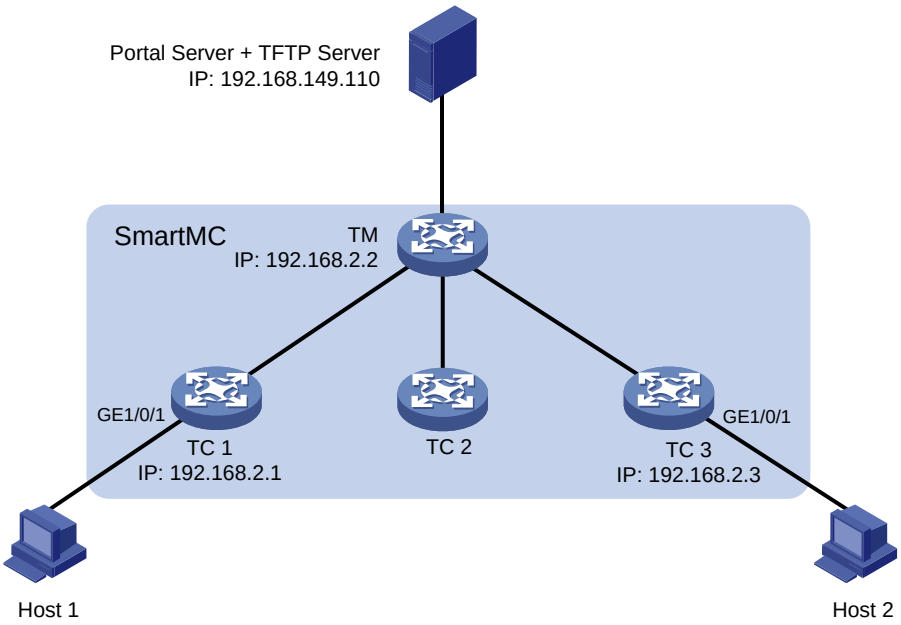
Verifying the configuration

On TC 1, display the online and offline information of endpoints.

```
[TC1] display epa monitor-information
Local device type   : SmartMC TC
Local device ID     : 3acc-58e2-0100
Endpoint information:
  Access device ID   MAC address    VLAN   Interface              Status
```

```
  3acc-58e2-0100     0001-0001-0001  1       GE1/0/1                 Online
```

On the TM, display the online and offline information of endpoints.



```
[TM] display epa monitor-information
Local device type    : SmartMC TM
Local device ID     : 3acc-58e2-0100
Endpoint information:
  Access device ID    MAC address     VLAN    Interface               Status
  3acc-58e2-0100     0001-0001-0001  1       GE1/0/1                  Online
  3acc-58e2-0300     0002-0002-0002  1       GE1/0/1                  Online
```

Example: Configuring automatic endpoint identification (portal authentication)

Network configuration

As shown in Figure 4, the SmartMC network is established automatically. Configure the devices in SmartMC network so EPA can automatically identify host 1 and host 2 when they access the SmartMC network through portal authentication.

Figure 4 Network diagram

Configuring the TM

1. Configure SmartMC:

   # Configure VLAN-interface 1.

   ```
   [TM] interface vlan-interface 1
   [TM-Vlan-interface1] ip address 192.168.2.1 24
   [TM-Vlan-interface1] quit
   ```

   # Enable HTTP and HTTPS.

   ```
   [TM] ip http enable
   [TM] ip https enable
   ```

   # Enable the Telnet service.

   ```
   [TM] telnet server enable
   ```

Enable NETCONF over SOAP over HTTP.

```
[TM] netconf soap http enable
```

Enable LLDP globally.

```
[TM] lldp global enable
```

Create a user. Set the username to **admin** and password to **hello12345**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TM] local-user admin
[TM-luser-manage-admin] password simple hello12345
[TM-luser-manage-admin] service-type telnet http https
[TM-luser-manage-admin] authorization-attribute user-role network-admin
[TM-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TM] line vty 0 63
[TM-line-vty0-63] authentication-mode scheme
[TM-line-vty0-63] quit
```

Enable SmartMC, set the device role to commander, and set the username to **admin** and the password (plaintext) to **hello12345**.

```
[TM] smartmc tm username admin password simple hello12345 enable
```

2. Enable EPA automatic endpoint identification on the commander.

```
[TM] epa auto-identify enable
```

Configuring TC 1

1. Configure SmartMC:

Configure VLAN-interface 1.

```
<TC1> system-view
[TC1] interface vlan-interface 1
[TC1-Vlan-interface1] ip address 192.168.2.2 24
[TC1-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TC1] ip http enable
[TC1] ip https enable
```

Enable the Telnet service.

```
[TC1] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TC1] netconf soap http enable
```

Enable LLDP globally.

```
[TC1] lldp global enable
```

Create a user named **admin**.

```
[TC1] local-user admin
```

Lower password complexity requirements. For more information about these commands, see password control commands in *Security Command Reference*.

```
[TC1-luser-manage-admin] password-control length 4
[TC1-luser-manage-admin] password-control composition type-number 1 type-length 1
[TC1-luser-manage-admin] undo password-control complexity user-name check
```

Set the username and password to **admin**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TC1-luser-manage-admin] password simple admin
[TC1-luser-manage-admin] service-type telnet http https
```

```
[TC1-luser-manage-admin] authorization-attribute user-role network-admin
[TC1-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TC1] line vty 0 63
[TC1-line-vty0-63] authentication-mode scheme
[TC1-line-vty0-63] quit
```

Enable SmartMC and set the device role to member.

```
[TC1] smartmc tc enable
```

2. Configure portal authentication:

Create an ISP domain named **dm1** and enter its view.

```
[TC1] domain dm1
```

Configure AAA methods for the ISP domain.

```
[TC1-isp-dm1] authentication portal local
[TC1-isp-dm1] authorization portal local
[TC1-isp-dm1] accounting portal local
[TC1-isp-dm1] quit
```

Configure a portal Web server.

```
[TC1] portal web-server newpt
[TC1-portal-websvr-newpt] url http://192.168.149.110:2331/portal
[TC1-portal-websvr-newpt] quit
```

Enable direct portal authentication on GigabitEthernet 1/0/1.

```
[TC1] interface gigabitethernet 1/0/1
[TC1-GigabitEthernet1/0/1] port link-mode route
[TC1-GigabitEthernet1/0/1] ip address 192.168.149.110 16
[TC1-GigabitEthernet1/0/1] portal enable method direct
```

Specify portal Web server **newpt** on GigabitEthernet 1/0/1.

```
[TC1-GigabitEthernet1/0/1] portal apply web-server newpt
[TC1-GigabitEthernet1/0/1] quit
[TC1] quit
```

Download an authentication page file from a TFTP server.

```
<TC1> tftp 192.168.149.110 get defaultfile.zip
```

Create an HTTP-based local portal Web service and enter its view.

```
<TC1> system-view
[TC1] portal local-web-server http
```

Specify file **defaultfile.zip** as the default authentication page file for the local portal Web service. (Make sure the file exist under the root directory of the router.)

```
[TC1-portal-local-websvr-http] default-logon-page defaultfile.zip
```

Set the HTTP listening port number to 2331 for the local portal Web service.

```
[TC1-portal-local-websvr-http] tcp-port 2331
[TC1-portal-local-websvr-http] quit
```

3. Configure a BYOD endpoint identification rule:

Configure a rule to identify BYOD endpoints containing HTTP UserAgent fingerprint **Mozilla/5.0**.

```
[TC1] byod rule http-user-agent Mozilla/5.0 device-attributes
```

Configure at least one piece of the following fingerprint information.

```
[TC1-byod-ua-Mozilla/5.0] device-category PC
[TC1-byod-ua-Mozilla/5.0] device-vendor Xerox
```

```
[TC1-byod-ua-Mozilla/5.0] device-os "Window Vista/7 or Server 2008 (Version 6.0)"
[TC1-byod-ua-Mozilla/5.0] quit
```

Configuring TC 3

Configure TC 3 in the same way TC 1 is configured. (Details not shown.)

Verifying the configuration

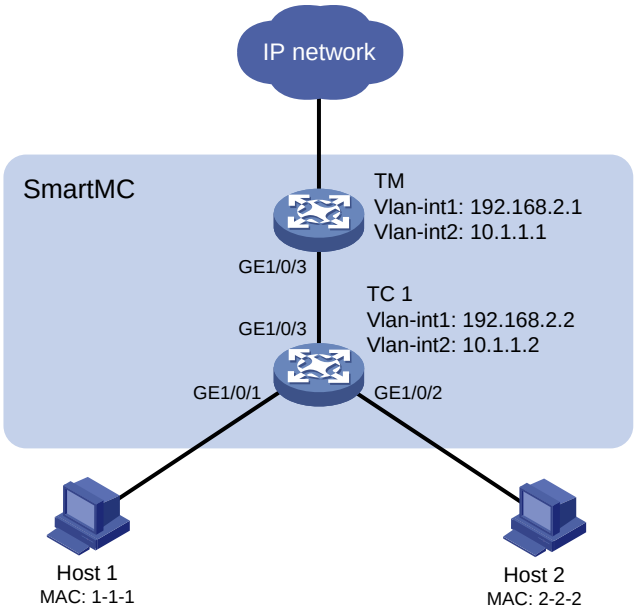
On TC 1, verify that EPA can successfully identify the hosts when they come online.

```
[TC1] display epa monitor-information verbose
Auto identification : Enabled
Local device type   : SmartMC TC
Local device ID     : 3acc-58e2-0100
Total endpoints identified by EPA: 1
Access device ID: 3acc-58e2-0100
  MAC address   : 0a00-2700-0010           VLAN  : -
  IP address    : 192.168.226.1
  Interface     : GigabitEthernet1/0/1     Status: Online
  Category      : PC                       Vendor: Xerox
  OS            : Windows Vista/7 or Server 2008 (Version 6.0)
```

On the TM, verify that EPA can successfully identify the hosts when they come online.

```
[TM] display epa monitor-information verbose
Auto identification : Enabled
Local device type    : SmartMC TM
Local device ID     : 90bc-1b85-0300
Total endpoints identified by EPA: 2

Access device ID: 3acc-58e2-0100
  MAC address    : 0001-0001-0001           VLAN  : -
  IP address     : 192.168.226.1
  Interface      : GigabitEthernet1/0/1     Status: Online
  Category       : PC                       Vendor: Xerox
  OS            : Windows Vista/7 or Server 2008 (Version 6.0)



Access device ID: 3acc-58e2-0300
  MAC address    : 0002-0002-0002           VLAN  : -
  IP address     : 192.168.226.2
  Interface      : GigabitEthernet1/0/1     Status: Online
  Category       : PC                       Vendor: Xerox
  OS            : Windows Vista/7 or Server 2008 (Version 6.0)
```

Example: Configuring automatic endpoint identification (DHCP)

Network configuration

As shown in Figure 5, the SmartMC network is established automatically. Configure the devices in SmartMC network so EPA can automatically identify host 1 and host 2 when they access the SmartMC network through DHCP.

Figure 5 Network diagram

Configuring the TM

1. Configure SmartMC:

Configure VLAN-interface 1.

```
[TM] interface vlan-interface 1
[TM-Vlan-interface1] ip address 192.168.2.1 24
[TM-Vlan-interface1] quit
```

Enable HTTP and HTTPS.

```
[TM] ip http enable
[TM] ip https enable
```

Enable the Telnet service.

```
[TM] telnet server enable
```

Enable NETCONF over SOAP over HTTP.

```
[TM] netconf soap http enable
```

Enable LLDP globally.

```
[TM] lldp global enable
```

Create a user. Set the username to **admin** and password to **hello12345**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TM] local-user admin
[TM-luser-manage-admin] password simple hello12345
[TM-luser-manage-admin] service-type telnet http https
[TM-luser-manage-admin] authorization-attribute user-role network-admin
[TM-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TM] line vty 0 63
[TM-line-vty0-63] authentication-mode scheme
[TM-line-vty0-63] quit
```

Enable SmartMC, set the device role to commander, and set the username to **admin** and the password (plaintext) to **hello12345**.

```
[TM] smartmc tm username admin password simple hello12345 enable
```

2. Configure the DHCP server:

   # Configure VLAN-interface 2.

```
<TM> system-view
[TM] vlan 2
[TM-vlan2] quit
[TM] interface vlan-interface 2

Configuring TC 1

1. Configure SmartMC:

   # Configure VLAN-interface 1.

```
<TC1> system-view
[TC1] interface vlan-interface 1
[TC1-Vlan-interface1] ip address 192.168.2.2 24
[TC1-Vlan-interface1] quit
```

   # Enable HTTP and HTTPS.

```
[TC1] ip http enable
[TC1] ip https enable
```

   # Enable the Telnet service.

```
[TC1] telnet server enable
```

   # Enable NETCONF over SOAP over HTTP.

```
[TC1] netconf soap http enable
```

   # Enable LLDP globally.

```
[TC1] lldp global enable
```

   # Create a user named **admin**.

```
[TC1] local-user admin
```

   # Lower password complexity requirements. For more information about these commands, see password control commands in *Security Command Reference*.

```
[TC1-luser-manage-admin] password-control length 4
[TC1-luser-manage-admin] password-control composition type-number 1 type-length 1
[TC1-luser-manage-admin] undo password-control complexity user-name check
```

Set the username and password to **admin**, add the **telnet**, **http**, and **https** service types, and authorize the user to use the **network-admin** user role.

```
[TC1-luser-manage-admin] password simple admin
[TC1-luser-manage-admin] service-type telnet http https
[TC1-luser-manage-admin] authorization-attribute user-role network-admin
[TC1-luser-manage-admin] quit
```

Set scheme authentication for VTY user lines 0 to 63.

```
[TC1] line vty 0 63
[TC1-line-vty0-63] authentication-mode scheme
[TC1-line-vty0-63] quit
```

Enable SmartMC and set the device role to member.

```
[TC1] smartmc tc enable
```

2. Configure DHCP snooping:

Enable DHCP snooping globally.

```
<TC1> system-view
[TC1] dhcp snooping enable
```

Assign an IP address to VLAN-interface 2.

```
[TC1] vlan 2
[TC1-vlan2] quit
[TC1] interface vlan-interface 2
[TC1-Vlan-interface2] ip address 10.1.1.2 24
[TC1-Vlan-interface2] quit
```

Assign GigabitEthernet 1/0/1 to VLAN 2, and configure it as a trusted port.

```
[TC1] interface gigabitethernet 1/0/1
[TC1-GigabitEthernet1/0/1] port access vlan 2
[TC1-GigabitEthernet1/0/1] dhcp snooping trust
[TC1-GigabitEthernet1/0/1] quit
```

Assign GigabitEthernet 1/0/2 to VLAN 2, and configure it as a trusted port.

```
[TC1] interface gigabitethernet 1/0/2
[TC1-GigabitEthernet1/0/2] port access vlan 2
[TC1-GigabitEthernet1/0/2] dhcp snooping trust
[TC1-GigabitEthernet1/0/2] quit
```

3. Configure GigabitEthernet 1/0/3.

```
[TC1] interface gigabitethernet 1/0/3
[TC1-GigabitEthernet1/0/3] port link-type trunk
[TC1-GigabitEthernet1/0/3] port trunk permit vlan all
```

4. Configure a BYOD endpoint identification rule:

If you use the default fingerprint information, skip this step.

Configure a rule to identify BYOD endpoints containing DHCP Option55 fingerprint **1,121,3,6,12,15,33,43,66,67,138,150**.

```
[TC1] byod rule dhcp-option 1,121,3,6,12,15,33,43,66,67,138,150 device-attribute
```

Configure at least one piece of the following fingerprint information.

```
[TC1-byod-opt-1,121,3,6,12,15,33,43,66,67,138,150] device-category PC
[TC1-byod-opt-1,121,3,6,12,15,33,43,66,67,138,150] device-vendor Xerox
[TC1-byod-opt-1,121,3,6,12,15,33,43,66,67,138,150] device-os "Window Vista/7 or
Server 2008 (Version 6.0)"
[TC1-byod-opt-1,121,3,6,12,15,33,43,66,67,138,150] quit
```

5. Configure host 1 and host 2 to obtain IP addresses through DHCP.

Verifying the configuration

On TC 1, verify that EPA can successfully identify the hosts when they come online.

```
[TC1] display epa monitor-information verbose
Auto identification : Enabled
Local device type   : SmartMC TC
Local device ID     : 3acc-58e2-0100
Total endpoints identified by EPA: 2
Access device ID: 3acc-58e2-0100
  MAC address   : 0001-0001-0001           VLAN  : 2
  IP address    : 10.1.1.3
  Interface     : GigabitEthernet1/0/1     Status: Online
  Category      : PC                       Vendor: Xerox
  OS            : Window Vista/7 or Server 2008 (Version 6.0)
Access device ID: 3acc-58e2-0100
  MAC address   : 0002-0002-0002           VLAN  : 2
  IP address    : 10.1.1.4
  Interface     : GigabitEthernet1/0/2     Status: Online
  Category      : PC                       Vendor: Xerox
  OS            : Window Vista/7 or Server 2008 (Version 6.0)
```

On the TM, verify that EPA can successfully identify the hosts when they come online.

```
[TM] display epa monitor-information verbose
Auto identification : Enabled
Local device type    : SmartMC TM
Local device ID     : 90bc-1b85-0300
Total endpoints identified by EPA: 2
Access device ID: 3acc-58e2-0100

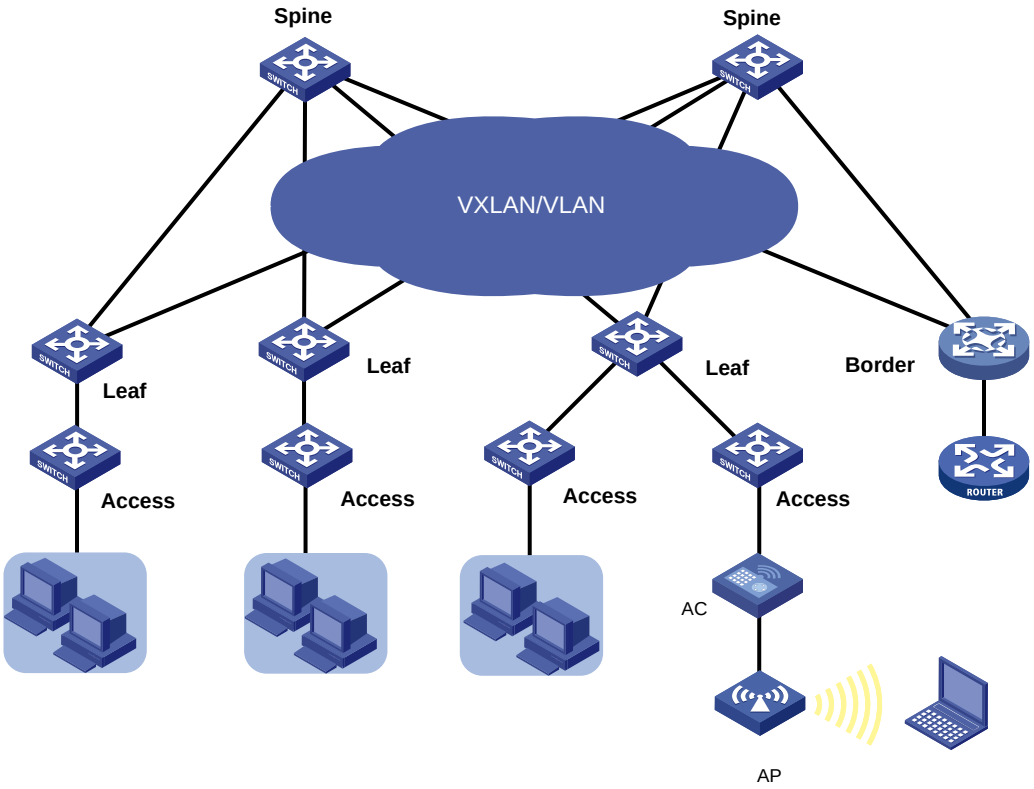
Configuring VCF fabric

About VCF fabric

Based on OpenStack Networking (Neutron), the Virtual Converged Framework (VCF) solution provides virtual network services from Layer 2 to Layer 7 for cloud tenants. This solution breaks the boundaries between the network, cloud management, and terminal platforms and transforms the IT infrastructure to a converged framework to accommodate all applications. It also implements automated topology discovery and automated deployment of underlay networks and overlay networks to reduce the administrators' workload and speed up network deployment and upgrade.

VCF fabric topology

VCF fabric topology for a campus network



In a campus VCF fabric, a device has one of the following roles:

- **Spine node**—Connects to leaf nodes.
- **Leaf node**—Connects to access nodes.
- **Access node**—Connects to an upstream leaf node and downstream terminal devices. Cascading of access nodes is supported.
- **Border node**—Located at the border of a VCF fabric to provide access to the external network.

Spine nodes and leaf nodes form a large Layer 2 network.

The switch series can be used only as access nodes.

Figure 1 VCF fabric topology for a campus network

Automated VCF fabric deployment

VCF provides the following features to ease deployment:

- Automated topology discovery.

  In a VCF fabric, each device uses LLDP to collect local topology information from directly-connected peer devices. The local topology information includes connection interfaces, roles, MAC addresses, and management interface addresses of the peer devices. If multiple spine nodes exist in a VCF fabric, the master spine node collects the topology for the entire network.

- Automated underlay network deployment.

  Automated underlay network deployment sets up a Layer 3 underlay network (a physical Layer 3 network) for users. It is implemented by automatically executing configurations (such as IRF configuration and Layer 3 reachability configurations) in user-defined template files.

Process of automated VCF fabric deployment

The device finishes automated VCF fabric deployment as follows:

1. Starts up without loading configuration and then obtains an IP address, the IP address of the TFTP server, and a template file name from the DHCP server.
2. Determines the name of the template file to be downloaded based on the device role and the template file name obtained from the DHCP server. For example, 1_leaf**.template** represents a template file for leaf nodes.
3. Downloads the template file from the TFTP server.
4. Parses the template file and performs the following operations:

- Deploys static configurations that are independent from the VCF fabric topology.
- Deploys dynamic configurations according to the VCF fabric topology.

  The topology process notifies the automation process of creation, deletion, and status change of neighbors. Based on the topology information, the automation process completes role discovery, automatic aggregation, and IRF fabric setup.

Template file

A template file contains the following contents:

- **System-predefined variables**—The variable names cannot be edited, and the variable values are set by the VCF topology discovery feature.
- **User-defined variables**—The variable names and values are defined by the user. These variables include the username and password used to establish a connection with the RabbitMQ server, network type, and so on. The following are examples of user-defined variables:

  ```
  #USERDEF
  _username = aaa
  _password = hello12345
  _rbacUserRole = network-admin
  _loghost_ip = 172.16.1.136
  ……
  ```

- **Static configurations**—Static configurations are independent from the VCF fabric topology and can be directly executed. The following are examples of static configurations:

  ```
  #STATICCFG
  #
   clock timezone beijing add 08:00:00
  #
   lldp global enable
  #
   stp global enable
  #
  ```

- **Dynamic configurations**—Dynamic configurations are dependent on the VCF fabric topology. The device first obtains the topology information through LLDP and then executes dynamic configurations. The following are examples of dynamic configurations:

  ```
  #
  interface $$_underlayIntfDown
   port link-mode route
   ip address unnumbered interface LoopBack0
   ospf 1 area 0.0.0.0
   ospf network-type p2p
   lldp management-address arp-learning
   lldp tlv-enable basic-tlv management-address-tlv interface LoopBack0
  #
  ```

VCF fabric task at a glance

To configure a VCF fabric, perform the following tasks:

- Configuring automated VCF fabric deployment

No tasks are required to be made on the device for automated VCF fabric deployment. However, you must make related configuration on the DHCP server and the TFTP server so the device can download and parse a template file to complete automated VCF fabric deployment.

- (Optional.) Adjust VCF fabric deployment

  If the device cannot obtain or parse the template file to complete automated VCF fabric deployment, choose the following tasks as needed:

  - Enabling VCF fabric topology discovery
  - Configuring automated underlay network deployment

Configuring automated VCF fabric deployment

Restrictions and guidelines

The default role of the switch in the VCF fabric of a campus network is an access node. You cannot change its role.

On a campus network, links between two access nodes cascaded through GigabitEthernet interfaces and links between leaf nodes and access nodes are automatically aggregated. For links between spine nodes and leaf nodes, the **`trunk permit vlan`** command is automatically executed.

On a campus network where multiple leaf nodes that have an access node attached form an IRF fabric, make sure only one link exists between each leaf node and its connected access node.

Do not perform link migration when devices in the VCF fabric are in the process of coming online or powering down after the automated VCF fabric deployment finishes. A violation might cause link-related configuration fails to update.

The version format of a template file for automated VCF fabric deployment is *x*.*y*. Only the *x* part is examined during a version compatibility check. For successful automated deployment, make sure *x* in the version of the template file to be used is not greater than *x* in the supported version. To display the supported version of the template file for automated VCF fabric deployment, use the **`display vcf-fabric underlay template-version`** command.

If the template file does not include IRF configurations, the device does not save the configurations after executing all configurations in the template file. To save the configurations, use the **`save`** command.

Two devices with the same role can automatically set up an IRF fabric only when the IRF physical interfaces on the devices are connected.

Two IRF member devices in an IRF fabric use the following rules to elect the IRF master during automated VCF fabric deployment:

- If the uptime of both devices is shorter than two hours, the device with the higher bridge MAC address becomes the IRF master.
- If the uptime of one device is equal to or longer than two hours, that device becomes the IRF master.
- If the uptime of both devices are equal to or longer than two hours, the IRF fabric cannot be set up. You must manually reboot one of the member devices. The rebooted device will become the IRF subordinate.

If the IRF member ID of a device is not 1, the IRF master might reboot during automatic IRF fabric setup.

Procedure

1. Finish the underlay network planning (such as IP address assignment, reliability design, and routing deployment) based on user requirements.

2. Configure the DHCP server.

   Configure the IP address of the device, the IP address of the TFTP server, and names of template files saved on the TFTP server. For more information, see the user manual of the DHCP server.

3. Configure the TFTP server.

   Create template files and save the template files to the TFTP server.

   The H3C DR1000 ADDC or ADCAM network management software can automatically create template files and save the files to the TFTP server. If no H3C DR1000 ADDC or ADCAM is available on the network, you must manually create template files and save the files to the TFTP server. For more information about template files, see "Template file."

4. (Optional.) Configure the NTP server.

5. Connect the device to the VCF fabric and start the device.

   After startup, the device uses a management Ethernet interface or VLAN-interface 1 to connect to the fabric management network. Then, it downloads the template file corresponding to its device role and parses the template file to complete automated VCF fabric deployment.

6. (Optional.) Save the deployed configuration.

   If the template file does not include IRF configurations, the device will not save the configurations after executing all configurations in the template file. To save the configurations, use the **`save`** command. For more information about this command, see configuration file management commands in *Fundamentals Command Reference*.

Enabling VCF fabric topology discovery

1. Enter system view.

   `system-view`

2. Enable LLDP globally.

   `lldp global enable`

   By default, LLDP is disabled globally.

   You must enable LLDP globally before you enable VCF fabric topology discovery, because the device needs LLDP to collect topology data of directly-connected devices.

3. Enable VCF fabric topology discovery.

   `vcf-fabric topology enable`

   By default, VCF fabric topology discovery is disabled.

Configuring automated underlay network deployment

Restrictions and guidelines

After automated underlay network deployment starts, you cannot use the CLI commands to modify the configuration. A violation might cause automated deployment failure. If you want to modify the configuration, first cancel or pause automated deployment. Additionally, do not start automated deployment after the modification. To cancel automated deployment, use the **`undo vcf-fabric underlay autoconfigure`** command. To pause automated deployment, use the **`vcf-fabric underlay pause`** command.

Specify the template file for automated underlay network deployment

1. Enter system view.
   system-view
2. Specify the template file for automated underlay network deployment.
   vcf-fabric underlay autoconfigure *template*
   By default, no template file is specified for automated underlay network deployment.

Pausing automated underlay network deployment

About this task

If you pause automated underlay network deployment, the VCF fabric will save the current status of the device. It will not respond to new LLDP events, set up the IRF fabric, aggregate links, or discover uplink or downlink interfaces.

Perform this task if all devices in the VCF fabric complete automated deployment and new devices are to be added to the VCF fabric.

Procedure

1. Enter system view.
   system-view
2. Pause automated underlay network deployment.
   vcf-fabric underlay pause
   By default, automated underlay network deployment is not paused.

Display and maintenance commands for VCF fabric

Execute **display** commands in any view.

Task	Command
Display the role of the device in the VCF fabric.	**display vcf-fabric role**
Display information about automated underlay network deployment.	**display vcf-fabric underlay autoconfigure**
Display the supported version and the current version of the template file for automated VCF fabric provisioning.	**display vcf-fabric underlay template-version**

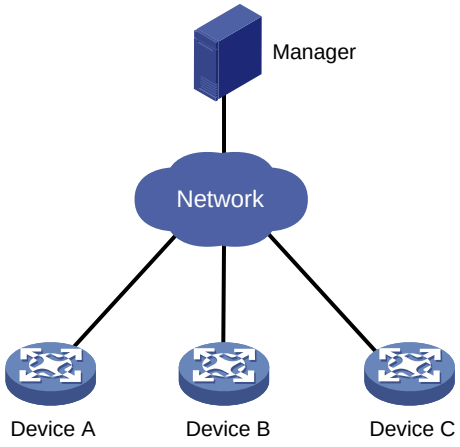
Using Ansible for automated configuration management 1

About Ansible 1
Ansible network architecture 1
How Ansible works 1
Restrictions and guidelines 1
Configuring the device for management with Ansible 2
Device setup examples for management with Ansible 2
Example: Setting up the device for management with Ansible 2

Using Ansible for automated configuration management

About Ansible

Ansible is a configuration tool programmed in Python. It uses SSH to connect to devices.



Ansible network architecture

As shown in Figure 1, an Ansible system consists of the following elements:

- **Manager**—A host installed with the Ansible environment. For more information about the Ansible environment, see Ansible documentation.
- **Managed devices**—Devices to be managed. These devices do not need to install any agent software. They only need to be able to act as an SSH server. The manager communicates with managed devices through SSH to deploy configuration files.

H3C devices can act as managed devices.

Figure 1 Ansible network architecture

How Ansible works

The following the steps describe how Ansible works:

1. On the manager, create a configuration file and specify the destination device.
2. The manager (SSH client) initiates an SSH connection to the device (SSH server).
3. The manager deploys the configuration file to the device.
4. After receiving a configuration file from the manager, the device loads the configuration file.

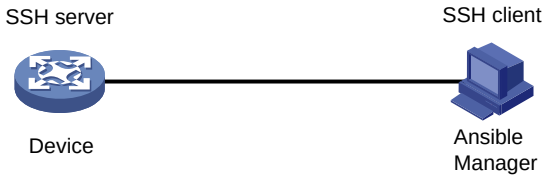
Restrictions and guidelines

Not all services modules are configurable through Ansible. To identify the service modules that you can configure by using Ansible, access the Comware 7 Python library.

Configuring the device for management with Ansible

Before you use Ansible to configure the device, complete the following tasks:

- Configure a time protocol (NTP) or manually configure the system time on the Ansible server and the device to synchronize their system time. For more information about time synchronization, see device management configuration in *Fundamentals Configuration Guide* and "Configuring NTP."
- Configure the device as an SSH server. For more information about SSH configuration, see *Security Configuration Guide*.



Device setup examples for management with Ansible

Example: Setting up the device for management with Ansible

Network configuration

As shown in Figure 2, enable SSH server on the device and use the Ansible manager to manage the device over SSH.

Figure 2 Network diagram

Prerequisites

Assign IP addresses to the device and manager so you can access the device from the manager. (Details not shown.)

Procedure

1. Configure a time protocol (NTP) or manually configure the system time on both the device and manager so they use the same system time. (Details not shown.)
2. Configure the device as an SSH server:

   # Create local key pairs. (Details not shown.)

   # Create a local user named **abc** and set a password for the user.

   ```
   <Device> system-view
   [Device]local-user abc
   [Device-luser-manage-abc] password simple 123456TESTplat&!
   ```

   # Assign the network-admin user role to the user and authorize the user to use SSH, HTTP, and HTTPS services.

   ```
   [Device-luser-manage-abc] authorization-attribute user-role network-admin
   [Device-luser-manage-abc] service-type ssh http https
   [Device-luser-manage-abc] quit
   ```

   # Enable NETCONF over SSH.

```
[Device] netconf ssh server enable
```

Enable scheme authentication for SSH login and assign the network-admin user role to the login users.

```
[Device] line vty 0 63
[Device-line-vty0-63] authentication-mode scheme
[Device-line-vty0-63] user-role network-admin
[Device-line-vty0-63] quit
```

Enable the SSH server.

```
[Device] ssh server enable
```

Authorize SSH user abc to use all service types, including SCP, SFTP, Stelnet, and NETCONF. Set the authentication method to password.

```
[Device] ssh user abc service-type all authentication-type password
```

Enable the SFTP server or SCP server.

- If the device supports SFTP, enable the SFTP server.

  ```
  [Device] sftp server enable
  ```

- If the device does not support SFTP, enable the SCP server.

  ```
  [Device] scp server enable
  ```

Procedure

Install Ansible on the manager. Create a configuration script and deploy the script. For more information, see the relevant documents.

Preface

This configuration guide describes gRPC features and configuration tasks.

This preface includes the following topics about the documentation:

- Audience.
- Conventions.
- Documentation feedback.

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators working with the S5570S-EI and S5500V3-SI switch series.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

Configuring gRPC

About gRPC

gRPC is an open source remote procedure call (RPC) system initially developed at Google. It uses HTTP 2.0 and provides network device configuration and management methods that support multiple programming languages.

gRPC protocol stack layers

Table 1 describes the gRPC protocol stack layers.

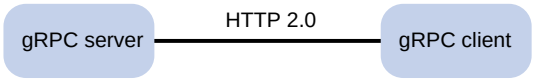

Table 1 gRPC protocol stack layers

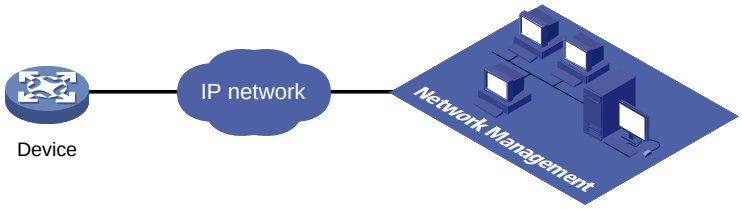
Layer	Description
Content layer	Defines the data of the service module. Two peers must notify each other of the data models that they are using.
Protocol buffer encoding layer	Encodes data by using the protocol buffer code format.
gRPC layer	Defines the protocol interaction format for remote procedure calls.
HTTP 2.0 layer	Carries gRPC.
TCP layer	Provides connection-oriented reliable data links.

Network architecture

As shown in Figure 1, the gRPC network uses the client/server model. It uses HTTP 2.0 for packet transport.

Figure 1 gRPC network architecture

The gRPC network uses the following mechanism:



1. The gRPC server listens to connection requests from clients at the gRPC service port.
2. A user runs the gRPC client application to log in to the gRPC server, and uses methods provided in the .proto file to send requests.
3. The gRPC server responds to requests from the gRPC client.

The device can act as the gRPC server or client.

Telemetry technology based on gRPC

Telemetry is a remote data collection technology for monitoring device performance and operating status. H3C telemetry technology uses gRPC to push data from the device to the collectors on the NMSs. As shown in Figure 2, after a gRPC connection is established between the device and NMSs, the NMSs can subscribe to data of modules on the device.

Figure 2 Telemetry technology based on gRPC

Telemetry modes

The device supports the following telemetry modes:

- **Dial-in mode**—The device acts as a gRPC server and the collectors act as gRPC clients. A collector initiates a gRPC connection to the device to subscribe to device data.

  Dial-in mode supports the following operations:

  - **Get**—Obtains device status and settings.
  - **CLI**—Executes commands on the device.
  - **gNMI**—gRPC Network Management Interface operations, which include the following subtypes of operations:
    - **gNMI Capabilities**—Obtains the capacities of the device.
    - **gNMI Get**—Obtains the status and settings of the device.
    - **gNMI Set**—Deploys settings to the device.
    - **gNMI Subscribe**—Subscribes to data push services provided by the device. The data might be generated by periodical data collection or event-triggered data collection.
- **Dial-out mode**—The device acts as a gRPC client and the collectors act as gRPC servers. The device initiates gRPC connections to the collectors and pushes device data to the collectors as configured.

gNMI

gRPC Network Management Interface (gNMI) is a gRPC-based protocol for network device management. It defines a series of RPC methods to obtain or configure the states of devices.

The device supports gNMI and non-gNMI subscriptions for pushing data to a collector.

Protocols

RFC 7540, *Hypertext Transfer Protocol version 2 (HTTP/2)*

FIPS compliance

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

gRPC is not supported in FIPS mode.

Restrictions and guidelines: gRPC configuration

Disabling the gRPC service deletes all gRPC-related settings.

Configuring the gRPC dial-in mode

gRPC dial-in mode configuration tasks at a glance

To configure the gRPC dial-in mode, perform the following tasks:

1. Configuring the gRPC service
2. (Optional.) Specifying the PKI domain for secure communication with collectors
3. Configuring a gRPC user
4. (Optional.) Enabling gRPC logging in dial-in mode

Configuring the gRPC service

1. Enter system view.
   system-view
2. Enable the gRPC service.
   grpc enable
   By default, the gRPC service is disabled.
3. (Optional.) Set the gRPC service port number.
   grpc port *port-number*
   By default, the gRPC service port number is 50051.
4. (Optional.) Set the gRPC session idle timeout timer.
   grpc idle-timeout *minutes*
   By default, the gRPC session idle timeout timer is 5 minutes.

Specifying the PKI domain for secure communication with collectors

About this task

By default, the gRPC connection between the device and a collector does not provide data encryption service or require authentication. After you specify a PKI domain, the device and the collector will use TLS for data encryption and bidirectional certificate-based authentication to improve communication security.

Restrictions and guidelines

The specified PKI domain must already exist and has correct certificate and key settings. For more information about PKI domains, see PKI configuration in *Security Configuration Guide*.

After you specify the PKI domain, the gRPC service will reboot, closing the connections to collectors. The collectors must re-initiate the connections.

Procedure

1. Enter system view.
   system-view

2. Specify the PKI domain for secure communication with collectors.

   grpc pki domain *domain-name*

   By default, no PKI domain is specified for secure communication with collectors.

Configuring a gRPC user

About this task

For gRPC clients to establish gRPC sessions with the device, you must configure local users for the gRPC clients.

Procedure

1. Enter system view.

   system-view

2. Add a local user with the device management right.

   local-user *user-name* [**class manage**]

3. Configure a password for the user.

   password [{ **hash** | **simple** } *password*]

   By default, no password is configured for a local user. A non-password-protected user can pass authentication after providing the correct username and passing attribute checks.

4. Assign user role network-admin to the user.

   authorization-attribute user-role *user-role*

   By default, a local user is assigned the network-operator role.

5. Authorize the user to use the HTTPS service.

   service-type https

   By default, no service types are authorized to a local user.

For more information about the **local-user**, **password**, **authorization-attribute**, and **service-type** commands, see AAA commands in *Security Command Reference*.

Enabling gRPC logging in dial-in mode

About this task

To identify gRPC issues, enable gRPC operations logging in dial-in mode.

This feature generates gRPC operation logs in dial-in mode and sends them to the information center.

With the information center, you can configure log destinations and output rules. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

gRPC operation logging might degrade device performance if gRPC operations are frequent. As a best practice, use gRPC operation logging only when necessary and log only gRPC operations of interest if gRPC operation logging is enabled.

Procedure

1. Enter system view.

   system-view

2. Enable gRPC logging in dial-in mode. Choose the options to configure as needed:
   - Enable gRPC logging for RPC operations in dial-in mode.

grpc log dial-in rpc { all | { cli | get }* }

By default, gRPC logging is disabled for RPC operations in dial-in mode.

- Enable gRPC logging for gNMI operations in dial-in mode.

  grpc log dial-in gnmi { all | { capabilities | get | set | subscribe }* }

  By default, gRPC logging is enabled for gNMI Set operations and disabled for other gNMI operations in dial-in mode.

Configuring the gRPC dial-out mode

gRPC dial-out mode configuration tasks at a glance

To configure the gRPC dial-out mode, perform the following tasks:

1. Enabling the gRPC service
2. (Optional.) Specifying the PKI domain for secure communication with collectors
3. Configuring sensors
4. Configuring collectors
5. Configuring a subscription
6. (Optional.) Enabling gRPC logging in dial-out mode

Enabling the gRPC service

1. Enter system view.

   system-view
2. Enable the gRPC service.

   grpc enable

   By default, the gRPC service is disabled.

Specifying the PKI domain for secure communication with collectors

About this task

By default, the gRPC connection between the device and a collector does not provide data encryption service or require authentication. After you specify a PKI domain, the device and the collector will use TLS for data encryption and bidirectional certificate-based authentication to improve communication security.

Restrictions and guidelines

The specified PKI domain must already exist and has correct certificate and key settings. For more information about PKI domains, see PKI configuration in *Security Configuration Guide*.

After you specify the PKI domain, the gRPC service will reboot, closing the connections to collectors. The device will automatically re-initiate the connections.

Procedure

1. Enter system view.

   system-view
2. Specify the PKI domain for secure communication with collectors.

grpc pki domain *domain-name*

By default, no PKI domain is specified for secure communication with collectors.

Configuring sensors

About this task

A sensor is a data path from which the device collects data and then pushes the data to a collector. You can create a sensor group and then specify sensor paths in the group. Sensor groups include non-gNMI sensor groups and gNMI sensor groups. If the collector uses gNMI, you must create gNMI sensor groups.

A sensor path supports either event-trigged or periodic data collection.

- **Event-triggered**—The device pushes data from the sensor path to the collector when certain events occur. For information about event-triggered sensor paths, see *NETCONF XML API Event Reference* for the module.
- **Periodic**—The device pushes data from the sensor path to the collector at intervals. For information about periodic sensor paths, see the NETCONF XML API references for the module except for *NETCONF XML API Configuration Reference* and *NETCONF XML API Data Reference*.
- **Condition-triggered**—The device checks the data of the sensor path periodically and pushes the data from the sensor path to the collector when certain conditions are met. For information about condition-triggered sensor paths, the sensor path check interval, and data push conditions, contact H3C Support.

  Condition-triggered sensor paths are supported only by gNMI sensor groups.

Restirctions and guidelines

As a best practice for the device to push data from sensor paths, specify sensor paths of the same type in a sensor group.

Configuring a non-gNMI sensor group

1. Enter system view.

   system-view
2. Enter telemetry view.

   telemetry
3. Create a non-gNMI sensor group and enter sensor group view.

   sensor-group *group-name*
4. Specify a sensor path.

   sensor path *path* [**selection-nodes** *node-list*]

   To specify multiple sensor paths, execute this command multiple times. If you execute this command multiple times with the same sensor path specified, the most recent configuration takes effect.

Configuring a gNMI sensor group

1. Enter system view.

   system-view
2. Enter telemetry view.

   telemetry
3. Create a gNMI sensor group and enter sensor group view.

   sensor-group *group-name* **gnmi**

To enter the view of an existing gNMI sensor group, you do not need to specify the **gnmi** keyword.

4. Specify a sensor path.

   sensor path *path* [**selection-nodes** *node-list*]

   To specify multiple sensor paths, execute this command multiple times.

Configuring collectors

About this task

Collectors are used to receive sampled data from network devices. For the device to communicate with collectors, you must create a destination group and add collectors to the destination group.

Restrictions and guidelines

As a best practice, configure a maximum of five destination groups. If you configure too many destination groups, system performance might degrade.

Prerequisites

To configure a collector that resides in a VPN instance, configure the VPN instance first.

Procedure

1. Enter system view.

   system-view

2. Enter telemetry view.

   telemetry

3. Create a destination group and enter destination group view.

   destination-group *group-name*

4. Specify a collector.

   IPv4:

   ipv4-address *ipv4-address* [**port** *port-number*] [**vpn-instance** *vpn-instance-name*]

   IPv6:

   ipv6-address *ipv6-address* [**port** *port-number*] [**vpn-instance** *vpn-instance-name*]

   The IPv6 address cannot be a link-local address. For more information about link-local addresses, see IPv6 basics configuration in *Layer 3—IP Services Configuration Guide*.

   To specify multiple collectors, execute this command multiple times. One collector must have a different address, port, or VPN instance than the other collectors.

Configuring a subscription

About this task

A subscription binds sensor groups to destination groups. Then, the device pushes data from the specified sensors to the collectors in the destination groups.

Subscriptions include non-gNMI subscriptions and gNMI subscriptions. To push data to a collector that uses gNMI, you must configure a gNMI subscription.

Restrictions and guidelines

For a non-gNMI subscription, specify non-gNMI sensor groups.

For a gNMI subscription, specify gNMI sensor groups.

You cannot use a destination group in both a gRPC subscription and a gNMI subscription.

For the device to correctly push data from sensor paths in a sensor group, make sure the subscription settings for the sensor paths are compliant with Table 2.

Table 2 Compatibility of sensor path types and subscription settings

Sensor path type	Push mode	Data push interval	Data push suppression interval
Periodical	Default	Configured	Not configured
Event-triggered	Default	Not configured	Not configured
Condition-triggered	Condition-triggered	Not configured	Configured

Procedure

1. Enter system view.

   system-view

2. Enter telemetry view.

   telemetry

3. Create a subscription and enter subscription view.
   - Create a non-gNMI subscription and enter subscription view.

     subscription *subscription-name*
   - Create a gNMI subscription and enter subscription view.

     subscription *subscription-name* **gnmi**

     To enter the view of an existing gNMI subscription, you do not need to specify the **gnmi** keyword.

4. (Optional.) Set the data push mode.

   push-mode condition-triggered

   Perform this step only if a sensor group specified for a subscription contains condition-triggered sensor paths.

   This command is available only for gNMI subscriptions.

   By default, the data push mode for a sensor path in a subscription is periodical or event-triggered.

5. (Optional.) Set the DSCP value for packets sent to collectors.

   dscp *dscp-value*

   By default, the DSCP value for packets sent to collectors is 0.

   A greater DSCP value represents a higher priority.

6. (Optional.) Specify the source IP address for packets sent to collectors.

   source-address { *ipv4-address* | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

   By default, the device uses the primary IP address of the output interface for the route to the collectors as the source address.

   Changing the source IP address for packets sent to collectors causes the device to re-establish the connection to the gRPC server.

7. Specify a sensor group.

   sensor-group *group-name* [**sample-interval** [**msec**] *interval* | **suppress-time** *suppress-time*]

   By default, no sensor groups are specified.

Parameter	Description
sample-interval	Data push interval. Specify this parameter only for periodic sensor paths.
suppress-time	Data push suppression interval. Specify this parameter only for condition-triggered sensor paths.

8. Specify a destination group.
   destination-group *group-name*
   By default, no destination groups are specified.

Enabling gRPC logging in dial-out mode

About this task

To identify gRPC issues, enable gRPC data collection logging in dial-out mode.

This feature generates gRPC data collection logs in dial-out mode and sends them to the information center.

With the information center, you can configure log destinations and output rules. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Restrictions and guidelines

gRPC logging in dial-out mode is unavailable for gNMI subscriptions.

Procedure

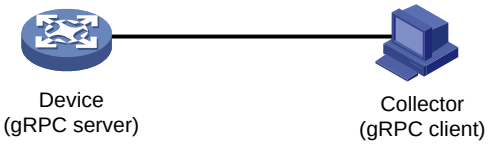
1. Enter system view.
   system-view
2. Enable gRPC logging in dial-out mode.
   grpc log dial-out { **all** | { **event** | **sample** }* }
   By default, gRPC logging is disabled in dial-out mode.

Display and maintenance commands for gRPC

Execute **display** commands in any view.

Task	Command
Display gRPC dial-in mode information.	**display grpc**

gRPC configuration examples



These configuration examples describe only CLI configuration tasks on the device. The collectors need to run an extra application. For information about collector-side application development, see "Developing the collector-side application."

Example: Configuring the gRPC dial-in mode

Network configuration

As shown in Figure 3, configure the gRPC dial-in mode on the device so the device acts as the gRPC server and the gRPC client can subscribe to LLDP events on the device.

Figure 3 Network diagram

Procedure

1. Assign IP addresses to interfaces on the gRPC server and client and configure routes. Make sure the server and client can reach each other.
2. Configure the device as the gRPC server:

   # Enable the gRPC service.

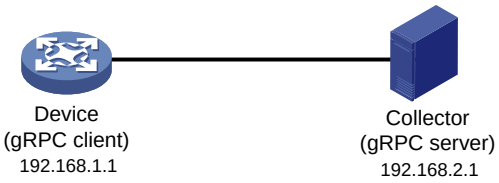
   ```
   <Device> system-view
   [Device] grpc enable
   ```

   # Create a local user named **test**. Set the password of the user, and assign user role network-admin and the HTTPS service to the user.

   ```
   [Device] local-user test
   [Device-luser-manage-test] password simple 123456TESTplat&!
   [Device-luser-manage-test] authorization-attribute user-role network-admin
   [Device-luser-manage-test] service-type https
   [Device-luser-manage-test] quit
   ```
3. Configure the gRPC client.
   a. Prepare a PC and install the gRPC environment on the PC. For more information, see the user guide for the gRPC environment.
   b. Obtain the H3C proto definition file and uses the protocol buffer compiler to generate code of a specific language, for example, Java, Python, C/C++, or Go.
   c. Create a client application to call the generated code.
   d. Start the application to log in to the gRPC server.

Verifying the configuration

When an LLDP event occurs on the gRPC server, verify that the gRPC client receives the event.



Example: Configuring the gRPC dial-out mode

Network configuration

As shown in Figure 4, the device is connected to a collector. The collector uses port 50050.

Configure gRPC dial-out mode on the device so the device pushes the device capability information of its interface module to the collector at 10-second intervals.

Figure 4 Network diagram

Procedure

Configure IP addresses as required so the device and the collector can reach each other. (Details not shown.)

Enable the gRPC service.

```
<Device> system-view
[Device] grpc enable
```

Create a sensor group named **test**, and add sensor path **ifmgr/devicecapabilities/**.

```
[Device] telemetry
[Device-telemetry] sensor-group test
[Device-telemetry-sensor-group-test] sensor path ifmgr/devicecapabilities/
[Device-telemetry-sensor-group-test] quit
```

Create a destination group named **collector1**. Specify a collector that uses IPv4 address 192.168.2.1 and port number 50050.

```
[Device-telemetry] destination-group collector1
[Device-telemetry-destination-group-collector1] ipv4-address 192.168.2.1 port 50050
[Device-telemetry-destination-group-collector1] quit
```

Configure a subscription named **A** to bind sensor group **test** with destination group **collector1**. Set the data push interval to 10 seconds.

```
[Device-telemetry] subscription A
[Device-telemetry-subscription-A] sensor-group test sample-interval 10
[Device-telemetry-subscription-A] destination-group collector1
[Device-telemetry-subscription-A] quit
```

Verifying the configuration

Verify that the collector receives the device capability information of the interface module from the device at 10-second intervals. (Details not shown.)

Protocol buffer code

Protocol buffer code format

Google Protocol Buffers provide a flexible mechanism for serializing structured data. Different from XML code and JSON code, the protocol buffer code is binary and provides higher performance.

Table 3 compares a protocol buffer code format example and the corresponding JSON code format example.

Table 3 Protocol buffer and JSON code format examples

Protocol buffer code format example	Corresponding JSON code format example

Proto definition files

You can define data structures in a proto definition file. Then, you can compile the file with utility protoc to generate code in a programing language such as Java and C++. Using the generated code, you can develop an application for a collector to communicate with the device.

H3C provides proto definition files for both dial-in mode and dial-out mode.

Proto definition files for dial-in mode

Public proto definition files

Dial-in mode supports the following public proto definition files:

- **grpc_service.proto**—Defines the public RPC methods in dial-in mode.
- **gnmi.proto**—Defines the public RPC methods for gNMI operations.
- **gnmi_ext.proto**—Defines the extended message structures required by file **gnmi.proto**.

Files **gnmi.proto** and **gnmi_ext.proto** are from Google. For information about the download paths, see "Obtaining proto definition files."

The **grpc_service.proto** file is provided by H3C. The following are the contents of the file:

```
syntax = "proto2";
package grpc_service;
message GetJsonReply {   // Reply to the Get method
    required string result = 1;
}
message SubscribeReply { // Subscription result
    required string result = 1;
}
message ConfigReply {    // Configuration result
    required string result = 1;
}
message ReportEvent {    // Subscribed event
    required string token_id = 1;    // Login token_id
    required string stream_name = 2; // Event stream name
    required string event_name = 3;  // Event name
    required string json_text = 4;   // Subscription result, a JSON string
}
message GetReportRequest{ // Obtains the event subscription result
    required string token_id = 1; // Returns the token_id upon a successful login
}
message LoginRequest {  // Login request parameters
    required string user_name = 1; // Username
    required string password = 2; // Password
}
message LoginReply {  // Reply to a login request
    required string token_id = 1; // Returns the token_id upon a successful login
}
message LogoutRequest { // Logout parameter
    required string token_id = 1; // token_id
}
```

```
message LogoutReply { // Reply to a logout request
    required string result = 1; // Logout result
}
message SubscribeRequest { // Event stream name
    required string stream_name = 1;
}
message CliConfigArgs { // Sends a configuration command and the parameters to the device
    required int64 ReqId = 1; // Command request ID
    required string cli = 2;  // Command string
}
message CliConfigReply { // Reply to a configuration command execution request
    required int64 ResReqId = 1; // Request ID, which corresponds to that in CliConfigArgs
  required string output = 2;    // Output from the command
    required string errors = 3;  // Command execution result
}
message DisplayCmdArgs { // Sends a display command and the parameters to the device
    required int64 ReqId = 1; // Command request ID
    required string cli = 2;  // Command string
}
message DisplayCmdReply { // Reply to a display command execution request
    required int64 ResReqId =1; // Request ID, which corresponds to that in DisplayCmdArgs
    required string output = 2;  // Output from the command
    required string errors = 3;  // Command execution result
}
service GrpcService {    // gRPC methods
    rpc Login (LoginRequest) returns (LoginReply) {}      // Login method
    rpc Logout (LogoutRequest) returns (LogoutReply) {}   // Logout method
    rpc SubscribeByStreamName (SubscribeRequest) returns (SubscribeReply) {} // Event
subscription method
    rpc GetEventReport (GetReportRequest) returns (stream ReportEvent) {} // Method for
obtaining the subscribed event
    rpc CliConfig (CliConfigArgs)  returns (stream CliConfigReply) {} // Method for
executing a configuration command and returning the execution result
    rpc DisplayCmdTextOutput(DisplayCmdArgs)  returns(stream DisplayCmdReply) {} //
Method for executing a display command and returning the execution result
}
```

Proto definition files for service modules

The dial-in mode supports proto definition files for the following service modules: Device, Ifmgr, IPFW, LLDP, and Syslog.

The following are the contents of the **Device.proto** file, which defines the RPC methods for the Device module:

```
syntax = "proto2";
import "grpc_service.proto";
package  device;
message DeviceBase { // Structure for obtaining basic device information
    optional string HostName = 1;    // Device name
    optional string HostOid = 2;     // sysoid
    optional uint32 MaxChassisNum = 3;    // Maximum number of chassis
```

```
    optional uint32 MaxSlotNum = 4;  // Maximum number of slots
    optional string HostDescription = 5; // Device description
}
message DevicePhysicalEntities { // Structure for obtaining physical entity information
of the device
    message Entity {
        optional uint32 PhysicalIndex = 1;    // Entity index
        optional string VendorType = 2;       // Vendor type
        optional uint32 EntityClass = 3;      // Entity class
        optional string SoftwareRev = 4;      // Software version
        optional string SerialNumber = 5;     // Serial number
        optional string Model = 6;            // Model
    }
    repeated Entity entity = 1;
}
service DeviceService { // RPC methods
    rpc GetJsonDeviceBase(DeviceBase) returns (grpc_service.GetJsonReply) {} // Method
for obtaining basic device information
    rpc GetJsonDevicePhysicalEntities(DevicePhysicalEntities) returns
(grpc_service.GetJsonReply) {}   // Method for obtaining physical entity information of
the device
}
```

Proto definition files for dial-out mode

Public proto definition files

Dial-out mode supports the following public proto definition files:

- **grpc_dialout.proto**—Defines the public RPC methods in dial-out mode.
- **dial_out.proto**—Defines the subscription message formats for gNMI subscriptions in dial-out mode.
- **gnmi.proto**—Defines the public RPC methods in gNMI subscriptions.
- **gnmi_ext.proto**—Defines the extended message structures required by file **gnmi.proto**.

File **dial_out.proto** is from SONIC, and files **gnmi.proto** and **gnmi_ext.proto** are from Google. For information about the download paths, see "Obtaining proto definition files."

The **grpc_dialout.proto** file is provided by H3C. The following are the contents of the file:

```
syntax = "proto2";
package grpc_dialout;
message DeviceInfo{  // Pushed device information
    required string producerName = 1; // Vendor name
    required string deviceName = 2;   // Device name
    required string deviceModel = 3;  // Device model
}
message DialoutMsg{   // Format of the pushed data
    required DeviceInfo deviceMsg = 1; // Device information described by DeviceInfo
    required string sensorPath = 2; // Sensor path, which corresponds to xpath in NETCONF
    required string jsonData = 3;  // Sampled data, a JSON string
}
```

```
message DialoutResponse{  // Response from the collector. Reserved. The value is not
processed.
    required string response = 1;
}
service GRPCDialout {  // Data push method
    rpc Dialout(stream DialoutMsg) returns (DialoutResponse);
}
```

Obtaining proto definition files

To obtain proto files, contact H3C Support.

You can also download files **gnmi.proto**, **gnmi_ext.proto**, and **dial-out.proto** from the following websites respectively:

- https://github.com/openconfig/gnmi/tree/master/proto/gnmi/gnmi.proto
- https://github.com/openconfig/gnmi/tree/master/proto/gnmi_ext/gnmi_ext.proto
- https://github.com/Azure/sonic-telemetry/blob/master/proto/dial_out.proto

Example: Developing a gRPC collector-side application

Use a language (for example, C++) to develop a gRPC collector-side application on Linux to achieve the following goals:

- Collect device data by using Get, gNMI Capabilities, gNMI Get, or gNMI Subscribe operations in dial-in mode or by using dial-out mode.
- Send settings to the device by using gNMI Set or CLI operations in dial-in mode.

Prerequisites

1. Obtain proto definition files.
   - For Get operations in dial-in mode, obtain the **grpc_service.proto** file and proto definition files for service modules.
   - For gNMI operations in dial-in mode, obtain files **grpc_service.proto**, **gnmi.proto**, and **gnmi_ext.proto**.
   - For CLI operations in dial-in mode, obtain the **grpc_service.proto** file.
   - For non-gNMI subscriptions in dial-out mode, obtain the **grpc_dialout.proto** file.
   - For gNMI subscriptions in dial-out mode, obtain the **dial_out.proto**, **gnmi.proto**, and **gnmi_ext.proto** files.
2. Obtain utility protoc from https://github.com/google/protobuf/releases.
3. Obtain the protobuf plug-in for C++ (**protobuf-cpp**) from https://github.com/google/protobuf/releases.

Generating the C++ code for the proto definition files

Dial-in mode

Copy the required proto definition files to the current directory, for example, **grpc_service.proto** and **BufferMonitor.proto**.

```
$protoc --plugin=./grpc_cpp_plugin  --grpc_out=. --cpp_out=. *.proto
```

Dial-out mode

Copy proto definition file **grpc_dialout.proto** to the current directory.

```
$ protoc --plugin=./grpc_cpp_plugin  --grpc_out=.  --cpp_out=. *.proto
```

Developing the collector-side application (dial-in mode)

In dial-in mode, the application needs to provide the code to be run on the gRPC client.

The C++ code generated from the proto definition files already encapsulates the service classes. For the gRPC client to initiate RPC requests, you only need to call the RPC method in the application.

The application performs the following operations:

- Log in to obtain the token_id.
- Prepare parameters for the RPC method, use the service classes generated from the proto definition files to call the RPC method, and resolve the returned result.
- Log out.

Using Get operations

Service classes GrpcService and BufferMonitorService are used in this example.

To develop the collector-side application in dial-in mode:

1. Create a GrpcServiceTest class.

In the class, use the GrpcService::Stub class generated from grpc_service.proto. Implement login and logout with the Login and Logout methods generated from grpc_service.proto.

```
class GrpcServiceTest
{
public:
    /* Constructor functions */
    GrpcServiceTest(std::shared_ptr<Channel> channel):
GrpcServiceStub(GrpcService::NewStub(channel))  {}

    /* Member functions */
    int Login(const std::string& username, const std::string& password);
    void Logout();
    void listen();
Status listen(const std::string& command);

    /* Member variable */
    std::string token;

private:
    std::unique_ptr<GrpcService::Stub> GrpcServiceStub;  // Use the
GrpcService::Stub class generated from grpc_service.proto.
};
```

2. Customize the Login method.

Call the Login method of the GrpcService::Stub class to allow a user who provides the correct the username and password to log in.

```
int GrpcServiceTest::Login(const std::string& username, const std::string& password)
{
    LoginRequest request;   // Username and password.
    request.set_user_name(username);
```

```
    request.set_password(password);

LoginReply reply;
ClientContext context;

    // Call the Login method.
    Status status = GrpcServiceStub->Login(&context, request, &reply);
    if (status.ok())
    {
        std::cout << "login ok!" << std::endl;
        std::cout <<"token id is :" << reply.token_id() << std::endl;
        token = reply.token_id();  // The login succeeds. The token is obtained.
        return 0;
    }
    else{
        std::cout << status.error_code() << ": " << status.error_message()
                  << ". Login failed!" << std::endl;
        return -1;
    }
}
```

3. Initiate an RPC request to the device. In this example, the application subscribes to interface packet drop events.

```
rpc SubscribePortQueDropEvent(PortQueDropEvent) returns
(grpc_service.SubscribeReply) {}
```

4. Create the BufMon_GrpcClient class to encapsulate the RPC method.

Use the BufferMonitorService::Stub class generated from BufferMonitor.proto to call the RPC method.

```
class BufMon_GrpcClient
{
public:
    BufMon_GrpcClient(std::shared_ptr<Channel> channel):
mStub(BufferMonitorService::NewStub(channel))
    {}

    std::string BufMon_Sub_AllEvent(std::string token);
    std::string BufMon_Sub_BoardEvent(std::string token);
    std::string BufMon_Sub_PortOverrunEvent(std::string token);
    std::string BufMon_Sub_PortDropEvent(std::string token);

    /* Get entries */
    std::string BufMon_Sub_GetStatistics(std::string token);
    std::string BufMon_Sub_GetGlobalCfg(std::string token);
    std::string BufMon_Sub_GetBoardCfg(std::string token);
    std::string BufMon_Sub_GetNodeQueCfg(std::string token);
    std::string BufMon_Sub_GetPortQueCfg(std::string token);

private:
   std::unique_ptr<BufferMonitorService::Stub> mStub; // Use the class generated
from BufferMonitor.proto.
```

```
};
```

5. Use std::string BufMon_Sub_PortDropEvent(std::string token) to implement interface packet drop event subscription.

```
std::string BufMon_GrpcClient::BufMon_Sub_PortDropEvent(std::string token)
{
    std::cout << "-------BufMon_Sub_PortDropEvent-------- " << std::endl;

    PortQueDropEvent stNodeEvent;
    PortQueDropEvent_PortQueDrop* pstParam = stNodeEvent.add_portquedrop();

    UINT uiIfIndex = 0;
    UINT uiQueIdx = 0;
    UINT uiAlarmType = 0;

    std::cout<<"Please input interface queue info : ifIndex queIdx alarmtype " <<
std::endl;
    cout<<"alarmtype : 1 for ingress; 2 for egress; 3 for port headroom"<<endl;

    std::cin>>uiIfIndex>>uiQueIdx>>uiAlarmType; // Set the subscription parameters
and interface index.
    pstParam->set_ifindex(uiIfIndex);
    pstParam->set_queindex(uiQueIdx);
    pstParam->set_alarmtype(uiAlarmType);

    ClientContext context;

    /* Token needs to be added to context */ // Set the token_id to be returned after
a successful login
    std::string key = "token_id";
    std::string value = token;
    context.AddMetadata(key, value);

    SubscribeReply reply;
    Status status = mStub->SubscribePortQueDropEvent(&context,stNodeEvent,&reply);
// Call the RPC method.

    return reply.result();
}
```

6. Use a loop to listen for event reports.

Implement this method in the GrpcServiceTest class.

```
void GrpcServiceTest::listen()
{
    GetReportRequest reportRequest;
    ClientContext context;
    ReportEvent reportedEvent;

    /* Add the token to the request */
    reportRequest.set_token_id(token);
```

```
    std::unique_ptr< ClientReader< ReportEvent>>
reader(GrpcServiceStub->GetEventReport(&context, reportRequest)); // Use
GetEventReport (which is generated from grpc_service.proto) to obtain event
information.

    std::string streamName;
    std::string eventName;
    std::string jsonText;
    std::string token;

    JsonFormatTool jsonTool;

    std::cout << "Listen to server for Event" << std::endl;
    while(reader->Read(&reportedEvent) ) // Read the received event report.
    {
        streamName = reportedEvent.stream_name();
        eventName = reportedEvent.event_name();
        jsonText = reportedEvent.json_text();
        token = reportedEvent.token_id();

          std::cout << "/***********EVENT COME**************/" << std::endl;
        std::cout << "TOKEN: " << token << std::endl;
        std::cout << "StreamName: "<< streamName << std::endl;
        std::cout << "EventName: " << eventName << std::endl;
        std::cout << "JsonText without format: " << std::endl << jsonText << std::endl;
        std::cout << std::endl;
        std::cout << "JsonText Formated: " << jsonTool.formatJson(jsonText) <<
std::endl;
        std::cout << std::endl;
    }

    Status status = reader->Finish();
    std::cout << "Status Message:" << status.error_message() << "ERROR code :" <<
status.error_code();
}  // Login and RPC request finished.
```

7. Call the Logout method to log out.

```
void GrpcServiceTest:: Logout ()
{
    LogoutRequest request;
    request.set_token_id(token);
    LogoutReply reply;
    ClientContext context;
    Status status = mStub->Logout(&context, request, &reply);
std::cout << "Logout! :" << reply.result() << std::endl;
}
```

Using gNMI Capabilities operations

1. Create a GrpcServiceTest class.

   See step 1 in "Using Get operations."

2. Customize the Login method.

   See step 2 in "Using Get operations."

3. Initiate an RPC request to the device.

```
rpc Capabilities(CapabilityRequest) returns (CapabilityResponse);
```

4. Create the gnmi_client class to encapsulate the RPC method.

```
class gnmi_client
{
public:
    explicit gnmi_client(const std::string &address,const std::string &tokenId);

    bool TestCapabilities();
    bool TestGet();
    bool TestSet();
    bool TestSubscribePool();
    bool TestSubscribeOnce();
    bool TestSubscribeStream();
    bool TestSubscribeStreamWithAlias();

private:
    void PrintCapabilityResponse(const gnmi::CapabilityResponse &response);
    void PrintGetResponse(const gnmi::GetResponse &response);
    void PrintSubscribeResponse(const gnmi::SubscribeResponse &response);
    void PrintSubscribeRequest(const gnmi::SubscribeRequest &request);
    void PrintGetRequest(const gnmi::GetRequest &request);
    void PrintSetRequest(const gnmi::SetRequest &request);

    void FillGetRequest(gnmi::GetRequest &request);
    void FillSetRequest(gnmi::SetRequest &request);
    void FillSubscribeRequestByOnce(gnmi::SubscribeRequest &request);
    void FillSubscribeRequestByPool(gnmi::SubscribeRequest &request);
    void FillSubscribeRequestByStream(gnmi::SubscribeRequest &request);
    void FillSubscribePool(gnmi::SubscribeRequest &request);
    void FillSubscribeAlias(gnmi::SubscribeRequest &request);

private:
    std::unique_ptr<gnmi::gNMI::Stub> mStubGnmiService;
    std::string mTokenID;
};
```

5. Use the TestCapabilities() method to obtain the capabilities.

```
bool gnmi_client::TestCapabilities()
{
    CapabilityRequest request;
    CapabilityResponse response;
    ClientContext context;

  context.AddMetadata("token_id", mTokenID);
```

```
    std::cout << std::endl << "CapabilitiesRequest => " << std::endl;
    Status ret = mStubGnmiService->Capabilities(&context,request,&response);

    if( StatusCode::OK != ret.error_code() )
    {
        cout << "TestCapabilities ErrorMessage:" << ret.error_message() << endl;
        return false;
    }
    else
    {
        PrintCapabilityResponse(response);
        return true;
    }
}
```

6. Call the Logout method to log out.
   See step 7 in "Using Get operations."

Using gNMI Get operations

1. Create a GrpcServiceTest class.
   See step 1 in "Using Get operations."
2. Customize the Login method.
   See step 2 in "Using Get operations."
3. Initiate an RPC request to the device.
   ```
   rpc Get(GetRequest) returns (GetResponse);
   ```
4. Create the gnmi_client class to encapsulate the RPC method.
   See step 4 in "Using gNMI Capabilities operations."
5. Use the TestGet() method to obtain the Device/Base/HostName.
   ```
   bool gnmi_client::TestGet()
   {
     GetRequest request;
     FillGetRequest(request);
     PrintGetRequest(request);
     GetResponse response;
     ClientContext context;

     context.AddMetadata("token_id", mTokenID);

     Status ret = mStubGnmiService->Get(&context,request,&response);

     if( StatusCode::OK != ret.error_code() )
     {
       cout << "TestGet ErrorMessage:" << ret.error_message() << endl;
       return false;
     }
     else
     {
       PrintGetResponse(response);
       return true;
   ```

```
  }
}

void gnmi_client::FillGetRequest(gnmi::GetRequest &request)
{
    auto prefix = request.mutable_prefix();
    auto pathelem01 = prefix->add_elem();
    pathelem01->set_name("Device");

    auto path1 = request.add_path();
    auto pathelem02 = path1->add_elem();
    pathelem02->set_name("Base");
    auto pathelem03 = path1->add_elem();
    pathelem03->set_name("HostName");
}
```

6. Call the Logout method to log out.
   See step 7 in "Using Get operations."

Using gNMI Set operations

1. Create a GrpcServiceTest class.
   See step 1 in "Using Get operations."
2. Customize the Login method.
   See step 2 in "Using Get operations."
3. Initiate an RPC request to the device.
   This example uses the Device module.
   ```
   rpc Set(SetRequest) returns (SetResponse)
   ```
4. Create a gNMITest class to encapsulate the RPC method.
   Use the gNMI::Stub class that is automatically created by gnmi.proto to call the RPC method.
   ```
   class gNMITest
   {
   public:
   gNMITest(std::shared_ptr<Channel> channel, const std::string tokenId ):

   mStubGrpcService(GrpcService::NewStub(channel)),

   mStubgNMIService(gNMI::NewStub(channel)),
                                                mTokenID(tokenId ){}
        SetResponse TestSetResponseInformation(SetRequest &request, const std::string
   tokenId);
   /*---delete: Device/Base/HostName. Restore the default for HostName -----------*/
   SetResponse DeleteDeviceBaseHostName();      /* delete: Device Base/HostName*/

   /* update: Device/Base/HostName, string_val("string_hostname") */
   SetResponse UpdateDeviceBaseHostNameStringVal();

   /* replace: Device/Base/HostName, string_val("string_hostname") */
   REPL_001 SetResponse ReplaceDeviceBaseHostNameStringVal();
   ```

```
private:
std::unique_ptr<GrpcService::Stub> mStubGrpcService;
std::unique_ptr<gNMI::Stub> mStubgNMIService;
std::string mTokenID;
};
```

5. Use customized methods to perform gNMI Set operations on service data, for example, on the Device module.

```
// Call the Set method to implement communication between client and server and get
the response.
SetResponse gNMITest::TestSetResponseInformation(SetRequest &request, const
std::string tokenId)
{
SetResponse reply;
ClientContext context;
context.AddMetadata("token_id", tokenId);

/* Call the Set method */
Status ret = mStubgNMIService->Set(&context,request,&reply);
if( StatusCode::OK != ret.error_code())
{
std::cout<<"error: "<<ret.error_message()<<std::endl;
}
return reply;
}
// Delete operation
SetResponse gNMITest:: DeleteDeviceBaseHostName ()        /* prefix == Device/Base
*/
{
SetRequest  request;
/* SetRequest->prefix */
Path        *path01 = request.mutable_prefix();
PathElem    *pathelem01 = path01->add_elem();
pathelem01->set_name("Device");
PathElem    *pathelem02 = path01->add_elem();
pathelem02->set_name("Base");

/* SetRequest->delete */
Path        *path02 = request.add_delete_();
PathElem    *pathelem03 = path02->add_elem();
pathelem03->set_name("HostName");
/* Gather response info. */
return TestSetResponseInformation(request, mTokenID);
}
// Update operation
SetResponse gNMITest::UpdateDeviceBaseHostNameStringVal()
{
SetRequest  request;

/* SetRequest->prefix */
```

```
Path        *path01 = request.mutable_prefix();
PathElem    *pathelem01 = path01->add_elem();
pathelem01->set_name("Device");
PathElem    *pathelem02 = path01->add_elem();
pathelem02->set_name("Base");

/* SetRequest->update */
Update      *update01 = request.add_update();
Path        *path02 = update01->mutable_path();
PathElem    *pathelem03 = path02->add_elem();
pathelem03->set_name("HostName");

TypedValue  *typevalue01 = update01->mutable_val();
typevalue01->set_string_val("string_hostname");

/* Gather response info. */
return TestSetResponseInformation(request, mTokenID);
}
// Replace operation
SetResponse gNMITest::ReplaceDeviceBaseHostNameStringVal()
{
SetRequest  request;

/* SetRequest->prefix */
Path        *path01 = request.mutable_prefix();
PathElem    *pathelem01 = path01->add_elem();
pathelem01->set_name("Device");
PathElem    *pathelem02 = path01->add_elem();
pathelem02->set_name("Base");

/* SetRequest->replace */
Update      *replace01 = request.add_replace();
Path        *path02 = replace01->mutable_path();
PathElem    *pathelem03 = path02->add_elem();
pathelem03->set_name("HostName");

TypedValue  *typevalue01 = replace01->mutable_val();
typevalue01->set_string_val("string_hostname");

/* Gather response info. */
return TestSetResponseInformation(request, mTokenID);
}
```

6. Call the Logout method to log out.
   See step 7 in "Using Get operations."

Using gNMI Subscribe operations

1. Create a GrpcServiceTest class.
   See step 1 in "Using Get operations."

2. Customize the Login method.
   See step 2 in "Using Get operations."
3. Initiate an RPC request to the device.
   ```
   rpc Subscribe(stream SubscribeRequest) returns (stream SubscribeResponse);
   ```
4. Create the gnmi_client class to encapsulate the RPC method.
   See step 4 in "Using gNMI Capabilities operations."
5. Create a subscribe method.

```
void gnmi_client::FillSubscribeRequestByOnce(gnmi::SubscribeRequest &request)
{
  auto subscribeList = request.mutable_subscribe();

  auto prefix = subscribeList->mutable_prefix();
  auto pathelem01 = prefix->add_elem();
  pathelem01->set_name("LLDP");

  auto subscribe = subscribeList->add_subscription();

  auto path = subscribe->mutable_path();
  auto pathelem02 = path->add_elem();
  pathelem02->set_name("NeighborEvent");

  auto pathelem03 = path->add_elem();
  pathelem03->set_name("Neighbor");
  (*pathelem03->mutable_key())["IfName"] = "xxx";

    subscribeList->set_mode(::gnmi::SubscriptionList_Mode_ONCE);
    subscribeList->set_encoding(::gnmi::JSON);
}

void gnmi_client::FillSubscribeRequestByPool(gnmi::SubscribeRequest &request)
{
    auto subscribeList =  request.mutable_subscribe();

    auto prefix = subscribeList->mutable_prefix();
    auto pathelem01 = prefix->add_elem();
    pathelem01->set_name("Device");

    auto subscribe = subscribeList->add_subscription();

    auto path = subscribe->mutable_path();
    auto pathelem02 = path->add_elem();
    pathelem02->set_name("CPUs");
    auto pathelem03 = path->add_elem();
    pathelem03->set_name("CPU");
    auto pathelem04 = path->add_elem();
    pathelem04->set_name("CPUUsage");

    subscribeList->set_mode(::gnmi::SubscriptionList_Mode_POLL);
```

```
    subscribeList->set_encoding(::gnmi::JSON);
}

void gnmi_client::FillSubscribeRequestByStream(gnmi::SubscribeRequest &request)
{
     auto subscribeList =  request.mutable_subscribe();

     auto prefix = subscribeList->mutable_prefix();
     auto pathelem01 = prefix->add_elem();
     pathelem01->set_name("Diagnostic");

     auto subscribe = subscribeList->add_subscription();

     auto path = subscribe->mutable_path();
     auto pathelem02 = path->add_elem();
     pathelem02->set_name("CPUEvent");
     auto pathelem03 = path->add_elem();
     pathelem03->set_name("CPU");
     (*pathelem03->mutable_key())["Chassis#condition"] = "equal:1";
     subscribe->set_mode(::gnmi::ON_CHANGE);
     subscribe->set_sample_interval(1000);
     subscribe->set_suppress_redundant(false);
     subscribe->set_heartbeat_interval(1000);

     subscribeList->set_mode(::gnmi::SubscriptionList_Mode_STREAM);
     subscribeList->set_encoding(::gnmi::JSON);
}

void gnmi_client::FillSubscribeAlias(gnmi::SubscribeRequest &request)
{
    auto aliases = request.mutable_aliases();
    auto alias = aliases->add_alias();

    auto path = alias->mutable_path();
    auto pathelem01 = path->add_elem();
    pathelem01->set_name("Device");
    auto pathelem02 = path->add_elem();
    pathelem02->set_name("CPUs");
    auto pathelem03 = path->add_elem();
    pathelem03->set_name("CPU");
    auto pathelem04 = path->add_elem();
    pathelem04->set_name("CPUUsage");

    alias->set_alias("#cpu_usage");
}
```

6. Call the Logout method to log out.
   See step 7 in "Using Get operations."

Using CLI operations

1. Create a GrpcServiceTest class.

   See step 1 in "Using Get operations."
2. Customize the Login method.

   See step 2 in "Using Get operations."
3. Initiate an RPC request to the device.

   This example uses the CliConfig method in file **grpc_service.proto**.

   ```
   rpc CliConfig (CliConfigArgs)  returns (stream CliConfigReply) {}
   ```
4. Use the GrpcServiceTest class to encapsulate the RPC method in the same way you do for Get operations.
5. Use a customized method to support CliConfig operations.

   ```
   // Make a thread to listen to the sever and get messages
   Status GrpcServiceTest::listen(const std::string& command)
   {
   CliConfigArgs reportRequest;
   ClientContext context;
   CliConfigReply reportedEvent;
   std::string key = "token_id";
   std::string value = token;
   context.AddMetadata(key, value);
   /* Add token to request */
   reportRequest.set_reqid(12345678);
   reportRequest.set_cli(command);

   std::unique_ptr< ClientReader< CliConfigReply>> reader(mStub->CliConfig(&context,
   reportRequest));

   std::string streamName;
   std::string output;
   int64 resreqid;

   std::cout << "Command result" << std::endl;
   while( reader->Read(&reportedEvent) )
   {
   streamName = reportedEvent.errors();
   output = reportedEvent.output();
   resreqid = reportedEvent.resreqid();
   std::cout << "resreqid: "<< resreqid << std::endl;
   std::cout << "errors: "<< streamName << std::endl;
   std::cout << "output: \n"<< output << "\n"<< std::endl;
   }
   Status status = reader->Finish();
   return status;
   }
   ```
6. Use a loop in the main function to wait for commands.

   Use the GrpcServiceTest class.

   ```
   int main(int argc, char *argv[])
   {
   ```

```
const char *cmd;
unsigned int i = 0;
unsigned int cycle = 0;

if (4 == argc)
{
g_server_address = argv[1];
g_username = argv[2];
g_password = argv[3];
std::cout << "server_address: " << g_server_address <<std::endl;
std::cout << "username: " << g_username << " " << "password: " << g_password <<
std::endl;
auto channel =
grpc::CreateChannel(g_server_address,grpc::InsecureChannelCredentials());
 // 1. Log in
GrpcServiceTest reporter(channel);
if(0 != reporter.Login(g_username, g_password))
        {
            return 0;
        }
        while(1)
        {// 2. Read a command and execute the command
                std::cout<<"\n\nPlease Input Command:\n";
                getline(std::cin,g_command);          // Read a command
                Status status = reporter.listen(g_command);
                if (!status.ok())
               {
                   std::cout << status.error_code() << ": " << status.error_message()
<< std::endl;
                    break;
               }
        }
    }
   std::cout<<"Complete exec Command."<<std::endl;
   return 0;
}
```

7. Call the Logout method to log out.

See step 7 in "Using Get operations."

Developing the collector-side application (dial-out mode)

In dial-out mode, the application needs to provide the gRPC server code so the collector can receive and resolve data obtained from the device.

The application performs the following operations:

- Inherit the automatically generated GRPCDialout::Service class, reload the automatically generated RPC Dialout service, and resolve the fields.
- Register the RPC service with the specified listening port.

To develop the collector-side application in dial-out mode:

1. Inherit and overload RPC service Dialout.

   # Create class DialoutTest and inherit GRPCDialout::Service.

```
class DialoutTest final : public GRPCDialout::Service { // Overload the automatically generated abstract class.
    Status Dialout(ServerContext* context, ServerReader< DialoutMsg>* reader, DialoutResponse* response) override; // Implement RPC method Dialout.
};
```

2. Register the DialoutTest service as a gRPC service and specify the listening port.

```
using grpc::Server;
using grpc::ServerBuilder;
std::string server_address("0.0.0.0:60057"); // Specify the address and port to listen to.
DialoutTest dialout_test; // Define the object declared in step 1.
ServerBuilder builder;
builder.AddListeningPort(server_address, grpc::InsecureServerCredentials());// Add the listening port.
builder.RegisterService(&dialout_test); // Register the service.
std::unique_ptr<Server> server(builder.BuildAndStart()); // Start the service.
server->Wait();
```

3. Implement the Dialout method and data resolution.

```
Status DialoutTest::Dialout(ServerContext* context, ServerReader< DialoutMsg>* reader, DialoutResponse* response)
{
        DialoutMsg msg;

        while( reader->Read(&msg))
        {
            const DeviceInfo &device_msg = msg.devicemsg();
            std::cout<< "Producer-Name: " << device_msg.producername() << std::endl;
            std::cout<< "Device-Name: " << device_msg.devicename() << std::endl;
            std::cout<< "Device-Model: " << device_msg.devicemodel() << std::endl;
            std::cout<<"Sensor-Path: " << msg.sensorpath()<<std::endl;
            std::cout<<"Json-Data: " << msg.jsondata()<<std::endl;
            std::cout<<std::endl;
        }
        response->set_response("test");

        return Status::OK;
}
```

4. After obtaining the DialoutMsg object (generated from the proto definition file) through the Read method, call the method to obtain the field values.

Appendix: Methods and attributes for gNMI operations

gNMI operations are intended for data tables and event tables.

- Some data tables are periodically reported and some data tables are reported only when triggered. The latter data tables are not supported in the current software version.
- All event tables are reported only when triggered.

Methods for adding columns in gNMI operations

Table 4 describes the methods for adding columns in gNMI operations.

Table 4 Methods for adding columns in gNMI operations

Request description	Sample request	Sample client-side code

Set a column of the key.
For example:
ifTypeExt=*colvalue*
	path:
	<
	elem:
	<
	name:"Interface"
	key:
	<
	name:"ifTypeExt"
	value:"*colvalue*"
	>
	>
	>
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("Interface");
		
		(*pathelem01->mutable_key())["ifTypeExt"] = "*colvalue*";

Set an attribute for a column of the key.
For example, set the attr attribute of ifTypeExt:
attr=*attrvalue*
	path:
	<
	elem:
	<
	name:"Interface"
	key:
	<
	name:"ifTypeExt#attr"
	value:"*attrvalue*"
	>
	>
	>
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("Interface");
		
		(*pathelem01->mutable_key())["ifTypeExt#attr"] = "*attrvalue*";

Set a column in a group of the key.
For example, set the Upper column of the Broadcast group:
Upper=*colvalue*
	path:
	<
	elem:
	<
	name:"Interface"
	key:
	<
	name:"Broadcast:Upper"
	value:"*colvalue*"
	>
	>
	>
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("Interface");
		
		(*pathelem01->mutable_key())["Broadcast:Upper"] = "*colvalue*";

Set an attribute for a column in a group of the key.
For example, set the attr attribute of the Upper column of the Broadcast group:
attr=*attrvalue*
	path:
	<
	elem:
	<
	name:"Interface"
	key:
	<
	name:"Broadcast:Upper#attr"
	value:"*attrvalue*"
	>
	>
	>
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("Interface");
		
		(*pathelem01->mutable_key())["Broadcast:Upper#attr"] = "*attrvalue*";

Set an attribute of a column through the key:
For example, set the attr attribute of Interface:
attr=*attrvalue*
	path:
	<
	elem:
	<
	name:"Interface"
	key:
	<
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("Interface");
		
		(*pathelem01->mutable_key())["#a

Request description	Sample request	Sample client-side code
	name:"#attr" value:"*attrvalue*" > > >	ttr"] = "*attrvalue*";

Set a column or column attribute in JSON:
For example:
Set Upper to *colvalue* and set the attr attribute of Upper to *attrvalue*.
	{
	"Upper": {
	"#text": "*colvalue*",
	"@#attr": "*attrvalue*"
	}
	}
		{
		"Upper": {
		"#text": "*colvalue*",
		"@#attr": "*attrvalue*"
		}
		}

The YANG files for different YANG models might have a top-level node with the same name. To specify the top-level node in the YANG file for a particular YANG model, add the YANG model name before the top-level node name. If you do not add the YANG model name, the top-level node in the first YANG file is specified.
For example, add oc-if before node interfaces to specify the interfaces node in the YANG file for OpenConfig.
	path:
	<
	elem:
	<
	name:"oc-if:interfaces"
	>
	>
		auto pathelem01 = path->add_elem();
		
		pathelem01->set_name("oc-if:interfaces");

gNMI Get operation attributes

gNMI Get operations support the following attributes:

- **regExp**—Regular expression.

  To implement a complex filtering with characters, you can add a **regExp** attribute for a specific column.

  The following example obtains the interface descriptions that contain only characters in upper case:

```
auto prefix = request.mutable_prefix();
 auto pathelem01 = prefix->add_elem();
 pathelem01->set_name("Ifmgr");

 auto path1 = request.add_path();
 auto pathelem02 = path1->add_elem();
 pathelem02->set_name("Interfaces");
 auto pathelem03 = path1->add_elem();
 pathelem03->set_name("Interface");
 auto pathelem04 = path1->add_elem();
 pathelem04->set_name("Description");
 (*pathelem04->mutable_key())["#regExp"] = "^[A-Z]*$";
```

- **match**—Conditional match.

  Table 5 describes the conditional match operators.

Table 5 Conditional match operators

Operation	Operator	Description
More than	match="more:*value*"	More than the specified value. The supported data types include date, digit, and character string.
Less than	match="less:*value*"	Less than the specified value. The supported data types include date, digit, and character string.
Not less than	match="notLess:*value*"	Not less than the specified *value*. The supported data types include date, digit, and character string.
Not more than	match="notMore:*value*"	Not more than the specified *value*. The supported data types include date, digit, and character string.
Equal to	match="equal:*value*"	Equal to the specified *value*. The supported data types include date, digit, character string, OID, and BOOL.
Not equal to	match="notEqual:*value*"	Not equal to the specified *value*. The supported data types include date, digit, character string, OID, and BOOL.
Include	match="include:*string*"	Includes the specified *string*. The supported data types include only character string.
Not include	match="exclude:*string*"	Excludes the specified *string*. The supported data types include only character string.
Start with	match="startWith:*string*"	Starts with the specified *string*. The supported data types include character string and OID.
End with	match="endWith:*string*"	Ends with the specified *string*. The supported data types include only character string.

The following example obtains extension information about the entity whose CPU usage is more than 50%:

```
auto prefix = request.mutable_prefix();
 auto pathelem01 = prefix->add_elem();
 pathelem01->set_name("Device");

 auto path1 = request.add_path();
 auto pathelem02 = path1->add_elem();
 pathelem02->set_name("ExtPhysicalEntities");
 auto pathelem03 = path1->add_elem();
 pathelem03->set_name("Entity");
 auto pathelem04 = path1->add_elem();
 pathelem04->set_name("CpuUsage");
 (*pathelem04->mutable_key())["#match"] = "more:50";
```

- **valuetype**—Attribute value type.

  When obtaining interface information, the device cannot identify whether an integer value for the IfIndex or vrfindex column represents an interface name or index. To resolve the issue, you can use the **valuetype** attribute to specify the value type.

  The **valuetype** attribute has the following values:

Value	Description
name	The column is carrying a name.
index	The column is carrying an index.
auto	Default value. The device uses the value of the column as a name for

Value	Description
	interface matching. If no match is found, the device uses the value as an index for interface matching.

The following example sets the valuetype attribute to index and set the index to 1 for IfIndex:

```
auto prefix = request.mutable_prefix();
 auto pathelem01 = prefix->add_elem();
 pathelem01->set_name("VLAN");

 auto path1 = request.add_path();
 auto pathelem02 = path1->add_elem();
 pathelem02->set_name("TrunkInterfaces");
 auto pathelem03 = path1->add_elem();
 pathelem03->set_name("Interface");
(*pathelem03->mutable_key())["IfIndex"] = "1";
(*pathelem03->mutable_key())["IfIndex#valuetype"] = "index";
```

- **count**—Specifies the data entry quantity.

  The example sets the count attribute:

```
auto prefix = request.mutable_prefix();
 auto pathelem01 = prefix->add_elem();
 pathelem01->set_name("Syslog");

 auto path1 = request.add_path();
 auto pathelem02 = path1->add_elem();
 pathelem02->set_name("Logs");
(*pathelem03->mutable_key())["count"] = "5";
 auto pathelem03 = path1->add_elem();
 pathelem03->set_name("Log");
(*pathelem03->mutable_key())["Index"] = "10";
```

- Value filtering

  You can specify a value for a column in a table to implement full match filtering. If you specify values for multiple columns, the system returns the data that matches all the specified values.

  The following example obtains information about interface whose IfIndex is 1.

```
auto prefix = request.mutable_prefix();
 auto pathelem01 = prefix->add_elem();
 pathelem01->set_name("VLAN");

 auto path1 = request.add_path();
 auto pathelem02 = path1->add_elem();
 pathelem02->set_name("TrunkInterfaces");
 auto pathelem03 = path1->add_elem();
 pathelem03->set_name("Interface");
(*pathelem03->mutable_key())["IfIndex"] = "1";
```

gNMI Set operation attributes

gNMI Set operations support the following attributes:

- **incremental**—Adds configuration data to a column without affecting the original data. This attribute applies to a list column such as the vlan permitlist column.

This example adds VLANs 1 through 10 to an untagged VLAN list that has untagged VLANs 12 through 15.

```
Path        *path01 = request.mutable_prefix();
PathElem    *pathelem01 = path01->add_elem();
pathelem01->set_name("VLAN");
PathElem    *pathelem02 = path01->add_elem();
pathelem02->set_name("HybridInterfaces");

Update  *Update01 = request.add_update();
Path        *path02 = Update01->mutable_path();
PathElem    *pathelem03 = path02->add_elem();
pathelem03->set_name("Interface");
(*pathelem03->mutable_key())["IfName"] = "262";
(*pathelem03->mutable_key())["UntaggedVlanList#incremental"] = "true";
(*pathelem03->mutable_key())["UntaggedVlanList"] = "1-10";
```

- **valuetype**—Attribute value type.

  When configuring an interface, the device cannot identify whether an integer value for the IfIndex or vrfindex column represents an interface name or index. To resolve the issue, you can use the **valuetype** attribute to specify the value type.

  The **valuetype** attribute has the following values:

Value	Description
name	The column is carrying a name.
index	The column is carrying an index.
auto	Default value. The device uses the value of the column as a name for interface matching. If no match is found, the device uses the value as an index for interface matching.

  The following example sets the valuetype attribute to index and set the index to 1 for IfIndex:

```
    Path    *path01 = request.mutable_prefix();
    PathElem*pathelem01 = path01->add_elem();
    pathelem01->set_name("VLAN");
    PathElem*pathelem02 = path01->add_elem();
    pathelem02->set_name("TrunkInterfaces");

    /* SetRequest->delete */
    Path    *path02 = request.add_delete_();
    PathElem*pathelem04 = path02->add_elem();
    pathelem04->set_name("Interface ");
(*pathelem04->mutable_key())["IfIndex"] = "1";
(*pathelem04->mutable_key())["IfIndex#valuetype"] = "index";
```

gNMI Subscribe operation attributes

gNMI Subscribe operations support the following attributes:

- All gNMI Get operation attributes. See "gNMI Get operation attributes."

  These attributes are used for subscription to periodically reported data tables.

- **condition**—Data pushing condition.

  This attribute is used for event table subscription. Values for this attribute are as follows:

  - **more**—More than.

- **less**—Less than.
- **notLess**—Not less than.
- **notMore**—Not more than.
- **equal**—Equal to.
- **notEqual**—Not equal to.
- **include**—Include.
- **exclude**—Not include.
- **startWith**—Start with.
- **endWith**—End with.

The following example monitors LLDP events:

```
auto prefix = subscribeList->mutable_prefix();
auto pathelem01 = prefix->add_elem();
pathelem01->set_name("LLDP");

auto subscribe = subscribeList->add_subscription();
auto path = subscribe->mutable_path();
auto pathelem02 = path->add_elem();
pathelem02->set_name("NeighborEvent");
auto pathelem03 = path->add_elem();
pathelem03->set_name("Neighbor");
(*pathelem03->mutable_key())["IfName"] = "GigabitEthernet1/0/1";
(*pathelem03->mutable_key())["IfName#condition"] = "equal";
```

- **match**—Conditional match.

  This attribute is used for data table subscription.

  The matching object can be a fixed value or another column. The latter supports only data tables that are reported only when triggered.

  Table 5 describes the conditional match operators for matching a fixed value. Attribute values for matching another column are as follows:

  - **refMore**—More than.
  - **refLess**—Less than.
  - **refNotLess**—Not less than.
  - **refNotMore**—Not more than.
  - **refEqual**—Equal to.
  - **refNotEqual**—Not equal to.

  In the following example, a report is triggered only if the current-usage column has a greater value than the alarm-threshold column:

```
auto subscribe = subscribeList->add_subscription();
auto path = subscribe->mutable_path();
auto pathelem02 = path->add_elem();
pathelem02->set_name("queue");
auto pathelem03 = path->add_elem();
pathelem03->set_name("state");
(*pathelem03->mutable_key())["current-usage#match"] = "refMore:alarm-threshold";
```

- **select**—Reports certain columns in a data table that is reported only when triggered

  The following example reports only the current-usage column and the available-usage column:

```
auto subscribe = subscribeList->add_subscription();
auto path = subscribe->mutable_path();
```

```
auto pathelem02 = path->add_elem();
pathelem02->set_name("queue");
auto pathelem03 = path->add_elem();
pathelem03->set_name("state");
(*pathelem03->mutable_key())["current-usage#select"] = "";
(*pathelem03->mutable_key())["available-usage#select"] = "";
```

H3C Network Technology Acronyms

A B C D E F G H I K L M N O P Q R S T U V W X Z

10GE	Ten-GigabitEthernet
1DM	One-way Delay Measurement
3DES	Triple Data Encryption Standard

EPS	Endpoints Profiling System
ER	Edge Relay

ERPS	Ethernet Ring Protection Switching
ERSPAN	Encapsulated Remote Switch Port Analyzer
ERT	Export Route-target
ES	End System
ES	Ethernet Segment
ESF	Extended Super Frame
ESI	Ethernet Segment Identifier
ESMC	Ethernet Synchronous Message Channel
ESN	Extended Sequence Number
ESP	Encapsulating Security Payload
ESS	Extended Service Set
ESS	Exchange Switch Support
ETR	Egress Tunnel Router
ETS	Enhanced Transmission Selection
ETSI	European Telecommunications Standards Institute
EUI	Extended Unique Identifier
EUI-64	64-bit Extended Unique Identifier
EVB	Edge Virtual Bridging
Event MIB	Event Management Information Base
EVFP	Exchange Virtual Fabrics Parameter
EVI	Ethernet Virtual Interconnect
EVPN	Ethernet Virtual Private Network
Extended-MAM	Extended Maximum Allocation Model
F	Return
FA	Foreign Agent
FA	Foreign-AC
FAC	Feature Access Code
FAS	Frame Alignment Signal
FC	Forwarding Class
FC	Fibre Channel
FC	Feasibility Condition
FCF	FCoE Forwarder
FCM	Fast Connect Modem
FCoE	Fibre Channel over Ethernet
FCPS	FC Port Security
FCS	Fabric Configuration Server
FCS	Frame Check Sequence
FD	Feasible Distance
FDB	Forwarding Database

FDMI	Fabric Device Management Interface
FE	Fast Ethernet
FEAC	Far End Alarm and Control signal
FEC	Forward Error Correction
FEC	Forwarding Equivalence Class
FECN	Forward Explicit Congestion Notification
FEP	Front End Processor
FF	Fixed-Filter
FFD	Fast Failure Detection
FFT	Fast Fourier Transform
FG	Forwarding Group
FHR	First Hop Router
FIB	Forwarding Information Base
FIFO	First In First Out
FIFO	First In First Out Queuing
FIP	FCoE Initialization Protocol
FIP Snooping	FCoE Initialization Protocol Snooping
FIPS	Federal Information Processing Standards
Flowspec	Flow Specification
FNG	Fault Notification Generator
FP	Forwarding Profile
FPGA	Field Programmable Gate Array
FPMA	Fabric Provided MAC Address
FQ	Fair Queuing
FQDN	Fully Qualified Domain Name
FR	Frame Relay
FRR	Fast Reroute
FRTP	Frame Relay Traffic Policing
FRTS	Frame Relay Traffic Shaping
FRU	Field Replaceable Unit
FS	Forced Switch
FS	Feasible Successor
FSK	Frequency Shift Keying
FSPF	Fabric Shortest Path First
FT	Fault Tolerance
FT	Fast BSS Transition
FTN	FEC to NHLFE map
FTP	File Transfer Protocol
FXO	Foreign Exchange Office
FXS	Foreign Exchange Station

G	Return
GAL	G-ACh Label
GARP	Generic Attribute Registration Protocol
GAS	Generic Advertisement Service
GDOI	Group Domain of Interpretation
GE	Gigabit Ethernet
GI	Guard Interval
GK	GateKeeper
GLB	Global Load Balance
GM	Group Member
GM	Grandmaster Clock
GMK	Group Master Key
GNE	Gateway Network Element
GNS	Get Nearest Server
GOLD	Generic OnLine Diagnostics
GPS	Global Positioning System
GR	Graceful Restart
GRE	Generic Routing Encapsulation
Group Domain VPN	Group Domain Virtual Private Network
gRPC	Google Remote Procedure Call
GSMPv3	General Switch Management Protocol Version 3
GTC	Generic Token Card
GTK	Group Temporal Key
GTP	GPRS Tunneling Protocol
GTP-U	GPRS Tunneling Protocol User
GTS	Generic Traffic Shaping
GTSM	Generalized TTL Security Mechanism
GVRP	GARP VLAN Registration Protocol
GW	Gateway
GWMP	Gateway Message Protocol
H	Return
HA	Home-AC
HA	High Availability
HA	Home Agent
HABP	HW Bypass Protocol
HBA	Host Bus Adapter
HDB3	High-density bipolar 3
HDLC	High-level Data Link Control
HDSL	High-speed Digital Subscriber Line

HESSID	Homogenous Extended Service Set IDentifier
HGMP	HW Group Management Protocol
HGMPv2	HW Group Management Protocol version 2
HMAC	Hash-based Message Authentication Code
HoPE	Hierarchy of PE
HoVPN	Hierarchy of VPN
HQoS	Hierarchical Quality of Service
HS	High-performance Switch
HTTP	Hypertext Transfer Protocol
HTTPS	Hypertext Transfer Protocol Secure
H-VPLS	Hierarchical VPLS
HWTACACS	HW Terminal Access Controller Access Control System
I	Return
IA	Identity Association
IACTP	Inter Access Controller Tunneling Protocol
IAD	Integrated Access Device
IANA	Internet Assigned Numbers Authority
IBGP	Internal Border Gateway Protocol
ICANN	Internet Corporation for Assigned Names and Numbers
ICMP	Internet Control Message Protocol
ICMPv6	Internet Control Message Protocol for IPv6
ICP	IMA Control Protocol
ICPIF	Calculated Planning Impairment Factor
ICRQ	Incoming Call Request
IDN	Integrated Digital Network
IDS	Intrusion Detection System
IE	Information Element
IE	Interconnect Element
IEEE	Institute of Electrical and Electronics Engineers
IETF	Internet Engineering Task Force
IGMP	Internet Group Management Protocol
IGMP Snooping	Internet Group Management Protocol Snooping
IGP	Interior Gateway Protocol
IGTK	Integrity Group Temporal Key
IIH	Intermediate System-to-Intermediate System Hello
IKE	Internet Key Exchange
IKEv2	Internet Key Exchange Version 2
ILM	Incoming Label Map
ILS	Internet Locator Service

IM	Instant Messaging
IMA	Inverse Multiplexing for ATM
IMAP	Internet Mail Access Protocol
iMC	Intelligent Management Center
IMSI	International Mobile Subscriber Identification Number
InARP	Inverse Address Resolution Protocol
IND	Inverse Neighbor Discovery
INT	In-band Network Telemetry
IntServ	Integrated Service
IPC	Inter-process Communication
IPE	Image Package Envelope
IPHC	IP Header Compression
IPL	Intra-Portal Link
IPN	IGTK Packet Number
IPng	IP Next Generation
IPoA	IP over ATM
IPoEoA	IP over Ethernet over ATM
IPP	Intra-Portal Port
IPS	Intrusion Prevention System
IPsec	IP Security
IPTA	IP Terminal Access
IPv6	Internet Protocol version 6
IPv6 MBGP	IPv6 Multicast BGP
IPv6 ND	IPv6 Neighbor Discovery
IPv6 PIM	IPv6 Protocol Independent Multicast
IPv6 PIM Snooping	IPv6 Protocol Independent Multicast Snooping
IPX	Internetwork Packet Exchange
IRB	Integrated Bridging and Routing
IRB	Integrated Routing and Bridging
IRB	Integrated Routing Bridging and Bridging Routing
IRDP	ICMP Router Discovery Protocol
IRF	Intelligent Resilient Framework
IS	Intermediate System
ISAKMP	Internet Security Association and Key Management Protocol
ISATAP	Intra-Site Automatic Tunnel Addressing Protocol
ISDN	Integrated Services Digital Network
I-SID	Backbone Service Instance Identifier
IS-IS	Intermediate System-to-Intermediate System
ISO	International Organization for Standardization
ISP	Internet Service Provider

ISPF	Incremental Shortest Path First
ISSU	In-Service Software Upgrade
IST	Internal Spanning Tree
ITA	Intelligent Target Accounting
ITR	Ingress Tunnel Router
ITSP	Internet Telephone Service Provider
ITU	International Telecommunication Union
ITU-T	International Telecommunication Union Telecommunication
IV	Initialization Vector
IVR	Interactive Voice Response
K	Return
KAT	Known-Answer Test
KCK	EAPOL-Key Confirmation Key
KEK	Key Encrytion Key
KEK	EAPOL-Key Encryption Key
KS	Key Server
L	Return
L2F	Layer 2 Forwarding
L2PT	Layer 2 Protocol Tunneling
L2TP	Layer 2 Tunneling Protocol
L2VPN	Layer 2 Virtual Private Network
L3VNI	Layer 3 VNI
L3VPN	Layer 3 Virtual Private Network
LAC	L2TP Access Concentrator
LACP	Link Aggregation Control Protocol
LACPDU	Link Aggregation Control Protocol Data Unit
LAN	Local Area Network
LB	Loopback
LB	Label Base
LB	Load Balance
LBM	Loopback Message
LBR	Loopback Reply
LC	Logic Channel
LCFO	Loop Current Feed Open
LCI	Logic Channel Identifier
LCP	Link Control Protocol
LDAP	Lightweight Directory Access Protocol
LDN	Local Dialing Number
LDP	Label Distribution Protocol

LDP ID	LDP Identifier
LDPC	Low-Density Parity Check
LER	Label Edge Router
LFI	Link Fragmentation and Interleaving
LFIB	Label Forwarding Information Base
LGS	Loop-start & Ground-start Signaling
LHR	Last-Hop Router
LI	Leap Indicator
LLC	Logical Link Control
LLDP	Link Layer Discovery Protocol
LLDPDU	Link Layer Discovery Protocol Data Unit
LLDP-MED	Link Layer Discovery Protocol Media Endpoint Discovery
LLID	Logical Link ID
LLQ	Low Latency Queuing
LM	Loss Measurement
LMI	Local Management Interface
LMM	Loss Measurement Message
LMR	Loss Measurement Reply
LNS	L2TP Network Server
LO	Label-block Offset
LOCV	Loss of Connectivity Verification defect
LOID	Logical ONU Identifier
LoRaWAN	Long Range Wide Area Network
LOS	Loss of Signal
LPU	Line Processing Unit
LPU Port	Line Processing Unit Port
LQR	Link Quality Reports
LR	Line Rate
LR	Label Range
LS	Link State
LSA	Link State Acknowledgment
LSA	Link State Advertisement
LSAck	Link State Acknowledgment
LSDB	Link State Database
LSDB	Link State DataBase
LSN	Large-scale NAT
LSP	Label Switched Path
LSP	Link State PDU
LSPDU	Link State Protocol Data Unit
LSR	Link State Request

LSR	Link State Record
LSR	Label Switching Router
LSU	Link State Update
LT	Linktrace
LTM	Linktrace Message
LTR	Linktrace Reply
LTS	L2TP Tunnel Switch
LVF	Listening Virtual Forwarder
LZ	Lempel-Ziv compression
M	Return
M flag	Managed Address Configuration Flag
MA	Mobility Agent
MA	Maintenance Association
MAC	Message Authentication Code
MAC	Media Access Control
MACsec	Media Access Control Security
MAD	Multi-Active Detection
MAM	Maximum Allocation Model
MAN	Metropolitan Area Network
MAP	Mesh Access Point
MBGP	Multicast BGP
MBS	Maximum Burst Size
MC	Mobility Controller
MCC	Mobile Country Code
MCE	Multi-VPN-Instance Customer Edge
MCS	Modulation and Coding Scheme
MCU	Multipoint Control Unit
MD	Maintenance Domain
MD	Multicast Domain
MDC	Multitenant Device Context
MDI	Medium Dependent Interface
MDL	Maintenance Data Link
mDNS	Multicast DNS
MDT	Multicast Distribution Tree
ME	Maintenance Entity
MEC	Multi-access Edge Computing
MED	Multi-Exit Discriminator
MEG	Maintenance Entity Group
MEP	Maintenance association End Point

MEP	MEG End Point
MFAS	Multiframe FAS
MFC	Multi-Frequency Compelled
MFF	MAC-Forced Forwarding
MFR	Multilink Frame Relay
MGCP	Media Gateway Control Protocol
mGRE	Multipoint Generic Routing Encapsulation
MIB	Management Information Base
MIC	Message Integrity Check
MIMO	Multiple Input, Multiple Output
MIP	Maintenance association Intermediate Point
MIP	Mobile IP
MKA	MACsec Key Agreement
MKD	Mesh Key Distributor
MKI	Master Key Identifier
MLD	Multicast Listener Discovery Protocol
MLD Snooping	Multicast Listener Discovery Snooping
MLSP	Mobile Link Switch Protocol
MME	Management MIC IE
MNC	Mobile Network Code
MoH	Music on Hold
MOS	Mean Opinion Scores
MOTD	Message of The Day
MP	Maintenance Point
MP	Mesh Point
MP	Merge Point
MP_REACH_NLRI	Multiprotocol Reachable NLRI
MP_UNREACH_NLRI	Multiprotocol Unreachable NLRI
MP-BGP	Multiprotocol Border Gateway Protocol
MPCP	Multipoint Control Protocol
MPDU	MAC Protocol Data Unit
MPE	Middle-Level PE
MPLS	Multiprotocol Label Switching
MPLS SR	Segment Routing with MPLS
MPLS TE	Multiprotocol Label Switching Traffic Engineering
MPLS VPN	MPLS Virtual Private Network
MPLS-TP	MPLS Transport Profile
MPP	Mesh Portal Point
MQC	Model QoS Command
MR	Map Resolver

MR	Merge Request
MRIB	Multicast Routing Information Base
MRP	Multiple Registration Protocol
MRPDU	MRP Protocol Data Unit
MRRA	Merge Request Resource Allocation
MRU	Maximum-Receive-Unit
MS	Manual Switch
MS	Map Server
MSCHAP	Microsoft Challenge Handshake Authentication Protocol
MSDP	Multicast Source Discovery Protocol
MSDU	MAC Service Data Unit
MSK	Multicast Session Key
MSOH	Multiplex Section Overhead
MSS	Maximum Segment Size
MSTI	Multiple Spanning Tree Instance
MSTP	Multiple Spanning Tree Protocol
MT	Multicast Tunnel
MTI	Multicast Tunnel Interface
MTP	Maintain Probe
MTR	Multi-Topology Routing
MTU	Maximum Transmission Unit
MTU-s	Multi-Tenant Unit switch
MU	Mobile Unit
MVPN	Multicast Virtual Private Network
MVRP	Multiple VLAN Registration Protocol
MVXLAN	Multicast VXLAN
MWI	Message Waiting Indication
MX	Mail Exchanger
N	Return
NA	Neighbor Advertisement
NAI	Network Access Identifier
NAPT	Network Address Port Translation
NAPT-PT	Network Address Port Translation-Protocol Translation
NAS	Network Access Service
NAS	Network Access Server
NAS-ID	Network Access Server Identifier
NAS-Port-ID	Network Access Server Port Identifier
NAS-VLAN-ID	Network Access Server VLAN Identifier
NAT	Network Address Translation

NAT-PT	Network Address Translation-Protocol Translation
NBAR	Network Based Application Recognition
NBMA	Non-Broadcast Multi-Access
NCP	Network Control Protocol
ND	Neighbor Discovery
NDA	NetStream Data Analyzer
NDE	NetStream Data Exporter
NDP	Neighbor Discovery Protocol
NDPP	Network Device Protection Profile
NE	Network Element
NEMO	Network Mobility
NET	Network Entity Title
NetBIOS	Network Basic Input/Output System
NETCONF	Network Configuration Protocol
NFAS	non–FAS
NFV	Network Function Virtualisation
NHLFE	Next Hop Label Forwarding Entry
NHRP	Next Hop Resolution Protocol
NI	National ISDN
NIB	Nexthop Information Base
NII	Network International Identifier
NIST	National Institute of Standards and Technology
NIT	Not Initial Terminal
NLB	Network Load Balancing
NLBS	Network Load Balancing Service
NLPID	Network Layer Protocol Identifier
NLRI	Network Layer Reachability Information
NM	Network Management
NMFAS	Non-Multiframe FAS
NMS	Network Management Station
NMS	Network Management System
NMS	Network Management Server
NNI	Network-to-Network Interface
NO-PAT	Not Port Address Translation
NPDU	Network Protocol Data Unit
NPE	Network Provider Edge
NPTv6	IPv6-to-IPv6 Network Prefix Translation
NPV	N_Port Virtualization
NQA	Network Quality Analyzer
NR	No Request

nrt-VBR	non-real-time Variable Bit Rate
NS	Neighbor Solicitation
NS	Name Server
NSAP	Network Service Access Point
NSC	NetStream Collector
NSF	Non-Standard Facilities
NSR	Nonstop Routing
NSS	Number of Spatial Streams
NTDP	Neighbor Topology Discover Protocol
NTE	Named Telephone Event
NTP	Network Time Protocol
NTT	Nippon Telegraph and Telephone Corpration
NVC	Network Virtualization Controller
NVE	Network Virtualization Edge
NVGRE	Network Virtualization using Generic Routing Encapsulation
O	Return
O Flag	Other Stateful Configuration Flag
OAA	Open Application Architecture
OAMPDU	OAM Protocol Data Unit
OAP	Open Application Platform
OC	Optical Carrier
OC	Ordinary Clock
ODAP	On-Demand Address Pool
ODF	Optical Distribution Frame
ODN	Optical Distribution Network
ODU	Optical Data Unit
OEM	Original Equipment Manufacturer
OFDM	Orthogonal Frequency Division Multiplexing
OI	Organization Identifier
OID	Object Identifier
OLT	Optical Line Terminal
ONU	Optical Network Unit
OOB	Out-of-Band
OPU	Optical Payload Unit
ORF	Outbound Route Filtering
OSI	Open System Interconnection
OSPF	Open Shortest Path First
OSU	Online Sign Up
OTN	Optical Transport Network

OTU	Optical Transmit Unit
OUI	Organizationally Unique Identifier
OVSDB	Open vSwitch Database
P	Return
P2MP	Point-to-MultiPoint
P2P	PW to PW
P2P	Peer-to-Peer
P2P	Point-to-Point
P2PTC	Peer-to-Peer Transparent Clock
PA	Provider Allocated
PADT	PPPoE Active Discovery Terminate
PAGP	Port Aggregation Protocol
PAM	Port to Application Map
PAM	Pulse Amplitude Modulation
PAN ID	Personal Area Network Identifier
PAP	Password Authentication Protocol
Passive-Stateful PCC	Passive-Stateful Path Computation Client
Passive-Stateful PCE	Passive-Stateful Path Computation Element
PAT	Port Address Translation
PBAR	Port Based Application Recognition
PBB	Provider Backbone Bridge
PBBN	Provider Backbone Bridge Network
PBN	Provider Bridge Network
PBR	Policy-based Routing
PBX	Private Branch Exchange
PCB	Protocol Control Block
PCC	Path Computation Client
PCE	Path Computation Element
PCEP	Path Computation Element Communication Protocol
PCM	Pulse Code Modulation
PCR	Peak Cell Rate
PD	Powered Device
PD	Prefix Delegation
PDH	Plesiochronous Digital Hierarchy
PDP	Policy Decision Point
PDU	Protocol Data Unit
PE	Provider Edge
PE-agg	PE Aggregation
PEAP	Protected Extensible Authentication Protocol

PEAP-GTC	Protected Extensible Authentication Protocol-Microsoft Generic Token Card
PEAP-MSCHAPv2	Protected Extensible Authentication Protocol-Microsoft Challenge Handshake Authentication Protocol v2
PEM	Privacy Enhanced Mail
PEM	Power Entry Module
PEP	Policy Enforcement Point
PFC	Power Free Connector
PFC	Priority-based Flow Control
PFC	Protocol-Field-Compression
PFS	Perfect Forward Secrecy
PHB	Per-hop Behavior
PHP	Penultimate Hop Popping
PI	Power Interface
PI	Provider Independent
PI	Progress Indicator
PIC	Prefix Independent Convergence
PIM	Protocol Independent Multicast
PIM Snooping	Protocol Independent Multicast Snooping
PIM-DM	Protocol Independent Multicast-Dense Mode
PIM-SM	Protocol Independent Multicast-Sparse Mode
PIM-SSM	Protocol Independent Multicast Source-Specific Multicast
PIN	Personal Identification Number
PIR	Peak Information Rate
PKCS	Public Key Cryptography Standards
PKI	Public Key Infrastructure
PLCP	Physical Layer Convergence Procedure
PLMN	Public Land Mobile Network
PLR	Point of Local Repair
PMK	Pairwise Master Key
PMTU	Path MTU
PoE	Power over Ethernet
POH	Path Overhead
POP3	Post Office Protocol - Version 3
POS	Passive Optical Splitter
POS	Point of Sale
PPP	Point-to-Point Protocol
PPPoA	PPP over ATM
PPPoE	Point-to-Point Protocol over Ethernet
PPPoEoA	PPPoE over ATM

PPTP	Point-to-Point Tunneling Protocol
PQ	Priority Queuing
PRBS	Pseudo Random Bit Sequence
PRC	Primary Reference Clock
PRI	Primary Rate Interface
PRL	Preferred Roaming List
PS	Protection Switching
PSB	Path State Block
PSC	Protection State Coordination
PSD	Power Spectral Density
PSE	Power Sourcing Equipment
PSK	Pre-Shared Key
PSN	Packet Switched Network
PSNP	Partial Sequence Number PDU
PSST	Principal Switch Selection Timer
PSTN	Public Switched Telephone Network
PTK	Pairwise Transient Key
PTP	Precision Time Protocol
PTR	Pointer Record
PTY	Pseudo-Terminals
PUK	PIN Unlocking Key
PVC	Permanent Virtual Circuit
PVC PQ	PVC Priority Queuing
PVID	Port VLAN ID
PVP	Permanent Virtual Path
PVST	Per-VLAN Spanning Tree
PW	Pseudowire
PW-ACH	PW Associated Channel Header
PWCT	Pairwise Conditional Test
PWE3	Pseudo Wire Emulation Edge-to-Edge
PXE	Preboot eXecution Environment
Q	Return
QCN	Quantized Congestion Notification
QL	Quality Level
QoS	Quality of Service
QPPB	QoS Policy Propagation Through the Border Gateway Protocol
R	Return
RA	Router Alert
RA	Router Advertisement

RA	Registration Authority
RADIUS	Remote Authentication Dial-In User Service
RAI	Remote Alarm Indication
RALM	RADIUS Authenticated Login Using MAC-address
R-APS	Ring Automatic Protection Switching
RAS	Registration, Admission, and Status
RB	Routing Bridge
RBAC	Role Based Access Control
RBM	Remote Backup Management
RCA	Release Change Authorization
RCF	Reconfigure Fabric
RCPI	Received Channel Power Indicator
RD	Routing Domain
RD	Reported Distance
RD	Route Distinguisher
RDI	Remote Defect Indication
RDM	Russian Dolls Model
RDP	Read Diagnostic Parameters
RED	Random Early Detection
RedisDBM	Redis Database Manager
REG	Registration Center
RFID	Radio Frequency Identification
RIB	Routing Information Base
RIP	Routing Information Protocol
RIP-2	Routing Information Protocol version 2
RIPng	RIP next generation
RIR	Resilient Intelligent Route
RLOC	Routing Locator
RLSN	Remote Link Status Notification
RMON	Remote Network Monitoring
ROA	Recognized operating Agency
Roam OI	Roam Organization Identifier
RP	Rendezvous Point
RP	Reflective Relay
RP	Reaction Point
RPA	Register Port Attributes
RPA	Rendezvous Point Address
RPC	Remote Procedure Call
RPF	Reverse Path Forwarding
RPI	Receive Power Indication

RPKI	Resource Public Key Infrastructure
RPL	Rendezvous Point Link
RPL	Ring Protection Link
RPR	Resilient Packet Ring
RPRT	Register Port
RPS	Redundant Power System
RP-Set	Rendezvous Point Set
RPT	Rendezvous Point Tree
RR	Route Reflector
RR	Reflective Relay
RR	Router Renumber
RRI	Reverse Route Injection
RRM	Radio Resource Management
RRPP	Rapid Ring Protection Protocol
RS	Router Solicitation
RSB	Reservation State Block
RSCN	Registered State Change Notification
RS-DCC	Resource-Shared DCC
RSH	Remote Shell
RSN	Robust Security Network
RSNA	Robust Security Network Association
RSNI	Received Signal to Noise Indicator
RSOH	Regenerator Section Overhead
RSSI	Received Signal Strength Indicator
RSSI	Received Signal Strength Indication
RSTP	Rapid Spanning Tree Protocol
RSVP	Resource Reservation Protocol
RT	Route Target
RTC	Remote Terminal Connection
RTCP	Real-Time Transport Control Protocol
RTM	Real-Time Event Manager
RTP	Reliable Transport Protocol
RTP	Real-Time Transport Protocol
RTPQ	Real-Time Transport Protocol Priority Queuing
RTS	Request to Send
RTSP	Real Time Streaming Protocol
RTT	Round-Trip Time
rt-VBR	Real-time Variable Bit Rate
RU	Rack Unit

S	Return
S/MIME	Secure/Multipurpose Internet Mail Extensions
SA	Security Association
SA	Source Active
SA Query	Security Association Query
SABM	Set Asynchronous Balanced Mode
SACK	Selective Acknowledgment
SAE	Simultaneous authentication of equals
SAFI	Subsequent Address Family Identifier
SAII	Source Attachment Individual Identifier
SAM	Security Accounting Management
SAN	Storage Area Networks
SAP	Service Advertising Protocol
SAToP	Structure-Agnostic TDM over Packet
SAVI	Source Address Validation Improvement
SB	Service Bridge
SBFD	Seamless BFD
SBM	Subnetwork Bandwidth Management
SCCP	Skinny Client Control Protocol
SCEP	Simple Certificate Enrollment Protocol
SCFF	Single Choke Fairness Frame
SCR	Sustainable Cell Rate
SCR	State Change Registration
SD	Signal Degrade
SDH	Synchronous Digital Hierarchy
SDLC	Synchronous Data Link Control
SDN	Software Defined Network
SDP	Session Description Protocol
SDSL	Symmetric Digital Subscriber Line
SDU	Service Data Unit
SE	Shared-Explicit
SEC	SDH Equipment Clock
SF	Super Frame
SF	Signal Fail
SFC	Stage Fabric Configuration Update
sFlow	Sampled Flow
SFM	Source-Filtered Multicast
SFP	Small Form-factor Pluggable
SFTP	Secure FTP

Short GI	Short Guard Interval
SIA	Stuck In Active
SID	Segment Identifier
SIP	Session Initiation Protocol
SIPS	SIP Secure
SLA	Service Level Agreement
SLAAC	Stateless Address Autoconfiguration
SLB	Server Load Balance
SLC	Service Logic Control
SLIP	Serial Line Internet Protocol
SLM	Single-ended Loss Measurement
SMA	State Machine based Anti-spoofing
SmartMC	Smart Management Center
SMET	Selective Multicast Ethernet Tag Route
S-MLAG	Simple Multichassis Link Aggregation
SMTP	Simple Mail Transfer Protocol
SN	Serial Number
SNA	System Network Architecture
SNAP	Subnet Access Protocol
SNAT	Source Network Address Translation
SNMP	Simple Network Management Protocol
SNMP-DCA	SNMP Data Collection Agent
SNP	Sequence Number PDU
SNPA	Subnetwork Point of Attachment
SNR	Signal-to-Noise Ratio
SNTP	Simple NTP
SOA	Start of Authority
SOAP	Simple Object Access Protocol
SOH	Section Overhead
SONET	Synchronous Optical Network
SoO	Site of Origin
SP	Strict Priority
SP	Service Provider
SP	Scheduler Policy
SPB	Shortest Path Bridging
SPBM	Shortest Path Bridging MAC Mode
SPBM	Shortest Path Bridging MAC
SPBN	Shortest Path Bridging Network
SPCS	Stored Program Control Switching System
SPE	Superstratum PE or Service Provider-end PE

SPF	Shortest Path First
SPI	Security Parameter Index
SPID	Service Profile Identification
SPM	Smart PoE Manager
SPSource ID	Shortest Path Source Identifier
SPT	Shortest Path Tree
SQL	Structured Query Language
SR	Segment Routing
Srefresh	Summary Refresh
SRGB	Segment Routing Global Block
SRLB	Segment Routing Local Block
SRLSP	Segment Routing Label Switched Path
SRMC	Segment Routing Mapping Client
SRMS	Segment Routing Mapping Server
SRST	Survivable Remote Site Telephony
sr-TCM	single rate TCM
SRTP	Secure Real-Time Transport Protocol
SRV	Service
SSA	SIP Stack Adapt
SSH	Secure Shell
SSID	Service Set Identifier
SSL	Secure Sockets Layer
SSM	Synchronization Status Message
SSM	Source-Specific Multicast
SSP	Switch-to-Switch Protocol
SSU-A	primary level SSU
SSU-B	second level SSU
ST	Shared Tree
Stateful PCE	Stateful Path Computation Element
Stateless PCC	Stateless Path Computation Client
Stateless PCE	Stateless Path Computation Element
STBC	Space-Time Block Coding
STP	Spanning Tree Protocol
STR	Switch Trace Route
SVC	Static Virtual Circuit
SVC	Switched Virtual Circuit
SVP	SpectraLink Voice Priority
T	Return
TA	Terminal Adapter

TACACS	Terminal Access Controller Access Control System
TACL	Temporary Access Control List
TAI	International Atomic Time
TAII	Target Attachment Individual Identifier
T-BC	Telecom Boundary Clock
TC	Topology Checksum
TC	Topology Change
TC	Topology client
TC	Traffic Class
TC	Transparent Clock
TCA	Topology Change Acknowledge
TCAM	Ternary Content Addressable Memory
TCI	Tag Control Information
Tcl	Tool Command Language
TCN BPDU	Topology Change Notification BPDU
TCP	Transmission Control Protocol
TCT-BC	Transparent Telecom Boundary Clock
TDM	Time Division Multiplexing
TDMA	Time Division Multiple Access
TE	Traffic Engineering
TEDB	TE DataBase
TEI	Terminal Endpoint Identifier
TEID	Tunnel Endpoint Identifier
TEK	Tranfic Encrytion Key
TFO	Transport Flow Optimization
TFTP	Trivial File Transfer Protocol
TI-LFA FRR	Topology-Independent Loop-free Alternate Fast Reroute
TIM	Traffic Indication Map
TK	Temporal Key
TKIP	Temporal Key Integrity Protocol
TLS	Transport Layer Security
TLS	Transparent LAN Service
TLV	Type/Length/Value
TM	Topology Master
ToS	Type of Service
TP	Traffic Policing
TP	Topology Protection
TPA	Third-part Application
TPC	Transmit Power Control
TPDU	Transport Protocol Data Unit

TPID	Tag Protocol Identifier
TPMR	Two-Port MAC Relay
TQ	Time Quantum
TRILL	TRansparent Interconnection of Lots of Links
TRIP	Triggered RIP
tr-TCM	two-rate TCM
TS	Traffic Shaping
TSA	Tunnel Switching Aggregator
TST	Test
T-TC	Telecom Transparent Clock
TTI	Trail Trace Identifier
TTL	Time to Live
TTLS	Tunneled Transport Layer Security
TTLS-GTC	Tunneled Transport Layer Security-Microsoft Generic Token Card
TTLS-MSCHAPv2	Tunneled Transport Layer Security-Microsoft Challenge Handshake Authentication Protocol v2
T-TSC	Telecom Time Slave Clock
TTY	True Type Terminal
TU	Tributary Unit
TUG	Tributary Unit Group
TWAMP	Two-Way Active Measurement Protocol
TxBF	Tx Beamforming
TXOP Limit	Transmission Opportunity Limit
TXT	Text
U	Return
UA	Unnumbered Acknowledge
UA	User Agent
UAC	User Agent Client
U-APSD	Unscheduled Automatic Power-Save Delivery
UAS	User Agent Server
UBR	Unspecified Bit Rate
UCM	User Connection Management
UDLD	Uni-directional Link Direction
UDP	User Data Protocol
UE	User Equipment
UFC	Update Fabric Configuration
UIM	User Identity Module
UNI	User-to-Network Interface
UNI	User Network Interface

UPE	User facing-Provider Edge
UPE	Underlayer PE or User-end PE
URI	Uniform Resource Identifier
URL	Uniform Resource Locator
uRPF	Unicast Reverse Path Forwarding
USK	Unicast Session Key
USM	User-Based Security Model
UTC	Coordinated Universal Time
UTM	Unified Threat Management
V	Return
V2V	Video to Video
VA	Virtual Access
VACM	View-based Access Control Model
VAD	Voice Activity Detection
VAM	VPN Address Management
VBR-NRT	Variable Bit Rate-Non Real Time
VBR-RT	Variable Bit Rate-Real Time
VC	Virtual Circuit
VC	Virtual Container
VCC	Virtual Circuit Connection
VCCV	Virtual Circuit Connectivity Verification
VCF	Vertical Converged Framework
VCFC	VCF Controller
VCI	Virtual Channel Identifier
VCN	Virtual Circuit Number
VCPM	Voice Co-processing Module
VD	Virtual Device
VDP	VSI Discovery and Configuration Protocol
VDSL	Very high-speed Digital Subscriber Line
VE	Virtual Ethernet
VE-Bridge	Virtual Ethernet Bridge
VEth	Virtual Ethernet
VF Owner	Virtual Forwarder Owner
VFW	Virtual Firewall
VLAN	Virtual Local Area Network
VM	Virtual Machine
VMM	Virtual Machine Management
VN	Version Number
VNC	Virtual Network Computing

VNI	VXLAN Network Identifier
VoD	Video on Demand
VoIP	Voice over IP
VP	Virtual Path
VPC	Virtual Path Connection
VPC	Virtual Private Cloud
VPDN	Virtual Private Dial-up Network
VPI	Virtual Path Identifier
VPLS	Virtual Private LAN Service
VPM	Voice Processing Module
VPN	Virtual Private Network
VPWS	Virtual Private Wire Service
VR	Virtual Router
VRF	Virtual Routing and Forwarding
VRRP	Virtual Router Redundancy Protocol
VSAN	Virtual Storage Area Network
VSD	Virtual Security Domain
VSI	Virtual Switch Instance
VSI	Virtual Station Interface
VSID	Virtual Subnet Identifier
VSIP	Virtual Service IP
VSRP	Virtual Service Redundancy Protocol
vSwitch	Virtual Switch
VT	Virtual Template
VTEP	VXLAN Tunnel End Point
VTP	VLAN Trunking Protocol
VTY	Virtual Type Terminal
VXLAN	Virtual eXtensible LAN
VXLAN-DCI	VXLAN Data Center Interconnection
W	Return
WAAS	Wide Area Application Services
WAF	Web Application Firewall
WAI	WLAN Authentication Infrastructure
WAN	Wide Area Network
WAP	Wireless Application Protocol
WAPI	WLAN Authentication and Privacy Infrastructure
WASS	Wide Area Application Services
WDS	Wireless Distribution System
WEP	Wired Equivalent Privacy

WFQ	Weighted Fair Queuing
WHA	WLAN High Availability
WIDS	Wireless Intrusion Detection System
WiNet	Wisdom Network
WINS	Windows Internet Naming Service
WIPS	Wireless Intrusion Prevention System
WLAN	Wireless Local Area Network
WLAN RRM	Radio Resource Management
WMM	Wi-Fi Multimedia
WPA	Wi-Fi Protected Access
